Some planners, looking from the perspective of system costs and pursuing efficient use of resources, propose the establishment of congregate facilities or the clustering of disabled persons around (or in) a central facility or a defined geographic area. Indeed, in larger cities with ample medical and social resources, one can imagine a virtual community of the disabled served by an organized system of care extending seamlessly from health care institutions to the communities and homes of the disabled. Pilot programs of this sort for the elderly, for children with continuing technological needs (e.g., ventilators), and for developmentally disabled children and adults have been successful. However, the initiative and continuing support for target populations has usually not come from health care systems, but from private or public service organizations. Such comprehensive approaches require sophisticated information and transportation systems, and a reservoir of professionals and support personnel. In rural areas and in small towns, such a network of services is difficult or impossible to construct, and disabled children and adults may have to travel great distances to engage with the needed health care and social services.

The development of congregate facilities for disabled individuals has been tried in several forms in Western Europe (e.g., Het Dorp in the Netherlands, a town of disabled individuals in which dedicated medical and social services are built around the daily lives and work of its residents). However, in the individualistic United States, the dominant philosophy is to support the integration of disabled individuals into everyday life. Many organizations (e.g., centers for independent living) work to connect individual disabled persons with accessible and appropriate health care and to find suitable living arrangements for them, including adapted housing.

For the more severely disabled who cannot live independently, there are several types of institutions that provide various programs of partial independence and sheltered workshops, some with permanent living arrangements. For those, the means of provision of health care services to clients vary; some have good working arrangements with local facilities, other negotiate on a case-by-case basis for adequate medical and health care services. Many of these organizations are private charities and work to mobilize additional available public funds (Medicaid, Social Security, Developmental Disability, Special Education) for their clients' health care and social service needs.

There is an understandable tension between philosophies promoting independent living and those supporting the various forms of congregate care. The greater efficiencies and access, especially to health care, gained by clustering disabled people is countered by restrictions on independence, social and physical mobility, and integration into the greater society. In the United States and other countries where geography and distance from centers of optimal medical care is a reality, those tradeoffs are sometimes seen as necessary. In more compact countries where medical care systems are regionalized (e.g., Sweden) and integrated with social service systems, the disabled may find less incentive to cluster around urban medical centers. Many disabled people say they find comfort and recognition in settings dedicated to people like themselves, with important psychological and social rewards. Especially for the majority who do not have continuous medical care needs, the real benefits deriving from congregate or clustered communities of the disabled may outweigh the potential benefits of independent living and the uncertainties about ongoing health care that go with it.

An encouraging trend has been the relatively recent development and growth of the specialty of geriatric medicine. The need for comprehensive care for the growing numbers of elderly persons, with and without disability, has brought attention to the need for integration of medical, social, and financial resources for all vulnerable populations. There are increasing numbers of demonstration projects and comprehensive programs for the elderly, from which models for the care of all disabled people, young and old, are emerging.

ISSUES IN FINANCING SERVICES

The ability to pay for medical services for the disabled in those countries without a comprehensive publicly funded universal health care system (most prominently, the United States) is very uncertain. Many of the services and therapies needed by the disabled are required for *maintenance* of present functional status, not for cure or even improvement of the primary causal illness or injury. Thus, they lie outside the benefits of most private insurance plans, and even of Medicare; they do not meet the criteria for "medical necessity." In the private insurance market, previously able-bodied persons who become disabled will usually find that their health insurance has a lifetime maximum benefit limit that can be quickly exhausted with high-cost medical procedures and specialized inpatient care. Those persons or their families must then seek support from public funds (Medicaid, Social Security) for continued access to medical care systems, some of which reject or refuse care to those supported by public funds. Because each state in the United States has different Medicaid, developmental disability, and special education programs, there is significant disparity in the services available across the country. This diversity of benefit packages sometimes leads disabled persons or their families to move from one state to another to improve their access to health care benefits.

Private insurance also limits access to coverage for "prior existing conditions"; such restrictions make it difficult or expensive to obtain private insurance (especially for those with congenital or early-acquired disabilities) and limit families' ability to relocate or change employment, where the change would require a new insurer.

While some advocates for the disabled have proposed that public and private funds available for their care be given directly to the patient or family, others are concerned that many families are not sufficiently informed or prepared to act in the disabled person's best interests. In addition, those disabled persons who are not part of a comprehensive medical care system may miss important therapeutic advances.

The future of disabled people in medical care systems is uncertain. It will be determined by the political and economic evolution of health care systems and will require vigilance and assertive participation of the disabled and their advocates.

HEALTH MANAGEMENT SYSTEMS

Management is an increasingly important component in the health and social care systems that provide services for people with disabilities. The rise of management science and specialist managers has coincided with a profound shift in the way organizations are run. Older forms of administration have been displaced by forms of active management that focus more clearly on economic efficiency, cost control, performance review, and accountability. Management thinking has influenced professional and policy networks so that it has been incorporated in the political, bureaucratic, and scientific discourses that affect health care organizations. The ranks of the specialist managers have been augmented by management-oriented physicians and other supporting experts. This has transformed the environment in which health professionals work and disabled people receive care.

Although there are cross-national variations in management philosophies and practices, differences appear to be diminishing as management science becomes a global phenomenon. In sociological terms, this may be linked to the spread of rational bureaucratic organization, which has helped to shape both private and public sector work. But from the 1980s onward, a new array of management technologies and practices emerged that made the micro-management of organizations more feasible. This has coincided with the creation of processes of regulation and control that permeate downward within organizations and introduce new forms of surveillance and accountability.

The management of health care affects disabled people in manifold ways. Aging populations and the increased burden of chronic illness in many countries mean that disability services have moved nearer the top of the policy agenda in both state and market-dominated health care systems. At the strategic level, senior managers play a leading role in planning the future shape of services and how consumers can access them. Planning decisions affect matters such as the volume and range of services, the degree of coordination of health and social care, the scope for patient choice, and how services are paid for. At the operational level, managers oversee the operation of the system, enforce the rules, and try to resolve emergent problems that arise in delivering services. Managers function as mediators or translators of policy fixed at a higher level in a public bureaucracy or corporation. Sometimes they actively shape policy as they adapt it in the course of implementation.

Much management work involves passing between high-level civil servants or corporate board members and the professional staff who provide frontline services. Managers liaise with professionals to determine the detailed procedures and practices that must be worked out as organizations are reformed and restructured. In many countries, better management systems have led to increased efficiency and also have provided a counterbalance to institutionalized professional power and the skewing of status and resources toward acute medicine. But this has also meant that managers are drawn into difficult decisions about priorities and the provision or nonprovision of services.

Precisely how managers undertake these tasks will depend on the nature of the health care system in which they work. There is a marked difference between a private market-based system, where managers remain at arms length from state regulators and work with owners or their representatives to determine corporate strategy, and a publicly funded/publicly provided system, where managers interact with civil servants and politicians to implement public policy.

The rise of management ideas is well illustrated by the global influence of U.S.-style managed care. The United States has a mixed, though mainly private, system comprising a range of organizations that purchase, provide, or coordinate health and social care services. *Managed care* is an umbrella term for a variety of systems and techniques used to control costs and quality. It typically involves review of patterns of utilization and the medical necessity of treatments, and the steering of patients toward certain providers and care pathways. Since the 1980s, against a background of rising health expenditures, there has been a drift away from traditional health insurance plans toward alternative products sold by managed care organizations (MCOs), such as health maintenance organizations. Some MCOs sought vertical integration by supplementing acute hospital provision with the buying up of outpatient clinics, nursing homes, home health care, and specialist psychiatric facilities, with the aim of creating large networks which could achieve economies of scale and force prices down. Largely for cost control and marketing reasons, other MCOs adopted the strategy of separating benefits for chronic illness or disability from the rest of their health plans. For example, mental illness, alcohol, and drug services were contracted out to specialist providers who would treat members who had purchased this coverage from the MCO. Because these arrangements often offered more limited benefits than indemnity insurance plans, they had the potential to reduce adverse selection and reduce costs.

Although MCOs have reduced the cost of health care, they have been criticized for limiting patient choice and excluding certain treatments from coverage. Managers play a key role in determining what plans will cover, and they consider issues such as cost and litigation risk alongside the question of the medical necessity of treatments. While research shows that denial of treatment for acute conditions is a relatively rare phenomenon in the United States, there are indications that exclusions may have more impact on people suffering from chronic illness and disability. For example, in a recent special issue of *Sociology of Health & Illness,* Gary Albrecht describes the constant battles faced by disabled people in securing access to desired forms of care, usually conducted via contact with middle managers in MCOs. Others have criticized the failure of specialist providers to liaise with cognate organizations and provide appropriate care networks. Recent efforts by some purchasing alliances to use buying muscle as a lever to drive up quality tend to focus on acute services and have so far had little impact on services for disabled people.

In a predominantly public service such as the British system, the role of managers centers more on the implementation and translation of government policy. The splitting of the National Health Service (NHS) into purchaser and provider divisions in 1991, together with the creation of a market in social care, led to significant changes in managerial roles. The interests of purchaser and provider organizations became more sharply differentiated, often leading to increased tensions between their respective managers.

Purchasing was regarded as part of a wider commissioning function, involving needs assessment and judgments about strategy and priorities, and better coordination between health and social services. Continued problems at the interface of health and social care have been partly blamed on continuing organizational barriers to collaboration, and an inability to move from communication at senior management level to effective team working on the ground. The heavy burden of work associated with the new system of contracting for clinical services resulted in growing numbers of managers, but along with new power came pressure to meet government-imposed "costs savings" and performance targets. Some commentators have argued that contracting became a financially driven exercise that paid insufficient attention to quality. There was also criticism from doctors who argued that managerial concentration on the key target of reduced surgical waiting times meant that clinical priority became less important than time on the waiting list.

The NHS reforms initially seemed set to improve the situation of people with disabilities because the quasi-market system was designed to end the system of historically based budgets, which had channeled money toward high-profile acute specialties and away from the so-called Cinderella services (long-stay hospitals and community services that had traditionally suffered from underfunding). However, in practice, spending patterns did not change as much as predicted, and there was little reallocation of resources to community and continuing care services that would meet the needs of disabled people. The concentration of spending on acute services was reinforced by the weight given by the government to surgical waiting times targets, and the way these were presented as a key indicator of the success of the reforms. Many district health authorities operated "exclusions" policies, usually formulated jointly by public health physicians and managers, which listed treatments that would not normally be purchased. This "postcode lottery" affected some high-cost drugs for disabling conditions, such as beta interferon for multiple sclerosis, anti-TNF medication for rheumatoid arthritis, Riluzole for motor neuron disease, and Memantine for Alzheimer's disease.

The Blair reforms introduced after 1997 marked a step away from the language of the market but retained the purchaser/provider split and the basic framework of service contracts. The burden of administration was reduced by a shift from annual to multiyear contracts. However, the government imposed new arrangements for "performance management" based on target setting and review, which increased providers' accountability for outcomes.

There were also new policies on "clinical governance," which aimed to achieve improvements in quality and safety. In practice, this involved the creation of clinical guidelines for a range of medical conditions, recommendations about whether new and controversial treatments should be provided on the NHS, and the development of a series of National Service Frameworks (NSFs), which defined expected care pathways for different condition groups. Several of these clinical guidelines affect disabling conditions such as chronic heart failure, chronic obstructive pulmonary disease (COPD), multiple sclerosis, diabetes, and "supportive and palliative care," and the NSFs include frameworks for older people, renal services, and diabetes. Sections of the British medical profession have helped shape these developments, but they go beyond professional self-regulation. Rather, they have emerged from a coalition of political, managerial, and professional groups, and they encapsulate a form of scientific/bureaucratic rationality that sets limits on the discretional decision making of individual professionals.

Although this short entry has focused on only two systems, most of the issues discussed have more general applicability. Converging trends in the health care systems of almost all developed countries ensure that management will continue to be a central component of disability services. Changing patterns of health and disease and the rising proportion of budgets directed toward chronic illness and disability must be considered alongside continuing technological advances and resource pressures. Disabled people will expect more, and it will be the management systems that are charged with finding ways of maximizing outputs for a given level of expenditure and placing limits on what a health or social care system can reasonably provide.

HEALTH PROMOTION

Health promotion is defined as the process of enabling individuals to increase control over their health and to improve their quality of well-being by engaging in a socially, physically, and spiritually fulfilling life. This definition applies to people with and without disabilities. The process of achieving good health depends on the synergy of personal engagement and commitment, and a supportive environment that includes ample opportunities for maintaining and improving health.

Research has demonstrated that the more supportive an environment is in terms of access to quality health promotion (e.g., available transportation to obtain good medical care, close proximity to a grocery store that sells fresh fruits and vegetables, sidewalks to walk or push a wheelchair in the neighborhood), the more likely the person is to engage in these health-enhancing behaviors. The primary goal of health promotion is to empower people with disabilities to engage in their own successful health-promoting strategies with as minimal assistance as possible, and with the freedom to make choices appropriate to their needs and desires.

There is growing awareness in the public health community of the need for more knowledge and awareness of effective health promotion programs for persons with disabilities. Innovative strategies for improving health, preventing complications associated with a disabling condition, and adequately preparing individuals with disabilities to better understand their own health has emerged as an important public health priority. While people with disabilities account for only 17 percent of the noninstitutionalized population of the United States, they constitute 47 percent of total medical expenditures. On average, their medical expenditures are more than four times those of people without disabilities. Many health experts believe that access to quality health promotion programs can reduce medical costs while improving quality of life in persons with disabilities, who are generally underserved and vulnerable to the effects of poor health.

OVERVIEW OF HEALTH PROMOTION

Prevention of Secondary Conditions

The paradigm shift from disability prevention toward the prevention of secondary conditions is still a relatively new and emerging concept. One of the primary goals in disability and health is to encourage health professionals to become aware of the growing needs of people with physical, cognitive, and sensory disabilities. Another goal is to recognize that people with disabilities can achieve similar health benefits as the general population provided they have equal access to health promotion services/programs that are offered to the general community.

The term *prevention* has a different connotation for people with and without disabilities. For people without disabilities, primary prevention starts with a person being absent of disease and includes efforts to eliminate or reduce the risk of disease or disability. Although primary prevention of disabilities remains a high priority for public health agencies and intervention specialists, prevention of secondary conditions in people with disabilities is beginning to receive more attention. In people with disabilities, primary and secondary prevention include initiatives to prevent secondary conditions in addition to preventing conditions associated with poor health behaviors (e.g., smoking, physical inactivity, poor nutrition). The term *secondary conditions* relates to any physical, medical, cognitive, emotional, or psychosocial consequences of a primary disability. This may include weight gain or weight loss, pressure ulcers, pain, fatigue, advanced osteoporosis, depression, social isolation, orthopedic changes, and reduced physical function such as loss in aerobic capacity or strength. Secondary conditions have a tendency to exacerbate a primary disability and can limit physical and social independence and reduce participation in important health-enhancing behaviors such as employment and recreation.

Healthy People 2010

During the late 1970s, the United States began monitoring the health of the nation in its *Healthy People* agenda. The most recent document, *Healthy People 2010*, targets people with disabilities as a subgroup of the population. A chapter titled "Disability and Secondary Conditions" has been added to the document to reflect various health disparities found in people with disabilities. This document will serve as an important benchmark for supporting the development of health promotion initiatives for people with disabilities in the coming years.

Barriers to Health Promotion

People with disabilities often experience health disparities because of the many environmental barriers that they are confronted with when trying to improve their health, including poor physical access, societal attitudes, and lack of quality medical care. Research has demonstrated that the more supportive an environment is in terms of access to health-promoting behaviors, the more likely the person is to engage in these health-enhancing activities.

While there is substantial information on health promotion for the general population and for people with chronic conditions (e.g., diabetes, arthritis, asthma), much of this information does not provide important adaptations or modifications to be engaged in by individuals with physical, cognitive, or sensory disabilities. Barriers to health promotion for people with disabilities include inaccessible materials and programs, lack of transportation to get to an exercise facility, lack of financial resources to purchase healthy foods or medication, and lack of access to good medical care. Materials in standard curriculums or textbooks are, for the most part, not available in alternative formats (i.e., large print, audio), and information is often too generic for individuals with specific types of disabilities who may have several secondary conditions (i.e., pain, fatigue, urinary incontinence) and/or impairments (lack of vision/hearing, low cognition, paralysis). These secondary conditions and/or impairments require specific adaptations to standard health promotion programs to ensure successful integration and outcomes.

An additional barrier to health promotion involves the lack of training among health care providers regarding the needs of people with disabilities. Most health promotion specialists are not trained to modify or adapt existing programs for people with various types and severities of disabilities. For example, many professionals will recommend walking as the primary mode of physical activity because it can be conveniently done in various settings (i.e., mall, outdoors), and it does not require expensive equipment or a membership to a fitness center. However, individuals with lower extremity disabilities may not be able to walk or may have difficulty walking. An alternative to walking would be to recommend hand cycling, wheeling, or performing chair exercises.

KEYS AREAS OF HEALTH PROMOTION

Physical Activity and Disability

The health benefits of an active lifestyle that includes moderate amounts of medium to vigorous physical activity on a regular basis have been detailed in the Surgeon General's report, *Physical Activity and Health* (U.S. Department of Health and Human Services 1996):

> Regular physical activity greatly reduces the risk of dying from coronary heart disease, the leading cause of death in the United States. Physical activity also reduces the risk of developing diabetes, hypertension, and colon cancer; enhances mental health; fosters healthy muscles, bones, and joints; and helps maintain function and preserve independence in older adults. (Foreword of the Executive Summary)

Unfortunately, the vast majority of people with disabilities are not obtaining the recommended amount of physical activity needed to confer health benefits and prevent secondary conditions associated with a sedentary lifestyle (e.g., heart disease, type 2 diabetes, obesity, and osteoporosis). The *Healthy People 2010* report notes that significantly more people with disabilities reported having no leisure-time physical activity, 56 versus 36 percent, compared to people who did not have a disability.

As persons with disabilities age, they often experience increasing difficulty performing activities of daily living (ADLs) (e.g., dressing, showering) and instrumental activities of daily living (IADLs) (e.g., ambulation, doing laundry, grocery shopping). Persons with disabilities also must overcome various physical obstacles during the day as a result of environmental barriers that require greater energy expenditure to perform certain physical tasks (e.g., wheeling up and down ramps and curb cuts, performing transfers). And various secondary conditions that often accommodate a disability (e.g., increased weight gain, pain, spasticity, weakness, fatigue, loss of strength and function) make it more difficult to sustain these physical tasks. When combined with the natural aging process, the likelihood of requiring assistance to perform various ADLs and IADLs is likely to increase.

Based on evidence from studies conducted with various disabled populations, deconditioning in the form of reduced strength, flexibility, and aerobic capacity result in an earlier onset of reduced health and function. There is a substantial amount of health improvement that can be obtained by people with disabilities with minimal increases in physical activity. Finding ways to overcome environmental barriers to physical activity participation is an important priority in public health.

One example of a primary barrier to physical activity participation among several groups of individuals with disabilities is the lack of information on where or how to exercise at home or in the community. Much of the general literature and public health messages promoting physical activity encourage Americans to walk more often, with the goal of 30 minutes a day most days of the week. While this recommendation may be appropriate for the general population, it is often inappropriate for people who have difficulty walking (e.g., cerebral palsy, multiple sclerosis, stroke) or who are unable to walk (e.g., spinal cord injury, polio) or must be supervised while walking (e.g., severe mental retardation or mental illness, Alzheimer's disease). A more inclusive message would have a greater likelihood of reaching a more diverse population.

National Center on Physical Activity and Disability

Through a grant from Centers for Disease Control and Prevention, National Center on Birth Defects and Developmental Disabilities, Disability and Health Division, the National Center on Physical Activity and Disability (NCPAD) was established to collect, synthesize, and disseminate information on various programs and services related to physical activity and disability. This web-based research and information center has many unique features that can assist health professionals in developing appropriate physical activity programs for people with disabilities. The website (http://www.ncpad.org) contains a national directory of accessible recreation and fitness facilities along with a listing of equipment vendors that manufacture or sell adaptive equipment. There is also an extensive database on physical activity and disability that allows the user to search for information by disability or activity. The toll-free telephone number (800-900–8086) allows end users to consult with an information specialist if they do not have access to a computer.

Nutrition and Disability

While government agencies responsible for nutritional information emphasize optimum levels of nutrients for the general population, specific guidelines for people with physical and cognitive disabilities are lacking. Although having a disability does not necessarily require a significant alteration from national dietary guidelines (e.g., low fat, low cholesterol, high fiber), certain modifications to the nutritional component of a health promotion program may need to be tailored to people with various types of disabilities. For example, individuals with cerebral palsy, Down syndrome, and spinal cord injury are more susceptible to osteopenia (reduced bone mass) and osteoporosis (significant bone loss). While there are no specific guidelines for daily calcium intake in younger, disabled populations with osteopenia or osteoporosis, it is plausible that a higher calcium intake may be required at an earlier age to slow or reduce the progression of bone loss.

Individuals with stroke who are taking the blood thinner Coumadin to prevent blood clots and a recurrent stroke may need to avoid a high intake of vitamin K. Vitamin K has an essential role in blood clot formation and counteracts the effects of Coumadin. A comprehensive nutrition program for stroke survivors would include food choices that have a low concentration of vitamin K while still maintaining adequate levels of other important vitamins and minerals.

Fluid intake is another area of nutrition that may need to be tailored to individuals with certain types of disabilities. For example, individuals with spinal cord injury (SCI) may require higher amounts of fluids to avoid dehydration. However, many individuals with SCI are reluctant to drink large amounts of fluids because of the difficulty with catheterization and/or the greater frequency of having to perform this task. Yet, without adequate hydration, people with SCI are more susceptible to urinary tract infections, syncope, and impaired thermoregulation. Constipation is another secondary condition found in various subgroups with disabilities, and increased fluid intake would help improve motility and evacuation of bowel contents.

Many individuals with disabilities have large increases in weight often related to medication use, lack of physical activity, and poor nutrition. For example, one of the major side effects of psychotropic medications is excess weight gain. Health professionals must be aware of the impact that various medications can have on nutritional status and take appropriate action to avoid large increases in weight through reductions in caloric intake and increased physical activity.

Good nutrition that is tailored to the needs of individuals with disabilities can have a dramatic effect on improving health and reducing various secondary conditions. In general, nutrition recommendations for the general population should be followed by people with disabilities. However, in cases where the individual's impairment may alter certain metabolic processes, specific nutritional guidelines must be included for that individual.

Health Behavior and Disability

Health behavior can have a significant impact on empowering people with disabilities to manage their own health. The current state of practice in most health behavior programs is to educate participants about the benefits of the various components of health promotion, which can include anything from cancer prevention screening (e.g., breast and prostate exams), to spirituality, stress management, exercise, and proper nutrition.

The transtheoretical model is one of the most widely used behavioral models in health psychology. The model uses the phrase "stages of change" to integrate change processes through a variety of intervention strategies. There are five primary stages that range from people who are not even thinking about making a change (precontemplation) to people who have changed a behavior and are working to maintain the new behavior and prevent relapse (maintenance). In between, people can be thinking about making a change in the next six months (contemplation), getting ready to make a change in the next 30 days (preparation), or be in the first six months of a behavior change (action).

Implementation of the transtheoretical model in health promotion programs for people with disabilities is a viable approach to ensuring better outcomes. Intervention strategies should be tailored to the stage of change that the person is currently in and that will serve as a useful guide for moving the individual to the final stage of maintenance. It is becoming increasingly clear that there is a greater likelihood of successful adherence to health promotion programs when the program is tailored to the needs, interests, and comprehension level of the individual learner.

HEALTH RESOURCE RATIONING

THE NEED FOR A SYSTEM OF RATIONING

Health care is uniquely important. Modern medicine has been extremely successful in discovering new kinds of health care and improving the old kinds. But medical innovations have come at increasingly high prices. The cost both of the best health care and even moderately good health care is rising much faster than our ability to pay for it. This creates a problem. If a society wishes to provide health care to its citizens, some form of rationing has become a necessity.

The very idea of health care rationing is objectionable to many people. Citizens of the United States are especially opposed. This is partly because the United States has no universal health care system. The two national U.S. health programs (Medicare and Medicaid) cover only 26 percent of the population, those who are elderly, poor, or significantly disabled. Health care for the remaining 74 percent is left to the marketplace. This is seen as desirable by many, who believe that a free market will ensure freedom of choice in health care. But the effect of this “free market rationing” by the year 2002 was that 15 percent of the population—more than 43 million people—had no health insurance at all, and that number is increasing. Some public system involving rationing is likely to be required in the future. It is already used in the U.S. national systems and in private health maintenance organizations, so U.S. citizens will have to accept the concept of rationing in some form. Most other developed countries have universal health care programs. Because rationing decisions are always made within these programs, the concept is seen as less objectionable.

Health care rationing is a genuine necessity within any publicly funded system. It is easy to argue that national health care systems are underfunded. Nevertheless, the funds that would be necessary to purchase unlimited health care for everyone are beyond any nation’s capacity. Increases in funding can produce better health care but not unlimited health care. If health care must be limited, then both fairness and efficiency demand that it must also be rationed in some way. We should spend health care funds *wisely,* so that expensive procedures are funded only when they are worth the expenditure in comparison to other procedures. This follows from the fact that an expenditure on any one patient reduces the funds available to other patients. But we should also spend funds *fairly,* so that everyone gets a just share of the benefits of the system. Crafting a health care rationing system that is both efficient and fair is a tremendously complex process. But it is also a necessity.

Both the efficiency and the fairness of a system of health care rationing are difficult to establish. The simplest programs are easy to apply, but they have serious moral flaws. These flaws have been recognized, and attempts have been made to circumvent them. One group of people is especially vulnerable to disadvantage from rationing systems: people with impairments and chronic illnesses. Even systems that are intended to fairly and efficiently distribute health care resources can discriminate quite seriously against disabled people, as we shall see. This discrimination results from questionable moral assumptions about the goals of health care, from questionable factual assumptions about quality of life, and even from disagreements about the nature of disability itself.

Conflicts between the medical community and the disability rights community are almost inevitable, for one simple reason. The medical community considers disability to be a medical problem, to be solved (if at all) by medical means. The disability rights community considers disability to be a social problem, to be remedied by social changes that make environments more accessible and integrate disabled people with the rest of society. These activists consider disabled people to be similar to an ethnic minority, harmed by discrimination from mainstream society. The so-called medical model of disability is a basic assumption of the medical community, but it is a misconception according to disability rights activists. This is one source of conflict over the relation between disability and health care policy.

SOME SYSTEMS AND THEIR PROBLEMS

One might think that statistical analyses of health care efficiency would result in simple statistical facts, not in moral problems. But statistical analyses often begin with hidden assumptions that infect their outcomes. One early analysis of health care efficiency was called cost-benefit analysis (CBA). The goal was to determine the costs of nationally funded health care in terms of its impact on economic productivity. The analysis indicated that health care expenditures on workers who were young, productive, and highly paid would repay the costs by increased productivity. But other expenditures did not produce the same payback. Health care for unemployed and elderly people was a bad investment. The use of these results to prioritize public health care was immediately recognized as unfair. The moral goal of health care is not only to maximize the nation's economic production but also to make its citizens healthier whatever their economic contribution.

It is not difficult to calculate the relative cost-effectiveness of different treatments when they are aimed at producing the same outcome. The calculation of the cost-effectiveness of certain screening tests for colon cancer, for example, is merely the cost of one test multiplied by the number of such tests it would take to detect a single tumor. This kind of analysis can lead to useful results. But this kind of analysis, alone, cannot compare different kinds of outcomes; it cannot compare treatments that extend life with those that control pain, or improve function. A way had to be found to compare the different health-related outcomes with each other. This would allow cost-effectiveness analysis to be applied to *health itself,* instead of being limited to individual kinds of outcomes. It would also remove the unfairness of CBA's focus on the economic consequences of health. The health of unemployed and elderly people would receive equal consideration as that of high-wage earners. This was surely a moral improvement. But how can one measure health itself? The concept has proven surprisingly problematic.

The first step in measuring health itself was the recognition that the goal of health care was not only to extend lives but also to make lives better. The relief of pain and discomfort and the improvement and maintenance of function are legitimate goals of health care even if lives are not lengthened. Life extension and life improvement were seen to be distinct dimensions of health care. To compare two distinct dimensions of health, a measure had to be constructed that incorporated them both. Some amount of life extension must be seen to be comparable to some amount of life improvement. This would be possible if health itself were seen to be the product of multiplying the *length* of life produced by a medical treatment (the longer the better) by the *quality* of the life produced (the better the quality, the better the outcome). But now we see another problem. One of those goals is easily measurable but the other is not. Length of life is simply a number of years. But how does one measure the "goodness" of life?

THE INVENTION OF "QUALITY OF LIFE"

In the 1970s, this problem led to the coinage of the expression "quality of life" (QOL). The expression rapidly became a buzzword. But it is important to remember its origin. Even though *quality of life* has entered ordinary language, it retains its specialized meaning among those who deal with health care rationing systems. In ordinary speech, quality of life refers to the subjective satisfaction and fulfillment that an individual experiences. But in its original technical sense, quality of life refers to *everything except life extension* that is a beneficial outcome of health care. Subjective satisfaction is irrelevant. The technical concept is quite problematic, as we will see. One of its ironies is that the technical term *quality* of life was invented only because of the need for *quantification.* Health care economists had to be able to quantify—to measure, count, add up, and compare—the valuable outcomes of health care. For the purposes of health care rationing, QOL is a quantity.

With QOL understood as a quantity, an amount of goodness, health care economists believed that they could calculate the total amount of *health itself* in an individual or in a population. Total health is a length of time multiplied by the QOL during that time. The quality adjusted life year (QALY) became the standard measure of total health. Numerical comparisons can now be made. One QALY is one year of life at its maximum quality (set at 1.0 by convention), or two years of life at the QOL of 0.5, or four years of life at the value of 0.25. The number of individuals involved does not matter: Four years of one person's life at a given QOL is equivalent to two years of two people's lives at the same QOL. Health care can now be rationed with the help of objective measures. A system called cost-utility analysis (CUA) was devised by applying cost-effectiveness analysis to the production of QALYs. (*Utility* is a term used by economists and philosophers to designate an amount of welfare or happiness. In the case of CUA, utility is measured in QALYs.)

To illustrate the use of CUA in health care policy, imagine a decision between two programs of life-extending treatment. Program A and Program B have the same costs and the same size patient groups (say, 1,000 patients), and each program extends the lives of its patients for one year. The patient group for Program A has the highest possible QOL of 1.0. The group for Program B has a lower QOL of 0.8. Which program should be funded? Clearly, Program A. It produces 1,000 QALYs (1,000 people with a one-year life extension at 1.0 QOL), while Program B produces only 800 QALYs. A greater amount of *health itself* is purchased for the same price. CUA shows that the QALYs produced by Program B cost 1.25 times as much as those produced by Program A. Given this choice, it would be a financial waste to fund Program B.

QOL AS A THREAT TO HEALTH CARE FOR SOME

We are very close to the point at which health care rationing discriminates against people with permanent impairments or chronic illnesses. One further step is needed, and it is almost always taken. It is this: People with impairments are determined to have a lower QOL than nondisabled people merely because of their impairments. The overall goal of maximizing QALYs implies that, under certain circumstances, people whose QOL is permanently low will receive a lower priority for certain kinds of health care than people whose QOL is high. This will not happen in every circumstance, of course. If two individuals with different QOLs contract a disease that lowers each of their life qualities an equal amount, then the treatment for the disease would result in the same QOL increase for each person, whatever their baseline QOL. Because each treatment results in the same increase, they have an equal priority for treatment even though they began at different QOLs. But consider life-saving treatments. Saving the life of a person with a high QOL produces a larger number of QALYs than an otherwise similar person who has a permanent impairment (and therefore a lower QOL). For treatments like these, disabled people will have a lower priority for health care than otherwise similar nondisabled people.

This version of CUA is beginning to sound like CBA, with its focus on economic outcomes. Instead of discriminating against non–wage earners, we discriminate against people who have a low QOL. One would think that the same objections would apply. Many non–wage earners have a lower QOL than wage earners, and so would be disadvantaged by a QOL-based CUA just as much as by the old income-based analysis. Presumably, many poor people, elderly people, lonely people, and people who have lost a loved one have a low QOL, and so would also be subject to discrimination. Shouldn't fairness dictate that health care not discriminate against these groups of people? Should all sad people be classified in the same category as disabled people, and have their access to health care reduced by their low quality of life? Is health care only for happy people?

Not according to the actual rationing systems that have been developed. Advocates of CUA are not interested in maximizing overall QOL, in the ordinary sense of the subjective enjoyment or fulfillment that individuals experience in their lives. Keep in mind the original purpose of the concept of QOL. It was meant to quantify non-life-extending health care so that it could be compared and traded off with life-extending health care. Unhappiness-causing characteristics such as poverty and loneliness are not treated by the health care system. So they are ignored by CUA advocates. The term *health-related quality of life* (HrQOL) is now used to call attention to this difference. CUA advocates insist that disability is health related and that loneliness and poverty are not. So a person whose life is made unhappy by disability receives a lower priority for health care. But a person whose life is made unhappy by widowhood or unemployment does not. All sadnesses are not equal.

But are these generalizations even true? Are the lives of people with impairments significantly lower in quality than nondisabled people? It depends on whom you ask. When people with impairments are asked about their lives, they report a QOL only slightly lower than that reported by nondisabled people about their own QOL. But when nondisabled people are asked about the QOL of disabled people, they report (or estimate, or guess) that it is extremely low. Even more paradoxically, health care workers have a lower estimate of the QOL of disabled people than does the general public. Gary Albrecht and Patrick Devlieger (1999) have reviewed the literature on this paradox.

WHO SHOULD WE BELIEVE ABOUT QOL?

So the question arises: Whose reports should be used in the rationing system? Should we incorporate the high-QOL reports of disabled people themselves, or the low reports that are given of disabled lives by nondisabled commentators? Biomedical ethicists have shown a strong tendency to trust only the nondisabled reports (or, more likely, their own intuitions). They dismiss the reports of disabled people as a mere lowering of personal standards. On the other hand, social psychologists have known of this discrepancy for much longer than the ethicists. Psychologists such as Daniel Kahneman and his colleagues (Kahneman, Diener, and Schwarz 1999) have taken the reports of disabled people seriously. The phenomenon fits into other psychological knowledge about how people find happiness in life. Ask yourself this: How happy would you be a year after you won a fortune in a lottery? You probably expect that you would be extremely happy. But the empirical facts do not fit your prediction. After an initial exultation, lottery winners almost always return to their original level of life satisfaction. The same happens with most people who experience major difficulties, whether from disability or the loss of a loved one. Nondisabled commentators *expect* that disability would cause them to have permanently low QOL, and lottery winning permanently high QOL. Both expectations are mistaken. This implies that people who are living with impairments (and those who are living with lottery fortunes) are the best judges of their own QOL. The contrary assessments of the nondisabled public, biomedical ethicists, and health care economists are clouded by a prejudice well known to psychological researchers.

So there is good empirical reason to doubt that the lives of most people with impairments have much less subjective satisfaction or fulfillment than the lives of nondisabled people. Insistence that they do would be seen as mere bigotry by disability rights advocates. But the CUA advocates have an additional argument to use in support of the lower QOL of people with impairments. They claim that it is logically incoherent to accept reports of high QOL from disabled people.

According to the principles of CUA, logical consistency requires us to link any expenditures dedicated to cures and prevention of a given condition with the QOL of a person who lives with that condition. If Condition A is regarded as extremely mild, then Condition A will have a low priority placed on it for purposes of prevention or cure, and people who live with Condition A will have a very high QOL. Conversely, if Condition B is one that is very important to cure and prevent, then a life with Condition B must involve a seriously reduced QOL. For example, if you consider it important to spend health care funds to prevent or cure blindness, then you are logically required to believe that people who are blind have a low QOL. If they did not, then why should we devote health care funds to prevent or cure blindness? The mere fact that we want to prevent disabilities logically implies that disabled people have a low QOL. What they report about their own QOL has no relevance to the matter.

This appearance of logical necessity is a consequence of the assumptions behind CUA accounts of rationing. CUA presupposes a utilitarian moral theory. Utilitarianism asserts that morality is a matter of the production of *consequences:* The rightness of an act is the amount of happiness it produces. A well-known shortcoming of utilitarianism is that it is unable to account for certain moral intuitions involving fairness, justice, and rights. Utilitarianism often seems to give the correct moral answers only when one assumes that no preexisting rights are involved in the question. CUA advocates make this assumption. The purpose of health care rationing is to maximize the amount of *health itself* that is created by the rationing system. No individual has any particular right to health or to health care. The only claim that any citizen has on health care comes from that citizen's ability to convert the expenditure of health care funds into high amounts of HrQOL.

Citizens who can "reimburse" health care expenditures with high HrQOL will receive health care. Those who cannot, will not. The status of an individual person within this system is merely to represent a potential health outcome, a contribution to the overall sum of *health itself.*

The utilitarianism behind CUA presupposes that the maximization of HrQOL is the categorical goal of health care, and therefore of health care rationing. But this assumption is challenged by many biomedical ethicists, and independently by the general public. Tom Beauchamp and James Childress (2001) have reviewed the ethicists' critiques. Peter Ubel (2000) and Erik Nord (1999) have conducted studies on how the general public perceives the importance of various kinds of health care. Ordinary citizens consider the strict application of pure CUA analysis to be unfair and would prefer systems that would actually produce a lower HrQOL than the maximum. For example, they would spend more funds on extremely ill patients than would be justified by CUA analysis. This "rule of rescue" requires that funds be spent on extremely ill patients even when the costs of their treatment are unlikely to be compensated by large improvements in their QOL. Ordinary citizens are also reluctant to give nondisabled people a higher priority than disabled people for life-saving treatments *even though they believe* that disabled people have a lower QOL. So the prejudice of the general public against the high QOL of disabled people seems to be compensated by their refusal to go along with CUA in its implication that disabled people should have a lower priority for health care than their nondisabled peers.

The utilitarianism of CUA is inconsistent with the concerns for fairness that are expressed by many biomedical ethicists and the general public. It is unclear which values will be reflected in future rationing schemes. With respect to life-saving measures at least, the general public seems to consider people with impairments to be similar to ethnic minorities—disadvantaged groups that should be protected from further discrimination. This matches nicely with the views of disability rights advocates. But the assumption that disability implies low QOL is shared by the general public and by CUA advocates.

The artificial notion of HrQOL is potentially hazardous to disability rights. HrQOL is a special form of quality of life that links disability and health care. But it artificially separates disability from other life experiences that can cause unhappiness—experiences such as sudden unemployment and the loss of a loved one. It reinforces the deep prejudice that the disadvantages of disability are a special curse from nature itself. A person's biology (not an inaccessible environment) is the cause of the person's unhappiness. This is merely a modernized reincarnation of the same old stigma that disability has always held. Unlike other causes of sadness that can be accommodated and learned from, disability is seen to be a permanent loss of life's goodness.

An important principle of the disability rights movement is the exact opposite. The disadvantages of disability arise not from biology but from social arrangements, such as inaccessible environments. Technical rationing concepts such as the HrQOL misrepresent the causes of disadvantage for disabled people. Even if disabled people are able to resist the loss of access to health care that would result from a CUA rationing system, they may be equally harmed by the assumption (shared by biomedical policy makers and the general public) that they "by definition" have a lower QOL than their nondisabled peers. If this were true, then improvements to environmental accessibility could benefit them only in small ways. Why bother trying to improve the life of a person who "by definition" has a low QOL anyway? If the technical concept of HrQOL reinforces the public's belief that disability is unavoidably associated with a low QOL, it may undercut the disability rights arguments for greater inclusion and more accessible environments.

HEALTHY PEOPLE 2010

Healthy People is the term used to identify the agenda for improving the health and safety of Americans. The publication of *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention* in 1979 set the initial objectives addressing the reduction of mortality across four age groups—children, adolescents, young adults, and adults. A fifth objective aspired to increase independent functioning among senior adults.

The second decade of Healthy People commenced in 1990 with *Healthy People 2000.* This agenda included 316 health-related objectives in 21 chapters. During deliberations about areas to include, disability was discussed during the late 1980s. Little data were available, however, to monitor the health and well-being of people with disabilities. Therefore, no specific emphasis was given to disability and health as the specific objectives were created. Throughout the 21 chapters of *Healthy People 2000,* 16 objectives referenced disability-related themes. Seven focused on the primary prevention of conditions associated with disability, and nine addressed health issues of people with disabilities. These seven included "people with disabilities" as a subpopulation in the analyses. The areas included leisure activity, weight, stress, mental health treatment, and clinical preventive services. The major emphasis for subpopulations was to assess differences with the general population. In the final review of *Healthy People 2000,* results indicated that of the six objectives that could be measured, half showed the disparities between people with and without disabilities to have been reduced or eliminated, and the remaining three to have stayed the same or moved away from the overall target.

In the mid-1990s, the U.S. Department of Health and Human Services began a dialogue with the Centers for Disease Control and Prevention to include people with disabilities in the third edition, *Healthy People 2010.* Disability has become an emerging public health issue due to the increased survival of children and adults experiencing limitations due to aging, chronic illness, traumatic injuries, and developmental disabilities. Two opportunities for inclusion were provided. First, "people with disabilities" was proposed as a demographic variable, alongside age, ethnicity, sex, and education level, for example, as subpopulations to describe the health of Americans. Second, a chapter specifically focusing on issues that are more specifically related to people with disabilities. The overarching goals of *Healthy People 2010* were to increase quantity of quality of life for all Americans and to eliminate health disparities. These goals were then able to be monitored for people with disabilities. The development of objectives took six years and included 250 individuals representing 75 advocacy, professional, university, and governmental entities. From the 28 chapters in *Healthy People 2010,* more than 100 objectives included "people with disabilities" as a subpopulation for data gathering. This will provide badly needed information that will allow health disparities among people with disabilities to be identified and monitored.

Chapter 6, "Disability and Secondary Conditions," is the disability-directed chapter and includes 13 objectives. There are several core issues addressed by the chapter:

> Challenging two commonly held false equations: that disability equals illness and that health equals medical intervention
>
> Affirming the role of the environment as critical to improving health and well-being
>
> Acknowledging the need for a standard definition of *disability* for use in surveys
>
> Establishing a common conceptual and coding framework for science, program, and policy—the World Health Organization's International Classification of Functioning, Disability, and Health

The 13 objectives are as follows:

> 6–1 Include in the core of all relevant *Healthy People 2010* surveillance instruments a standardized set of questions that identify "people with disabilities."
>
> 6–2 Reduce the proportion of children and adolescents with disabilities who are reported to be sad, unhappy, or depressed.

6–3 Reduce the proportion of adults with disabilities who report feelings such as sadness, unhappiness, or depression that prevent them from being active.

6–4 Increase the proportion of adults with disabilities who participate in social activities.

6–5 Increase the proportion of adults with disabilities reporting sufficient emotional support.

6–6 Increase the proportion of adults with disabilities reporting satisfaction with life.

6–7 Reduce the number of people with disabilities in congregate care facilities, consistent with permanency planning principles.

6–8 Eliminate disparities in employment rates between working-aged adults with and without disabilities.

6–9 Increase the proportion of children and youth with disabilities who spend at least 80 percent of their time in regular education programs.

6–10 Increase the proportion of health and wellness and treatment programs and facilities that provide full access for people with disabilities.

6–11 Reduce the proportion of people with disabilities who report not having the assistive devices and technology needed.

6–12 Reduce the proportion of people with disabilities reporting environmental barriers to participation in home, school, work, or community activities.

6–13 Increase the number of Tribes, States, and the District of Columbia that have public health surveillance and health promotion programs for people with disabilities and caregivers.

Workshops were convened in 2000 and 2002 to develop strategies to initiate new activities or encourage already-existing strategies to achieve the objectives. Workgroups are currently convened in five areas—data, policy, program, training, and children—to implement the strategies that were developed. *Healthy People 2020* should provide opportunities for furthering the objectives for which work has begun.

HEARING IMPAIRMENT

The central issue for people with hearing impairments is that they cannot hear. While that seems totally obvious, its importance cannot be overlooked. Whether people with hearing impairments can hear some sounds; which sounds they can hear; when they can hear; and whether they can talk, use a telephone, read lips, or sign are all variable, but the fact of not being able to hear is not. Thus, one can make few assumptions about people with hearing impairments other than that they cannot hear some or all of the sounds in the environment. Hearing impairments make communication difficult; thus, the most disabling result of hearing loss can be isolation.

The physical nature of hearing impairment is also extremely varied. Hearing impairments may be genetic or environmentally caused, usually by illness. They may be accompanied by other conditions or they may not: Some hearing impairments coexist with other conditions, but often a person with a hearing impairment is otherwise perfectly healthy. Thus, the assumption that a person with a hearing impairment is ill is unwarranted without further information.

People with hearing impairments who know sign language can communicate effectively and at as high a level as their education will permit—but only with other people who know how to sign. People who can read lips are able to interact with speaking people, but lipreading itself is problematic. In English, for example, lipreading is about 25 percent successful for the average user and 50 to 75 percent for really skilled lipreaders.

Various types of assistive technology can provide remedies for the communication impairment that results from hearing losses, but none remedy the hearing impairment itself. Hearing aids can attenuate the hearing loss, but they work better for some people and in some situations than in others—primarily in one-to-one situations in quiet rooms. Cochlear implants also appear to be variably successful; although the predictors of success or failure are not fully established at this writing, people with previous knowledge of sound seem to do better than people without. Assistive listening systems, captioning systems, and computer technologies can be useful in ameliorating the communication impairment, although they are expensive and depend on more advanced technology than is likely to be available in developing countries. Several types of telephone substitutes can be used successfully where adequate phone systems exist.

Sign language, cued speech, or oral interpreters are available in some situations, as are phone relay systems that use operators as intermediaries. All are expensive and are not sufficiently available, even in developed countries, and they are of no use to someone without the requisite skills.

The variability in causes, presentation, amelioration potential, and results means that people with hearing impairments are not homogeneous. Some feel they are members of a deaf community, although many do not.

Deaf communities have tended to form whenever a sufficient "critical mass" is achieved. In the United States, where schools for deaf children began in 1817, deaf people tended to stay in the area after they graduated, sometimes finding jobs at the same school. Other deaf communities formed in localities where a concentration of deaf people worked in a specific industry. For example, deaf workers were "drafted" for work in tire plants in Akron, Ohio, during World War I, so a large deaf community formed there. In the United States, the fact that many deaf men worked as printers facilitated the growth of newspapers for the deaf community and contributed to its solidarity. In many countries in Europe and Africa, deaf communities formed around residential schools. Sometimes the communities were so separated that, because transportation was difficult and interacting unlikely, each had its own sign language. For example, in Zimbabwe, four sign languages had grown up around the residential schools, but the National Association of the Deaf was only formed (officially) in the late 1980s.

With the founding of the World Federation of the Deaf in 1951, the deaf community became international. Its goals at this time are improving the status of national sign languages, attaining better education, improving access to information and services, and improving human rights for those in developing countries.

Members of a deaf community may refer to themselves as "Deaf, not deaf." The capital *D* indicates a political or ideological stance that includes a strong preference for the use of sign language, an acceptance of deafness as a normal condition and not a disability, an unwillingness to accept the idea of becoming hearing, a desire for deaf children, and a desire to see the deaf community continue (and thus may include objections to mainstreaming and the closing of residential schools for deaf children).

People who live in deaf families or deaf communities or spend time among other deaf people have very different experiences from those who spend most of their time with hearing people, since they are unlikely to experience the communication barriers and consequent isolation experienced by people who cannot communicate with those around them.

There are two major dimensions that have a large impact on the experience of hearing impairment: age of onset and severity of hearing loss. Combined, these two dimensions create four categories, which are shown in Figure 1 and discussed below.

Cell 1: People with severe, prelingual hearing losses. Early-onset deafness can cause major problems in learning to speak, read, and write. These problems can lead to subsequent problems in education and employment. Children in this situation are at high risk for educational impairments unless they can develop an early linguistic foundation. Some children do succeed in developing that linguistic base through lipreading, but many do not. The earlier linguistic interaction starts, the more likely a child is to develop the necessary linguistic base, whether the interaction is spoken or signed. People in this category are most likely to consider themselves to be culturally deaf.

	Severity of Hearing Loss	
Age of Onset	more severe	less severe
prelingual	Cell 1	Cell 3
postlingual	Cell 2	Cell 4

Figure 1 Conditions of Hearing Impairment

Cell 2: People with severe, postlingual hearing losses. For some people, postlingual hearing impairment emerges slowly, over months or years, while others may literally wake up deaf after an illness or injury. For some, this happens in their teens or young adulthood, and for others it happens in later life. People who develop postlingual hearing impairments have very different experiences from those with prelingual impairments, because they can talk and can interpret speech if it is mechanically amplified. Their deafness may be as isolating as it is for earlier deafened people, but some of their communication modalities, such as speaking and writing, may remain useful. But with postlingual deafness comes the necessity for resocialization. That is, formerly hearing people must "become" deaf. Not only may they need to learn a sign language or another form of communication, but they may also need to overcome a cultural stigma against deaf people, since now "they" are "me." They may need to reorganize family relationships, occupational situations, and social networks.

Cell 3: People with less severe, prelingual hearing losses. People in this category may be even more marginalized than those with more severe impairments. Children may be considered to be "hard of hearing" and taught to speak and lip-read (often to the detriment of academic subjects), or they may be considered just to have "a little hearing problem." Some may succeed in developing a linguistic base through lipreading, but many do not. They are more likely to be sent to mainstreamed educational programs, where they may get a better education than those in "deaf" schools, but they are likely to be more socially isolated. As adults they may find themselves not able to function well with hearing people and so may need or want to move toward the deaf world. But the deaf community may not accept them because they are "not deaf enough." Especially if they do not know how to sign, they may find themselves between two worlds.

Cell 4: People with less severe, postlingual hearing losses. People in this category are likely to have lost their hearing at a later age than people in the other three categories. In developed countries, such people make up by far the largest proportion of people with hearing impairments. However, they are the group that is least likely to identify with other deaf people and/or to have any desire to learn a sign language. They are the most likely to experience the isolating consequences of hearing loss, although newer technological remedies may provide some assistance.

Overall, the variability of the condition of hearing impairment as discussed above is reflected in the polarizations within the deaf population. Some of the divisive issues are oralism (speech and lipreading) versus signing, assimilation (to the hearing world) versus separation, segregated versus integrated education, and Deaf versus deaf. These issues have led to contentious political actions, including the "Deaf President Now!" protest at Gallaudet University in 1988 as well as many others in all parts of the world. These polarizations make the possibility of one unified deaf community unlikely.

HEATH, JEFF 1955–2004

Australian activist and author

Jeff Heath was a self-described social entrepreneur, who gained public recognition for pursuing innovative projects aimed at social change for people with impairments. Heath had a significant physical impairment and was a wheelchair user from childhood. He was a Paralympian and sailor, who loved family life and cooking. Throughout his 30 years as a disability and antiwar activist, he was a persistent lobbyist who became a force in access campaigns, opposing economic rationalist dogma and euthanasia.

Heath subscribed to the belief that knowledge is power. Professionally, he was a writer, journalist, and editor of Australia's leading disability magazine, *Link*. He was a founder of the Disability Information Resource Centre in Adelaide, a prolific contributor to mainstream media, and a popular motivational speaker.

Heath had allies in countless forums in many countries was a member of many advisory structures. From 1988 to 1993, he was executive director of Disabled Peoples' International (DPI) South Australia. However, all who worked with him knew his impatience with group processes. Heath was at his energetic best when focused on tasks, analyzing public policy and hassling for positive change for people with impairments and subsequently the wider Australian community.

HIP FRACTURE

In the United States, approximately 300,000 people fracture their hip every year, and half of them are age 80 or older. The incidence of fracture has increased as people are living much longer, and elderly people's unsteadiness on their feet can be affected by medication, dementia, and general frailty. Often the reason for the hip fracture is a fall, either in the home or on the street, and it is the way that elderly people fall that makes them particularly vulnerable to this type of fracture. For the younger patient, hip fractures are often caused by accidents, often involving motor vehicles and to a lesser extent sporting activities. Studies have shown that it is essential that treatment be carried out quickly, within 24 hours. Treatment usually consists of surgery to insert a bone plate or, in some cases, a hip replacement. The average cost to the health services for a patient with a hip fracture estimated in 1990 was US$20,000, and the entire cost to both private and public providers is estimated to be about US$5 billion per year.

The prognosis for very elderly people surviving hip fracture is poor in the immediate to long term. Complications for elderly people include thrombosis, pneumonia, and infections after surgery. Even with ever improving medical and surgical techniques, the long-term prognosis for the older person is still poor. In a study in six New England states, 24 percent of hip fracture patients died in the first year following surgery. Class and gender affect rates; for example, women have better survival rates than men, and those from lower socioeconomic groups have the worst.

To aid recovery after surgery, ward off potential complications, and increase the likelihood of survival, patients are encouraged to move and begin to walk with aids as soon as possible. Generally, for the younger patient this presents few difficulties. However, many elderly people are not able to take advantage of the rehabilitation programs due to their frailty, so sometimes their ability to improve after surgery is limited. In some cases, rehabilitation programs are not available so many elderly people who have fallen endure a diminished quality of life due to the disabling effect of a hip fracture and the loss of confidence that it can cause. As to be expected, younger people have better rates of recovery, although total hip replacement may be required as the patient gets older.

Since the results following surgery remain mixed, it seems that prevention of hip fractures for elderly people may be the best way to ensure that they do not have to endure surgery, the threat of complications, the potential for long-term disability, and a reduction in their quality of life. Charities in Britain run fitness training courses particularly for elderly people in order that they retain some flexibility and strength. Engineers are developing aids that reduce the potential for a fractured hip if an elderly person does fall. These include hip guards that are inserted in pockets in a special undergarment and act as a type of body armor to protect the hip. As research into preventive strategies improves, it can be hoped that the incidence of hip fracture and its disabling effects, which can cause a significant reduction in the quality of life of individuals, can be limited.

HIPPOCRATES (428–347 BCE)

Greek physician

Hippocrates was a physician, teacher, and author on the island of Cos in Greece. Little is known of his life. A corpus of roughly 60 Greek works (written between 420 and 350 BCE) has been associated with his name, though no text is certainly attributed to his hand. The sweep of the Hippocratic corpus includes texts on disease, deontology, therapy, and physiology among others. A cardinal feature of the corpus is its emphasis on natural, rather than divine or religious, etiologies of disease, often an imbalance of one of the four humors. The clearest evocation of this feature is in the case of epilepsy, which in other ancient sources was considered a religious or magical phenomenon. In the Hippocratic text *The Sacred Disease,* epilepsy was categorically identified as having "specific characteristics and a definite cause," namely, a surfeit of the humor phlegm. Similarly, paralysis, the Hippocratic *Aphorisms* tell us, is a sign of melancholia, or too much black bile.

By and large, the Hippocratics were more interested in generating a *prognosis*, or description of the past, present, and future of a condition (particularly its likelihood of improving) rather than theoretical etiologies and even diagnoses, though both are manifest.

The Hippocratic corpus includes references to scoliosis, limb fractures and lameness, epilepsy, paralyses, congenital conditions, sexual dysfunction, general debility, autoamputation, pain, and sensory impairments. Deafness was often seen more as a diagnostic sign than as a disability. Etiologically, the bowels were linked to deafness, which connection was used by later authors as a therapeutic mandate. Therapy within the corpus includes fracture reduction, crutches, orthoses, and humoral management. Psychiatric and cognitive conditions are also well represented.

The power of the Hippocratic corpus exists in large measure because of the emphasis that later authors placed on it, particularly Galen (AD 129–ca. 199/216); the first university professors of the Middle Ages; and eighteenth-century Western clinicians. To this day, a form of the "Hippocratic Oath" is still taken by many graduating medical students, thus demonstrating the long influence of authors more than 2,400 years ago on the medical model.

HISTORY OF DISABILITY: ANCIENT WEST

The "ancient West " is a difficult term, calling into question cultural and geographic perception (*whose* west?). For the purposes of this entry, the term will refer to the ancient Graeco-Roman world, which was itself a shifting amalgamation of cultures, often distinctly "non-Western" cultures. The ancient Graeco-Roman world spans several millennia, from the third millennium BC through the fall of Rome in the fourth or fifth century AD. In short, the generalizations presented here do not necessarily apply to all places and phases of Graeco-Roman society.

Ideas about disability in the ancient world are part of our common consciousness. Images of Homer, Oedipus, and the Emperor Claudius—along with the phenomenon of Spartan infanticide of deformed infants—are often the first images that come to mind.

Greek civilization, especially fifth- and fourth-century classical Greek civilization, is generally considered the cultural and philosophical ancestor of the West. Current scholarship, though, is quick to qualify the view of antiquarians such as Johann Winckelmann, the eighteenth-century foundational scholar of art history, who viewed classical Greece as the pinnacle of human achievement and who assumed that Greek people themselves were the embodiment of perfection. As Charles Freeman wrote in *The Greek Achievement* (1999), "This was certainly a sanitized version of the original Greece and one could be forgiven for believing that ordinary human beings did not exist in ancient Greece at all." Indeed, people with disabilities are simply omitted in the earliest accounts of daily life such as Jerome Carcopino's *Daily Life in Ancient Rome* (1940).

But people with a wide variety of somatic and psychiatric variations did inhabit both the Greek and Roman worlds, and disability is one of the most recent categories of ancient social history to be examined. Interpreting disability has been influenced both by the romanticized vision of a heritage of perfect Western antiquity and by modern assumptions about what disability means. If one assumes a medical model of disability, in which disability is an individual misfortune to be corrected as far as possible by medical technology, the picture is indeed bleak. Howard Haggard's *The Lame, the Halt, and the Blind* (1932) tells dramatic tales about societies that lack rational medicine.

There has been a growing scholarly interest during the past decade in variations of the human body in the ancient world. Veronique Dasen couched her 1995 iconographic study, *Dwarfs in Ancient Egypt and Greece,* as a study of physical minorities. Daniel Ogden published *The Crooked Kings of Ancient Greece* in 1997. In addition, interest in the study of the human body in the ancient world is represented by a special volume of *Arethusa*, titled "Vile Bodies: Roman Satire and Corporeal Discourse" (Braund and Gold 1998). In 1999, the University of Michigan Press published *Constructions of the Classical Body*, a collection edited by James Porter.

A few scholarly works explicitly employ the perspective of disability studies, which is based on the tenet that disability is at least in part a socially constructed phenomenon—that is, no matter how real a missing limb or a psychiatric disorder might be, the meaning that any given society applies to the condition shifts over time and between cultures.

Among scholars of disability studies, there is no static or intrinsic universal assumption about what the human body should look like. Robert Garland, in *The Eye of the Beholder* (1995), transcends the understanding of disability in the modern, developed world and considers deformity from the perspective of the ancient Graeco-Roman world. Garland considers not only familiar categories of disability such as blindness, but he goes on to discuss emaciation and obesity and points out that baldness was a "serious and inhibiting social handicap." Nicholas Vlahogiannis also transcends the medical model by exploring the formation of attitudes in the discourse of social constructions of disability. Vlahogiannis looked at the disempowerment of disabled people through such systems as punishment and social positioning. Vlahogiannis's essays can be found in *Changing Bodies, Changing Meanings* (1998), edited by Dominic Monserrat, and in the collection *Health in Antiquity* (2005), edited by Helen King. My own work, which examines the intersection between ancient Greek and modern, Western portrayals of disability, is summarized in *The Staff of Oedipus* (Rose 2003).

Disability studies includes all types of disability, including cognitive and psychiatric. While there is no shortage of writing on mental illness in the ancient world, such as Bennett Simon's *Mind and Madness in Ancient Greece* (1980), most works focus on the interaction between Greek mythology and Freudian psychology. Allen Thither's *Revels in Madness* (1999) is refreshing in that it treats "madness" as a shifting concept. Patricia Clark's dissertation, "The Balance of the Mind" (1993), is the only work that examines the effects of mental health and illness on ordinary human beings, in the context of ancient daily life. This work is, unfortunately, not yet published. Even less scholarly material exists for cognitive disability, but quality makes up for quantity in the work of Chris Goodey's essays such as "Politics, Nature, and Necessity" (1999); Tim Stainton, too, has examined the phenomenon in essays such as "Reason and Value" (2001).

Some disabilities are mentioned in the ancient medical texts, most notably epilepsy, the standard work on which is Oswei Temkin's *The Falling Sickness* (1971). Many other disabilities are not even mentioned in the ancient medical literature, as disabilities were not seen as the categorizable medical phenomena that they are today. The evidence for physical disability is scattered, scant, and often contradictory. No discussion of disability survives that is composed by a person who identifies himself or herself as disabled. Nevertheless, literary, papyrological, and archaeological primary sources contribute to our knowledge about disability. Following are sketches of three impairment categories: mobility impairment, deafness, and blindness. These are modern categories, not ancient; many other disabilities existed; and people would have had multiple disabilities, not necessarily one at a time. Still, this sketch provides a sample and an overview of a few issues of disability studies in the Graeco-Roman world.

The ancient landscape included a wide variety of human variation, far more varied than portrayed in images of Graeco-Roman perfection that is the Renaissance and neoclassical artistic legacy. Some people acquired disabilities in the womb or in infancy; an ancient physician writing in the Hippocratic tradition observed that lameness lies in heredity. Impairments such as spinal malformation and clubfoot can be acquired in the womb regardless of genetic configurations. A mother's inadequate nutrition was a significant factor in the ancient world in terms of producing offspring with physical anomalies, and even if a fetus were to grow unharmed in the womb, its birth might be premature. Prematurely born babies are at risk for disability such as cerebral palsy and motor incoordination.

Children born without a handicap could acquire one from a variety of circumstances later in life. Permanent physical disability could result from injured, diseased, and lost limbs; from diseases such as arthritis; and from several other conditions. Even the most minor injury could have permanent consequences. Accidents or events causing fractures were common. Whether as a result of improper healing or as the result of infection, fractured and dislocated bones were likely to result in a permanent physical handicap in the ancient world. In the developed world, we take for granted that, with medical attention, even the most severe fracture will be undetectably repaired. Without medical attention, fractures sometimes spontaneously and completely heal, but not always.

While it is assumed in the developed world that medical attention to a broken bone will result in its healing, a visit from a doctor in the ancient world could have a range of possible results. In the ancient world, a doctor's training was not standardized, licensed, or necessarily respected. There was no standard medical treatment for any given malady, but rather a variety of treatment methods. Some treatments seem sound; others seem of dubious value to the modern eye. For example, the second-century AD Roman physician Galen was in favor of letting blood as a remedy for injured limbs.

Even if a bone is tended to and set properly, it must remain immobilized to effect complete healing. While animals with broken bones do this by instinct, the need to tend a shop or a field would probably override any human instinct to remain idle. The paleopathologist Srboljub Živanović, in *Ancient Diseases* (1982:27), wrote that "the morphological deformities that arose are really beyond imagination at the present time."

Ancient material about deaf people in the ancient world is even more limited than that about people with mobility impairments, but the evidence that exists suggests a grim life for the deaf person who did not speak. There is no suggestion of any sort of formal sign language. Muteness went beyond a physical condition in ancient perception. An inability to speak went hand in hand with an inability to reason, hand in hand with stupidity, embodied even today in the obsolete expression "deaf and dumb." Deafness was indeed a curse, sometimes literally. The word *deaf* appears in the surviving Greek inscriptions almost exclusively as a curse, and a powerful one. Deprivation of hearing, because it meant a deprivation of verbal communication and perceived intelligence, meant separation from the political and intellectual arena. A curse of deafness was appropriate not only for one's political opponents, whose speech could harm, but also for anyone who had too much power—many curse tablets are aimed at litigants.

In trying to reconstruct the daily realities of deaf people from scraps of information, it is worth considering that issues of speech and intelligence were different for the literate elite than they were for the bulk of the population but that we rely on the literate elite for almost all our information about deafness. The elite valued the very skills—such as fluency in communication—that they thought deaf people lacked. The deaf child of a farmer or shepherd, even if considered utterly stupid and incapable of political activity, could certainly carry out any number of tasks. Life in the ancient Graeco-Roman world for anyone who did not speak must have been frustrating occasionally. But while the consequences of deafness are synonymous with exile or death in the literature, it is important to remember that more people in the ancient world were interested in farming than in rhetoric; that is, the majority of the population was composed of peasant farmers, not politicians. Limited conversational ability among peasants might have been a frustration, but not an insurmountable condition.

In contrast to the dearth of deaf people in ancient literature, several blind archetypes are household names. The blind bard Homer, the blind seer Tiresias, and Oedipus Rex, who was blinded by divine punishment, dominate most discussions of blindness in the ancient Greek world. By supplying an apparent historical precedent, generalizations made from the tales of these figures support modern attitudes toward blindness and blind people, such as the idea that blind people are special but horrifying. It is fallacious, though, to transfer attitudes seen in the grand sweep of legend and tragedy to everyday life and to generalize that Greeks and Romans viewed blindness as a fate worse than death. In fact, the ancient concept of vision had little to do with the modern one. There was no measured scale of vision, from perfect sight to legal blindness. One was able to see, even if only a little, or one did not see at all.

No one in the ancient world was immune to blindness. Most of us in the developed world live in the luxury of assuming that we will not—among other fates—become blind. In the ancient world, it was perhaps more reasonable to assume that one would lose at least some of one's sight. It follows that in the ancient world, sighted people knew blind and sight-impaired people well enough to understand the abilities and limitations of failing vision and that there was not the cultural gulf between the sighted and the blind that exists today.

Ancient myths and tales reflect truths and anxieties about sight and blindness in the ancient world. The tales of blind people come from the ancient, contextual understanding of what blindness meant. Blindness meant adapting one's life and activities to the individual's unique condition. In contrast, measurements and categories for degrees of vision determine one's legal status as a sighted or blind person in the modern, developed world. Blindness itself, regardless of individual circumstances, is seen as pitiful and tragic, and, like any evident disability, overrides any other physical characteristic.

In conclusion, and in general, disability in the ancient world was treated as a family and civic issue, rather than a medical one, in which what was conceived of as a "problem" was inherent in the individual. Disability status was defined and negotiated between individuals on a case-by-case basis within a community. On one hand, this does not suggest a utopia; indeed, the lack of a recognized disability status negates the possibility of systematized accommodation and service. On the other hand, people with what we call disabilities were not discriminated against as a group.

HISTORY OF DISABILITY: EARLY MODERN WEST

In the early modern West (1500–1800), *disability* was commonly defined as the inability to work sufficiently to take care of life’s necessities. Physically disabling conditions that were recognized by contemporaries included chronic illness, maims, deafness, blindness, mental problems (illness and intellectual impairment), and infirmity brought on by age or service. Several disabling conditions were understood via reference to the Christian religion and the dominant humoral theory of medicine, especially early in the period. Charitable and state provision became increasingly important, with the origins of disability benefits emerging as military pensions. That disability is a social and political construct is clear in its origins, with medicine being brought in only later merely to serve certain functions in the administration of benefits. In the seventeenth and eighteenth centuries, there were efforts to educate those with certain disabling conditions. Special institutions were created for that purpose.

During the medieval period, there were institutions for lepers (a disease that receded from the fourteenth century in Europe, but not in other places such as Brazil), almshouses, and hospitals for the sick poor. Institutions became more significant from the late sixteenth century for many disabled people, and they grew in number and size (madhouses; workhouses; hospitals for the poor, orphaned, aged; as well as veterans’ and military hospitals). The emergence of these institutions was a result of a change in policy. Whereas in the medieval period the disabled poor were free to wander and beg, this was curtailed from the early sixteenth century on, with begging criminalized. Increasingly, efforts were made to force the able-bodied to work. Efforts were also made to create pensions and to house those disabled to work in institutions. The old English poor law largely emphasized relief outside institutions in the parishes, paid for from compulsory local taxes from 1598 on. This system was influential to a greater or lesser degree in colonial North America. In much of continental Europe, private institutions run by religious confraternities or municipalities were created and grew in size. By 1591, Rome, with a population of nearly 120,000, had nearly 4,000 hospital residents, for example.

In seventeenth-century France, the Catholic Church reformed its charitable institutions, with the Company of the Holy Sacrament creating the Hôpital Général in Paris, housing and detaining thousands of disabled people. By 1700, more than 100 hôpitaux généraux existed in France, with over 100,000 inhabitants, including the insane, the chronic sick, alongside petty thieves, prostitutes, and single mothers. Some scholars have termed this development "the great confinement" (Michel Foucault). Large city hospitals—the Hôtel Dieu—treated the sick and disabled poor and became more medicalized in the eighteenth century, hiring surgeons and appointing physicians. Nursing orders such as the Daughters of Charity (1633) provided practical nursing skills and hospital labor.

Institutional treatment became increasingly important for those afflicted with a disease that was new to the West in the early modern period: venereal disease. Classic secondary symptoms of this disabling disease include terrible pains in bones leading to limited mobility and skin disruptions resulting in disfiguring scars, and for some, collapse of the nose. Although it had previously been believed that sufferers afflicted with this disease could not gain access to a hospital place, recent scholarship has proven that, on the contrary, hospital provision was widespread and a significant factor in the lives of those most affected. For example, up to 30 percent of patients in St. Thomas's Hospital in late-eighteenth-century London were victims of venereal disease (known as "foul" patients).

The origins of disability as a social and political category emerged with military pension schemes. The first state disability benefits were created in England in 1593, when Parliament enacted Europe's first national system for those disabled in war. Initially, the system had a very strong basis of entitlement: Disability experienced in military service entitled men to lifelong pensions. Poverty and financial assets were not criteria. Soldiers and sailors wounded in the service of the realm were treated as members of the community of honor, with hospitality extended to them in a way reminiscent of traditional noble hospitality. Even though the veterans were economically and socially inferior, they were nevertheless to be treated as part of the social world of the host (to enquire too closely into their financial resources would have been dishonorable). Governed (veterans) and governors (council and Parliament) in Elizabethan England thus agreed that disabled ex-servicemen were entitled to statutory relief. This strong conception of entitlement was not, it should be noted, rooted in modern notions of equality or citizenship but in premodern ideals of hierarchical social obligation based on status. In time, this entitlement basis was challenged in practice and later in law by developing, contemporary, poor law notions of disability that were based on the belief that only those disabled to work should be accorded benefits.

From the late sixteenth century, pension evidence from the disabled themselves shows the influence of the humoral understanding of the body on the disabled and those who administered pension schemes, military, and later, poor law. The disabled would narrate their service or life history, their wounds, describing the ways in which their wounds disabled them physically. Some also cited colds and disease, violent fevers and fluxes, which they had contracted in service or domestic life. These continued to plague them for a long time afterward, so as to make labor difficult. Several of the citations of cold and disease correspond to contemporary understandings of the humoral theory of the body, a theory that was understood and accepted by laypeople of different social classes as well as medical practitioners. Thus, the diagnosis was offered by the disabled veterans or domestic poor themselves, and it was generally accepted by those administering the pension systems.

Within the medical theory of humoralism, the human body was believed to be a semipermeable, irrigated vessel in which moved the four humors (blood, phlegm, yellow bile, and black bile). Health was maintained by the preservation of internal stability—balance—through evacuation of bodily fluids and the avoidance, if possible, of environments and conditions of life that upset one's internal stability. The humors moved with differing degrees of fluidity. And they left with varying degrees of efficiency. Heat was believed to promote solubility, cold to hamper it. Several disabled petitioners demonstrated a keen awareness of the permanent effect of heat and, especially, cold in military service and life upon their physical state.

In their general descriptions of wounds, men sometimes mentioned their loss of blood and bruises (the extravasation of blood) suffered on the battlefield. This was often combined with citing old age. It is clear that people believed that a significant loss of blood, or its being forced from its proper vessel in the case of serious bruising, could have permanent effects on the human body. The blood was believed to carry the humors, and as such an inordinate loss of it could irreparably upset one's internal balance. As one got older, the loss of a great deal of blood on one or more occasions would have a greater effect on one's health and strength. This was because it was believed that the bodies of the aged contained less blood than the bodies of younger adults. Aging was understood as a process of people gradually drying out. Thus, although in 1628 William Harvey revealed that blood circulated and that more of it flowed through the heart than could be created as a result of digestion, people continued to believe for some time that the body's production of blood was related to consumption and other factors such as age.

The meaning of some illnesses, as with wounds, was thus cast in historical terms by petitioners. What we would deem medically insignificant events triggered long-term chronic disability. It is clear from the petitions that although age was important in contemporary notions of pensionable disability, one had to be old and disabled to be considered: People were expected to work as long as possible.

By the late eighteenth century, petitions from the war disabled exhibit a marked decline in explanations founded in humoral theory, with mention of the effect of bad humors, as well as cold and heat in service, disappearing. Instead the surgeon's opinion is cited much more than it was in the seventeenth century, and explanations tended to be based more on physical diagnosis rather than the patient narrative. It may be that the decline of humoral medical theory in midcentury among elite physicians—the body as a machine—was filtering through, entering popular culture. In addition, developments in military medicine were influential, with an increasing emphasis on identifying diseases as entities and the development of standardized diagnosis and treatment. These developments contributed to the gradual decline in practice and importance of the disabled patient's story within a humoral context. Within pension systems, medical practitioners gradually became influential as functionaries from approximately the mid-seventeenth century on, after which they were gradually brought in to assist with the assessment of disability.

Some illnesses and disabling conditions in individuals (e.g., madness, epilepsy) and society (e.g., the plague) were linked traditionally to supernatural causes—fate, the devil (i.e., witchcraft), or more commonly, God's will (divine providence). This declined from the late seventeenth century. Contemporary links between illness, disability, and divine providence did not arise within the context of veterans' and old age benefits. Maims experienced in military service were the work of other men, and not God (no matter which side He fought on), and it was accepted that the elderly were more susceptible to disabling conditions.

Over the course of the early modern period, developments in science, philosophy, and medicine had a significant impact on understandings of disabling illnesses. This was particularly the case with respect to mental illness. Cartesian mind/body dualism fundamentally challenged the previous view that mental illness was caused by disturbances in the immortal soul or the mind. Instead, it gradually became accepted that such illnesses were caused by material, corporeal, problems within the body and brain. Thomas Willis (1621–1675) studied the pathology of the brain and the nature of the nerves, developing ideas about the physical origins of problems that had previously been assigned supernatural causes (e.g., epilepsy, narcolepsy). This shift occurred at the same time as a move away from the belief in an interventionist God to one that was much more distant and respectful of universal scientific laws. In addition, scientists became more careful to distinguish between mental illness and intellectual disability. With these intellectual changes over time madness lost much of its stigma, and new ideas about humane and scientific care and treatment developed.

Technological changes also had an impact on the way disabled people were perceived. With the invention of printing, for example, society saw a very gradual movement away from a primarily oral culture in which there was a link between civilization and deafness. Printing brought increased literacy and interest in improving eyesight, with the common use of eyeglasses by the sixteenth century.

From the sixteenth century on, there was increasing interest in understanding the nature of a number of disabling conditions. First deaf people and later the blind were studied and educational methods were developed. Education for the deaf is believed to have begun in Spain in response to inheritance laws that prevented deaf males from inheriting if they could not speak (early legal codes of nearly every European country did not allow a disabled person to make a deed, contract, or will or to testify in court). Aristocratic sons were taught to read and speak by a Benedictine monk, Pedro Ponce de Leon (1520–1584).

This work was continued by Jean Pablo Bonet (1579–1629), who used a hand alphabet and lipreading in his educational methods, an account of which he published in 1620. Seventeenth-century developments in England were influenced by the Spanish experience, with Sir Kenelm Digby (1603–1665), John Wallis (1616–1703), and others in and outside the Royal Society studying practical ways to teach the deaf. Attention was also devoted to the blind. John Bulwer (*bap.* 1606–1656) suggested a special school for the mute in the mid-seventeenth century, and later, Henry Baker (1698–1774) made his living educating the deaf. The British commonly used finger alphabets, likely with some use of signs, whereas in Europe teachers such as Johann Conrad Amman (1669–1724, Swiss) focused on teaching the deaf to speak. In the eighteenth century, deaf schools were established throughout Europe, with a dozen up and running by 1789.

Eighteenth-century developments in the education of the deaf and blind were influenced by intellectual changes. John Locke's *Essay Concerning Human Understanding* (1690) was significant in this regard. Locke (1632–1704) argued that the mind developed as a result of sensory perception and reflection (rather than innately). Accordingly, new experiences could develop new faculties: The deaf and blind could be taught.

The National Institute for Blind Youth was opened in Paris in 1784, founded by Valentin Haüy (1745–1822), who was one of the first to employ embossed print. Similar institutions were later founded in Berlin, Liverpool, and elsewhere. During the seventeenth century, an Italian, Francesco Lana-Terzi (1631–1687), recommended a system of lines and dots representing letters of the alphabet. In 1825, Charles Barbier, a sighted military officer, invented a raised-dot system intended to allow officers to communicate with one another in the dark. This system was refined by Louis Braille (1809–1852).

The growth of institutions for particular disabilities included the development of specialized treatments and educational services. Although positive in many ways, this process also reinforced existing, and created new, boundaries between the normal and those perceived as abnormal in society.

HISTORY OF DISABILITY: KOREA

Disability is *jang-ae* in Korean, which means barrier or hindrance, and *jang-ae-in* is the widely used term to call disabled people. The term for disabled people has been changed over time from *byeongsin*, *bulguja, janghae-ja, simsinjang-ae-ja*, and *jang-ae-ja* to *jang-ae-in*.

Historical studies of disability in Korea, which mostly emerged in special education, rehabilitation, and social welfare policy, have focused on legislation and state policies for people with disabilities. Traditional attitudes toward disability have been explored through the examination of proverbs, ancient folklores, religious scriptures, royal chronicles, and literature. Some explorations of disability history in Korea find parallels with the Western histories such as the experience of stigma, the interpretation of disability as moral punishment, and widespread and institutionalized exclusion of disabled people. Through modernization and Western influence, disability policies have been thought to enhance disabled people's lives. Others sought to read Confucian, Taoist, and Buddhist principles regarding body and disability as the indicators of traditional attitudes toward disabled people before modernization and generalized them as "humane," "benevolent," and "holistic" in comparison to Western maltreatment of disabled people.

ANTIQUITY AND MIDDLE AGE

The alleged earliest reference to disability is in *Samguk Sagi* (*The History of Three Kingdoms*, 1145). This book documents King Yuri Isageum of Silla (a kingdom that existed from 57 BC to AD 935), who provided food to widows, widowers, orphans, people without families, the elderly, the diseased, and people who were unable to support themselves in the winter of AD 25. Similar records appear regarding Goguryeo (37 BC to AD 668) and Bakje's (18 BC to AD 660) relief policies around the fourth century. The stories of disabled people in the text of *Samguk Yusa* (*The History of Three Kingdoms*, complied approximately in the 1280s by Ilyeon) provide rich texts in which one can explore the meaning of disability within ancient Korea from the fourth century BC to the seventh century AD. It contains stories about a disabled person being exorcised and receiving eyesight and being healed from an illness by the power of Buddhism. These stories show that disability was appropriated to expand the power and influence of Buddhism. In parallel, there is a story where the state rewards a daughter who sold herself as a slave to support her blind mother, and this story is also used to emphasize Confucian value of filial piety (Ji'eun story in *Samguk Sagi* and a filial daughter in *Samguk Yusa*). Similar stories have appeared later including "Sim Cheong Jeon" ("The Story of Sim Cheong"), which deals with a blind father whose disability is eventually cured through the sacrifice of his daughter. Disabled figures in other Confucian tales often provide moral challenges to nondisabled characters by becoming obstacles to overcome. For example, Tomi's story from *Samguk Sagi* is about chastity of a wife after her husband was made blind as a punishment.

It is common to interpret ancient texts presenting disability as a punishment of moral wrongdoing, as well as reflecting karma from a previous life. Disability is often positioned as a sign of sin or as dishonor of the family in this context and is often blamed on the parents, mothers in particular. Interestingly, however, disability is also presented as a sign of being more likely to reach spiritual transcendence in some ancient texts, such as in the Chinese Taoist scripture *Chuang-Tzu* (or *Zang-Za*) and often considered as vantage point due to the possible exemption of labor conscription and military services.

Later, in the Goryeo Dynasty (936–1392), there is a record in *Goryeosa* of blind people, shamans, and blind monks as having superstitious power. In *Dongsagangmok* (1778), there is a reference to a guide dog for a blind orphan who managed to survive when the parents died in a disease epidemic. In this period, oriental medicine facilities were developed to provide relief care and shelters to people who suffered from poverty and diseases through Dongseo Daebiwon and Hyeminguk. King In-Jong gave people with disabilities and minors reduction of the punishment, and King Won-Jong required that a person be designated to support each sick person in the village. Disabled people and their caregivers began to be exempted from army service and labor draft (Im An-Su 1993). Seonghyun wrote in *Yongjechongwha* that blind people were hired and educated in Myeongtongsa as prognosticators for royal governance.

In the Chosun Dynasty (1392–1897), blind people continued to receive royal education in prognostication studies (Myeonggwahak), yin and yang studies

(Eumyanghak), and music education in Seowungwan until the fifteenth century. Gwanhyeon Maeong'in refers to royal blind musicians. Royal chronicle shows a record of the official position and promotion given to blind musicians (Chosun Wangjo Sillok, 1431). Specialization of blind people as musicians appeared in the *Analects of Confucius* (when Sagwang made himself blind to sharpen his hearing sensibility and Confucius taught how to accommodate blind musicians). There were legislations and vocational trainings to provide poverty assistance for people with disabilities (especially blind people) to assist their independence (An Byeong Zeup and Jeong Jae Gweon 1983). Some folklores tell that blind people in this period were farmers and teachers in addition to fortune tellers, and the origins of their blindness vary from the ancestor's sin, punishment of heaven, fung sui, violation of taboo, and aging. Rules of decorum, *Sasojeol*, written in the eighteenth century taught that it was unfair and dangerous to call disabled people pejorative names. Military exemption became systematized in the constitutional law *Kyeongguk Daejeon* (1485) for the eligible group of people including minors below age 16 and people with epilepsy; blind in two eyes; who had amputations of more than two limbs; who were mute, deaf, or dwarf; or who had paralysis in more than one limb.

PREMODERN LITERARY REPRESENTATIONS

"Nocheonyeoga" ("Song of an Old Spinster") appeared in *Samseolgi* and introduces a first-person poetic narrative that addresses how the narrator's "deformed" status causes her singleness in the traditional kasa form (Choi 2001). It consists of a narrator's prose preface and epilogue and the spinster's soliloquy and shows that the disabled spinster attempts to address her abilities and effort to get married. In addition, this story demonstrates the normalization of disabled people through marriage by showing that the spinster's disability disappears after the marriage; this transformation also appears in the folk tale "The Half Man." There is another nineteenth-century short reference in "Heungbu Jeon" ("The Tale of Heungbu"), in which a party of blind men came out of a gourd, picking their way with their longsticks, while their sightless orbs were raised toward the unseen heavens and offered them to tell the fortunes of the family. They were employed in order to chastise the brother of Heungbu for his stinginess and greediness and to extort money from him with other groups of people such as shamans, kisaeng, Buddhist priests, a jester, and officials.

In the premodern period, disabled people were called *byeongsin,* which means sick body as an overall term. There were individual terms referring to specific disabilities such as *jeolleumbari* (a lame person); *anzeunbang'i* (a quadriplegic); *jangnim*, *sogyeong*, *chambong,* or *bongsa* (a blind person); *beong'eori* (a mute person); *kwimeogeori* (a deaf person); *kopchu* or *kopsadeung-i* (a person with a humpback) and *kombaepari* (a person with a short arm); and *babo*, *cheonchi*, and *meojeori* (a person with cognitive disability). It seems that there were less terms for cognitive disability in this era, which is read to be due to the emphasis placed on physical ability by the primarily agricultural society. *Byeongsin* is still used today often as a curse word. Bak Hee Byeong traces the usage of this term in premodern literature and concludes that it was used in a descriptive way referring to a sick body but started to have pejorative meaning implying inferiority of the persons in the late eighteenth century. According to Bak, in the late nineteenth century during the Enlightenment period, this word started to be employed as a symbol of the old customs that must be eliminated in order to build a strong nation.

In the Patriotic Enlightenment period (1905–1910), disabled characters were culturally employed to represent Korean identity amid the conflicts between traditional values and customs and modernization. Kyeong-Hee Choi argues that the trope of disability surfaced largely within a sociopolitical perspective that emerged in response to a sense of national crisis. The newspaper *Daehan Mae'il Sinbo* presented the unique genre of a serialized story in 21 installments with two disabled characters, "Sokyeong'gwa Anzeumbang'i Mundap" ("Questions and Answers between a Blind Man and a Quadriplegic") from November 17 to December 13, 1905. The anonymous writer's dialogue style satire subjects able-bodied people and the social situation to the scrutiny of two disabled characters; however, two characters signify old value and custom.

MODERN SPECIAL EDUCATION

Modern special education and institutions for disabled people were first introduced in Korea by the imperial inspectors Sinsayuramdan, sent to Japan to learn modern civilization, and Yu Gil Jun, who traveled Japan and Western countries. Yu Gil Jun introduced asylums in the West and special education facilities in his book *Seoyugyeonmun* (1895). With the arrival of American missionaries, modern special education is believed to have begun in Pyeongyang in 1894 by Rosetta S. Hall when she first started teaching a blind girl. Western missionaries fed imperialism in the form of medical and educational practices without making evident the Christian mission in order to get permission to start their activities. Missionaries especially focused on disabled people and women. Jung Keun Sik (2002) argues that missionaries "rediscovered" lepers in Korea in the process of implanting modern medicine and Protestantism. Jung also argues that missionaries maintained competitive relationships with Japanese colonial management for disabled bodies.

It is possible to see the effects of the Christian origins of the special education system, particularly in its cultural positioning of such education as an act of mercy and because many private special education schools are affiliated with Christian organizations. Hall's first special education class was initially located in the Hospital for the Children and was directed toward teaching blind and deaf girls and also providing medical treatment to women. It developed into the special education school called the School for the Blind and Deaf in 1909. Other residential schools for the blind opened in different areas including the School for Blind Boys established by the Presbyterian missioner Alice Moffett in Pyeongyang (1903) and the Custodial Care Facility in Seoul established by the British missionary Jean Perry in 1914. In 1923, Pak Du Seong established the Korean Braille system, Hunmaengjeong'eum, when Hall's New York style Braille was found insufficient in the application to Korean letters.

Until the late 1960s, special education was mostly aimed at blind, deaf, and cognitively disabled children. Children with mobility impairments started to be educated in special schools in the late 1960s. In 1911, the Japanese colonial government opened Jaesaengwon to provide custodial care to orphans and deaf, blind, and other disabled children. Maeng'abu in Jaesaengwon was the first public school for the disabled and provided vocational training. After decolonization, Maeng'abu changed into the National School for Blind and Deaf. Paramedical vocational trainings such as acupuncture and massage therapy were set up as the curriculum for blind people. The first special education class was installed in a regular elementary school, Dondaemun gongnip gukminhakguo, in 1937 (Kim Byeong Ha 1983).

Special education was moved from the public health domain into the category of education after the Korean War. The war left many people disabled and led to the establishment of the rehabilitation institute and the growth of rehabilitation medicine. Postwar institutions for orphans and disabled children were usually connected in some way to church or charity organizations. The independent South Korean government set various laws and regulations with respect to mandatory education. However, Article 98 of the Education Act exempted certain children from elementary schooling. These children are "those with a disability, developmental delay, imperfection, illness or any other condition making school education impossible." The disability movement would later argue that this exclusion amounted to discrimination against disabled children. In the 1950s, legislation focused on supporting disabled veterans and their families, and in the 1960s, policies for compensating veterans were reinforced. Policies also started focusing on supporting industrial disability compensation insurance.

SURVEYS

In 1961, the first national-level survey of disabled children, *Hankuk Janghae Adong Josa* (Handicapped Children's Survey), was conducted and funded in part by the Pearl Buck Foundation and the U.S. Army. Categories of the survey include "paralytic or palsied, deaf and dumb, deaf only, blind in one eye, hunchback, stuttering, totally blind, hare lip or cleft palate, epileptic, partially blind, psychotic, clubfoot, and racially mixed." It is noteworthy that racially mixed children mostly born between Korean women and U.S. soldiers are included and labeled as "socially handicapped."

The 1966 census of people with disabilities, *Janghaeja josa,* by the Ministry of Health and Social Affairs was based on the 1961 survey and maintained the same categories. "Children of mixed racial parentage" disappears in later statistics and definitions of disability. Later categories appeared to have a more medically influenced definition system including mental retardation, mental disability, physical disability, visual disability, hearing disability, and language disability.

Saenghwalbohobeop (Social Security Law, 1961) allowed the establishment of rehabilitative institutions, and minimum social security was promulgated; 1961 marks an important beginning of governmental control over the disabled population by forwarding institutionalization under the banner of "protection." Mojabogeonbeop (Maternity and Child Health Law, 1973) started allowing abortion in case of "genetic or eugenic causes" or "contagious diseases." The government from this period drove an intensive economic development policy and the welfare of the citizens was left behind.

Statistical surveys on disability people continued in 1962 by the Institute for Economic Planning on injury rates, the 1966 census of disabled people, and the 1968 and 1975 national statistics on disabled people supplemented the population census. The effort to identify the realities and the magnitude of the disabled population was forwarded even more in the 1980s. National surveys of disabled people from 1980 and 1985 show this effort, and after 1990, it became required by law to conduct surveys every five years. The 1980 survey did not include disabled people who lived in the institutions. The term *jae-ga-jang-ae-in* referring to disabled people who reside in the domestic space started to be used in 1991 national statistics as a distinctive category as opposed to institutionalized disabled people, *si-seol-jang-ae-in*. In 1988, the government began to require that all disabled people register to be identified as having a disability to be eligible for benefits. It is common to see disabled people explain their gradients of disability given by this registration procedure and medical examination along with the types of disability. The gradient is entitled based on the degree of limitations, and the first degree of disability refers to the greatest limitations. These gradients reflect the categorization of disability according to functional limitations and its effect on disabled people's identities.

In 1973, there was an attempt to embark the Sterilization Law of Mentally Retarded People (Kim Mi-Ok et al. 2004). In addition, given that the competitive educational system allowed only six years of universal education and required entrance examinations for middle school and high school, which included physical fitness tests, people with post-polio syndrome—who were more frequently included in regular education in spite of its inaccessibility—were often subjected to this specific discrimination until the exemption of physical tests was enacted in 1972. Many people with post-polio syndrome born in the 1950s and 1960s attempted careers in medical or paramedical disciplines, pharmacies, and oriental medicine; this practice was in line with the public belief that those professions were appropriate for some disabled people—mostly those who could walk or had minimal physical disabilities—with less discrimination. However, in the 1970s universities often rejected them due to their disabilities. In 1967, Hanguk Ilbo forwarded a campaign reflecting the social attention to people with post-polio syndrome under the slogan "Let able-bodied people take care of children with polio" (Kim Mi-Ok et al. 2004).

Under the influence of the 1981 International Year of Disabled Persons, the Ministry of Health and Social Affairs developed the Welfare Law for Mentally and Physically Handicapped (Simsinjang'aeja Bokjibeop) under the military government's "Welfare State" propaganda. Paradoxically, the number of institutions grew in this period significantly and custodial care started to be supplemented by medical rehabilitation, therapies, and vocational trainings in the institutions. The Special Education Promotion Law was enacted in 1977. However, less than 20 percent of disabled people benefited from formal education until the early 1990s. The expansion of special education classes from the mid-1970s is also characterized by an effort to exclude students who are identified as below certain standards in school achievement or who are considered as interrupting the education of others. Economic support started to be provided to people with disabilities such as social security pensions and tax exemptions in the 1980s. The legal term for people with disabilities changed to *Jangae'in* from *Jangaeja* in this period.

The International Year of Disabled Persons in 1981 and the declaration of disabled people's human rights and the principles of antidiscrimination provided a background as the disability movement in Korea emerged during the mid-1980s. The discourse of social responsibility of disability rather than individual fault regarding the problems faced by disabled people emerged. The human rights of disabled people became the dominant rhetoric of the disability movement. In 1986, various disability groups such as National Union of Physically Disabled Students became very politically active, aiming at the presidential election the following year. In April 1988, the public protest of disabled people was held in front of the Myeongdong Catholic Church. The disability movement had opposed the hosting of the Paralympics in Seoul because it was believed to cloak the severe violations of the rights of disabled people in their everyday lives and extreme poverty. For instance, sterilization is still practiced on many women with cognitive disabilities as a form of contraception. Depo-Provera has been suggested by medical doctors to parents as a means of removing the menstruation of females with cognitive disabilities. Also, corrupt private institutions that exploit disabled people by using them to raise funds were also the targets of the disability movement. The shared goal of disability organizations was to amend the welfare law to enhance social status of people with disabilities, and to establish legislation for employment and affirmative action in higher education. Activists often viewed disability oppression mainly as a class and poverty issue under the capitalist system that considers disabled body as useless in terms of labor power.

The disability movement celebrated the passage of legislation of the Employment Promotion Act for People with Disabilities in 1990, which requires a 2 percent quota system for eligible workplace. The Accessibility Promotion Law for disabled people, pregnant women, and the elderly enacted in 2000. The amendment of the Welfare of People with Disabilities Act expanded the definition of disability. It includes physical disability, brain neurological impairment, visual impairment, hearing impairment, chronic illnesses, language disability, cognitive disability, mental disability, and developmental disability.

The emergence of the disabled women's movement illustrates the importance of gender in the experience of disability (Kim Eunjung 1999). Disabled women asserted their different needs and experiences from disabled men and nondisabled women during the late 1990s. For instance, sexual violence in institutions and communities especially against women with cognitive disabilities has been a neglected issue from both the women's movement and disability movement. Often staff and volunteer workers were responsible for this violence. Disabled female activists who encountered a male-centered atmosphere within disability movement started to organize feminist groups with an alliance of non-disability-identified women. The disabled women's movement came forward launching cultural celebration of different bodies and pride as women with disabilities and providing challenges and different perspectives on the body, sexuality, beauty, and femininity. There has also been increased awareness among disabled women of the needs of an alliance with marginalized groups such as lesbians and women laborers, and some links have been made with the organizations for women in the sex industry in which the exploitation of disabled women occurs as well. Enhanced penalties for sexual violence when the victim has a physical disability were expanded to include mental and cognitive disability in the Sexual Violence Act.

Access to public transportation has been an important issue in contemporary Korea. Prompted by the deaths of several disabled people while using unsafe devices such as a stair lift in the subway that had been employed as an expedient remedy for accessibility, the disability movement has undertaken militant actions such as hunger strikes, blocking public railroads, and delaying subway trains in 2001. Along with these protests, some organizations called for antidiscrimination legislation.

In spite of the efforts of disability organizations, many people in Korea continue to see assistance for disabled people as an act of kindness or a benefit, rather than an issue of human rights. The disability movement continues to raise important issues such as cultural invisibility, economic hardship, unemployment, insufficient medical services, lack or inaccessibility of education, inaccessible housing and transportation, institutionalization, and human right violations such as forced sterilization, infanticide, and double suicide of parent and disabled child.

With regard to the North Korean situation of disabled people, very little information is available and only through the testimony of people who escaped or through international human right reports. It has been reported that in the 1960s, there was a massive forced migration of little people in one village in Hamgyeognamdo by the command of Kim Il Seong. Pyeongyang, the capital of North Korea, has been kept from having disabled people in public by expelling disabled people to rural areas. It is allegedly known that due to city beautification and reproductive control, little people and people with hereditary diseases or physical disabilities are institutionalized. The 1998 North Korean Human Rights White Paper documented that there has been forced sterilization of disabled people practiced (Choi Eui Cheol et al. 1998).

HISTORY OF DISABILITY: MEDICAL CARE IN RENAISSANCE EUROPE

The European Renaissance lasted roughly from 1400 to 1600, its period varying somewhat by region, but it had little effect on medical practice. The two events that influenced medical concepts significantly were the writings of Paracelsus (1493–1541) that opened the possibility of questioning Galenic dogma, and the two anatomical texts of Andreas Vesalius (1514–1564) that corrected some Galenic anatomical beliefs. Health care was practiced according to the 1,300-year-old traditions of Galen (AD 129–ca. 199/216) by a few university-educated physicians who largely served the clerical and secular nobility. There were a larger number of apprenticeship-trained barber surgeons, as well as itinerant quacks, while the peasantry in general cared for themselves. The little information there is regarding care for the chronically disabled pertains mainly to the institutional management of those diagnosed with leprosy. Some towns, Nuremberg, Bavaria, for example, made a considerable effort to provide financial aid to the unemployable.

This entry presents a sampling of sixteenth-century medical opinions regarding some of the causes and treatments of psychiatric, neurologic, orthopedic, and gastrointestinal conditions that would now be considered potentially disabling. It is based on four books published between 1543 and 1596, each of which had earlier editions. The authors were Giovanni de Vigo, an Italian, who was surgeon to Pope Julius II; Felix Wirtz, a Swiss surgeon; Christoph Wirsung, a German physician; and Hieronymus Brunschwig, a German surgeon. The first three were texts for other practitioners, the last a home medical guide.

The symptoms these writers have provided frequently are inadequate to make a modern diagnosis, being lumped or split into diseases consistent with pathologic concepts of the time but inconsistent with ours. On the other hand, the modern reader may be tempted to make a diagnosis by interpreting an astute observation quite differently from the observer's belief. Pathologic explanations were based almost entirely on the imbalance of or obstruction by humors. A principal pathogenetic diagnosis was "aposteme" or its synonym, "impostume." This may be "hot" or "cold." Specifically, it is an abscess, a localized accumulation of pus. Any superficial swelling might have been so designated, as well as any localized internal symptom. Palpation and color could determine whether a superficial aposteme was hot or cold. Internally, this differentiation appears to have been arbitrarily made by the writer. Surgeons wrote less about humoral pathology than physicians because they dealt more with trauma.

Overall, more space was devoted to "effective cures" than to the description of diseases. The "cures" were largely botanical, and the descriptions were only occasionally accompanied by instructions for their preparation and administration. Actually, few people ever were treated by a physician, and there is no information about how extensively a particular medicine really was employed. Furthermore, a remedy may have appeared in numerous publications because of its reputation rather than its availability. Some circumstances were deemed incurable and some signs of imminent death were specified. However, descriptions of the duration of an illness were consistently lacking.

While medical symptoms had humoral explanations, behavioral peculiarities still were widely attributed to magico-religious causes. Wirsung addressed this unequivocally. In regard to phenomena that we might interpret as preconvulsive auras or hysteria:

> They are not signs of a pinching devil or witches . . . but in truth none other but a natural sickness. [Describing either coma or hysterical rigidity:] the common people [believe that] Satan mingles his wiliness, . . . but this numbness agrees with infirmities of the brain. There are three kinds of "altered disposition": [1.] Delirium, which when associated with fever is called frenzy, is caused by the admixture of phlegm to hot humors. [2.] Mania is caused by hot humors, mainly yellow bile. [3.] Dementia, in which the patient is "wholly out of his right mind" only results from cold humors.
>
> The brains are the uppermost and chiefest of all the inward members of man's body, a place and abode of the understanding, memory and judgment. . . . Hence do also spring all the sinews and spread themselves through the back over all the body, strengthening and conjoining it, making it movable and sensible. (p. 117)

In Wirsung's psychiatric discussion, nerves are "sinews," while in the musculoskeletal section "sinews" clearly are tendons and ligaments. Contrary to "sinews," tendons and ligaments lack sensation. The brain is "insensible," but "this precious and tender part is subject to many accidents which bring very great inconveniences. . . . When sinews become inflamed the brain is affected so that there is mental deterioration."

"Palsy is indeed a swift, grievous and terrible disease which has its offspring in the brain" (p. 134). This comprehensive designation includes a gradually developing lethargy (perhaps encephalitis); tremor or small palsy (perhaps including Parkinson's disease); epilepsy in old men and young children which occurs with or without motion, and is most severe if there is incontinence; sudden loss of motion and sensation without loss of consciousness; and the most severe, apoplexy. This may initially resemble death. The main indicator of its severity is the characteristic of the respiration.

Residuals of a stroke are not described, but "albeit that it were cured, yet it does turn to some other sickness."

Palsy may result from trauma: "If so be that one falls so hard, or is beaten or struck that thereby forthwith he is taken with the Palsy, then it is not to be helped; but if it comes slowly afterwards upon one." There are various medications. Facial palsy is considered separately. "[It] is a convulsion of the mouth and lips to the right or left side, at other times shutting one eye." (This probably includes Bell's palsy.) Lameness has many causes such as apoplexy, the pocks (possibly syphilitic arthropathy), hectic consumption (possibly tuberculous arthropathy), and chronic dislocations. It is associated with withering of limbs and contractures and is mainly treated with poultices.

De Vigo succinctly attributed various functions and dysfunctions to specific parts of the brain. Each of its four parts is controlled by a different humor: blood in the front, phlegm in the rear, bile in the right, melancholy (black bile) in the left. He conceived there to be three ventricles: The largest, in front, receives sensations; the rear houses imagination; and the middle, common sense. An aposteme in the substance of the brain is fatal. A cold aposteme in the middle ventricle causes forgetfulness. Vapors in this region cause vertigo or loss of vision, while obstructive humors cause a palsy. If all ventricles are blocked, the result is apoplexy. "The cure of the palsy . . . I will leave to my masters, the Physicians, for most often it has a physical cause and therefore its cure pertains to them." Nevertheless, since palsy may result from head trauma, some medicines will be described.

Three writers differed in their discussion of joint diseases, while Brunschwig ignored them. According to Wirsung, arthritis is "the pain of the joints, or an inflammation of the joints, which proceeds from within the body, and the Tendons be annoyed, hurt and pained. It is none other than a dispersed Podagra over the whole body." Tophaceous (genuine) gout is incurable. Wirsung and de Vigo agree that hot gout is indicated by erythema and is associated with blood. It has dire and potentially fatal consequences. Cold gout is indicated by pallor and mild discomfort, but it is the most protracted. Its cause is predominantly phlegm. Wirsung defined an intermediate severity caused mainly by the bilious humor, with sharp pain but no erythema. In addition to appearance, cold gout is differentiated from the most severe variety by the quality of the pulse.

Wirtz, like de Vigo, a surgeon, did not concern himself at all with etiology, but discussed trauma that causes drainage of synovial fluid from an injured joint. Normal synovial fluid, he believed, is produced by ligaments and is required for joints to function. It must be differentiated from pus, but in an improperly treated wound may become purulent. Prolonged loss of this fluid from a joint can destroy it, or can fatally drain moisture from the entire body. Such an injury must be treated by drying medicines and proper bandaging. The treatment of fractures by setting, splinting, and binding is primarily the responsibility of surgeons. However, advice is offered in regard to auxiliary medical remedies.

Worm infestation was the one medical ailment for which the pathogen did not require invocation of humors. Its causes included (presumably communal) bathing and eating pork. This suggests that trichinosis was recognized, but since muscle pain is not cited, this is unlikely. The association of worm infestation with children who eat much fruit suggests a belief that maggots in fruit become intestinal worms. Wirsung recognized three varieties: long worms (possibly tapeworms) that reside in the upper intestine, ascarids that reside in the stomach, and small worms "like maggots" (possibly pinworms) that reside in the rectum and cause severe itching. The surest sign of infestation is that the patient excretes in the stool small things resembling gourd kernels. The main symptoms in children are irritability and restless sleep. Adults experience severe abdominal pains. Treatment is necessary because obstruction and, last, painful death may occur. High-lying worms are best treated orally and low-lying worms by enemas or suppositories. The choice of vermifuges is particularly large. Some treatments were biphasic: the first potion to kill the worms, the second to expel them.

Wirsung warned in regard to blood letting: "Good heed is to be taken of the strength and power of the patient, for . . . the veins in the lower parts weaken the body more when they be opened than those in the uppermost parts." Compared to medications and bleeding, bathing was infrequently recommended, probably because this was less effective than bleeding or purging in eliminating noxious matter. One may bathe in seawater or sulfur water. Simply bathing in lukewarm water after a stroke was permissible, but would be more effective if steeped cooling herbs were added. Baths that opened the pores and caused perspiration were more effective, but not necessarily by immersion in hot water. Alternatively, the patient might be exposed to a vapor created by spreading powdered herbs over hot irons over which scented water is poured. He is then washed with water after he leaves the steam. Since bathing opens the pores, it is potentially hazardous because it permits entry of "infection." In a communal bath "as well the pores of the [plague] infected as of the sound are opened, whereby the venomous vapor of the infected is let forth, and may easily be received of the healthy. . . . If one cannot sweat, heat bricks or other stones very hot and wrap them in a wet cloth. Place them under the feet, armpits, on his sides or between the legs. The vapor will cause the patient to sweat."

Little advice is given for convalescence, and none for the care of the disabled. According to Wirsung, when "sick folks begin to mend, and the disease wears away, the breath begins to be free, the pain to cease, the sleep to come, and have appetite for meat . . . the patient begins to recover" and a light diet is recommended. Above all else for the recovery from all diseases, the patient should relocate, "especially to draw near to mountains or hills where it is dry, far from the sea and stinking lakes." Brunschwig, writing for families rather than colleagues, did not describe signs of convalescence nor diets. He recommends baths "for them that have been long sick or whose bone marrow is corrupt, or whose blood is corrupt and deficient." Various ingredients should be put into as much water as is practical, and "bathe in the morning fasting so long as he can endure it," but do not add more water, presumably because this would dilute the effect of the additives.

Opinions about opium, one of the few botanicals having major pharmacologic effects (henbane, the source of atropine alkaloids, is another), varied. Wirtz was particularly positive. "It calms agitation, eases pain in the head, creates calm sleep, drives off visceral pain, strengthens the brain, stimulates the spirits, brings on happiness and a good appetite. . . . You must first evaluate the patient carefully because dosage depends on the circumstances." His only warning was not to prescribe opium in the presence of pulmonary symptoms. The authors leave the implication that apothecaries had ready access to opium.

Wirsung gave several receipts for oral or topical administration using seeds of the white poppy. Made into an oil, it "assuages all pain, cools, and by anointing the temples sedates and as the hot vapors draw to the head in any hot sickness it assuages throat pain, the heat of agues and nightmares." He stated that poppy seeds are used in almost all receipts for sleep, but if such receipts are not effective "then opium of necessity must be used" to obtain some rest, but not without the counsel of an experienced physician.

De Vigo believed that there are 15 kinds of pain, but three types of treatment: (1) external medicines that evaporate the cause by restoring normal heat; (2) altering the evil complexion (humoral imbalance); and (3) "suppressing the natural heat of the member and taking away its feeling, which is done by medicines of opium." De Vigo appears to have been the most reluctant to use opium. Opiate medicines palliate pain but should be used only "in great necessity." Although the pain will temporarily be suppressed, "it will return with greater vehemence." A purge should be given before administering opium, and opium should not be given to a weak patient. "The malicious nature of opium" is reduced by the addition of other herbs. Whether it may be used orally or only as a plaster is not clear. Among home remedies Brunschwig mentions neither opium or poppy seed concoctions, presumably because of their perceived danger.

A considerable amount of the clinical writings, both of physicians and surgeons, in the sixteenth century described proper behavior toward patients. The following example is unusual in that a surgeon (Wirtz) appears to hold physicians up as superior models:

> A surgeon for many reasons should guard against submitting to drunkenness. Would a complete physician rather be able to diagnose an injury or a wound if he is confused in his head and bereft of proper understanding? How can he examine a wound correctly, view the signs and decide on their significance while he is not sharp, or sharp enough, or sees everything double? And how can he grasp and palpate a fracture properly while his hands tremble and are in other ways clumsy and coarse? (p. 105)

The ideals of healers were the same as those of modern medicine, as Brunschwig indicated: “Let every Physician and Chirurgion follow this rule: to well and exactly know and search for the cause of the disease, so that he the more certainly know how to heal the patient.”

HISTORY OF DISABILITY: MEDIEVAL WEST

There is a medieval nursery rhyme,

> I saw three headless [people] play at a ball,
> A handless man served them all;
> While three mouthless men lay and laughed,
> Three legless [men] away them drew.

The fact that children might learn of disability in their crib and at play suggests how profoundly quotidian was medieval disability. However, disabilities in the Middle Ages are only now beginning to be investigated as a group. For the medieval child or adult, aggregating experiences and conditions, which we would consider disabling, would have been peculiar.

The period of the Middle Ages in the West, conventionally is held to run from roughly 500 to 1500 CE, although the nature of the medieval world shifts dramatically from the south of Europe, which experienced the Renaissance earlier, to the north of Europe from the extreme west to the extreme east. In general, the Middle Ages embraced social and intellectual changes from the fall of the Roman Empire to the rebirth of antique culture in the Renaissance and the origins of the nation-state.

Our view of disability during this period is still highly fractured. This entry presents an overview of several of the fragments. Ideas about and experiences of disability during the Middle Ages varied dramatically. The conceptualization and experience of disability by a serf with a lower-extremity paralysis in twelfth-century England was notably different from that of a fifteenth-century Italian duke with a speech impediment or an eleventh-century German nun with depression. In addition, the social expectations of medieval people were rather different from those today in the West. As a consequence, the following survey will be at best imagistic.

Medieval disability originated from many directions. Given that, some studies report, nearly 50 percent of children died before age 21, death was a fiercely regular occurrence in the home and community. Nearly a third of the inhabitants of a York cemetery were children during the Middle Ages. Parasites were frequent, suggested by archeological studies of cesspits. Accidents were a regular occurrence. Hunger and starvation were probably common in the full life of a medieval rural person; conditions of nutritional deficiency, such as rickets, were not uncommon. Still, infectious diseases were probably the most common cause of death. But death was only an extreme.

Owing to variable survival of sources, it is difficult to generate any kind of accurate epidemiologic statistics of disabling conditions from the Middle Ages. We know that tuberculosis, plague, and leprosy, among others, were infectious diseases, which could leave survivors with long-term disabilities as attested to by both archeological and textual evidence. Data derived from miracle records at the shrines of saints suggest a range of symptomatic/diagnostic conditions with disabling features, including blindness, deafness, mutism, a variety of paralyses, and leprosy. While we have only the barest sense of epidemiology for medieval disabling conditions, we can gather that disabilities were common enough both to provoke notice and yet often to deny total "otherness" by the degree of accommodation and integration invoked by society at large.

The experience of disabilities by medieval people is only now beginning to be elucidated. Biographically, we know any number of figures with disabling conditions. Henry the Minstrel, fifteenth-century chronicler of William Wallace of Scotland, was known as "Blind Henry," though not all scholars agree to the veracity of that epithet. Some famous figures with disabling conditions, like Hermann von Reichenau (also known as Hermann "the Lame" because of a congenital lower-extremity impairment), were born into the nobility and went on to positions of great intellectual productivity denied to the poorest medieval peasant. Hermann was educated at an abbey and became a well-known chronicler, poet, musician, and mathematical astronomer. Teresa de Cartagena, who became deaf as a child in the fifteenth century, 20 years later, as a nun, wrote *Arboleda de los enfermos* (*Grove of the Infirm*), possible only because her family was wealthy enough to have her tutored. King Baldwin IV of Jerusalem was a child when he contracted leprosy, and yet he continued to fight in crusades before his death at around age 24. Another leper, this one very poor, lived in Venice and spent much of his life begging on the fourteenth-century streets. The Old Norse *Landnámabók* refers to a certain Bjargey Valbrandsdóttir, wife of Hávarðr halti ("the lame"). A famous woman with a potentially disabling condition, the mystic Hildegard of Bingen had visions, which have been postulated to be severe migraine headaches with scotoma. Rather than impairing her vision while toiling in the fields, these images became a religious experience, which transformed both her individual relationship to God and also those influenced by her writings. On the other hand, King Sancho the Fat (r. 955–958 and 958–960) of León in the eleventh century was driven from his throne for severe obesity. It was not until after he was successfully treated by the Jewish physician Hasdai ibn Shaprut, perhaps with opiates, that he was able to return to the thrown. As well as class, religion, race, and gender certainly altered the experience of disability.

The world around the medieval person was potentially disabling at all times. In one example, a medieval fisherman netting a torpedo fish became paralyzed in his upper extremities. The often-analyzed Hippocratic *Aphorisms* explained how winds from the south make one deaf. In addition to the vagaries of nature, accident, happenstance, and bad fortune were clearly agents of disabling etiology. More frequently, etiology was attributed to witchcraft or evil magic, as when King Alfred the Great was enjoying his wedding night and was attacked by a severe pain, which some attributed to witchcraft. But religious explanations were widespread and promulgated by ecclesiastical doctrine. As a consequence, the role of relics and saints' shrines in miraculous cures of disabling conditions is undeniable (see below).

Increasingly, into the thirteenth and fourteenth centuries, a process of "medicalization" provided another explanatory system. This was hardly to the extent of the medicalization of the nineteenth and twentieth centuries, but still significant. For many disabling conditions, a common medieval medical explanation was framed in terms of humoral theory. Having been propagated by Hippocrates and Galen in antiquity, the four humors were initially understood incompletely in the early Middle Ages prior to being recovered in the wave of translations from Greek and Arabic into Latin in the eleventh through fourteenth centuries. Thus, elite theories about disabilities may be divided in a bimodal fashion—the early medieval and the late medieval conceptualization. Characteristic of the early medieval is a vague understanding of the four humors; characteristic of the late medieval is a highly complex understanding. Where medical experts in antiquity were greatly interested in prognosis, the role of the late medieval physician increasingly fell to diagnosing conditions, and indeed in officially certifying them. That certification could become a tool for market competition. One thirteenth-century university physician, Jean de Saint-Amand, described a drug he prescribed for its special property of attracting phlegm from the head if scrubbed on the palate. In this way, he treated a patient who according to common wisdom was essentially dead because of her inability to talk and listlessness. Using the drug, he restored her ability to talk long enough for her to give her final confession then died. In this example, Jean not only displayed his ability to alter humors, relieve a disability, and assist a patient in her crucial religious function, but he also distinguished his refined knowledge from that of the untutored. Jean also treated a patient with another drug to forestall leprosy; the therapy worked for three years, when the patient contracted the condition. In stories like these, elite physicians used the care, treatment, and prevention of disabilities to their marketplace advantage. As the physicians became more influential in social circles, surmounting surgeons, apothecaries, and barbers in their medical roles, the "lesser" disciplines tried to emulate the physicians and disabilities could play a role. Thus, Lanfranco of Milan, a thirteenth-century surgeon in Paris, treated a patient only after a lay healer admitted his ignorance of the condition.

For disabling conditions such as leprosy, medicalization was an important shift. As a consequence, the rise of institutions, previously devoted to charitable care like leprosaria, increasingly allowed for population-wide "social control" of some of those with disabilities. Disabilities could offer complications to the elite theoretician. At times, the presence of a disabling condition, such as epilepsy, could incite caution for doctors in the drugs they prescribed. Thus, Avicenna, an eleventh-century Arabic physician widely studied in Latin translations in Europe, noted that celery was contraindicated in epileptics as it could cause status epilepticus. On the other hand, one condition could induce another disabling one. According to Taddeo Alderotti, a thirteenth-century Bolognese physician, diarrhea could induce stuttering or stammering. Similarly, chronic, untreatable conditions of a disabling nature could be cause to withhold certain kinds of charity care. Thus, the Hospital of St. John the Baptist in Oxford did not accept people with those conditions, nor did it accept those with epilepsy or women pregnant out of wedlock. Simply taking mercury could cause paralysis in everyone. Occasionally, medical and technical interventions for disabilities have had long-standing consequences. The invention of eyeglasses in the fourteenth century, for example, has accommodated presbyopia ever since.

In addition to elite theories of disabling conditions, religious explanations helped people with disabilities and those caring for them to understand their conditions. Thus, the ill will of the devil could cause a crippling pain, the loss of faith in a patron saint could cause the reoccurrence of blindness, or unrepentant breakage of a Commandment could cause mania. Not surprisingly, the Catholic Church's role in ministering to the disabled was considerable; that role was even represented in religious symbology. Hence, the bishop's crosier was designed to indicate a support for the disabled and infirm. The Bible and its multiple exegeses are rife with metaphoric descriptions of intellectual and spiritual blindness and deafness, many of which were then cured through divine intervention.

The twelfth-century monk and pioneering biographer Guibert de Nogent tells how his mother became paralyzed after a devil's visitation. Even the divine could have disabilities. Angels, for example, were considered by some medieval theologians to have a kind of disability in lacking the bodies to experience sensory passions; they could only experience intellectual passions (cognition). Yet the divine was, in Bible and sermon, frequently the source of healing for disabilities. Appeals to saints for miracle-based cures were commonplace. In this role, religious healing was an economic competitor of lay medical "cures." Even those perceived as holy by laypeople, such as the flagellants during the Black Death, could generate healing imagery. So the blood of flagellants was sometimes collected by women on the street side and applied to the eyes for preventing or curing blindness.

At other times, the two certified systems of healing—religion and medicine—could team up to stave off the ministrations of the magical healer, of whom both the doctor and the priest disapproved. Such magical healing was based on "superstitious" notions of causation ranging from the evil eye to fear of a particular color to belief in malignant magical elves or dwarfs who shot arrows of disease into a person. Consequent cures ranged from application of folk remedies containing various plant, mineral, and animal products to the verbal chant of Old Norse poetry. These latter were considered magical by the Christian theologian, but for the pre-Christianized Icelander, they hearkened to his own polytheism, including Odin the All-father, who had one eye, and Völundr, the Norse god of smiths, who was lame. The Old Scandinavian *Vọlundarkviða* and *Þiðrikssaga* retell the story of the elf Vọlundr, who was hamstrung by his enemy, King Niðuðr, and forced to become the royal smith. Similarly functional in literature were dwarfs who played critical roles in plots from the *Niebelungelied* to *Tristan and Iseult*. Disability in religion and magic was all in the eye of the beholder.

Certainly, people with disabilities themselves could be identified as etiologic agents of disease, enhancing their nature as "others." Thus, with the advent of the Black Death in 1347–1348, some lay people targeted "cripples" or "the mutilated poor" as the source of the epidemic, along with Jews and the wealthy. The cause of such fear was clearly a sense of otherness. Disability was as ostracizing a feature of the life of a medieval commoner as non-Christian religion or elite status. In this latter translation, we can detect an inherent association between poverty and disability. Disabilities could also be part of curses—"may you go blind," "damn your eyes"—in the Middle Ages and beyond, furthering the negative imagery of disabilities. Similarly, as charity provoked almsgiving some beggars in thirteenth-century Paris disguised themselves as disabled people to generate more alms. When they were discovered, a more general backlash against all beggars ensued.

But the topos of disability, feigned or otherwise, had less sinister meanings and more nuanced as well. The residents of Norwich, for example, feigned madness when King John was to visit their town in order to avoid having to pay to feed his retainers; disability could have its uses. The topos of concealing body-type could be important for recognition of the ideal. In one version of the lay of *Tristan and Iseult*, Tristan feebly disguises himself, and Iseult says he is not her lover, Tristan, because he is not "tall and straight-backed." Disability in medieval literature could be used as comedic counterpoint, as moralistic trope or as social wedge to address liminal issues such as homosexuality, as in the thirteenth-century French play *The Boy and the Blind Man*.

Medieval disabilities, through the lens of concepts such as charity, transformed the medieval landscape, literally and figuratively. Thus, institutions, notably the Catholic Church but also municipal and early state governments, played a significant part in resource allocation for people with disabilities who were unable to achieve social independence. Charity was a critical religious guide for medieval disability. Given the depredations of war, disease, natural disasters and climatic shifts, economic cycles, crime, old age, large but young families, and accidents, many medieval people, more often among the poor but not infrequently among the wealthy, experienced periods of deprivation, which threatened their life and health. It is noteworthy that the relationship between the "haves" and the "have-nots" in the Middle Ages was complex. While the poor lacked terrestrial power, they, as recipients of alms, held the metaphorical power to obviate sins. Poverty was not seen as an alleviable condition, but a state of permanence, betokened in part by the plethora of the poor, especially in the urban setting. The Biblical parable of the rich man feasting while his dog licked the wounds of beggars at his door, the two then reversing benefits in heaven, suggested the dangers of wealth, which could be mitigated by the gratitude and prayers of recipient poor. The tension in the Church between its rhetoric of poverty and its evident wealth, notably among its "princes," sparked internal and external criticism, reform and backlash, especially in the thirteenth century with the Franciscan order's creation. But with the high-wage labor shortages of the later fifteenth century, hostility to the poor rose, even among Church leaders.

Medieval Christian charity took many forms—for example, almshouses, hospitals, clothes, food, money, and goods dispensed at church doors, even temporary employment. Some 20,000 leper hospitals were established by 1300 throughout Europe dotting the spaces circumscribed by town walls and notions of "us/them." Yet in any one locale, that charity was probably insufficient to meet the needs of a populace of poverty, including the disabled. Even in a time of decreased population, after the Black Death, relative plenty could not do away with the permanence of poverty and the need for charity.

Tensions also existed in the characterization of the poor—significantly in anticipation of the early modern differentiation of the deserving and undeserving poor. Disability played some role in these assignations, as at times, lepers were castigated with moral inequity, often of a hypersexual variety. On the other hand, lepers and those unable to work because of physical incapacity (e.g., old age or physical disability) were often the specific target of open charity. To that end, the poor were sometimes impugned with allegations of cutting off one of their children's extremities or blinding them in hopes of attracting more charity. In the end, the repulsive forces inherent in notions of difference were offset by the attractive needs of living in fairly small communities. For example, medieval laws, which governed cognitive disabilities, changed over time from the comparatively tolerant to the more invasive, yet they frequently allocated full rights of land ownership. The poor disabled could be pitied, reviled, reared, and acknowledged as part of the community. The heavenly world overlapped the terrestrial in a myriad of ways.

The Roman Catholic Church, both materially and doctrinally, had an enormous role in shaping the experience of disabilities in the Middle Ages. From pulpits, parishioners heard of the laudable need for charitable works. But they also heard stories of miraculous cures of the disabled by Jesus. Certain conditions, such as leprosy, increasingly were castigated by the Church as being the result of sin, thus accentuating social stigmatization. And the doctrinal relationship between medieval Christians and their body changed markedly from the early to the late Middle Ages. Notably, the rise of mimicry of Jesus' suffering ennobled pain as a venue toward redemption. Throughout the Middle Ages, the symbolic power of Jesus' body motivated creation and recreation of the import of the physical body. In the early Middle Ages the *body* was most closely associated with the peasant and manual labor. In the later Middle Ages it became an emblem of contest between the individual and the community and an object of redemption. Thus, painful conditions or pain in general, previously perhaps more socially disabling, became badges of Christian virtue to be sought out and embraced. Similarly, the rise of the Franciscan order in the early thirteenth century and new modes of charity altered the potential reaction of the disabled beggar and the almsgiver.

Documentation of a wide range of conditions, which we associate with "disabilities," exists from throughout the Middle Ages. Differentiation into "physical" and "mental" is anachronistic and does not convey the complex intermingling of the medieval mind, body, and soul. Hrabanus (Rabunus) Maurus, a ninth-century monk, for example, observed that "disabilities/infirmities of the flesh mirror disabilities of the mind, and earthly ointments represent the soothing agents of heavenly grace" (Maurus 1864). Examples of paralyses, amputations, scolioses, seizures, madness, blindness, deafness, developmental disabilities, birth defects, chronic infection, and many others abound from this time period. Collectively, it is difficult to identify words that one may clearly translate as the modern, nuanced *disability*, from medieval Latin, French, German, Italian, English, Spanish, Catalan, and the other tongues of the Middle Ages. Thus, modern scholars must be cautious in generalizing and adducing synthetic conclusions from medieval statements.

> Henry Hotspurs hath a halt,
> And he is falling lame.
> Francis Physician for that fault
> Swear[s] he was not to blame.

This medieval children's rhyme reminds us that the signification of disabilities in the Middle Ages was manifold. At once founded in the historically objective and in the culturally inflected, medieval disabilities are redolent for the modern reader and worthy of much more investigation.

—Walton O. Schalick III

HISTORY OF DISABILITY: PLEISTOCENE PERIOD

THE ANTIQUITY OF HUMAN DISABILITY

Assessments of the presence, severity, and incidence of forms of disability among early human societies can provide us with indications of the degrees to which afflicted individuals were able to survive under conditions vastly less conducive to recovery and persistence than is normally found in modern, technologically aided human societies. In particular, it is helpful to evaluate the presence of significant disabilities among Pleistocene human populations since it is during this time period that the underlying biological pattern characterizing all of living humanity appeared. This period, from approximately 1.8 million years ago to about 10,000 years ago, began with the emergence of the genus *Homo,* saw its spread throughout the Old World and eventually into the Pacific and Americas, and concluded with the emergence of humans of modern form about 100,000 years ago and the beginnings of sedentary life by 10,000 years ago.

Any evaluation of human disabilities in the Pleistocene era must acknowledge the nature of the evidence and the series of steps necessary for the identification and interpretation of possible impairments of normal function. The evidence consists entirely of the incomplete skeletal and dental remains of extinct human groups. Until people began burying their dead about 100,000 years ago, it consists principally of cephalic portions of the calcified tissue. In addition, sample sizes remain small, geographically scattered, and spread out over thousands of years, making calculations of incidence levels largely meaningless.

The interpretive issues involve a series of logical steps. First, the observed skeletal/dental anatomy has to be identified as abnormal and not confused with expected normal ranges of variation, bearing in mind that there have been significant changes in human anatomy during the past 1.8 million years. Second, accurate diagnoses must be made of the observable lesions or abnormalities in overall skeletal morphology. Third, the lesions have to be integrated into a more general diagnosis of the individual’s abnormalities. In so doing, the scholar must consider that the observed alterations may be linked or independent and may have occurred synchronously or sequentially. Often, given the limitations of fossilized remains, it may only be possible to narrow the diagnosis to a set of possible etiologies, rather than specifying a specific cause for the lesions. Fourth, depending on the diagnosis, the presence of significant soft tissue abnormalities must be assessed, ones that can only be inferred from the skeletal biology. Fifth, a determination has to be made whether the diagnosis would imply any loss of function. Sixth, if some reduction of function is implied, the individual’s disability must be evaluated in terms of whether it would have affected the survivability of the individual in its social, technological, and environmental context. However, since survival of the condition is required for the formation of skeletal lesions or abnormalities, all known cases are by definition cases of some degree of survival. A methodological consequence is that we have little or no data on socio-biomedically lethal disabilities, only the chronic ones.

In addition to the compounding levels of inference from lesion identification to survivability, one must realize that all of these Pleistocene human populations were hunters and gatherers, living exclusively from foraged resources naturally occurring on the landscape. For most of the Pleistocene, until less than 30,000 years ago, population density was extremely low, and the associated social integration behaviors were strictly local. Fundamental aspects of technology, such as effective weaponry and fire, were established only about 400,000 years ago, and mobility on the landscape was essential. In fact, before 10,000 years ago, there are no known cases of lesions of the lower limbs that would have impaired walking, and there are several cases of individuals persisting in walking despite severe osteoarthritis and less disabling injuries to the legs and feet.

Despite these limitations of the human fossil record and the inferential process, there are numerous identified cases of lesions among Pleistocene humans. Most are relatively minor traumatic and degenerative lesions, and only a few would be classified as disabilities. The extent to which each one would have affected survivability without significant social assistance remains debated.

The oldest known case is from Salé, Morocco, from 400,000 years ago. It consists of a partial cranium of a young adult with reduced and altered development of the nuchal plane, which has been interpreted as the result of congenital torticollis. It is followed about 200,000 years ago by an isolated adult mandible from Aubesier, France, with pervasive periodontal inflammation, apical abscesses, and almost complete tooth loss, requiring complete processing of any ingested food outside of the mouth. Slightly younger, at 150,000 years ago, is the isolated mature cranium from Singa, Sudan, with unilateral labyrinthine ossification, which would have seriously impaired the individual's equilibrium.

One Neanderthal specimen, from Shanidar Cave, Iraq, dated to about 50,000 years ago, survived multiple, possibly related, lesions. The more serious of them include a lateral facial fracture disrupting the functioning of the left eye and multiple fractures, atrophy, infection, and possible amputation at the elbow of the right arm, leaving little more than a withered stump. The same individual had sufficient leg and foot injuries to induce an abnormal gait that resulted in bowing of the left leg. He also represents the oldest known case of DISH (diffuse idiopathic skeletal hyperostosis). To this individual could be added two other Neanderthals, one from Shanidar that survived a unilateral pneumothorax for at least several weeks and another from the original Neanderthal site in Germany that had a fractured elbow with sufficient deformity to reduce elbow flexion and produce atrophy of the arm bones.

Among early modern humans, there is a child from Qafzeh, Israel, who lived to about three years of age with pronounced hydrocephaly, resulting in both characteristic cranial changes and limb alterations. A more recent individual from Dolní Vestonice, Czech Republic, survived to young adulthood with an undetermined congenital dysplasia, which produced asymmetrical shortening of the legs, abnormal bowing of the right thigh and upper arm, and secondary changes of the left arm and facial skeleton. Yet, this latter individual exhibits a level of limb strength similar to those of other humans from the same time period, implying that he kept up with and assisted his highly mobile social group.

These few examples are those for which there is sufficient confidence in the identification and diagnosis of the individual lesions and deformities and are likely to have caused more than short-term reduction of some vital function (bearing in mind that what was "vital" in the Pleistocene need not be essential for survival in current sedentary and technologically aided societies). What remains uncertain is the degree to which any one of these sets of abnormalities would have directly affected the survivability of the individuals in their prehistoric social contexts, requiring the prolonged direct assistance of other members of the social group. However, it is probably not coincidental that these conditions first appear in the human fossil record about the time (400,000 years ago) that there are significant improvements in weaponry, fire control, and other aspects of human behavior, all of which would have facilitated survival in harsh environments.

HIV/AIDS

As we enter the third decade of the AIDS pandemic, its global impact is highly evident. Since the first reported cases of AIDS in the United States in June 1981, the disease has crossed all geographic boundaries; numerous countries in Africa and Asia already confront serious decimation of their populations while other global regions and countries are on the edge of emergent crises. The statistics are staggering. The World Health Organization (WHO) estimates that, worldwide, approximately 40 million people are living with HIV/AIDS; 22 million men, women, and children have died; and 14,000 new infections are contracted every day. Around the world, in the year 2003, the AIDS epidemic claimed an estimated 3 million lives, and almost 5 million people acquired HIV, 700,000 of them children. Over the next decade, the only prognosis for those without effective treatment will be to endure its complications and die.

THE VIROLOGY OF HIV/AIDS

The human immunodeficiency virus (HIV) mediates its effect in the human body by interfering with cell-mediated immunity that eventually destroys the entire immune system and compromises all major organ systems. Without successful medical treatment, most people infected with HIV go on to develop the most advanced stage of the disease known as acquired immunodeficiency syndrome (AIDS). In addition to provoking immunodeficiency in the body, HIV also activates autoimmunity and nervous system dysfunction. AIDS manifests itself clinically as a spectrum of diseases that cause both physical and mental disability in those affected. People living with the virus can experience a wide variety of symptoms due to opportunistic infections, malignancies, and wasting.

Early HIV symptoms, which typically occur between 1 and 4 weeks following exposure, often mimic flu or mononucleosis-like symptoms. These symptoms include headache, loss of appetite, night sweating, a sore throat, and swelling of the lymph nodes. A skin rash may develop on the chest, abdomen, and/or back. HIV seroconversion, which refers to the development of detectable HIV antibodies in the blood, is most likely to take place at 3 to 6 weeks following exposure, although it can occur at any point in the following six months.

The incubation period for AIDS refers to the interval that begins with HIV infection and ends when the person exhibits the first signs of developing AIDS, as specified by a set of clinical criteria. In young to middle-age adults, the median incubation period is about 10 years, although the interval appears to be lengthening or even forestalled as new and more effective treatment options become available. While this incubation period tends to be shorter in children and individuals over age 50, it does not appear to vary significantly by gender or race. A host of cofactors are believed to play a role in disease progression, including genetic factors, age, gender, route of HIV infection, drug use, smoking, nutrition, and the co-occurrence of other infectious diseases. Without treatment, the period from AIDS diagnosis to death, known as AIDS survival time, ranges from 1 to 20 years with a median interval of 10 years.

DISEASE CLASSIFICATION AND STAGING

A variety of classification and staging systems have been proposed for understanding and mapping the full progression of the disease from HIV infection to the advanced stages of AIDS and possible death. Most use some combination of the CD4 lymphocyte count and symptoms. In 1993, the Centers for Disease Control and Prevention (CDC) made the CD4 lymphocyte count central to its classification system for HIV disease. Since then, CDC expanded its AIDS surveillance case definition to include all HIV-infected persons who have < 200 CD4+ T-lymphocytes/microL, or a CD4+ T-lymphocyte percentage of total lymphocytes of < 14, as well as the addition of pulmonary tuberculosis, recurrent pneumonia, and invasive cervical cancer to the 23 clinical conditions in the AIDS surveillance case definition published in 1987.

The progression of HIV immunosuppression generally correlates with CD4 lymphocyte count or percentage; thus, CD4 lymphocyte count is currently the principal laboratory test used in clinical management of HIV infection, including antiviral therapy as well as prophylaxis of opportunistic infections. The combination of CD4 lymphocyte count, viral load (quantity of HIV detected in the peripheral blood), and clinical symptoms is likely to provide the basis for future attempts at staging HIV disease.

Counting subsets of lymphocytes is often impossible in developing countries because the needed technology is not available or is too expensive for routine use. As an alternative, the World Health Organization (WHO) Global Programme on AIDS proposes the following simplified staging system that does not rely on lymphocytes testing, and its diagnostic criteria are clinically based and sufficiently flexible for use in different parts of the world:

Early HIV disease (Stages 1 to 3). In these stages, individuals may develop opportunistic infections such as tuberculosis, malaria, pneumococcal pneumonia, shingles (herpes zoster), staphylococcal skin infections, and septicemia. These diseases can also occur in individuals with normal immune systems. With HIV, these diseases occur at much higher rates.

Advanced HIV disease (Stage 4, equivalent to AIDS). This stage is characterized by the development of opportunistic infections such as pneumocystis and toxoplasmosis. In addition, the diseases listed under Stages 1–3 are present in atypical ways, for example, tuberculosis disseminated from the lung or recurrence of non-typhi salmonella septicemia. Malignancies such as Kaposi's sarcoma and other cancers may also arise.

MODES OF TRANSMISSION AND RISK FACTORS

The principal modes of transmission for HIV are through sexual contact, introduction of the virus into the blood stream by blood or blood products, and through vertical transmission from mother to infant either before and during childbirth or via breastfeeding. Body fluids, which have been scientifically proven to transmit HIV, include blood, semen, vaginal fluid, and breast milk. Other suspected but unproven possibilities include cerebrospinal fluid, synovial fluid, and amniotic fluid. Extensive research documents that HIV is not transmitted through casual contact such as handshaking or insect bites. Globally, the leading cause of HIV infection is through sexual contact.

The first AIDS cases reported in June 1981 in the United States were among younger men who had sex with men. Later, it became known that people of both sexes and all age groups are susceptible to HIV and AIDS. Groups in the United States who are particularly vulnerable to infection are men who have sex with men, injection drug users and their sexual partners, members of racial/ethnic minorities, and an increasing number of women. The following are the most common modes of transmission in the United States:

> unprotected sexual contact, particularly with multiple partners;
>
> use of HIV-contaminated equipment among injection drug users, including needles, cotton, cookers, and water used in drug administration; and
>
> needle stick injuries among health care professionals.

Although once a serious problem, the risk of transmission though blood transfusion from infected blood and blood products has decreased significantly since the mid-1980s after legal enactment of national blood-screening requirements. The United States also has seen dramatic reductions, since the mid-1990s, in mother-to-child transmission due to widespread promotion of routine HIV counseling and voluntarily testing of pregnant women for HIV, and as the result of offering antiretroviral therapy to infected women during pregnancy and delivery and for infants after birth.

HIV PREVENTION STRATEGIES

Without a vaccine available to protect against HIV, the major focus of preventive efforts at the individual, dyadic, and social network levels are designed to minimize the transmission of HIV through unsafe sexual practices and the sharing of contaminated injection drug equipment. A number of methods have been developed and scientifically shown effective in reducing risky behavior when applied under specific conditions. These methods include indigenous leader and peer outreach strategies, prevention case management, needle hygiene and syringe distribution programs, social support groups organized around risk reduction, and Internet interventions. At the health services level, prevention efforts focus primarily on promoting HIV counseling and testing, offering therapy for HIV-positive pregnant women and their infants, continued stringent screening of all products used medically for blood transfusions, and appropriate protection of health care workers.

The process of "partner notification" is gaining increasing attention for preventing the spread of infection from patients with diagnosed HIV (index patients) to healthy persons. Through this process, sex and needle partners of index patients are informed of their possible exposure to infection and the need for medical evaluation. There are two basic mechanisms of partner notification: provider referral and patient referral. *Provider referral* is a confidential process in which public health personnel or other appropriate counselors request names and identifying information about sex partners from the index patient to notify those partners of their exposure. *Patient referral* is a process by which partners are notified by index patients on their own without assistance. The goal of partner notification is to help ensure that individuals who are HIV seronegative remain so and to identify and bring those individuals who have unknowingly contracted the virus into the health care system for early treatment and care.

HIV/AIDS DIAGNOSIS

Early detection of HIV infection is critical to instituting timely and effective therapeutic regimens. Since the first HIV antibody tests became commercially available in 1985, HIV diagnostic technology has progressed remarkably. The most common types of screening and confirmatory assays are the following:

Enzyme-linked immunosorbent assays (ELISAs). These are the most widely used type of assays; they have high sensitivity and specificity and are able to detect HIV-1/HIV-2 and HIV variants. ELISAs are especially useful for screening large numbers of specimens needed for surveillance and centralized blood transfusion services. The most recent "combination assays" combine p24 antigen ELISAs with traditional antibody ELISAs, allowing for the simultaneous detection of HIV antigen and antibodies using a single test.

Simple/rapid assays. These are the high-quality, easy-to-use HIV tests, which require little or no additional equipment. The tests are designed for use with individual or a limited number of samples. These tests are increasingly being used in voluntary counseling and testing centers and antenatal clinics where making same-day results available can result in timely treatment interventions.

Confirmatory assays. These assays are used to confirm whether specimens found reactive with a particular screening test contain antibodies specific to HIV. The most commonly used confirmatory test is the Western Blot (WB). However, it is a very expensive test and produces large numbers of indeterminate results. Similar confirmatory assays, generically called Line immuno-assays (LIAs), have been developed, which in general produce fewer indeterminate results as compared to WB, although they are equally expensive. There is evidence that combinations of ELISAs or simple/rapid assays can provide results as reliable as the WB at a much lower cost.

p24 antigen and nucleic acid technologies. A number of other assays have been introduced in recent years that in addition to establishing the diagnosis of HIV infection may also be used to monitor the progress of the infection and the response to therapy. These procedures are particularly valuable for early diagnosis of mother-to-child transmission and for monitoring the viral load of patients who are taking antiretroviral therapy. From a practical standpoint, this technique can have limited specificity; needs sophisticated equipment, rigorous laboratory conditions, and highly trained staff; and is very expensive.

Alternative specimens. HIV diagnostic technology has also evolved to the development of assays that can use alternative body fluids to serum/plasma such as saliva, whole blood, and urine. Potential advantages include safety, convenience, noninvasiveness, and cost-effectiveness. The quality of these assays as compared to conventional serological tests, however, is still undetermined.

HIV/AIDS TREATMENT

In the first 15 years of the AIDS epidemic, individuals with HIV infection had few treatment options. Since then, research has shown that certain antiretroviral drugs can inhibit HIV replication, delay immune deterioration, and improve survival and quality of life. Prior to the initiation of antiretroviral therapy, patients require a clinical assessment, which includes a thorough clinical history, physical examination, and ancillary tests. Other critical elements of the assessment include a past medical history, current and past HIV-related illnesses, coexisting medical conditions (such as tuberculosis, hepatitis B or C, or pregnancy), and concomitant medications in use that may influence choice of therapy. Minimum laboratory tests include an HIV antibody test and hemoglobin or hematocrit level. Where resources permit, it is preferable to get a complete blood count, CD4 count, serum alanine and aspartate aminotransferase levels, serum creatinine, blood urea nitrogen, serum glucose, bilirubin, and lipids levels, and pregnancy tests for women.

Treatment modalities for HIV are rapidly changing as the result of scientific research. No single medical regimen is universally accepted, although some are now preferred for initial therapy. At the time of this writing, the Food and Drug Administration (FDA) has approved the use of 20 different drugs to combat HIV infection—often in some form of combination. These drugs fall into four main types:

1. *Nucleoside and nucleotide analog reverse transcriptase inhibitors* inhibit HIV's ability to copy a healthy cell's DNA. HIV needs the cell's DNA, or genetic instructions, to replicate itself. Without complete DNA, HIV cannot make new virus copies. Drugs include zidovudine, lamivudine, stavudine, abacavir, didanosine, zalcitabine, emtricitabine, and tenofovir. Brand combination drugs include Combivir (lamivudine and zidovudine) and Trizivir (abacavir, lamivudine, and zidovudine).
2. *Nonnucleoside reverse transcriptase inhibitors* also prevent HIV from using a healthy cell's DNA to make copies of itself, but they have a different mechanism of action. Drugs include nevirapine, delavirdine, and efavirenz.
3. *Protease inhibitors* prevent infected cells from releasing HIV into the body. Drugs include saquinavir, indinavir, ritonavir, nelfinavir, amprenavir, lopinavir (combined with ritonavir as Kaletra), fos-amprenavir, and atazanavir.
4. *Fusion inhibitors* prevent the entry of the HIV virus into healthy cells. Presently, the only FDA-approved drug in this class is enfuvirtide.

Highly active antiretroviral therapy (HAART) refers to combination antiretroviral regimens of three or more drugs from one or more different classes of anti-HIV drugs to suppress HIV replication and prevent progression to AIDS and death. Two key classes of drugs include those that prevent the virus from copying itself (reverse transcriptase inhibitors) and those that prevent the virus from becoming infectious (protease inhibitors). The main goal of using combination therapy is to address the issue of constant mutations of the HIV virus, which leads to the ongoing emergence of new and drug resistant strains. Resistance to any single drug is thought to occur almost universally at the baseline even prior to initiation of drug therapy. It is not uncommon, however, for the effectiveness of different drug combinations to diminish over time. Hence, new combinations may need to be implemented over the course of a person's treatment. The actual drugs and their regimens are constantly under investigation and are revised as new information and medications become available.

A recent study from the National Institute of Allergy and Infectious Diseases, at the National Institutes of Health, indicates that the combinations and particular order of antiretroviral drugs must be considered when designing treatment strategies for patients new to antiretroviral therapy. When HIV-infected individuals begin treatment with a combination of the drugs zidovudine (better known as AZT), lamivudine, and efavirenz, the treatment retains its effectiveness for a longer period of time than when individuals begin treatment with one of several other three-drug regimens.

Meanwhile, administering a single dose of nevirapine to an HIV-infected woman at the onset of labor and to her child within 72 hours of birth have been found to markedly reduce the rate of HIV transmission in newborns. The WHO endorses this method as routine procedure for preventing mother-to-child transmission in HIV high-prevalence developing countries. However, this strategy is not without controversy; some recent evidence suggests that administering nevirapine treatment at infancy may result in greater vulnerability to infection following HIV exposure in later life.

GLOBAL DISPARITIES

The AIDS epidemic takes on different prevalence patterns and epidemiological profiles in different parts of the world. The continent of Africa, particularly the southern region, continues to have the highest HIV/AIDS incidence and prevalence rates globally. Many of the highly industrialized countries of the Western Hemisphere, including the United States, report declining epidemiological trends in AIDS overall, but their incidence rates in certain subpopulations are rising. In the Eastern Hemisphere, countries that once formed the Soviet Union face a young and rapidly growing epidemic. Latin America and the Caribbean exhibit evidence of a growing threat, while East and Southeast Asia, which include countries such as China and India that contain some of the world's largest populations, may someday outstrip Africa in terms of their absolute number of cases if their current escalating rates of HIV/AIDS go unchecked. Not all countries, however, are experiencing such acceleration. Brazil, Thailand, and Uganda serve as role models for others in successfully reducing previously rising transmission rates.

Throughout the world, the high cost of antiretroviral drugs places treatment beyond the range of many individuals living with the virus, particularly residents of the developing world. The exact cost of antiretroviral therapy in a particular geographic location varies and is determined by a complex set of factors including global politics, the existence of donor funds, public and private insurance and/or entitlement programs, and the policies and drug-testing activities of large pharmaceutical firms. At present, the cost of antiretroviral therapy in the least developed countries ranges from US$300 to US$1,200 per annum, a sum that places it out of reach for many. Currently, 6 million people infected with HIV in the developing world are estimated to need access to antiretroviral therapy to survive. Only 400,000 have this access. A number of global programs are either poised for or actively engaged in facilitating or providing treatment, but the demand throughout the world far exceeds the numbers to be served.

WHO policy, in recognizing that the multiple challenges involved worldwide in stopping the HIV/AIDS epidemic, calls for the adoption of a comprehensive public health approach to reach this goal. Not the least of these challenges lies in improving access to and reducing the cost of antiretroviral drugs. Other recommendations include establishing sustainable financing for AIDS treatment and drug procurement, regulatory mechanisms to ensure blood safety and appropriate delivery of HIV/AIDS services, improvement in health infrastructure, training of health care workers, education and involvement of communities, and the mobilization of diverse stakeholders. In addition to the development of a vaccine to end the AIDS epidemic, WHO recommendations also point to the need for developing and implementing scientifically proved strategies to encourage technology transfer and the successful adoption of evidence-based behavioral interventions and appropriate clinical treatment and care.

GLOBAL COST OF THE AIDS PANDEMIC

Besides taking an enormous toll in human life, the AIDS epidemic also erodes both personal and national capabilities including those of human sustenance and economic development. Private costs of living with HIV/AIDS can be categorized into direct and indirect costs. The direct costs of living with HIV/AIDS include service-related expenses for medication, general therapy and ongoing care in health care facilities or at home, and increasing dependence on transport for traveling to and from health providers and care facilities due to reduced mobility. Among the disease's many indirect costs are the possibilities of increased absenteeism from work, loss or reduction of income, lowered productivity both at home and in society's public/private sectors, and the incurring of personal stigma associated with the disease. Family members of those with HIV/AIDS and others in their social networks also may incur some level of costs directly and indirectly, as do the functionary agencies and institutions that serve human economic, social, and health services needs. In some parts of the world, the AIDS epidemic, in combination with its emergent fiscal and health care crises, is driving countries toward insolvency. In Zimbabwe, for example, one-third of the population between the ages of 15 to 49 is infected with HIV/AIDS.

Such grim statistics remind us that AIDS is more than a life-threatening illness; its occurrence is also a societal problem inherently linked to and fed by existing social disparities and invidious socioeconomic conditions. Lack of access to antiretroviral therapy and the social stigma attached to the disease mitigate against many HIV-infected individuals' chances of living a long and symptom-free life. Almost universally, a diagnosis of HIV infection engenders significant stigma that can result in the shunning of infected individuals by their communities and even family members. Many HIV-positive persons also face difficulties in finding or retaining employment or housing once their HIV status is known. Meanwhile, growing gender imbalances in HIV rates among women globally, and the tendency for the virus to be found disproportionately among marginalized and disadvantaged populations throughout the world, mirror deeply entrenched systems of societal inequality that help to fuel further spread of the epidemic.

Even in the face of such societal and personal disaster, it should be acknowledged that most people worldwide have not acquired the virus. An important public health challenge is to enable individuals at risk to protect themselves against HIV while providing appropriate treatment to those living with the virus. Although a number of drugs currently are available that halt or modify AIDS disease progression, no vaccine currently exists to prevent infection, and once acquired, there is no cure for HIV infection. Until these become available, societal and behavioral prevention remain the world's main defense in halting the epidemic and its consequences.

HIV/AIDS AND DISABILITY

The creation and reinforcement of physical, mental, and social disabilities constitute some of the epidemic's most serious and far-reaching consequences in the world's fight against AIDS. Physical disability related to HIV/AIDS is mainly due to the manifestations of the disease process and/or the adverse effects of therapy that result in some form of physiological impairment. HIV-infected persons also may experience disabling mental health conditions including memory loss, depression, and psychosis. These conditions require clinical or other forms of effective treatment such as HIV counseling and testing and follow-up referral services to ensure needed psychosocial support. Social disabilities occur when people with HIV/AIDS, due to their illness, lose or encounter reduced opportunities to take part in society on an equal level with others. These three categories of disability are not mutually exclusive, and some individuals experience all three forms.

Because AIDS affects almost all the organs of the body as well as all systems, only patients who have a positive response from therapy are likely to lead a life that does not require some form of adaptation to physical disability or somatic compromise. Among those receiving HIV/AIDS treatment, the difficulties associated with ongoing multiple-drug intake and their adverse effects are substantial. Adverse effects include gastrointestinal symptoms, such as bloating, nausea, and diarrhea, which occur commonly and may be transient or persist throughout therapy. Generalized fatigue, malaise, headache, anemia, peripheral neuropathy, and hypersensitivity reactions are other adverse effects associated with various individual and combination drugs. More serious but less common adverse effects include lactic acidosis, hepatic steatosis, hyperlactatemia (elevation of venous lactic acid), hepatotoxicity, hyperglycemia (leading to diabetes mellitus), fat maldistribution (lipodystrophy), hyperlipidemia, bleeding disorders, bone loss, and skin rashes. Fatigue is common among patients with HIV/AIDS and may contribute to limitations in physical functions and disability. Fatigue may occur in conjunction with multiple AIDS-related opportunistic infections, wasting, myopathy, adrenal insufficiency, and hypogonadism.

The physical conditions of HIV/AIDS and its treatment can negatively influence the mental well-being of people living with the virus and also engender considerable social stigma and other disadvantages. Consider the example of the physical, mental, and social effects of developing *lipodystrophy.* This medical term denotes the changes in body shape that were first reported in 1998 among people taking anti-HIV therapy. Originally thought to result from treatment using protease inhibitors, the condition later was found among people who had never been treated for HIV or whose therapy did not include such drugs. The literal meaning of lipodystrophy is accumulation of fat. The pathogenesis of lipodystrophy is complex and likely due to combined endocrine and metabolic abnormalities including dyslipidemias (low levels of high-density lipoprotein and high levels of low-density lipoprotein and triglyceride in the blood), high blood sugar, insulin resistance and raised liver enzymes, and accelerated bone loss. Associated conditions include heart disease, stroke, and pancreatitis. Risk for lipodystophy is greater for people with other co-occurring disorders such as high blood pressure, diabetes, obesity, smoking, or a family history of heart disease. It also occurs in 15 to 50 percent of those taking antiretroviral therapy.

The body fat changes often seen in people with HIV include both fat gain and fat loss. Fat deposition mainly occurs around abdomen, breasts, jaw, and dorsocervical spine (upper back and neck)—causing the “buffalo hump.” The abdominal fat gain is due to visceral fat accumulation around internal organs, causing the belly to feel taut and pushed out. This symptom (absence of squeezable fat) is distinguishable from the fat deposition due to overeating or lack of exercise. Fat loss is usually evidenced by facial wasting, especially of the cheeks, wasting of the buttocks, and prominent veins in the arms and legs. Such visible evidence of HIV and its alteration of the body may call attention to the person’s illness and become the basis for or exacerbate negative reactions from others. The resulting stigma and the challenges of coping with an altered body image are potential sources of stress and worry among people who experience the condition.

As is true for many AIDS-related illnesses, the best course of treatment for lipodystrophy is unknown. Treatments under study to stem the disorder span a gamut of drug and behavioral options including the use of human growth hormone, anabolic steroids, appetite stimulants, weight training, regular exercise, smoking cessation, switching from the contraceptive pill to another form of birth control, dietary changes, and/or changing anti-HIV therapy.

Lipodystrophy is just one of numerous conditions that people living with HIV may need to physically, mentally, and socially manage. For those individuals who receive life-prolonging treatment or otherwise achieve effective symptom management, HIV/AIDS constitutes a chronic condition that must be managed similarly to other serious long-term or permanent debilitating illnesses. This includes coping with the treatment itself. Therapy with antiretroviral drugs is not free from adverse effects, and most drugs have potential interactions with other drugs. Up to 25 percent of patients discontinue their initial HAART therapy due to treatment failure, toxic effects, or noncompliance. Drug toxicity needs to be monitored clinically based on patient reports and physical examination, supplemented by laboratory tests. After initiating therapy, viral RNA tests need to be performed every 4 to 6 weeks until reaching the therapeutic goal of undetectable viral RNA. Subsequently viral RNA tests are needed every 3 to 4 months. In case of treatment failure, a second-line regimen is recommended. In sum, living with HIV and AIDS is an ongoing physical, mental, and social challenge for those afflicted.

CO-OCCURRING DISABILITIES

While a substantial body of literature addresses the array of disabilities associated with HIV and AIDS in previously healthy individuals, there is a paucity of research concerning individuals who were living with a disability prior to contracting HIV/AIDS. Globally, *approximately 600 million people are estimated to be living with a physical, sensory, intellectual, and/or mental health disability. Some unknown proportion of these individuals either has, or is, at some risk for HIV/AIDS.*

In this regard, from the standpoint of normal human behavior, it is highly probable that the major risk factors associated with HIV infection also are present among people who experience disability through other conditions. Unfortunately, in terms of HIV/AIDS vulnerability, individuals living with a disability also are more likely than their unimpaired peers to live in poverty, to be less educated, and to be unemployed. In addition, due to experiencing more than one disabling condition, they may encounter multiple stigmatizations that decrease their likelihood of participating fully in the social, legal, religious, and political decision making and affairs of their communities that would give them a voice in managing their own health care. From the standpoint of prevention programming, all too often, people living with a disability are assumed to be sexually inactive, nonusers of illicit drugs, and unlikely to be victims of violence including rape. In reality, they can be at risk for HIV/AIDS for all of the same reasons as people without disabilities.

Misconceptions about the risk for HIV infection in persons with disability translate into insufficient preventive and therapeutic efforts targeting this population, and few research studies are conducted that would help inform this effort. One notable exception is a global survey on HIV/AIDS and disability, sponsored by the World Bank, currently under way by researchers at the Yale University School of Public Health in the United States. The study includes a survey that was distributed to more than 3,000 organizations, advocates, and activities in July 2003, and thus far has yielded responses from 57 countries. Although collection and analysis of the survey are still under way, some preliminary results indicate the following:

> HIV/AIDS is a significant and almost completely unrecognized problem among populations of people with disabilities worldwide;
>
> while all individuals with a disability are at risk for HIV infection, certain population subgroups are a higher risk—most notably women, members of ethnic and minority communities, adolescents, and institutionalized individuals; and
>
> HIV/AIDS educational, testing, and clinical programs are largely inaccessible to individuals with disabilities.

Further results from the study are expected to provide additional information regarding risk factors and interventions to mitigate risk to persons with disabilities.

PROTECTION OF HUMAN RIGHTS

Even with the challenges that living with HIV/AIDS presents, people who receive appropriate treatment are typically capable of successfully carrying out their daily lives. Also, with more effective drug therapies becoming available, HIV-positive individuals are living longer and remaining in or returning to the workforce as productive workers in increasing numbers. In many, but not all, countries, those who experience disabling conditions due to the disease have the right to the same legal protection, care, and consideration given to people confronting other physical and/or mental disabilities.

The American with Disabilities Act (ADA) enacted in 1990 in the United States aims to provide broad protection against disability discrimination, including discrimination against people infected with HIV. The act is based on a U.S. Supreme Court ruling that declares that HIV infection must be regarded as a physiological disorder with an immediate, constant, and detrimental effect and, therefore, the properties of the illness satisfy the definition of a disability during every stage of the disease. The ADA, which covers employers of 15 or more people, applies to employment decisions at all stages. Despite enactment of this legislation, however, individuals infected with HIV face discrimination in finding employment, and lawsuits filed by HIV-infected workers continue under the ADA. Similar problems of job discrimination and social stigma are reported worldwide, although efforts are under way on a number of fronts to reduce this condition.

The increasing involvement of people living with HIV/AIDS in community-based organizations and at national and international forums for the development of policies and the delivery of services on their behalf is an encouraging trend toward meeting their needs. Of note is the “Montreal Manifesto,” released at the V International AIDS Conference in 1989, in Montreal, Canada. It advocates for an international code of rights to promote the active involvement of effected communities of people with HIV disease in decision making that may affect them. This document, while more than a decade old, is a continued call to action by everyone to ensure that all people affected by HIV/AIDS have proper food, housing, education, employment, and health care and that they are able to exercise their rights in this regard without any hindrance whatsoever.

HOFFMAN, C. COLDEN

(1819–1865)

American missionary

Reverend Cadwallader Colden Hoffman, an American Episcopalian minister, was a missionary in Liberia from 1849 until his death (Fox 1868). He included some deaf boys in his schools (Brittan 1860) and started teaching blind people to read using Moon's embossed script. While itinerating up-country, Hoffman came in contact with many disabled people leading what he considered pitiful existences. He opened a small center on the coast, where blind and other disabled people could live while learning handicrafts and reading: "I have received into it a native man, armless and with a crooked spine, who is only 3 ft. 5 3/4 ins. in height, but of good mind. He begins to read, and can thread a needle, turn a hem, and sew, with his toes" (Moon 1877). Hoffman also planned a center for deaf people, but died before this could be achieved. In sub-Saharan Africa, Hoffman's efforts are among the earliest recorded formal educational and vocational work with blind and deaf people.

HOME MODIFICATION

Home modification represents the area of assistive technology in which accessibility and universal design concepts are incorporated into private residences. Through this application, an individual with a disability is able to maximize his or her independence in areas that include entry to and exit from the home, personal care, transfers, meal preparation, cooking, and housekeeping.

In the United States, the Americans with Disabilities Accessibility Guidelines (ADAAG) provide information on the required architectural elements for accessibility in public spaces. Regarding private residences, a municipality may refer to ADAAG, state guidelines, or local codes that address accessibility. Where guidelines differ from one another, the stricter code takes precedence.

Where sufficient space exists, entry to and exit from the home is addressed through the use of ramp systems. The maximum slope allowed for ramp systems is 1:12 (one inch/unit of rise for every 12 inches/units of run). Level platforms are required at the top landing, so that individuals with disabilities can maneuver through the doorway without being on a ramped surface, and at any turns or rest areas. Where space is limited, an electrically powered vertical platform lift may be appropriate.

Accessible bathroom designs include elements to maximize access and safety. This may include the use of a cantilevered sink, lever-profile water faucet handles, and insulated water supply and drain lines. A taller toilet profile makes use easier for those who have difficulty in sitting or standing, or for those who transfer from a wheelchair. Grab bars provide surfaces for stability as an individual transfers or uses the toilet. For bathing, roll-in or walk-in showers with limited-threshold profiles enable individuals to enter and exit the space. Single-lever water controls not requiring fine motor control can make setting of a comfortable temperature possible. Pressure-balancing valves within the wall help keep the water at the set temperature, compensating for water pressure fluctuations due to water use elsewhere in the home. Grab bars assist in this area as well.

Transfers between bed and mobility bases can be assisted through the use of powered transfer lifts. Supported from the ceiling, these electrically powered devices provide vertical travel of a sling or frame support, enabling the user to be lifted safely. For individuals transferring independently, the device can be powered in the lateral direction as well, traveling along a ceiling track to a position above the second surface. For others, the device travels along this track via a ball bearing system, making it easy for the person providing assistance to move the user laterally.

Modifications made in the kitchen to promote independence include lowered countertops, cabinets with D-shaped door handles and carousels or pull-out shelves, countertop or table space with knee clearance beneath, stoves with controls along the front edge, side-by-side refrigerators, and sinks with knee clearance beneath.

In general, wide doorways and pathways within the home, lever-profile doorknobs, and accessible-height light switches and outlets can make efficient use of the space feasible. Retrofitting of these elements into existing homes is usually possible. Home modification elements can easily be incorporated into new home design.

HOME SUPPORT

Home support—otherwise known as home care, personal supports, or attendant care—is the provision of human assistance to a person with a disability that enables his or her greater participation in society. Dumont-Lemasson, Donovan, and Wylie (1999) defined home care as "an array of services which enables clients, incapacitated in whole or in part, to live at home, often with the effect of preventing, delaying, or substituting for long-term care or acute care alternatives." The service can assist people with disabilities to perform activities of daily living such as eating, bathing, meal preparation, and errands when it is difficult or impossible for them to do these things on their own. Importantly, in some regions of the world this service facilitates the achievement of life goals in areas associated, for example, with employment, education, health, recreation, and spirituality.

Home support is a concept that is most frequently found in the developed world and in particular countries where social and health care programs exist. People with disabilities consider this a critically important service because it can enable an individual who lives with physical, emotional, or cognitive impairment to engage in society as a participating citizen, particularly when the home support activities are directed and controlled by the disabled user of the service. The development of the notions of user flexibility, choice, and control of personal assistant service is closely tied to the independent living movement. It is also a service that has become increasingly necessary in a context of people leaving institutions to live in the community and as people are discharged earlier from hospital care.

ISSUES

Direct Funding

When people who receive the home support service play a direct role in determining how to implement it, this is often referred to as direct funding or self-directed care. This approach to the provision of home support exists for people who live in countries such as the United States, the United Kingdom, and Canada and is guided by the independent living principles of flexibility, choice, and control. Users are provided with resources to pay for the service, and they are responsible for administrative duties, including interviewing, hiring, training, and firing their attendants. Consumers of the service are not paid for doing administrative work, which reduces overall costs. However, it is important for such programs to involve a local disability organization, which can provide support to individual consumers.

This approach is distinct from other systems of support provision affiliated with government departments or private health care agencies that are guided by principles of efficiency rather than consumer control. High staff turnover results in workers not becoming aware of the preferences, personality, and life goals of the individual they are expected to support.

Unionization of Workforce

This is an important issue, currently being debated in Canada. People who provide assistance are primarily women who are paid a relatively low wage. While those who receive home support services recognize that workers deserve protections and a decent wage, they may be concerned that unionization will further transform their homes into institution-like workplaces and reduce their choice in directing their own care and lives.

Pressures on Informal Care Providers

As populations age, governments are projecting an increase in the need for home support, and as private agencies become increasingly involved in the provision of this service, there is a greater concern for economic returns. Over the past decade, efforts have been made to make it increasingly difficult to be eligible for services and, when services are provided, to narrow the range of services. These factors put greater pressure on families, friends, and neighbors to provide needed care, which in turn has had a negative impact on the health, both of those receiving assistance and the informal unpaid caregivers. Children are expected to care for a disabled parent, a spouse is expected to provide care while also working to meet the family's financial needs, and older women with impairments themselves are having to care for their spouses as their health deteriorates.

DEVELOPMENT: THE EXAMPLE OF CANADA

In countries such as Canada, home support has undergone significant changes during the past decade. In some regions of Canada, the eligibility requirements have become more restrictive, resulting in fewer people accessing the service. The range of services in some regions has now been reduced to basic personal care—bathing and toileting—and no longer includes meal preparation, household cleaning, or any other activity relating to the person's social, economic, political, or spiritual participation in society. In fact, many users can only receive this support inside their own homes. People who have received supports for years are being reassessed using the newer, more restrictive, criteria. There are few arms-length appeal mechanisms for people with impairments to use when they have their services reduced or denied. Disability organizations have found that it can be particularly problematic for people, more often women, who have impairments that are invisible and fluctuating.

Although the Canada Health Act is in place to protect universal access to health-related services in Canada, home support has never been included under this act. At the time the act was developed, deinstitutionalization, community-based models of health care, and the independent living movement had not yet increased awareness of the need for home support service. Because the service is not protected under the act, it is particularly vulnerable to social and economic pressures. The same is true in the United States and other countries with partial health coverage such as Medicare and Medicaid.

Policy making in this area has been influenced by medical models of disability and economic reductionism. Policies reflect and emphasize the notion of disability as a biological limitation rather than one that recognizes the role of society in creating barriers for people who accomplish their goals differently. Services in some regions aim to keep people merely alive and are unconcerned with providing supports that would allow them to leave their homes or bedrooms. This has led some disability activists to see this move as another form of institutionalization.

Policies also tend to be guided by notions of economic restraint, further fueled by rhetoric about the rising cost of health care and the growing number of older Canadians requiring care. Some regions of the country have developed policies that emphasize the goal of spending less on home support service, viewed in isolation. The policy ignores the holistic analysis in which the objective of home support not only is self-direction of one's life but also maintaining its role in health prevention and promotion (e.g., by addressing the social determinants of health and increasing basic nutrition). When people with physical impairments, for example, no longer receive basic care to maintain their lifestyle and health in the community, they can experience a worsening of their health, which in time will require more costly acute care treatment. Home support is clearly less expensive than institution- or hospital-based care, but more important, the disability community views this economic emphasis as a step backward in terms of their human rights.

THE NEED FOR NATIONAL STANDARDS

In Canada and other countries, the administration of home support programs tends to be decentralized to provinces, regions, or smaller administrative units. Studies have indicated that without a national standard there will be significant differences in eligibility criteria, user fees, and range of services across the country. Variation in approaches to service delivery will also exist. In some areas, services are directly provided by public employees, in others competitive tendering results in private agencies delivering services, and in yet others a partnership is created between government and nonprofit providers.

Differences in eligibility criteria are a particular problem, as they appear to be designed to create ineligibility simply in order to reduce costs, rather than to facilitate the exercising of rights. Competition between provinces or municipalities to "reduce costs" threatens the eligibility for services of people who live with long-term impairments. Reassessment can be introduced across the board in regions or it can be initiated by factors such as an individual's move to a region. People with disabilities are not free to move from one location to another because there is no assurance that their services would continue under new local eligibility criteria. A set of national standards for home support established by the central government could help to solve this problem, especially if, as in Canada, the standard-setting, federal government makes adherence to the standards a condition for qualifying for federal funding or cost-sharing.

INTERNATIONAL CONTEXT

Home support should also be seen in light of internationally developed conventions and treaties developed to protect or ensure rights of children and adults who live with disability. Article 23 of the Convention on the Rights of the Child states that "parties recognize that a mentally or physically disabled child should enjoy a full and decent life in conditions that ensure dignity, promote self-reliance, and facilitate the child's active participation in the community." The UN Standard Rules of Equalization of Opportunity was developed in collaboration with member states and disability representatives with the intent of developing a guiding framework for developing policy and services while supporting community participation for people with disabilities. Rule 4 of the UN Standard Rules stipulates that "states should support the development and supply of services including assistive devices, personal assistance and interpretation programs to people with disabilities."

What the future holds for home support depends to a degree on pressure from the international community to live up to the standards set by the UN Standard Rules and possibly in the near future, to the UN Disability Convention. Much will also depend on the willingness of the United Nations and national and local governments to directly involve those who are affected by these home support policies—people with disabilities, parents of children with disabilities, family members—to contribute and be listened to.

At the same time, the growth and ever-increasing power of multinational health care corporations, guided entirely by economic concerns, will redirect attention away from consumer control and citizen-based outcome criteria for services. Government may increasingly feel the pressure to transfer health care services to the multinationals. An increasingly aware, and active, disability movement, joining forces with the rest of the population whose life and health will be affected by these developments, will be required to ensure that home support can involve, and be under the control of, those who are directly affected by these services.

▣ HOMER (EIGHTH CENTURY BC)

Greek epic poet

The earliest surviving Greek epic poems, the *Iliad* and the *Odyssey* (dated around the eighth century BC) have traditionally been attributed to Homer, even though his existence has been questioned by many since antiquity. He was believed to have been born blind or to have lost his sight from an eye disease early in life, before completing the *Iliad* or beginning the *Odyssey.* His blindness was accepted by such ancient authors as Herodotus, Theopompus, Plutarch, Cicero, Pausanias, Silius Italicus, Hesychius, and Suidas. It is also represented in several ancient portraits of the poet, whereas others depict him with a piercing gaze. His account, in the eighth book of the *Odyssey*, of Demodocus the blind bard of the Phaeacians (with its implicit notion of the gift of song as a compensation for loss of sight) has been taken as a self-portrait of the poet. The Greek historian Thucydides (fifth century BC) regarded as a genuine work of Homer the "Hymn to the Delian Apollo" in which the author describes himself as a "blind man living in harsh Chios."

Several ancient biographers of Homer mention his blindness, but all of them are late. In the *Phaedrus* (Section 243a), Plato draws a strange parallel between Homer and the poet Stesichorus, who was said to have been punished with blindness for his attack on Helen.

Many modern scholars contend that Homer's blindness is apocryphal, being the result of a misattribution projected from one of the characters of the *Odyssey*. Rejection of Homer's blindness is implied by authors who stress the importance of visual memory for description, such as Velleius Paterculus (AD first century) among the ancients and Minchin (2001) in modern times. Similarly, although Homeric references to eyes and vision are formulaic, Homeric facial gestures may reflect aspects of character and reveal psychological situations, thus standing in for acts and, especially, words (Soteroula 1994). The idea, suggested by Schumann in 1955, that the peculiar structure of Homeric dreams is a proof of their author's blindness has been rejected by scholars such as Mirko Grmek in 1989.

The picture of the blind Homer has left its profound impact on the notion of the blind singer, although the notion itself is not confined to classical Greece. Some recent scholars have endeavored to understand the role of the blind characters in the Homeric poems (such as Tiresias, Demodocus, and Polyphemus) in connection with the legendary blindness of the poet himself.

HOUSING: LAW AND POLICY

Throughout North America and in most European countries, organized housing for people with disabilities was historically derived from charity-based models relying on institutionalization in one form or another. For example, much of the Western approaches to housing law and policy have roots in the Elizabethan poor laws of 1601. These laws were an attempt in early industrial England to dichotomize the poor as either deserving or nondeserving. Those orphaned, blind, or otherwise disabled were viewed as deserving by their conditions and thus were more entitled to charity than the nondeserving poor. Housing for the deserving poor took the form of almshouses and other charity-based facilities. Individuals who were blind, deaf, or had cognitive or other types of disabilities would move into a facility for shelter and education and live out their entire lives within walls.

Contemporary Western approaches to housing policy have seen a shift from charity and welfare models to a focus on community-based models of housing. This has given rise to the adoption of a number of antidiscrimination housing laws and policies in the United States and internationally. Nevertheless, institutions housing individuals with disabilities still exist today, although their numbers are decreasing.

U.S. HOUSING LAW AND POLICY

Fair Housing Act of 1937

Federal housing policy in the United States emerged from the Great Depression of the 1930s and the economic conditions that produced widespread unemployment. In the housing sector, both the finance and construction markets were severely challenged by the Depression. In response, policy makers created the Federal Housing Administration (FHA). The FHA insured private mortgages in order to increase housing construction and stabilize the housing economy.

To assist the poor, a group that included people with disabilities, policy makers also created a public housing program. Under the Fair Housing Act of 1937, the federal government created a program to fund almost the entire cost of public housing. The housing itself was built and managed by local housing authorities, who were required to manage the public housing following federal guidelines.

By the 1960s, new solutions to housing problems emerged including housing for senior citizens, rent supplements, and housing allowances, followed by the Section 8 program in 1974. The Section 8 housing allowance program provided funding through local housing authorities to subsidize housing rehabilitation, implement new construction, and subsidize rents in private housing.

The Section 8 program exists today. In the program, housing vouchers are issued to low-income families and families with members who have disabilities. These vouchers allow the individual or family to do a housing search and find private housing that fits their needs. Under the Section 8 program, the family pays 30 percent of its total income for rent and the housing authority pays the remainder. The local housing authority maintains a listing of public housing and allocates the housing to individuals who meet its eligibility requirements. Housing authorities may choose to give preference to certain groups including individuals living in unsatisfactory conditions, terminally ill people, and people with disabilities. Individuals who fit within these criteria are allowed to move into housing sooner than others on the registry.

Government subsidization is not a program unique to the United States. A number of countries, including the United Kingdom, Austria, and Australia, have created housing programs for people with disabilities subsidized with government funds.

Housing Law

Until the early 1970s, housing laws generally did not include individuals with disabilities as a protected class. Rather, laws such as the Fair Housing Act (Title VIII of the Civil Rights Act of 1968) addressed discrimination on the basis of race. It was not until the passage of the Rehabilitation Act of 1973 in the United Sates that housing law specifically dealt with discrimination faced by individuals with disabilities in housing.

Section 504 of the Rehabilitation Act

Under Section 504 of the Rehabilitation Act of 1973, qualified individuals with disabilities are protected from discrimination in housing programs that receive federal funding. Qualified individuals with disabilities are defined as persons who have a physical or mental impairment that substantially limits them in one or more major life activities. Impairments may include, but are not limited to, visual or hearing impairments, mobility impairments, psychiatric impairments, HIV infection, cognitive impairments, and drug addiction (not current illegal use).

Major life activities include caring for oneself, performing manual tasks, walking, seeing, hearing, speaking, breathing, learning, and working. Substantial limitation in these activities is determined by whether or not the average person can perform them with little or no difficulty.

Newly constructed federally funded housing is required to be physically accessible to tenants with disabilities under Section 504. At least 5 percent of units (or a minimum of at least one unit) must be accessible to tenants in wheelchairs and other mobility devices. Two percent (or at least one unit) must have the accessibility features needed by individuals with hearing or vision impairments. Accessible units are to be distributed throughout housing sites to ensure that tenants with disabilities have a variety of options in location and amenities. There are also requirements for physical accessibility when federally funded housing is altered as well.

Reasonable accommodation for tenants with disabilities is another major feature of Section 504. Accommodations may include changes to a policy, program, service, or dwelling unit that allow tenants with disabilities to fully participate in the housing experience. For example, the federally funded housing program may install a ramp for a tenant in a wheelchair or allow a service animal despite a “no pets” policy. These modifications are to be carried out at the expense of the federal funding recipient, unless it would result in an undue financial or administrative burden. Undue burden is defined as substantial administrative difficulty or expense. When deciding whether or not an action would be an undue burden, the housing entity must consider all resources available to them.

Fair Housing Act Amendments of 1988

The Fair Housing Act of 1968 prohibits discrimination in housing practices on the basis of race in almost all forms of housing sold or rented in the United States. It was amended in 1988 to include protections for people with disabilities. This amendment extended protection for people with disabilities beyond those in Section 504 to include private housing. Disability is defined under the Fair Housing Act using the same criteria as under Section 504 and the Americans with Disabilities Act.

Actions prohibited under the act include the refusal to sell or rent to an individual with a disability or to a family that includes a member with a disability. The Fair Housing Act also prohibits the refusal to negotiate; making housing unavailable; denying a dwelling; setting different terms, conditions, or privileges for sale or rental; providing different housing services; falsely denying that housing is available for sale or rental; persuading owners to sell or rent; or denying anyone access to or membership in a facility or service to people with disabilities.

Mortgage lenders are not allowed to refuse to make a loan, refuse to provide information regarding loans, impose different terms or conditions on a loan, discriminate in appraising property, refuse to purchase a loan, or set different terms or conditions for purchasing a loan when working with individuals with disabilities protected under the Fair Housing Act.

Similar to Section 504, housing entities must make reasonable modifications to policy and procedure to allow individuals with disabilities to use their housing. For instance, an apartment complex that provides unassigned parking to its tenants would have to allow a tenant with a mobility impairment a reserved accessible parking space near his or her unit.

Tenants with disabilities are also allowed to make reasonable modifications to their dwellings as well as to the common areas of the complex if this will allow them the use of their unit or the public areas. For instance, if a tenant with a disability needed to widen the doorways in an apartment, under the act, the landlord would have to allow the tenant to make the needed changes. The tenant would be responsible for restoring the unit to its original state when he or she moves. The costs of the reasonable accommodations provided by federally funded housing programs under Section 504 of the Rehabilitation Act are the responsibility of the housing provider, but reasonable modifications under the Fair Housing Act are at the expense of the individual with a disability.

Housing complexes that first had occupancy after March 13, 1991, and have an elevator or four our more units are required to be physically accessible to tenants with disabilities. In addition to the accessibility of the public and common areas, ground-floor dwelling units must also be accessible. Accessible features include doors and hallways that are wide enough for wheelchairs, accessible light switches and other environmental controls, reinforced bathroom walls for the possible installation of grab bars, and kitchens and bathrooms that are usable by tenants with mobility impairments.

Americans with Disabilities Act of 1990

The Americans with Disabilities Act of 1990 (ADA) prohibits discrimination in employment, state and local government programs, the provision of goods and service in business, transportation, and in certain circumstances, housing. Individuals with disabilities are protected under the ADA in housing in several situations. If housing is part of a public accommodation or business that is open to the public such as a hotel, it is covered under the ADA. Specifically, hotel rooms need to be physically accessible under the ADA. Hotels are also required to provide auxiliary aids and services such as visible alarms and text telephones (TTY) for guests who are deaf. Places of lodging might also have to modify policies and procedures if those policies discriminate against guests with disabilities such as eliminating a no-pets policy for guests with disabilities who have service animals.

Hotels that include residential areas would be covered both under the ADA and the Fair Housing Act. The area occupied by individuals living in the hotel would be subject to the requirements outlined in the Fair Housing Act, while the transient lodging section of the facility would be held to the regulations in the ADA. Public areas in housing complexes such as rental offices and community rooms may also be covered under the ADA. For instance, if the community room of a housing complex is rented to community members for events, it would then fall under the ADA and need to be accessible to individuals with disabilities.

INTERNATIONAL CIVIL ANTIDISCRIMINATION LAWS

Many countries across the world have enacted civil antidiscrimination laws protecting people with disabilities from discrimination. Some of the most extensive antidiscrimination laws including protection for individuals in housing have been enacted in Australia, Canada, the United Kingdom, and the United States. These laws in general protect people with disabilities from discrimination in employment through the provision of accommodations and public accommodations or business in regard to the provision of physical access and policy modification.

Internationally, Hong Kong, the Philippines, Costa Rica, Hungary, India, Israel, Japan, Nepal, New Zealand, Peru, and Thailand all have antidiscrimination laws that include protection for people with disabilities in employment, services, and public accommodations but not housing.

Disability Discrimination Act of 1992 (Australia)

The Australian Disability Discrimination Act of 1992 (DDA) prohibits discrimination against people with disabilities in employment, education, land possession, the provision of goods and services, and access to premises, clubs, sports, other facilities, and housing.

Under the act, it is illegal for housing agents to discriminate against an individual with a disability or anyone associated with an individual with a disability by refusing the person's application for housing, discriminating in the way the housing is offered, deferring the application of a person with a disability, limiting or denying access to any service or privilege related to housing, evicting due to disability, and refusing to allow the individual with a disability to make alterations to housing related to disability at the individual with disabilities' expense.

Human Rights Act of 1985 (Canada)

The Canadian Human Rights Act of 1985 prohibits discrimination against individuals with disabilities in the provision of goods and services and facilities that are open to the general public, employment, commercial premises, and housing. Under the act, discriminatory practices in the provision of housing or residential accommodation include denying occupancy to an individual with a disability or giving preferential treatment to a person without a disability over an individual with a disability in any housing negotiation.

Disability Discrimination Act of 1995 (United Kingdom)

The Disability Discrimination Act of 1995 (DDA) provides protection for individuals with disabilities in employment, access to goods and services, and housing. In the area of housing, the DDA makes it illegal to sell or rent property in ways that would discriminate against people with disabilities.

FUTURE OF HOUSING LAW AND POLICY

The future of housing law and policy as it relates to people with disabilities is predominantly a positive one. Throughout the world, many laws have been enacted and policies created that give greater and greater protection to people with disabilities in almost every aspect of housing rental, sale, and purchase. Housing law and policy has moved from a welfare and charity focus to one of empowerment and independence. If the past is any indication, this trend should continue to grow in the future.

HUMAN RIGHTS ACT OF 1998 (UNITED KINGDOM)

"Disability was, until very recently, the forgotten dimension of human rights and unacknowledged as a subject for a right to equality" (Daw 2000:8). It is fair to say, however, that the implementation in October 2000 of the UK Human Rights Act 1998 has led to an increase in the (successful) use of human rights arguments in the context of disability specifically in the United Kingdom.

Prior to the implementation of the act, anyone who wished to complain of a violation of the EU European Convention on Human Rights (referred to below as the convention) had to exhaust domestic remedies for complaint and then take their case before the European Court of Human Rights—there was no means by which a claim of breach of the convention could be brought in the UK courts.

The act—as well as making virtually all of the convention rights directly enforceable in the UK courts—brought fundamental change to the way in which courts and tribunals interpret legislation. Section 6 of the act provides that it is unlawful for a public authority to act in a way that is incompatible with a convention right (i.e., it cannot act in a way that would breach any of the rights in the convention—this is a positive duty placed on public authorities to uphold the convention rights); Section 3 of the act obliges courts to "read and give effect" to legislation in a way that is compatible with the convention rights (this means that when considering any piece of legislation, the court must interpret it in line with the convention rights; e.g., any family law provisions will have to be considered in light of Article 8, the right to respect for private and family life). And courts can make a "declaration of incompatibility" where a legal provision cannot be read and given effect in a way that complies with the convention (i.e., state that it is not possible to interpret the provision in such a way as to be compatible with the convention). Although the government would not be obliged to act following such a declaration, it is likely that it would do so, as otherwise a successful claim against the government could be brought in the European Court of Human Rights.

The convention rights, listed in Schedule 1 to the act, are as follows:

Right to life

Right to freedom from torture and inhuman and degrading treatment

Right to freedom from slavery or servitude

Right to liberty and security

Right to a fair trial

Right to no punishment without law

Right to respect for private and family life

Right to freedom of thought conscience and religion

Right to freedom of expression

Right to freedom of assembly and association

Right to marry

Right to enjoyment of the rights and freedoms without discrimination on any ground

Some of the rights—such as the right to life—are absolute, while others are qualified.

In purely numerical terms, mental health has been one of the areas in which the Human Rights Act has been frequently raised—there have been 10 declarations of incompatibility, three of which have related to the Mental Health Act 1983 and one of which has led to remedial legislation being introduced. Many of these challenges have related to Articles 5 and 6, the right to liberty and the right to a fair trial, respectively.

The key articles that have otherwise been invoked in relation to disability have been Article 2, the right to life (particularly in relation to the withdrawal/refusal of treatment of disabled people); and Article 8, the right to respect for private and family life (and dignity—successfully invoked in a case involving the provision by the local authority of care in the home, and the provision of local authority housing). While it is too early to fully judge the impact of the act in relation to disability, it can nevertheless be said that it is being increasingly invoked by disabled people and there have been some significant successes in cases brought under it.

HUMANITIES

Disability studies in the humanities has arrived somewhat belatedly, the field having been dominated by medical professionals, rehabilitation specialists, or social scientists who tended to focus on institutional or pathological contexts. Certain studies within the social sciences such as Erving Goffman's *Stigma* (1968), Georges Canguilhem's *Le normal et le pathologique* (1966), and Michel Foucault's *The Birth of the Clinic* (1963) provided humanist scholars with significant tools for complicating the medical model that had dominated the field until the mid-1980s. The emergence of cultural studies in the 1990s helped link disability with identity categories based around gender, race, and sexuality and provided a set of methodological tools for doing cross-cultural analysis. Publications such as David Mitchell and Sharon Snyder's collection, *The Body and Physical Difference,* Rosemarie Garland Thomson's *Extraordinary Bodies,* and Lennard Davis's *Enforcing Normalcy* explored the cultural meanings of disability and linked the disabled body to other identity categories. Special issues of journals devoted to disability issues, the formation of the Modern Language Association's Committee on Disability Issues, the emergence of the Disability in the Humanities chatlist (DS-HUM), and the evolution of interdisciplinary disability studies programs at various universities created a context for studying disability within the humanities.

Disability studies has proceeded through several stages, analogous to those undergone within feminism, queer, or minority activism. Unlike these other identity movements, these stages within disability studies are relatively coterminous, each modifying and adumbrating the other rather than succeeding each other in a linear sequence. The first stage has involved identifying stereotypes of the disabled figure in cultural texts and exploring ways that a physical impairment has been used figuratively as a sign of lack, instability, or moral phobia. First-wave disability studies has created an archive of texts—novels, films, poems, autobiographies, paintings—in which disability is featured and assesses the possibilities for resistance to and rearticulation of those stereotypes.

The second stage—the cultural nationalist moment—coincides with the rise of an activist disability movement and involves establishing a disability community. On the one hand, this implies wresting the category "disability" from definitions established within the medical and psychoanalytic professions. On the other hand, it means establishing consensus among constituencies who may be isolated within medical and therapeutic regimes. Vital to this stage of disability studies is the proliferation of first-person accounts by disabled artists and intellectuals such as those by Nancy Mairs, Audre Lorde, Paul Monette, Robert Murphy, John Hockenberry, and Susan Sontag. Such life-stories are essential for a population that often lacks access to official publishing and media venues and whose narratives are often told by doctors and health care professionals. At the same time, a renewed interest in disabled artists creates a new consciousness of the role that disability has played in the arts (Toulouse Lautrec, Chuck Close, Goya), literature (John Keats, Samuel Johnson), and music (Beethoven). Thus, a main component of second-wave disability work involves giving voice to the disability rights slogan "Nothing about us without us."

A third stage of disability studies emerges in the 1990s, influenced by work in cultural studies and post-structuralism, that attempts to understand processes by which a physical or cognitive impairment becomes stigmatized. Key works by Rosemarie Garland Thomson, Simi Linton, Michael Bérubé, and Lennard Davis focused on the ways that bodily normalcy is reinforced within able-bodied (or what Thomson calls "normate") society. These works remove the emphasis on the impairment and shift the focus to the ways that society enforces certain cognitive, physical, and sensory ideals.

The stress on a social rather than medical model has led to significant research on the cultural meaning of disability in literature, art, film, and history. Historical work on late nineteenth-century medicine, for example, has revealed the extent to which the concept of disability was invented through projects of national consolidation and racialization. Rosemarie Garland Thomson and Robert Bogdan showed how the phenomenon of freak shows, in which nontraditional bodies were displayed as "human curiosities," becomes an extension of a larger impulse toward standardization of the body. Such scholarship suggests that disability, like homosexuality or race, is largely a product of a specific historical period for which technologies (photography, film), methodologies (statistics, comparative anatomy, psychoanalysis), and social theories (eugenics) contribute to an ideal of normalcy in the Victorian period.

Third-stage disability studies by Lennard Davis, David Mitchell, Sharon Snyder, and Tobin Siebers, while drawing on key formulations by Judith Butler and Michel Foucault, have nevertheless questioned the limitations of social constructionist definitions when faced with actual, historical bodies. Many social constructionists, Siebers (2001:742) argued, "assume that it is extremely difficult to see through the repressive apparatus of modern society to any given body, but when they do manage to spot one, it is rarely disabled. It is usually a body that feels good and looks good." Davis similarly observed that identity is perhaps not the "sharpest instrument" around which to base an intellectual project if the end of all rights-based claims is the ideal of achieving the status of white, middle-class males. It is possible that beneath the liberatory rhetoric of identity politics lurks an idealized norm, for which the disabled body provides an antidote. In *Bending over Backwards* (2002), Davis has created a portmanteau term, "dismodernism," to describe how disability undermines identity positions that emerged with early modernism and that were based around medical and eugenics models.

Third-stage disability studies builds on a cross-cultural analysis, finding parallels between disability and queer or colonial or racialized identities. Many disability theorists have seen their critical projects as analogous to queer theory, "cripping" (on the analogy of "queering") normative discourse to reveal implications of able-bodiedness. Instead of seeing the person with a disability as a metaphor for some other condition (castration, moral phobias), scholars and disability activists have studied the constitutive function of such figures in various cultural objects and documents. David Mitchell and Sharon Snyder, for example, noted that the disabled figure in novels and films perform a "prosthetic" function for narrative. Not only do novels rely on a disabled character to create pathos (Tiny Tim, the Elephant Man) or pathology (Ahab, Lear); such figures are foundational for narrative form itself. What, for example, would be the meaning of Oedipus's tragic loss if he were not blind? Like the prosthetic limb, the disabled person provides an illusion of presence and wholeness that must be eliminated by the end of the novel or film so that the able body can be restored.

These developments in scholarship have important implications for humanities pedagogy. If the humanities is underwritten by an idealized body, what happens when that body does not match Michelangelo's heroic David or Leonardo's Vitruvian Man? More specifically, what happens when the humanities classroom includes a disabled student or instructor? At one level, both have greater access to the physical classroom itself, due to legislation such as the Americans with Disabilities Act and the growth of new technologies (computers, voice translators, distance learning) that make learning more accessible. On another level, the introduction of disability as a subject challenges the student to ask new questions about the self-evident categories of aesthetic and epistemological endeavor. What might the study of poetry be like for a Deaf student for whom "heard melodies" may not be so sweet as those produced by sign language? What is this student to make of terms such as "oral tradition," "limping meters," "eye rhymes," "accentual verse," and other basic terms of prosody that presume a hearing readership and print representation of a spoken text? In like manner, what might humanities study be like if we were to treat *Paradise Lost* as the product of a blind person, the dissonant harmonies of Beethoven's late quartets as the product of a deaf person? Disability asks such questions in order to rethink the "human" in "humanities" and imagine that it includes a woman with a cane, a child using sign language, a man with a compromised immune system.

HUMORS, THEORY OF

Humors are bodily fluids that according to some ancient physicians presided over illness and health. The excess of any one of the humors would lead to specific diseases, as a good balance was the condition of health. The theory of humors, which was central in medical theory for centuries, is now completely banished from the field of medicine, even if it is still part of the heritage of some alternative medicines.

The first medical references to humors are found in the Hippocratic corpus:

> The body of man has in itself blood, phlegm, yellow bile and black bile; these make up the nature of his body, and through these he feels pain or enjoys health. Now he enjoys the most perfect health when these elements are duly proportioned to one another in respect of compounding, power and bulk, and when they are perfectly mingled. ([Hippocrates], *Nature of Man* 4, translation by W. H. S. Jones)

These were to become the canonical four humors, but even the Hippocratic corpus contains variations. For instance, the treatise *Diseases* IV lists phlegm, blood, bile, and water ([Hippocrates], *Diseases* IV, 32).

The text *Nature of Man* not only names the humors but also links them with the four seasons and with the mixtures of the qualities warm, cold, dry, and humid. Although the humors are always present in the body and are necessary to life, they are found in greater quantities according to the times of the year: phlegm in the winter, blood in the spring, yellow bile in the summer, and black bile in the autumn. The predominance of one humor is connected with a similarity between the humor and the season. For instance, the increase of phlegm in the winter is related to the fact that phlegm is the coldest humor. Daily occupations, the way you live, and food influence the quantity of the humors in the body: Dark wines, lentils, snails, and the meat of bulls and goats are all prone to produce black bile. Humors are natural and necessary to life, but their mixture needs to be in a state of balance toward one another. An increase in the amount of one humor or in the concentration of one humor in one place can cause diseases, such as hemorrhoids, anthrax, and cancer in the case of black bile. The cures to such imbalances are found in purgation and bloodletting.

The names of the four humors and the theory of humors were to become prevalent because they were attached to the name of Hippocrates and because they were adopted and developed by Galen, the second-century AD physician, who was to become central both in occidental and Arabic medicine. Yet there were competing theories. Praxagoras of Cos, for instance, was able to distinguish 11 humors. On the other hand, Erasistratus of Iulis did not reject the theory of humors, but showed caution, and was bitterly reproached by Galen for this reason. Asclepiades of Bithynia and the Methodists, a medical school that became popular in Rome, rejected the explanation of humors as a cause of diseases.

Galen adopted a system relating the humors to the four elements—earth, air, fire, water —and to a mixture of qualities—warm, cold, dry, humid—and to a certain extent to seasons and ages. Some of the developments of the theory were specifically medieval: the complete theory of the four ages of life; the four temperaments, namely, phlegmatic, sanguine, choleric and melancholic; and the perfect integration of the microcosm into the macrocosm. Critiques of the humoral theory appeared as early as the Renaissance, but the system was influential until the nineteenth century.

HUNT, PAUL (1937–1979)

British activist

Paul Hunt is regarded by many disability activists as the founder of the modern disabled people's movement. He has been influential not only in the United Kingdom but internationally. It was at Le Court Leonard Cheshire residential home that he and other disabled people first developed the ideas and philosophy that were to inform the Union of the Physically Impaired against Segregation (UPIAS). UPIAS was established in 1972 and can be seen as a key starting point for the development of the British disabled people's movement. Its Fundamental Principles of 1976 gave birth to the social or social oppression model of disability.

Paul Hunt's edited collection (1966) of disabled people's accounts is now identified as one of the key texts in the development of the British disabled people's movement and disabled people's thinking more generally. He was influential both through his writings and as a key participant in UPIAS. Hunt also played a pioneering role in the development of disabled people's (emancipatory) research. He and other disabled people invited academic researchers into Le Court to hear their views and felt betrayed when these researchers conceived of them instead as "parasites." Paul Hunt in turn described such researchers as "parasites, questioned the balance and neutrality of traditional disability research, and raised the question of "whose side are you on?" which continues to concern disability research.

HUSSEIN, TAHA (1889–1973)

Egyptian intellectual and modernizer

Taha Hussein (also spelled Husayn) was born in an obscure village of Upper Egypt and lost his sight in early childhood. He learned locally to memorize and recite the Qur'an and continued in 1902 to Al-Azhar University where for centuries there has been a school for blind students of Islam (Dodge 1974). He studied further at the new secular university at Cairo, writing a dissertation on the freethinking blind poet Abu 'l-`Ala al-Ma`arri, with whom he identified. Taha Hussein's abilities and persistence earned him a ticket to study in France from 1915 to 1919. He acquired a doctorate and some Braille, but he relied also on a French reader, Suzanne, who became his wife. Returning to Egypt, Hussein taught literature at the University of Cairo. His first book, using source criticism on pre-Islamic poetry, seemed to impugn parts of the Qur'an, which led to a great uproar. The first volume of his autobiography *Al-Ayyam* (*The Days*) had a better reception, and it is this cumulative work for which he became internationally celebrated (Husayn 1926–1927, 1940, 1955; Malti-Douglas 1988). A prolific writer, critic, and energetic campaigner for modernization, he was briefly Egypt's Minister of Education (1950–1952), and in the longer term a cultural ambassador between the Arab and Western worlds (Goldschmidt 2000).

HYDROTHERAPY

Common usage of the term *hydrotherapy* refers to use of relatively large quantities of water on the external surface of the body, including wounds, for water's properties of buoyancy, cleansing, and high thermal capacity, that is, its ability to heat or cool. Related terms include *aquatic physical therapy*, *hot tub therapy*, and *whirlpool bath*. As with other forms of therapeutic heat and cold, hydrotherapy is a treatment, or adjunct to treatment, and not a cure in itself.

The property of buoyancy comes from the pressure exerted on the body by the surrounding water, in proportion to the volume of water displaced by the body. Buoyancy, depending on the depth of the water, allows walking with reduced weight bearing on the joints of the lower limbs. It also reduces the load on the back. This affords the patient with rheumatoid arthritis and other forms of arthritis the chance of near pain-free ambulation. This, in turn, results in improved range of joint motion and even increased fitness, if the patient is very deconditioned to begin with, and the exercise is done with progressively increasing vigor.

The cleansing action of water is greatly helped by agitation and the use of a detergent. This is similar to the action of a clothes washing machine, except that far less detergent is used or needed in hydrotherapy, and the detergent may have antibacterial and emollient (skin softening) properties in addition to breaking up the surface tension of the water, allowing it to "wet" better. Hydrotherapy of this type may be applied with the large Hubbard Tank, which is shaped like the "angels" children make when they lie on their backs in the snow and spread their arms and legs. This shape permits the nurse or therapist to come close to the buoyant patient and remove adherent dressings as they begin to float away from the burns or other wounds. Jets around the sides of the Hubbard Tank agitate the water.

Various sizes and shapes of whirlpool baths enable the patient to sit in a tub or place an arm and hand or leg and foot in the water. Jets can provide more concentrated agitation than is possible with the Hubbard Tank. The most focused form of hydrotherapy for cleansing is applied with pulsatile lavage. With this, no part of the body is submerged, but a device similar to the one used in many homes for teeth and gum hygiene applies sterile saline (salt water in a concentration similar to that of human blood) directly to the wound, to improve the local environment for healing. With pulsed lavage, care must be taken to be sure that there is no *Acinetobacter* in the wound or this can result in pneumonia of the patient treated or other patients in the hospital.

Finally, hydrotherapy allows application of therapeutic heat or cold. The larger the amount of the body submerged, the more care must be taken not to greatly disturb the core (center) temperature of the body. This high thermal capacity of water can be used to the advantage of multiple sclerosis patients, whose symptoms are greatly worsened by heat. They can swim in cool (about 72 degrees F) and obtain aerobic exercise benefit without the adverse effects of increased body temperature.

Water can also be used to "couple" ultrasound to the body part being treated, but no agitation should be used, since the bubbles will reflect ultrasound and make it ineffective.

HYPERTENSION

Hypertension is one of the most frequently diagnosed disorders in the developed world. In the United States, the cost of antihypertensive drugs accounts for about 10 percent of the country's total spending on medications. Increasingly, hypertension is viewed as a problem also in the developing world. In 2001, the African Union placed it second only to AIDS in the health challenges facing African countries.

Hypertension today is predominantly treated as a risk factor for stroke and heart disease, and treatment is preventive. This has not always been the case. Well into the 1950s, hypertension itself, in its malignant phase, was feared as a disabling and often deadly disease. Most noticeably disabling were effects on patients' eyesight, breathing difficulties, and headaches. Before effective treatments became widely available, people with hypertension were expected to die within one year of diagnosis. Malignant hypertension has become rare in the developed world since the 1940s and 1950s, when more and more patients were treated first by surgery and later with the new antihypertensive drugs. However, poorer sections of the population and members of ethnic minorities still face a higher risk of complications from undiagnosed and untreated hypertension than the more affluent.

The modern, noninvasive method of measuring blood pressure was devised in 1905 by a Russian army surgeon, Nicolai Korotkoff. Physicians examining applicants for industrial life insurance policies in the United States were the first to systematically apply this method. Compilations of actuarial data gathered by the insurance companies, as well as several long-term epidemiological studies undertaken in different countries since World War II, produced evidence of a statistical association between blood pressure and life expectancy, indicating that the higher a person's blood pressure, the higher was the probability that this person might die prematurely. However, the causes of the high blood pressure itself have remained unclear for the majority of patients.

As moderately high blood pressure is statistically associated with a higher probability of early death but does not produce any immediate symptoms, questions of treatment and the determination of a clear boundary between normal and pathological blood pressures have been the subject of intense debates among medical experts. The early drug therapies caused serious side effects, often worse than the symptoms of the disease. These drugs demonstrated that long-term treatment increased the life expectancy of patients with malignant hypertension, but only the development of drugs with less severe side effects, such as thiazide diuretics or beta-blockers, allowed the preventive treatment of patients with mild and moderate hypertension.

Most physicians today follow a pragmatic approach to therapy. They prescribe antihypertensive drugs if the benefits of long-term treatment are likely to be greater than the risks associated with the medication. However, some have continued to argue that in many cases both the neurosis caused by being labeled "hypertensive" and the side effects of the antihypertensive drugs might have worse consequences than the high blood pressure itself.

HYPOCHONDRIA

Hypochondria, a word of Greek origin, meaning literally "below the cartilage" (referring to ailments in the abdominal region), gradually acquired the designation of a psychological malady: the morbid preoccupation with serious illness without demonstrable organic disease. This preoccupation is based on a misinterpretation of bodily sensations, functions, or symptoms and persists despite appropriate medical evaluation and reassurance. Affected patients are significantly distressed, and there is impairment in personal, social, and occupational functioning. The beliefs about illness are not delusional in that the individual can acknowledge the possibility of exaggerating symptoms and admit that a dreaded disease state may not exist. Nevertheless, there tends to be a high use of medical care, repeated doctor visits, and costly laboratory and diagnostic testing. The persistence of this pattern for at least six months is necessary to classify it as a psychiatric disorder.

Prevalence estimates for hypochondria in the medical setting, both in the United States and internationally, range from 3 to 5 percent of this population, and it is equally common in males and in females. There does not appear to be any correlation with socioeconomic status, educational level, race, or marital status. Onset can occur at any age but tends to be most common in young adults. There tends to be a high comorbidity with other psychiatric conditions, such as depression, anxiety disorders, and personality disorders. Hypochondria is distinguished from other psychosomatic illnesses by its core feature of fear of having or contracting a disease, as opposed to concern about symptoms (as in somatization disorder), concern about physical appearance (as in body dysmorphic disorder), or disturbances in motor or sensory functions (as in conversion disorder). In addition, hypochondria should be distinguished from malingering or manipulation in that the hypochondriacal patient actually experiences symptoms and is quite anguished about them.

There are various theoretical explanations regarding the psychological origins of hypochondria. These include the transformation of unacceptable hostile or aggressive feelings into physical complaints, that is, to reproach one's caregivers with unremitting suffering; the physical expression of wishes for care and nurturance; a defense against low self-esteem; a defense against guilt, with physical suffering serving as atonement; an attempt to gain sympathy or to control and manipulate, that is, what can be thought of as the secondary gain of the sick role; and as a form of selective attention and cognitive distortion regarding physical sensations.

Although hypochondria tends to be chronic and episodic, some patients do recover, and many respond to a sensitive, individualized treatment approach. Cognitive-behavioral therapy, group therapy, and psychodynamic therapy have all demonstrated some effectiveness. In addition, pharmacotherapy, such as the use of antidepressants, can be used as an adjunct to psychotherapy and educational treatments, especially if there are comorbid symptoms such as depression. In general, a guiding principle of treatment is care rather than cure. The goal of treatment should be aimed at helping the individual cope with and tolerate symptoms rather than trying to eliminate them. An attempt should be made to disconnect the experience of bodily symptoms from receiving care and to encourage the direct, verbal expression of feelings. In the words of the nineteenth-century British anatomist Henry Maudsley: "The sorrow that has no vent in tears makes other organs weep" (quoted in Cantor 1996:60).

HYSTERIA

No longer part of psychiatry's official diagnostic nomenclature, *hysteria* is a term that continues to capture the public imagination, despite the fact that its significance is largely historical. The term, whose origins and definition have been the subject of centuries of scholarly debate, is generally used to describe a wide range of behaviors and symptoms—from paralysis to blindness to cough—that do not appear to result from physical illness. From the ancient Egyptians to Hippocrates to Freud and Charcot to contemporary psychiatry, hysteria has played an important role in our efforts to understand the duality of mind and body.

ANCIENT ORIGINS

Taking its name from the Greek *hystera,* meaning uterus, hysteria originated as a disorder of women. Although the standard historical account dates its inception to Hippocrates, called the father of medicine, references to the disorder can be found as early as 1900 BC in the *Kahun Papyrus,* an Egyptian medical manuscript. The ancient Egyptians believed that the uterus was an independent organism whose movement within the body led to behavioral disturbances. This idea was further elaborated by classical healers and philosophers (including Plato), who believed that as the womb wandered throughout the body, it created symptoms particular to its location. For example, cough and loss of voice, as well as a choking sensation known as *globus hystericus,* were believed to be the result of the uterus migrating to the throat.

Hippocratic texts linked uterine migration to abnormal sexual activity, including abstinence, and consequently recommended marriage and pregnancy as primary treatments. Additional measures—derived from the ancient Egyptians—focused on returning the womb to its proper location, either by cleansing the woman's vagina with fragrant substances to attract the uterus or by ingesting foul-tasting potions to drive the womb away from the upper body. Galen of Pergamon (AD 129–ca. 199/216), who believed that hysteria was due not to movement of the uterus but to uterine retention of a fluid analogous to male semen, proposed a cure that involved release of the congested sperm through increased sexual activity or digital manipulation by the physician—essentially, cure by orgasm.

Beginning in the seventeenth century, the uterine theory of hysteria gave way to a neural etiology, as physicians such as Thomas Sydenham (1624–1689) began to describe hysteria as an affliction of the mind that found expression in the body. It was now theoretically possible for men, in whom similar symptoms had previously been diagnosed as hypochondriasis, to suffer from hysteria. In practice, however, most of the patients remained women.

JEAN MARTIN CHARCOT (1825–1893)

Jean Martin Charcot, a French physician who was the director of the Paris women's hospital, the Salpêtrière, in the 1880s, is widely considered to be the father of modern hysteria. A neurologist who had made a name for himself using the "anatomical-clinical method" to study multiple sclerosis, poliomyelitis, neurosyphilis, and amyotrophic lateral sclerosis, Charcot turned his considerable nosologic skills to hysteria. He described a four-stage epileptiform attack, three categories of hysterical stigmata (sensory disturbances, such as anesthesias; disturbances of the senses, such as deafness or blindness; and motor disturbances, such as paralysis), and 20 hysterogenic zones on the female body. Charcot demonstrated the attacks at two weekly public performances at the Salpêtrière, in which hysterical patients would be hypnotized and display their symptoms to audiences of as many as 500. Toward the end of his life, Charcot's ideas were challenged by his rivals, including both some of his own students and Hippolyte Bernheim of the University of Nancy (known as the Nancy school), who suggested that

Charcot's patients had been coached and were not acting under natural hypnosis.

After his death, Charcot's study of hysteria was continued by his protégé, Pierre Janet, a French physician who delivered a famous series of 15 lectures titled "The Major Symptoms of Hysteria" at the inauguration of the new buildings at Harvard Medical School in 1906. Janet described hysteria as characterized by *idée fixé* (fixed ideas) that lingered below the surface of consciousness, and he may have predated Freud in his belief that treatment of hysteria involved making these unconscious ideas manifest.

SIGMUND FREUD (1856–1939)

Sigmund Freud, the father of psychoanalysis, studied with Charcot at the Salpêtrière in 1885 and 1886 and developed his own account of hysteria's neurotic origins. Based on 10 years of work with hysterical patients, he and Joseph Breuer wrote *Studies on Hysteria* (1895), a volume of case studies in which they argued that hysterical symptoms were the expression of psychic trauma and that the cure involved retrieving memories of the originating event, often through hypnosis. Breuer's first case was of Anna O. (a pseudonym for Bertha Pappenheim, who later became an active feminist), a young woman who developed multiple physical symptoms—cough, headaches, contractures of her right arm and leg, sleepwalking, and loss of voice—in the context of nursing her ill father. During the course of her treatment with Breuer—a method she called "the talking cure"—she translated her symptoms into a narrative, bringing to light her internal conflict between her guilt over her father's death and her desire to escape a repressive, patriarchal family. "Hysterics suffers mainly from reminiscences," Breuer and Freud wrote, theorizing that hysterical symptoms are due to selective blockage of memory. Out of hysteria, psychoanalysis was born.

By 1896, Freud had developed the "seduction theory," a model of hysteria based on the notion that the condition originated from repressed memories of childhood (and sometimes infantile) sexual abuse, often perpetrated by the father. By the following year, however, he had abandoned this theory, hypothesizing instead that hysterical patients were expressing fantasies based on their own unconscious Oedipal desires. In 1905, he published "Fragment of an Analysis of a Case of Hysteria," in which he described the case of Dora (a pseudonym for Ida Bauer), a young woman with relatively mild hysteric symptoms—chronic cough, headaches, and depressions—who had been brought to see Freud by her father after threatening suicide. Dora accused her father of having an affair with a family friend, Frau K., and felt that because of his desire to protect the secret of his own adultery, her father had turned a blind eye to the fact that Frau K.'s husband, Herr K., was making sexual advances toward Dora. Freud interpreted the situation in light of his own Oedipal theories, concluding that Dora was unconsciously attracted to Herr K. as a stand-in for her father. After 11 weeks, Dora broke off the treatment; but despite its short duration, this case remains one the most important in the history of hysteria, providing the first example of Freud's theory that hysteria represented a conversion of forbidden (and unconscious) libidinous impulses into physical symbolization.

Women treated for hysteria in the nineteenth century were often significantly disabled. Unable to engage in the work of relationships and daily life, they frequently required 24-hour care at home, or—if their families could not afford in-home care—were institutionalized for life.

IN THE TWENTIETH- AND TWENTY-FIRST CENTURIES

In the years after Freud, hysteria splintered into multiple psychiatric diagnoses, including hysterical conversion (or conversion hysteria), hysterical personality, and multiple personality disorder. The change reflected the conflict between a symptom-based approach (hysteria as something that one *has*) and a character-based approach (hysteria as something that one *is*). *Conversion hysteria* described the disorder in which psychological phenomena are expressed through physical symptoms, while *hysterical personality* described a character structure distinguished by emotional instability, dependency, self-dramatization, vanity, attention seeking, seductiveness, self-centeredness, and immaturity (traits listed in the second edition of the *Diagnostic and Statistical Manual of Mental Disorders* of the American Psychiatric Association). In 1952, hysteria was removed from psychiatry's lexicon, partially in response to criticisms that the term was too nebulous and that it perpetuated misogyny. Around the same period, in an attempt to clarify and destigmatize the disorder, hysteria was renamed *Briquet's syndrome*, after the French physician Pierre Briquet, who treated hysterics in the mid-nineteenth century.

With the publication of *DSM-III* (*Diagnostic and Statistical Manual of Mental Disorders*, third edition), hysteria was subsumed by three major categories: somatoform disorders, dissociative disorders, and personality disorders. In *DSM-IV* (American Psychiatric Association, 2000) conversion hysteria is now known either as *conversion disorder*, a disorder in which pseudo-neurological symptoms (including blindness, numbness, paralysis, and pseudo-seizures) appear without organic etiology and context of stressful life events, or *somatization disorder*, in which unexplained physical symptoms occur in three domains (sexual, pseudo-neurological, and gastrointestinal). Hysterical personality is now known as *histrionic personality disorder*, a disorder diagnosed mostly in women and characterized by excessive emotionality and attention seeking.

The notion of dissociated traumatic memories, once so important to understanding hysteria, has been relegated to the category of dissociative disorders, including a range of phenomena, from *dissociative fugue*, characterized by a brief period of amnesia, to *dissociative identity disorder*, in which a person's consciousness has been splintered into multiple distinct identities (often as a result of childhood sexual abuse).

I

IBN AL-ATHIR (1149–1210)

Arab scholar

Majd Ad-Din ibn Al-Athir was a learned man of Mosul who wrote works on hadiths and philology and held high office in the administration. Eventually the opportunity of associating with powerful men lost its charm. While working as secretary of state to the lord of Mosul, Ibn Al-Athir suffered paralysis of his arms and legs, which obliged him to retire from public service. A healer from the Maghreb came to treat him, and Ibn Al-Athir began to regain the use of his limbs. He then asked his brother to pay the healer a suitable fee and send him away. He explained that, in his present condition, he was under no obligation to visit the great and court their favor with the usual tedious ceremonies. He was enjoying rest and solitude. If anything serious occurred that needed his attention, people would come and ask his advice. To remove this liberty by continuing in therapy would be pointless. He preferred to spend his remaining days in peace. Ibn Al-Athir's family admitted the strength of his argument and discontinued the treatment.

IBN SIRIN (654–728)

Arab law lecturer

Muhammad ibn Sirin of Basra was an esteemed law lecturer, also valued as an accurate transmitter of sayings of the prophet Muhammad, though these skills seem hardly to have been lucrative. His father had been a coppersmith, a trade hazardous to the hearing of anyone near the noise. Ibn Sirin worked as a draper but was imprisoned for debt and is said to have died in debt. He was well known to have impaired hearing. To students of law, "As-Shabi used to say 'Stick to that deaf man!' meaning thereby Ibn Sirin; because he was dull of hearing" (*Ibn Khallikan's Biographical Dictionary* 1842–1871), but evidently he was worth hearing on law and on the sayings of Muhammad. He also became famous for interpreting dreams and was a man of great piety and notable eccentricity.

IBN UMM MAKTUM (SIXTH CENTURY)

Companion of the prophet Muhammad

Abdullah ibn Umm Maktum, a companion of the prophet Muhammad and relative of Muhammad's wife Khadijah, was born blind. He was among the earliest believers in Islam and was reportedly keen to learn the Qur'an from the mouth of Muhammad. Once when Muhammad was debating with leaders of the Quraysh tribe, Ibn Umm Maktum interrupted the prophet, who frowned and turned away. Afterward, Muhammad announced a revelation from Allah, which appears in the Qur'an, Sura 80. This seems to censure Muhammad for turning away from Ibn Umm Maktum (other interpretations also exist). Several incidents are recorded in which Ibn Umm Maktum's blindness figured. For example, once he failed to give the dawn call to prayer until a sighted person told him it was morning; another blind man was allowed to pray at home because he lacked anyone to guide him to the mosque, but Ibn Umm Maktum was not granted this dispensation, possibly because he was a potential prayer leader. Sometimes when Muhammad needed to be away from Madinah, he is said to have made Ibn Umm Maktum governor of the city during his absence, indicating high confidence in his character and ability.

IDENTITY

Identity can be defined as the way people view themselves and how others understand them and their roles and relationships in society. Identity is important because it allows individuals to answer the questions Who am I? and Who are you? Identities have personal and social dimensions—they have both commonalities (what people share with each other) as well as unique elements (which characterize an individual alone). The development of identity is therefore a continual, reflexive process.

Like other forms of identity, disability identity is an incredibly complex phenomenon. The experience of disability is only one element of a person's identity—among the many other factors that may also influence identity are age, gender, race, religion, class, sexuality, and nationality. Some people with disabilities argue that disability is one of the least important elements of their identities, whereas others suggest that it is central to their lives and personalities. Negative stereotypes about disability mean that some people are reluctant to identify as disabled for fear that they might face discrimination and prejudice. On the other hand, others have been encouraged to identify publicly as disabled by the growth of disability culture and the disability pride movement.

Identity formation is often influenced by wider cultural processes of representation and stereotyping, which can give individuals a sense of their expected roles in society. These social processes can allocate some groups to the social margins and give others a sense of entitlement and power. A number of common stereotypes regarding disability have influenced the identity formation processes of many disabled people. The work of Wolf Wolfensberger has helped to identify many of the stereotypes that have historically been associated with disabled people, including representations of disabled people as animals or as subhumans, as a burden, as eternal children, as a menace to society, as sick or diseased, as objects of ridicule, and as holy innocents. Each of these stereotypes, in its own way, contributes to the social devaluation and exclusion of disabled people. Such stereotypes not only lead some disabled individuals to feel less valuable than other persons, they can also contribute to wider social processes of rejection, segregation, abuse, loss of opportunities, and poverty. Two quite different responses have developed in regard to these processes of devaluation: a conservative response, known as *normalization,* and a more radical response, known as *disability pride.*

Normalization involves attempts to organize the lives of disabled people and to structure service delivery in ways that will ensure that disabled people occupy "socially valued" roles. Wolfensberger and

Thomas (1983) argue that human services should support disabled people in participating "in valued activities, in valued settings with valued citizens" (p. 1). This means that service-providing agencies should blend in with their community settings. They should also be located away from devalued groups and should engage in activities that enhance the social image of their clients. Within the disability rights movement, normalization is often regarded as a conservative philosophy and practice, because it is an approach that tries to change disabled people rather than the practices of a disabling society. Also, it assumes that the norms of the dominant group in society are unproblematic—that disabled people need to adopt "socially valued" identities rather than build their own positive social identity as disabled people. In this regard, normalization seems quite hostile to diversity and difference.

A more radical approach to difference can be found in the cultural politics known as disability pride, which is based on the idea that developing a positive sense of disability identity involves challenging narrow conceptions of normality. It therefore involves finding merit in the atypical, beauty in the uncommon, and value in the unusual. Disability activists who support this philosophy have often argued that *normality* and *abnormality* are value-laden terms that have enormous power to harm. For instance, Linton (1998) suggests that these concepts affect individuals' most private thoughts about their worth, social position, and acceptability. The association of disability with abnormality denies legitimacy to the experiences of disabled people. Likewise, Davis (1995) understands disability not as an object of the body but as part of a hegemonic way of thinking about the body and its role in the body politic. Davis believes that the goal of disability activists has often been "to help 'normal' people to see the quotation marks around their assumed state."

Carol Gill (2001) argues that the identities of disabled people are often devalued by messages of partial acceptance. She highlights the contradictory nature of many responses to disability, such as admiration and nurturance combined with charity and paternalism. Many disabled people are socialized into believing that parts of them are unacceptable, and they feel compelled to hide some parts of themselves in order to project a more acceptable image. Gill stresses that such processes can reduce a person's self-esteem and self-determination. In an article first published in 1995, Gill identifies four distinct elements of the development of disability identity and disability culture: fortification, unification, communication, and recruitment. She argues that collective gatherings of disabled people and expressions of disability culture fortify the identities of disabled people; unite disparate sections of the disability movement around common issues; promote a shared appreciation of certain art, language, symbols, and rituals; and form the basis for recruiting new members into a vibrant community. It nevertheless needs to be recognized that membership in the disability community is different from belonging to many other cultures. In particular, unlike people who are members of ethnic minority groups, many disabled people grow up in families where they are the only members with that identity. This can make it difficult for a disabled person to develop a positive sense of identity, as family members are sometimes ashamed of the disabled person or feel guilty about his or her disability. Like many people with nonheterosexual identities, many disabled people experience familial estrangement and look elsewhere for peer support.

A SENSE OF "US" AND "THEM"

When people organize in groups, they mark their identities by distinguishing themselves from others. In times of crisis, people tend to desire a sense of certainty and may gain security from the feelings of belonging that their identities bestow on them. Group identities are therefore based on a sense of difference, and there is often a temptation within groups to develop a binary approach to identity—that is, a strong sense of "us" as very distinct from "them." In practice, members of groups often strengthen their own sense of identity by exaggerating group members' differences from nonmembers and ignoring the diversity that may exist within their own group. For instance, within a group of disabled people there may be individuals from different socioeconomic groups, ethnicities, and locations, but the group members may develop a sense of collective identity by highlighting what they have in common rather than focusing on their differences.

The boundaries of identities are always open to dispute. Groups always exclude some people who challenge that exclusion by contesting the boundaries of the groups' identities. Likewise, some people assert their right to their own unique identities and object to assumptions that they are represented by any group. A good example of this issue within a disability context is the case of Deaf people. Some people who are Deaf assert that they belong to a unique cultural and linguistic group, and they believe that they are not "disabled." Others emphasize the experiences of discrimination based on physical difference that they have in common with disabled people in general and strongly identify as disabled. This example reflects one of the biggest problems with identity politics—the fact that boundaries are not as secure as some political rhetoric might suggest.

Identities are often represented symbolically. For instance, in many Western countries, a common symbol used to represent disability identity is that of a wheelchair. Depictions of wheelchairs are used on signs in malls, parking garages, and other public spaces in order to indicate that a space can accommodate the needs of disabled people. However, there is often an element of exclusion embedded in such symbols (for instance, a wheelchair symbol may not seem appropriate for people who do not use wheelchairs and whose impairments are located in other parts of their bodies). Identities require a personal emotional investment, and when people feel alienated by symbols that they feel do not include them, they may resist identifying with the groups represented by those symbols.

Mental health system survivors constitute another group of people who have voiced significant problems with the disability identity. Barnes and Shardlow (1996) point out that there are particular exclusions from citizenship rights (such as involuntary commitment, forced medical treatment, and supervision following discharge from hospital) that mental health system survivors alone experience, and the disability movement in general has avoided discussion of these issues. Also, people who have experienced severe mental distress may be very reluctant to identify as disabled when they are well (i.e., when they are not experiencing any symptoms of their illness).

The long-term process of living with a disability identity is very different from the "sick role" that Talcott Parsons envisioned in 1951. Parsons suggested that "being sick" was a temporary, socially sanctioned interruption to good health. His arguments were innovative because he realized that illness is as much a social role (excusing people from work for a short period of time) as it is a medical condition. Although this concept was useful in the 1950s because it challenged the biological reductionism of that era, it relied on a health/illness binary that did not exist in practice, and it did not recognize that many disabled people are not ill (although some are). The process of developing and maintaining a positive disability identity involves a far more complex dynamic than simply managing one's health.

For people with developmental disabilities, the advocacy group People First has provided an important impetus for a positive disability identity. Based on principles of self-advocacy, this organization's work is based on the principle that developmentally disabled people need to engage in self-advocacy, emphasizing, "We are people first; our disabilities come second." This emphasis on a language of "people first" is different in some respects from the approach of those British disability activists who have chosen to identify as "disabled people." The rationale for this language is that disability is a form of oppression similar to racism and sexism, and in the same way as one would not use the language "person with racism" or "person with sexism," one would not refer to a "person with a disability." This argument is very popular in Britain, but it is a minority position in other countries.

The concept of stigma, as developed in the work of Erving Goffman (1961, 1963), has been very important in terms of an understanding of disability identity. According to Goffman, stigma is a deeply discrediting experience that separates certain groups of individuals (such as disabled people) from what he calls "normals." Goffman highlights many of the social processes that can undermine a disabled person's self-esteem, such as public staring, unwanted help, and invasions of privacy. He also addresses the differences in experiences between people whose stigma is visible and those whose stigma is invisible. For the latter group, Goffman notes, negotiating identities involves making decisions about "passing" and disclosure. Michael Oliver (1990) has criticized Goffman's concept of stigma because it suggests that disability is an individual trait rather than a social dynamic rooted in structural oppression. Watson (2003) argues that Oliver's reading of Goffman is unfair and incomplete, however, and asserts that the connections between stigma and broader social structures are present in Goffman's work.

NARRATIVES AND IDENTITY

Tom Shakespeare (1996) stresses the importance of narratives in terms of disability identity, stating, "Disability identity is about stories, having the space to tell them, and an audience that will listen" (p. 111). He suggests that the stories we tell about the lives of disabled people are very important in terms of their individual and collective effects. Positive narratives of disability help disabled individuals to develop a sense of pride and overcome internalized oppression, but such narratives also are a condition for collective organization. Likewise, Shakespeare argues that involvement in the collective disability movement can assist individuals in the development of a positive disability identity.

Major cultural stereotypes have significant effects on the types of narratives told about disabled people, with attendant effects on disability identities. One of the major cultural constructions around disability that has had a significant impact on the identities of many disabled people is the image of the poster child. In his history of the American disability rights movement, Joseph Shapiro (1993) comments that "no other symbol of disability is more beloved by Americans than the cute and courageous poster child—or more loathed by people with disabilities themselves" (p. 12). The concept of the poster child is controversial because it assumes the presentation of the disabled child as a symbol of pity, and pity is associated with identities that are inferior, tragic, helpless, and dependent. The images of disability associated with the poster child are also controversial because of their connections to another important disability stereotype: the "supercrip"—that is, a disabled person who has successfully "overcome" his or her disability, triumphing over presumed tragedy. This image also has important effects on disability identities. Shapiro argues that fear underlies both pity for the poster child and the celebration of the supercrip. Neither the supercrip nor the poster child is accepted as equal to the nondisabled—both, in different ways, are positioned as "Other." Another historically important barrier to positive disability identities was the freak show. In the freak show, disabled people were often positioned as "monstrous," "deformed," and "bizarre." Hierarchies of embodiment were cultivated by the freak show, leading many disabled people to loathe themselves and their bodies. Cultural spectacles such as the freak show helped to establish a disability identity as a mark of otherness.

The development of a disability culture and the rise of disability pride have been major influences on the identities of many disabled people in recent years. Eli Clare (1999) has highlighted the importance of disability pride in providing an impetus for collective action, such as the campaigns of disability rights activists around the inappropriate placement of disabled people in nursing homes. Clare believes that the significance of disability pride lies in its capacity to overturn shame, isolation, and silence around human rights abuses. Whereas pride involves strength, joy, and anger, internalized oppression involves shame, denial, fear, and self-loathing. It is therefore an act of resistance, Clare argues, to turn internalized oppression into pride.

Clare promotes a transgressive disability identity that involves *flaunting,* which includes the reclaiming of words of hatred to turn them into words of pride. In recent years, some disability activists have reclaimed words such as *crip* and *gimp* as a form of cultural defiance. However, Clare notes that flaunting may be a double-edged sword, because words of hate still retain their original meanings at some level. Those who argue for transgression and flaunting often also explicitly reject another political position—assimilation. The argument for assimilation rests on the common humanity of disabled and nondisabled; it emphasizes that disabled people are "just like you" and therefore deserve exactly the same rights as nondisabled people. The proponents of transgression suggest that this is a minimalist agenda that leaves unchanged some of the major elements of disability oppression, such as restrictive notions of body shape, beauty, normality, and intellect.

Ian Parsons makes an argument similar to Clare's in his book *Cripples, Coons, Fags and Fems: A Look at How Four Human Rights Movements Have Fought Prejudice* (1999). Parsons argues that social movements encourage their participants to move beyond a simple pride in their humanity into a celebration of their difference. In this context, Parsons encourages disabled people to develop transgressive identities that accentuate, rather than minimize, their sense of difference. According to Parsons, in order to challenge and change traditional structures, people must sometimes adopt confrontational and controversial tactics, such as organizing along separatist lines (as do organizations that accept only disabled people as members).

VARIABLES AFFECTING DISABILITY IDENTITY

Disability is only one of many identities that disabled individuals have. Diversity is the hallmark of the disability movement, and no one person or group can speak on behalf of all disabled people. Disability scholars from ethnic minority backgrounds, such as Ayesha Vernon (1998), have argued that there is a temptation to separate discussions of disability from other dimensions of social life, such as experiences of racism and sexism. Vernon asserts that such an approach is based on a problematic additive model of identity that fails to examine the ways in which social forces often operate together. Vernon stresses that sexism, racism, and disableism can operate in isolation or in combination, and that when these forces operate simultaneously, they are often more powerful than the sum of the parts. In this context, Vernon argues that disabled people who are also members of ethnic minority groups can often be positioned as "multiple Others." Likewise, Ahmad, Darr, and Jones (2000) suggest that cultural diversity within the Deaf community is often ignored, and experiences of racist marginalization among Deaf people are rarely acknowledged. These authors note that self-organization by ethnic minority Deaf people involves negotiating an identity that includes Deafness as well as ethnicity and religion. What this means in practice is that professionals have a responsibility to assist Deaf children in becoming aware of their ethnic and religious backgrounds as well as their Deafness.

Historically, disability has been central to debates about social inequality, immigration, and citizenship. People with other stigmatized identities have often made significant efforts to distance themselves from disability, which has often been assumed to be a marker of real, biological inferiority. Douglas Baynton's (2001) excellent historical research on immigration policy in the United States—an area not usually associated with disability—suggests that the central discourse used by various immigrant groups in order to define their worthiness as U.S. citizens was that *they were not disabled.* The absence or presence of disability was a key factor in debates over who deserved to be included and excluded as citizens. Likewise, Rosemarie Garland Thomson (1997) observes that discursive links have often been drawn between women and disabled people in attempts to denigrate and sometimes to defend women. In making this connection, however, Thomson notes an important difference between feminization and disability when she argues that people stare at disabled people, whereas they gaze at women.

Over the past 30 years, disabled women and feminist scholars have consistently emphasized the fundamental importance of gender in the experience of disability and in the development of disability identities. However, Morris (1991) argues that the political agenda of the disability movement has tended to ignore the specific concerns of disabled women with regard to gendered family and domestic roles. Meekosha and Dowse (1997) assert that disabled women are often placed in an ambiguous position relative to the public and private spheres—somewhere between the public and the private, and yet framed as a "burden" in both. These authors stress that disabled women's identities are structured by the intersection of gender, disability, and the denial of citizenship rights in many areas, including sexuality, reproductive rights, and marriage rights.

Rolland (1988) argues that the type of identity developed by a disabled person is strongly dependent on the type of impairment the individual has and whether the impairment is new, chronic, or terminal. For instance, for people with progressive impairments such as Lou Gehrig's disease or diabetes, the increasing severity of their impairment over time has a huge impact on their individual identities. Rolland suggests that although it may be possible for a person in the early stages of such impairment to deny a disability identity, as the impairment becomes more severe, the individual needs to incorporate this experience into his or her identity. In contrast, people with sudden and traumatic impairments often experience crises of identity as they struggle to come to terms with their new life experiences. Rolland asserts that such a sudden identity crisis is less likely in an individual whose impairment has existed since birth. Rolland suggests that people who have relapsing or episodic impairments face a different set of identity issues, particularly relating to disclosure, denial, and anxiety over relapses.

Priestley's (1999) examination of the experiences of disabled children in mainstream schools suggests that the identities of disabled children are structured by the discourses that circulate throughout the education system, such as those of "charity," "treatment," and "provision." Middleton (1999) notes that disabled children are often assumed to be genderless, raceless, asexual, and classless, and so they need to be supported in developing positive self-images in all these areas. In their study of children and disability, Baker and Donelly (2001) found that four important social dynamics have significant effects on the identities of disabled children: Disabled children (a) generally have few disabled friends, (b) socialize with peers who are not disabled, (c) are less popular and more often abused than nondisabled children, and (d) have more unstable, conflictual, and uncooperative relationships than do nondisabled children. Baker and Donelly therefore argue that increased attention needs to be placed on the environments in which disabled children grow up; family and school responses to disability need to be changed in order to cultivate safer environments and more positive identities among disabled children.

Marks (1999) identifies four major psychological processes that discourage acceptance of a disability identity: splitting, projection, reaction formation, and rationalization. These defenses against disability can, respectively, lead people to attribute negative characteristics to all disabled people, to project negative attributes onto disabled people, to hide or obscure their real feelings around disabled people, and to rationalize discriminatory treatment.

Robert Scott's classic study *The Making of Blind Men* (1969) emphasizes another important factor in the development of a disability identity: contact with the disability service system. Scott argues that blindness is a learned social role, rather than a biological fact: "Blind men are not born, they are made" (p. 121). He stresses the social nature of this role by pointing out that the vast majority of people who are classified as blind can actually see at some level. Rather than being completely sightless, Scott presents these people as "sighted people who experience difficulty seeing" (p. 43). The importance of socialization is evident because of the key role that "blindness workers" play in the development of the attitudes, behaviors, and emotions associated with being blind. In effect, Scott argues, these workers teach their clients how to behave like "blind people."

ERIKSON'S THEORY OF IDENTITY DEVELOPMENT

One of the most influential psychoanalytic theories dealing with identity development is that presented by Erik Erikson (1963). This theory suggests that human beings pass through eight stages of identity development over the life cycle. In the first stage, from birth to 18 months of age, babies develop their sense of trust, or mistrust. From 18 months to 3 years, toddlers develop some sense of autonomy—or a sense of shame and doubt. In the preschool age, from 3 to 6 years, children develop a sense of initiative, or they develop a fear of failure as a result of guilt or punishment. From 6 to 11 years, children develop a sense of industry (confidence and skills for work as they learn to enjoy their achievements), or they develop a sense of inferiority. In adolescence, from 12 to 18 years, young people develop a sense of identity (or role confusion) in terms of sex roles, occupation, religion, and politics. Erikson invented the term *identity crisis* to explain the troubled sense of self that some people experience. In young adulthood, from 19 to 40 years, people develop a sense of intimacy or isolation in terms of personal relationships. From ages 40 to 65, adults face a basic conflict regarding generativity or stagnation—finding a meaningful way to support the next generation. After 65, individuals reflect on their lives and experience either ego integrity or despair. Erikson believed that each of these developmental crises occurs at a certain stage in a person's life but is never resolved permanently. For instance, people return to the struggle over trust and mistrust at various stages of their lives. There is a danger that people's achievements in one of these areas may be undermined by later developments—but, conversely, failure to negotiate one of the stages of identity development successfully can be rectified by later growth.

A number of disability scholars have taken issue with Erikson's theory. By mechanistically applying the stages described by Erikson, psychologists have positioned many disabled people as having automatically missed key stages of human development. In their critique of Erikson's theory, Mackelprang and Salsgiver (1999) argue that nondisabled people are the template for the theory, which ignores the healthy development of disabled people—or assumes that such development is impossible.

ESSENTIALIST AND SOCIAL CONSTRUCTIONIST APPROACHES TO IDENTITY

Political rhetoric often draws on notions of a well-defined community with a shared past and tradition in order to bind people to a common identity. This rhetoric, which relies on a sense of clear-cut boundaries around an unchanging, fixed identity, has been called a tendency toward essentialism within identity politics. An essentialist approach to disability identity would suggest there are certain characteristics that all disabled people share. An essentialist approach to identity can be contrasted with a social constructionist approach, which emphasizes the socially constructed, contingent, and fluid nature of identity. A social constructionist approach to disability identity would suggest that there are significant differences as well as similarities among disabled people and would recognize that the meaning of disability changes over time and across cultures. It would therefore problematize any claim that one set of experiences is the only "true" disability identity.

Some sociologists, such as Anthony Giddens (1991), argue that the modern world could be characterized as a "risk society"—that is, a society in which social change is progressing at such a rapid rate that people experience a heightened sense of uncertainty that profoundly affects their identities. Giddens asserts that traditional patterns and habits are less influential in a risk society, where people are pressured to express their identities through their lifestyles. As a sociologist, Giddens is interested in the social and economic pressures that operate in modern consumer societies. He highlights the social and economic changes that have resulted in a veritable explosion of ways in which to express individual lifestyles, preferences, and identities. These social and economic pressures make essentialist notions of identity even less credible.

In his book *Bending over Backwards: Disability, Dismodernism and Other Difficult Positions* (2002), Lennard Davis argues that disability identity is inherently unstable, but that this malleability can be part of a new way of thinking about identity. Davis asserts that essentialist notions of identity are discredited and outdated, but that the instability inherent in self-definitions of disability allows disability identity to transcend the problems of identity politics. Davis therefore believes that disability may be "the postmodern subject position." His argument is very similar to that of Corker and Shakespeare (2002), who also acknowledge that postmodern ideas present significant challenges to the ways in which disability has traditionally been conceptualized. Postmodernism problematizes issues of identity, embodiment, discourse, power, and agency far more than do traditional notions of disability. Corker and Shakespeare suggest that the rich tapestry that makes up the disability movement, involving people of all ages, with different impairments, challenging dominant notions of embodiment, exerting their own agency while they experience disabling barriers and simultaneously face a range of other inequalities, means that disability is "the ultimate postmodern concept."

CONCLUSION

Identity is of fundamental importance to the modern world, allowing people to connect with others as well as to experience feelings of uniqueness. Many disabled people lack disabled role models in their families, do not necessarily feel connected to the wider disability movement, and struggle to develop a positive disability identity. For others, developing a positive self-image often involves challenging internalized oppression and refusing to be defined by rigid definitions of normality. Disability identity is also influenced by such factors as the nature of the impairment and the ethnicity and gender of the person. Identity presents different challenges at various stages of the life course. Therefore, disability identity is a complex topic. For some people, becoming involved in the disability movement, connecting with disability culture, and developing disability pride are very helpful actions in terms of building self-esteem and a sense of belonging. Others see their experience of disability as shameful and seek to avoid the stigma of disability by hiding their identity. Many people try to find individual solutions for themselves, for instance, by being critical of rigid notions of normality and by finding beauty in difference.

IMMIGRATION: LAW AND POLICY

One of the driving forces behind early U.S. federal immigration law, beginning with the first major legislation, the Immigration Act of 1882, was the exclusion of "defective" people (as well as those considered criminal or immoral, problems seen at the time as resulting from "mental defect"). Federal legislation throughout this period repeatedly, and with ever-increasing urgency, identified defective immigrants as a threat to the nation. In 1907, the *Annual Report of the Commissioner of Immigration* declared that "the exclusion from this country of the morally, mentally, and physically deficient is the principal object to be accomplished by the immigration laws" (U.S. Bureau of Immigration 1907:62). When immigration quotas based on nationality were enacted in 1924, a rhetoric of "inferior races," based on claims that people of certain nationalities are prone to be physically and mentally defective, was instrumental in creating the image of the "undesirable immigrant."

The desire to keep disabled immigrants out of the United States was not an isolated development; rather, it was one aspect of an era that saw the segregation of disabled people into institutions, the sterilization of the "unfit" under state eugenics laws, intensified stigmatization of disability, and increasing willingness to exclude disabled people from social and cultural life. The Immigration Act of 1882 prohibited entry to any "lunatic, idiot, or any person unable to take care of himself or herself without becoming a public charge." Those placed in the categories of "lunatic" and "idiot" were supposed to be automatically excluded. The "public charge" provision was intended to encompass people with disabilities more generally, and decisions were left to the examining officer's discretion (*United States Statutes at Large* 1883:214). The criteria for excluding disabled people were steadily tightened as the eugenics movement and popular fears about the decline of the "national stock" gathered strength. The Immigration Act of 1891 replaced "*unable* to take care of himself or herself without becoming a public charge" with "*likely* to become a public charge" (*United States Statutes* 1891:1084; emphases added). In 1907, the law was modified to deny entry to anyone judged "mentally or physically defective, such mental or physical defect being of a nature which *may affect* the ability of such alien to earn a living" (*United States Statutes* 1907:899; emphasis added). Although nondisabled immigrants were still admitted unless found to be "likely to become a public charge," disabled people were subject to this more rigorous standard.

Exclusions for mental defect were steadily expanded. In 1903, people with epilepsy were added, as well as "persons who have been insane within five years previous [or] who have had two or more attacks of insanity at any time previously" (*United States Statutes* 1903:1213). In 1907, "imbeciles" and "feeble-minded persons" were barred, in addition to "idiots" (*United States Statutes* 1907:898). In 1917, the classification of "constitutional psychopathic inferiority" was added, which inspection regulations described as including "various unstable individuals on the border line between sanity and insanity, such as persons with abnormal sex instincts." Officials were instructed to exclude persons with "any mental abnormality whatever . . . which justifies the statement that the alien is mentally defective." This provision, the regulations explained, was intended "as a means of excluding aliens of a mentally inferior type, not comprehended in the other provisions of the law, without being under the necessity, as formerly, of showing that they have a defect which may affect their ability to earn a living" (U.S. Public Health Service 1917:25–26, 28–29, 30–31).

The rules governing exclusion for physical disabilities were equally vague and expansive. Regulations specified that "each individual should be seen first at rest and then in motion" so that officials could detect "irregularities in movement" and "abnormalities of any description." Among the many defects listed as causes for exclusion were arthritis, asthma, bunions, deafness, deformities, flat feet, heart disease, hernia, hysteria, poor eyesight, poor physical development, spinal curvature, vascular disease of the heart, and varicose veins (U.S. Public Health Service 1917:16–19). An Ellis Island medical inspector later wrote that his task was "to detect poorly built, defective or broken down human beings" (Safford 1925:244).

These laws were usually presented as an economic issue. Many immigrants who were excluded, however, had been self-supporting before they left their home countries. Others had been offered jobs while awaiting their immigration hearings but still were deported as likely to become public charges. More important, the laws located the problem in individual bodies rather than in social structures, despite the fact that immigration restriction was just one aspect of a pervasive system of discrimination that made it difficult for disabled people to live and move about independently. For example, the diagnosis of "poor physique" was often used to exclude immigrants as "likely to become a public charge." The immigration service defined it as covering those "who have a frail frame, flat chest, and are generally deficient in muscular development" or who are "undersized—markedly of short stature—dwarf" (Stoner 1912). As one official explained, the "immigrant of poor physique is not able to perform rough labor, and *even if he were able,* employers of labor would not hire him" (McLaughlin 1905:532; emphasis added). That is, the belief that an immigrant was unfit to work justified exclusion, and so did the belief that an immigrant was *likely to encounter discrimination* because of a disability. The diagnosis was also in part a eugenic judgment, as this 1905 memo from the commissioner general of the Bureau of Immigration illustrates:

> A certificate of this nature implies that the alien is undersized, poorly developed and physically degenerate, and not only unlikely to become a desirable citizen, but also very likely to transmit his undesirable qualities to his offspring, should he unfortunately for the country in which he is domiciled, have any. (Sargent 1905)

On January 30, 1906, immigrant Israel Bosak was certified for "poor physique." He was not destitute, having $65 in his possession, usually more than enough for admittance. Bosak had owned a tailor shop in Russia before it was destroyed by a mob during an anti-Jewish pogrom. He intended to send for his wife and children as soon as he got established, explaining that he had "plenty of countrymen here who are just as good as relatives, to help me." Two members of the board voted for admission, but the third held firm for deportation, which meant that the secretary of the U.S. Department of Labor would decide. In his letter to the secretary, the third board member emphasized the danger to the nation's eugenic health of admitting such people, "whose offspring will reproduce, often in an exaggerated degree, the physical degeneracy of their parents." The secretary concurred, and Israel Bosak was returned to Russia (National Archives, file no. 49,968/4).

Because the screening of immigrants was mostly a matter of detecting visual abnormality, the appearance of an individual played a central role. Inspectors prided themselves on making "snapshot diagnoses" as immigrants streamed past them, single file. For most immigrants, a normal appearance meant a quick passage through the immigration station. An abnormal appearance, however, meant a chalked letter on the back—"L for lameness, K for suspected hernia, G for goiter, X for suspected mental illness," and so on (Kraut 1994:55). Once an individual was chalked, a closer inspection was required.

Donabet Mousekian had an abnormal appearance. On April 23, 1905, this Armenian Turk stood before the Board of Special Inquiry with an inspection certificate that read "feminism." In other instances, the term used for his condition was "lack of sexual development." In this case, "feminism" meant an absence of male sexual organs; in others, it referred to insufficient development. Mousekian's hearing was extraordinarily brief. No one mentioned the diagnosis. After asking the most basic questions concerning Mousekian's identity and background, and noting that he brought $48 with him, the board quickly voted to exclude him as likely to become a public charge. In his appeal, Mousekian explained that he had fled the violent oppression of Armenians in Turkey and had officially renounced his citizenship. As he would never be permitted to return to Turkey and remain free, rather than be sent back, he wrote, "it would be much better that you kill me." His relatives were all in America, including his two brothers who were citizens and well employed. A photographer by trade, as well as a skilled weaver and dyer of rugs and a cook, Mousekian could have worked at any of these trades. He wrote:

> I am not ill, have no contagious disease; my eyes, feet, hands and ears are sound; only I am deprived of male organs; this is not a fault because it has come from God and my mother: what can I do? It won't do any harm to my working; or what harm can I do to the U.S. by my being deprived of male organs?

His brothers wrote in much the same vein, asking plaintively,

> How is it his fault? Our father and mother are dead; he is our only brother; we guarantee that he will not be a public charge; we are able to give the required guarantee; he can not return to Turkey; we are US citizens, hence we beg US government not to separate our brother from us.

The commissioner at Ellis Island supported the board's decision on the basis of Mousekian's appearance: "Appellant is devoid of every external evidence of desirability. He is weak, repulsive in appearance, the doctor's certificate furnishing sufficient indication of his physical defects." Mousekian was returned to Turkey, where, if he lived that long, he would witness the "Armenian holocaust" 10 years later (National Archives, file no. 48,599/4).

The U.S. surgeon general explained in a memo the reasoning behind this exclusion:

> These persons present bad economic risks. . . . [T]heir chief failure to adjust is due to the fact that their abnormality soon becomes known to their associates who make them the butt of coarse jokes to their own despair, and to the impairment of the work in hand. Since this is recognized among employers, it is difficult for these unfortunates to get or retain jobs, their facial and bodily appearance, at least in adult life, furnishing a patent advertisement of their condition. (Cumming 1922)

The disabilities that justified exclusion in the cases described above were matters of abnormal appearance that might invite discrimination and therefore poverty. Thus, these exclusions were based on economic arguments, but at two steps removed.

The justifications given for exclusion were not always economic, however, whether directly or indirectly. Nicolaos Xilomenos was refused entry in 1912 for "lack of sexual development." The commissioner noted that while "the individual may appear strong and robust" and brought with him sufficient cash, his condition indicates the probability of "perversions or mental instability" (National Archives, file no. 53,452-952). In a similar case in 1908, Helena Bartnikowska was refused entry. The physician explained that "this supposed woman" was a hermaphrodite, and that hermaphrodites are "usually of perverted sexual instincts, and with lack of moral responsibility." He added significantly that Bartnikowska's voice was masculine and that she had facial hair. Although her family was willing and able to guarantee her support, she was deported (National Archives, file no. 51,806-16).

In March 1905, Domenico Rocco Vozzo, a 35-year-old Italian immigrant, was puzzled to find himself barred from entering the United States at the port of Boston. Vozzo was a migrant worker on his second trip to the United States, and he had encountered no difficulty on his first trip three years earlier. He was certified for "debility" and excluded as likely to become a public charge. Vozzo's attorney argued in his appeal that Vozzo was robust and healthy. He noted that Vozzo "looks perfectly healthy below the head" but has a "curiously shaped head, and his skin looks rather white, almost bleached, and his ears are quite thin." During his previous two-year sojourn in the United States he had fully supported himself while saving money. He brought with him $20 in cash and had friends who filed affidavits on his behalf. The commissioner at the Boston station, however, recommended against admission: "I enclose his picture which I think will convince you that he is not a desirable acquisition." Vozzo was deported (National Archives, file no. 48,462).

The principle that persons of abnormal appearance were not "desirable acquisitions" was neither universally held nor consistently applied. For example, when Abram Hoffmann, a 25-year-old tailor with a prosperous brother in New York, was deemed likely to become a public charge in 1906 because of a curved spine, his attorney labeled "ridiculous and absurd" the assumption "that one who is unfortunate enough to suffer from a certain infirmity, is likely for that reason alone, to become a public charge." Warming to the subject, the attorney asked, "Are we living in this enlightened Twentieth Century where everyone is supposed to be given a fair opportunity, or are we going back to the times of the Salem witch-craft, when, because a woman was old and afflicted with a high back [spinal curvature], she was considered and treated as a witch? . . . The immigrants affliction can in no wise affect his earning capacity as a tailor." The commissioner at Ellis was torn. On the one hand, he noted, visually "the spinal curvature for which [Hoffmann] is certified is quite obvious." On the other, "I may state in appellant's behalf, that he is a man of considerable intelligence, is very well dressed, and came as a second cabin passenger." In the end, the positive aspects of Hoffmann's appearance and class status trumped the negative appearance of his disability, and he was admitted (National Archives, file no. 49951-1).

The precise number of immigrants turned away from the United States for disability each year is difficult to pin down. Until 1908, exclusions based on physical defects were mixed with nondefectives in the category of "likely to become a public charge." After 1908, rejected immigrants were counted in the category of "mental or physical defective" if they were deemed defective but not likely to become public charges, and counted in the "public charge" category if they were determined to be both defective and potential paupers. In any case, taken together, exclusions in both categories grew considerably, if erratically, over the years. In 1895, 1,720 were excluded, or .6 percent of all immigrants. By 1905, the number excluded had increased to just over 8,000, or .7 percent of all immigrants. And in 1910, 16,000, or 1.6 percent, were excluded. Due to wartime disruptions, the numbers during and just after World War I fluctuated widely, making useful comparisons difficult (U.S. Immigration Commission 1911).

These numbers are all likely to be only the tip of the iceberg, however. Those inspected at American ports had already been through several screens. First, many were deterred by the general inaccessibility of transportation. Second, given that American immigration laws were widely advertised, many must have decided not to risk the journey, knowing they might be turned back. Third, ship captains were required to examine passengers and certify that they were not physically or mentally defective (*United States Statutes* 1893:569, 1907:901–902). Fourth, the shipping companies that brought rejected immigrants to the United States were required to return them and pay a fine for each, and immigrants later discovered to have disabilities that initially passed unnoticed could be deported for up to three years at the expense of the companies (*United States Statutes* 1903:1218, 1907:901, 905). Shipping companies therefore had strong incentives to refuse passage to disabled people, and ship captains became an unofficial arm of the immigration service. Finally, ticket agents stationed throughout inland Europe were fined by the shipping companies if they sold tickets to anyone turned away at boarding time. In 1894, the superintendent of immigration noted approvingly that steamship lines instructed their agents to refuse tickets to "the blind, deaf and dumb, and crippled persons" (U.S. Immigration Service 1894:12–13). There is reason, then, to suppose that those rejected at the borders were a small minority of those who were deterred. In 1911, the U.S. Immigration Commission estimated that about 10 times as many were refused transportation for medical reasons as were barred at U.S. ports (U.S. Immigration Commission 1911:26).

In 1924, a new quota system was instituted, based on national origin, that severely limited immigration from southern and eastern Europe. In the debate leading up to this legislation, disability figured prominently. Quota advocates, as well as superintendents of institutions, philanthropists, immigration reformers, and politicians, warned that certain nationalities were disproportionately prone to be mentally defective (Trent 1994:166–169). Rhetoric about "slow-witted Slavs," the poor physiques of Jews, the "neurotic condition of our Jewish immigrants," and the "degenerate and psychopathic types, which are so conspicuous and numerous among the immigrants," was pervasive (Grayson 1913:103, 107–109). Quota advocates emphasized the inferior appearance of recent immigrants. One wrote that "the physiognomy of certain groups unmistakably proclaims inferiority of type." In "every face there is something wrong, . . . sugar-loaf heads, moon-faces, slit mouths, lantern-jaws, and goose-bill noses." Most were physically inadequate:

> South Europeans run to low stature. A gang of Italian navvies present, by their dwarfishness, a curious contrast to other people. The Portuguese, the Greeks, and the Syrians are, from our point of view, undersized. The Hebrew immigrants are very poor in physique . . . the polar opposite of our pioneer breed. (Ross 1914:285–290)

The issues of race, ethnicity, and disability were inextricably intertwined. The characterization of people as physically and mentally defective, and therefore inherently inferior, was used to stigmatize people and to rationalize their exclusion. Similar rhetoric worked to incarcerate, institutionalize, and sterilize untold numbers of disabled and minority citizens during the same period. The label "defective person" was used to justify the denial of basic human rights. Although it is certain that immigration restriction rested in good part on a fear of "strangers in the land," in John Higham's phrase, it was fueled at least as much by a fear of defectives in the land.

National quotas were removed in 1965, and most of the restrictions that applied specifically to disability were removed from U.S. law in 1990. Today, disabled immigrants can still be denied an entry visa on the basis of the "likely to become a public charge" clause, but because records are not kept of such exclusions, it is not known how often this occurs (Stanton 1996:451).

IMMUNOLOGIC DISEASES

Immunology is the field of science encompassing the study of the specialized molecules and cells involved in defending an organism against infection. Human immunology has its beginnings in the empirical observations of Edward Jenner on the prevention of smallpox in English milkmaids previously infected with cowpox. These important studies provided our initial understanding of the ability of the immune system to acquire memory of an infecting organism and formed the basis for our current practice of immunization against myriad potential infectious diseases. Immunodeficiency diseases arise from defects in the immune system and are classified as primary, usually inherited genetic causes, or secondary, arising from infection or drugs that impair immune system function. In all cases, immunodeficiency diseases may result in considerable physical disability with long-term requirements for medical and rehabilitative care.

The widespread introduction of antibiotic use into the practice of medicine in the middle of the twentieth century permitted recognition of children with multiple recurrent episodes of bacteremia (bacteria in the bloodstream), pneumonias, or skin abscesses. These primary immunodeficiencies are the results of inherited defects in specific genes required for normal immune responses. The study of children with these rare diseases has revealed a great deal about how the normal immune system functions and has resulted in the development of specific therapies aimed at replacing or restoring normal immune system function. In some cases affected children survive with a lifetime of infusions of immune sera, whereas in other cases bone marrow transplantation is required. In all circumstances, affected children as well as their parents and siblings require considerable support for these lifelong chronic diseases.

Secondary immunodeficiencies may arise from infection of the immune system and destruction of cells critical for the normal immune response. The most serious of such infections is caused by the human immunodeficiency virus (HIV), which infects lymphocytes, a specialized white blood cell required for immune function, resulting in acquired immunodeficiency syndrome (AIDS). There is currently no effective vaccine against HIV, and infection is fatal in the absence of long-term treatment with complex, expensive, and relatively toxic drug regimens. The current worldwide pandemic of HIV infection has resulted in devastating human and economic disability for entire nations in Africa and Southeast Asia. In developed countries such as the United States, the disabling effects of HIV infection have imposed enormous cost restraints on the health care system.

Secondary immunodeficiency also occurs following treatment with drugs that suppress immune system function, such as glucocorticoids. These medications are required in patients with diseases such as rheumatoid arthritis and multiple sclerosis and following organ transplantation. In all circumstances these drugs create the potential for serious life-threatening infections. Given the prevalence of these diseases in the population and the increasing frequency of solid organ transplantation in developed nations, such secondary immunodeficiency is becoming a common cause of disability and chronic care in the population. When combined with HIV infection, these immunodeficiency diseases are among the most prevalent and costly sources of human disability worldwide.

IMPAIRMENT

Impairment is one of the most contested and complicated terms in disability studies, second only to *disability* itself in terms of multiple definitions and theoretical arguments made around its meaning and significance in the experience and scholarship of the body. It can be traced both chronologically and ideologically, and it continues to be the subject of considerable debate.

The origins of *impairment* as a term in disability studies may be positioned in the development of documents by such organizations as the Union of the Physically Impaired Against Segregation (UPIAS) in Great Britain and the World Health Organization (WHO). In 1976, UPIAS offered its own definitions, omitting *handicap* as a term of art and drawing a distinction between impairment and disability: *Impairment* refers to "lacking part or all of a limb, or having a defective limb, organ or mechanism of the body"; *disability* refers to the social oppression (whether due to stigma or to restrictions) imposed on people with impairments. The important distinction for UPIAS lies in location: Impairment is located in the body; disability is located in society or culture.

In 1980, the WHO's International Classification of Impairments, Disabilities, and Handicaps (ICIDH, revised in 1993 and again in 2001, when it became the International Classification of Functioning, Disability, and Health, or ICF) distinguished among *impairment, disability,* and *handicap* as terms to describe what might be categorized as "nonnormate" bodies. The ICIDH defined impairment as "any loss or abnormality of psychological, physiological or anatomical structure or function." It defined disability as the lack of ability to perform particular acts or functions in a way that is "normal," and handicap as the disadvantage(s) resulting from impairment and disability. Like most such classification systems, all versions of the WHO's definitions were criticized from various corners of the scholarly and professional world, often because such critics thought the distinctions either too rigid and unrealistic in representing the overlaps among the categories or because they saw the definitions as lacking in social consciousness or analysis.

From these competing sets of definitions arose a body of scholarship—originating primarily in Great Britain with such writers as Michael Oliver and Tom Shakespeare—that distinguished between a "social model of disability" and a "medical model of disability." *Impairment* as a term was assigned to the medical model, which was also seen as positing the location of the body's "problems" within the individual and which looked to such tropes as cure, charity, personal tragedy, and pain and suffering as dominant modes of thought. In some circles, much, if not all, of rehabilitative science and practice came to be understood to be located within the medical model. Thus, *impairment,* which in its earlier usage might have been viewed as a neutral term (if such a thing can be said to exist), became a negative, oppressive term in this binary of social/medical pairing, if only by association.

Some theorists argued that discussions of impairment (by which they meant the physical, psychological, and cognitive experiences of individuals) should either be eliminated from disability studies discourse or, at the very least, shared only within the disability community "behind closed doors." Reasons for this argument varied, but they included concerns that any frank discussion of what might be construed as "limitations" might be used to oppress disabled persons even more (i.e., such discussions might be considered evidence that disabled persons really are, in important ways, "inferior" because of their bodies) and might, for example, be used in arguments supporting such things as discriminatory employment practices and physician-assisted suicide. Others feared that too much emphasis on narratives of impairment might depict disabled people as participants in victimology—that such narratives might represent disabled persons as passive, or whiny, or irrational. Later, as the 1990s drew to a close, many of the original theorists of the social/medical dichotomy began to rethink its efficacy, and the term *impairment* began to be reintroduced in a more wide-ranging set of discursive formations. One of the criticisms of the dichotomy between social model and medical model was that it created an unreal or inaccurate division between impairment and disability; another was that it in some respects was guilty of setting up two "models" where only one group had actually articulated a model—in other words, it is unlikely that physicians and therapists would ever have agreed that they subscribed to all of the things attributed to the "medical model" per se.

One of the most significant critiques of the impairment/disability binary and its respective medical/social model rhetoric came from feminist disability scholars. Most vocal among these were such figures as Susan Wendell, Sharon Stone, Jenny Morris, and Liz Crow. These theorists were particularly articulate in deconstructing the often masculinist assumptions present in the binary, including a devaluing of the significance of pain and suffering in the lived bodies of people with impairments/disabilities and the ways in which bodies affected by invisible or less-visible impairments were often neglected in such discourse. It is probably no accident that many of these lesser-discussed impairments are conditions that disproportionately affect women: chronic fatigue syndrome, depression, and others. Such theorists called for a return of lived experience to the discourse of disability studies and, along with it, a fuller and more detailed theorizing and representation of impairment. Whereas social model scholarship tended to draw its theoretical underpinnings from Marxism and materialist cultural studies, feminist disability studies often came out of phenomenological and ethnomethodological bases. It is important to remind ourselves that to draw a simple gender binary is to be as guilty of reductionism as was the social/medical model; nonetheless, the contribution of feminist disability scholars, particularly women, cannot be underestimated in the reintroduction of impairment as a legitimate area for discussion, scholarship, and theorizing.

A "third wave" of *impairment* as a terminological basis for disability studies theory and scholarship may be seen as emerging in the past several years. In important respects, this wave is actually a cluster of approaches and perspectives, all of which respond to various previous uses of the term and the theories surrounding it. One area is what is being called "sociology of impairment" by theorists such as Bill Hughes and others. This approach argues that the division between social and medical models is incomplete not simply because it runs the risk of demonizing impairment as a concept, but because it misses or underestimates the degree to which impairment itself may be viewed as a social product. For example, Alex Lubet, a disability scholar and trained professional musician, has argued that the field of classical music training in the West has been both disabling and impairing. As instruments and pedagogy have assumed right-handedness as normate, people who are left-handed dominant are required to learn to play music not only in a way that is not natural to their bodies, but in ways that may produce impairments through strain and stress on parts of the body. One can imagine many more examples of instances where either workplace or public facilities that do not accommodate various kinds of bodies may result in different and additional impairments, which, in turn, lead to any number of kinds of disabling conditions, such as limitations on work opportunities or access to various venues of participation in public and private activities.

In addition to the "sociology of disability," there has also been a growing interest (or revival of interest) in what might be termed the phenomenology of impairment, either with or without explicit sociopolitical implications. Disciplinary approaches to such phenomenological methods range from philosophy (e.g., those who build explicitly from the work of such Continental writers as Merleau-Ponty and Husserl) to occupational therapy (e.g., Gary Kielhofner's work on a "model of human occupation" and his various accounts of the phenomenology of hand impairment) to sociologists (e.g., Rod Michalko, who combines phenomenological accounts of his blindness with consideration of socially oppressive implications of this impairment for himself and others) to humanists and artists who either represent or write critically about representations of impairment in the arts and in culture at large. One might include here writers of personal narratives and other literary accounts of impairment ranging from Lucy Grealy's *Autobiography of a Face* (1994) to Kenny Fries's *Body,* *Remember* (1997) as well as fictional accounts of impairment by writers such as Mark Salzman and dramatic texts by John Belluso, Susan Nussbaum, Tony Kushner, and others. Visual artists such as Riva Lehrer and performance artists such as Greg Walloch, Terry Galloway, and Petra Kuppers create a discourse of impairment representation in their work as well. There is a sociopolitical dimension to the work of almost all these artists, bringing the once seemingly disparate concepts of impairment and disability closer together through their embodiment in artistic texts.

Impairment will continue to be a "word in process" in disability studies, mapping out different concerns, emphases, and rhetorical positions in various contexts, times, and sites. It is unlikely that, like *handicap,* it will disappear anytime soon, as there is a genuinely productive value in drawing certain distinctions between impairment and disability as phenomena to be analyzed; what is useful is the continuing opening up and inclusion of it in the growing body of disability studies scholarship.

INBORN ERRORS OF METABOLISM

The identification and categorization of inborn errors of metabolism are among the most important conceptual advances in medical genetics during the twentieth century. Credit for this intellectual revolution belongs primarily to the English physician and scientist Sir Archibald Garrod, whose curiosity was evoked by alcaptonuria, an arthritic disorder in which the urine turns to a reddish brown color when exposed to air. Garrod, who was familiar with the principles of Mendelian genetics, noted the appearance of this syndrome in siblings and its occasional passage through successive generations. He proposed that the discoloration of alcaptonuric urine reflects the inherited deficiency of a "ferment" (enzyme) that in healthy subjects favors the breakdown of homogentisic acid (alkapton), a metabolite of the amino acid tyrosine. Accumulation of this acid, he theorized, gives rise to the arthropathy and discoloration (onchronosis) of cartilage and urine that characterize the disorder. Furthermore, the disease appears only if both (unaffected) parents transmit a "latent factor" to the child.

The estimated incidence of the inborn errors of metabolism is approximately 1 in 5,000 live births, making these disorders a significant source of human disability. They may involve any aspect of human metabolism, including the handling of amino acids, lipids, carbohydrates, and nucleic acids. In most instances the underlying cause is the inheritance of a mutant enzyme or transport system that mediates either the metabolic transformation of one metabolite to another or the movement of a compound across a cell membrane. Inheritance of these diseases usually conforms to an autosomal recessive pattern, although dominant and sex-linked mechanisms are well documented.

Detection of inherited metabolic disease has been facilitated by the advent in recent decades of two complementary technological developments. The first of these has been the development of chromatographic, electrophoretic, and enzymatic techniques for the isolation and quantitation of relevant metabolites in blood and urine. As a result, it is possible to define those departures from the biochemical norm that ratify Garrod's (1923) insight that "behind a superficial uniformity there exists a diversity which is no less real than that of structure, although far less obvious" (p. 1).

Diagnosis is enabled by a second technological development: the revolution in molecular biology that permits the characterization of mutations in either nuclear or mitochondrial DNA. This methodology can unambiguously characterize those fundamental alterations of the genetic code that give rise to metabolic aberrations. Genetic analysis has proved invaluable for the diagnosis of affected individuals, the detection of heterozygotes, and the assessment of the fetus at risk.

Inborn errors of metabolism can result in injury to virtually any tissue, but the most dramatic and characteristic consequence is damage to the developing brain. In most instances the encephalopathy reflects the accumulation of an otherwise normal metabolite that becomes toxic when present in excess concentration. An example is the extreme elevation of the amino acid phenylalanine that accompanies a congenital defect of phenylalanine hydroxylase, the mutant enzyme in classical phenylketonuria. The biochemical sequence that leads from phenylalanine accumulation to frank mental retardation remains obscure, although it is likely that the underlying pathophysiology evokes alterations of brain energy metabolism, neurotransmitter synthesis, and myelin formation.

The outlook for the affected child has improved dramatically in recent years. Diet therapy, or the purposeful interdiction of a potentially injurious nutrient, often attenuates or even prevents brain injury and permits normal neurological development, even when the underlying metabolic defect is near complete. For many disorders, transplantation of bone marrow or of liver or kidney has palliated the underlying lesion and afforded near-normal metabolism. A particularly exciting therapeutic prospect is gene therapy, or the administration of a vector that safely and efficiently carries the deficient gene to cells of the affected patient, thereby reconstituting normal or near-normal enzymatic competence.

—Marc Yudkoff

▣ INCLUSION AND EXCLUSION

The question of the inclusion and exclusion of disabled people cannot be separated from the way in which a society constructs social cohesion or produces social dissociation. Each society has its own way of integrating and rejecting certain categories or certain subjects, that is, of creating social links or not. The two terms *inclusion* and *exclusion* go in tandem and can be understood only in relationship to each other; for any definition of inclusion there is a corresponding definition of exclusion.

MECHANICAL INCLUSION, ORGANIC INCLUSION

Durkheim (1930) accurately saw that in modern societies, with their growing complexity, an evolutionary process is initiated, namely, that the fundamental forms of solidarity in traditional societies, "mechanical" or through resemblance, increasingly give way to solidarities that are "organic" or effected through complementarity. But the latter bring with them a growing individualism, which comes into conflict with the priority traditionally given to the social whole.

The dynamic character of our present-day societies is emphasized, but so is the permanent challenge that confronts them. Thus, there are greater risks of social dissociation than in traditional societies but also increased possibilities, because of their organicity, of integrating the new and alien.

Societies characterized by mechanical solidarity are strongly integrated but cannot admit "foreign bodies." When they exclude, they do so in radical fashion and are often incapable of assimilating the new. Modern societies have a very broad capacity for inclusion but, on the other hand, are in danger of putting apart by creating enclaves within themselves.

In societies with mechanical inclusion, the individual is a constituent of an indestructible whole. He or she has a fixed place, given at birth, and in this sense is fully integrated, a cog in the overall works. There is no question of changing place, which would disrupt the global mechanics, leading the society to defend itself against the defective part that no longer performs its task and punish it. Thus, integration can be defined as a place—a single, fixed place—in a whole that has no plans to change. The person who does not have a place of this type is literally not part of the society. This person is the stranger, excluded by negation and not through a positive act. Barbarians could not become Romans; foreigners could not (except through a special procedure) become citizens of Athens, and so on. A positive act of exclusion, on the other hand, can occur in cases where an individual questions his "integration."

In societies featuring organic solidarity, the individual tends to be isolated. He or she cannot count on a place assigned by tradition and culture. Integration is a long road and a constantly reimposed obligation to take further steps, because the division of labor and social division entail the continuous refinement of legislative, institutional, and financial procedures, so that individuals are not exposed to the rigors of competition and isolation. When these procedures are relaxed, individuals risk being set adrift. There are no longer sufficient common measures to maintain the social link. In addition, there need to be enough shared representations on the global level that these procedures are maintained.

Everything has contributed to the formation of societies that, relying only on themselves and on the strength of their members, have become entirely responsible and accountable for people "living together." We must recall the "autonomization" of society with regard to any reference to the transcendent (a characteristic of modernity) and the autonomization of the individual (Weber 1920). This also explains such societies' vulnerability; the risks of marginalization, even of social abandonment or exclusion, are substantial.

THE PROCESS OF NORMALIZATION

One of the principal procedures in the attempt to effect integration is normalization. Here it is a matter of defining averages, comparing discrepancies with these averages, and then trying to close the distance to come as close to the average as possible.

For children with mental impairments to be admitted to schools, for example, they must be able to follow along in class and thus reach the required level of competence, failing which they are placed in separate institutions that are supposed to bring them (back) to the norm. In the event that this proves impossible, they risk being segregated for almost their entire lives. For disabled adults to gain employment in the business environment, they must acquire personal autonomy and vocational competencies equivalent to, once again, the average. It is on this idea of deviation from the conventional norm that the notions of the first International Classification of Impairments, Disabilities and Handicaps, proposed by the World Health Organization in 1980, are based. Here we can recall Goffman (1963), who quite humorously described the average American by showing how anyone who deviated in any respect from the standard was considered defective and more or less to blame.

The will toward normalization is tied to another force active throughout contemporary societies: the attraction of the universal. Modern Western societies, which are driven by the necessity of establishing on their own the conditions of inclusion to further cohesion and reduce inequalities, consider their forms of sociability to be the most advanced.

From this follows the preference for the *assimilation* model.

The point of departure is the undeniable universality of humanity. The human species is a unity. The other can only be another I. There are, in principle, no limits to the rights of human beings as such. This is the great achievement of democratic revolutions. But we move very quickly from a recognition of equality to a desire for identicalness. It is this discourse that more or less is generated by the assimilation model: There are common values, common objectives, canons of conduct—averages that we must strive to approach. One must agree to live according to these norms, and this kind of public space can become "blind to differences." The critical point is this: If we fall into what might be called "assimilationism," we end up denying others their irreducible differentness, their right to be themselves, just the way they are.

In contrast to the assimilation model, a *differentiation* model has been formulated. The first form of the differentiation model is the "hierarchical" one. It is a way of integrating differences by holding them together in a coherence, which is at the same time a system of submission. For example, man and woman represent two ways of being human but, because of the traditional relationship of dominance, the social roles associated with these two ways of being have resulted in one having precedence, greater dignity, and greater worth than the other (political vs. domestic role, productive vs. nurturing role, authoritative vs. affective role). The hierarchical model makes it possible to control differences. Still in the universe of differentiation, we meet a second model: that of "juxtaposition." The recognition of a difference is pushed far enough that each individual remains on his or her own, a stranger in the midst of strangers. With the juxtaposition model in its extreme form, which can be called differentialism, it is said: You are another but you have nothing to do with me unless it is to submit to a scale of value on which I am more perfect than you. Juxtaposition, like hierarchy, is a way of putting some people at the top and giving the impression that they alone represent the universal.

THE DIFFERENT FORMS OF EXCLUSION AND INCLUSION

The doubtless most dynamic notion of inclusion leaves room for the work of adjustment, acceptability, and social participation, while the idea of integration presupposes conformity, an alignment that is always experienced as domination, even oppression, by the group that defines the norms or of the majority over the minority. Being included can signify a situation of which one is organically a part, without being necessarily obliged to behave according to a rigid norm. On the other hand, inclusion, like insertion, can prove to be weak and may merely be synonymous with simple presence, simple admission, simple tolerance. You can be tolerated without being recognized. You can be admitted without being incorporated.

On the other hand, exclusion may reference several phenomena: radical exclusion from society, segregation within society, discrimination, also within, concerning access to goods and social spaces, disaffiliation, and an exit from the social exchange system.

Varying according to cultural practices (Ingstadt and Reynolds 1995) and historical periods (Stiker 1999), inclusion and exclusion may assume different meanings; they are not univocal and are not historically fixed. There is diversity in exclusion and diversity in inclusion.

We can observe that each of these kinds of exclusion, even if it has been generally characteristic of a given ancient society, nonetheless displays survival in contemporary Western societies. Establishing a typology of the different forms of inclusion and exclusion that can be observed in the social treatment of disability is comparable to a construction in terms of ideal-type according to Max Weber. An ideal-type is always a mixture of abstract relations and contingent data. By raising practices, albeit empirically different and historically separated, to the point where they can be subsumed in an abstract characterization, we try to associate possible configurations with some conjectural behavioral outcomes.

The Elimination Model

The most extreme form of social exclusion is death. One of the first identifiable types of exclusion, then, is exclusion through elimination. The elimination of disabled people can be effected directly by putting them to death or indirectly by radical abandonment or the withholding of care. Elimination, less of persons than of disability itself, may also be considered to occur before birth; this raises questions related to the termination of pregnancy when an impairment is discovered in the fetus, and even before pregnancy with new developments in genetic testing. Eugenicist theories show the possible link in continuity between the social practices of elimination of ancient societies and the practices associated with the most recent advances in technology of contemporary societies. Making this observation is not in contradiction with a legal right to abortion.

The Abandonment Model

The practices of abandonment can be distinguished from those of elimination by the fact that they do not entail death, or at least not in such direct fashion. Practiced in ancient cultures, exclusion through abandonment is also reflected in the contemporary forms of "social death" and social abandonment. Examples of abandonment practices are not lacking: the abandonment of children born deformed, the severely wounded, and very dependent elderly people.

Abandonment may amount to conferring of parental authority on another, leaving the fate of a newborn in God's hands, or in more modern fashion anonymously giving up a child for adoption (Dumaret et al. 1998). Abandonment can also be ceasing to look after people, depriving them of care. Relevant here is the question of passive *euthanasia.* The "surplus population thesis" has been advanced as one of the chief explanations of exclusion through abandonment (Oliver and Barnes 1998).

The Segregation Model

Sequestration and the whole set of practices of putting apart constitute one of the most widespread forms of exclusion. It is also the form of social treatment that, by clearly distinguishing an inside and an outside, offers the best fit with the basic meanings of inclusion and exclusion. The point here is that this putting apart does not necessarily take place outside the community but frequently at its very heart. Lastly, we may note that this segregation may be more or less constraining, with a greater or lesser deprivation of freedoms.

One of the paradoxes is that what is often called a segregating detour, for example, through temporary schooling in a separate institution, is often touted as having integration as its ultimate goal. And indeed today this form of segregation is most often conceived of as a side trip that will facilitate a sound return to the ordinary environment (even if the detour never proves to be a way back). Thus, the will is not to exclude, but to include at a later stage. Segregation is as well an attempt of *deferred inclusion.*

The Assistance Model

The relationship with work invites consideration of another form of exclusion: exclusion through assistance, an "economic" form of exclusion that been a social issue since the end of the Middle Ages.

Assistance is a form of close protection and concerns those who, through their inaptitude for work, cannot meet their own needs. Assistance admittedly creates a weak form of participation in society. It confers social substatus. But to assist is not to exclude in the strongest sense of the term, since those helped are part of society simply by virtue of society's concern for them. Those so assisted are part of society on the condition that they stay in their place. Georg Simmel (1908) has convincingly shown that poverty lies not in being without means but rather in being assisted, such assistance itself being a means to ensure social cohesion. The ideal-type that assistance represents can be expressed by the idea of *conditional inclusion.* On one hand, it is still a form of exclusion, because the disabled person is not allowed to acquire a status equivalent to that of the able-bodied and other social groups, but on the other hand, it is a form, albeit weak, of inclusion.

The Marginalization Model

In the precise meaning of the term, *marginalization* is the process of moving to the side through the refusal of, or the impossibility of accepting, current recognized rules of social functioning. The marginalized are defined by transgression of, or protest against, commonly held values and habits, whether this is a decision to become an outsider or rejection by the dominant group. What has been at stake in rehabilitation has thus been to reduce this deviation from the norm. The action on the individual who is to be reintroduced into the mainstream is therefore informed by the goal of effacing differences. The individual should "act like" others even if this necessitates technical aids, devices, or prostheses.

But it is this same concern for a reduction of the deviance that lies at the ground for the normalization developed by Wolfensberger (1972) with regard to people with mental retardation. Here we can see, more clearly than previously, that even a position on the margin can be qualified as *inclusion through normalization.*

The Discrimination Model

To discriminate is to distinguish or to separate out a social group and restrict its rights. These distinctions made in social life at the expense of disabled people may be judged unacceptable because they violate social norms and the principle of equality before the law, even though in other societies and at other times they may be current practice.

To define discrimination as the action of treating equal individuals inequitably shows to what extent the concept is tied to modern society, which puts equality at the center of its value system.

With the development of civil rights, most modern democracies instituted judicial protections against intentional negative discrimination based on criteria relative to the impairments of an individual. Nonetheless, forms of statistical discrimination are no less evident (Ravaud, Madiot, and Ville 1992), and these are much more difficult to contend with.

Discrimination can also be positive and have the restoration of equality as its goal. Positive discrimination can be effected by social assistance measures in cases with an extrinsic character (e.g., income). It can be effected through authoritarian measures (which raises the question of personal freedoms) or finally by preferential measures (e.g., employment quota policies that favor disabled workers). It can be conceived of as a compensatory measure and defended on the basis of distributive justice.

CONCLUSION

The principal question posed today in Western countries is the nature of the citizenship that can be exercised by disabled people. Modern policy excludes the possibility of distinguishing among different categories of people in the public sphere. Behind these questions of discrimination and exclusion we discern the principle of equality rights of citizens as a moral ideal of a democratic nation.

Exclusion needs to be seen from a global perspective that comprises both the views of the excluded people and those of the entity that rejects them. For, contrary to contemporary representations now in circulation, exclusion is not an abstract phenomenon, implacable, agentless, in its extreme form a fatality resulting from the entry into a new global economy. Exclusion is clearly also inscribed in the social relationships of power (Elias 1965).

It seems impossible to ignore the fact that the two poles are always in evidence: civic universalism, on the one hand, and differentiated groups and individuals, on the other.

—Jean-François Ravaud and
Henri-Jacques Stiker

INCLUSIVE EDUCATION

The concept of inclusive education is grounded in the principle of "normalization," which asserts that individuals with disabilities have a right to access the same opportunities, including the same daily experiences and routines, as persons without disabilities. Inclusive education has been strongly endorsed by the international community. Article 23 of the United Nations Convention on the Rights of the Child states:

> A mentally or physically disabled child has the right to a full and decent life in conditions which ensure dignity, promote self-reliance and facilitate active participation in the community. The state shall provide special care, free of charge, whenever possible, to ensure that the disabled child receives education, training and services leading to the fullest possible social integration and individual development.

This stance by the United Nations represented a major leap forward in establishing education as a "right" of children with disabilities. The UN convention did not, however, provide a definitive statement regarding inclusion. The international community has adopted a vision of "education for all" (EFA), which means that every child, regardless of status, is entitled to an education. The World Declaration on EFA was first adopted in Jomtien, Thailand, in 1990 by more than 1,500 persons representing the international community, including government officials, members of nongovernmental organizations, policy makers, researchers, and key international donors such the World Bank. (UNESCO, the lead UN organization for special needs education, was one of five organizations that convened the Jomtien conference and continues to work with other international agencies and nongovernmental agencies to achieve the goal of providing equal access to education to children with disabilities.) Subsequent conferences, such as the Salamanca World Conference on Special Needs Education in 1994 and the Dakar World Education Forum in 2000), reaffirmed the goal of EFA, and the international community has increased its commitment to promoting policies that support educational opportunities for all.

According to the Salamanca Statement, every child has a fundamental right to an education, and schools should develop a child-centered philosophy to accommodate the needs of all children. The design of education systems and programs needs to account for the wide diversity of child characteristics, including those of a range of children with disabilities, gifted children, street children, working children, children from remote and nomadic populations, children from minority groups (whether linguistic, ethnic, or cultural minorities), and children from other disadvantaged areas or groups.

According to the Salamanca Framework for Action:

> The fundamental principle of the inclusive school is that all children should learn together, wherever possible, regardless of any difficulties or differences they may have. Inclusive schools must recognize and respond to the diverse needs of their students, accommodating both different styles and rates of learning and ensuring quality education to all through appropriate curricula, organizational arrangements, teaching strategies, resource use and partnerships with their communities. (UNESCO 1994:11, para. 7)

The Salamanca Statement advocates educating children with disabilities within regular schools and eliminating, as much as possible, the use of segregated special schools for these children.

DEFINITIONAL ISSUES

Within the international community, the notion that every child is entitled to an education is not debated. Inclusive educational policies are those that address the specific needs of every child of school age regardless of gender, race, ethnicity, language, culture, economic status, or disability. However, where the education is provided continues to be confounded by disability classifications. The International Classification of

Functioning, Disability, and Health (ICF), developed by the World Health Organization (WHO 2001) is the dominant tool used for defining disability in policy and research. This classification system focuses on the types and levels of interventions appropriate for individuals with disabilities within specific contexts, such as in education. Its purpose is to assist in the development of inclusive policies and research through refinement of classification. Yet the idea that children with disabilities need to be categorized has been challenged by some in the international community because of concerns about the stigmatizing effect of labeling children. For example, in many countries, a child's ICF classification can determine whether or not the child will be allowed to stay in a regular public school. Thus, the preferred approach is not to focus on the disability and instead create schools that can meet the needs of any child.

However, this is not a universal goal. To illustrate: Consider students who have physical and sensory disabilities and no cognitive or intellectual impairments. Children with these types of disabilities will likely require some adaptations to their physical environment in order to be able to access education. These can include accessible facilities as well as transportation. Students with sensory impairments may also require specially designed interventions and curricular materials (e.g., interpreters, large-print or Braille materials). While all such interventions may be provided within regular schools and classrooms, advocates for some of the sensory disabled populations question the capacity of regular schools and/or classrooms to provide interventions for individual children who may be hearing or visually impaired. Advocates for the deaf and hearing impaired also maintain that it is important for children with these impairments to be educated with others like themselves so that they are included in Deaf culture. They assert that equality of educational opportunity is best achieved in specialized settings, such as special schools.

Children with intellectual and learning disabilities have special educational needs, although the latter are not universally recognized as having a disability. For children experiencing difficulties learning to read as well as those children with marked levels of cognitive and developmental disabilities, inclusive education means individually designed and child-centered pedagogy. However, where that education is provided may be subject to debate. For example, in the United States and Canada, where learning disability is recognized as a classification, advocates question whether the regular classroom can provide the intensive instruction these students need to access and progress in the curriculum (McLaughlin & Jordan forthcoming). For students with moderate to severe intellectual disabilities, inclusive education is often interpreted as both individualized and provided in regular classrooms. Education for these students places great emphasis on developing communication strategies and social competencies that will permit these students to interact with and be integrated into the community at large.

EMERGING ISSUES

Several issues have emerged in recent years concerning inclusive education in countries with and without well-developed special educational systems. First and foremost, *every* child with a disability must have access to public education. Within developing countries, there is growing acknowledgment that a paucity of data are available pertaining to childhood disability. The WHO and the United Nations generally agree that approximately 10 percent of the world's population is affected by some kind of physical, mental, or sensory impairment (Metts 2000). However, reported estimates on the proportion of disabled persons in the population have ranged from 5.2 percent to as high as 20 percent. The WHO has stated that it is not possible to determine the percentages of individuals with disabilities more accurately because of differences among the classification systems used to determine who is disabled. For example, children with severe disabilities are sometimes not included in estimates because they are hidden from society and excluded completely from the educational system. These children may also reside in institutions or, as is the case in many developing countries, may be receiving care or education in one of a number of small community organizations supported by various charitable organizations (Peters 2003).

Another emerging issue concerns increased demand for educational accountability in the form of higher levels of student academic achievement. Greater attention to educational productivity is challenging schools to improve the performance of students with disabilities in specific academic content areas (McLaughlin & Jordan forthcoming). Whether accountability demands will lead to improvement or restriction of the education of students with disabilities in regular schools and classrooms remains to be seen. Some believe that increased scrutiny of the academic achievement of students with disabilities, and other subpopulations of at-risk students, will motivate schools to implement curricula and pedagogy that will address diverse learners. Others are concerned that such scrutiny will lead regular schools and classrooms to become less tolerant of students who require extensive support or adaptations and to see these students as better served in more specialized settings.

Inclusive education, in all of its meanings, is not a specific program that can be implemented. Rather, inclusion is a philosophy and a process that must be implemented at many different levels of the educational system (Hegarty 1995). Inclusion requires the restructuring of the physical environment, the broadening of instructional strategies and curricula, and changes in the social and psychological attitudes of teachers, administrators, and students.

INDEPENDENT LIVING

ESSENTIAL DEFINITIONS

The term *independent living* refers to the emancipatory philosophy and practice that empowers disabled people and enables them to exert influence, choice, and control in every aspect of their lives. Independent living is an ideology as well as a social and political movement. Originally inspired by the example of the American civil rights movement and also by the growth of the women's movement, participants in the independent living movement see it as a civil rights movement of disabled people.

The Washington Declaration, which came out of a global summit on independent living held in Washington, D.C., in 1999, defines the principles of independent living as follows:

> That all human life has value and that every human being should have meaningful options to make choices about issues that affect our lives;
>
> That the basic principles of Independent Living Philosophy are human rights, self-determination, self-help, peer support, empowerment, community inclusion, cross-disability inclusion, risk-taking and integration.

Within this broad understanding, the concept of independent living has developed a different character in different regions of the world.

HISTORY

Some of the ideas inherent in independent living predate the naming of the first center for independent living (CIL). Within the United Kingdom, for example, disabled people with sensory impairments were uniting to press for rights to education and to paid work as early as the nineteenth century. Most people, however, accept that the birth of the modern independent living movement took place in Berkeley, California, in the 1970s. There a group of physically impaired students rebelled against the notion that they should accept living in a nursing home and united to demand the right to an accessible living environment and to paid aides to give them the personal assistance necessary for them to lead normal daily lives.

This group, originally called the Rolling Quads, worked to support other disabled students at Berkeley. The group swiftly extended its services to the community, and the Berkeley Center for Independent Living was born. The concepts that underpinned the Berkeley initiative—of accessible environments, affordable technology (e.g., a wheelchair repair service), personalized daily living support (personal assistance), and peer advice (disabled people supporting and helping each other)—have remained central in the independent living movement. The CIL came into being at an institution with a reputation for social radicalism, in an era of social radicalism. So the other characteristic it embodied was a political dimension, an identification with struggles for social justice.

SPREADING THE IDEA

The CIL concept was exported to Europe in the late 1970s through the work of a few well-traveled disabled activists. The concept was taken up enthusiastically in northern Europe, including the United Kingdom. Activists from these countries and from the United States took the idea to other parts of the world. There is now a global independent living movement.

The movement has developed in various ways from region to region. In most of the developing world, independent living has been associated with economic independence, so the movement has focused on employment opportunities, often linked to providing services to other disabled people. In Zimbabwe, for example, a wheelchair manufacture business provides both work and a service for disabled people as well as generating income for the CIL.

AGAINST INSTITUTIONS

In Western Europe the independent living movement has focused on ensuring that disabled people have alternatives to residential care institutions. Most European CILs, as well as the European Network on Independent Living (ENIL), focus on personal assistance as a key component of independent living. This is because lack of personal assistance is closely linked to individuals' being forced to live in institutional care. ENIL was set up in 1989 at a conference held in Strasbourg. The conference resolution (known as the Strasbourg Resolution) states:

> This conference has focused on Personal Assistant Services as an essential factor of Independent Living, which itself encompasses the whole area of human activities, e.g. housing, transport, access, education, employment, economic security and political influence. . . .
>
> We condemn segregation and institutionalisation, which are direct violations of our human rights, and consider that governments must pass legislation that protects the human rights of disabled people, including equalisation of opportunities.
>
> We firmly uphold our basic human right to full and equal participation in society as enshrined in the UN Universal Declaration of Human Rights . . . and consider that a key prerequisite to this civil right is through Independent Living.

This resolution locates independent living firmly within the framework of human rights. This is not about doing good to disabled people, or providing them with welfare. It is about ensuring that disabled people can exercise their human and civil rights equally with nondisabled people. The Strasbourg Resolution expresses independent living philosophy in a form that governments can understand.

DIRECT PAYMENTS

One of the tools that disabled people have developed as a way of achieving the control and choice that characterize independent living is direct payments. This is a method of giving disabled people cash to pay for personal assistance instead of having assistance arranged on their behalf by local authorities. Direct payments have been popular in Europe, including the United Kingdom, because they provide an alternative to home care or residential care. The fact that direct payments give disabled individuals control over the budget and over hiring (and, if necessary, firing) the people who assist them has been a major challenge to the prevailing welfare philosophy.

In the traditional mode of service provision, disabled people are seen as dependent precisely because they need help with daily tasks such as getting dressed. With direct payments, disabled persons can take control over these daily tasks. More important, when they can accomplish such basic tasks as getting dressed or washed efficiently, disabled people can use their time doing more productive and enjoyable things, such as working, bringing up children, and going to art galleries.

Some welfare professionals have opposed direct payments, stating concerns that users may spend the money on the "wrong" things or hire the "wrong" workers. Such concerns are born of a belief that disabled people are vulnerable, that they need professionals to hire the "right" workers for them. These concerns also reflect a belief that public money should be spent only on activities sanctioned by professionals. Both these ideas are based on a view of disabled people as less than wholly adult, not able to make their own decisions and take their own risks. Direct payments challenge this view. However, supporters of direct payments do not pretend that disabled people do not need help in making choices or implementing decisions. They argue that CILs, run by and for disabled people, can provide this help. A number of CILs in operation today started as peer support groups for people using direct payments.

A COMPREHENSIVE PHILOSOPHY

Independent living is more than an individual aim. It encompasses a change in social relations. It is both a philosophy and a practical approach. It brings disabled people together to work for civil and human rights. They espouse equal opportunities for everyone as well as self-determination for themselves. The basic meaning of independent living can be expressed very simply: "Independent Living means that disabled people want the same life opportunities and the same choices in everyday life that their non-disabled brothers and sisters, neighbours and friends take for granted" (Ratzka 1996). This simple definition encompasses all of social and economic life. Many disabled people are still denied the opportunity to grow up alongside nondisabled siblings, to go to the neighborhood school, to use the same buses and get the same kinds of jobs as their nondisabled friends. The independent living movement says that they can attain these simple aims through collective action.

CHANGING SOCIAL RELATIONS

The independent living movement wants to change the social relations of disabled people, particularly to remove enforced reliance on family members as primary caregivers. Simon Brisenden wrote one of the most memorable criticisms of being forced to rely on a family member for assistance: "It exploits both the carer and the person receiving care. It ruins relationships between people and results in thwarted life opportunities on both sides of the caring equation" (quoted in Morris 1993:27).

This view is not universally accepted—some people see giving assistance to a family member as an expression of love or of wider familial duty—but it is one that underpins much of the work of the independent living movement. Nasa Begum has described the "burden of gratitude" placed on people who are always beholden to others for simple things such as taking a bath; the independent living movement attempts to remove that burden by making assistance into a straightforward working relationship, rewarded with appropriate wages, delivered in ways chosen and directed by the disabled person. This approach does not reject the family—rather, it values family members in their own right, as wives, fathers, sisters, sons, rather than forcing them into the role of unpaid attendant.

INDEPENDENCE IS NOT ISOLATION

Some critics of independent living have argued that it is an individualistic philosophy, that the focus on supporting individual people ignores the wider social and economic pressures facing disabled people. This claim ignores the whole culture of independent living.

At the 1999 global summit on independent living mentioned above, delegates noted:

> The Independent Living Philosophy recognizes the importance of accepting responsibility for our own lives and actions, and at the same time, the importance of community to foster Independent Living.

Achieving the social aims of independent living requires collective action. Independent living is developed through the self-organization of disabled people. The movement is based on collectively developed solutions to individually experienced barriers. The movement recognizes that many disabled people will not manage to achieve independence on their own, that the system we live in puts too many obstacles in the way. "The cornerstone of Independent Living Philosophy is . . . control and choice. . . . Systems advocacy is of ultimate importance because some choices for disabled people still need to be created" (Holdsworth 2000).

This recognition, that society needs to create choices for disabled people, is one of the reasons disabled people have come together to set up their own organizations, including centers for independent living. CILs are always controlled by disabled people; often all of the voting members on the governing boards of CILs are disabled people. This is not because of hostility toward nondisabled people. Rather, it is an expression of a necessary step toward independent living. As Adolf Ratzka (1992) notes: "Disabled people need to be in charge of their own lives, need to think and speak for themselves without interference from others." This is as true in organizations as it is in the lives of individuals.

INDEPENDENT LIVING AND THE SOCIAL MODEL

In the United Kingdom, the philosophy of independent living is closely linked to the ideas embodied in the social model of disability. Some of the theorists of the social model were pioneers of the U.K. independent living movement. This model shows us that (a) historically, society's reaction to impairment (and failure to meet needs relating to impairment) has undermined disabled people's human and civil rights; and (b) this is not inevitable—in other words, impairment does not have to determine life chances. Biology is not destiny.

The social model recognizes that disabled people are different from nondisabled people in that they have *additional requirements,* such as mobility needs and needs for communication assistance or personal assistance. These additional requirements stem both from experiences of impairment and from the disabling barriers of negative attitudes and unequal access.

The pioneers of independent living in the United Kingdom identified 7 "basic needs" of disabled people—that is, essential additional requirements that must be met if disabled people are to achieve independent living and thus equality of opportunity with nondisabled people. That initial list was later extended to the following 12 basic needs:

- Full access to the environment
- A fully accessible transport system
- Technical aids (equipment)
- Accessible adapted housing
- Personal assistance
- Inclusive education and training
- Adequate income
- Equal opportunities for employment
- Appropriate and accessible information
- Advocacy (toward self-advocacy)
- Counseling
- Appropriate and accessible health care provision

This list echoes similar priorities identified a few years previously at the CIL in Berkeley.

INDEPENDENT LIVING AND INCLUSION

Historically, CILs have struggled to provide services for all sections of the disabled community. In most cases their founders have been people with physical impairments, but they have always taken an inclusive approach to disability, aiming to serve all disabled people, regardless of the nature of their impairments. Some CILs have had problems in fulfilling their inclusive aims, often because of limited material and human resources. CILs' success in achieving such aims can also be affected by entrenched opposition from vested interests within agencies that provide traditional disability services. For example, some traditional service providers have castigated CILs in the United Kingdom for being insufficiently knowledgeable about the communication needs of people with learning difficulties (intellectual impairments) while at the same time jealously guarding their own knowledge. In such cases, the concept of sharing knowledge in order to make the service better is not put into practice.

Some disability activists, particularly in the United Kingdom, where social model thinking is especially influential, have adopted the terms *integrated living* and *inclusive living* in place of the original *independent living* to characterize the philosophy on which their activities are based. By doing so, they demonstrate their recognition that humans are by definition "social" beings, and that *all* humans, regardless of the degree and nature of impairment, are interdependent and, therefore, a truly "independent" lifestyle is inconceivable. This recognition is especially important to the independent living movement in regions where interdependence is a strong part of the culture, such as in Southeast Asia.

GLOBAL SUMMIT

As noted previously, in 1999 a global summit on independent living was held in Washington, D.C. The summit brought together activists from more than 70 countries. Despite regional variations in how independent living was being developed around the world, the delegates agreed on a set of basic principles. These principles, which are laid out in the Washington Declaration, include a restating of the basic needs identified by CILs in the United States and United Kingdom: "that we recognize the importance of equal and inclusive education, employment opportunities and entrepreneurship, assistive technology, personal assistance, accessible transportation and a barrier free environment to promote Independent Living." The principles also restate the movement's aspiration to universality:

> that the Independent Living Principles and Philosophy have applications on a global scale and are to be implemented on the local, national and international levels without regard to disability, sex, religion, race, language, ethnic background, political affiliation, age or sexual orientation.

INDEPENDENT LIVING IN THE TWENTY-FIRST CENTURY

Current concerns in the independent living movement center on sustaining the movement, on creating real independent living opportunities in the developing world, and on promoting the link between independent living and human and civil rights. These concerns are interlinked. Activists who meet at global and regional gatherings devoted to the topic of independent living have noted that many of the pioneers of the movement are aging and that no large cohort of younger activists is replacing them. One result of the success of independent living in the United States and Europe has been that more disabled people can now take it for granted that they can get education, get assistance, get a job. They thus have less direct motivation to devote time to managing and supporting independent living organizations. The movement is looking for ways to sustain its collective base in an era when individual consumerist culture is the dominant mode.

One method by which advocates of independent living are sustaining a wider perspective is found in Scandinavia, where national disabled people's organizations support independent living projects in several developing countries. By emphasizing the global links among disabled people, they are helping to create a sense of community.

Finally, the movement is revisiting the philosophical roots that informed the first CIL in Berkeley, stressing that disabled people have the same civil and human rights as everybody else. Independent living is a tool for achieving these rights. Activists are now challenging residential institutions, not just because they stifle individual autonomy but because they rob those who live there of essential human rights. In the United States, the Free Our People campaign uses the direct action tactics developed by Adapt. In the United Kingdom, the government-sponsored Disability Rights Commission is backing a campaign for a right to independent living on the grounds that it is essential to enable disabled people to enjoy civil rights. This reaching out from disability organizations to the wider world of civil and human rights has been the hallmark of the independent living movement and distinguishes it from other, welfare-based approaches to meeting disabled people's needs.

Independent living can be summed up in two words: freedom and participation. Independent living gives disabled people the freedom to make choices and the means to participate in their communities, taking both opportunity and responsibility.

INDIA, IMPACT OF GENDER IN

Historically, disability has been defined as a medical condition and perceived as the personal tragedy of the "affected" person. However, slowly but surely disabled people have come to question this understanding. As the disability movement has gained impetus, the experiences of marginalization and multiple exclusions associated with disability have come to be comprehended as the results of social oppression. It has become clearly evident that factors such as widespread inaccessibility in the built environment, segregation in education, rampant unemployment, unavailability of alternative formats of communication, and a general lack of acceptance in society have been responsible for the subjugation of the disabled. Disability therefore is in reality a social construction and not a natural category.

Gender, on the other hand, has historically been synonymous with sex. In the 1970s, however, the concept of gender as different from sex made its appearance in feminist discourse. Since then, the term *sex* has been understood to refer to the biological characteristics that make men and women different, and *gender* has been conceived as referring to the social and psychological characteristics related to femininity and masculinity. To the feminist world, this distinction is extremely significant in that it underlies the different forms of domination experienced by women universally. According to feminist theorists, every societal configuration has a sex-gender system—a set of arrangements by which the biological raw material of human sex and procreation is shaped by desired social interventions. Sex is related to what was bestowed by nature, and gender is related to what results from nurture. Within the emerging feminist understanding of the 1970s, this distinction was significant as it avoided the underpinning of *women* as a natural category. It thus became evident that femininity and masculinity are to be understood as acquired characteristics with social significance.

Despite a clear enunciation of the gendered character of societal parameters, mainstream feminism went on to replicate the inequities of the patriarchal society by leaving out of its ambit many categories of women who are marked by given systems as "different" and are oppressed due to factors such as class, ethnicity, caste, and physical or mental diversity. Implicit in mainstream feminism was the idea of universal sisterhood, which signified that all women experience similar oppressions; however, this idea was contested by those who felt that their unique life conditions were not reflected in the collective experience. Disability was one of the categories excluded from deliberations within the evolving awareness of feminism.

The inevitable fallout of this reasoning was that the disability movement mirrored the gendered nature of larger society, making the female members uncomfortable habitants of the resistance that the disability movement has been putting up against the hegemony of the normality. Even sensitive students of disability have focused on disability as a singular concept and have taken it to be not merely the primary status, but apparently the exclusive status of disabled people. Disability is not the only social marker of distinctiveness, as gender coalesces and makes the experience increasingly doubly oppressive. Thus, both disability and gender are social constructions, endorsing the cultural inscriptions on the bodily impairment and the biological sex, respectively. The realization that both identities are similar in that they are biological entities that are assumed to become problems when placed in a hostile social context has become crystal clear. It is precisely this understanding that has rendered the lives of disabled women across the globe invisible and devoid of any control.

The process of discrimination against disabled people starts at birth. It is not uncommon in some parts of the world for disabled infants and very young children to be killed or left to die. In India, technological advances that allow the determination of the sex of the fetus have created a eugenics movement that might be unheard of in the West. The widespread desire for male offspring has translated into the abortion of many female fetuses. While activists in the West have been vehemently protesting against the killing of disabled infants in India, the preference for sons has resulted in the lowest ratio of female to male births ever. Although feminists have engaged in plenty of debates about the ethical contradictions involved in the selective killing of female fetuses, as well as the right to abort, the use of new technologies for prebirth genetic screening to predict disability has not been addressed. Coupled with the predominant negative presumptions held about impairment and disability, it is not in the least surprising that the abortion of impaired fetuses is not even mentioned in these debates.

The survival to birth of a disabled girl child, however, does not guarantee her a struggle-free existence. The road she will have to traverse is not easy. In any nation, a disabled girl child is likely to experience inequities in terms of basic entitlements (such as food, health care, education, and employment opportunities) and often has little hope of being included in the cohesive net of the family. Although most if not all disabled girls around the world are subject to such difficulties, a majority of disabled girls who live in developing countries are currently living lives in which every one of their human rights is being violated.

In the early 1980s, feminists in the West drew attention to the danger inherent in applying the feminist critique of patriarchy to disabled women's experiences. They realized that this critique would not offer an adequate account of the oppression of disabled women, as disabled women have not been "ensnared" by many of the social expectations feminists have challenged. In reality, this "freedom" from expectations signified the loss of traditional roles that provided living space to women marked as disabled. The constant privileging of "normal" women worsened the situation of disabled women. The intimidation of hegemony that worships physical and mental perfection has a definite impact on the resistance that disabled women can put up against their recurrent marginalization.

In such a context, it is not easy to think of viable strategies. Despite swift social, cultural, and economic changes and the current drive toward a global society, women are still defined in terms of their connectedness with traditional social roles. For instance, in India, throughout her life, a woman is largely defined by her roles as daughter, wife, and mother. Any position she holds outside the home is not considered to be her primary role. However, disabled women are not considered "marriageable" because their impairments are seen as "imperfections" that could be passed on to their children. Their ability to fully look after a home and family is also questioned.

The incidence of marriage for disabled women is lower than that for disabled men throughout the world, but it is lowest in cultures where traditional roles are highly valued. In a similar vein, whereas specific cultural taboos may vary, the universal reality is that disability and motherhood are not perceived as complementary. Even in cultures where single motherhood is acceptable, disabled women often find it difficult to express their desire for this role. The denial of traditional roles thus adds to disabled women's vulnerability and desolation.

Much of the uncertainty about disabled women's suitability for the role of motherhood stems from assumptions concerning their physical capacity to carry pregnancies. If disabled women do manage to be reproductive, grave doubts still exist in most societies about their competence as mothers. The emotional strength that they can provide their children is viewed as inconsequential, as the stereotypical image of disabled women is that of dependency. That disabled women can be caretakers too is often missed in the dialogue of care. This appears in contrast with more emancipated "normal" women, because of the limitations imposed on disabled women, who cannot become partners in this celebration because they do not have opportunities to participate in the more productive activities of a given culture.

The economic strain and isolation created by the relatively few opportunities disabled women have for productive work or gainful employment lead to a lack of participation in the labor market, producing and reinforcing the dependency that is assumed to be characteristic of disabled women. In this sense, feminist positions are guilty of amplifying the importance of women's employment until it has become a standard of womanhood against which disabled women shrink into invisibility. Striving for equality not only with men but also with "normal" women induces in disabled women a desire to be recognized as persons first and then as being female.

In many societies, women who are considered intellectually disabled frequently encounter the severest form of oppression in the form of forced sterilization. Without their consent or even their knowledge, they are provided with an "effortless" and "realistic" solution to their "predicament." Sterilization is said to "relax" the disabled woman, as she no longer has to manage menstrual hygiene or deal with pregnancy or the "risk" of bearing a disabled child. It is often argued that sterilization protects a woman from sexual abuse. Although sterilization is imposed predominantly on women who are intellectually different, many women with physical and sensory disabilities are also subjected to this inhumane treatment.

This is quite paradoxical, as it is popularly assumed that disabled women are asexual. This contradiction places them in an extremely perilous situation. In a society that imposes ruthless standards for attractiveness and desirability, disabled women require a sort of physical legitimacy in order to obtain love and acceptance, with a certain sexual model as the entrée to both. This creates confusion, as disabled women obviously cannot adhere to rigorously defined standards of acceptable body dimension, weight, and physical competence with the ability to be sexual. This becomes a discouraging and inexorable process for those who don't measure up to the normative standards. The consequences for these women are feelings of guilt, shame, and fear when they are confronted with the possibility of sexual intimacy. Slowly but surely, this conveys messages of unattractiveness as well as leads to a state where it seems that the body has lost the potential to respond to sexual cues. Thus, all these measures are designed to control disabled women rather than to address the societal arrangements that do not provide security and support for these women.

The oppression and invisibility that disabled women experience have negative impacts on their self-esteem. Stigmatized from birth, through neglect they grow up with the tyranny of a society that demands perfection. In addition, disabled women—especially those who are severely disabled and fully dependent on the assistance of others to accomplish their day-to-day life activities—have to contend with caregivers who objectify disabled women, often completely disregarding their feelings and their right to decide on matters concerning them.

The difficulties that disabled women experience are rooted in the meanings that impairment has for nondisabled people. If the nondisabled view the difference of disabled women as deviance, this has a negative impact on disabled women's internal strength and resistance. It is not easy to acknowledge and retrieve one's agency to resist dominant patterns when the signals communicated to one by others are those of dismay, fear, and pity. The right to self-definition and an evolving worldview is a fundamental political right that is denied to many disabled women. As disabled women confronting their recurrent exclusion, they are deprived of the right to have expertise regarding their own lives. Thus, disabled women must struggle not only to assert their own identities but also to assert their difference and to account for the injustices done to women that have not found expression in the language of feminism.

The stigma attached to disabled girls and women does not leave their mothers unblemished. A form of torture accrues to them for having given birth to disabled daughters. Once again, the feminist discourse in India has paid scant attention to the issues faced by women who are the mothers of disabled children, especially girls. Women who cannot validate their social status as mothers who have borne healthy children for their husbands' families, such as those who have given birth to disabled children, are condemned to live in shame. There have been instances in India of women being divorced or even tortured because they gave birth to disabled children. Given the preference for sons, "mother blaming" is even more severe when the disabled child is a girl.

In addition to such direct onslaughts—which are always met with protests—disabled women have to contend with the use of their life situations as a metaphor to illuminate the issues and concerns of nondisabled women. The genesis of this probably lies in the fact that the sociocultural meanings ascribed to female bodies and those assigned to disabled bodies are similar. Excluded from full participation in public and economic spheres, both are conceived in opposition to a norm that is assumed to possess natural superiority. Such comparisons can be both emancipatory and oppressive. If the objective of invoking such comparisons is to understand the lived experiences of people and grasp their legitimacy, the potential is immense. However, when the underlying realities of the categories serve only at a metaphorical level, this can lead to a total erasure of the category that is being invoked. The consequent effect is that whereas one category gets "valorized" the other is very often "suppressed" in the process. Consequently, when nondisabled women are portrayed as experiencing social disability, the strategic advantage of the metaphor gets lost.

A shift from the theoretical/metaphorical to the material, which is essential to render visible the "cultural constructions" that have supported the currently flawed conceptualizations of disability and womanhood, is critical. A careful analysis of metaphors that use disability as explanatory categories is required to unearth their meanings and functions, if their power is to be subverted. Until the popular refrain that "being a woman is the biggest form of disability" operates, the road to empowerment is going to be a difficult one. Another significant issue to remember is that disabled women are also divided by many factors, such as class, caste, ethnicity, rural/urban divide, sexual orientation, and type of disability. In the context of the relationship between disability and gender, we must understand how these marginalizing aspects play a significant role.

For disabled women to resist the hegemony of normality, both advocacy and research are essential. Within India what is perhaps needed is an interrogation of the normative standards that construct disabled women as passive and dependent. However, given the cultural context, this cannot be accomplished through an emphasis on "independence and autonomy," as family structures are interdependent in Indian society. Whereas women in the West have attained a reasonable amount of success in challenging the "perfection-driven norm," this has been a result of a significant attitudinal change that has led to a more accessible built environment and changes in other structural inequalities. Research in developing countries needs to focus on actual living conditions so that it can accurately assess the impact of disabling conditions associated with gender. Researchers need to resist the tendency to borrow from the Western understanding, as the local reality is extremely important.

The cause of disabled women in India would be greatly supported by cross-cultural research that listens to diverse voices and recognizes that there is no single grand narrative of "the disabled woman." Thus, the idea of universal sisterhood, while sound in principle, will remain a myth if researchers overlook the nuances of specific realities in order to arrive at broad generalizations. Although rhetorically the women's movement may be represented as inclusive, the reality belies the claims. Encapsulating diversity within every universal category can be a daunting task, but the initiation has to come from the grass roots. It is only then that the necessary agency can be located and the hegemonies of both the disability movement and the women's movement can be challenged.

—Anita Ghai

INDIA, MARRIAGE AND DISABLED WOMEN IN

A study of the literature on disabled women reveals that the issue of marriage has been addressed very little from an empirical perspective. Most of the claims about the marital status of disabled women are based on estimates rather than actual research conducted with large samples. In countries such as the United States, Canada, and the United Kingdom, where disability studies is evolving as an independent discipline, a significant body of literature discusses gender, feminism, personal experiences, and the sexuality of women with disabilities. This literature briefly alludes to the issue of marriage, but it does not move beyond giving a selected group of women with disabilities the choice between remaining single or getting married. In developing countries such as India, hardly any research has been conducted on this issue, and therefore very little archival material, if any, is available. The subject of marriage and disabled women in India needs to be critically and thoroughly researched and documented. This entry is offered with the hope that it will provide scholars with some leads into the issue.

Before this discussion can begin to approach the significance or insignificance, and the availability or nonavailability, of the institution of marriage for disabled women, it must briefly address the basic question of the importance of marriage for women, the changing perception of the institution in the wake of awareness generated by the feminist movement, and how a single woman is looked at in a volatile yet strongly traditional Indian society. Also, marriage is addressed here as it exists between men and women; the topic of same-sex marriage is not considered, as this practice is not a norm and therefore uncommon in India. Of late, however, some deaf lesbian women have come out, but it is beyond the scope of this entry to delve into multiple issues; the focus here is primarily on the traditional institution of marriage and its availability to women with disabilities in India.

It is pertinent to note that, owing to the diversity of India's population and the country's colonial history, which has been questioned as not allowing subalterns sufficient voice, this entry does not seek to offer a monolithic picture of the issue. While some aspects of the topic may fall into a linear singular pattern, others may be contextualized and located in diverse cultural, educational, regional, religious, caste, and socioeconomic realities. Although the experience of discrimination, deprivation, and exclusion is common to most disabled women in India and cuts across different contexts, the primary focus here is on Hindu women. This entry attempts to trace a recurring pattern of experiences of disabled women in the majority Hindu community because constraints of time, space, and scope as well as the availability of literature on the experiences of Hindu women make it most feasible to concentrate on this group.

IMPORTANCE OF MARRIAGE FOR WOMEN IN INDIA

In Hindu society, even today, one of the key roles a woman is expected to subscribe to is that of a wife. In fact, from the time of birth itself, the girl child is groomed, trained, and prepared to take this role after marriage. By and large, the feminist literature in India has regarded marriage as an oppressive institution, as it operates to strengthen patriarchy and perpetuate women's exploitation. Women are expected to conform to the laws or rules laid down in the Laws of Manu—the ancient lawgiver—and the ideals of womanhood described in several other ancient Hindu religious scriptures, epics, mythological tales, rituals, and practices. According to Desai and Krishnaraj (1987), these prescribe an ideal of womanhood that confines the woman to the roles of devout wife and doting mother. In these roles she does not function as an entity independent of her husband or children. Together, these roles put women in a lower, dependent position. Many writers, including Rao and Rao (1982), Dhruvarajan (1989), Bumiller (1990), Bagchi (1995), Nair and John (1998), Gandhi (1942), and Sharma (2002), have endorsed similar views, stating that a woman's career path is oriented toward marriage, which is arranged by parents in more than 90 percent of cases. It is the religious and social responsibility of parents to "settle" their daughters in marriage. Fruzzetti and Östör (1992) have observed that marriage is central to the lives of Bengali women. They note: "Daughters are not meant to remain permanently in their father's house. It is expected that all women will marry and leave for their husband's place. Marriage completes the cycle of cultural expectation for women" (pp. 39–40). In conjunction with such expectations, it is difficult to find aspirations or models for single women in this society. This practice of placing a premium on the virtues of wifely duty and maternity is followed in other cultures and religions in India as well, including Sikhism, Jainism, and Christianity.

In a 1953 study, Margaret Cormack found that single women were considered unholy and inauspicious in Hindu culture. This may not be an absolute truth today, because with changing times the numbers of women choosing to remain single have increased, but they still constitute a minuscule minority. In fact, a recent study conducted by economists of the London School of Economics found that among Indian cities Mumbai has the largest number of single women; based on their findings, the researchers projected that with growing economic and social independence, many Indian women may prefer not to marry (cited in Mukhopadhyaya 2004). In discussing the reasons some women remain single, Cormack observes that a majority of single women do not have the option of getting married for one or more of the following four reasons: They may be considered unattractive, they may be too qualified and hence cannot find husbands with higher qualifications than themselves, their parents may be unable to provide sufficient dowry, or they may not be able to find the "right man." In urban areas of India, a small proportion of women are found to be wedded to their careers and professions, which brings some amount of respect. A career provides some buffer because unmarried women without good careers are treated as objects of pity or lead lives of social exclusion and stigma.

Despite the feminists' reprobation against the age-old institution of marriage, it is imperative to understand why such a premium is still placed on it, especially for women in Indian culture. Marriage, for women, is seen as an institution that confers certain entitlements, privileges, status, respect, and access to other life accomplishments, such as motherhood, family life, and experience of sexuality. It is a means of gaining social acceptance in society; hence, it ensures participation and inclusion. These avenues become shut off to women who never marry. In most cases, marriage is also a route to economic and financial security. Although the Hindu Succession Act of 1956 gives equal rights to women to inherit parental property, as Kishwar (2004) points out, in practice women have little access to property.

EXPERIENCES OF DISABLED WOMEN IN INDIA

If marriage is perceived as the ultimate destiny of nondisabled women, then why is the destiny of disabled women different from that of their able-bodied counterparts in India? This is not to suggest that marriage should be the destiny of disabled women, but rather that disabled women might have the alternative of choosing—that is, of deciding their destiny vis-à-vis marriage. A considerable literature indicates that disabled women are less likely to be married than are disabled men or able-bodied women. The 1996 report on the National Conference of Disabled Women put the proportion of unmarried disabled women in India at that time at 80 percent. Another report on the status of blind women in India, published by the Women's Committee of the Asian Blind Union in 2000, put the proportion of unmarried blind women at 73 percent. However, the latest findings of the National Sample Survey Organisation of India, brought out in December 2003, project a completely different picture. They show a higher number of disabled women being married than disabled men, but the percentage of widowed, divorced, or separated disabled women is about 30 to 31 percent, in contrast with 7 to 8 percent of disabled males. This pattern is observed in both urban and rural areas.

Researchers need to probe further into the reasons behind these higher rates of widowhood, divorce, and separation among disabled women in comparison with disabled men. This difference suggests problematic partnerships and devaluation of status for women after marriage. It could be possible that young disabled women are married off to men much older than themselves, or another possibility could be that they are tied to ailing men and therefore suffer a higher rate of widowhood. The higher rate of divorce and separation postmarriage for disabled women is again indicative of the fact—as Jeeja Ghosh and Shampa Sengupta (2003) projected based on the findings of a study in West Bengal, India—that they are often abandoned or physically and mentally abused, treatment associated with their disability. It is a situation of double bind: Whether disabled women are unmarried or married, they are in a disadvantageous position because the stigma of disability is permanently marked on their bodies. They either cannot get married because of their disability or, if they do marry, disability makes the survival of a happy marriage difficult.

At times, having disabilities opens several avenues for women in India that may otherwise be denied to them, such as education, employment, and subsequent financial independence. But such benefits come at the cost to disabled women of having it instilled in their minds that the avenue of marriage is closed to them and that it is futile even to think of it. According to Anita Ghai, this nonavailability of the traditional roles puts disabled women in a state of rolelessness. In her book *(Dis)Embodied Form: Issues of Disabled Women* (2003), she presents case studies in which she examines in detail the experiences of disabled women within and outside marriage. Ghai asserts that while feminists analyze the oppression of able-bodied women within the traditional role of wife and mother, they have chosen to ignore the oppression that disabled women feel due to the unavailability of traditional roles. She notes that in India marriage and motherhood have a cultural value, and that when disabled women are denied these markers of womanhood, the result is "a social obscurity and annulment of femininity" (p. 68).

Many educated and professionally accomplished disabled women refuse to marry disabled men or men who are not their equals in professional terms. The same holds true for disabled men as well. From my personal experience I can corroborate that professionally qualified disabled men prefer less than equal, able-bodied woman as partners to qualified and accomplished disabled partners. Marriage entails many compromises for disabled women that are humiliating. To begin with, due to the lack of choice they have owing to disability, they are left with no option but to accept spouses who are socially, economically, and intellectually not their equal. Sometimes they are physically and mentally abused and tortured, disability again being a major cause of their victimization. As indicated by the proceedings of the National Conference on Empowerment and Mainstreaming of Women with Disabilities, held in Jaipur, India, in August 2002, given such realities, many educated disabled women are choosing not to marry.

Where disabled women have little or no education or any skills that allow them to be productive and contributing members of society and thus improve their chances of marrying, they are treated by their families as a burden, and at times like damaged property that can be bargained in the matrimonial market. In a bizarre incident reported recently in the *Times of India* (Farooqui 2003), a father who had failed to find a groom for his disabled elder daughter, Preeti, who is a wheelchair user, laid the condition that he would give the hand of his younger, nondisabled daughter, Ragini, to any man who would marry his disabled daughter as well. The marriage of both the daughters to one man was solemnized with Amarnath Verma—who has been lauded by many people for setting a precedent in rehabilitating a helpless disabled woman—on November 25, 2003; and, to the shock of everyone, the feminists remained silent toward this open practice of bigamy, something that is prohibited by Hindu Personal Law. This incident raises many questions about the options and choices available to disabled women, especially in India. Disabled women have no role models and little access to any community in India. The issues of their education and employment, their sexuality, and the violence, abuse, exploitation, and denial of rights and deprivation to which they are subject are rarely talked about or raised by disability activists or scholars. The disability movement has kept these issues under wraps, and disabled women activists as well as scholars hesitate to address them. India's disability movement is dominated by men with disabilities who set the agenda. And the agenda is based on the issues that concern them. Disabled women activists just follow that agenda. One disability activist recently had the following to say on this subject:

> Though we come across as strong activists shouting slogans, fighting for our rights . . . who takes care of our right to be loved (emotionally and physically), to be a life partner, to be mother and so on? Yes one can never force someone to love. It is the most natural process of life. But sadly it is dependent on the outward looks of a human. . . . I have kind of become numb and immune to these feelings though I am very emotional, sentimental and romantic at heart but I don't have the strength and guts to go through any pain. . . . And besides there is no future (marriage) even if I got involved with someone cause I can't manage things the way other women do. And our culture and traditions don't allow live-in relationships or have affairs w/o marriage . . . so there's no point. Of course, I feel lonely and crave for a companion but I can't do anything about it. (personal communication, November 5, 2003)

The yardstick used to measure a disabled woman's eligibility for matrimony is set by the traditional precedence of an able-bodied woman's roles of wife and mother. In an anthropological study conducted in rural South India, Erb and Harris-White (2002) found that disabled men are not interested in marrying disabled women because they feel such women will not be able to perform household or work tasks and undertake child-rearing activities. These researchers also found that disabled women decide against marriage due to fear of childbirth and fear of being abandoned. This may be seen as their internalization of disability oppression. In fact, the myths that disabled women are not sexually active, do not marry, and therefore do not even become mothers keep them out of the purview of government family and child welfare programs as well as reproductive and child health care programs. Although feminists criticize these programs for relegating women to the role of mother, the programs' exclusion of disabled women deprives them of access to marriage by perpetuating the myth that disabled women are incapable of becoming mothers and thus succeeding in family life. This also puts them in a cycle of economic deprivation, for, in India, marriage is also sometimes a route to financial empowerment (although the high percentage of widowed, divorced, and separated disabled women indicates otherwise).

Although some disabled women in India have made successful marriages, disabled women have no role models or ideals in this area to emulate. Those disabled women who have been successful in marriage tend to negate their disability identity; as Ghai (2003) has observed in her examination of Meekosha's work, they are "reluctant to share their personal stories, in fear that they might be seen as spectacles" (p. 100).

For the status quo to change, so-called privileged disabled women must come out of their closets and prove by example that disability is not a barrier to experiencing sexuality, motherhood, love, and family life. The news and entertainment media need to be enlightened on this issue and motivated to play a more active role in challenging the stereotypes of disabled women by bringing to light positive instances and precedents. And above all, disabled women activists and scholars should discuss the issue of marriage more openly, lobby for the inclusion of disabled women in reproductive and child health programs, and seek to revise the feminist agenda so as to shatter the myths that disabled women are incapable of motherhood and of taking part in child-rearing activities. In India, marriage is as much a route to social rehabilitation for women with disabilities as it is an issue of their right to have family lives and to be mothers. Marriage is a rights issue for disabled women in developing countries as much as it is in developed countries. The only difference is that in developed countries, disabled women themselves have taken up the issue more forthrightly.

INDIVIDUALIZED EDUCATION PROGRAM (IEP)

According to Section 300.15 of the U.S. Department of Education federal legislation, the acronym IEP stands for *individualized education program.* Since the passage of the Education for All Handicapped Children Act (P.L. 94-142) in 1975, the IEP has been a mechanism for ensuring that students with disabilities up to the age of 21 receive a free appropriate public education (FAPE) in the least restrictive environment (LRE) that is individualized to meet their needs. The IEP process is also intended to hold educational systems accountable for student progress. An IEP initiates a process that is completed and guided through the creation of a document that communicates legal intent. In the United States, the Individuals with Disabilities Education Act (IDEA) of 1997 requires that an IEP be developed for every student with a disability who receives special education and/or related services.

Before any student is identified as having a disability, a comprehensive evaluation must be completed. This evaluation includes an assessment of the student's potential and achievement, home and social environment, biological development, and (if related areas of difficulty are observed) speech and language ability and fine and gross motor skills. An IEP is developed only if the identified disability has a negative impact on the student's learning and/or academic progress. In cases where the disability does not have such an impact, a section plan may be developed for the provision of accommodations and modifications in accord with Section 504 of the U.S. Rehabilitation Act.

A student's IEP is developed with information gathered by an interdisciplinary team through a comprehensive evaluation of the student. The IEP is designed to ensure that a student with any type of disability that affects his or her progress in learning receives specialized and individualized instruction. These outcomes are reached primarily through the development of annual goals and quarterly benchmarks. Goals and objectives are linked to individual student progress and are not based primarily on available professionals' services. Goals and objectives are developed with parental and student involvement and consider individual student strengths and needs. The parents are required members of the IEP team, and the student is also encouraged to attend and participate in planning sessions. Special education experts recommend that a student's IEP goals and objectives, not his or her disability diagnosis, be used to determine the service delivery setting. Furthermore, the model calls for services to be provided in the LRE, ensuring that students with disabilities are not segregated from nondisabled peers as a direct result of their disabilities.

The IEP process provides an opportunity for the individualization of educational services for students with disabilities. The IEP details individualized services and teaching that focus on the attainment of goals and objectives. Attention to individual student progress on set goals and objectives is intended to ensure that educators and service providers address the student's learning needs. Well-developed IEPs have the power to have a positive impact on students' learning if the services are implemented and interventions and progress are reviewed and revised on at least an annual basis. Although individualized education plans are not mandated for students in general education, many educational systems recognize the benefits that IEPs afford and are beginning to adopt such strategies for general education settings.

The IEP model is used in early childhood, elementary, and secondary school education. Thus, adults with disabilities do not benefit from IEPs in workplaces or in institutions of higher education. However, careful attention to including secondary school students with disabilities and their families in the IEP process can help to prepare these students to access services later, as adults with disabilities. Furthermore, adults with disabilities can use the IEPs developed during their school years to provide proof of disability when they desire to access services and resources from adult service agencies. The information contained in an IEP can potentially guide the creation of supports within higher education and/or employment settings.

The implementation of the IEP model has not been without challenges. Primary among these has been the ability of schools to include parents and students in the IEP process and obtain students' perspectives on transition issues. This issue of meaningful involvement arises in part because IEP team meetings often are held on weekdays, while the parents of affected students are at work. Parents may lack familiarity with the law and/or the school system and thus may be unaware of their rights. As students with disabilities approach adulthood, it is also increasingly critical to prepare them for their adult lives. While the IEP can establish a mechanism to promote this goal, affording students with disabilities an equal voice in the process demands a change in the culture of the school, which can be more deliberate than speedy.

Other significant concerns include creating individualized plans that are adjusted annually and changing schools so that students with disabilities learn in the least restrictive environment. School professionals who head IEP development are often responsible for many students, and it is frequently extraordinarily difficult for them to allocate sufficient time to the creation of goals that are adequately individualized to each student and updated regularly. A national teacher shortage in special education only adds to the difficulty of addressing this problem. Finally, school systems have been slow to develop environments that do not segregate students with disabilities from other students solely because of disability. It is important to note that the IEP process can be powerful in overcoming this challenge, at least at an individual level.

INDIVIDUALS WITH DISABILITIES EDUCATION ACT OF 1990 (UNITED STATES)

The Individuals with Disabilities Education Act (IDEA) is the title of legislation passed by the U.S. Congress in 1990 guaranteeing the right to free and appropriate education for children and youth with disabilities. The IDEA was the reauthorization of the Education for All Handicapped Children Act (EHA), which was passed in 1975 as the first separate federal legislation authorizing special education for children and youth. Previous legislation had included the legal basis for special education as early as 1965, but it was included in acts pertaining to elementary and secondary education. The EHA was reauthorized in 1986 and later as the IDEA in 1990 and 1997. As federal legislation, it requires states to provide specific services to eligible individuals with disabilities who are ages 3 to 21 and to have procedural safeguards in place to ensure that those services are in fact provided in an equitable and nondiscriminatory manner. Under the IDEA, children with disabilities are entitled to evaluations of their needs as the basis for individualized education plans (IEPs) and placement in the least restrictive environment (LRE) for their education. They are also entitled to the provision of related services, such as transportation, therapies, medical support, and assistive technology, to ensure that they receive maximum benefit from the educational experience.

Procedural safeguards are built into the legislation in the form of requirements for parental involvement in evaluation, planning, and placement activities; parental consent to school decisions; and parents' right to appeal decisions made about their children's placement. For children under three years of age, the 1986 reauthorization encouraged states to extend services under the IDEA to children from birth to age three, encompassing early intervention and support for families in their caregiving roles.

HISTORY OF THE IDEA

Prior to 1975, children and youth with disabilities in the United States were either denied education altogether or did not receive education appropriate to their needs. Children did not have a right to education, and schools could selectively refuse to admit any children they judged to be ineducable. The consequence was that only a fraction of children with disabilities were provided an appropriate education. In the 1960s and early 1970s, parents and advocates challenged the exclusion of children with disabilities from public education under the provisions of the equal protection and due process clauses of the Fourteenth Amendment of the U.S. Constitution. Two key cases were brought before the courts to argue for the rights of children with disabilities to equal access to education—*Pennsylvania Association for Retarded Children (PARC) v. Commonwealth of Pennsylvania* (1971) and *Mills v. Board of Education of the District of Columbia* (1972). The success of these cases was incorporated into the passage of the EHA in 1975, defining a free and appropriate public education for children with disabilities from the ages of 5 to 21.

The first reauthorization of the EHA occurred in 1986, with two important modifications. The first was the downward extension of the age range from five to three years of age for eligibility for special education. The second was the formalization of early intervention services for infants and toddlers from birth through age two years. In 1990, the EHA was reauthorized as the Individuals with Disabilities Education Act. The most recent reauthorization was in 1997, and it is likely that the reauthorization process will be repeated at regular intervals. Although the IDEA does not compel states to provide free and appropriate education for children with disabilities, it does require states to adhere to the specific elements of the act if they wish to receive federal funds.

ELEMENTS OF THE IDEA: SPECIAL EDUCATION

In the 1997 reauthorization of the IDEA, provisions are divided into four parts: Part A defines the various terms used in the law, Part B spells out the special education services required for children and youth ages 3 through 21, Part C describes requirements for the provision of early intervention services for children birth through 2 years of age, and Part D constitutes the capacity-building component of the law, in terms of how education and related agencies in states need to ensure the provision of special education and early intervention to all children needing such services. Part D also specifies the ongoing role of the federal government in ensuring the preparation of personnel by institutions of higher learning, the development of new instructional approaches and technology, and the conduct of research on effective practices.

The rights of children with disabilities as defined in the IDEA can be summarized as falling within the following major themes: eligibility, assessment, parent involvement, the IEP, LRE, and related services. In order to receive special education services under the IDEA, a child must meet the criteria for assignment to 1 of 13 categories defined in the act. Eligibility determination is based on individualized assessment carried out by qualified specialists and approved by a school-based team.

Eligibility Determination and Categories

Under the IDEA (1997), eligibility for special education encompasses children who are defined as

> (i) . . . children with mental retardation, hearing impairments, deafness, visual impairments including blindness, deaf-blindness, multiple disabilities, speech and language impairments, serious emotional disturbance, orthopedic impairments, autism, traumatic brain injury, other health impairments or specific learning disabilities and (ii) who by reason thereof, need special education and related services.

Following referral by a parent or by health care or school professionals, a child is given an evaluation appropriate to the referral to determine whether he or she meets the criteria for 1 of the 13 categories. Eligibility was expanded beyond these 13 categories in the 1997 reauthorization to include children ages three to nine years

> (i) experiencing developmental delays as defined by the State and as measured by appropriate diagnostic instruments and procedures, in one or more of the following areas: physical development, cognitive development, communication development, social or emotional development or adaptive development and (ii) who by reason thereof, need special education and related services.

In contrast to the 13 categories, the use of developmental delay as the basis for special education eligibility is at the discretion of individual states and is variably implemented.

Assessment

Comprehensive assessment is carried out to identify the nature and extent of a child's need for special education. Such assessment involves a school-based team, the members of which include a school psychologist; physical, occupational, and speech therapists; and teachers in both regular and special education. The assessment may involve the use of standardized tests, observation, parent interview, and professional judgment. Every child who is found to be in need of special education is reevaluated at three-year intervals to determine whether he or she continues to be eligible for one of the categories and thus eligible to receive special education services.

Individualized Education Plan

The IEP provides a yearly specification of goals for the child and a road map for the services the child needs in order for appropriate learning to occur. The IEP is produced by the school-based team in conjunction with the child's parents and the child whenever possible. It is a living document that is used for periodic review of the child's progress. In addition, the IEP should be seriously reviewed each year in which the child is in need of special services, as it is important that the next year's plan reflect evaluation of the child's progress each year. If the child has not made progress, it is important that the IEP reflect changed expectations, alternative educational interventions, or a combination of the two.

Parent Involvement

Parents are deemed to be partners with school staff in crafting the child's IEP. They are supposed to be involved at each step of the process, and the IDEA provides them with recourse to school- or system-based mediation if they have differences with the school over the child's plan. If resolution is not achieved through these means, differences between parents and the school can be dealt with through due process.

Least Restrictive Placement

The IDEA's underlying principle for student placement is full inclusion—that is, a child is to be placed in the setting that will allow him or her the greatest participation with peers of the same age without disabilities. The nature and extent of inclusion of the child's placement is spelled out in the IEP.

Related Services

In addition to direct instructional accommodations to meet the child's educational needs, other services that are needed to improve the child's performance in school are also provided under IDEA. These services may include physical, occupational, and speech therapy as well as the provision of assistive technology. Environmental accommodations may also be provided under Section 504 of the act.

IMPLEMENTATION ISSUES

Accountability

Under the IDEA, documentation that special education is beneficial for children and youth with disabilities has taken two forms. The first is the monitoring of each child's progress on an annual basis with a review of the goals spelled out under the IEP. This typically leads to revision of the goals defined for the child in the IEP. The second form of accountability is the expansion of the participation of children and youth with disabilities in the large-scale assessments carried out for general education students. In this context, special accommodations may be made for students with disabilities; for example, they may be provided with additional time and/or modified materials to allow them to complete the annual tests taken by all students. As noted earlier, due process is another form of accountability for the child.

Transition

In addition to education services, students with disabilities are also eligible under the IDEA for individualized transition plans to assist them in making the move from school to the community. This is a crucial process and may begin during early adolescence although children may continue in special education through the age of 21 years.

INDUSTRIALIZATION

Industrialization is the process by which manufacturing displaces agriculture and commerce to become the dominant economic activity in a society. Driven by inanimate sources of power, industrialization allows the concentration of machines in factory settings and their regular, reliable deployment. In Britain—the first industrialized nation—this transformation was initially understood as a cataclysmic event. Subsequent interpretations have stressed the long-term origins in the breakdown of the feudal system and the emergence of capitalist modes of production and exchange, particularly associated with the growth of towns since the late seventeenth century. Revolutions in commerce, transport, and agriculture consolidated these developments. During the 40 years after 1660, Britain's foreign trade increased by more than a third, generating unprecedented prosperity. By 1760, long before the mid-Victorian railway boom, an impressive network of canals and turnpike roads was springing up, and simultaneous improvements in agricultural productivity not only freed up labor for industrial purposes but also prevented inflationary food prices, thus releasing surplus income for the purchase of manufactured consumer goods.

Entrepreneurs, who thrived in Britain thanks to the stimulus of religious nonconformity and the potential for social mobility, faced few constraints in exploiting these economic conditions. The lax enforcement of apprenticeship regulations, for instance, aided the recruitment of new workers, and landowners and merchants had little difficulty in financing ambitious projects despite legislation intended to discourage irresponsible speculation. Consequently, for almost a century prior to 1780—the traditional starting point of the Industrial Revolution—real national income in Britain was expanding at an average rate of 0.70 percent each year. This indicator peaked at a mere 1.97 percent during the decades of fastest growth between 1801 and 1831. None the less, the accumulated effects of this gradualism were dramatic. In 1760, agriculture and related economic activities accounted for 37 percent of British national income; by 1871, the proportion had slumped to 14 percent. Conversely, manufacturing, mining, and building had escalated in importance, explaining just 20 percent of national income in 1760 compared with 38 percent in 1871. The factors shaping this particular experience were not exactly replicated elsewhere. In the second half of the nineteenth century, however, the Industrial Revolution spread to other areas of Europe, the United States, and Japan, ending Britain's tenure as the "workshop of the world."

Industrialization has been pivotal to the social model of disability and its location of disability—as opposed to impairment—in the material and ideological organization of modern societies. In 1980, Vic Finkelstein blamed new productive technologies for the rise of the segregated institution; the production lines of big industry were designed to fit able-bodied norms and thus shut out disabled people, who had previously been integrated and socially active members of their classes and communities. Michael Oliver (1990) later put forward a more detailed case, arguing that whereas full-fledged capitalism was exclusive, agriculture and small-scale industry did not prevent most disabled people from being economically active. Most recently, Brendan Gleeson (1999) has suggested that bodily impairment, an accepted and constituent element of medieval peasant life, became problematic only when industrial workplaces severed the connection between home and employment and began to discriminate against uncompetitive workers.

Like the heroic reading of the Industrial Revolution, however, the assumption that premodern societies were friendly to disabled people neglects the significance of incremental change. Long in advance of industrialization, the religions and cultures of ancient Greece and Rome, and the art and literature of Renaissance Europe, were constructing impairment in a pejorative light. Work was also a preoccupation before the Industrial Revolution. In early modern Britain, for example, the Tudor Poor Law struggled to distinguish "deserving" from "undeserving" or work-shy applicants. Similarly, letters recommending patients for admission to eighteenth-century hospitals such as the General Infirmary at Bath stressed the contributions of these individuals to their households' economies. For men, the emphasis was on paid employment: For instance, Newton Highhorn, a painter of 20, had been "greatly afflicted" by lead poisoning and had "so far lost the use of his hands as to be disabled from working at his trade or earning his bread." For women, the emphasis was on family responsibility: Mary Coombs, a married woman of 32, had experienced severe rheumatic pains for six months and was "now in great measure disabled and incapable of performing the usual labour for the support of her family" (Bath City Record Office 1750–1758). Regardless of gender, impairment was represented as a deficiency with damaging economic consequences.

Although disabled people were economically marginalized before the Industrial Revolution, the raft of changes that followed in the wake of industrialization transformed their predicament. Economic changes were themselves a cause of impairment because industrial enterprises polluted the human environment and led to workplace injuries and diseases. Furthermore, the inequalities that motivated the capitalist economy bred impairments that were correlated with social deprivation, such as rickets, tuberculosis, and infantile paralysis. Governments wedded to the virtues of private enterprise were slow to regulate the harmful effects of industrialization, and disabled people disadvantaged in the labor market had no option but to exist on meager incomes or parsimonious poor relief. The Great Depression of the 1930s compounded their financial difficulties. Conversely, World War II temporarily opened up job opportunities as able-bodied workers joined the armed services. After 1945, however, the employment policies implemented in industrial societies were largely ineffective in achieving economic inclusion. Even the British welfare state—celebrated for its health provision—offered little more than a minimally enforced quota of disabled employees.

The industrial societies that were inhospitable to impairment underwent profound social and political changes, although the changes were sometimes slow in coming. One example is found in the social implications of the factory system, often regarded as the emblem of the Industrial Revolution. As late as 1851, only 6 percent of the total labor force was working in textile factories, the sole employment sector where this mode of production had made significant inroads, and principal cotton workers continued to recruit their relatives to factory teams, preserving a reduced economic role for the formerly self-sufficient preindustrial family. Nevertheless, the adoption of heavy machinery did ultimately entrench a geographic separation of home and work that became a defining feature of industrial societies.

Andrew Scull (1993) has linked such change in family life to the rise of the segregated institution. Examining madness in nineteenth-century Britain, he concluded that the relatives of the mentally ill were compelled to incarcerate them because industrialization had eroded families' capacity to provide care. In sprawling industrial cities social networks were fragile, but smaller industrial towns developed complementary support mechanisms through workplace clubs, friendly societies, and cultural groups. Therefore, factors aside from industrialization explained the asylum, not least the appearance of a psychiatric profession with a scientific discourse on insanity and, later, mental deficiency. Other medical specialists endorsed the confinement of physically disabled people, reinforcing the influence of the eugenics movement. The voluntary sector was a pioneering supplier. As industrial states became more interventionist, however, the health and welfare professions increasingly collaborated with the public sector to deliver institutional solutions.

Although industrialization did not invent the work ethic, its protection through low taxation was perceived as essential to a thriving economy. In the "developing" world, where the modern plants that permitted extensive industrial production were not widely dispersed, the resources had never been available to build expensive institutional infrastructures. In the industrialized world, however, from the second half of the twentieth century concerns about costs encouraged community care as a cheaper, and more humane, alternative to institutional provision. At the same time, industrialization was entering a new phase. Manufacturing was being overtaken by the service industries, the benefits of limitless economic growth were being challenged, and innovative technologies were transforming the acquisition, processing, and distribution of information. Sociologists debate whether these postindustrial societies are now postmodern. Work has indeed been reconfigured by the information revolution, the welfare state has been fragmented into a mixed economy with charitable and commercial as well as statutory inputs, and professional power has been weakened by a loss of faith in scientific rationalism. But for disabled people there is no escape from the discrimination that is a characteristic of industrialization.

—Anne Borsay

INFANT STIMULATION PROGRAMS

Infant stimulation is a form of sensory enrichment that is used with clinical populations (i.e., at-risk and disabled) of infants as well as nondisabled (i.e., healthy) infants. For at-risk infants, infant stimulation is a process of providing supplemental sensory stimulation in any or all of the sensory modalities (visual, auditory, tactile, vestibular, olfactory, gustatory) to an infant as a therapeutic intervention. The intervention uses supplemental stimulation to compensate for the lack of normal/typical environmental sensory stimulation or the presence of abnormal/atypical environmental sensory stimulation. For example, sick infants born prematurely and hospitalized in a neonatal intensive care unit (NICU) are exposed to high levels of intense and aversive sensory stimulation related to necessary medical care (e.g., venous and arterial punctures, heal sticks, injections) and the general NICU environment (e.g., intense lights and alarms). Further, these sick infants do not receive the same caregiver stimulation and interaction that healthy full-term infants generally receive from their parents in the home environment.

Infant stimulation programs are instituted to compensate for the atypical sensory stimulation of NICU hospitalization. Such programs include the administration of sensory stimuli—including tactile (e.g., touching, rubbing, massage), vestibular (e.g., rocking, positioning, picking up), auditory (e.g., soft music, human voice), and/or visual (e.g., high-contrast pictures, mobiles) modalities—by nurses or therapists. The stimulation may be unimodal or multimodal and is usually presented on a regular schedule for specific amounts of time (e.g., 30 minutes per day for 20 days). The most frequently used stimulations are tactile, vestibular, and/or auditory, administered to approximate the stimulation the infant would have received in the womb. As the sick infant gets older and healthier, visual stimulation is added, and the program is modified to approximate the typical sensory environment of the home and caregiver.

Much of the research that has evaluated the efficacy of these types of infant stimulation procedures (e.g., regularly scheduled presentation of sensory stimuli) with sick preterm infants has generally been of poor scientific quality (e.g., use of heterogeneous groups, lack of control groups), and even the most scientifically sound studies have found little evidence of effectiveness. Thus, infant stimulation programs are currently evolving to be more "infant centered" and to have an important "social-psychological component" (SPC). Infant-centered programs focus on the infant's communication to the caregiver about the types and amounts of sensory stimulation the infant can tolerate (e.g., an infant's eye-to-eye contact with a caregiver indicates tolerance of the stimulation, whereas the infant's looking away from the caregiver indicates lack of tolerance). This allows the caregiver to cease stimulation of the infant prior to the infant's becoming "overloaded" (homeostatically challenged and dysregulated); additionally, the caregiver can recognize the signals of the infant's readiness for stimulation. The SPC of infant stimulation programs includes the use of the infant's own primary caregiver (e.g., mother, in contrast to nurse or therapist) as the provider of the sensory stimulation. The caregiver administers stimulation interactively with the infant, modulating the stimulation by reading the infant's communication of tolerance levels and preferences for the sensory stimuli. This component adds a more natural interaction between the caregiver and infant and facilitates the caregiver's understanding of the infant's behavioral capacity and potential. The infant-centered focus and SPC of NICU infant stimulation programs are also applicable to impoverished infants and their families, as well as other at-risk subgroups.

For healthy infants, infant stimulation enrichment programs generally include early experiences with classical music, being read to, educational play, home schooling, and participation in organizations such as Parents-as-Teachers. One of the major rationales for infant stimulation programs for both atypical and typical infants is based on the plasticity of the nervous system. Neuroplasticity is the ability of the nervous system to change throughout the lifespan. Research with a variety of species, including humans, indicates that the brain can change (e.g., growth of nerve cells, generation of new nerve cells, increases in neural connections and circuits) as a function of use and experience (e.g., using fingers to learn computer keyboarding, being challenged by enriched and complex environments). The ability of sensory experience to modify the nervous system has been shown to be greater for infants than for adults, because of the high nervous system growth rates already present during early development. There is also evidence that certain sensory experiences are required during important periods for normal development of the nervous system. The visual system, for example, requires "early visual experience" for normal structural and functional development of the visual cortex that enables form and depth perception. Research also indicates that sensory stimulation is important for brain and behavioral development of brain-injured populations. Thus, the importance of infant stimulation is becoming well established; current research questions are focusing on evaluating different types of stimulation, when and how stimulation should be administered, how much stimulation infants should receive and how often, and who is best suited to provide the stimulation, for different infant populations.

Infants, as well as adults, are constantly being bombarded with sensory stimulation during both waking and sleeping hours. Nevertheless, infant stimulation programs seem particularly beneficial for at-risk and disabled infant populations, and these programs continue to be an important focus of clinical and research attention as well as public interest. Although infant stimulation programs often supplement sensory stimulation to counter sensory deprivation, they may also focus on reducing sensory stimulation based on sensory appropriateness.

Modern interest in infant stimulation programs was energized in the 1940s when Rene Spitz showed that long-term hospitalization of infants with little or no stimulation was associated with abnormal behavioral development. Similarly, in the 1950s Harry Harlow showed that monkeys raised in isolation (i.e., without maternal stimulation) displayed abnormal development. These findings, coupled with the relatively long-term hospitalization of sick infants in NICUs, indicated a potential need for infant stimulation programs to promote normal development. However, hospitals and agencies throughout the world differ considerably with regard to their use of infant stimulation programs.

As therapeutic interventions in NICUs, infant stimulation programs became relatively popular in the 1970s. However, these programs began to evolve dramatically during the 1980s, and that evolution continues today. In the 1970s, medical practice was expanding to allow increasing use of infant stimulation programs, especially for infants born prematurely who were isolated within NICUs. This was based in part on two realizations: that the long-term hospitalization of infants born prematurely was generally associated with a high frequency of invasive medical procedures that were disruptive and painful to these infants (e.g., aversive conditioning or learning) and that the general hospital environment was associated with forms of environmental stimulation that were considerably different from those found in the home and family environment. Thus, early stimulation programs with preterm infants were designed to overcome the abnormal sensory environment of the NICU. The earliest programs focused either on mimicking the environment of the womb (e.g., use of water beds to provide for tactile and vestibular stimulation) or on correcting the sensory deprivation or abnormality of the NICU environment. An important finding of early research was that some types of stimulation procedures (including typical medical procedures) could actually be harmful to infants (e.g., producing hypoxemia). Such findings led to major changes in the form of infant stimulation programs. Since the 1980s, and continuing through the present time, programs have been moving away from the simple presentation of unimodal or multimodal sensory stimulation to infants on some arbitrary timing and intensity schedule. In recent years, many infant stimulation programs have moved toward infant-centered and SPC approaches. Another important change, brought about by the movement toward infant- and family-centered care in the NICU, has been the reorganization of the timing of medical procedures and nursing care. Rather than having medical procedures administered to infants at any time throughout the day, these procedures are now grouped together within short periods so that infants can experience longer periods without aversive stimulation and increased time in interaction with caregivers.

Thus, the evolution of infant stimulation programs toward infant- and family-centered approaches is providing infants with meaningful sensory stimulation with a social-psychological component within the NICU environment. Such programs maximize the opportunity for attenuation of aversive sensory stimulation to facilitate optimal growth and development. Future research on infant stimulation programs will include a focus on determining the effects of infant- and family-centered approaches on the short- and long-term development of at-risk infants.

INFANTICIDE

The ancient Greeks and Romans practiced exposure, the discarding of unwanted infants. Because it is often assumed that disabled babies were unwanted babies, the issue of exposure is intimately connected to the question of physical disability in the ancient Graeco-Roman world. That the Greeks, especially the Spartans, regularly disposed of newborns with visible physical anomalies was commonly accepted in nineteenth- and twentieth-century scholarship and popular culture. For example, in *Should the Baby Live? The Problem of Handicapped Infants* (1985), Helga Kuhse and Peter Singer write that infanticide was common among the Greeks and Romans, and that the recommendations of the philosophers to destroy defective infants "would not have seemed anything out of the ordinary to their contemporaries" (p. 111). A deeper inquiry, however, reveals that the source material is far too thin to support the drawing of such certain conclusions. More important, it is misleading to superimpose modern social, economic, religious, and military assumptions about the value of disabled people on the ancient world.

The Greek material that discusses or alludes to the exposure of deformed infants is limited, comprising five short passages ranging from the fourth century BCE through the second century CE. Two of these passages are from the works of Plato, and there is one each from Aristotle, Plutarch, and the second-century physician of the Roman imperial period, Soranus. The sources that discuss deformed offspring in the ancient Greek world are too sparse to support the conclusion that the exposure of such infants was standard practice; in fact, there is evidence that children born with disabilities survived. For example, the fifth-century BCE tragedian Sophocles has the chorus in *Oedipus at Colonus* ask

Oedipus if he had been born blind (lines 148–149). Roman primary sources are also scant. Robert Garland (1995) finds instances of "defective" babies' survival, and adds that "there are . . . indications of a somewhat sympathetic attitude towards deformed infants in the Roman Imperial period" (p. 18).

For discussion of the exposure of children with physical disabilities in the ancient Greek world, see my book *The Staff of Oedipus* (Rose 2003), and regarding the Roman world, see Robert Garland's *The Eye of the Beholder* (1995). Good literature on ancient infanticide in general includes articles by Marc Huys (1996) and Cynthia Patterson (1985). Ruth Oldenziel (1987) traces and discusses the secondary literature on infanticide in Greece in her chapter in a collection titled *Sexual Asymmetry,* and John Boswell summarizes the literature for Rome in his book *The Kindness of Strangers* (1988:40–41, n. 96).

Modern assumptions about the economic worth and aesthetic appeal of deformed people, cloaked in the standards of medical health, do not provide an appropriate framework of interpretation for the evidence about the lot of anomalous infants in the ancient Graeco-Roman world.

INFECTIOUS DISEASES

Infectious diseases and disability are intricately linked in terms of both causal relationships and complicating factors. In considering these issues, it is helpful to distinguish between those infectious diseases that cause disability and those that complicate preexisting disability.

Ample evidence links certain infectious diseases to the onset of disability in previously able-bodied individuals. Well-known examples include the profound central motor and cognitive neurological disabilities resulting from viral brain infections (e.g., St. Louis encephalitis and West Nile virus infection) and from overwhelming bacterial infections of the brain and/or its coverings (e.g., syphilis, meningococcal infection, and Rocky Mountain spotted fever). Certain other infections when suffered in pregnancy are implicated as important causes of long-term disability in the neonate, such as the so-called TORCHES group of infections (toxoplasma, rubella, cytomegalovirus, herpes simplex virus, syphilis). A progressive inflammation of the nerves (e.g., an ascending polyneuropathy such as Guillain-Barré syndrome) is often seen as a postinfectious complication following a viral or bacterial infection (classically seen after campylobacter diarrhea). Additionally, some investigators have proposed an infectious etiology for such disabling illnesses as multiple sclerosis, diabetes mellitus, and chronic fatigue syndrome, although these linkages are controversial. Finally, it is important to note the disabling nature of chronic, long-term infectious syndromes such as AIDS, hepatitis C, tuberculosis, and certain parasitic diseases such as filariasis or malaria, which clearly have negative impacts on quality of life and impair sufferers' ability to perform daily activities.

Perhaps more immediate and of greater day-to-day consequence for both patient and clinician is the extent to which disability predisposes individuals to acute and chronic infections. In general, disability serves to impair the normal host's natural defense mechanisms against invasion by microorganisms, thereby increasing the likelihood of colonization and subsequent pathogenic transformation. Integrity of the body is dependent on satisfactory functioning of host defense strategies. When these are impaired, infectious complications commonly develop. Bacterial colonization of normally sterile sites leads to acute and chronic infection. Repeated treatment with antibiotic medications preferentially selects for the persistence of resistant organisms, making future treatment more difficult. Conditions that impair the host immune response (e.g., diabetes, cancer, AIDS) place the individual at increased risk for infection with unusual or difficult-to-treat organisms.

Respiratory, genitourinary, and integumentary systems are most crucially at risk for infection in the disabled, with those structures at particular risk being dictated by the nature of the host disability. For example, clearance of bacterial pathogens from the upper respiratory tract is facilitated by adequately functioning cilia, and individuals with impaired ciliary function (as in chronic obstructive pulmonary disease) are at greater risk for bacterial colonization and development of recurrent lung infections. Genitourinary tract integrity is preserved through the maintenance of urine production and flow through the kidneys, ureters, and bladder. Impairment of flow leading to urinary stasis (as in persons with neurogenic bladder due to spinal cord injury) predisposes the individual to bacterial colonization and urinary tract infection. Catheterization of the bladder is another complicating factor, inasmuch as bacteria adhere to and are introduced into the urinary tract with the catheter. In general, the use of an indwelling catheter presents a greater long-term infectious risk than chronic intermittent catheterization for those patients requiring repetitive bladder drainage. Finally, disability may predispose skin and soft tissue structures to breakdown due to chronic pressure on particular dependent or insensate areas of the body. Ulcerations that develop at these pressure sites are at risk for colonization and invasive infection and may lead to deep-seated infection of underlying structures (e.g., osteomyelitis).

Treatment of infections among the disabled should be tailored to the particular circumstances of the host and should take into consideration the nature of the host disability, the body system involved, the specific pathogen being targeted, and the acute versus chronic nature of the infection. Certain infections, once established, may become very difficult to cure, requiring instead suppressive therapy to control and limit progression. Other infections may require combined medical and surgical approaches to achieve cure. With this in mind, caregivers need to anticipate potential infectious complications and seek to implement preventive measures to avoid serious outcomes.

INFERTILITY

Infertility is typically defined as the inability to become pregnant after a year of having intercourse without contraception. The American Society for Reproductive Medicine (ASRM) and RESOLVE, the principal advocacy organization for the infertile, describe infertility as a "disease" that hinders "the body's ability to perform the basic function of reproduction." Ordinarily, however, infertility is considered a *condition* that might be caused by one or more diseases. In women, some examples of such diseases are endometriosis (in which the tissue that lines the uterus grows outside the uterus), polycystic ovary syndrome (in which the follicles in which the woman's egg is enclosed mass together to form a cyst, and no mature egg is released), and premature ovarian failure (in which a woman under age 40 no longer produces ova). Among men, infertility can result from mumps experienced after puberty, certain infections (e.g., prostatitis, orchitis), and diseases of the pituitary or hypothalamus, all of which can reduce or destroy the capacity to produce sperm. Various testicular injuries as well as chromosomal abnormalities and those of the testes, such as cryptochrodism (failure of the testes to descend into the scrotum), cancer, and direct trauma, are also among a range of conditions that can cause male infertility. Infertility is distinct from surgical sterilization, which was once used as a form of state-sponsored social control, but today—at least in the United States—is more often a voluntary procedure.

The term *infertility* is of relatively recent origin. American colonists in the seventeenth and eighteenth centuries used the word *barrenness* to describe the inability to bear children. Only a woman could be barren; any man capable of sexual intercourse was automatically deemed fertile. In the nineteenth century, especially as gynecologists became more prevalent in treating the condition, the term *sterility* came into common use. The terminology was important; *sterility* conveyed the growing medical conviction that men as well as women were affected. As early as the 1860s, a few physicians advocated the microscopic analysis of semen, and by end of the nineteenth century several prominent gynecologists began to urge husbands to be tested, although many men refused to subject themselves to what they considered an outrage against their masculinity. *Infertility* gradually replaced the older term in the 1940s and 1950s, as optimism about treatment soared. Most experts currently believe that about a third of infertility cases are caused by conditions that affect men and another third are caused by those that affect women, with the rest attributable to both halves of the couple. About 20 percent of cases, overall, remain unexplained.

Authorities nowadays generally agree that infertility affects about 10 percent of the population. In spite of a widespread perception that infertility rates rose dramatically in the late twentieth century, the 10 percent figure is consonant with estimates made in the late nineteenth and early twentieth centuries. The national fertility studies begun in the United States in 1965 put the infertility rate at 11.5 in the 1960s and 8.5 in the 1980s, albeit with a rise in primary infertility and a decline in secondary infertility. (*Primary infertility* is the term used to describe those couples who have never been able to conceive or carry a pregnancy to term. *Secondary infertility,* once called *one-child sterility,* describes couples who have borne children but are no longer able to do so.)

Most cases of infertility are treatable by conventional medical techniques, including surgery, artificial insemination (practiced since the nineteenth century), and the use of ovulation-inducing therapies. However, an estimated 15–17 percent of the infertile make use of assisted reproductive technologies, 99 percent of whom undergo in vitro fertilization using their own or donor eggs. In vitro fertilization may be accompanied by ICSI (intracytoplasmic sperm injection), a technique that seeks to compensate for male subfertility through the injection of a single sperm directly into the woman's egg. Whether the treatment is low-tech or high-tech, about two-thirds of the infertile are able to achieve biological reproduction. The other third may circumvent their condition through adoption or surrogacy or learn to live with it.

Infertility can have profound social, cultural, and psychological effects on those who have the condition. Societies everywhere assume that women want to become mothers, and women who choose not to have children, or who fail to express maternal feelings, frequently face social opprobrium. In turn, those who long for children and are unable to bear them often feel that they have been denied a fundamental right, the "right" to reproduce. Although infertility affects men just as often as it does women, social scientists have discovered that women in infertile unions often find their situation intolerable, a threat to their fundamental identity as women. Men, in contrast, tend to be disappointed but not devastated. Many who fruitlessly yearn for children often internalize a profound feeling that their bodies have betrayed them. In this sense, then, infertility might be viewed as a psychological disability as well as a social and medical condition.

INFORMATION TECHNOLOGY

Information technology (IT) may be seen as both enabling and disabling. From the earliest days of computers, people with disabilities have been integrally involved with this technology, yet it has continued to be shaped by nondisabled norms. As computers and other IT developed and became ubiquitous features of work, education, home, and everyday life, they developed a profound role in the shaping of ability and disability. People with disabilities began to make their mark as users of IT with the advent of the personal computer (PC), although the accessibility of the technology was limited. Although accessibility has increased, barriers remain, and new forms of IT have been disabling as well as enabling. Disableism is ever present in the ideologies, structures, and power relations that are part of, and inform, IT. Nondisabled designers often incorporate disability in the technology through taken-for-granted norms.

THE RISE OF THE PERSONAL COMPUTER

The early computers that featured in the advent of commercial computing after World War II operated with punch cards, which required of users the manual dexterity associated with card readers and other input devices. Herman Hollerith, who devised the punch cards used for processing and tabulating data in the 1890 U.S. Census, is said to have had great problems learning spelling, something that might be regarded today as a learning disability. In 1896, Hollerith founded the Tabulating Machine Company, which later became International Business Machines (IBM).

In the early 1970s, the invention of the microprocessor displaced both mainframe and minicomputers and led to the rise of the personal computer in 1974–1975. The PC's development paralleled the increasing role of IT in everyday lives. The basic PC unit was built around particular norms of design, code, and input and output, requiring people to conform to those norms. The PC needs of people with disabilities led to a set of contests regarding three key technologies: hardware, operating systems, and applications.

Specialized assistive technology, both hardware and software, emerged for people with disabilities. This showed the potential range of input and output devices that could be used in conjunction with computers, such as Braille embossers to create documents readable by blind people and hardware and software for speech synthesis (e.g., the 1976 Kurzweil Reading Machine). Yet such developments also raised the political and practical question of whether disability demands special or mainstream solutions. The consumer and disability movements took an early lead, for example, when they formed the Committee on Personal Computers and the Handicapped in Illinois in 1981.

Breakthroughs in the accessibility of mainstream computing proved elusive. Apple introduced the Macintosh computer in 1984, and although many acclaimed its graphical user interface as user-friendly, and it greatly influenced the development of its now ubiquitous Windows counterpart, for some users with disabilities, such as blind users, it was not ideal. However, Macintosh took an early lead in incorporating accessibility into its operating system.

In contrast to the graphical interface, the MS-DOS operating system was a text-based platform that worked in conjunction with text-based programs such as early versions of Word and WordPerfect. Computer users who were blind or vision impaired could use screen readers that would speak the text of DOS files.

Many hailed Microsoft's relatively late introduction of a graphical user interface with Windows (especially its successful 1990 Windows version 3) as a breakthrough, but blind and vision-impaired users viewed it as a great threat. The move from text-oriented DOS-based to graphical Windows-based computer operating systems resulted in serious losses in access and jobs for persons using speech or Braille for communication.

Corporate initiative alone was not sufficient to stimulate the development of products to increase IT accessibility for people with disabilities, so activists used other strategies, such as lobbying for legislative protections. One result was the inclusion of IT requirements in the Americans with Disabilities Act (ADA) of 1990. Also critical was Section 508 of the 1973 Rehabilitation Act, which requires that information technology procured, developed, maintained, and used by federal agencies must be accessible to people with disabilities unless such requirement imposes an undue burden. Effectively, U.S. federal and state governments could use their purchasing power to encourage companies to make IT accessible. Activists in Massachusetts took the lead, lobbying the state government to use Section 508 to require the purchase of accessible computers.

The IT industry took several years to develop adequate accessibility strategies for Windows software, with little interest among mainstream software developers. In the early 1990s, Microsoft had only one person working on accessibility issues. Even as late as 1998, the company shipped Internet Explorer 4.0 with fewer accessibility features than had been in the previous version. The disability movement had to fight pitched battles with Microsoft before the company began to incorporate accessibility features in its operating systems and programs.

Despite positive corporate moves in this area, accessibility remains a threshold issue. Accessibility is vital for the incorporation of people with disabilities into computing technology, and thus the information society.

COMPUTER NETWORKING

The networking of computers through telecommunications to share resources, exchange data, and facilitate communications developed from the 1960s. In the 1980s, with the growth of bulletin boards, private networks such as America Online (AOL) and Compuserve, and the spread of the Internet, people with disabilities started to communicate and to share computer files online. Blind people as well as other people with disabilities were among the early Internet pioneers.

Disability accessibility has been a key issue for networked IT. In one important test case, a group of blind people invoked the ADA to force AOL to adopt accessibility measures. After requesting that AOL provide accessible Internet services for a number of years, the National Federation of the Blind filed suit against AOL in November 1999. Negotiations commenced, and the suit was suspended in July 2000 when AOL agreed to make its software accessible by April 2001.

Accessibility has been an integral feature of the design and deployment of the World Wide Web since the launch of the World Wide Web Accessibility Initiative (WAI) in April 1997. The WAI has raised the level of awareness of disability accessibility issues within the Internet community, especially among those who design and implement web pages. In principle, information on how to make web pages accessible is easily available—online. W3C is a consortium of organizations that work together consensually and issue recommendations regarding online accessibility. However, it is left to others to implement those recommendations, and many organizations do not. Hence the accessibility of the Internet for people with disabilities remains quite precarious (as is illustrated by the 2000 case of *Maguire v. Sydney Organising Committee for the Olympic Games*).

IT EVERYWHERE

IT has become pervasive in everyday business and private life in developed countries, and it is arguably a more subtle form of colonization in developing countries. Computer processors feature not only in PCs and modems, but also in media and communications devices (from televisions and radios to personal digital assistants, cameras, and mobiles), household appliances (refrigerators, ovens, alarms, lights, heaters), cars, and clothes (wearable computers). The average home in the twenty-first century is soon likely to contain hundreds of computer processors, with many of these devices likely to be connected to computer networks.

Information technology now actually has impacts on every major form of technological system utilized in Western society, incorporating norms that are rarely critically examined. The vision of the “smart home” and the “information society” is slowly being realized, and the convergence of the different sorts of IT involved presents important disability-related issues. To date, some IT companies, designers, and policy makers have reluctantly gained an understanding of the diverse expectations and needs of various people with disabilities. As IT is increasingly woven into the fabric of everyday life, accessible technology becomes all the more imperative because other alternatives may disappear. A further difficulty lies in the proliferation of different IT devices and applications, only some of which incorporate accessibility.

DESIGNING IT FOR DISABILITY

People with disabilities are often mentioned as being among the primary beneficiaries of IT, yet more often than not they are actually neglected in IT development. Sophisticated use of IT is providing smart homes and enabling lifestyles for people with severe disabilities, but such technology remains costly for individuals and society. In general, the potential uses of IT by people with disabilities are not systematically incorporated into the design, implementation, and marketing of IT products. Accessible IT still tends to be achieved through costly and tardy specially built solutions and retrofitting rather than through development that envisages disabled users and builds accessibility into mainstream design. Some innovative work has occurred around disability and design, including under the banner of universal design, but the issues of designing IT for all people with disabilities are complex, requiring an integrated approach, from invention and standards setting to manufacturing, procurement, promotion, marketing, product delivery, and training.

INSPIRATION

Inspiration is a popular-culture ritual that signifies the partial, ambivalent identification of normals with disabled people based on the willful “overcoming” of the putatively devastating effects of disability. In ubiquitous, stylized media stories presented by and for a normal perspective, disabled people are held up as (pseudo-) role models for refusing to quit against the overwhelming odds assumed to be posed by their own disabilities; rather, inspirers courageously mobilize their wills to superhuman heights, persevere, and overcome their disabilities, thereby pointing to and proving the existence of the “power of the human spirit.” Neither the specific activities themselves nor the skill with which they are performed is important to the inspirational relation, which can be invoked any time normals encounter disabled difference. Disabled people may thus be marked as inspirational for any participation whatsoever, from mountain climbing while blind to playing the piano with a mental illness diagnosis to shopping while using a wheelchair. All such activities represent the contradiction of patterned social expectations, namely, that the “normal” response to disability would be bitter, angry surrender.

To *inspire* literally means to “breathe into” another person, to have an animating or exalting influence on, and the concept of inspiration surely exists in some form in all societies. Traditionally, inspirational forces were traced either directly or indirectly back to the divine, but the secularizing trends of modernity have centered the unified, self-directing will of the individual. Stories about inspirational role models (e.g., Martin Luther King Jr., Mother Teresa) stand in for the divine in their selfless transcendence for the common good. Identification with such inspirers supposedly allows admirers to achieve by overcoming resistance, both external and internal.

Disability inspiration became prominent in the twentieth century and appears (its history has not been written) to draw on facets of nineteenth-century Victorian sentimentalism and the ideology of the freak show. From the latter, inspiration preserves conformist normality's horror before otherness—indeed, it collapses without it—along with an identificatory fascination regarding "How do they do it?"; from the former, it continues the narcissistic self-congratulation of beneficence before social inferiors while subtly shifting its point of identification from empathic understanding to willful overcoming.

In its valorization of a similar, if extraordinary, human will thought to reside within its objects of admiration, disability inspiration reflects a generalized advance in social status for people with disabilities. Although cross-cultural comparisons await, it would seem unlikely that disability inspiration can exist in societies in which disability presents as uniformly and overwhelmingly negative.

Nevertheless, as scholars such as Paul Longmore (2003) and Beth Haller (1999) have noted, disability inspiration places a drag on the quest for equality: It functions to deny *social* oppression by individualizing disability and maintains deviance by presuming an inability that must be "overcome" through "supercrip" achievement. Disabled people tokenized as inspirational also become ideological hammers against the rest of the group, for if one can succeed, why can't the rest? Inspiration is thus fundamentally reactionary and works against political solutions. In the end, inspiration reveals itself as a relationship of bad faith, wherein what disabled people supposedly overcome is precisely what has been done to them in the first place.

INSTITUTIONALIZATION AND SEGREGATION

The writer Jack London once noted that "the chief horror of leprosy obtains in the minds of those who do not know anything about the disease." The same can be said about many conditions that affect the ordinary physical appearance of a person and confer visible physical distortions in the body together with obvious physical disabilities. In this entry, leprosy, particularly in colonial South India, is used as a context within which the characteristics of institutionalization and disability are examined.

LEPROSY AND DISABILITY

Knowledge about leprosy and the reasons for the physical damage it can cause has increased significantly since the late nineteenth century, although much about the illness remains a mystery. *Mycobacterium leprae,* the bacillus that causes leprosy, was discovered in 1873 by Gerhard Henrik Armauer Hansen, from whom the common name for leprosy, Hansen's disease, comes. Even so, the action of the bacteria was not understood until medical science advanced further in understanding the role of bacteria in causing illness and even disability. The advent of sulfa drugs in the 1940s offered the first effective medical cure for leprosy. However, the emergence of drug-resistant strains of the disease by the 1960s swiftly returned leprosy to the status of an intractable illness. Only with the development of a consistently effective form of multidrug therapy in the 1980s did a cure for leprosy again become viable.

Owing to the persistent difficulties with the diagnosis and treatment of leprosy through to the 1980s, together with the physical disfigurement and accidental damage to limbs anesthetized as a consequence of the body's immune response to the disease, those with leprosy have tended also to suffer disabilities.

In the context of modern rehabilitative medicine and occupational therapies, leprosy has been studied as a cause of physical disabilities that can to some extent be minimized and managed even if not entirely remedied by treatment and physical therapy. Typically, a person with leprosy experiences a range of physical disabilities according to the type, severity, and duration of the illness. The hands often become clawed as fingers are foreshortened and lose sensation, resulting in loss of fingers through ulceration and accidental damage. Similarly, feet lose nerve sensation, and bones and joints deteriorate. Toes and even whole feet can be lost through accidental damage and ulcerating infection. It is not unusual for a person with leprosy, particularly when left without treatment or care, to have only stumps where hands and feet once were. Damage to eyes, nose, and palate also occurs in some forms of the disease, inhibiting and even destroying the capacity for sight, smell, and speech.

Stigma

In many, although not all, societies and times, those suffering from leprosy, like those with many disabilities, have been stigmatized because of their physical appearance. The external manifestation of leprosy in facial deformity, loss of limbs, and blindness has made the leprosy sufferer vulnerable to social ostracism and segregation from the economic, religious, and domestic life of their communities. During the nineteenth century, horror at the appearance of leprosy sufferers contributed to the establishment of systems for the isolation and segregation of those with the disease as much as did concerns about the contagiousness of the illness.

Segregation

Segregation and institutionalization of leprosy sufferers has occurred in a variety of countries throughout the history of the disease. The Hawaiian island of Molokai, where Father Damien lived and died among the leprosy sufferers, and the later island settlements of Makogai in Fiji, Peel Island off the Queensland coast of Australia, and Quail Island in New Zealand's South Island port harbor of Lyttleton are all famous examples of state efforts throughout the late nineteenth and twentieth centuries to segregate leprosy sufferers completely from the world. In each of these instances, the response to leprosy of the indigenous population was not necessarily the same as that of the white colonial or settler government. However, principally because of settler fear of contagion and the horrific appearance of those suffering the disease, complete physical separation and confinement of leprosy sufferers within the physical space of an island was believed necessary.

Institutionalization

Dedicated residential care for leprosy sufferers in institutions, often termed *asylums* in the nineteenth century, was also a typical response of colonial authorities to the disease. It was not, however, unique to British and other colonies. In the United States, a national leprosarium was completed in 1922 at Carville, Louisiana, on the Mississippi River to provide the best available medical treatment, rehabilitation, and assistance in living for those disabled by the physical effects of the illness. Built on 4,000 acres of land, it also provided accommodation as effective as the island settlements in segregating those with leprosy from the larger community.

Attempts to institutionalize leprosy sufferers occurred in a broader social as well as medical context. Systematic confinement of the sick, including leprosy sufferers, and the creation of *cordons sanitaires* to contain disease were the results of plague experience in fifteenth-century Europe. In nineteenth-century Europe and America, prisons, mental hospitals, workhouses, and almshouses emerged concurrently, providing, in an age of reform and social change, apparent solutions to both the social problems of crime and disorder and the demands of charity. Although in the late eighteenth century the doctor Philippe Pinel in Paris and the Quakers in Northern England instigated supportive care as an alternative to incarceration of the "insane," institutional confinement prevailed as the preferred medical and social means of managing those perceived as "deviants and dependents"—that is, people who did not conform to social and economic "norms."

The French intellectual Michel Foucault (1975, 1988) has written on marginalization and the confinement of ostracized groups, including leprosy sufferers and the insane. The value of Foucault's work lies in his invitation to consider the symbolic significance of those who are excluded and marginalized and to understand confinement as a logical progression from other forms of complete isolation, such as island segregation. Through Foucault's eyes we are drawn to see institutional confinement and isolation more as a consequence of the symbolic status of the poor, the leprosy sufferer, the mentally ill, and the criminal than as any direct result of a societal concept of the best way to provide economic or medical care or administer justice.

The rise of institutions in the nineteenth century reflected not only changes in psychiatric and social thinking but also greater reliance on government and law, rather than private philanthropy and religious organizations, to resolve social problems. A strong relationship developed between the provision of residential facilities for health care and administration of justice and the emergence of legislation compelling both quarantining of the unfit and institutional confinement.

INSTITUTIONAL CONFINEMENT OF THE DISABLED

Leprosy Sufferers in Nineteenth-Century South India

In the light of contemporary medical understanding, the physical disability of leprosy sufferers is seen as the effect of leprosy but not essential to the disease. This has not always been the case. In nineteenth-century India, for example, leprosy was conceptualized in traditional Hindu and colonial British culture as both disease and infirmity. Both Hindu and British concepts of infirmity included those suffering physical disabilities such as blindness and lameness as well as those with physical signs of leprosy. It is the historical position of the leprosy sufferer as infirm/disabled in both the Indian and British traditions that makes a focus on the experience of the leprosy sufferer in colonial India suitable for this exploration of the confinement and institutionalization of those with disabilities.

Not all physical infirmities attracted confinement and institutionalization in colonial India. Although the Lepers' Act, a form of vagrancy legislation, was passed in 1898 to enforce the confinement in asylums of leprosy sufferers who were poor and vagrant and thus visible on the streets, others who were vagrant and lame, deaf, or blind (the principal forms of disability recognized in both colonial and Hindu Indian culture) were not similarly targeted. The legislation, developed after years of debate, was virtually impossible to enforce, but it did confirm the tenor of nineteenth-century social, medical, and governmental thinking on the social status of the leprosy sufferer in India.

Vulnerability to confinement was not a consequence of the disability itself, nor even of the contagiousness of the leprosy causing the disability, but of societal perception of the disabled. In the case of leprosy in India, the fact that the condition was incurable raised for colonial government and medical authorities the issue of contagion as a factor in their decision making concerning whether or not leprosy sufferers should be confined. Ultimately, however, socioeconomic issues were the deciding factor. The vulnerability of leprosy sufferers to institutionalization increased as their socioeconomic status declined. Despite being known to run the highest risk of spreading infection, those who lived and were supported within their families or were still able to earn their own living were not the subject of legislation. Rather, the poor and vagrant, those who posed the least risk of communicating infection through close personal contact, were targeted. Those who were so disabled that they were not able to support themselves became the subject of police and, later, legal attention.

Further, part of the justification for removing leprosy sufferers from the streets had less to do with health than with aesthetics. Leprosy sufferers, ravaged in appearance by the disease, were considered offensive to the eye and disturbing by both Indian and British in the colony. The value of the disabled leprosy sufferer was thus measured in both socioeconomic terms—according to his or her place in the family and capacity to earn a living—and aesthetic terms. While often arousing compassion, the horrific physical appearance of the leprosy sufferer resonated strongly with British concepts of morality and stigmatizing illness and with Hindu ideas of the karmic responsibility of the individual for his or her condition. For both leprosy sufferer and the community, the physical degradation of the body was felt to reflect a deeper spiritual and moral decay.

The Nature of the Institution

The government institutions developed for leprosy care in nineteenth-century colonial India could not be termed *total institutions* in the sense defined by the sociologist Erving Goffman (1987). Rather than the complete separation of patients/inmates from family and community ties—an essential element of Goffman's concept of the total institution—these institutions featured constant interaction between patients and their families and the outside world. Although visiting hours were restricted at the Madras Leper Hospital, patients were permitted to leave the hospital, and there was little restraint on their continued social and personal interaction. As the hospital's surgeon in charge noted in 1889, some aspects of family life remained. Husbands and wives could visit each other, and many babies were born to inpatients.

Even so, tension and confusion existed concerning the true nature of these institutions, whether they were hospitals for patient care or prisons to ensure the confinement of a diseased and disfigured population. Linked with these issues was ambivalence over the status of leprosy sufferers, whether institutionalized individuals were patients or prisoners.

The issue of compulsion was never far away from attempts to institutionalize leprosy sufferers, and it aroused complex intercultural and class-related questions concerning the nature of medical care and the purpose of segregation. India was not acculturated to any form of institutional care for the sick or disabled. Rather, the family and community, supported by religious beliefs and indigenous medicine, were the context for care. Thus, any form of institution, even where compulsion to remain was not a factor, could be perceived as a prison. The building of the Madras Leper Hospital in 1816, with its high surrounding wall, made fear of imprisonment in the hospital inevitable.

Experience of Institutions

Despite considerable confusion as to whether the leprosy asylum was a prison or a hospital, until the passage of the 1898 Lepers' Act, there was no law in India under which leprosy sufferers could be forcibly confined in institutions. The difficulties in implementing the act meant, however, that enforced institutionalization was the experience of only a few with leprosy, notably those who were also imprisoned for criminal offenses and occupied the Leprosy Hospital at Port Blair in the Andaman Islands penal colony and, later, the Criminal Leper Ward of the Madras Leper Hospital. For most leprosy sufferers, institutionalization was a temporary experience that they resorted to by choice to obtain food and shelter when family and friends were unable to support them and destitution overcame them. The hospital was rarely seen as a place for cure, although at times rumors of leprosy cures did bring people into the hospital.

The ambiguous status of leprosy sufferers living in institutions had implications for their experience of institutional life. Some climbed the wall to escape the Madras Leper Hospital, not realizing that voluntary departure was an option. Medical staff were well aware of the voluntary nature of institutionalization, however, and in the interests of attracting and retaining patients for long enough to at least improve their physical condition, they tried to make hospital life acceptable and even appealing.

Hospital staff recognized that incentives were necessary, not just to lift patient morale and encourage compliance with the treatments available, some of which were painful and unpleasant, but to prevent leprosy sufferers from leaving the institution for the more stimulating, if hazardous, life of begging, pilgrimage, and relative freedom. Patients who had families to support and crops to tend found it impossible to enjoy the benefits of hospitalization for long. The need to find money and food, even by begging, and the seasonal demands of cultivation and harvest made flight from hospitals a necessity for the survival of the whole family.

Institutions made considerable efforts to meet the spiritual and cultural needs of leprosy patients in order to encourage them to stay. South Indian institutions made provisions to enable patients to practice their religion and for patients of different castes to live according to their cultural requirements. Generally, the staff of leprosy institutions recognized the tedium and routine irritations of hospital life, and to counteract this, in some hospitals they encouraged patients to cultivate plots of land and to sell for their own profit any garden produce they could raise.

Living conditions for those with leprosy in institutional care were generous in comparison with what was available to other hospital populations. Basic clothing, fuel for fires, and lamp oil enabled patients to follow ritual practices and to cook for themselves according to caste rules if necessary. A diet rich in protein and fats was provided, with the additional luxuries of betel nut to chew and tobacco allowances. The generosity of the diet was matched, however, by its monotony. In 1878, in an incident that indicates the negotiating power of the patients within the institution, Indian patients at the Madras Leper Hospital convinced the surgeon in charge that the benefits to patient happiness, improved discipline, and greater treatment compliance would far outweigh the additional cost of providing greater variation in the evening meal.

As noted above, patients were free to leave the Madras Leper Hospital; however, certain areas of discipline were enforced with the threat of discharge. Patients were permitted only hospital food and were forbidden to give food away or to take food out of the hospital. Similarly, except in cases where patients were bedridden, smoking was not permitted in the wards. Generally, discipline was in place to maintain the routine working and safety of the institution and to ensure that patients received the benefits of good food, treatment, and healthy activity rather than to coerce or demean them. Even so, staff sometimes applied pressure to patients to enforce cooperation, using the threat of reduced privileges or diet.

The agency of the patients within the Madras Leper Hospital in the face of such pressure is evident in the action taken by a group of inpatients in 1873 in protest against a request from the surgeon in charge that they take on some work, including light labor, tailoring, and running messages. The surgeon considered such work to be both a beneficial diversion for the patients and a means of reducing the need for salaried help in the hospital. The rebel group disagreed, however, and, given the ultimatum of compliance or reduction to a "spoon diet"—broth for the European patients and rice porridge for the Indian—left the hospital to take their protest directly to the local magistrate at the Madras Town Police Office. The magistrate heard their complaint but upheld the surgeon's request. The patients returned to hospital and took up the work, having asserted both their freedom to leave without restraint and their right to negotiate, even if unsuccessfully, the types of conditions under which they wished to receive treatment in the institution.

FUTURE DIRECTIONS

In the last decades of the twentieth century, institutionalization again became less attractive in the "developed" world as a means of managing issues of health and justice. The decline in the growth of institutional "solutions" has as much to do with the often high capital value of institutional land and the costs of institutional care as with shifts in ideological and cultural understandings of the benefit of institutions to either the individual or society. Disability care has followed the trend of deinstitutionalization, although leprosy care in India has been slower to follow suit.

In "developed" countries today, individuals with moderate to severe disabilities are more likely to receive government or insurance funding for independent living within the community than to be offered institutional care. The movement away from institutional care toward independent living has been further supported by public advocacy through disabled support groups, increased government awareness, and the development of antidiscrimination legislation. Individuals with disabilities have also benefited from technological advances in computers and other devices designed to assist in daily life and work as well as from developments in physical and occupational therapeutics. Today, public perception of disability is moving toward recognition of those who face its challenges as worthy of respect and admiration rather than as requiring separation from society and community in institutions.

INTERDISCIPLINARY TEAM

Within the medical model of disability, clinical activities have been broken down into professionalized disciplines, such as nursing, occupational therapy (OT) and physical therapy (PT), and social work. The interdisciplinary team is a managerial concept that has as its goal the efficient execution of care by team members through cooperation, communication, and identity as a unit within a larger structure.

Currently, four models of "team" dynamics exist: (a) the strict medical model, in which the physician maintains all authority for both communication and referral to "team" members in a strictly vertical hierarchy; (b) the multidisciplinary model, in which the physician coordinates all communication, usually vertically, but occasionally horizontally, among consulting services (e.g., PT, OT); (c) the interdisciplinary model, in which communication takes place laterally between consulting services as well as vertically through the physician; and (d) the transdisciplinary model, in which individuals are trained in several disciplines, encompassing their own interdisciplinary team. Each model has disadvantages and advantages, and consequently each is valuable in some situations but not in others. Too little research has been conducted to allow an "objective" delineation of the differences.

The "team" has traditionally followed the hierarchical medical model, with the physician "leading" it, but recently broader social shifts have made the pyramid of authority less vertical, encompassing interdisciplinary and transdisciplinary models. The concept of the team is based on a Western model, and so it is examined here in that milieu.

The idea of an interdisciplinary team necessitates the existence of disciplines. In the West, medicine—the area of expertise of the putative leader of the medical team, the physician—appeared as a discipline during the high Middle Ages. With the birth of the medical universities came an increasingly verticalized pyramid of authoritative health care. Physicians, in concert with civil and religious authorities, often sought out means to regulate broader medical care. From its inception, physician-coordinated regulation also implied that the physician would be working with other kinds of health care providers. Nursing, too, had its start in late antiquity and the Middle Ages, although the modern incarnation of nurses as professionals dates at the latest from the 1860s, when Florence Nightingale, the "Lady-in-Chief," applied statistical and managerial techniques to create a nursing hierarchy. This movement established nursing "teams" inside broader medical teams. Within nursing, the "team" concept has remained an especially potent paradigm from Australia to the United States. Social workers, occupational therapists, physical therapists, dieticians, psychologiss, and others joined the ranks from the last quarter of the nineteenth century into the late twentieth. With such a panoply of disciplines, it is not surprising that the concept of the interdisciplinary team did not become formally voiced until the mid-twentieth century.

Similarly, a location for these workers to come together and function as a team in actuality was not necessitated until the rise of the modern hospital. An early form of the hospital started in antiquity and got on its feet during the Middle Ages; the hospital reached its apotheosis at the end of the nineteenth century and the beginning of the twentieth. The hospital as the home of the operating theater, expensive equipment, and the locus for controlling patients and staff has been particularly nurturing to this form of organization.

In the English medical literature, at least, during the nineteenth century it was uncommon to find the word *team* unless in reference to accidents occurring with runaway horse teams. By the first two decades of the twentieth century, even before World War I, the term appeared most frequently in reference to surgical teams, although Cooter (2004) suggests that it entered medicine from social work through Harvard physician Richard Cabot's 1909 book *Social Service and the Art of Healing.* The war certainly accelerated diffusion of the team concept into the medical profession through the experience with military organization. Thereafter, it appeared in literature from psychiatry to general practice to dentistry to public health to hospital ward care, finding particularly fertile ground in anesthesia and the surgical suite. World War II enhanced that association. By the 1960s, medical literature was rife with descriptions of psychological and sociological characterizations of medical team dynamics from the operating room to the schoolroom. Increasingly, too, business-oriented management techniques and educational concepts have infiltrated the military connotations.

In rehabilitation care, particularly in institutions, the team model also became popular. The metaphorical power of the body's systems working together as a "team" often entered the language of early advocates of team care, such as the pioneering British orthopedist Robert Jones (1857–1933). As it was used in the 1920s and 1930s, the word *team* was applied equally to groups of people with disabilities working together and to health care professionals providing multidisciplinary care. In the late 1940s and early 1950s, however, physiatrists increasingly employed this concept to describe their role in rehabilitation. They envisioned directing the many multidisciplinary ("integrated") activities of the health care providers surrounding those with disabilities. It became one more tool in their professionalizing armamentarium.

To take a specific example, in pediatric care, the rudiments of the team model undoubtedly started in the mid-nineteenth century in institutions such as the Hôpital des Enfants Malades in Paris and the Great Ormond Street Children's Hospital in London, among others. The laicization and professionalization of nursing and the creation of training programs specifically in pediatric nursing reinforced this process. In the first third of the twentieth century, medical care providers for children with cerebral palsy included physicians, social workers, nurses, teachers, psychologists, and therapists. The full model, if not the term, was pioneered in New York through the Society for the Ruptured and Crippled and in Boston at the Children's Hospital. The stated goal of these pioneers was usually the reintegration of the child into an educational setting; this necessitated work with teachers as well as with early social workers to apply new techniques in social engineering. Developmental psychology, which was becoming increasingly influential in the clinics, in research halls, and in the popular press, also demanded that pediatricians work alongside psychologists. In the eyes of some interdisciplinary pioneers, the inherent dependence of the developing child, with or without disabilities, necessitated careful coordination among professionals.

By the middle of the twentieth century, interdisciplinarity became the founding mantra of professional organizations such as the American Academy of Cerebral Palsy, was the subject of testimony before the U.S. Congress, and inspired celebratory articles in the lay press about patients who had been saved by the team process. Governmental agencies sponsoring both clinical research and health services redesign also began sponsoring team models in the last half of the century.

In the United States this occurred through the Veterans Administration and eventually Medicaid/Medicare; in the United Kingdom it took place through the National Health Service. U.S. national accreditation standards now require that rehabilitation facilities maintain interdisciplinary teams. Multidisciplinary clinics, however, in which multiple specialists saw children with disabilities simultaneously, offering families efficiencies of time, were rejected by U.S. governmental reimbursement models in the late 1980s.

In some measure, the impulse of the clinical team model paralleled the growth of ever-specializing "team science" in the biomedical sciences. Since the mid-nineteenth century, the reductionist style of laboratory science provoked knowledge production models in which workers (technicians and students) are supervised by the manager (the scientist). The parallel processing inherent in the system increased productivity, but it also sparked many of the false steps of capitalist production models in general. In physiology, for example, conflicts at times arose around the team or "factory" model, in which there are many laborers but one person gets the credit. Thus, Ivan Pavlov's candidacy for the Nobel Prize in physiology was hampered by the Nobel committee's concerns about who really generates knowledge in a large laboratory model.

In the clinical realm, at times, physicians have directly altered the constituency of teams, even at the level of redirecting already established disciplines. Thus, in a highly resource-rich rehabilitation network in Brazil the directors have favored developing their own in-house universal therapist, replacing the traditional occupational, physical, and speech-language therapists while creating new managerial flexibility outside the bounds of traditional disciplinary teams.

As a management paradigm, the team has proliferated, from the transplant procurement team to the hospital restructuring team to the palliative care team, all joining the surgical and rehabilitation teams. However, the application of the term *team* in multiple situations has also given it a protean expression, sometimes valuably. For example, in many settings, the "patient" has finally joined the model formally as a nearly full participant in his or her care and in the literature about team dynamics. In addition, the pressure of, for example, interdisciplinary team structures has led to a change in language—from "prescriptions" written for PT and OT, implying a hierarchical status, to "referrals," implying a coequal relationship. Although the *Oxford English Dictionary* still includes a definition of "team" as yoked beasts of burden, health care systems and organizational centers widely advocate the use of "teams" for their part in reducing the burden borne.

INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY, AND HEALTH (ICF/ICIDH)

Since its creation in 1947, the World Health Organization (WHO), based in Geneva, Switzerland, has had the mandate of collecting information about the health of populations around the world to provide input into public health policy. Although the collection of information on causes of death that the WHO undertook initially was useful for calculating life expectancies, the organization recognized early on that information about the lived experience of health would be valuable, and in particular data about levels of functioning in all areas of life. Given the WHO's very broad definition of health ("a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity"), the collection of complete functional status information was considered to be fully within its mandate. Because functional status is continuous rather than dichotomous, unlike mortality, collecting this information required sophisticated assessment and measurement instruments. But first, a classification of kinds of human functioning was needed, as well as a conceptual map of the complex domain of functioning. These needs led, by 1976, to the initial draft of the WHO's International Classification of Impairments, Disabilities, and Handicaps (ICIDH), a groundbreaking and controversial classification system tentatively released for trial purposes in 1980.

ICIDH (1980)

In the ICIDH, "disablement" (the overall phenomenon of decrements in human functioning) was modeled as a sequence of levels of health experience flowing from disease, trauma, mental illness, and chronic or age-related health conditions. An initial pathological change may lead to awareness of an impairment, defined as "any loss or abnormality of psychological, physiological, or anatomical structure or function." Impairments involve parts of bodies or body systems; they are temporary or permanent differences of structure or function. If an impairment adversely affects a person's range of activities, then the person is said to have a disability, defined as "any restriction or lack (resulting from an impairment) of ability to perform an activity in the manner or within the range considered normal for a human being." Finally, impairments and disabilities may disadvantage the individual by limiting or preventing the fulfillment of six "survival" roles: orientation, physical independence, mobility, occupation, social integration, and economic self-sufficiency. When that happens, the negative social consequences—that is, the social disadvantages of being a person with impairments and disabilities—constitute a handicap, defined as "a disadvantage for a given individual, resulting from an impairment or a disability, that limits or prevents the fulfillment of a role that is normal (depending on age, sex and social and cultural factors) for that individual."

The drafters of the ICIDH wished to incorporate the insights of what is often called the social model of disablement without losing sight of the fact that the concept of disability is grounded in the biomedical reality of impairments and, ultimately, background health condition. They were fully committed to the view that both the existence and the experience of disabilities and handicaps are created in part by the social and physical environment in which the individual lives. The social disadvantage of a handicap is as much a product of demands imposed by the environment as it is of the functional decrement of the impairment itself: "Handicap is thus a social phenomenon, representing the social and environmental consequences for the individual stemming from the presence of impairments and disabilities." Unfortunately, this insight—that the experience of disability is an outcome of an interaction between features of the person and features of the person's environment—was obscured by careless expression. Throughout, the ICIDH refers to the disadvantage of handicap resulting from the individual's "being unable to conform to the norms" of his or her social universe, as if the "problem" lies exclusively with the individual rather than with the norms.

The ICIDH had a negligible impact on disability statistics or data collection, because the classifications were viewed as incomplete, idiosyncratic, or difficult to use. The research community, however, argued that the ICIDH was a vast improvement over the purely medical classifications and assessment instruments that had dominated clinical practice up to that time. Therapists in particular appreciated the fact that the ICIDH acknowledged the role of the person's social and physical environment in both the creation and severity of his or her handicaps. Disability scholars tended to ignore the ICIDH or to dismiss it as little more than a modified medical classification, which is ironic given that, as Mike Bury (2000) has noted, the aim of the ICIDH was precisely to challenge the medical model.

ICF (2001)

By the 1990s it was clear that, at best, the ICIDH was a first attempt, and if it was ever to be of use in data collection or management, it needed to be substantially revised. Disability scholars criticized the ICIDH for defaulting to a medical model in which impairments created disabilities, which in turn created handicaps. They objected that the ICIDH only paid lip service to the crucial role of the social environment in the creation of disability, and that it was a classification of "inferior" people that would facilitate eugenics and other practices of eliminating people with disabilities. They also asserted that the ICIDH promoted Western imperialism in that it ignored cultural and linguistic differences.

These were substantial and damning criticisms, yet the urgent need for an international classification of human functioning remained. By 1993, an international collaborative process to revise the ICIDH had begun. In the end, the revision clarified the underlying model of disability, reconceptualized the dimensions, added a complete classification of environmental factors, and expanded, reorganized, and updated the three classifications. Each item was operationally defined within a strict hierarchical structure, and the coding system was revamped. Drafts of the new classification system were subjected to extensive field trials to determine cross-cultural and linguistic applicability of the model and the classificatory structure and language. In May 2001 the renamed International Classification of Functioning, Disability, and Health (known as the ICF) was unanimously endorsed by the World Health Assembly and released for use in international research, surveillance, and reporting.

Time will tell whether the ICF's classifications transform the world's health and disability data collection systems or become the basis for "state-of-the-art" clinical assessment tools. The "biopsychosocial" model of the ICF may well be more influential than the classification system itself in the long run.

Briefly, the ICF identifies three dimensions of human functioning: body function or structure, activity, and participation. Observable or measurable decrements in these are dimensions of "disability" (understood in the ICF as an umbrella term referring to one or more of the three dimensions): impairments, activity limitations, and participation restrictions. Depending on how the ICF is used, the classification provides a coding structure that identifies specific categories of functioning in these three dimensions, with qualifiers to roughly assess severity and to identify whether the category is being understood as a "capacity" (inherent functioning of the person, usually measured in a standardized environment) or "performance" (a description of what the person actually does in his or her actual current environment). The definitions of these elements of the ICF model are presented in Table 1.

Table 1 Definitions of Elements of the ICF Model

Body functions are physiological functions of body systems (including psychological functions).

Body structures are anatomical parts of the body, such as organs, limbs, and their components.

Impairments are problems in body function or structure, such as significant deviations or losses.

Activity is the execution of a task or action by an individual.

Participation is involvement in a life situation.

Activity limitations are difficulties an individual may have in executing activities.

Participation restrictions are problems an individual may experience in involvement in life situations.

Finally, the environmental factors classification sets out in general categories all features of the physical, human-built, social, and attitudinal world that may either create disability (and, in particular, participation restrictions) by acting as barriers or lessen (or eliminate) disability by acting as facilitators. (Another contextual dimension, personal factors, is not explicitly classified in the ICF.) In general structure, as Figure 1 illustrates, disability phenomena (that is, impairments of body function or structure, activity limitations, and participation restrictions) are outcomes of interactions between features of the person, including background health condition, and environmental factors.

This model can be understood as a synthesis of what is useful in both the medical and social models of disability, without making their mistake of reducing the whole, multidimensional notion of disability to one of its aspects. This integration of the biomedical and the social means that "disability" can be disaggregated into its interacting components. The biomedical phenomena inherent within the physiological function of the person can be clearly identified and distinguished from features of the inherent capacity of the person to execute discrete simple and complex actions and from the extent of the person's participation in his or her actual environment, in the full range of socially constructed areas of human life.

Significantly, the ICF model offers no account of how or *why* disability comes about, beyond the statement

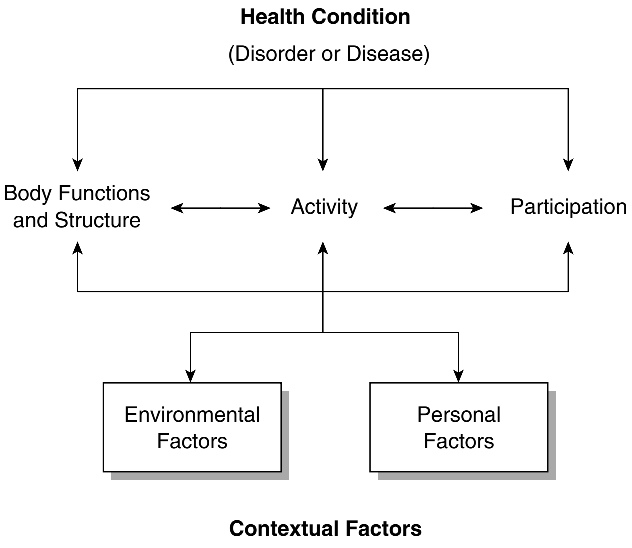

Figure 1 The Structure of Disability Phenomena

that disability arises out of an interaction between person and environment. If a researcher wishes to show, for example, that employment restrictions for people with mobility problems are the product of social prejudice, unaccommodating workplace environments, the underlying impairment, or some combination of these, the researcher can rely on the ICF to collect relevant evidence. The model of the ICF is itself (relatively) theory neutral, in the sense that it is compatible with whatever explanation of how disability arises, at the individual and population levels, that evidence may confirm.

The ICF is thus based on a *multidimensional* and *interactive* model of human functioning and disability. It is nonreductive (in the sense of not assuming that, e.g., the medical dimension is fundamental or "what disability really is") and, as just described, relatively theory neutral. In this sense, the ICF's model is closer to Saad Nagi's influential model, inasmuch as it offers a general structure for functioning and disability phenomena for data collection and management, policy development, and administrative and scientific research rather than an explanatory account of what causes or is responsible for disability, as in the medical model or the model developed by the Union of the Physically Impaired against Segregation (UPIAS).

Another important conceptual feature of the ICF model is universality. This can best be explained in terms of three other principles that guided the development of ICF. The first might be called etiological neutrality—that is, no assumption should be made about the nonenvironmental causal background of any particular functional decrement. For example, "reading" is a complex activity found in the ICF's "Activities and Participation" classification. The operational description of this item makes no reference to any disease, injury, or other health condition, or to specific impairment such as vision or cognitive problems. Problems in a person's capacity to read or in his or her actual reading performance are associated with many potential background health conditions or impairments. There undoubtedly are causal connections, but a classification must not assume these connections. The second principle is that classification is based on parity between the mental and the physical. Indeed, the ICF does not distinguish between "physical" and "mental" disability at all—it is all a matter of human functioning. Finally, in the ICF functioning and disability lie on a continuum, a spectrum from "complete functioning" to "no functioning" with an infinite number of gradations between the two extremes. Depending on user purposes, explicit "threshold" points can be determined (e.g., "mild," "moderate," "severe"), but this is a matter of usage and is not dictated by the ICF itself.

These three principles (etiological neutrality, parity, and continuity) taken together ensure that the ICF is not a classification for or about a particular group of people ("the disabled"); rather, it is about all of humanity. This is truly a paradigm shift in our way of thinking about disability, which is usually construed as an all-or-nothing phenomenon, a medical or social label that applies or not, or a social minority group to which an individual either belongs or does not. The ICF, in contrast, presents disability as a continuum that is relevant to the lives of all people in different degrees and at different times in their lives. Disability is not something that happens only to a minority of humanity, it is a common (indeed natural) feature of the human condition. The ICF is for all people, not just people traditionally referred to as "disabled" and isolated as a separate group.

The ICF thus "mainstreams" the experience of disability and recognizes it as a universal human experience. By shifting the focus from cause to the full range of lived experiences, it places all health conditions on an equal footing, allowing us to compare them using a common metric—the ruler of health and disability. From emphasizing people's disabilities and labeling people as "disabled," we now focus on the level of health and functional capacity of each individual. This may be the most important, and politically significant, aspect of the ICF's model of functioning and disability.

—Jerome E. Bickenbach

INTERNATIONAL DISABILITY ORGANIZATIONS

Supports and services for people with disabilities are recorded as far back as the Old Testament. However, the emergence of organizations of and for persons with disabilities is a much more recent phenomenon, and the emergence of an international disability movement is newer still.

The Stockholm Deaf Club, established in 1868, is the first recorded organization of people with a disability. Since 1922, when Rehabilitation International was established, organizations of and for people with disabilities have been linking together internationally. Interest in sharing information related to disability increased following World War II. The World Federation of the Deaf and Inclusion International were founded in 1951 and 1962, respectively, and the International Association for the Scientific Study of Intellectual Disability (originally the International Association for the Scientific Study of Mental Deficiency) was founded in 1964.

Until the early 1980s, the Council of World Organizations Interested in the Handicapped represented the community of nongovernmental disability organizations in dealings with the United Nations. The council comprised the following organizations, all of which had consultative status with the United Nations: Rehabilitation International, the World Federation of the Deaf, the International League of Societies for the Mentally Handicapped (now Inclusion International), and the World Blind Union. However, in 1981 the creation of Disabled Peoples' International (DPI), with its strong focus on empowering "a voice of our own" for people with disabilities, changed the balance of power in disability organizations' dealings with the United

Nations. DPI played an important role in coordinating the work done during the International Year of Disabled People (1981) and in the subsequent development, together with other international disability organizations, of the World Programme of Action Concerning Disabled Persons and of the International Decade for Disabled Persons (1983–1992).

In 1987, a group of experts evaluated the outcome of the first five years of the International Decade. They determined that too little progress had been made toward the overall goal of "full participation and equality" for persons with disabilities. The international disability organizations therefore requested that the United Nations establish more concrete guidelines. The result was the UN General Assembly's adoption, in December 1993, of the Standard Rules on the Equalization of Opportunities for Persons with Disabilities. An important element of the Standard Rules was the creation of an independent and active monitoring mechanism, which included three elements: the UN Commission for Social Development, a special rapporteur whose duties were to conduct the monitoring and report to the commission, and a panel of experts named by the nongovernmental disability organizations. Bengt Lindqvist, a former Swedish cabinet minister, founding member of DPI and leader of the World Blind Union, was named special rapporteur. The panel of experts was composed of five women and five men representing Disabled Peoples' International, Inclusion International, Rehabilitation International, the World Blind Union, the World Federation of the Deaf, and the World Federation of Psychiatric Users (now the World Network of Users and Survivors of Psychiatry).

THE INTERNATIONAL DISABILITY ALLIANCE

During his tenure of three terms as special rapporteur, which ended in 2002, Lindqvist consistently worked with the panel of experts. This not only enabled the disability groups to play a significant role in monitoring the implementation of the Standard Rules, but it also served as an education for the disability organizations about international issues and created a spirit of collegiality among the groups. Individuals who did not have leadership positions within their organizations represented several of the groups, and so the presidents of the various organizations began to hold regular meetings, at first in conjunction with the panel meetings (see Lindqvist 2003-2004). These informal gatherings led to the establishment of the International Disability Alliance (IDA) in Cape Town, South Africa, in 1999.

There was a lapse between the end of Lindqvist's term as special rapporteur and the appointment of his successor, Sheika Hessa K. A. Al-Thani, but the IDA continued to meet. The network became a mechanism for collaboration among the world's major international disability organizations on matters of common concern, especially on matters related to the United Nations and its agencies. Currently, the IDA's member organizations are Disabled Peoples' International, Inclusion International, Rehabilitation International, the World Blind Union, the World Federation of the Deaf, the World Federation of the Deafblind, and the World Network of Users and Survivors of Psychiatry. In order to encourage cross-disability collaboration, and also to support the participation of international disability organizations in the elaboration of a proposed UN convention on disability, the IDA received financial support from the Swedish International Development Cooperation Agency.

Although each IDA member organization has its own mission and objectives, there is a strong commonality of approach among members. Enns (n.d.) summarizes the roles of organizations of disabled people as follows: self-representation, identification of grassroots needs, representation to government service providers and UN bodies, evaluation and monitoring of services, self-development, mutual support and solidarity, provision of a vehicle for self-help projects, provision of networking mechanisms, and promotion of public awareness. The current IDA member organizations are described below (some of these also have their own separate entries in this encyclopedia).

Disabled Peoples' International (DPI)

Disabled Peoples' International, a network of national organizations and assemblies of disabled people, was established to promote the human rights of disabled people through full participation, equalization of opportunity, and development. DPI has consultative status with the UN Economic and Social Council, the World Health Organization, and the special list of the International Labor Organization.

DPI's mission is to ensure equal representation of its members through a decentralized "regional" structure that also facilitates leadership and strategy development at the local level. DPI currently has approximately 120 national members, more than half of which are in developing nations. Any organization controlled by disabled people can be a member of the national assembly in that organization's country.

A major goal of DPI is the full participation of all disabled people in the mainstream of life, particularly those in developing countries.

Inclusion International (II)

Inclusion International is a federation of more than 200 associations, in more than 115 countries, whose individual members are people with intellectual disabilities, their families, and other supporters. II's vision is a world where people with intellectual disabilities can participate equally and be valued in all aspects of community life. II has consultative status with the United Nations and its agencies.

With its member societies, II is an agent for change based on four main principles affecting the lives of people with intellectual disabilities and their families: inclusion of all persons in all aspects of everyday society, full citizenship for all that respects individual human rights, self-determination and individuals' control over decisions affecting their lives, and family support through adequate services and support networks.

II's Millennium Development Goals use the UN Millennium Development Goals as a framework for expressing the organization's objectives on behalf of people with intellectual disabilities. These goals, which provide a clear agenda and targeted objectives, focus on the following major issues: inclusive education, poverty reduction, children and families, maternal and child health, values and ethics, and human rights.

Rehabilitation International (RI)

Rehabilitation International is a federation of approximately 200 national and international organizations and agencies in 80 nations covering all of the world's regions. RI maintains official relations with the UN Economic and Social Council, the World Health Organization, the International Labor Office, UNESCO, UNICEF, the Organization of American States, the European Union and the Council of Europe, the UN Economic and Social Council for Asia and the Pacific (UNESCAP), and others.

RI develops and promotes initiatives to protect the rights of people with disabilities, to improve rehabilitation and other crucial services for disabled people and their families, and to increase international collaboration toward these objectives. Adopted in March 2000 at the World NGO Summit on Disability, RI's agenda emphasizes working toward the following in regard to people with disabilities: improvement of overall quality of life; reduction of deprivation, hardship, and poverty; improvement of education, training, remunerative work, and participation in decision making; elimination of discriminatory attitudes and practices; elimination of information, legal, and infrastructure barriers; and increased allocation of resources to ensure equal participation.

World Network of Users and Survivors of Psychiatry (WNUSP)

The stated purpose of the World Network of Users and Survivors of Psychiatry is to serve as a global forum and voice through which the users and survivors of psychiatry can promote their rights and interests. The WNUSP began as the World Federation of Psychiatric Users in 1991; it adopted its current name in 1997.

The WNUSP's aims are as follows: to advocate for the advancement of human rights, to provide international representation and consultation to the users and survivors of psychiatry, to encourage the development of national user/survivor organizations, to facilitate effective information exchange among user/survivor organizations, to develop networking opportunities for individual users and survivors of psychiatry, and to carry out any other activities that are consistent with WNUSP's purpose. The organization is also concerned with the advancement of human rights and expresses this concern by preparing, developing, lobbying for, and supporting human rights work. At the same time, the WNUSP promotes the facilitation of national and international user/survivor networks.

World Blind Union (WBU)

The World Blind Union represents 180 million blind and visually impaired persons from 600 different organizations in 158 countries. The WBU, which has consultative status within UN agencies and the UN Economic and Social Council, is a nonpolitical, nonreligious, nongovernmental, and nonprofit organization divided into six regions, each with its own constitution.

The WBU is based on a commitment to the concept that all persons, including the blind and partially sighted, are born equal and entitled to personal dignity and fundamental human rights. The WBU is working to achieve inclusion of blind and partially sighted people in all UN conventions and covenants in all countries of the world, to increase in number and strength the organizations of the blind and partially sighted, and to take on the role of information provider to society in general. The WBU seeks to promote the interests and societal involvement of all blind and partially sighted people of the world. The organization works to strengthen its close contacts with the United Nations, governments, and national politicians in order to ensure that all blind and partially sighted persons enjoy the same rights and opportunities as others. The WBU uses all available ways and means, including existing laws and regulations, to fight for equal rights and full participation for all blind and partially sighted people through the United Nations, national governments, and nongovernmental organizations, and to provide information to the general public at the international, regional, and national levels.

World Federation of the Deafblind (WFDB)

The World Federation of the Deafblind is an international organization created by and for Deafblind persons in 1988 during the Helen Keller World Conference in Paipa, Colombia. The WFDB is a nonprofit, benevolent society that includes as members national organizations of Deafblind persons, Deafblind individuals, and other concerned individuals. It was organized for the purpose of advancing the economic, educational, and social welfare of Deafblind persons.

World Federation of the Deaf (WFD)

The World Federation of the Deaf is an international nongovernmental organization comprising national associations of Deaf people worldwide. A nonprofit organization, the WFD works for human rights and equal opportunities for Deaf people everywhere. The organization's goals are to improve the status of national sign languages, to improve the education of Deaf people, to improve Deaf people's access to information and services, and to improve human rights for Deaf people in developing countries.

The WFD was established in 1951 during the first World Deaf Congress in Rome, Italy, which makes it one of the oldest organizations in the world for people with disabilities. The WFD's 123 Ordinary Members represent all five continents, and the organization's regional secretariats are as follows: Asia and the Pacific, Central America and the Caribbean, Central Europe, Eastern Europe and Middle Asia, Eastern and Southern Africa, South America, and the Arab Region (Interim). It also has a regional cooperating partner in Europe. The WFD has consultative status with the United Nations.

INTERSEX

Intersex is a term used to describe someone who has an anatomy that is not clearly either male or female. Various medical terms have been used to refer to such anatomy, including *androgen insensitivity syndrome, Kilefelter's syndrome, progestin virilization, mixed gonadal dysgenesis,* and *true hermaphroditism.* As these terms suggest, the experience of being an intersexed person is often pathologized through the medical model as a birth defect that should be corrected. Like many disabled people, intersex people often report significant pressures to change their bodies through surgery in order to make them more "socially acceptable" and "normal."

Many intersexed people are forced into surgery to adjust their bodies at very young ages. Common operations of this type include clitoral reduction and vaginoplasty. These surgeries often leave intersexed people feeling ashamed about their bodies as well as confused about their sexuality or their gender. In recent years, intersexed people have responded by starting a political movement to prevent infant surgeries and change medical practices toward children with ambiguous sexual anatomies. The intersex movement challenges dominant social interpretations of bodily differences, such as medical practices that define some penises as "too small," some clitorises as "too large," and the absence of a vagina as meaning a person is "not a real woman." The intersex movement generally objects to anatomy-changing surgery unless it is absolutely medically necessary, such as a lifesaving operation in which a urethra is rerouted so that a child can urinate.

In the past, many intersexed people were labeled "hermaphrodites." However, the category of intersex includes many people who do not conform to the standard medical definitions of "hermaphroditism"—namely, having both ovarian and testicular tissue. It is actually more common among intersexed people for their genitals to be ambiguous, regardless of whether they have ovaries or testes. When there is gender ambiguity, the child is usually allocated a female gender. In this context, it is important to note the social factors that often influence medical decisions—such as the common desire of doctors and family members to assign a gender to the child as soon as possible. The social importance placed on announcing a child's gender at the time of birth, regardless of whether the infant's gender is clear, often places the child and the child's family in uncertain territory in terms of personal identity. Many doctors assert the need to assign gender decisively and irreversibly at birth, but such a pronouncement often belies the complexities presented by intersexed infants. In major medical centers, the medical teams that are involved in assigning gender may include the original referring doctor, an obstetrician, a pediatric surgeon, a geneticist, and a pediatric endocrinologist. Team members may conduct tests and rely on procedures that take months to provide results.

In addition to emotional ordeals, many intersexed people experience physical complications and side effects as a result of the surgeries they have undergone. Although reports of complications from genital surgery are rare in the medical literature, some of the complications that can arise include stenosis (a narrowing of the vaginal canal), scarring, and urinary tract infections.

INVALID WOMEN

Although the term *invalid* has fallen out of use as a medical category and now colloquially refers to someone who is incapacitated, there was a time when it meant simply weakness and a tendency toward illness. During the nineteenth century, women were presupposed to be weak, and femininity itself was considered akin to illness, so in one sense, all women—no matter their actual state of health—were seen as invalids. This representation of women as ill pervades the literature, art, and medical tracts of the period. Modern feminist critics have understood this phenomenon in four ways: as the result of misogynist cultural conditioning and the patriarchal power to define and control women's bodies, as resistance to such conditioning, as a kind of power in itself, and as a specific manifestation of cultural privilege and power in which illness functions as both power and powerlessness.

The double meaning of *invalid*—that is, both ill and not valid—serves to challenge women's standing as full citizens and was in fact used in arguments against suffrage and equal opportunity for women; middle- and upper-class women were assumed to be too frail to stand up to the rigors of officeholding, voting, or employment, despite the evidence of working-class women's stamina throughout the world. In this way, invalidism paralleled disability: Unfounded assumptions about a group's physical inferiority led to discrimination. Although there are and have been some important differences between invalid women and women with disabilities, quite often the two are indistinguishable, and the cultural associations attached to them are very alike. At the same time, women have sometimes further stigmatized disability in their attempts to deny invalidism. More recently, however, many articulate writers about disability have been women with chronic diseases who have drawn important links between illness and disability and have called attention to the role of gender in thinking about disability.

In the mid-nineteenth century, Edgar Allan Poe (1846) claimed that "unquestionably, the most poetical topic in the world" is the "death . . . of a beautiful woman" (p. 165). Representations of ill and dying women throughout the nineteenth century bear out his claim. Whether in paintings of mad, dead, or dying women (such as Albine and Ophelia), in operatic and dramatic renderings of tragic illness (as in *La Dame aux Camelias, La Traviata,* and *La Bohème*), or in literary depictions like Poe's, the numerous tubercular heroines of sentimental novels, or the delicate ladies fainting on couches that populate many novels and stories, representations of women in this period are often representations of illness and weakness. Nor did such depictions of women end in the nineteenth century. Many contemporary films and other fictional works continue to focus on dramatic episodes of women's illnesses; to mention just a few, one could point to such films as *Girl, Interrupted* and *One True Thing* or to novels such as Ana Castillo's *So Far from God* and Jane Smiley's *A Thousand Acres.*

Explanations of how women came to be understood as invalid usually focus on the cultural conditioning that is part of a patriarchal system. These arguments usually take one of two forms, maintaining either that oppression actually caused the illness or that oppressive norms caused women to be defined as ill no matter what their actual physical condition. Proponents of the former view argue that many expectations of women—that they wear corsets, that they bear numerous children, and that middle- and upper-class women refrain from much exercise—would in fact have led to illness; they point out further that powerlessness over life choices (whether to have a career, whom to marry, how to manage finances, or even whether to play a role in government) would have led to mental and emotional strains that likewise could have caused illness. Proponents of the latter view point out that in the mid-nineteenth century, normal experiences of feminine physicality (menses, pregnancy, menopause) were coming to be circumscribed by medical intervention.

Critics have addressed female illness not only as an issue of powerlessness, however. Elaine Showalter (1997), for example, argues that female illness in the nineteenth century can be read as resistance to power. She asserts that hysteria, especially, might be read as a mode of protest. Thus, many women who were diagnosed as ill might in fact have been rebellious or politically resistant. Other critics have examined the way that scenes of illness may provide audiences with moral exempla of virtue and stoicism. Finally, it is important to note, too, that not all uses of illness for power are positive; there are numerous examples of female characters who dominate whole communities through feigned illness and demands for attention, probably nowhere more famously than in Harriet Beecher Stowe's *Uncle Tom's Cabin.*

Rosemarie Garland Thomson (1997) points to some important similarities between cultural assumptions about women's bodies and the bodies of people with disabilities. She argues that in many ways, especially if one traces writings about disabilities back to Aristotle, femininity itself can be seen as a disability—Aristotle classified the absence of a penis as a deformity—and that both femininity and disability have been understood as bodily differences that are not simply alternative forms but deficient ones. Thomson points out that by reading disability through a historical lens of discrimination against women, we can see that such oppression is a matter of social "norms" rather than concrete bodily differences.

We cannot, however, make an easy or historically continuous connection between feminist politics and disability politics. In the course of their historical struggle to gain access to political and social rights, women have sometimes argued against their "invalidity" by expressly contrasting themselves to the disabled. Suffragists argued their fitness to vote and hold office by defining their abilities against those of physically, emotionally, and intellectually disabled men. As historian Douglas Baynton (2001) argues, this sets out able-bodiedness as an unquestioned positive value. In many ways, then, the suffragists did not urge a rethinking of the paradigm of invalidism—that it equaled invalidity—they simply argued that they did not fit that paradigm.

In recent years, writers about female illness and disability have thought through the relation between the two in a much more nuanced way. Perhaps the most important of these writers has been Nancy Mairs, whose nonfiction prose collections explore the relationship between femininity—especially as it is connected with sexuality and beauty—and disability, when it takes the form of visible difference, but Lucy Grealy and Anne Finger have likewise grappled in their work with the overlaps between illness and disability. In *The Rejected Body* (1996), Susan Wendell tackles philosophical questions that link feminism, disability, and illness. Most contemporary representations no longer depict women's illness as a result of their own weakness or invalidity, and often do not feature women who are ill as "poetical" or beautiful subjects, either. Contemporary writers and artists are tackling the question of women's illnesses today without casting the ill woman as the invalid. In addition to those mentioned above, one might see the work of Lucille Clifton, Marilyn Hacker, and Margaret Atwood. Many of these representations challenge contemporary culture as the cause of "dis-ease" for women and, as Ann Folwell Stanford (2003) argues, urge a more cultural idea of healing.

IQ

IQ stands for *intelligence quotient,* a numerical score derived by combining a person's chronological age with his or her "mental age" as determined by the person's performance on a standardized intelligence test. Intelligence testing has become a standard tool in the diagnosis of two specific forms of disability: learning disabilities and intellectual disabilities (also known as developmental disabilities or mental retardation). Intelligence tests are also used in the assessment of giftedness and in the assignment of students to ability tracks within public schools.

Individual intelligence tests such as the Stanford-Binet Intelligence Scale, the Wechsler Intelligence Scale for Children, and the Wechsler Adult Intelligence Scale are used to provide a single measure of overall intellectual functioning. Intelligence tests are statistically normed so that all scores are distributed according to the pattern of a normal or bell curve. A high number of scores cluster at or near the center around an average value of 100. Fewer scores occur along the two tails of the curve. About 2.3 percent of all scores occur at or below 70, and 2.3 percent occur at or above 130.

Intelligence tests generally consist of two subscales, verbal and performance, each of which comprises five separate tests of specific skills within that domain. Verbal scale tests use language-based items, whereas performance scale tests use visual-motor items, which are less dependent on language skills. The two subscales contribute equally to the individual's total or full-scale score.

Learning disability diagnosis typically involves a formula that sets a specific criterion (often 1.5 or 2 standard deviations) for discrepancy between a total IQ score and a score on a standardized test of academic achievement. The purpose of comparing scores on an intelligence measure and an academic skills test is to uncover any unexplained deficit in a basic area of academic skill (such as reading, mathematics, writing). IQ is viewed as the measure of global intellectual capacity, a gauge of how well a student or other individual is expected to fare on academic tasks. The achievement test provides an actual measure of academic ability in a specific skill area. It is expected that a person scoring in the average range on an intelligence test will score in the average range on an achievement test. When a person scores significantly lower on an achievement test than on an intelligence test, that discrepancy is viewed as a possible indication of a learning disability.

The diagnosis of intellectual disabilities typically involves the use of an intelligence test and other measures of social functioning, such as adaptive behavior scales. An IQ score below 70 is generally interpreted as an indication of a significant intellectual deficit that may (depending on agreement of other measures) be described as an intellectual disability.

Educators and psychologists have often used intelligence tests as part of systems of intellectual stratification that interpret individuals' ability to learn and function in school and society based primarily on IQ. Educators have often categorized individuals across three cognitive levels: educable, trainable, and untrainable. Students classified as *educable* (IQ approximately 50–75) were viewed as being able to learn simple academic skills but not able to progress above a fourth-grade skill level. Children believed to be *trainable* (IQ approximately 25–50) were expected to be able to learn to care for their daily needs but to learn very few academic skills. Children who appeared to be *untrainable* (IQ approximately 0–25) were viewed as totally dependent and in need of long-term care in residential settings.

Psychologists have often used a similar stratification system consisting of either three or five general levels of intellectual disability. The more recent five-level system consists of the following categories: *borderline* (IQ 67–83), *mild* (IQ 50–66), *moderate* (IQ 33–49), *severe* (IQ 16–32), and *profound* (IQ < 16).

Often educators and psychologists have translated intelligence test scores into a concept of a *mental age.* If a score of 100 means that a person is functioning intellectually at the developmental level expected of his or her age peers, then a score of 50 indicates cognitive functioning equivalent to half that person's age. In this way, adults with intellectual disabilities have often been viewed as operating much like children.

For many years, the diagnosis of intellectual disabilities relied solely on the use of a single intelligence test. Also, the usual cutoff score for intellectual disability diagnosis was 80 or 85. In the 1960s, concern arose in the United States about the overidentification of intellectual disability in African Americans and members of other minority groups. Many educators, psychologists, and social critics maintained that intelligence tests were biased against minority and lower-class populations. In 1973, the American Association on Mental Retardation responded by reducing the diagnostic criterion level for intellectual disability (or mental retardation) to 70 to account for problems of bias and measurement error.

In the public schools, a series of court cases struggled with the same issues. In *Larry P. v. Riles* (1979), a California class-action case, it was argued that African American students had been inappropriately placed in educable mentally retarded (EMR) classrooms solely on the basis of IQ scores. The case also claimed that the IQ tests used were culturally discriminatory against African American children. The court found that the IQ tests were culturally biased against African American students. This case and others brought about a shift in public school utilization of intelligence tests, leading to a requirement that no special education diagnosis be made based solely on a single intelligence test.

In 1904, the French minister of public education commissioned Alfred Binet to develop a technique to identify students who could benefit from special education assistance. Binet put together a hodgepodge of tasks and games designed to enable the assessment of a wide variety of cognitive skills. His original insistence that no intelligence test could capture the many human abilities in a single score was generally ignored by the American psychologists who translated and popularized his test.

H. H. Goddard, Lewis M. Terman, and Robert Yerkes were prominent American psychologists who adapted Binet's test for various applications in the early twentieth century. The work of these three men reflected and perpetuated common prejudices of the times. Goddard believed that social problems such as violence, drug abuse, and poverty are rooted in individual mental deficit that is both innate and inherited. His answer was to develop intelligence tests to identify the high-level feebleminded in order to isolate them, thereby segregating social evil in institutions and reducing the chances of defective offspring. Yerkes developed intelligence tests for the U.S. Army during World War I that were given to thousands of soldiers for the purpose of matching individual intelligence with military rank and responsibility. The intelligence data gathered through these tests documented disproportionate levels of mental defect among immigrants and African Americans, providing scientific support for anti-immigrant and racist sentiments among many citizens and leaders. Yerkes's research was instrumental in the passage of the Immigration Restriction Act of 1924, which set strict limits on the numbers of immigrants accepted from Southern and Eastern Europe and Asia. Terman reached similar conclusions in his application of a version of the Binet test (early Stanford-Binet) to schoolchildren in northern California. He found that children of immigrants from Latin American as well as Southern and Eastern European countries fared very poorly in comparison with students of Northern and Western European backgrounds. His work simultaneously introduced intelligence testing to the public schools as a means of sorting students into ability-level groups and supported racist and jingoistic attitudes.

Racial issues returned to the forefront of the discussion regarding intelligence in 1969 when Arthur Jensen claimed in an article in the *Harvard Educational Review* that African Americans typically score lower than white persons on intelligence tests because African Americans are intellectually inferior. This racial argument returned again more recently in Herrnstein and Murray's book *The Bell Curve* (1994). Both of these publications continue a version of a philosophy of intelligence called *hereditarianism,* which was put forth in various ways by Goddard, Terman, and Yerkes. According to this philosophy, intelligence is an innate, unitary mental capacity that is primarily inherited through genetic transmission. Thus, variations in intelligence scores across different social groups are indications of real differences in intellectual ability between the groups.

The opposing position, which has often been called *environmentalism,* asserts that variations in intelligence scores across social groups occur primarily because of differences in the social and physical environments in which various groups live and in the experiences and kinds of education that individuals within those groups tend to have.

More recently, proponents of a third position, called *multiculturalism,* have maintained that intelligence tests primarily test the extent to which an individual has experienced and learned the language and cultural features of middle-class Anglo-America. According to this stance, low scores achieved by various minority groups and lower-class whites demonstrate a cultural mismatch between the content of the tests and the cultural experience of the individuals.

Despite social critique, intelligence testing has become a mainstay of diagnostic practice among educators and psychologists. A wide variety of institutional authorities—including special education systems, vocational rehabilitation programs, adult disability service providers, and even courts deciding on issues of mental capacity in criminal cases and sentencing hearings—rely on intelligence testing as an authoritative guide to intellectual capacity.

ISOLATION

In the summer of 1995, more than 700 people died in Chicago during a prolonged heat wave. More than 10,000 individuals died in France under similar circumstances during a three-week period in the summer of 2003. Many of these individuals were elderly and suffering from one or more chronic diseases or disabilities. Of even greater interest to public health officials was the recognition that most of the deceased died alone, isolated from social networks that might have identified their high-risk situations and intervened before the consequences were so severe.

The term *isolation* is used to refer to both voluntary and involuntary lack of contact with others in the community. An individual may be involuntarily separated from others for several reasons. Physical limitations may keep the person from leaving home easily or from accessing facilities where he or she can engage in either business or social activities. Psychological or behavioral conditions may also prevent an individual from establishing satisfactory relationships with others in the community with whom he or she should interact. Some individuals desire solitude and so choose to isolate themselves from the community as much as possible. The majority of isolated individuals, however, do not wish be isolated and often experience physical and emotional impairments because of their isolated status.

In the 1970s, individuals with disabilities were "mainstreamed" from institutions into the larger body of society. This change signified a change in attitudes toward the disabled, but even so, a large segment of this population became segmented from the mainstream. Despite the existence of community training centers and rehabilitation programs, some individuals with disabilities became separated from their communities and isolated in their homes. Reasons for this included limitations caused by disability itself, the limited ability of some individuals to adapt emotionally to the challenges of their disabilities, and the limited ability of some individuals to communicate with other members of society. Using a broad definition of disability that includes chronic illnesses, researchers who conducted an analysis in 1999 using data from the Survey of Income and Program Participation estimated that one in five American adults suffers from some disability. The major causes of disability were reported to be arthritis, rheumatism, back or spine problems, and cardiovascular disease. Less than 4 percent of those with disabilities reported a mental or emotional problem to be their primary cause of disability, and 20 percent of disabled individuals reported difficulty getting around outside of the home. Individuals over the age of 65 were only slightly more likely to report this difficulty than were those in the 18–64 age group.

Social isolation can result from a number of factors, including physical limitations. The issue of interest resulting from social isolation is the relationship between isolation and social loneliness, or the inability to derive satisfaction from interaction with other individuals or groups. The perception of loneliness results from a discrepancy between the level of those relationships that the individual desires and what he or she can achieve given the level of isolation dictated by the disability.

Several scales have been developed to measure loneliness. Studies using the UCLA Loneliness Scale have found that men are more likely than women to be lonely. In other studies using other scales, females have been found to have higher levels of loneliness. Although there is no consistent agreement on the variables that predict loneliness, an emerging body of literature has begun to link loneliness with poor physical and mental health.

Individuals with disabilities interact with primary health care providers with greater frequency than they interact with providers of rehabilitative or assistive services. This is especially true for individuals living in the community rather than in institutions, where rehabilitative services may be more accessible. There are differences in provision of services by gender as well. For females, most health care provided is related to the disability, and often women's preventive or wellness-based care is ignored. Females are also more likely to present with depressive symptoms.

Some research has attempted to differentiate between isolation and loneliness. Lonely young men and women have both been found to have poorer cardiac function than young people who are not lonely. Loneliness has not been found to be related to poorer health behaviors per se, but it has been found to be predictive of stress and poorer social interactions. In elderly persons with disabilities, attitudes toward social engagement have been found to be more important to overall rehabilitation than actual health condition or type of disability. Attitudes toward social participation related to the use of rehabilitative devices and services are often more predictive of the use of such services than the actual level of disability.

Coexisting psychosocial issues that occur in individuals with physical disabilities may not only increase the effects of their disabilities but also lead to further inability to self-manage as well as increase the incidence of new and preventable physical and emotional problems. Depression in older patients with coronary conditions has also been found to be correlated with poor quality of life, self-report of disability, and decreased physical endurance. Using volunteers who were willing to engage in community-based exercise programs, one study found that exercise improved physical function. Individuals with disabilities have been found to have higher rates of obesity than their counterparts who do not report such conditions. Obesity can aggravate the effects of some disabilities and lead to even less mobility.

Most studies of isolation in the disabled have focused on people with disabilities who live in urban areas. The problem may be even more acute in rural areas. One study found that individuals with HIV/AIDS living in rural areas, where such clients have even greater limitations on access to care than do those in urban areas, were more likely to be isolated and living in poverty. More than one-third of the affected individuals in the rural group reported that they had thought about suicide, and 6 percent seriously considered it to be an option.

Differences in age and the length of time individuals have had to deal with their disabilities may affect their ability to interact socially. As individuals with disabilities get older, they may have a tendency to move away from social interaction and develop self-imposed isolation because of changes in the social pressures on them to interact with others and because of general societal attitudes toward the elderly.

A major limitation of all of the published research findings to date on isolation among people with disabilities is that estimating the true number of individuals who are isolated is difficult, whether the isolation is caused by limitations associated with disability itself or by individuals' inability to function in social networks. The problem of isolation is receiving worldwide attention, however, and programs have been developed on every continent to address the problem. Approaches to the management of isolation have centered on case management and the use of telehealth and technology to assist the disabled in maintaining contact with society.

Most efforts to date have centered on community-based programs that provide home-based services, monitoring, and/or arrangements for specialized transportation. Although such approaches have assisted a great number of isolated disabled individuals, many more have been missed for a number of reasons. For example, health care providers may fail to recognize the special needs of their disabled clients, insurance may not cover the provision of specialized services, or disabled individuals may have ceased contact with the health care system because of their inability to leave home and make initial contact with health care providers. Disabled individuals residing in rural areas are especially vulnerable to isolation and inability to receive services.

In recent years, approaches to reaching the population of isolated individuals with disabilities have incorporated the use of various communication technologies. Social service organizations and health care facilities have used the telephone to establish contact with homebound individuals; such contact may be made by employees of these organizations or facilities, but this work is often done by volunteers. Senior citizens residing in assisted-living facilities have participated in phone contact programs with other senior citizens living alone in their communities. This approach not only creates peer support but also helps to identify individuals who need further intervention. The Internet is emerging as a useful tool for assisting isolated individuals, as it enables them to communicate with peers, other persons of interest, and health care providers. Ease of use, continuous availability, and ability to span geographic boundaries have made the Internet a powerful contributor to efforts to address isolation, as it enables individuals to develop and maintain the levels of social interaction they desire. Some studies have found a decrease in loneliness among isolated individuals after introduction of Internet communication access, but long-term research is needed to determine the economic and health status benefits that may be derived from Internet use. Most of the Internet-related interventions examined to date have involved the use of chat rooms, but continued development and increased availability of audio and video communication over the Internet may further enhance the benefits of this approach. As with the limitations of case management, recognition of individuals who may benefit from this type of intervention is key.

Finding and assisting isolated persons with disabilities is a societal obligation; working against isolation is not solely the responsibility of the isolated individual. Since the deadly heat wave of 1995, the city of Chicago has instituted programs to ensure that elderly and disabled citizens are contacted during times of extreme weather conditions by community volunteers who go door-to-door to check on them. This expensive, time-consuming process is limited to crisis management, but it has been effective in reducing deaths. Communities need to develop similar approaches to case finding and support that are cost-efficient and meet the needs of individuals in a variety of geographic areas and cultures.

ITARD, JEAN MARC GASPARD

(1774–1838)

French physician

Jean Marc Gaspard Itard was born in Oraison near Digne in southern France in 1774. He was charged by Lucien Bonaparte, interior minister during the Consulate, and by Abbé Sicard, director of the Institute for Deaf-Mutes on the Rue Saint-Jacques in Paris, with the care of a boy who had just arrived, in July 1800, and who was already being called "the wild boy of Aveyron." Itard undertook to teach him to speak and to civilize him, rejecting the diagnosis of idiocy made by Philippe Pinel, the famous specialist in mental disorders at the Salpêtrière asylum.

Contrary to Pinel, Itard judged that the wild boy had not acquired the benefits of civilization because he had been isolated in the forest without human contact. Dealing with a natural being, he thought that through education—the fundamental empirical concept—he could "return him to society," as the celebrated Sicard was doing with deaf-mutes. To achieve this, Itard employed methods intended for the deaf. These methods failed, however, since the wild child was very different from them. More different, in fact, than he would have thought, since we now know that early alterations in the brain are not, or are hardly ever, open to modification.

After some years of fruitless efforts, Chaptal, Napoleon's interior minister, suspended the financial support that had until then been given for the education of "Victor," so named because he had learned at least to sound the letter *O.* Itard then turned back to the deaf, for whom he invented a method of physiological education to teach them to speak. Before his death in 1838, he supported Eduoard Séguin's efforts in treating and training the mentally impaired.

In 1970, French filmmaker François Truffaut wrote and directed *The Wild Child,* a film based on Itard's work.

—Jean-René Presneau

CHRONOLOGY

1500 BCE Egypt: The Ebers Papyrus, a medical textbook, devotes an entire chapter to eye diseases. It also shows that deafness is well understood and that clinical knowledge has developed.

400 BCE Graeco-Anatolian Hippocratic writings coin the word e*pilepsy* for a convulsive condition they view as a disease rather than a possession or punishment. Today, it is estimated that more than 80 percent of the 40 million people who currently have epilepsy throughout the world have little access or no access to contemporary treatments.

300 BCE China: *The Yellow Emperor's Internal Classic* is the first text to outline acupuncture. Ordinances on emergency relief for the disabled date to the Han Dynasty, 206 BCE–AD 220. Fiscal and administrative disability classification date at least to the Tang Dynasty, 618–907.

1250–1350 High point of medieval medicalization during which theoretical explanations for conditions gain currency in Western Europe. Prior to this time, in the most general of terms, lay explanations held more sway, ranging from the superstitious to the spiritual to the vindictive. With the founding of the universities, medical theory, typified by the four humors, became more influential in governmental, legal, and elite social circles. Disabling conditions like epilepsy, strokes, and paralyses, as well as psychiatric conditions, increasingly fell under the social control of doctors.

1400 Turkey: Deaf people work in the Ottoman Court from the 15th to the 20th centuries. Sign language becomes a recognized means of communication among both hearing and deaf courtiers.

1593 England: The origins of disability as a social and political category emerge with the first state disability benefits being enacted by Parliament for those disabled in war.

1593 Europe and the United States: English Parliament initiates Europe's first national system of benefits for rank-and-file disabled veterans. The first veterans' homes—France's Hôtel des Invalides, Britain's Chelsea Hospital, and Frederick the Great's Invalidenhaus in Berlin—are established in 1633, 1685, and 1748, respectively. Following the American Civil War, the U.S. government responds with a system of homes, preferences in government hiring, land grants, free prosthetics, and pensions for disabled veterans (however, southern veterans were limited to usually scanty state pensions).

1601 England: The Poor Law is passed to provide family and community support for those unable to make a living for themselves.

1604 Laws on witchcraft in the colonies all evolve from a 1604 English Statute that makes "being a witch" punishable by death. During outbreaks of witch-hunting, the "different" body itself is targeted as a sign and symptom of one's confederation with demonic forces.

1697 England: The first English workhouse for people with mental and physical disabilities is established in Bristol in 1697.

1704 Bethlem Hospital in the United States has 130 residents housing the "furiously mad."

1714 ◆ Canada: The Bishop of Quebec opens the first building in Canada exclusively for the confinement of mentally disturbed individuals. It is adjacent to Quebec General Hospital.

1749 ◆ France and England: Denis Diderot pens one of the most influential treatises on the blind and education in his *Letter on the Blind* in which he argues that the blind can be educated. In 1784, Valentin Haüy opens the first school for the blind in Paris. He perfects a system of raised *letters* to enable the blind to read. In 1828, Louis Braille modifies a raised *dot* system invented by Charles Barbier, which is used today by blind persons to read and communicate. In 1847, William Moon, an Englishman, develops an embossed script based on Roman capitals that blind adults can learn to read in a few days. It is the first reading system for the blind to be widely adopted across the world, but because it is costly to print, the Braille system, which can be produced by blind individuals for themselves, overtakes Moon's system.

1755 ◆ France, the United States, and Germany: The Abbé Charles-Michel de l'Épée establishes the first state-supported school for the training of young deaf children, where he teaches sign language. The school serves as an inspiration for the establishment of other European schools and has a dramatic impact on social attitudes toward the deaf. In 1817, Thomas Gallaudet and Laurent Clerc establish the Asylum for the Deaf (now American School for the Deaf) in Hartford, Connecticut. Clerc imports the French sign system, which influences the makeup of contemporary American Sign Language (ASL). In 1778, Samuel Heinicke establishes a school in Leipzig, Germany, where the "oral method" is used.

1800 ◆ France: Victor of Aveyron, a "feral child" found in southern France, is brought to Paris. Jean Marc Gaspard Itard, a French physician, develops a systematic training program for the boy and works intensively with him for five years. Itard considered his attempt at educating Victor to be a failure because the boy did not learn to use a language. Nevertheless, Itard's disciples, including Edouard Séguin, Maria Montessori, and Alfred Binet, continue his work by establishing classes for children considered to be "mentally retarded."

1802 ◆ France: The world's first pediatric hospital, L'Hôpital des Enfants Malades, is founded.

1817 ◆ The American School for the Deaf is founded in Hartford, Connecticut. It is the first school for disabled children in the Western Hemisphere.

1817 ◆ James Parkinson, a London physician, describes what is to become known as Parkinson's disease.

1817 ◆ Thomas Gallaudet and Laurent Clerc open the American Asylum for the Education of the Deaf and Dumb in Hartford, Connecticut.

1828 ◆ Frenchman Louis Braille, blind from childhood, modifies a raised-dot system of code, one of the most important advances in blind education. It not only allows the blind to read at a much faster rate but also makes it possible for the blind to be teachers of the blind. UNESCO creates the World Braille Council in 1952.

1829 ◆ France: Louis Braille publishes an explanation of his embossed dot code.

1832 ◆ Samuel Gridley Howe is chosen to direct what is later to be called the Perkins School for the Blind in Boston. It becomes the model for schools around the nation. Laura Bridgman and Helen Keller attend Perkins. In 1837, Ohio establishes the first state-sponsored school for the blind.

1834 ◆ England: The English Poor Law Amendment stipulates five categories of those unable to work: children, the sick, the insane, defectives, and the aged and infirm. This sets the stage for the development of specialty institutions that isolate the disabled from the community.

1841 ◆ P. T. Barnum purchases Scudder's American Museum in New York City. This moment is considered to be the beginning of the "Golden Age" of freaks, which persists until the 1940s. The tension

between freaks and disability rights comes to a head in 1984, when disability rights activist Barbara Baskin successfully lobbies the New York State Fair to remove Sutton's Incredible Wonders of the World Sideshow, featuring a limbless man who performs as the "Frog Boy," from the midway.

1843 ◆ Due to the influence of Dorothea Dix, an American social reformer, the Massachusetts legislature allocates funds to greatly expand the State Mental Hospital at Worcester. Dix also plays an instrumental role in the creation of 32 mental hospitals and becomes nationally known for her reform efforts. By the late 1840s, Dix focuses on developing a national plan that addresses the treatment of people with mental illness.

1846 ◆ William Thomas Green Morton discovers anesthesia and in 1867 Joseph Lister provides a model for antisepsis. These new technologies play a central role in the future of aesthetic surgery as well as surgical intervention for every type of disability that calls for it. Penicillin is discovered in 1929, cutting mortality rates in hospitals dramatically.

1848 ◆ The North Carolina School for the Deaf begins the first publication for Deaf persons with its school newspaper, *The Deaf Mute.* First published in 1907, the *Matilda Ziegler Magazine for the Blind* is an ongoing Braille publication.

1848 ◆ Samuel Gridley Howe founds the first residential institution for people with mental retardation at the Perkins Institution in Boston.

1851 ◆ In the United States there are 77 residential institutions for children, 1,151 by 1910, and 1,613 by 1933. By the 1950s and 1960s, family members and politicians throughout Western Europe, Canada, and the United States push for the deinstitutionalization of people with disabilities.

1851 ◆ The first International Sanitary Conference is held in Paris, France, with 12 countries participating. It leads to the World Health Organization, the WHO, which formally comes into existence in 1948.

1857 ◆ Edward Miner Gallaudet, youngest son of Thomas Hopkins Gallaudet, establishes the Columbian Institution for the Instruction of the Deaf, Dumb, and Blind, located in Washington D.C. Its college division, eventually known as the National Deaf-Mute College, is the world's first institution of higher education for deaf people. Abraham Lincoln signs its charter on April 8, 1864; today it is known as Gallaudet University.

1857 ◆ English philosopher Herbert Spencer is first to use the expression "survival of the fittest." The application of his idea in combination with Charles Darwin's theories in his 1859 book, *The Origin of the Species,* is called Social Darwinism. It is widely accepted and promoted in Germany in the 1920s and leads Adolf Hitler to express prejudice against the weak, sick, and disabled.

1863 ◆ Louis Agassiz, a significant American naturalist, advocates the permanence of different races and worries about the "tenacious influences of physical disability" if races were mixed.

1864 ◆ Germany: Karl Ferdinand Klein, teacher for deaf-mutes, and Heinrich Ernst Stotzner are considered the founding fathers of the *training school,* which calls for schools to be created for less-capable children with the goal of improving their lot. Training schools remain in effect today, but critics maintain that there is an over-representation of socially and economically underprivileged students in this type of setting experiencing little academic success.

1868 ◆ Sweden: The Stockholm Deaf Club is the first recorded organization of people with disabilities.

1870 ◆ England and Wales: Education for children with disabilities begins when universal elementary education is first introduced around this time. From 1895 onward, schools for "defective" children spring up. In 1899, Alfred Eichholz, an inspector of special education, draws up key recommendations, which leave their mark on the historic 1994 Education Act legislation. In 1978, the Warnock report

introduces the term *special needs education,* which soon gains acceptance worldwide. With the 1994 UNESCO Salamanca Statement and Framework for Action on Special Needs Education, a major shift in organizing educational services for children with disabilities is confirmed internationally.

1876 ◆ Isaac Newton Kerlin, Edouard Séguin, and others establish the Association of Medical Officers of American Institutions for the Idiotic and Feeble-Minded Persons. Today, it is known as the American Association on Mental Retardation. Séguin, who staunchly believes in the educability of those with significant cognitive disabilities, is styled as "apostle to the idiots," by Pope Pius X, reflecting the attitude of the time.

1880 ◆ The United States National Association of the Deaf (NAD), the first organization of deaf or disabled people in the Western Hemisphere, is established. In 1964, the Registry of Interpreters for the Deaf (RID) is formed to establish a national body of professionals who are trained and certified to enable communication between deaf, signing persons and nondeaf, speaking persons.

1880 ◆ Helen Keller is born in Tuscumbia, Alabama. An illness at the age of 19 months leaves her totally deaf and blind. In 1887, Anne Sullivan, recently graduated from Perkins Institution for the Blind, joins the Keller household as Helen's teacher and remains Keller's companion for nearly 50 years. For many, Keller's story is the quintessential overcoming narrative.

1881 ◆ The Chicago City Council enacts the first American "ugly law" forbidding "any person, who is diseased, maimed, mutilated or deformed in any way, so as to be an unsightly or disgusting object, to expose himself to public view."

1882 ◆ The first major federal immigration law in the United States, the Immigration Act of 1882, prohibits entry to "lunatics," "idiots," and persons likely to become unable to take care of themselves. Most of the restrictions that apply specifically to disability are removed from U.S. law in 1990. Today, disabled immigrants are still denied an entry visa if they are deemed "likely to become a public charge."

1887 ◆ Walter Fernald serves as superintendent of the Massachusetts School for the Feeble-Minded (now known as the Fernald Center) from 1887 to 1924. Unlike most of his colleagues, Fernald moderates some of his earlier extreme views and eventually develops one of the country's largest "parole" systems for moving institutional residents back into smaller, community-based residences.

1887 ◆ The American Orthopaedic Association is founded. German and British counterparts are founded in 1901 and 1918, respectively.

1895 ◆ The chiropractic profession is founded. This type of care is used to relieve musculoskeletal pain, one of the most common causes of disability.

1899 ◆ Maria Montessori and a colleague open the Scuola Magistrale Ortofrenica in Rome, an educational institute for disabled children and a training institute for instructors. Her method relies on the concept of sensory-based instruction as a means for developing intellectual competence. Her methods allow the child the greatest possible independence in order to foster his or her own development (the child's own inner "building plan").

1904 ◆ Sir Francis Galton, half first cousin of Charles Darwin, defines the term e*ugenics* (which he coined in 1883) in a paper he presents to the Sociological Society on May 16. He argues for planned breeding among the "best stock" of the human population, along with various methods to discourage or prevent breeding among the "worst stock." Galton also develops the idea for intelligence tests. The term *feeblemindedness* is defined as broadly as possible and is widely used by eugenic social reformers to conflate myriad social problems. Further naming, classification, and labeling provides eugenicists with a troubling rationale for treating people with coercion, disrespect, and profound inhumanity. Persons within the various categories of sub-normality become particularly vulnerable

to state-sanctioned segregation, institutional confinement, and enforced sterilization. Eugenics is widely practiced in Europe, the United States, and Canada, culminating in the systemic murder of more than 260,000 disabled people by the Nazis between 1939 and 1945. Today, the so-called new eugenics, known as "human genetics," appeals to the needs of the individual. Critics (some of the first in Germany), however, criticize individualistic eugenic approaches and disclose the connections between human genetics, national socialist racial hygiene, and eugenics.

1905 ◆ Alfred Binet and Theodore Simon publish the first intelligence scale, known as the Binet-Simon Test.

1908 ◆ The publication of Clifford Beers's *A Mind That Found Itself* initiates the mental health hygiene movement in the United States. Speaking out against mistreatment and neglect within the system, Beers establishes the Connecticut Committee of Mental Hygiene, which expands in 1909, becoming the National Committee for Mental Hygiene and is now known as the National Mental Health Association. In 1940 there are 419,000 patients in 181 state hospitals. In 1943, the patient-doctor ratio is 277:1, and by the mid-1950s in New York state alone, there are 93,000 inpatients. The Bazelon Center for Mental Health Law, founded in 1972 by a group of committed lawyers and professionals in mental health and mental retardation, attempt to improve mental health service provision through individual and class action suits. In 1980, a group of these lawyers form the National Association of Rights Protection and Advocacy (NARPA). One-third of its board of directors must identify themselves as current or former recipients of mental health care. The association is committed to the abolishment of all forced treatment.

1908 ◆ Pastor Ernst Jakob Christoffel establishes a home in Turkey for blind and otherwise disabled and orphaned children. This grows into Christoffel-Blindenmission (CBM), an independent aid organization of Christians of various denominations united to help disabled people in third world countries. Today, it supports more than 1,000 development projects in 108 countries. In 1999, CBM, other agencies, and the World Health Organization initiate VISION 2020: The Right to Sight, a global initiative for the elimination of avoidable blindness by the year 2020.

1909 ◆ Germany: The German Organization for the Care of Cripples is created as an umbrella organization for the care of the physically disabled. The Prussian Cripples' Care Law of 1920 for the first time provides a right to medical care and scholarly and occupational education for this group.

1912 ◆ Henry H. Goddard publishes *The Kadikak Family,* supports the beliefs of the eugenics movements, and helps create a climate of hysteria in which human rights abuse of the disabled, including institutionalization and forced sterilization, increases. In 1927, the U.S. Supreme Court, in *Buck v. Bell,* rules in favor of forced sterilization of people with disabilities, further fueling eugenics movements—the number of sterilizations increases.

1914 ◆ By this date, Sigmund Freud develops his most enduring influence on the study of disability, namely, the theory of psychosomatic illness in which a psychopathological flaw is given corporeal form as a symptom, thereby establishing the notion that people succumb to disease or disability because they feel guilty about past or present repressed desires.

1918 ◆ The Smith-Sears Veterans Rehabilitation Act passes, authorizing VR services for World War I veterans. In 1916, the National Defense Act marks the beginning of the U.S. government's supportive attitude toward rehabilitation. In 1920, the Smith-Fess Act marks the beginnings of the civilian VR program. The Social Security Act of 1935 establishes state-federal VR as a permanent program that can be discontinued only by an act of Congress.

1919 ◆ Edgar "Daddy" Allen establishes what becomes known as the National Society for Crippled Children. In the spring of 1934, the organizational launches its first Easter "seals" money-making campaign. Donors place seals on envelopes containing their contributions. The seal is so well-known that it

becomes part of the organization's official name. Today, Easter Seals assists more than one million children and adults with disabilities and their families annually through a nationwide network of more than 500 service sites. During the 1920s, Franklin D. Roosevelt inspires the March of Dimes.

1920 At about this time, the Shriners open hospitals for the care of crippled children. President Herbert Hoover establishes a "Children's Charter" in 1928 highlighting the need to attend to the needs of crippled children.

1921 Franklin D. Roosevelt contracts poliomyelitis. Despite damage to his legs (which makes him a wheelchair user) and deep depression, through enormous rehabilitative effort, he eventually re-enters politics and becomes president of the United States. His triumph over personal disability becomes legendary. Critics, however, fault him for choosing to minimize his disability in what is called his "splendid deception." He establishes a center for the treatment of polio patients in Warm Springs, Georgia, called the Georgia Warm Springs Foundation (1927), which hires medical specialists from Atlanta to direct orthopedics. In 1937, President Roosevelt becomes the prime mover behind the National Foundation for Infantile Paralysis Research.

1921 Mary L. McMillan (Molly) establishes the American Women's Physical Therapeutic Association, which is known today as the American Physical Therapy Association (APTA).

1921 The American Foundation for the Blind is established.

1921 Canada: Researchers isolate the hormone insulin. In 1922, Frederick Banting, Charles Best, J. B. Collip, and J.R.R. Macleod produce and test the pancreatic extract on people with diabetes, for which they are awarded a Nobel Prize. Insulin becomes a wonderful treatment for diabetes, but not a cure.

1921 France: Three historical waves of advocacy movements can be identified beginning with the National Federation of Injured Workers (FNAT) in 1921 and other organizations that focus essentially on the protection of rights. Another factor that stimulates advocacy groups in the first wave is the wounded veterans of World Wars I and II. A second wave dates from the period after World War II. Many advocacy groups form between 1950 and 1970, such as the Union of Associations of Parents of Maladjusted Children (UNAPEI) in 1960. A third wave finds a gradual emergence of three types of associations: those that run specialized facilities (for example, Living Upright, which, in 1970, leads to the creation of the first group living facility); those interested in trade unions; and those represented by user-advocate associations. Financing comes in large part from public funds, thereby creating a government-association partnership.

1922 The founding of Rehabilitation International sets the stage for the establishment of other international organizations of and for people with disabilities that link together throughout the world. Later international organizations include, among numerous others, the World Federation of the Deaf (1951), Inclusion International (1962), the International Association for the Scientific Study of Intellectual Disability (1964), Disabled Peoples' International (1981), and the International Disability Alliance (1999).

1925 The American Speech-Language-Hearing Association, today the American Academy of Speech Correction, is established to provide high-quality services for professionals in speech-language pathology, audiology, and speech and hearing science, and to advocate for people with communication disabilities.

1928 Charles Nicolle is the first deaf person to be awarded a Nobel Prize.

1929 Seeing Eye establishes the first dog guide school in the United States.

1930 The Veterans Administration is created to administer benefits, promote vocational rehabilitation, and return disabled veterans to civil employment. There is a record of provision for disabled veterans in the United States since the Revolutionary War and the Civil War. After World War I, three agencies administer veteran's benefits.

1932 Herbert A. Everest, a mining engineer with a disability, and Harry C. Jennings collaborate to design and patent the cross-frame wheelchair, which becomes the standard for the wheelchair industry that exists today. Developed during World War I, the first powered wheelchair appears, but doesn't gain popularity for another 30 years.

1935 President Franklin D. Roosevelt signs the Social Security Act of 1935 on August 14. Beginning in 1956, SSA amendments provide disability benefits.

1935 By 1935, in the United States more than 30 states pass laws allowing for the compulsory sterilization of those deemed genetically unfit in state and federal institutions. By 1970, more than 60,000 people are sterilized under these laws.

1935 As a result of being denied participation in the Works Progress Administration (WPA), six young people with disabilities hold a sit-in at the offices of New York City's Emergency Relief Bureau, demanding jobs in non-segregated environments and explicitly rejecting charity. The League of the Physically Handicapped is born out of this activism and operates in New York from 1935 to 1938. The League identifies social problems that remain issues today.

1935 Peer support in the United States is traced to the establishment of Alcoholics Anonymous in this year. Interest in peer support increases in the 1960s and is adopted by the disabled community. Movements, such as the Center for Independent Living, and groups, such as the National Spinal Cord Injury Association, make peer support one of their major activities.

1936 The American Academy of Physical Medicine & Rehabilitation is founded, leading to the approval of the American Board of Physical Medicine & Rehabilitation by the American Medical Association in 1947.

1937 The Fair Housing Act of 1937 passes with a mandate to assist the poor, a group that includes people with disabilities, by creating public housing. However, it is not until the Rehabilitation Act of 1973 that housing law specifically deals with discrimination faced by individuals with disabilities in housing programs that receive federal funding. The 1988 amendment to the Fair Housing Act of 1968 extends protection for people with disabilities beyond those of Section 504 of the Rehabilitation Act to include private housing.

1939 The Nazi regime institutes the Aktion T4 program in Germany. Children and, later, adults with disabilities are selectively killed both in hospitals and in special centers. The program was officially terminated by Adolf Hitler in August 1941, but practitioners "informally" continued it through a phase historians have called "wild euthanasia."

1940 State activists for the blind, including Jacobus Broek, come together in Wilkes-Barre, Pennsylvania, to charter the National Federation of the Blind (NFB). In 1957, the NFB publishes the first edition of the *Braille Monitor,* which is still in print today. In 1960, dissatisfied NFB members form the American Council of the Blind (ACB).

1940 Paul Strachan establishes the American Federation of the Physically Handicapped, the nation's first cross-disability, national political organization.

1942 The American Psychiatric Association develops a position statement in favor of the euthanasia of children classified as *idiots* and *imbeciles.*

1943 The LaFollette-Barden Act, also known as the Vocational Rehabilitation Amendments, adds physical rehabilitation to federally funded vocational rehabilitation programs.

1943 The United Nations is established on October 24 by 51 countries. The global Programme on the Disability is the lead program concerning disability. Many other types of programs, activities, and instruments include the 1975 Declaration on the Rights of Disabled Persons, the 1981 International Year of

Disabled Persons, the 1982 World Programme of Action Concerning Disabled Persons, the 1983–1992 UN Decade of Disabled Persons, and the 1993 Standard Rules on the Equalization of Opportunities for Persons with Disabilities. In 1988, the first UN Disability Database (DISTAT) publishes statistics from 63 national studies covering 55 countries and the 2001 publication presents 111 national studies from 78 countries, indicating a growing interest worldwide for the collection of usable data. In 2005, a UN Ad Hoc Committee continues to consider a Convention on the Rights of Disabled Persons that is a legally binding human rights instrument. Today the UN membership totals 191 countries.

1943 Sweden: In possibly the first reference to the concept of normalization, the most significant driving force in the ongoing closure of state-run or state-funded institutions for people with a disability is made by the Committee for the Partially Able-Bodied, established by the Swedish Government. Through the advocacy of people such as Niels Erik Bank-Mikkelsen, normalization, with its profound positive effect on the lives of people who were once removed and segregated from society, remains relevant today.

1944 Richard Hoover invents long white canes known as Hoover canes that are used by many blind people.

1944 The word *genocide* first appears in a book by a Polish lawyer Raphael Lemkin titled *Axis Rule in Occupied Europe* in which he describes Nazi Germany's practices but also seeks the adoption of legal restrictions so that genocide will not occur. In 1948, the United Nations adopts a declaration and then a convention on genocide that describe both against whom genocide might be directed and acts constituting genocide. Article 6 of the Rome Statute of the International Criminal Court (ICC), established in 2002, uses language identical to that in the UN convention to define genocide. More than 90 countries are parties to the ICC, but not the United States.

1945 President Harry Truman signs into law an annual National Employ the Handicapped Week. In 1952, it becomes the Presidents' Committee on Employment of the Physically Handicapped, a permanent organization, which reports to the President and Congress.

1945 Canada: Lyndhurst Lodge, the first specialized rehabilitation center for spinal cord injury (SCI) in the world, and the Canadian Paraplegic Association, the first association in the world administered by individuals with SCI, are established.

1946 The first chapter of what will become the United Cerebral Palsy Association, Inc. is established in New York City. It is chartered in 1949, and along with the Association for Retarded Children, it becomes a major force in the parents' movement of the 1950s.

1946 The National Mental Health Foundation is founded by attendants at state mental institutions who aim to expose abusive conditions. Their work is an early step toward deinstitutionalization.

1946 The National Institutes of Mental Health (NIMH) are founded in the United States.

1946 Europe: The European Union is founded on September 17 in Paris. It consistently shows its commitment to eliminating discrimination on many fronts through joint declarations, resolutions, directives, and action programs. With regard to disability, the European Union supports actions in favor of people with disabilities, principally in the form of European Social Fund interventions. Action programs aim at facilitating the exchange of information between member states and nongovernmental organizations with a view to identifying good practices, integrating people with disabilities into society, and raising awareness of related issues. The EU Council of Ministers Recommendation on the Employment of Disabled People (1986) calls on member states to "eliminate negative discrimination by reviewing laws, regulations and administrative provisions to ensure that they are not contrary to the principle of fair opportunity for disabled people." Further

steps are taken in 1996 when a communication on equality of opportunities for disabled people sets out a new European disability strategy that promotes a rights-based approach, rather than a welfare-type approach. This is strengthened in 1997 when the heads of state act to strengthen Article 13 of the European Community Charter of Fundamental Social Rights of Workers (1989), giving the European Community specific powers to take action to combat a broad spectrum of discrimination that includes disability.

1948 The National Paraplegia Foundation is established as the civilian branch of the Paralyzed Veterans of America.

1948 The World Health Organization is established. The WHO actively promotes human rights and the principle of equity in health among all people of the world, including persons with disabilities. Today it consists of 191 member states, but strives for universal membership. In 1980, the WHO publishes the International Classification of Impairments, Disabilities, and Handicaps (ICIDH) and issues a revised version in 2001, the International Classification of Functioning, Disability, and Health (ICF).

1948 The United Nations General Assembly adopts the "Universal Declaration of Human Rights," which promotes and affirms the fundamental rights to life, liberty, and security; to medical care and social services; and to the benefit from scientific progress and its uses.

1948 Sir Ludwig Guttmann organizes the first Stoke Mandeville (England) Games for the Paralysed, thus launching the Paralympic movement. The Games become international in 1952. In 1960, the first Paralympic Summer games are held in Rome and the first Paralympic Winter Games follow in 1976. The Paralympic Games are multi-disability, multi-sport competitions and have become the second-largest sporting event in the world, only after the Olympic Games.

1948 World War II bomber pilot and war hero Leonard Cheshire establishes what is to become the largest charitable supplier of services for disabled people in the United Kingdom. In the 1960s, the resistance of disabled people who live in one Leonard Cheshire home, Le Court, plays a major role in establishing the British disabled people's movement. In the late 1990s, the Leonard Cheshire organization establishes the Disabled People's Forum, which is run by disabled people and supports disabled people's involvement and empowerment.

1949 Timothy Nugent founds the National Wheelchair Basketball Association, and the first Annual Wheelchair Basketball Tournament takes place.

1949 Europe: The Council of Europe, an intergovernmental organization, is founded. Its activities cover all major issues facing European society other than defense. Human dignity, equal opportunities, independent living, and active participation in the life of the community form the heart of the Council of Europe's activities in relation to people with disabilities. The European Social Charter of 1961 and its revision in 1996 include specific wording and expand the rights of individuals with disabilities.

1950 The Social Security Amendments of 1950 provide federal-state aid to the permanently and totally disabled (APTD), which serves as a limited prototype for future Social Security assistance programs for disabled people.

1950 The National Mental Health Association is formed with the mission to continue 1908-advocate Clifford W. Beers's goals of "spreading tolerance and awareness, improving mental health services, preventing mental illness, and promoting mental health."

1950 The National Association for Retarded Children (NARC) is established by families in Minneapolis. It is the first and most powerful parent-driven human-services lobby in the nation to emerge in the 1950s.

1950 Amniocentesis is developed by a Uruguayan obstetrician. Later, advanced prenatal testing provides a battery of powerful medical tools to predict risk of disability and provide information to parents about their pregnancies.

1951 With the founding of the World Federation of the Deaf, the deaf community becomes international.

1953 Francis Crick and James Watson propose a three-dimensional structure for the DNA molecule. The paper they publish also gives clues to genetic mechanisms. Today, more than 6,000 monogenic disorders have been identified, and these affect approximately 1 in 200 live births.

1955 The polio vaccine, developed by Dr. Jonas Salk, becomes available, thus ending polio epidemics in the Western world. A new oral vaccine, developed by Dr. Albert B. Sabin, is approved for use in 1961.

1956 Social Security Disability Insurance (SSDI) becomes available through amendments to the Social Security Act of 1935 (SSA) for those aged 50–64. Other important amendments to SSA include the following: 1958: provides for dependents of disabled workers; 1960: removes age limit; 1965: Medicare and Medicaid provide benefits within the framework of the SSA (until 1977); 1967: provides benefits to widows and widowers over the age of 50; 1972: Supplemental Security Income (SSI) establishes a needs-based program for the aged, blind, and disabled; 1984: the Social Security Disability Reform Act responds to the complaints of hundreds of thousands of people whose disability benefits have been terminated; 1996: President Clinton signs the Personal Responsibility and Work Opportunity Reconciliation Act, making it more difficult for children to qualify as disabled for SSI purposes.

1959 The UN Declaration of the Rights of the Child is adopted; the UN Convention on the Rights of the Child is adopted in 1989. A central principle of both documents is access to education for all children including those with disabilities. In 1993, a related UN document, the Standard Rules for the Equalization of Opportunity, extends this to preschool children, and in 1994, UNESCO's Salamanca Statement and Framework for Action specifies the provision of special education for children with disabilities or learning difficulties. These documents constitute a universal bill of rights that can serve as a framework in the development of national policies worldwide.

1961 The American Council of the Blind is established.

1961 Europe: The European Social Charter (ESC) protects "the right of physically and mentally disabled persons to vocational training, rehabilitation and social resettlement." In 1996, it is revised, updated, and expanded to take account of social changes.

1961 Michel Foucault's work *The History of Madness in the Classical Age* becomes obligatory reading for those concerned with the archaeology of madness and its treatments. It continues to be an academic *rite de passage.*

1962 Battered child syndrome is defined. Researchers estimate that the incidence of maltreatment of children with disabilities is between 1.7 and 3.4 times greater than of children without disabilities.

1962 Russia: The Moscow Theater of Mime and Gesture is the first professional deaf theater in the world. It has been in continuous operation for more than 40 years and has staged more than 100 classic and modern plays.

1963 Congress enacts new legislation to ensure funding for a comprehensive program of research on mental retardation through the National Institute on Child Health & Human Development. In 1965, the Office of Economic Opportunity launches the Elementary and Secondary Education Act (ESEA), commonly known as Project Head Start. The goal is to prevent developmental disability by providing increased opportunities for disadvantaged children in the preschool years.

1963 The Developmentally Disabled Assistance and Bill of Rights Act (DD ACT) is authorized, with its last reauthorization in 1996. It focuses on individuals with developmental disabilities such as intellectual disability, autism, cerebral palsy, epilepsy, and hearing and visual impairments, among others.

1964 The Civil Rights Act is passed. It becomes the model for future disability rights legislation.

1964 France: L'Arche is established. By the beginning of the twentieth-first century, it includes more than 113 communities in 30 countries. "The Ark" is a distinctive style of community living, based on "core members" and "assistants," who view their commitment as sharing life *with* people with disabilities, rather than as caregivers.

1965 Newly enacted Medicare and Medicaid provide national health insurance for both elderly (over 65) and disabled persons.

1965 The Vocational Rehabilitation Amendments of 1965 are passed. They provide federal funds for the construction of rehabilitation centers and create the National Commission on Architectural Barriers to Rehabilitation of the Handicapped.

1965 The Autism Society of America is founded.

1967 Deaf actors establish the National Theatre of the Deaf (NTD). It is the world's first professional deaf theater company and the oldest continually producing touring theater company in the United States. Today, after almost 40 years, the NTD chronicles over 6,000 performances. The National Theatre Workshop for the Handicapped begins in 1977 and the Other Voices Project in 1982. These groups are among the earliest groups formally to place the disability experience at the heart of their creative endeavors.

1967 Heart transplantation is introduced. This technology is preceded by open-heart surgery developed in the 1950s and coronary bypass and internal pacemakers in the1960s. The Framingham Heart Study begins in 1948. It collects data over the next decades that help identify major risk factors contributors to heart disease.

1967 Paul Lemoine in France in 1967 and Kenneth Jones and David Smith in the United States in 1973 independently describe the condition fetal alcohol syndrome (FAS), which comprises a recognizable pattern of birth defects attributable to the adverse effects of maternal alcohol abuse during pregnancy.

1967 England: St. Christopher's Hospice in South London opens. It is the first attempt to develop a modern approach to hospice and palliative care.

1968 Congress enacts the Architectural Barriers Act. The ABA requires access to facilities designed, built, altered, or leased with federal funds.

1968 The Fair Housing Amendments to the Civil Rights Act of 1968 guarantees civil rights of people with disabilities in the residential setting. The amendments extend coverage of the fair housing laws to people with disabilities and establish accessible design and construction standards for all new multifamily housing built for first occupancy on or after March 13, 1991.

1968 Sweden: The origins of People First® go back to a meeting of parents of children with intellectual disabilities whose motto is "we speak for them." However, the people with disabilities in attendance wish to speak for themselves and start their own self-advocacy group. Similar groups quickly spread to England and Canada. The name People First is chosen at a conference held in Salem, Oregon, in 1974. People First is an international self-advocacy organization run by and for people with intellectual disabilities to work on civil and human rights issues.

1970 ◆ Landmark legal cases such as *Diana v. State Board of Education* (1970; Latino students) and *Larry P. v. Riles* (1971–1979; minority students) challenge biases inherent in standardized testing procedures used to identify students as eligible for special education. Both cases call into question the widespread use of "scientifically" objective measures to gauge intellectual ability. Today, despite reforms, a disproportionate number of students from racial, ethnic, and linguistic minorities continue to be placed in special education classes.

1970 ◆ Japan: The Disabled Persons' Fundamental Law (DPFL) becomes one of the 27 fundamental laws that stipulate basic principles in each policy area. Major revision takes place in 1993 reflecting a progress of guiding principles in disability policy that are deeply influenced by international movements such as the International Year of Disabled Persons (1981) and the UN Decade of Disabled Persons (1983–1992). Disability Studies as well as modern disability movements are born this same year, when members of Aoi Shiba, a group of people with cerebral palsy, protest publicly for the first time against sympathetic views toward the killing of disabled children by their parents. Aoi Shiba and other disability movements join in the establishment of Disabled Peoples' International in 1981. In 1986, the Rehabilitation Engineering Society of Japan (RESJA) is established. In 1992, disability movements in Japan initiate the Asian and Pacific Decade of Disabled Persons 1993 to 2002. The Japan Society for Disability Studies is established in 2003 and a unified national organization, Japan Disability Forum (JDF), is established in 2004.

1970 ◆ United Kingdom: The Chronically Sick and Disabled Persons Act (CSDPA) strengthens the provisions in the 1948 National Assistance Act (NAA). Later, the Disability Discrimination Acts of 1995 and 2005, together with the Disability Rights Commission Act of 1999, constitute the primary source of antidiscrimination legislation for disabled people.

1971 ◆ A U.S. District Court decision in *Wyatt v. Stickney* is the first important victory in the fight for deinstitutionalization.

1971 ◆ WGBH Public Television establishes the Caption Center, which provides captioned programming for deaf viewers.

1971 ◆ Gerontologist M. Powell Lawton defines *functional assessment* as any systematic attempt to objectively measure the level at which a person is functioning in a variety of domains. Over 30 years later, functional assessment, in combination with *outcomes analysis,* is considered one of the "basic sciences" of rehabilitation. In 1980, the World Health Organization proposes a series of definitions, which have a profound impact on the assessment of functional status and outcomes in rehabilitation. It is modified and revised in 1993 and 2001.

1971 ◆ The Declaration on the Rights of Mentally Retarded Persons (UN 1971), the Declaration on the Rights of Disabled Persons (UN 1975), and the World Programme of Action Concerning Disabled Persons (UN 1982) indicate the emergence of a global discourse of rights for disability.

1972 ◆ A group of people with disabilities (including Ed Roberts, John Hessler, and Hale Zukas), known as the Rolling Quads, living together in Berkeley, California, formally incorporate as the Center for Independent Living (CIL). This first CIL in the country becomes the model for Title VII of the Rehabilitation Act of 1973. In the late 1980s and early 1990s the group's advocacy efforts help pass the Americans with Disabilities Act (ADA). CILs are always controlled by disabled people. Accepted by most people as the birth of the modern independent living movement, the Berkeley concept migrates to other countries. In 1999, a global summit on independent living is held in Washington D.C. The summit brings together more than 70 countries. The Washington Declaration that comes out of the conference establishes a set of basic principles. In 1996, the Ed Roberts Campus, an international center and a service facility, is created in Berkeley, California, in memory of Edward V. Roberts, founder of the independent living concept.

1972 ◆ A young television reporter for the ABC network, Geraldo Rivera, is given a key to one of the wards at Willowbrook State School on Staten Island, New York. Established in the late 1930s as a state-of-the-art facility for the "mentally deficient," by 1972, Willowbrook becomes a warehouse for the "socially undesirable" of New York City, with a substantial minority having no disability at all. The inhumane conditions deteriorate to the extent that a visitor remarks, "In Denmark we don't let our cattle live this way." Rivera's exposé leads to a lawsuit that results in the Willowbrook Consent Decree of 1975, which creates a detailed system of monitoring and oversight of all residents living there at that time, to be met until the last of the "class clients," as they are sometimes referred to, pass on. The property has since been sold to a college.

1972 ◆ Paul Hunt's call for a consumer group to promote the views of actual and potential residents of institutional homes for the disabled in the United Kingdom results in the establishment of the Union of the Physically Impaired against Segregation (UPIAS). The group's aim is to formulate and publicize plans for alternative forms of support in the community. Hunt is regarded by many disability activists as the founder of the modern disabled people's movement.

1972 ◆ New Zealand: Three key pieces of legislation pass have long-term effects on the disabled community: the 1972 no-fault Accident Compensation Act that provides monetary compensation to victims based on level of impairment suffered; the 1975 Disabled Persons Community Welfare Act, giving assistance to disabled people, parents, and guardians, as well as voluntary associations; and the Human Rights Act of 1977, which does not include disability as a recognized grounds for discrimination. Today, disabled populations in New Zealand continue to fight to establish an identity as disabled people rather than a group needing "welfare." One task is to promote legislation that includes disability as a group against whom discrimination is outlawed.

1973 ◆ The Rehabilitation Act of 1973 lays the foundation for the disability rights movement. Its Section 504 asserts that people with disabilities have equal rights that prevent discrimination based on their disability in programs or activities that receive federal funding. This is the first major nationwide antidiscriminatory legislation designed to protect disabled Americans. These rights are further protected with the landmark Americans with Disabilities Act (ADA) of 1990.

Section 501 of the Act requires affirmative action and nondiscrimination in employment by federal agencies of the executive branch. Section 502 creates the Access Board, which grows out of the 1965 National Commission on Architectural Barriers to Rehabilitation of the Handicapped. As a result of the commission's June 1968 report, Congress enacts the Architectural Barriers Act (ABA). Section 503 requires that to receive certain government contracts, entities must demonstrate that they are taking affirmative action to employ people with disabilities. The enduring hallmark of the act, Section 504, provides that no otherwise qualified individual with a disability shall, solely by reason of his or her disability, be excluded from the participation in, denied the benefits of, or subjected to discrimination under any program or activity receiving federal funds. However, it would take five years of lobbying and protesting before the American Coalition of Citizens with Disabilities (ACCD) wins the release of regulations that allow Section 504 to be implemented.

The Act is in many ways the direct predecessor to the ADA. However, the primary focus is vocational training and rehabilitation, and over the next half-century, disability law and advocacy move from the medical (medical issues) and vocational (often a justification for welfare and benefits) models to a civil rights model, which seeks to remove the barriers that impede the full integration of people with disabilities into society.

1973 ◆ The term *mainstreaming* emerges within the educational jargon associated with the Education for All Handicapped Children Act (EHA), the early U.S. legislation subsequently reauthorized as the Individuals with Disabilities Act (IDEA) in 1990.

1973 ◆ Ronald Mace is the driving force behind the creation of the first accessible state building code in the United States (North Carolina, 1974) and in the drafting of national accessibility codes and

standards. He coins the term *universal design* to capture and promote his expanded philosophy of "design for all ages and abilities"—curb cuts being his favorite example.

1973 Washington D.C. introduces the first handicap parking stickers. The Federal-Aid Highway Act funds curb cuts.

1974 First Lady Betty Ford and investigative reporter Rose Kushner are diagnosed with breast cancer. They help break the public silence on this topic. In 1954, Terese Lasser begins Reach to Recovery, a program of volunteers who have previously undergone radical mastectomies who provide emotional support to hospitalized women who have just had the operation. Today, one in eight women is diagnosed with breast cancer during her lifetime.

1975 The Education for All Handicapped Children Act, the first separate federal legislation authorizing special education for children and youth, passes, due, in part, to the advocacy efforts of a group of parents. In 1990, it becomes known as the Individuals with Disabilities Education Act, or IDEA.

1975 The Developmentally Disabled Assistance and Bill of Rights Act, providing federal funds for programs that provide services for people with developmental disabilities, passes.

1975 The Association of Persons with Severe Handicaps (TASH) is founded. It calls for the end of aversive behavior modification and deinstitutionalization of people with disabilities.

1975 The UN General Assembly adopts the Declaration on the Rights of Disabled Persons, which states that all persons with disabilities have the same rights as other people. This document is not legally binding and can be attributed in part to a UN Ad Hoc Committee set up in 2001 to consider a Convention on the Rights of Disabled Persons that is legally binding.

1975 United Kindom: The Union of the Physically Impaired against Segregation (UPIAS) publishes a paper that redefines the term *disability,* which becomes known as the social model of disability as it radically transforms the way disabled people see themselves and their place in society.

1976 The Higher Education Act of 1965, which establishes grants for student support services aimed at fostering an institutional climate supportive of low-income and first-generation college students, is amended to include individuals with disabilities. In March 1978, the Association on Handicapped Student Service Programs in Post-Secondary Education is founded. It later becomes the Association on Higher Education and Disability (AHEAD).

1976 Sponsored by Ralph Nader's Center for the Study of Responsive Law, the Disability Rights Center is founded in Washington D.C.

1977 Protesting the federal government's delayed enactment of the rules and regulations for the implementation of the Rehabilitation Act of 1973, disabled activists on April 1 organize protests at the federal offices of the Department of Health and Human Services in various cities across the United States. In San Francisco, protesters hold the regional offices hostage for 28 days, gaining national attention and resulting in an agreement with federal officials for the rapid establishment of the rules and regulations to implement Section 504 of the Act.

1977 Max Cleland is appointed to head the U.S. Veterans Administration. He is the first severely disabled person to hold this post.

1977 S. Z. Nagi defines *disability* as an individual's performance of tasks and activities related to achievement of social roles—a distinct concept, different from *impairment*. It is further formalized with the introduction of the World Health Organization's International Classification of Impairments, Disabilities, and Handicaps in 1980 and further refined in 2001 in its International

Classification of Functioning, Disability, and Health. Nagi's model is used as the basis for the Americans with Disabilities Act, for almost all disability social policy in the United States, and for statistics at the United Nations and in Europe.

1978 ◆ The Child Abuse Prevention and Treatment and Adoption Reform Act of 1978 and the Adoption Assistance and Child Welfare Act of 1980 promote the adoption of children with special needs, including disabilities.

1978 ◆ The Atlantis Community, the second independent living center in the country after Berkeley, is established in Denver, Colorado, in 1975. On July 5–6, 1978, twenty disabled activists from the Atlantis Community block buses with their wheelchairs and bodies and bring traffic to a standstill at a busy downtown intersection. This act of civil disobedience results in the American Disabled for Accessible Public Transit, the original name for the American Disabled for Attendant Programs Today, or ADAPT.

1978 ◆ Legislation creates the National Institute on Handicapped Research. In 1986, it is renamed the U.S. National Institute on Disability and Rehabilitation Research (NIDRR). Its mission is to contribute to the independence of persons of all ages who have disabilities. It is located in the Department of Education under the Office of Special Education and Rehabilitation Services.

1978 ◆ The World Health Organization starts to promote the concept of community-based rehabilitation (CBR) as a means of helping people with disabilities in the developing world. It emerges, in part, from the WHO primary health care campaign Health for All by the Year 2000. Around the same time, in Western countries, home-visiting programs in which a trained worker regularly visits the family to advise on ways of promoting child development become one of the success stories of modern disability services. Among the best-known programs are those based on a model originating in Portage, Wisconsin, and now used in many countries.

1978 ◆ England: The Warnock report introduces the term *special needs education.* It marks a major shift in organizing educational services for children with disabilities and results in the new conceptualization of special needs education. This change is confirmed internationally by the Salamanca Statement and Framework for Action on Special Needs Education at the UNESCO's Conference held in Salamanca in 1994. This theoretical shift is marked with the change of the term *integration* to *inclusion* or *inclusive education.*

1978 ◆ USSR: The Action Group to Defend the Rights of the Disabled is established to advocate for legal rights for Soviets with disabilities.

1979 ◆ The Disability Rights Education and Defense Fund (DREDF) establishes itself as a leading cross-disability civil rights law and policy center. It is founded by people with disabilities and parents of children with disabilities. Because its philosophy is closely aligned with other civil rights struggles, in 1981, DREDF is invited to join the executive committee of the national's largest coalition of civil rights groups, the Leadership Conference on Civil Rights. In 1987, DREDF establishes the Disability Rights Clinical Legal Education Program and begins teaching disability rights law at the University of California's Boalt Hall School of Law.

1979 ◆ The National Alliance for the Mentally Ill (NAMI) is founded. NAMI is an advocacy and education organization.

1979 ◆ Germany: The first Cripples' Group is founded as a cross-disability group with emancipatory aims. In an attempt to reinterpret disability in positive terms, the cofounders choose the term *Krüppel* over handicapped or disabled.

1979 ◆ Nicaragua: The Organization of the Revolutionary Disabled is set up in the wake of the Sandinista victory.

1980 ◆ The California Governor's Committee on Employment of People with Disabilities and entertainment and media industry professionals establish the Media Access Office (MAO).

1980 ◆ About the time Congress is considering passage of the ADA (1990), marketers begin to acknowledge the economic potential of the disabled community; consequently, the appearance of disabled characters in consumer goods advertising mushroom and ability-integrated advertising becomes much more commonplace. Organizations such as MAO and NOD (National Organization on Disability) provide advertising strategies and guidance.

1980 ◆ The Rehabilitation Engineering and Assistive Technology Society of North America (RESNA), an interdisciplinary association composed of individuals interested in technology and disability, is founded.

1980 ◆ The World Health Organization's International Classification of Impairments, Disabilities, and Handicaps (ICIDH), a groundbreaking, but controversial, classification system is tentatively released for trial purposes with the goal of uniform information collection worldwide. It has a negligible impact on disability statistics or data collection; however, researchers argue that it is a vast improvement over available tools. It is renamed and vastly revised in 2001.

1980 ◆ England: Graeae Theatre Group, composed of disabled actors, directors, and other theater professionals, is founded in London by Nabil Shaban and Richard Tomlinson. It takes its name from the the Graeae of Greek mythology, three gray-haired sisters who shared one eye and one tooth. Graeae's first production is *Sideshow*.

1980 ◆ Netherlands: The Liliane Foundation starts by assisting 14 children. In 2002, it helps 31,982 children spread over 80 countries. The Foundation's efforts are directed primarily toward children with disabilities living at home. Its aim is to have direct contact with the child within the home situation and to assist the personal growth and happiness of the child, thus providing "tailor-made" assistance.

1980 ◆ Taiwan: The Physically and Mentally Disabled Citizens Protection Law is promulgated. It guarantees legal rights for the disabled and creates a significant improvement in their welfare. Although most of the disabled people in Taiwan still struggle to earn their due respect, today, public awareness of this group is emerging gradually and significantly.

1980 ◆ United Kingdom and Europe: The Black Report (*Report of the Working Group on Inequalities in Health)* is published. Among other groups it targets disabled people for better conditions that lead to better health. The report does not find favor with the Conservative government, but begins to be implemented under the Labour government in 1997. With its central theme of equity, the report plays a central role in the shaping of the World Health Organization's Common Health Strategy of the European Region.

1981 ◆ The Reagan Administration begins to amend and revoke disability benefits, a policy that continues throughout his administration and leads several disabled people who are in despair over the loss of their benefits to commit suicide.

1981 ◆ Justin Dart, recognized as the founder of the Americans with Disabilities Act (ADA, 1990), is appointed to be vice-chair of the National Council on Disability. The council drafts a national policy on equal rights for disabled people; the document becomes the foundation of the ADA.

1981 ◆ The Committee on Personal Computers and the Handicapped is established in Illinois, an indicator of the disabled community's interest in information technology (IT) accessibility, but in order to stimulate the development of suitable products, activists lobby for legislative protections, which are included in the Americans with Disabilities Act of 1990. In 2000, a suit brought by the National Federation of the Blind against AOL is suspended when AOL agrees to make its software accessible by April 2001. The World Wide Web Accessibility Initiative (WAI) launches in 1997. It raises the level of awareness of disability accessibility issues within the Internet community, especially among those who design and implement web pages.

1981 ◆ The first reported cases of AIDS in the United States appear in June. Today, the World Health Organization estimates that worldwide, approximately 40 million people are living with HIV/AIDS; 22 million men, women, and children have died; and 14,000 new infections are contracted every day. Around the world, in the year 2003, the AIDS epidemic claims an estimated 3 million lives, and almost 5 million people acquire HIV, 700,000 of them children. Currently, 6 million people infected with HIV in the developing world are estimated to need access to antiretroviral therapy to survive, but only 400,000 have this access.

1981 ◆ Disabled Peoples' International (DPI) is officially founded at a meeting in Singapore. The establishment of such international organizations around this time represents the disability movement becoming a global social movement instead of a national one. DPI is directed by persons with disabilities working in human rights advocacy. It sponsors World Assemblies, which are held every four years to develop a multiyear action plan. The most recent one is held in 2002 in Sapporo, Japan, where delegates from more than 100 countries come together. A leading slogan for DPI and other disability groups, coined in the early 1990s, is "nothing about us without us."

1981 ◆ The International Year of Disabled Persons encourages governments to sponsor programs that assimilate people with disabilities into mainstream society. Despite the positive worldwide effects it has, the UN program also creates some angry activists with disabilities who protest against the charity approach officially adopted for the event. Consequently, the activists build their own infrastructure consisting of counseling and advocacy facilities as well as job creation programs.

1981 ◆ Australia: Australia's modern disability policy takes shape after the 1981 International Year of Disabled Persons. Examples: The 1980s see a shift away from institutional care; the Commonwealth Disability Service Act provides a framework for the provision of disability services; and in 1991, the federal Disability Reform Package maximizes the employment of disabled. In 1995, a legal decision represents a watershed in telecommunications policy for people with disabilities when a commission's inquiry finds the national carrier, Telstra, guilty of discrimination against people with severe hearing or speech impairments. The success of the action results in the Telecommunications Act of 1997, which includes new provisions for the deaf community.

1981 ◆ Mexico: The Program of Rehabilitation Organized by Disabled Youth of Western Mexico begins as a rural community-based rehabilitation program.

1981 ◆ Soweto: The Self Help Association of Paraplegics begins as an economic development project.

1981 ◆ United Kingdom: Disabled people set up the British Council of Disabled Persons (BCOPD), the United Kingdom's national organization of disabled people, to promote their full equality and participation in UK society.

1981 ◆ Zimbabwe: The National Council of Disabled Persons, initially registered as a welfare organization, becomes a national disability rights group.

1982 ◆ Disability Studies originates with the formation of the Society for the Study of Chronic Illness, Impairment, and Disability. In 1986, it officially changes its name to the Society for Disability Studies (SDS). Disability Studies is a critical field of study based in human and social science.

1982 ◆ *In re Infant Doe* (commonly known as the Baby Doe case) launches the debate as to whether parents or medical authorities should choose to let a disabled infant die rather than provide the necessary medical treatment and nourishment essential to sustain life. In response to this and other cases, the U.S. Department of Health and Human Services creates a rule maintaining it unlawful for any federally funded hospital to withhold medical treatment from disabled infants. In 1984, the U.S. Congress enacts the Child Abuse Amendments, which calls for the medical treatment of newborns with disabilities unless the child would die even with medical intervention. The issue makes it to the U.S. Supreme Court in 1986 with the *Bowen v. American Hospital Association* case. The Court holds that denying treatment to disabled infants does not constitute legally protected discrimination under Section 504 of the Rehabilitation Act and that hospitals and physicians are to implement the decision of the parents. The decision results in the passage of the Child Abuse Prevention and Treatment Act Amendments of 1984. In the year 2000, a scholar argues that the Amendments, presidential commission writings, and disability advocates "have all combined to ensure that most babies who can benefit from medical interventions do receive them."

1982 ◆ Disability Awareness in Action (DAA) and other groups such as the Disabled Peoples' International (DPI) and International Disability Alliance (IDA) are the driving force behind the globalization of disability issues through the World Program of Action (1982), the United Nations Standard Rules of Equalization of Opportunities for People with Disabilities (1993), the World Summit for Social Development (1995), and the Education for All Framework for Action (2000), as well as the current campaign to secure a UN convention on the rights of disabled people.

1982 ◆ The National Council on Independent Living (NCIL) is formed in the United States. It provides an excellent example of leadership for people with disabilities by people with disabilities.

1982 ◆ Canada: The Charter of Rights and Freedoms section of the Constitution provides protection to persons with disabilities.

1982 ◆ France: Handicap International is founded in Lyon. It is active in various areas associated with all the causes of handicaps, both traumatological (land mines, road accidents) and infectious (polio, leprosy). In the 1990s it begins working on mental disability issues as a result of experience with Romanian orphanages and the war in the Balkans. In 1992, Handicap International creates its first two mine clearance programs and in 1997 it is the joint winner of the Nobel Peace Prize for its leading role in the fight against landmines.

1983 ◆ Rights-based approaches to disability rapidly gain currency in many developing countries since the UN Decade of Disabled Persons, 1983–1992. UNESCAP's Biwako Millennium Framework for Action towards an Inclusive, Barrier-Free and Rights-Based Society for People with Disabilities in Asia and the Pacific sets the priorities for the extended Decade of Disabled Persons, 2003–2012.

1983 ◆ Access and accessibility are concepts discussed throughout the World Programme of Action Concerning Disabled Persons passed by the UN General Assembly. The General Assembly in 1993 passes the Standard Rules on the Equalization of Opportunities for Persons with Disabilities.

1983 ◆ England: The first Covent Garden Day of Disabled Artists is held in London.

1983 ◆ Thailand: DPI-Thailand is established.

1984 ◆ The Access Board issues the "Minimum Guidelines and Requirements for Accessible Design," which today serves as the basis for enforceable design standards. The 1990 Americans with

Disabilities Act (ADA) expands the board's mandate to include developing the accessibility guidelines for facilities and transit vehicles. The Rehabilitation Act Amendments of 1998 give the Access Board additional responsibility for developing accessibility standards for electronic and information technology. In 2001, Section 508 of federal law establishes design standards for federal websites, making them accessible to individuals with disabilities.

1985 ◆ The U.S. Department of Health and Human Services issues the first comprehensive national minority health study, which shows racial disparity in health and concludes that the difference in mortality is not acceptable. In 1998, studies indicate that racial disparity has not improved as much as hoped; consequently, President Bill Clinton launches an initiative that sets a national goal of eliminating disparities in six key areas by the year 2010. Some of these areas include diseases and conditions considered to be disabling as well as life threatening.

1986 ◆ The Air Carrier Access Act (ACAA) passes. It requires the U.S. Department of Transportation to develop new regulations that ensure that disabled people are treated without discrimination in a way consistent with the safe carriage of all passengers. The relevant regulations, Air Carrier Access rules, are published in March 1990.

1986 ◆ The National Council on the Handicapped publishes its report *Toward Independence.* It recommends that "Congress should enact a comprehensive law requiring equal opportunity for individuals with disabilities" and suggests that the law be called "the Americans with Disabilities Act." In its 1988 follow-up report, *On the Threshold of Independence,* the council takes the somewhat unusual step of publishing its own draft of the ADA bill.

1986 ◆ The Equal Opportunities for Disabled Americans Act allows recipients of federal disability benefits to retain them even after they obtain work, thus removing a disincentive that keeps disabled people unemployed.

1986 ◆ Australia: The Disability Services Act provides that a person with disability has the right to achieve his or her individual capacity for physical, social, emotional, and intellectual development. In 1992, the Disability Discrimination Act supports nondiscrimination in education and training. It also makes it unlawful to discriminate in relation to access to premises, including public transportation.

1986 ◆ Canada: The Employment Equity Act mandates the institution of positive policies and practices to ensure that persons in designated groups, including persons with disabilities, achieve at least proportionate employment opportunities.

1986 ◆ England: The first issue of the magazine *Disability Arts in London* (DAIL) is produced in London.

1986 ◆ Southern Africa: The Southern Africa Federation of the Disabled is formed as a federation of nongovernmental organizations of disabled persons.

1988 ◆ The Technology Act (Technology-Related Assistance for Individuals with Disabilities Act of 1988 and its 1994 amendments), and, in 1998, the Assistive Technology Act (AT) provide financial assistance to states to support programs of technology-related assistance for individuals with disabilities of all ages. The1988 act defines *assistive technology* (AT). The Americans with Disabilities Act of 1990 prohibits discrimination against people with disabilities in employment, public institutions, commercial facilities, transportation, and telecommunications, which includes accessibility to all entrances, bathrooms, program areas, and parking spaces as well as interpreters for the deaf and Braille and large-print materials for the blind. The Telecommunications Act of 1996 requires the telecommunication industry to make equipment that will support transmission of information in forms accessible to people with disabilities including broadband and television program captioning. By 2000, approximately 10 percent of the U.S. population uses AT devices and/or modifications to their home, work, or school that allow them to participate in major life activities.

1988 Congress introduces a series of amendments to the Civil Rights Act of 1968, including a prohibition of housing discrimination against people with disabilities. These amendments are known as the Fair Housing Act Amendments of 1988.

1988 China: Deng Pufang, a wheelchair user and son of the late Chinese leader Deng Xiaoping, is the driving force behind a series of laws and programs initiated to improve life for the disabled. In 1984, he sets up the China Welfare Fund for Disabled Persons and, in 1988, the China Disabled Persons' Federation, which endeavors to improve public images of disabled people. Today, there are 60 million disabled people in China.

1989 The European Network on Independent Living (ENIL) is set up. It focuses on personal assistance as a key component of independent living.

1990 ADAPT, the American Disabled for Attendant Programs Today, originally called the American Disabled for Accessible Public Transit, continues to gain public awareness through tactics of civil disobedience until regulations are finally issued with the passage of the Americans with Disabilities Act (ADA).

The ADA passes, after ADAPT uses tactics of civil disobedience, in the tradition of other civil rights movements, in one of the largest disability rights protests to date (600 demonstrators), the "Wheels of Justice March," during which dozens of protesters throw themselves out of their wheelchairs and begin crawling up the 83 marble steps to the Capitol to deliver a scroll of the Declaration of Independence. The following day 150 ADAPT protesters lock wheelchairs together in the Capitol rotunda and engage in a sit-in until police carry them away one by one.

George H.W. Bush signs the ADA on July 26. It provides employment protections for qualifying persons with disability. It is the most prominent and comprehensive law prohibiting discrimination on the basis of disability in the United States, expanding the mandate of Section 504 of the Rehabilitation Act of 1973 to eliminate discrimination by prohibiting discrimination in employment, housing, public accommodations, education, and public services.

In June 2000, the National Council on Disability issues a report, *Promises to Keep: A decade of Federal Enforcement of the Americans with Disabilities Act,* which includes 104 specific recommendations for improvements to the ADA enforcement effort. On December 1, 2004, the council issues a final summary report, *Righting the ADA,* in order to address "a series of negative court decisions [that] is returning [Americans with disabilities] to 'second-class citizen' status that the Americans with Disabilities Act was supposed to remedy forever."

1990 The ADA requires public entities and businesses to provide effective communication to individuals with disabilities. Title IV of the ADA mandates that nationwide telecommunication systems be accessible to persons with speech or hearing disabilities. The Federal Communications Commission (FCC) requires relay services to be in place by July 26, 1993. The Telecommunications Act of 1996 adds provisions to the Communications Act of 1934 that requires manufactures and providers of telecommunications equipment and services to ensure accessibility to persons with disabilities. In 2000, President Bill Clinton establishes regulations governing the accessibility to people with disabilities of the electronic and information technology used within the federal government.

1990 The Individuals with Disabilities Education Act (IDEA) is enacted. It guarantees the right to free and appropriate education for children and youth with disabilities and focuses on higher expectations, mainstreaming students where possible, and an increased federal rule in ensuring equal educational opportunity for all students. IDEA requires schools to provide a free and appropriate public education to eligible children with disabilities. It also requires schools to develop an individualized education plan (IEP) for each child and placement in the least restrictive environment (LRE) for their education. IDEA is amended in 1997 and reauthorized again in 2004 as the Individuals with Disabilities Education Improvement Act.

1990 ◆ Legislation establishes the National Center for Medical Rehabilitation Research (NCMRR), whose mission is to foster development of scientific knowledge needed to enhance the health, productivity, independence, and quality of life of persons with disabilities. It has primary responsibility for the U.S. Government's medical rehabilitation research that is supported by the National Institutes of Health (NIH).

1990 ◆ The World Declaration on Education for All (EFA) is adopted in Jomtien, Thailand, by more than 1,500 persons representing the international community. Article 23 of the UN Convention on the Rights of the Child states that disabled children have the right to a "full and decent life" and that member nations provide free education and training to disabled children whenever possible in order to provide the "fullest possible social integration and individual development." UNESCO is the lead UN organization for special needs education.

1990 ◆ Korea: The disability movement celebrates the passage of the Employment Promotion Act for People with Disabilities. The government imposes control over the disabled population in the 1960s and 1970s by forwarding institutionalization under the banner of "protection," promoting sterilization, and violating the rights of disabled people in general. The 1981 International Year of Disabled Persons influences the government, and new laws, such as the Welfare Law for Mentally and Physically Handicapped, are enacted, and the human rights of disabled people becomes the dominant rhetoric of the disability movement.

1990 ◆ United Kingdom: The National Disability Arts Forum is launched at the UK-OK Conference at Beaumont College in Lancashire, UK.

1991 ◆ The Resolution on Personal Assistance Services is passed at the International Personal Assistance Symposium. Personal assistance services are the most critical services for individuals. Critical aspects of these services are that they must be available up to 24 hours a day, 7 days a week, to people of all ages, and with access to governmental payments. In the United States alone, personal assistance services affect the lives of more than 9.6 million citizens with disabilities.

1991 ◆ Australia: The federal Disability Reform Package is introduced; the Disability Discrimination Act, which covers issues of discrimination in education, is enacted in 1992; and the Commonwealth Disability Strategy, designed to provide equal access to government services for people with disabilities, is first introduced in 1994 and then revised in 2000. During the 1990s similar discrimination legislation emerges in other countries, such as New Zealand's Human Rights Act, the U.K.'s Disability Discrimination Act, Israel's Disabled Persons Act, Canada's Human Rights Act, and India's Disabled Person's Act.

1991 ◆ China: The most important laws and initiatives reside in the 1991 Law on Protection of Disabled Persons and a series of National Work Programs for Disabled Persons (1988, 1991, 1996, 2001), which integrate disability into the government's Five-Year Plans. China participates heavily in the United Nations Decade of Disabled Persons, 1983–1992, and initiates the Asia Pacific Decade of the Disabled Persons, 1993–2002. China continues to collaborate with UN projects involving the disabled and will host the 2007 International Special Olympics in Shanghai.

1991 ◆ Serbia and Montenegro: From the 1960s to the 1980s, post–World War II Yugoslavia is lauded for being a socially advanced nonaligned nation, but the contemporary wars that decimate Yugoslavia begin in 1991, and today there are more than one million disabled citizens, refugees, and casualties due to the wars. Disabled people in Serbia and Montenegro (formally named the Federal Republic of Yugoslavia—FRY) are left with shattered pieces of the spent past with little hope for the near future. Although the FRY constitution prescribes special protection of disabled persons in accordance with legal provisions and Serbia is party to numerous UN documents and acts, a disabled expert in 2004 admits that discrimination against persons with disability in Serbia and Montenegro is a

long-term problem that people without disability tend to ignore. Two of the most effective advocacy groups making in-roads today are the Association of Students with Disabilities and the Center for Independent Living in Belgrade.

1992 ◆ The UN Economic and Social Commission of Asia and the Pacific (ESCAP) proclaims a 10-year program known as the Asian and Pacific Decade of Disabled Persons 1993–2002 with goals of full participation and equality for persons with disabilities.

1993 ◆ The United Nations publishes the Standard Rules on the Equalization of Opportunities for Persons with Disabilities, which becomes the international legal standards for disability programs, laws, and policies. Although not legally enforceable this instrument sets an inclusive and antidiscriminatory standard that is used when national policies are developed. It marks a clear shift from the rehabilitation and prevention paradigm to the human rights perspective on disability.

1993 ◆ Slovak Republic: The Czech and Slovak Republics separate into two independent countries. They both join the European Union in 2004. In Slovakia, a large number of highly innovative and resourceful grassroots nongovernmental organizations emerge to address the human rights, quality-of-life, and independent living priorities of citizens with disabilities. They pursue this mission, however, with extremely limited resources and with varying degrees of support from a multiparty parliament.

1993 ◆ Sweden: The Independent Living Institute (ILI) is founded.

1994 ◆ Two networks, one for elderly persons and the other for persons with disabilities, join together to form the U.S. National Coalition on Aging and Disability. In following years, policy makers and advocates begin to see the benefits of merging some services.

1994 ◆ Germany: The disability rights movement is successful in using for its own aims the reform of the German constitution, which is made necessary by the reunification process. An amendment to the constitution forbids discrimination on the grounds of disability. Other such laws as the Rehabilitation of Participation Law (2001) and the Federal Equal Rights Law (2002) are formulated with the active contribution of disability rights activists, and in 2003, the official German program of the European Year of People with Disabilities is organized by a prominent activist.

1994 ◆ Sweden: The Swedish Disability Act (LSS) comes into force. It expands the 1985 Special Services Act. The LSS is also more ambitious than its predecessor, calling for "good living conditions" rather than just an "acceptable standard of living."

1995 ◆ The National Council on Disability, a federal agency, makes recommendations to the president and Congress on disability issues. Among other issues, it calls for the end to the use of aversives (techniques of behavior control such as restraints, isolation, and electric shocks) because they are abusive, dehumanizing, and psychologically and physically dangerous. Other organizations follow, such as the Autism National Committee in 1999, TASH in 2004, and the International Association for the Right to Effective Treatment in 2003.

1995 ◆ The Commission for Case Management Certification (CCMC) incorporates. Case management is a process of care planning and coordination of the services and resources used by people with disabilities and their families.

1995 ◆ Europe: The Association for the Advancement of Assistive Technology in Europe (AAATE) is founded as an interdisciplinary association devoted to increasing awareness, promoting research and development, and facilitating the exchange of information. AAATE is composed of more than 250 members from 19 countries. It interacts with sister organizations in North America, Japan, and Australia to advance assistive technology worldwide. The Tokushima Agreement, signed in 2000 by AAATE, the Rehabilitation Engineering and Assistive Technology Society of North America

(RESNA), the Rehabilitation Engineering Society of Japan (RESJA), and the Australian Rehabilitation and Assistive Technology Association (ARATA), promotes exchange of information and collaboration.

1995 ◆ United Kingdom: The campaign for antidiscrimination legislation begins in earnest with the emergence of the disability movement in the late 1970s. The Disability Discrimination Act of 1995 (DDA) together with the Disability Rights Commission Act of 1999 constitute the primary source of antidiscrimination legislation for disabled people in the United Kingdom. The Disability Discrimination Act 2005 extends the protection.

1996 ◆ There are 1.4 million fewer disabled older persons in the United States than would have been expected if the health status of older people had not improved since the early 1980s.

1996 ◆ Advocates for mental health parity such as the National Alliance for the Mentally Ill (NAMI; 1979) believe that mental illnesses are real illnesses and that health insurance and health plan coverage for treatment should be equal with coverage of treatment for all other illnesses. Due in part to advocacy, the Mental Health Parity Act becomes law in 1996. In 1999, mental illness ranks first in causing disabilities among many industrialized nations, including the United States, which experiences a loss of productivity in this year of $63 billion. In the United States, 5 to 7 percent of adults suffer from serious mental disorders and 5 to 9 percent of children suffer from serious emotional disturbances that severely disrupt their social, academic, and emotional functioning.

1996 ◆ Costa Rica: Approval of a law called Equal Opportunities for People with Disabilities is a turning point for the population with disabilities, which is among the most excluded sectors of society. The law is inspired in part by the United Nations Standard Rules on the Equalization of Opportunities for Disabled People (1993). Disability experience in Costa Rica is definitely transformed as a result of the mandates of this generic law, as people with disabilities and their families start to use this legal instrument as a strategy to empower themselves.

1996 ◆ Europe: Created in 1996, the European Disability Forum (EDF) is today the largest independent, trans-European organization that exists to represent disabled people in dialogue with the European Union (EU) and other European authorities. Its mission is to promote equal opportunities for disabled people and to ensure disabled citizens full access to fundamental and human rights through its active involvement in policy development and implementation in the EU. The EDF has national councils in 17 European countries and has 127 member organizations. The European Year of People with Disabilities 2003 is one of the EDF's most important campaigns.

1996 ◆ India: The Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act, 1995, becomes law. It is the first legislation for equal opportunities for disabled people. Prior to this, disabled persons receive services but not legal protection. Improvements in conditions begin in 1981 with the International Year of Disabled Persons. India is a signatory to the UN resolution of 1976 establishing it and is thereby committed to improving the lot of the disabled. The Lunacy Act of 1912 is repealed and the National Mental Health Act is passed in 1987. Nonetheless, with approximately 70 million disabled people residing in India (in a population of over a billion), the government does not include the domain of disability in the 2001 census, which reflects the attitudinal barriers in acknowledging the disabled identity.

1997 ◆ Government expenditures on behalf of persons with disabilities may total as much as $217.3 billion (taking into account the costs that would be expected among persons with disabilities in the absence of the disability), the equivalent of 2.6 percent of the gross domestic product in the United States for 1997.

1997 ◆ The landmark 1997 UNESCO Universal Declaration on the Human Genome and Human Rights frames the actual application of the new scientific developments raised by genetics. As a policy

statement, it provides the first signs that genetics will be applied in ways that maintain human rights. In 2003, the Council of Europe and the council's Steering Committee in Bioethics issue policy statements in a working document titled Application of Genetics for Health Purposes. In the case of gene therapy, in 1994, the Group of Advisors on the Ethical Implications of Biotechnology of the European Commission voices concern regarding equity, maintaining that all genetic services that are available for the entire population should be equally available for persons of disability. Today, UNESCO's Human Genome Organization's Ethics Committee, the World Health Organization, the Council of Europe, and consumer organizations such as Inclusion International, Rehabilitation International, and Disabled Peoples' International play major roles in translating genetic innovations into health service and public health fields, helping develop policies that focus on the general recognition, respect, and protection of the rights to which all people, whether disabled or nondisabled, are entitled. Concerns related to the possible undermining of human rights are expressed in 2003 when Disabled People's International demands a prohibition on compulsory genetic testing.

1997 Colombia: The General Act for People with Disabilities, also known as the Disability Act: Law for Opportunity, passes. The 2003–2006 National Plan of Attention to Persons with Disabilities estimates that 18 percent of the general population has some type of disability. Despite the existence of at least 37 disability-related legal policies (2001), the government provides limited spending on programs that protect the rights of people with disabilities, and the lack of enforcement of rights remains a major concern. Today's awareness efforts include marathons with the participation of the general population to raise money for educational programs for children with special needs, Special Olympics, new organizations such as the Colombian Association for the Development of People with Disabilities, and media awareness campaigns.

1998 President Bill Clinton issues an executive order ensuring that the federal government assumes the role of a model employer of adults with disabilities.

1998 President Clinton signs into law the Rehabilitation Act of 1973 Amendments. Section 508 requires that electronic and information technology (EIT), such as federal websites, telecommunications, software, and information kiosks, must be usable by persons with disabilities.

1998 Ireland: The Irish Employment Equality Act entitles all individuals, including disabled persons, equal treatment in training and employment opportunities. The Education Act of 1998 requires schools to provide education to students that is appropriate to their abilities and needs. The Education for Persons with Disabilities Bill passes in 2003. A Disability Bill published in 2001 fails to underpin a rights-based approach and is withdrawn amid a storm of protest in 2002; a redrafting of a new Disability Bill is suffering from continuing delays. Traditionally, Irish voluntary organizations play a reactionary role in the development of services for people with disabilities and a key role as pressure groups trying to keep disability issues on the political agenda.

1999 The National Center on Physical Activity and Disability (NCPAD) is established as an information and resource center that offers people with disabilities, caregivers, and professionals the latest information on fitness, recreation, and sports programs for people with disabilities.

1999 Established by a panel of experts brought together to evaluate the UN Standard Rules on the Equalization of Opportunities for Persons with Disability, the International Disability Alliance (IDA) encourages cross-disability collaboration and supports the participation of international disability organizations in the elaboration of a proposed UN convention on disability.

1999 England: The first disability film festival, Lifting the Lid, is held at the Lux Cinema in London.

2000 ◆ The National Telability Media Center collects documentation of 3,000+ newsletters, 200 magazines, 50 newspapers, 40 radio programs, and 40 television programs dedicated to disability in the United States alone. *The Ragged Edge, Mainstream* (Internet-based), and *Mouth* are examples of disability rights-focused publications.

2000 ◆ *Healthy People 2000,* the second edition of the Surgeon General's report on health promotion and disease prevention (the first edition published in 1979), includes some reference to the health and well-being of people with disabilities, but few data are available. In the mid-1990s, the U.S. Department of Health and Human Services begins a dialogue with the Centers for Disease Control and Prevention to include people with disabilities in the third edition, *Healthy People 2010.* The resulting report includes more than 100 objectives that include "people with disabilities" as a subpopulation for data gathering.

2000 ◆ The World Bank, increasingly concerned with how to include disabled persons in the economies and societies of developing nations, establishes an online clearinghouse to make documents concerning the disabled readily available to member nations and the general public and holds its first course on disability issues in 2004 in Guatemala.

2000 ◆ Africa: The African Decade of Persons with Disabilities, 2000–2009, is adopted by the Declaration of the Organization of African Unity. The African Network of Women with Disabilities (2001) and the community-based rehabilitation organization CBR Africa Network (CAN) are examples of the many activities that result from the African Decade.

2000 ◆ Brazil is one of the few countries to include an entire section on disability in its 2000 census. Results show that 14.5 percent of the population, roughly 24 million people, report having some form of disability, the poorest region, the northeast, reporting the highest percentage and the richest, in the south, the lowest. People with disabilities in the first half of the twentieth century have no voice or representation. In 1932, the first Pestalozzi Society, a community-based school for children with intellectual disabilities, is founded. By the end of the twentieth century, there are 146 Pestalozzi Societies and more than 1,700 chapters of the Association of Parents and Friends of the Exceptional. The first center for independent living is established in 1988 (CVI-RIO). In 1992 and 1995, CVI-RIO organizes two international conferences on disability issues called DefRio, out of which comes "Goals of the ILM," a document that delineates the basis for the independent living movement in Brazil; however, financial support is not provided by the government, creating a struggle for sustainability. Brazil has progressive policies toward disability. The constitution includes sections on the rights of people with disabilities, and laws have been passed with regard to accessibility, education, and employment.

2000 ◆ Europe: A European Community directive requires all member states to have introduced antidiscrimination laws in the fields of employment and training by the end of 2006. It seeks to establish a general framework for equal treatment in employment and occupation and to render unlawful discrimination based on, among other categories, disability. The European Union Charter of Fundamental Rights sets out in a single text, for the first time in the EU's history, the whole range of civil, political, economic, and social rights of European citizens. Disability is included in the general nondiscrimination clause (Article 21), but Article 26 specifically states that the Union recognizes and respects the rights of persons with disabilities to benefit from measures designed to ensure their independence, social and occupational integration, and participation in the life of the community.

2000 ◆ The Human Genome Project (HGP), an international effort to specify the 3 billion pairs of genes that make up the DNA sequence of the entire human genome, produces its first draft in June 2000. Formally begun in October 1990, it is completed in 2003.

2001 President Clinton declares in Executive Order No. 13217 the commitment of the United States to community-based alternatives for individuals with disabilities. This ensures that the *Olmstead v. L.C.* decision (1999), which mandates the right for persons with disability to live in the least-restrictive setting with reasonable accommodations, is implemented in a timely manner. The executive order directs federal agencies to work together to tear down the barriers to community living.

2001 In the United States, census data indicate that only 48 percent of citizens 25 to 64 years old with severe disabilities have health insurance compared with 80 percent of individuals with nonservere disabilities and 82 percent of nondisabled Americans. Women with disabilities in general are more likely to live in poverty than men. Minorities with disabilities are more likely to live in poverty than nonminorities with disabilities. In 2003, in the United States, about 28 percent of children with disabilities live in poor families compared with 16 percent of all children.

2001 A UN Ad Hoc Committee begins discussions for a legally binding convention under the draft title Comprehensive and Integral Convention on the Protection and Promotion of the Rights and Dignity of Persons with Disabilities. Its fifth session is held in early 2005.

2001 A new World Health Organization classification of people with disabilities, the International Classification of Functioning, Disability, and Health (ICF), replaces the old International Classification of Impairments, Disabilities, and Handicaps (ICIDH). The ICF definition shifts the focus from disability as an innate deficit (“medical model”) to disability as constructed through the interaction between the individual and the environment (“social model”). This shift encourages a focus on the kinds and levels of interventions appropriate to the needs of individuals.

2001 UNESCO launches pilot education projects for disabled children in Cameroon, the Dominican Republic, Egypt, Ghana, India, Madagascar, Mauritius, Nicaragua, Paraguay, South Africa, Vietnam, and Yemen. The global initiative Education for All 2000 has as its primary millennium development goal universal education by the year 2015.

2002 The U.S. Supreme Court rules that executing persons with mental retardation is unconstitutional.

2002 Disabled Peoples’ International’s 2002 Sapporo Platform, developed by 3,000 delegates from more than 90 countries, urges members to take every opportunity to seek publicity and awareness in order to change negative images of disabled people.

2002 Canada: The Canadian International Development Bank announces the approval of the Canada-Russia Disability Program, a four-year $4 million project, focusing on education, disability studies, social work practice, social policy, and information dissemination.

2003 A national survey that updates the Disability Supplement to the 10-year-old National Health Interview Survey highlights barriers to care among the uninsured. The uninsured are four times as likely to postpone care and three times as likely to go without needed supplies.

2003 The National Association of Social Workers (NASW) issues a policy statement that discusses their core values with respect to working with people with disabilities, including self-determination, social justice, and dignity and worth of the person. The statement emphasizes that social workers are responsible to take action with people who have disabilities in advocating for their rights to fully participate in society.

2003 The Disability Awareness in Action (DAA) database contains a total of 1,910 reports of known abuse affecting nearly 2.5 million disabled people. In the area of education alone, it documents

118 cases affecting 768,205 people in 67 countries. Responding to this documentation and other reports, the United Nations Commission on Human Rights creates the Global Rights campaign to address human rights abuses. Disability rights organizations use this information to insist on a UN convention on the rights of disabled people that would be legally binding on nation-states.

2003 The International Association for the Study of Pain has more than 6,700 members, representing more than 100 countries and 60 disciplinary fields. Chronic pain is one of the leading causes of recurrent and permanent disability in the developed world today, yet less than 1 percent of the U.S. National Institutes of Health's budget supports research into mechanisms and management of pain. The U.S. Congress declares 2000–2010 the Decade of Pain Control and Research.

2004 The *Journal of Gene Medicine* (January) reports that 636 gene therapy clinical trials are completed or ongoing, involving 3,496 patients. The first gene therapy clinical trials begin in the early 1990s.

Today Seventy to eighty percent—approximately 400 million—of the world's disabled people (600 million, or 10 percent of the world's population) live in the developing world, and of the world's poorest of the poor, 20 to 25 percent are disabled. In most countries, 1 out of 10 persons has a disability. Many international efforts are under way to address poverty and disability, such as those of the Action on Disability Development and the Chronic Poverty Research Centre.

Today E-health is the use of emerging interactive telecommunications technologies such as the Internet, interactive TV, kiosks, personal digital assistants, CD-ROMs, and DVD-ROMs to facilitate health improvement and health care services, including those with disabilities. E-health relies on environments that use a variety of technologies that can compensate for the lack of sensory ability. Telerehabilitation is an example of services delivered information technology and telecommunication networks.

Today Celebrating difference is the mantra and visible manifestation of disability culture in all regions of the world.

SEARCHING FOR AND EVALUATING WEBSITES

Anne Armstrong

The Internet, or Web, provides a vast number of channels through which researchers can find information on virtually any subject. The expansiveness of the Web can be daunting to new researchers. On the other hand, researchers often assume that they have mastered the Web in its entirety when indeed they have merely scratched the surface in terms of the numbers of resources they have consulted and searches they have performed.

Because the field of disability studies is continually evolving and inherently multidisciplinary, Web searchers can draw on previously conducted research from disciplines within the humanities, social sciences, and health sciences. This guide aims to expose beginning researchers to a mixture of general and subject-specialized Web-based search tools, as well as strategies for performing sophisticated Web searches and criteria for evaluating websites. In addition to its broad subject coverage, the field of disability studies differs from most fields in that many researchers may themselves have disabilities affecting their ability to perform research on the Web. For this reason, this description concludes with an overview of accessibility issues on the Web and suggestions for further reading.

OVERVIEW OF WEB-BASED RESEARCH TOOLS

When approaching Web searching, researchers should be aware of the multitude of search tools available to them, in addition to the varying purposes of these tools. Many users approach Web searching with the assumption that "everything is in Google," but this is a limiting misconception. No single search engine contains everything on the Web. Furthermore, all search engines function differently and rank results differently. Therefore, sampling various search tools increases the comprehensiveness of results on any topic. This discussion outlines multiple types of search tools available on the Web and offers potential starting points for Internet research on issues related to disability studies, whether from a health sciences, social sciences, or humanities perspective.

The Web-based search tools outlined in this chapter include general search engines, subject-specialized search engines, directories, indexes, catalogs, and Listservs. It is important to note that different types of search tools cover different parts of the Web. The Web is composed of layers. The top layer is detectible by general search engines, while a deeper layer termed "the invisible Web" can be penetrated only by specialized search engines, indexes, and catalogs. Readers should be aware that because the Web is in a constant state of flux, currently available resources may become obsolete over time, and newer, more sophisticated search tools will undoubtedly evolve.

General Search Engines

Most people who have searched the Web are familiar with sites such as Google, HotBot, or Lycos, which allow them to enter a string of keywords into a search box to retrieve a list of relevant websites (see Table 1). These sites, referred to as search engines, search the Web by means of a program called a *spider* (also

Table 1 Selected General Search Engines

Name	*URL*
AltaVista	www.altavista.com
Excite	www.excite.com
GO	www.go.com
Google	www.google.com
HotBot	www.hotbot.com
Lycos	www.lycos.com
Yahoo!	www.yahoo.com

called a *robot* or *crawler*). Since search engines tend to index millions of websites, they are most useful for entering specific search terms rather than broad concepts such as disability studies.

While Web searchers tend to pick a favorite search engine and return to it repeatedly, it is important to note that different search engines produce varying results, and that a truly comprehensive Web searcher should compare the results of multiple search engines. The variation between search engines can be attributed to differences between the spiders fueling the search engines as well as differences in the level of indexing and the order in which results are ranked. While some search engines index the full text of documents, others may index only the first page, or merely the *meta-tags*, which are lines of code containing keywords. Web searchers should be aware that developers of websites may intentionally increase their usage of certain words or meta-tags to increase the prominence of their website among search results. This practice has been referred to as *spamdexing* and is most prevalent among the developers of commercial websites advertising products and services. Due to the constant fluctuation of the Web, no search engine is entirely up-to-date; results produced by identical searches can vary greatly from one day to the next, even when one is using the same search engine.

Subject-Specialized Search Engines

Subject-specialized search engines (also referred to as subject portals) developed by educational institutions, associations, government agencies, and corporate entities narrow the broad scope of the Web, providing a focused channel by which researchers can search for information when they have determined the discipline from which their topic stems. Examples of such search engines are listed in Table 2. While subject-specialized search engines index considerably fewer websites and documents than general search engines, the information contained within them has been preselected, ideally by experts within a given field. Many subject-specialized search engines expose searchers to parts of the "invisible Web" not indexed by general search engines. Subject-specialized search engines can ease the research process by whittling down the Web to a more manageable size. However, researchers who use them should take the time to view the criteria for selection of

Table 2 Examples of Subject-Specialized Search Engines

Directories

Directories are hierarchically arranged subject guides composed of websites chosen by or recommended to editors of the directory (Table 4). Usually, directories follow a template in which major subject categories such as health, sciences, social sciences, or humanities are posted on the top-level page. Each of these links leads to lists of narrower subcategories. The links on the second level lead to narrower subcategories, and so on. A sample hierarchy from the directory created by Google (available at http://directory.google.com) lists the following subject breakdown: Society → Disabled → Disability studies.

Directories provide Web searchers with the ability to browse recommended resources in various subject areas without having to enter specific search terms. Other useful attributes of directories are that they often contain summaries and evaluations of websites.

LookSmart	www.looksmart.com
Yahoo! Directory[a]	www.yahoo.com

a. These sites contain both directories and general search engines.

Article Indexes

Article indexes allow researchers to search by topic for published articles in magazines and scholarly journals. Researchers could certainly locate journal and magazine articles using a freely available search engine such as Google, but they would merely be skimming the surface of what has been published. While the Web provides access to *more* content, it does not provide comprehensive access to research published in journal articles. Article indexes are for the expressed purpose of finding journal articles. With a few exceptions (such as PubMed, an article index of health sciences journals developed and maintained by the National Library of Medicine), article indexes are not freely available on the Web. Libraries purchase subscriptions to multiple article indexes covering a wide spectrum of disciplines. The indexes available through a given library are often dictated by the curriculum of the college or university that the library serves. Thus, large research institutions offer a greater number of specialized article indexes than smaller institutions and public libraries. Due to licensing agreements between article index providers and libraries, off-site access to indexes is usually limited to faculty and students of a college or university. However, there are many libraries that allow members of the public to use their article indexes from within the library. A local public library would be a good starting place for those not connected with academic or commercial organizations.

Since article indexes are proprietary products developed by companies for sale to libraries, they tend to offer specialized search features that are not always available on freely available search engines. These features include subject headings, thesauri, abstracts (summaries of articles), and frequently the full text of articles. Researchers should familiarize themselves with online tutorials, "help" screens, and "about" pages to increase the effectiveness of their searching.

Freely available article indexes relevant to disability studies include the following:

- PubMed: A product of the National Library of Medicine, which includes more than 14 million citations for biomedical articles dating back to the 1950s. URL: http://www.ncbi.nlm.nih.gov/entrez

- CIRRIE: Center for International Rehabilitation Research Information and Exchange, a database containing more than 24,000 citations of international research published from 1990 to the present. URL: http://cirrie.buffalo.edu

Catalogs

While researchers can search indexes to find articles on specific topics, they can search online catalogs to find books. Some catalogs list the books available at individual libraries, while others contain the holdings of multiple libraries and institutions. The individual catalogs of public libraries and universities are usually freely available on the Web. The most comprehensive catalog is called WorldCat, developed by an organization called OCLC (Online Computer Library Center). WorldCat lists books available at public and academic libraries throughout the world. Like most article indexes, WorldCat is not freely available on the Web and must be accessed through a library.

Listservs

Listservs are mailing lists on the Internet that facilitate online discussions on various subjects. They allow researchers within a given field to communicate about scholarly issues via email. People customarily sign up for Listservs by sending an e-mail to the Listserv address stating that they wish to subscribe. Several Listservs related to disability studies are listed in Table 5. In addition, Web searchers can perform a search on a database called tile.net to search for Listservs by topic.

SEARCH STRATEGIES

Since search capabilities vary from site to site, Web searchers should use online "help" screens and tutorials to learn search tips and strategies for improving their search results. Some search techniques common to several Web-based search tools are summarized below.

Quotation Marks

When entering a search, users should enter phrases in quotation marks to stipulate that they would like the results to contain a specific word combination and order. For instance, multiword concepts such as "disability studies," "adaptive technology," and "section 508" should be entered within quotation marks. Proper names can also be entered within quotation marks.

Truncation

Truncation symbols allow Web searchers to simultaneously search for multiple endings of a given word. For instance, assuming that the asterisk is the designated truncation symbol in a search engine, entering the word "impair*" would produce results including all forms of the word after the root, including "impair," "impaired," "impairment" and "impairments." In addition to adding truncation symbols to the end of words, users may also insert internal truncation symbols if there are potential variations for the spelling of the middle of a word. For instance, entering the word "colo*r" would simultaneously search for the words "color" and "colour." "Help" screens or "search tips" usually list the designated truncation symbol for a given database.

Boolean Logic

Developed by the English mathematician George Boole, Boolean logic is a mathematical framework that Web searchers can apply to broaden or refine their searches. There are three words, or *operators*, that Web searchers can use to combine their keywords to perform more complex searches: AND, OR, and NOT. The three Boolean operators are summarized below, along with potential applications. It is important to read the online "help" section of a database before performing a Boolean search, as Boolean searching does not work in all databases.

Using the Boolean Operator "AND"

Combining words with "AND" narrows a search, as the database retrieves only items that contain *all* the words entered. The second search example below will produce fewer results than the first, since there are three keywords that must appear within the content of each result.

"disability studies" AND theory
"disability studies" AND theory AND history

Using the Boolean Operator "OR"

Entering the term "OR" between keywords stipulates that any, but not all, of the words entered must appear within the search results. Using "OR" is a way of searching for synonyms or related terms when there are multiple words for the same concept. The example below shows how you could broaden your search if you wanted to search for multiple adaptive technology applications in a search engine. The second search example will potentially produce more results than the first, since there is an additional keyword that the results could include.

JAWS OR "Ruby OpenBook"
JAWS OR "Ruby OpenBook" or "window eyes"

Using the Boolean Operator "NOT"

Entering the Boolean operator "NOT" after a word stipulates that the word should not appear within the results. Using "NOT" in a search can be particularly useful if a word is frequently used in multiple contexts and you wish to eliminate results dealing with a particular topic. In the example below, the second search will ideally eliminate items relating to the state of New Mexico, given that the researcher is looking for information on legislation related to disabilities in the country of Mexico. The use of NOT can be too limiting. The second search would eliminate results that discussed both Mexico and New Mexico.

Disabilities AND legislation AND Mexico
Disabilities AND legislation AND Mexico NOT "new mexico"

Nesting

Nesting allows Web searchers to simultaneously search for multiple search terms relating to the same topic. The grouping of synonymous terms within parenthesis is referred to as nesting, as multiple terms relating to the same idea are clustered together as a single concept. When using nesting, the words within the parenthesis are connected by the Boolean operator "OR."

To find information about software for people who are visually impaired, search results are increased by using nesting to group multiple words for each facet of the topic:

(software or "adaptive technology") AND ("visually impaired" or blind)

Plus and Minus Signs

Most general search engines allow users to enter plus or minus signs before a particular word. Entering a plus sign before a word (e.g., +ADA) stipulates that the word must appear within the search results. A minus sign before a word (e.g.,–mobility) stipulates that the word should not appear within the results. Since some search engines also use plus and minus signs as substitutes for Boolean operators, it is important to view online "help" or "search tips."

Search Limits

Most search engines allow users to limit their results by date, language, or document type. Limiting capabilities vary from site to site and are customarily outlined in online "help" screens. In general, article indexes have more sophisticated limiting capabilities than search engines that are freely available on the Web.

EVALUATING WEBSITES

A researcher weighing the quality of a journal article faces a lesser challenge than a researcher considering a website as a potential resource. The publishing industry applies labels to periodicals of varying type: Scholarly journals, popular magazines, trade publications, and newspapers comprise the major categories. Articles submitted to scholarly journals undergo a peer review process by experts in a given field. If in doubt as to the suitability of journal for scholarly purposes, a researcher can consult a directory of periodicals such as *Ulrich's Periodicals Directory,* which indicates whether or not a journal is peer reviewed.

The fact that the Web has no comparable methods of control complicates the task of determining whether a website is appropriate for research purposes. While websites produced by certain types of agencies and organizations certainly undergo a form of *internal*

review, the Web is a free forum; people can post anything they want, and no one has the right to force to take it down if it fails to meet certain standards of quality or accuracy. To complicate the matter, inaccurate or inexpert information can hide like a wolf in the sheep's clothing of sophisticated graphics, layout, and design. The Web has no peer review process to ensure quality. While none of the evaluation criteria outlined below can provide the final word as to the suitability of a website for scholarly use, a researcher who searches the Web with multiple evaluation criteria in mind expedites the process of finding quality information.

Authorship

When determining the credibility of a website, researchers should use multiple techniques to determine the credentials of the author as well as the character of the organization hosting, or sponsoring, the site. If individuals are listed as authors, researchers should take steps to determine their credentials and reputation in the field by performing a search in a general search engine to find biographical information or other documents written about the author. This will also produce references to the author on the sites of other authors within a field. Researchers can also consult a number of biographical sources available at libraries, such as *Who's Who in the America* or sources tailored to particular fields of study, such as *Who's Who in Science and Engineering.*

Website addresses, or URLs (Uniform Resource Locators) can also provide hints as to author affiliations and potential bias. Personal websites are often hosted on commercial ISP (Internet Service Provider) Web servers such as aol.com, or geocites.com. URLs of personal websites often contain first or last names, as well as percent (%) or tilde (~) signs. While personal websites may contain authoritative information, researchers should question why the same content does not appear on a site sponsored by an educational or research organization.. Was the site created as a pastime or to serve as a forum for airing personal views? Or does the site reflect serious scholarship backed up by other credentials and research published in scholarly publications?

Every website URL ends with a *domain name*, usually a series of three letters preceded by a period. The domain name denotes the type of institution that hosts the website and can often provide clues as to the purpose or potential bias of a site. Common domain names include the following:

Educational sites: .edu
Government sites: .gov, .mil, or country codes (e.g., .uk = United Kingdom, .au = Australia, .do = Dominican Republic)
Nonprofit organization sites: .org
Commercial sites: .com

Most URLs contain multiple levels separated by slashes (e.g., http://www.nod.org/stats/). To learn more about the sponsor or publisher of a particular site, you can remove levels of the URL one by one to see where the site is hosted and determine the character of the sponsoring entity. For instance, if a site is hosted on the site of an association, viewing the mission statement on the home page of the association can provide clues as to the bias or purpose of the content. When judging the credentials of the publishing entity, researchers should look for contact information and institutional logos. In general, sites devoid of identifying information or contact numbers and addresses should raise suspicion.

Audience

When evaluating a site, researchers should determine whether the content succeeds in addressing the stated audience through tone and presentation. Sites for adults should not have a childlike appearance or tone. Likewise, sites may be deliberately overrun by technical language or jargon to confuse or mislead a particular audience. High-quality sites clearly define their intended purpose.

Currency

Medical research findings or population statistics may become obsolete at a faster rate than research in the humanities. Web researchers should check sites for copyright dates and the date of the last update. Broken links are a sign of neglect, as they may indicate that URLs have changed or become obsolete since the last update of the site. To verify the currency of information on a site, researchers should check for several sites covering the same subject matter.

Accuracy

Determining accuracy involves further research to ensure that the claims or findings on a site are substantiated by other sources. If a site presents original research, the methods of the research and instruments used should be clearly explained, as well as potential limitations of the research. If authors make claims or conclusions, they should cite their

sources, and these sources should be tracked down to ensure their existence and authenticity. Websites should contain a list of works cited or footnotes on par with any print book or article. Since websites sometimes include fabricated resources, and erroneous or incomplete citations, sources should be verified using library tools such as indexes and catalogs. Lists of works cited with multiple errors reflect irresponsible research. If a website contains links, the links should be checked. Researchers should be wary of websites populated by broken links or links to defunct websites.

Quality

In general, sites that are poorly organized or sloppy should be approached with caution. Shoddy design may point to further weaknesses. Poor grammar and spelling errors are also red flags.

Bias

While bias is not always a negative attribute, Web searchers should be cognizant of bias as the search for information. The bias of a website can be partially discerned by the domain name (as discussed above under "Authorship"). Commercial websites may be motivated by the goal to market a product or service. Nonprofit organizations may promote a political agenda. While bias may be clearly stated in mission statements and "about" pages, many websites deliberately shroud their bias. Thorough research involves consulting additional sources to determine the history and activities of a particular organization. If a site contains links to other sites, those links should be checked to discern the character and activities of the other organizations listed. If a site is sponsored by other organizations, researchers should consider the relationship between the sponsors and the creators of the site.

Special Considerations for Evaluating Health Information on the Web

The American Medical Association (AMA) has published "Guidelines for Medical and Health Information Sites on the Internet" outlining evaluation criteria for websites publishing health information, whether for consumers or health professionals. While these guidelines are technically enforced only on sites sponsored by the AMA or affiliated organizations, they could be applied to all sites containing health information. Many of these guidelines mirror the previously outlined criteria for evaluating all websites, but there are certain factors that are heavily emphasized in the AMA guidelines, including the importance of peer review by experts in the field, the importance of clearly identifying sources of funding, an explanation of the relationship between individual researchers and the institutions sponsoring the research, the importance of clearly stating the purpose and intended audience of a site, and the need to address the stated audience in a consistent and effective tone. Seven criteria for assessing the quality of health information on the Internet have been developed by the Health Summit Working Group (Health Information Technology Institute 1999).

Information on health-related websites should be verified by checking sources such as journal articles, books, and other websites. These measures are needed as health information on the Web frequently includes unsubstantiated claims.

OVERVIEW OF ACCESSIBILITY ISSUES ON THE WEB

Disability studies research is unique in that many scholars in the field have disabilities that may impact their ability to effectively search the Web. While in many ways the Web "evens the playing field" by making a vast number of resources available electronically, inaccessible design frequently places barriers on Web searchers with disabilities.

Principles of Web accessibility have been developed by the World Wide Web Consortium's (W3C) Web Accessibility Initiative (WAI). The WAI establishes guidelines for creating accessible websites, browsers, and authoring tools to increase the ease of use of the Web for users with disabilities. Multiple scenarios outlining potential challenges to Web searchers with disabilities are summarized in a W3C working draft titled "How People with Disabilities Use the Web" (2001). Among other scenarios, the document emphasizes that many Web searchers with cognitive or visual disabilities use OCR (optical character recognition) software, which reads Web page text and transmits the information to a speech synthesizer and/or refreshable Braille display. Many users with visual disabilities use text-based Internet browsers instead of standard graphical browsers. The successful use of these tools requires that images on websites be accompanied by descriptive text and *ALT tags*. ALT tags are textual labels that appear on the computer screen when a mouse moves over an image. Since visually impaired

Web searchers often enlarge Web-based text using screen magnification programs, Web designers must create pages with nonfixed font sizes that can be altered as necessary. These are only a few of the issues facing Web searchers with disabilities. Other population groups with disabilities discussed in the guidelines include individuals with cognitive disabilities, hearing impairment, and mobility-related disabilities. Readers should consult the WAI website for the complete guidelines (http://www.w3.org/WAI/).

To support the goals of WAI, an online tool called Bobby™ helps website developers test the accessibility of their sites and adhere to accessibility guidelines. By entering a URL into the Bobby website, a Web developer can generate a report outlining which features of the site need to be adjusted to make it "Bobby compliant" and adhere to both W3C accessibility guidelines and guidelines established by the U.S. government's Section 508, a 1998 amendment to the Rehabilitation Act requiring that all federal agencies make their electronic and information technology accessible to people with disabilities. Complete information about these guidelines can be found on the Section 508 website (www.section508.gov).

CONCLUSION

While "one-stop shopping" in Google may be tempting, there is no single search engine leading to everything on the Web. Comprehensive and effective research in disability studies involves consulting multiple search tools, including but not limited to general search engines, subject-specialized search engines, directories, and indexes. In addition to using multiple search tools, Web searchers should experiment with multiple search strategies to maximize the effectiveness of their searching. As there are no standards of quality on the Web, researchers should apply multiple evaluation criteria to every website, verifying that research findings posted on sites are supported by other sources. Web accessibility is a crucial component to disability studies, as the Web has the potential to deliver equal content to all users but frequently presents barriers to people with disabilities by failing to adhere to standards of accessible design. Researchers can develop an awareness of accessibility issues on the Web by familiarizing themselves with the standards outlined by W3C's Web Accessibility Initiative and Section 508.

SENIOR EDITORIAL BOARD

INTERNATIONAL ADVISORY BOARD

LIST OF ENTRIES

READER'S GUIDE

The Reader's Guide is provided to help readers locate entries and primary sources by topical category. It classifies the A–Z entries (Volumes I–IV) and primary source documents (Volume V) into twenty-five categories: Accessibility, Arts, Biographies, Children and Infants, Deafness and Deaf Culture, Disability Studies, Economics and Employment, Education, Ethical Issues, Experience of Disability, Health and Medicine, Health Care, History of Disability, Information Technology, Language of Disability, Law and Social Policy, Models, Organizations, Politics, Rehabilitation, Rehabilitative Engineering and Assistive Technology, Religion, Science, Sports, and Therapies. Some entries and documents may appear in more than one category.

Page numbers for primary source documents and illustrations can be found in the Table of Contents and List of Illustrations for Volume V, which appear in the front matter of each volume, and in the index.

J

▣ JACKSON, WILLIAM HENRY (1889–1931)

English educator and priest

Father William Henry Jackson lost his sight in early childhood, became an Anglican priest, and worked in Myanmar (formerly Burma) for 14 years.

Formal education for blind children had been started at Moulmein by a newly blind teacher, Maung Pe Gyu, in 1900. A school opened at Rangoon in 1901, and some Burmese Braille books were produced. The Mission to the Blind of Burma was begun in 1914 by Will and Mary Purser, bringing people to Rangoon for eye surgery and providing education and job training to some blind children. Mary Purser's brother, "Willie" Jackson, who was ordained in 1912, had studied at London, Oxford, and Leeds. He traveled to Burma in 1917 with Will Purser and immersed himself in Burmese language and lifestyle: He "adopted Burmese dress and food; he sleeps on the floor without a mosquito curtain, and he eats his food with his hands and goes about without any covering on his feet or head" (Purser 1922).

Jackson engaged vigorously in education and skill training of blind Burmese children and young people, and he was a powerful role model. He accepted no limits to what blind people could do. In 1930, the government of Burma awarded him the highest civilian honor, the Kaiser-i-Hind gold medal. He died young but had inspired many Burmese blind people with the confidence to live fuller lives.

▣ JAHIZ, AL- (ABU OTHMAN AMR BIN BAHR) (776–777)

Arab intellectual and essayist

Al-Jahiz, nicknamed for his "goggle eyes" (*jahiz*), was an erudite, prolific, and notably ugly writer at Basra and Baghdad. His essays on many topics are still much quoted in the Middle East. Reacting against public disdain for his own facial appearance, he became one of the earliest advocates for greater acceptance of disabled people. Al-Jahiz (1954) asserted that impairments or odd appearance "do not hinder an individual from being a fully active member of the Muslim community or bar him from important offices"; on the contrary, these "may be called signs of divine blessing or favor." He distinguished various levels of hearing impairment and noted that when a deaf person could not speak it was because "having never heard sounds, articulated or otherwise, he does not know how to produce them" (Al-Jahiz 1969). Elsewhere, Al-Jahiz (1983) commented on the silent language of signs and gestures used at meal-times by courtiers under the Sassanid rulers (224–636 CE).

JERNIGAN, KENNETH

(1926–1999)

American activist

Kenneth Jernigan, born blind, was one of the pre-eminent leaders of the struggle for equality waged by blind people during the twentieth century. He served as president of the National Federation of the Blind (NFB) from 1968 to 1986, with one brief interruption in 1978–1979. As president emeritus, he remained actively involved in the NFB and its operations until his death in 1999. Jernigan was mentored by Jacobus tenBroek, the NFB's first president, and one of the most influential voices addressing discrimination against the blind in the United States.

Born in Detroit, Jernigan grew up in Tennessee on a family farm. He held many jobs as a young man, including furniture maker, insurance salesman, and, briefly, professional wrestler. He received a degree in literature from Peabody University, and soon after went to teach at the Tennessee School for the Blind. In 1953, he was encouraged by tenBroek to move to California to work at the Orientation Center for the Blind in Oakland. In 1958, he became the first blind director of the Iowa Commission for the Blind, a position he held until 1978. During his time in Iowa, the commission was transformed from the worst to the best agency serving blind adults in the United States, and Des Moines became the epicenter of the blind movement.

Jernigan joined the NFB in 1949, and he was its vice president by 1958. Jernigan's rise to power occurred in the context of a bitter struggle for the leadership and direction of the NFB, resulting in the expulsion of several state affiliates and the creation of a splinter group in 1961, the American Council of the Blind (ACB).

Jernigan's philosophy of blindness was that the average blind person could do the work of an average sighted person when the former was given proper blindness adjustment training. With such training, Jernigan asserted, blindness could be reduced to a mere physical nuisance.

JIRI, JAIROS (1921–1982)

African philanthropist

As African philanthropist and founder of the Jairos Jiri Association in 1950, Jairos Jiri and his accomplishments in Zimbabwe stand out in the history of

African rehabilitation services. The son of a local chief, Jiri obtained virtually no education. At the age of 18, he set out to Bulawayo, where he was struck by the fate of disabled people as beggars. Encouraged by the knowledge that something could be done, he took them into his home and generated help from others in teaching them basket making and shoe repair. The efforts institutionalized very quickly, first with the assistance of the colonial administration, and later with international aid.

This led to one of the largest associations of its kind, the Jairos Jiri Association, serving more than 13,000 disabled children and adults annually. Among its many establishments are schools, clinics, homes, hostels, vocational training centers, community-based rehabilitation programs, scholarship funds, orthopedic workshops, and outreach and follow-up integration programs. The association looks to (1) assist, treat, and rehabilitate persons with physical, visual, and hearing impairments; (2) establish clinics, schools, centers, and other institutions for the education and welfare of the handicapped; and (3) liaise with the government of Zimbabwe and local and international agencies.

JOB ANALYSIS AND PLACEMENT

JOB ANALYSIS

The goal of a job analysis is to describe the tasks associated with the job and then articulate the human attributes necessary for successfully performing those tasks. Job analysis is an important part of what an industrial/organizational (I/O) psychologist does. Information from a job analysis is used for many purposes, and there are many methods for conducting a job analysis. This entry briefly describes these purposes and methods.

Purposes of Job Analysis

Information from job analysis can be used for many different purposes, such as job description, recruitment and selection, placement, performance assessment, training, compensation, criterion development, career development, legal issues, job design and redesign, and workforce reduction and restructuring. Professionals in human resources departments of business organizations and government agencies make extensive use of the information from a job analysis for these and other purposes. A disability-related application of job analysis occurs when rehabilitation counselors develop vocational plans to assist persons with disabilities obtain employment.

Methods of Job Analysis

Many of the methods used in performing a job analysis can be categorized into either a work-oriented approach or a worker-oriented approach. In a work-oriented approach, the emphasis is on the tasks performed by an incumbent or what a person does on the job. These tasks can be further subdivided into activities, and each activity may consist of several actions or elements. Two of the most well-known methods of job analysis in the work-oriented approach are the functional job analysis (FJA) and task inventories.

FJA was used in developing the *Dictionary of Occupational Titles* (*DOT*), which was designed to match people to jobs in the U.S. economy. The fifth edition of the *DOT*, published in 1991, provides information on more than 13,000 occupations in the U.S. economy. Task inventories are very popular in business organizations. Based on interviews with a small, representative sample of subject matter experts (SMEs) such as incumbents and supervisors, task inventories are developed and administered to incumbents and supervisors for gathering information on which tasks are performed on the job, how frequently tasks are performed, and their importance. In general, more tasks are included in a task inventory than in an FJA. Finally, another example of a work-oriented approach to job analysis is the critical incident technique (CIT). With CIT, SMEs are asked to recall specific instances of worker behavior, which represent either exceptional or unacceptable performance on the job.

In a worker-oriented (or person-oriented) approach, the emphasis is on obtaining information about the attributes and characteristics required for a successful performance on the job. These attributes and characteristics are commonly referred to as KSAOs (knowledge, skills, abilities, and other personal characteristics such as personality variables, interests, training, and experience). One of the most popular methods of job analysis in the worker-oriented approach is the Position Analysis Questionnaire (PAQ). It is a commercially available questionnaire, with computer scoring and multiple report-generation options. The PAQ consists of 194 items. Other examples of methods in the worker-oriented approach are the job element method, Job Element Inventory, Job Components Inventory, Occupational Analysis Inventory, and Common Metric Questionnaire.

A new method of job analysis, which reflects both the work-oriented and worker-oriented approaches, is the Occupational Information Network or O*NET. It was developed by the U.S. federal government and was designed to replace the *DOT*. The O*NET is a collection of databases with an expert computer system for facilitating person-job matches. The foundation of the content model underlying the O*NET centers on worker requirements, experience requirements, worker characteristics, occupational requirements, occupation-specific requirements, and occupation characteristics. The O*NET system is relatively new and web based, but it does not include all jobs/occupations.

Sources of Information

Typically, job analysts, incumbents, supervisors, and trained observers are the sources of job analysis information. This information can be obtained in interviews, via questionnaires, by observation, and by actually performing the job in question. Multiple sources and collection methods are often used in practice.

Each job analysis method has its own strengths and weaknesses, and no one method is adequate for all purposes. So the choice of a method must be based on the purpose for a job analysis. Careful consideration should also be given to the costs associated with implementing a given job analysis method.

JOB PLACEMENT

In filling vacancies in a given job, the emphasis is on finding the most qualified people for the job (or individuals most likely to succeed on the job). This is a case of straightforward selection. When there are vacancies for several jobs, one is concerned about how best to fill all vacancies simultaneously with the same applicant pool. This is a case of placement. That is, one is called on to *place* an applicant rather than to *select* an applicant. One may think of selection as choosing one applicant from among many applicants to fill a job opening. In contrast, placement involves matching multiple applicants with multiple jobs. In general, placement is more involved and complex than selection. In either case, reliable and valid job analysis information is a prerequisite.

Selection has received much more attention than placement by I/O professionals. Failure to attend to issues of placement can be long-lasting. All individuals who want to work should have the opportunity to do so. If an individual does not meet the minimal requirements for one job, she or he should be considered for other available jobs. That is, job placement should be given a top priority.

JOB RETENTION

Involuntary job loss either by plant closings, layoffs due to slack demand, or firings for cause will have negative short-run effects on discharged workers' earnings and can have significant long-term effects on the economic well-being of their families. Because the U.S. labor market is considerably less regulated by government than other Organization for Economic Cooperation and Development (OECD) countries and because only about 10 percent of U.S. private sector workers belong to unions, American workers have much less formal protection against involuntary job loss than workers in other OECD countries.

On the other hand, the greater flexibility of American labor markets also means that American workers are better able to enter the labor market and voluntarily move from one job to another. In addition, American firms are better able to adjust their mix of machines and labor in their production process, introduce new technologies, and compete in the international marketplace.

The end result is that the American labor market is more flexible, allows greater voluntary job mobility, and is better able to reward skilled and highly educated workers but also has greater wage inequality, more lower-paying jobs, and greater risks of involuntary job loss than the more regulated labor markets in other OECD countries.

Working-age people with disabilities in the United States likewise have much less formal job protection either via government regulation or union protection and must compete in much more dynamic labor markets than their counterparts in other OECD countries. Germany, for instance, has a formal quota system (that penalizes firms that do not employ a minimum percentage of workers with disabilities) and prohibits employers from dismissing workers based on their disability. In contrast, the United States forbids the use of job quotas and allows employers much greater freedom in hiring and firing workers. The Americans with Disabilities Act of 1990 (ADA) is the most significant piece of protective legislation for U.S. workers with disabilities and has strict limits on whom and how much firms must accommodate.

The United States experienced two major business cycles over the past two decades of the twentieth century—1979 through 1989 and 1989 through 2000. Over the first, the employment rates of working-age people with and without disabilities were pro-cyclical, falling over the recession years of the early 1980s and rising over the long period of growth from 1982 to 1989. However, the rise in the employment of those with disabilities was not as great as those without disabilities, so over the decade their employment rate fell relative to those without disabilities.

The relative employment rate of people with disabilities fell even more over the 1990s business cycle. While the employment of both those with and without disabilities fell from 1990, the business cycle peak year, to 1993, during the growth years 1993 to 2000 the employment of those without disabilities rose while the employment of those with disabilities fell. The employment rates of both those with and without disabilities fell between 2000 and 2003, but the employment rate of those with disabilities fell faster than that of those without disabilities.

Between 1979 and 2000, the household income of working-age people with disabilities remained about the same. Their wage-earning declines were offset by increases in their disability transfers (Social Security Disability Insurance [SSDI] and Supplemental Security Income) and by the greater earnings of other household members. But their overall household income fell relative to those without disabilities, whose income rose significantly over this period of substantial economic growth.

Most working-age people with disabilities experience the onset of their disability after they enter the labor market. Research shows that the social environment, rather than the impairment itself, is the critical factor in determining how long workers with disabilities remain in the work force. The average length of time before they apply for SSDI benefits following onset is 15 years, and only 72 percent of workers with disabilities will ever apply for SSDI benefits. The rest continue in the labor force until they exit onto the

Social Security retirement program. The timing of SSDI application is affected (holding the seriousness of the worker's impairment constant) by a worker's characteristics and the economic incentives he or she faces.

The variables that most affect how long a worker will delay application for SSDI following the onset of a work-limiting health condition are the worker's age at the onset of the condition, the worker's education, whether the worker was accommodated, and the relative rewards of working versus going onto SSDI.

Other things equal, younger and better-educated workers will delay application longer than older or less-educated workers. But accommodation matters. Employees who are accommodated by their employer stay in the labor force longer than those who are not. This is true across a wide range of accommodations. The most frequent firm accommodations are not costly from an accounting perspective, although they may be from a work organization perspective. They are changes in job hours and changes in job responsibilities.

But economic incentives also matter. Those workers whose future earnings are higher or who are less likely to be accepted onto SSDI will delay applying for benefits and continue in the labor force longer than workers with lower future earnings and higher likelihoods of SSDI acceptance.

These findings are based on the accommodation behavior of firms and their workers prior to the implementation of the ADA in 1992. About 23 percent of workers who experienced a disability were accommodated prior to 1992. Simulations that project the experience of these accommodated workers on all workers suggest that their average duration before applying for SSDI benefits would rise by about 2.5 years, if accommodation were provided to all workers following the onset of a disability. But this positive employment policy initiative could be offset by further easing of SSDI acceptance rules or increases in SSDI benefits relative to future earnings.

The recent employment experience of working-age people with disabilities is discouraging. Despite the increased duration in employment that accommodation brings and the likely rise in the percentage of workers with disabilities who were accommodated in the 1990s following the implementation of the ADA, their employment rates fell over the entire 1990s business cycle and has done so, relative to those without disabilities, since the mid-1980s. The causes of this decline in relative employment are controversial, but the preponderance of the evidence suggests that it was not caused by an increase in the severity of their impairments. Rather, the causes are related to the changing social environment faced by workers with disabilities.

The most likely cause is the substantial reduction in the eligibility standards for entry onto the SSDI rolls that occurred in the mid-1980s. Research has shown that U.S. workers who experience the onset of a disability in states with higher SSDI acceptance rates are quicker to apply for benefits and that in such states the employment rates of workers with disabilities are lower relative to those without disabilities.

It has also been argued that the increased costs firms must bear to accommodate workers with disabilities have made them less likely to hire such workers and that this unintended consequence of the ADA offsets its positive impact via increased duration on the job for those who are accommodated. The evidence of a negative ADA effect on employment is more controversial and has been shown to be sensitive to alternative definition of the population with disabilities.

Market forces influence the employment of working-age people with and without disabilities. The skills that people with disabilities bring to the job will affect their chances of employment, their duration on the job, and the age they leave the labor market. The wage premium that those with more than a high school education command has dramatically increased over the past two decades. This is true both for those with and without a disability. The best predictor of job market success is one's level of education, and in the constantly changing American job market, the long-term rewards to well-educated workers demonstrate its value. Hence those workers with good job skills and high education levels are the most likely to be retained by their employers during bad times and to command higher salaries during both good and bad times.

Government policy can also influence the employment of working-age people with disabilities. Pro-work policies that foster rehabilitation, job-enhancing skills, and accommodation will increase job retention and more generally integrate working-age people with disabilities into the labor market. Reduction of eligibility standards for SSDI and other disability transfer programs that require beneficiaries to demonstrate that they are not able to work before they can receive benefits will have the unintended consequence of further reducing the employment of working-age people with disabilities who could work.

JOB TRAINING

Job training, both for those employees new to the work setting and those needing to acquire additional work skills, is often viewed as a way of assisting the employee in mastering the essential function of a job. The outcome of such training is the development of skills that will allow the employee to meet the standards set by the employer. Job training can be viewed as generalized preservice and mentorship/apprentice training or training that occurs in response to a specific job. For persons with disabilities, when considering job training one has to consider the broader perspective of identification, accessing, and maintaining employment since these are intertwined in the process of securing and advancing in employment.

This entry briefly reviews the principles driving job training, approaches for persons with disabilities, and the challenges and opportunities to job training in the future. This overview will provide the reader with a broad view of job training for persons with disabilities from a philosophical as well as a practical level. While this entry addresses job training for individuals who have a disability, it is important to note that the approaches used are more similar than different for all job seekers, those with as well as without disabilities.

PRINCIPLES DRIVING JOB TRAINING

The changing perceptions about the capacity of persons with disabilities, advances in job training strategies, and new technologies have all contributed to a new way of looking at job training for persons with disabilities. The realization that persons with disabilities can and in many instances want to work has been supported in many countries by changes in legislation, policies, and practices that have encouraged persons with disabilities to consider employment and employers to view persons with disabilities as part of the workforce.

Legislation banning discrimination, providing incentives to hire, and establishing hiring quotas have all contributed to an increased awareness about the employment of persons with disabilities. In a complimentary fashion, the recent movement toward self-advocacy has also served to increase the awareness by persons with disabilities about the opportunities that may exist in the labor market. The combination of increased self-advocacy, changing ways to support and match individual skills to industry needs, and administrative incentives has served to support increased employment of persons with disabilities in many countries.

APPROACHES TO JOB TRAINING

The evolution of employment for persons with disabilities is reflective of overall societal perceptions of disability in general. This evolution has gone from no expectation to a recognition that persons with disabilities can and want to work. Job training approaches for job seekers who have a disability have moved from a pretraining or readiness design to one that places greater emphasis on on-the-job training. Early training efforts focused on the identification of individual deficits, the remediation of those deficits, and then the development of work-hardening or work tolerance skills. A myriad of work samples, paper-and-pencil, and trial work strategies were the cornerstone of job training strategies in many countries. These assessment approaches were based on deficit identification followed by remediation and skill development. This focus on deficit identification and work conditioning placed the entire responsibility for job success on adaptations by the individual with little recognition of any modifications in the actual work setting.

In the past two decades, the emphasis on job training has shifted to one of building on skills and interests and maximizing the abilities of the individual. Informal and formal assessments addressing preferences and interests were providing greater information than the more traditional work assessment tools. There was also a growing recognition that situational assessment, conducting an assessment in an actual work setting, provided greater information on both skills and interests. There continued to be, however, a focus on the person fitting the job. Moving from the utilization of situational assessments, job training in many countries has embraced the strategy of matching individual skills and interests to demands in the work setting. This focus has led to a "goodness of fit" perspective where job training is a combination of skill building and job modifications. Here both the individual and the job setting are adapting.

Paralleling this evolution of focus was a shift in the nature of the training setting. Total reliance on specialized training and work settings is giving way to direct placement and on-site supports based on the results of considerable research in supported employment. Job training is happening in the workplace with the assistance of an outside support, an employment training specialist, or job coach. This support addresses not only skill acquisition but also identification of available social supports that are naturally present in the work setting. The employment training specialist facilitates initial training, fading support and shifting the training and support to the employer and coworkers as the individual with disabilities approaches employer expectations and assimilates into the culture of the workplace. The linking of external supports to those naturally existing in the work setting and the training of coworkers as support resources, the hallmark of supported employment, are now common practice in many countries.

As a reflection of this shift, trainers have evolved from more formal skill trainers who may offer classroom instruction in an external setting to on-site employment training specialists. Training on the essential tasks of the job is not the only function of the employment training specialist. Job accommodations and job modification may be introduced to both support productivity and assist the individual with a disability in being successful on the job. Modifications may include the restructuring of tasks, the simplification of task sequences, the use of assistive devices and aids (e.g., pictures, cue cards), and the identification of coworker supports for the individual. Job training has moved away from specific skill acquisition to whole-job training including skill acquisition, social supports, and job modification.

FUTURE CHALLENGES

As the nature of an economy changes so do the demands of businesses. These demands require that the workforce adapt, continually acquiring new skills. During the farming and manufacturing periods, it was not uncommon for workers to remain at one job for their entire work history. With the advent of the technology and information era, job movement and job change became the rule rather than the exception and changes in tasks were at times a daily event in some industries.

More recently, with globalization, technology changes, and virtual work settings, the demands for increased flexibility and greater proficiency in the use of technology continue to change the job training arena. The idea of initial training has given way to continuous training where changes in the consumer marketplace have given rise to the creation of new products and new jobs. New approaches and technologies such as multitasking, voice-activated information systems, smart technologies, and virtual work settings, along with globalization and workforce diversity, are all requiring those involved in job training to think and behave differently.

These challenges are requiring job training professionals to think differently about both the nature of training strategies and the setting for the delivery of training. The rate of job change, the changes in job duties, and the increased use of distance education resources are an opportunity for job training to use technology for delivery of information as well as a way of reinforcing skill acquisition. Web-based training, Listservs, and chat rooms are all ways that job training can be delivered now and in the future. Common instructional materials delivered through electronic media and reinforced by local trainers or support staff assist persons with disabilities in learning new skills not only at time of job access but also as a way of maintaining employment. The use of multistimulus input systems (seeing, hearing, touching), vehicles for immediate feedback, and strategies for rapidly refreshing learned skills are all ways that job training can support both initial learning and job growth for persons with disabilities.

Effective strategies for job training have relevance for all employees. With older workers remaining on the job for longer periods of time, workforce mobility reflecting not just local but global tendencies, and increased recognition of the employment potential for job seekers with disabilities, effective job training strategies can be applied not only to job seekers who have a disability but also to older workers and the nonnative workforce in many countries. Job training has the potential for broadly supporting access and career development for both the emerging workforce and the typical workforce in the coming decades.

JOHNSON, SAMUEL (1709–1784)

English author and lexicographer

Both a "great Cham" (tartar monarch) and "Caliban" (Shakespeare's deformed slave in *The Tempest*) of letters, Samuel Johnson gave his name to an age as the most prominent literary author of his day. Best known for his Herculean (and Sisyphean) achievement of the first modern dictionary of the English language (1755), Johnson also was an editor of Shakespeare, a moralist in a variety of genres—periodical essay, Juvenalian satire, heroic tragedy, apologue, travel narrative—and in his *Lives of the Poets* (1779, 1781) a legislator of the English literary canon. Yet he was often remembered by subsequent generations more as a character than an author.

Blind in one eye, deaf in one ear, scarred by childhood tuberculosis of the lymphatic system (known as "scrofula") and by smallpox, Johnson suffered throughout his life from what his biographer James Boswell termed "a horrible hypochondria," what the psychology of the period would have termed religious melancholy (his greatest fear was damnation) and what would now be considered severe depression. This inner torment was accompanied by rituals, compulsions, and convulsive "tics and gesticulations" that have recently been diagnosed as evidence of Tourette's syndrome but that during Johnson's own time evinced eccentricity (the stuff of eighteenth-century English notions of individuality) rather than pathology. At his life's close, Johnson survived a stroke, while suffering congestive heart failure, kidney disease, emphysema, severe arthritis, and "dropsy" manifested most dramatically as a hydrocele of the testis. He fought death to the last, deploring his doctors' caution in treating his dropsy and hastening his demise by self-scarification. Johnson's embodied afterlife arises partly from Boswell's devoted preservation of his conversation in the *Life of Johnson* (1792), but also from his epitomization of literary authority as a paradox that united monumental style with a singular body in ambiguous motion.

JOURNALISM

Although the political issues of people with disabilities rarely made the mainstream news until the 1990s, the people themselves have been in the news since American journalism began the practice of identifying sources by physical characteristics. The norms of journalism that developed by the early twentieth century meant that anyone who was not white or able-bodied would, in many cases, be identified by their ethnicity or disability. For example, an *Atlantic Monthly* article about the blind African American pianist and composer Thomas Bethune in 1862 was headlined "Blind Tom," which was his well-known moniker. Most disabled people did not garner the nineteenth-century media attention of Blind Tom, but any journalist writing about a person with a disability in the nineteenth century or the present would rarely fail to mention a disability, especially blindness or deafness. When Erik Weihenmayer climbed Mount Everest in 2001, every journalist mentioned his blindness.

However, these reports of individual people with disabilities in the news did not mean the issues that affected them made the news. In fact, journalism's focus on specific individuals with disabilities became the standard of coverage for decades. When the disability rights movement arose in the 1970s, activists and media researchers began questioning why journalists continued to write primarily about individuals with disabilities, rather than the major civil rights initiatives afoot.

RESEARCH ON REPRESENTATIONS IN JOURNALISM

The concept of handicapism is germane to journalistic coverage of people with disabilities. In developing the concept in 1977, Robert Bogdan and Douglas Biklen defined *handicapism* as "a set of assumptions and practices that promote the differential and unequal treatment of people because of apparent or assumed physical, mental, or behavioral differences." Their data and impressions suggested that mass media, by portraying prejudicial or stereotypical images of disabled persons, contributed to handicapism in society.

Therefore, many researchers began to take seriously the influence of journalism on the understanding of disability. Researchers from the areas of rehabilitation began to look at news representations. For example, rehabilitation researcher E. Keith Byrd and Timothy Elliot of Auburn University studied various aspects of media images of disability over the course of the 1980s. Psychologists also looked at news images of disability. James M. Gardner and Michael S. Radel studied both newspapers and prime-time television coverage of disabled people in 1978 to identify the major themes in coverage: dependence, independence, abuse, and deviance.

Disability studies scholars paid attention to journalistic images of disability in the 1980s as well, especially when major media issues arose. Douglas Biklen looked at the print media coverage of the 1984 Baby Jane Doe case, in which parents and doctors fought over the severely disabled baby's right to live or die, and the Elizabeth Bouvia case, in which a severely disabled woman wanted the right to starve to death. Biklen found that journalists uniformly "cast in terms of tragedy, of charity and its attendant emotion, pity, or of struggle and accomplishment."

The language used in journalism to characterize people with disabilities also has significance. Disability studies scholar and historian Paul Longmore studied the social meaning of language that referred to disabled people in 1985 and found three forms. One form represents people solely in terms of a disability and are therefore medicalized and dependent. This form creates abstract nouns from adjectives (the disabled, the deaf) or borrows medical labels such as "suffers from." Another form used euphemistic labels such as "special" or "exceptional." And the third form refers to politicized language that allows disabled people to create their own identity.

More mass communication scholars turned their attention to journalism and disability topics in the 1990s. The preeminent scholar in this area was John Clogston, a former radio journalist who was a wheelchair user. He wrote his dissertation at Michigan State University, "Reporters' Attitudes toward and Newspaper Coverage of Persons with Disabilities." In 1990, Advocado Press, the publisher of *The Disability Rag,* published Clogston's content analysis of the coverage of disability topics in more than a dozen major U.S. newspapers. Through his research, he developed five models of news media representation of disability, which fit into either a traditional or progressive category.

Clogston's traditional categories include the medical model, the social pathology model, and the supercrip model. In the medical model, disability is presented as an illness or malfunction. Persons who are disabled are shown as dependent on health professionals for cures or maintenance. In the social pathology model, people with disabilities are presented as disadvantaged and must look to the state or to society for economic support, which is considered a gift, not a right. In the supercrip model, the person with a disability is portrayed as deviant because of "superhuman" feats (e.g., ocean-sailing blind man) or as "special" because they live regular lives "in spite of" disability (e.g., deaf high school student who plays softball).

Clogston's progressive categories include the minority/civil rights model and the cultural pluralism model. In the minority/civil rights model, people with disabilities are portrayed as members of the disability community, which has legitimate political grievances. They have civil rights that they may fight for, just like other groups. Accessibility to society is a civil right. In the cultural pluralism model, people with disabilities are presented as a multifaceted people and their disabilities do not receive undue attention. They are portrayed as nondisabled people would be.

News media researcher Beth Haller used Clogston's models in her 1995 dissertation, "Disability Rights on the Public Agenda: News Coverage of the Americans with Disabilities Act." However, she added three models to reflect the changes in society that came with the 1990 Americans with Disabilities Act (ADA). In addition, Haller expanded the use of the models by recognizing that more than one model may be present in a story. This was especially appropriate in news stories about the ADA, in which government, business, and disability rights sources came together.

Haller's added traditional category model was the business model, in which people with disabilities and their issues are presented as costly to society and businesses especially. Making society accessible for disabled people is not really worth the cost and overburdens businesses; in other words, accessibility is not profitable. The two added progressive models were the legal model and consumer model. In the legal model, the media explain that it is illegal to treat disabled people in certain ways. The ADA and other laws are presented as legal tools to halt discrimination. In the consumer model, people with disabilities are shown to represent an untapped consumer group. Making society accessible could be profitable to businesses and society in general, because if disabled people have access to jobs, they will have more disposable income and less need for government assistance.

These models created a systematic way to study and categorize representations of people with disabilities in journalism. Clogston was also instrumental in developing the Media and Disability Interest Group as part of the Association for Education in Journalism and Mass Communication (AEJMC), which is the major academic organization for journalism scholars. Another founding member of the interest group and important journalism and disability scholar is Jack Nelson. He gathered together media scholars and edited a 1994 book looking at many aspects of the topic in *The Disabled, the Media, and the Information Age.* This was the first solely news media/disability-research focused book in the United States, although in 1987 Alan Gartner and Tom Joe edited a scholarly collection called *Images of the Disabled, Disabling Images,* which included some chapters on news and disability. A British study of disability images on TV, both fiction and nonfiction, resulted in a book in 1992. Guy Cumberbatch and Ralph Negrine's (1992) *Images of Disability on Television* found themes in news programs such as fitting into normal life, the physical progress of a person with a disability, the lack of understanding by society/individuals, and fighting for civil rights.

JOURNALISM FROM THE DISABILITY COMMUNITY

All this research over the years confirmed that news media do a mediocre job of covering people with disabilities and their issues. Because mainstream media presented stereotypes or no information at all, many disability groups created their own journalism. Many disability publications have a long history in the United States; for example, one that has been ongoing since 1907 is *The Matilda Ziegler Magazine for the Blind* Braille publication.

Like ethnic publications or the alternative press, the disability publications react to the same kind of exclusion and stigmatization that other outsider groups have experienced. Disability publications allow people to pull themselves together as a community with similar goals and aspirations. As Erving Goffman (1963) suggested in *Stigma,* people with a stigmatized status in society develop their own publications because they allow them to debate the societal issues related to them that rarely make the mainstream press.

Charlie Winston, who tracks the disability press annually in *America's Telability Media* guide, estimated that in the late 1990s at least 1,200 mass media resources for the disability community in the form of magazines, newspapers, newsletters, radio/TV programs, and recurring newspaper columns existed. Winston said the disability media range from an individual creating a two- to four-page newsletter at a very low cost to a glossy, four-color magazine such as *New Mobility* (telephone interview by author with C. Winston, March 26, 1999).

Lillie Ransom, in her 1996 dissertation on disability publications, identified three main patterns among the publications: activist/political, mainstreaming/assimilationist, and special interest. She said that a publication such as *The Ragged Edge* is embedded within the disability rights social movement, making it an activist/political model publication; *The Arc and the Dove,* a publication for the ARC of Maryland, fits within the mainstreaming/assimilationist model because they want people with mental retardation to be accepted in the mainstream community; and a publication such *as The National Amputee Golfer* is described as a special interest model. However, whatever their pattern, each publication has the commonality of serving people who are "outsiders" and who face societal barriers due to physical or mental difference. Disability journalist Douglas Lathrop explained that these disability publications reflect that people with disabilities think of themselves as a community.

In addition to giving a voice to the entire community of Americans with disabilities, disability journalism gives apt examples that people with disabilities are a multifaceted community. Because different disabilities make for different societal barriers, publications based on specific disabilities arose. For example, the U.S. deaf community has a long tradition of its own journalism. The North Carolina School for the Deaf began the first publication for deaf persons in 1848 with its school newspaper, *The Deaf Mute.* Other disability-related publications continued a tradition of fostering solidarity within the different subcultures of the disability community. After World War II, soldiers who had been disabled in war came home, which led to the Paralyzed Veterans of America's development of the magazine *Paraplegia News,* in 1946.

In terms of disability rights–focused journalism, disability publications such as *The Ragged Edge, Mainstream,* and *Mouth* helped fuel the disability community's civil rights agenda. *Mainstream* magazine began in 1975. (Its print publication ceased in 1999.) The precursor to *The Ragged Edge, The Disability Rag,* started in 1980. *Mouth* began in 1990. Lucy Gwin, the editor of *Mouth,* explained: "Nobody [in the mainstream media] is going to cover the disability-rights movement, so we're just going to have to cover it our own damn selves."

EFFORTS TOWARD BETTER JOURNALISM

A few people still believed that mainstream journalism could change its coverage patterns and do a better job of reporting on disability issues. They also realized that most Americans get their information from mainstream news media and that they could have significant influence on the general public's perception of disability rights. In 1988, the U.S. government tried to foment this change. The National Institute on Disability and Rehabilitation Research (NIDRR) funded a national workshop on news media and disability issues. A workshop organizer said the reason behind the project was that "recent news articles and features have tended to divide disabled individuals into two categories: the poor pathetic creature of charity or the heroic, undefeatable 'super crip.'"

Another government-funded project to improve journalism on disability topics was produced in 1989 by the Advocado Press. Edited by Mary Johnson, *The Disability Rag* editor, and Susan Elkins, the publications coordinator for the Research and Training Center on Independent Living at the University of Kansas, the manual, *Reporting on Disability: Approaches & Issues,* drew together contributions from activists, ethicists, writers, and broadcasters, all of whom had experience covering disability issues. Intended for use with journalism students, the manual gave guidance on reporting issues specific to disability topics, how to find new and less stereotypical angles in covering disability, information about disability rights history and laws, ethical considerations, and examples of good reporting on disability topics.

Several journalists who contributed to the manual went on to write important books about disability rights, which included information about news media coverage. In 1993, Joseph Shapiro of *U.S. News & World Report* wrote *No Pity: People with Disabilities Forging a New Civil Rights Movement,* considered one of the best journalistic books on the disability rights movement. Tari Susan Hartman and Mary Johnson wrote a book called *Making News* in 1993 that provided a guide to activists on how to get news coverage of disability rights issues. Johnson then deconstructed backlash against the ADA in her 2003 book, *Make Them Go Away: Clint Eastwood, Christopher Reeve and the Case against Disability Rights.*

Associations of journalists gained awareness of their flaws when reporting on disability issues by 1990. The American Society of Newspaper Editors formed its Disabilities Committee and in 1990 published a booklet, *Reporting on People with Disabilities.* Bill Beisky, the editor of the *Cape Cod Times* and the father of a daughter with a disability, instigated the development of the booklet. The booklet makes some suggestions on reporting issues but was primarily a language guide on the preferred terminology when referring to disability topics. In a similar effort, the Research and Training Center on Independent Living at the University of Kansas also released a terminology guide in 1990, *Guidelines for Reporting and Writing about People with Disabilities.* The guide is now in its sixth edition. To pursue similar efforts at journalism education, freelance photographer Suzanne Levine developed the National Center on Disability and Journalism (NCDJ) in 1998. NCDJ created an online style guide about disability terms, as well as posting tip sheets on topics such as interviewing people with disabilities and developing curriculum for teaching about disability in the college journalism classroom.

In 1993, the Freedom Forum Media Studies Center at Columbia University also addressed the news media's problematic reporting on disability in *A Parallel and Imperfect Universe: The Media and People with Disabilities* (Gazsi 1993). The Society of Professional Journalists (SPJ) began acknowledging the need for better coverage of disability issues as well. Its society magazine, *The Quill,* had been publishing occasional articles about the topic since the 1980s when Laura Rensom Mitchell wrote “Beyond the Supercrip Syndrome.” By 2002, SPJ developed an online searchable Rainbow Sourcebook, which included sources on disability issues.

In the late 1990s, NIDRR again identified the need to better educate the public about disability issues through the mainstream media. It funded the San Diego–based Center for an Accessible Society, run by the former publisher and editor of *Mainstream* magazine, Cyndi Jones and William Stothers, and Mary Johnson of *The Ragged Edge.* Its charge is to get information about disability topics and independent living out to the general public. It does this by creating an online resource guide for journalists on a myriad of disability topics and by providing sources on disability issues for journalists. It also funds research to track major news media coverage of disability topics.

JUDAISM

Central to Jewish disability issues is Scripture Tanach (Old Testament) and its interpretation, Talmud (oral law). Collectively, these (and later commentaries) are known/studied as Torah. References to numerous impairments abound, often conflated with other conditions including, most notably, childhood. With Scripture, especially Talmud (the first diasporic literature), virtually the only record of ancient everyday Jewish life, the nature of these references must be considered. Much of Talmud is utopian/idealistic. Largely composed of religious case law, its admonitions may more reflect common transgressions than common practice. In addition, disabilities are often used hypothetically to illustrate extremes in test cases.

Judaism prior to the destruction of the Second Temple and the first state of Israel (70 CE) was rooted in the priestly Temple cult and sacrificial rite. The "perfect priest" required physical "blemishlessness" to withstand the ardors of animal sacrifice in God's presence within the temple. The priest represented an archetypal ideal rather than a norm, a far higher standard than mere able-bodiedness. Although restoration of the temple and priesthood remains an idée fixe in Judaism, the diaspora's practical archetype became the sage (the professional rabbinate emerged only later). The precarious nature of diaspora—metaphorically, a disabled Israel—idealized intellectual attainment through Torah study, rather than physical perfection. Throughout and beyond the era of Bavli (the definitive Babylonian Talmud, fifth–seventh century CE) impairments become progressively better understood and accepted, if only incrementally until recent times.

A culture that idealizes intellectual discourse would naturally regard cognitive/communication impairments as most disabling. The Talmud subsumes these in the category *cheresh, shoteh v'katan*: deaf/mute persons, mentally ill/mentally disabled persons, and children. More than earlier Scriptures, Bavli recognizes nonverbal communication by the deaf/mute, the intermittency of some mental illness, and practical attainments of the developmentally disabled and maturing children. Thus, correspondingly, it advocates, within limits, greater rights and responsibilities for these groups. Judaism has never sanctioned infanticide.

With cognition and communication so privileged, mobility impairments are of little concern in Jewish law. Blindness is regarded as a disability only in a few contingencies. Several Talmudic sages were blind, including Rabbi Yosef, whose advocacy of rights and responsibilities for the blind is considered definitive. Still, disability is sometimes regarded as God's punishment, though also, as in Buddhism, an opportunity for atonement and even a conduit for prophecy.

Contemporary Judaism has virtually abolished the category *cheresh;* deaf/mute persons are no longer consider insensate. There are deaf synagogues, a deaf seminary, and deaf Jewish community centers. Israeli Sign Language is very similar to Palestinian Sign Language. Since 1992, Vertigo, an Israeli mixed-ability dance company, has toured worldwide.

Anti-Semitism is often expressed in a discourse of pathology and defect. In the context of nineteenth- and twentieth-century Western racism and eugenics, the Nazis implemented genocidal programs against Jews, people with disabilities, and others including Sinti/Roma ("Gypsies") and gays and lesbians.

JUKES, THE

The first of many editions of Richard L. Dugdale's *The Jukes, a Study in Crime, Pauperism, Disease, and Heredity* appeared in 1877. The book told the story of five generations of poverty, crime, and disability in the Jukes family, the fictitious name of a real family. Departing from the dominant antebellum claim that heredity represented capricious degeneration, Dugdale held that hereditary disabilities followed intergenerational patterns. Thus, alcoholism would not necessarily produce so-called insanity or feeblemindedness in later "skipped" generations, but it might well produce more alcoholism in the next generation, and with alcoholism came poverty.

Dugdale also stressed a relationship between heredity and the environment. Juke family members who lived in healthy surroundings were less likely to be paupers than were family members who lived in unhealthy environments. Drawing the attention of the emerging "scientific charities" movement, the book reached its largest audience after Dugdale's death in 1883. Departing from his insistence on the interrelationship between the environment and heredity, this audience appropriated the story of the Juke family to argue for the immutability of heredity. From 1883 to the 1920s, North American social welfare officials portrayed many poor, and often rural and white, families like the Jukes as hopelessly degenerate, victims of their ancestral vices and ignorance. For this reason, the story of the Jukes became a precursor of the eugenics movement in the United States and Western Europe.

JUSTICE

Theories of justice are, in part, about what people are entitled to—as members of a political community, or more controversially, merely as human beings. These theories differ in what they regard people as entitled to: fair play, respect, a minimum or an equal share of material resources, access to the various goods of life, psychological satisfaction, and recompense or redress for past wrongs by others or punishment for one's own wrongs. These entitlements are not mutually exclusive, of course, but theories of justice differ in the importance or emphasis they place on them. For example, concerns about appropriate and proportionate punishment are often seen as matters of corrective justice; appropriate resources, access, or satisfaction as matters of distributive, patterned, or end-state justice; and fair play and respect as matters of procedural or relational justice. The lines between and relationships among these different types of justice are vague and disputed. But more important, there is strong disagreement about what people are entitled to under all three rubrics.

These distinctions among types of justice are well illustrated by the claims of people with disabilities, claims that figure significantly in contemporary disputes about justice. For example, many disability advocates have questioned the claim of recent theories of distributive justice that people with disabilities have strong entitlement to the resources needed to correct their impairments. Without rejecting such entitlements altogether, advocates regard them as unduly influenced by a medical model, which sees disability exclusively in terms of biological impairment or dysfunction. Drawing on an interactive model of disability, they stress the need for resources to accommodate disabilities, to make the built environment accessible to people with disabilities. And because most societies have failed to make such accommodations, disability advocates often insist that people with disabilities are entitled to restitution or compensation for past exclusion. Finally, some disability advocates have seen the focus on distribution as misplaced: What disadvantages people with impairments is largely their stigmatization not their impairments. On this view, the primary goal of justice should be to eliminate that stigma and the social exclusion accompanying it; the redress of material disadvantages will follow.

For all these critiques, one of the challenges facing contemporary theories of justice in relation to disability is to avoid the strictures of the medical model; to see disabilities in interactive terms and to find justice and injustice in the terms of that interaction. Unfortunately, the recent debate among competing theories of justice has tended to reinforce the medical model, by assuming that the justice claims of people with disabilities are not only medical and rehabilitative but virtually inexhaustible, and by assuming that significant impairments preclude a high quality of life. In reviewing these theories, this entry points out their reliance on such dubious assumptions and then suggests ways in which those theories have been, or could be, modified and strengthened in response to the disability critique.

RELEVANCE OF IMPAIRMENT TO JUSTICE

Most societies make provisions for persons with disabilities. Medical, rehabilitative, educative, and other resources are provided to cure or treat health conditions or improve functional capacities. Social assistance, pensions, workers' compensation, and other forms of income supplements attempt to compensate people with disabilities for their inability to work. Antidiscrimination laws seek to redress intended or unintended denials of equal opportunity associated with misperceptions, stereotypes, and the stigma of disability. These and other laws require public accommodations, employment and education settings, and communications and transportation services to be accessible. Yet other laws and programs directly provide assistive technology and educational and employment opportunities to raise the level of economic and political participation by people with disabilities.

Some laws view impairments as functional deficits that get in the way of the person's social participation; others emphasize the social stigma of impairments and the obstacles that that creates for people with disabilities. As functional deficits, impairments create needs for services, resources, and accommodations. When laws and policies address these needs, the underlying rationale is distributive justice: Impairments negatively affect social participation, so justice requires that these disadvantages be ameliorated as much as possible. Laws that focus on the social stigma of impairments view lack of participation in basic areas of social life as harms inflicted on people with disabilities either through prejudice, misunderstanding, or neglect. On the face of it, the underlying rationale is compensatory, namely, to undo the damage to people with disabilities caused by individuals or, systematically, through existing social institutions.

Since impairments are relevant to social justice in two different ways—as functional deficits and as social markers—there is potential for confusion about the appropriate objectives of laws and regulations. A law requiring public schools to allocate resources to accommodate the specific requirements of children with disabilities should be viewed as responding to a demand of distributive justice (e.g., that all children should benefit from the educational experience). If we treat it as a compensatory law, then it is vulnerable to the plausible objection that most needs of most disabled children are not harms that any individual or institution has caused. On the other hand, an antidiscrimination law such as the Americans with Disabilities Act of 1990 (ADA) cannot be easily justified as a tool for securing distributive justice, since it exempts individuals and institutions from making reasonably accommodations for people with disabilities if doing so would impose an "undue burden" or "hardship" and it does not require the state to assume that burden, however reasonable the accommodation. But it is also difficult to see the ADA strictly as demanding procedural justice, because it *does* require that individuals and institutions sometimes incur substantial (although not undue) costs for reasonable accommodations, a material burden that has no obvious counterpart in most other antidiscrimination laws.

A more plausible stance to take here is that impairments are relevant to justice in several ways: For the sake of justice, we need to acknowledge that people differ with respect to their repertoire of functional capacities, and so differ in what material and social provisions they require to fully participate in society. We also need to recognize that impairments are fraught with social meaning, most of which is disadvantageous to people with disabilities, and that the harms that are caused—either intentionally or not—need to be addressed for the sake of justice. In some instances, it must be said, disability raises justice concerns that appear to move among compensation, distribution, and respect: If public buildings are not accessible to a person with a mobility problem, one might argue that the failure to retrofit the building is discriminatory, in failing to treat people with mobility impairments as potential users or residents of that building. And such a slight may require compensation. But one could also argue that the benefits of access to public buildings must be distributed, as fairly across the public as possible, and so excluding this individual is distributively unjust.

One might contend that if justice demands a response to unfair disadvantages associated with impairments, it does not matter whether that response is understood in terms of procedural, distributive, or compensatory justice. It is difficult to distinguish the disadvantages "naturally" associated with impairments from those created by the attitudes and behaviors of others, or social arrangements generally. It should therefore not matter much if we view accommodation and retrofitting as conferring on people with disabilities the resources they are entitled to as a matter of distributive justice, treating them with the respect due to them as equal members of the community, or compensating them for having failed to do what distributive or procedural justice requires.

Of course, neither accommodation nor compensation will be thought to be owed if one denies that the state has any obligation to achieve a particular distribution of resources or opportunities, if one regards disadvantages associated with impairments as "natural," and if one insists that the only procedural or relational obligations we owe, in the absence of special relationships, are honesty, trustworthiness, and conformity to jointly accepted rules. But most people reject such a minimalist view of distributive and procedural obligations, and a generation of disability scholarship has made it clear that many of the disadvantages associated with impairments cannot be regarded as natural. But the rejection of minimalist views leaves room for disagreement about the character and extent of the entitlements that people with disabilities can claim.

Much of the philosophical activity in this area has been in the domain of "patterned" distributive justice, in particular, in the explication of the kinds of equality, or constraints on inequality, that distributive justice should seek. Because distributive theories have been the most fully developed, and the most frequently criticized by disability scholars and others, especially feminists, this entry focuses next on those theories and their treatment of disability. The entry then assesses the challenges they face and the adequacy of alternative and hybrid approaches in meeting those challenges.

THEORIES OF DISTRIBUTIVE JUSTICE

Despite the obvious relevance of impairment to justice, recent theories of justice have by and large alternated between a benign neglect, tabling provisions for the impaired until a just "basic structure" for society has been established, and an oppressive solicitude, treating people with impairments as having a greater claim to restoration of normal functioning than the claims of "normal" members of society have to material resources. As Martha Nussbaum has pointed out in an important critique, the neglect or postponement of justice for people with impairments by the leading political philosopher of the past century—John Rawls—arises from three factors of continuing relevance for justice and disability. One is the basic "contractarian" character of Rawls's theory of justice, in which justice is derived from the agreement reached by self-interested bargainers ignorant of their position in society or conception of the good life. Although the stipulated ignorance secures a kind of moral objectivity to the contract, the objective remains individual benefit, and people with impairments, assumed to be less productive or costly to accommodate, tend to be excluded as unattractive bargaining partners. The second factor is the theory's need for a simple metric of comparative advantage—deficits in physical or mental function do not fit easily beside wealth and income in a single, summary metric of well-being. Third, and particularly relevant to cognitive impairment, the bargainers are assumed to be rational. People who cannot engage in practical reasoning, let alone elaborate calculations of expected utility, do not have a place at the bargaining table.

Other philosophers have attempted to accommodate people with disabilities within a Rawlsian, or more broadly contractarian, framework. The most well-known, and controversial, effort has been made by Norman Daniels. Rather than ignoring people with impairments or tabling their claims, Daniels makes the correction of impairments a matter of utmost urgency by insisting that claims to the restoration of normal functioning are stronger than even those of the economically worst-off members of society. Arguing that normal human functions are essential to equality of opportunity, Daniels gives priority to health care and other impairment-correcting resources. A person with disabilities on his view has a special claim on society if his or her level of functioning falls short of the normal range (as determined biostatistically). Impairments directly reduce the range of opportunities open to a person. So too do deficits in talent and skill, but justice only requires fair equality of opportunity, namely, the equalization of opportunity for persons with similar skills and talents.

Many critics, including disability scholars, have contended that Daniels's augmentation of Rawls requires excessive and inappropriate redistribution of resources to people with lower functioning at the expense of people with limited talents and skills, who may well experience greater social disadvantage. They dispute the centrality that Daniels accords to normal functioning for fair equality of opportunity, and the priority he assigns to its achievement or restoration. They suggest that his exaggerated premium on normal functioning reflects his uncritical acceptance of a medical model of disability, and his resulting neglect of the social contribution to disability.

Another influential philosopher offering a quasi-contractarian theory of justice, Ronald Dworkin, does recognize that social preferences and practices play some role in the creation of disability, but his response may be even less appropriate than Daniels's. Unlike Rawls, Dworkin simply stipulates that the members of society are entitled at the outset to an equal share of the world's resources, but he does not believe that this entitlement can extend to individuals' highly variable "internal" resources—functionings and talents. Dworkin attempts to deal with the "brute bad luck" of poor internal resources—impairments as well as limited, obsolete, or undesirable talents—by relying on a hypothetical insurance scheme. We are to imagine what people, ignorant of what opportunities they might want to pursue in life, would be willing to pay by way of insurance against the prospect of acquiring a disability. If we could reach a social consensus on what would provide fair compensation for blindness, immobility, or cognitive deficit, then that would be an objective measure of the cost of relevant resources that the state should, in justice, provide people with disabilities. The hypothetical insurance buyer is willing to insure against deafness or blindness, not because he believes that these conditions directly lower his quality of life but because they would be impediments to life plans he would have likely had, given the social environment in which it is reasonable to expect he will find himself.

Central to Dworkin's approach is the recognition that the social impact of disabilities is not identical to the functional impact of impairments: The extent to which an impairment limits one's equality of opportunity depends on the physical, social, and attitudinal environmental in which the individual with that impairment lives. Although this is an important insight from a disability perspective, Dworkin blunts its impact by assuming that we can generalize about the overall impact of impairments in any social environment. More important, he implicitly ignores the effects of systemic accommodation and environmental modification. The price the hypothetical insurer thinks is prudent is based on the need for individual material resources to deal with an utterly hostile and unaccommodating social environment. In short, while Dworkin recognizes the environmental cause of the disadvantages of disabilities, his scheme for a "just" solution involves no more than paying people with disabilities to live in a disability-unfriendly world.

It might be suggested that the underlying difficulties with Dworkin's account can be traced to the fact that it relies on material resources as a metric of advantage, measuring outcomes and compensating shortfalls by money. Dworkin favors resources over welfare, preferring a more objective metric over a subjective one, such as feelings of pleasure or satisfaction. A resource metric would not punish those with low expectations and modest tastes nor reward those with high expectations and extravagant tastes. Several philosophers have argued, however, that it is possible to have a metric of advantage based on capabilities, which are as objective as material resources but more sensitive to the multivalued character of well-being. The economist Amartya Sen and the philosopher Martha Nussbaum have proposed accounts of the goal of distributive justice in terms of equality of capability.

Sen (1980:217) defines *functionings* as the things and activities that people have a realistic choice among in their lives. A functioning is more than a physical or mental capability (and so more than the mere absence of an impairment). It also includes all of the social, physical, and attitudinal features of the person's environment that are preconditions to the realization of a choice. A *capability*, then, is a set of functionings over which a person has a choice. In general, the complete set of a person's capabilities describes his or her "positive" freedom over alternative ways of living.

Sen's approach is well suited to account for what disability scholars argue are the true disadvantages associated with disability. A limitation of functioning in Sen's sense is either the incapacity caused by impairments or, more often, the barriers imposed by features of the person's world that aggravate the incapacity or otherwise restrict the person's freedom to achieve his or her life plans. When both the impairment and the social environment contribute to the disadvantage, justice requires both impairment-relevant resources and public policy and social action to remove the environmental obstacles. Justice requires, in short, equalization of capabilities.

Achieving justice in this sense would not be without practical difficulties. Even if we agreed on what capabilities were critical and what level of each capability had to be reached—matters on which Sen is deliberately silent—it would not be an easy matter to identify all the barriers to achieving them or ascertaining what would effectively remove or circumvent them. Yet we are now in the territory of public policy, where these practical issues are at least well-known. There are, moreover, several potential policy tools that can be brought to bear: cash by way of compensation or income maintenance; tax adjustments; in-kind services; provision of employment and educational opportunities; provision of assistive technology and other impairment-relevant resources; antidiscrimination law to address specific abuses; mandated, publicly funded accommodations for work, school, and home; and public education to remove stigma and stereotyping. There are legal models for each of these strategies in most developed countries.

But once one moves to this practical level, some troubling features of Sen's approach come into view. Does justice require equality of capability across the board, and for everyone? Does every measurable decrement of capability entitle one to resources in the name of justice, or is there a minimal core of capabilities relevant to justice? If so, what is this core, and must it be the same for everyone? These are huge questions. Even if we could agree on the core, it is extremely unlikely that anyone, across a lifespan, would possess complete capability in all its domains. Impairments are ubiquitous across the population; almost everyone develops joint aches, muscle fatigue, and diminished vision, hearing, and memory as they age. Each of these impaired functionings, in unaccommodating settings, may limit some core capability. If we think it absurd that everyone should qualify for disability benefits, how do we set the thresholds? How much inequality in capability can we tolerate?

Some of these questions have been addressed in a forthright—if not always satisfactory—way, by Martha Nussbaum, who is specific and concrete, where Sen is vague and schematic, about the capabilities required for humanity and human flourishing. She has come up with a list of 10 capabilities that a just society must ensure its members achieve, at least to a minimal degree. Over the years, her description of these capabilities has become more general, in part because the more narrowly framed they are, the more categorically they are precluded by specific impairments. Thus, Nussbaum has gone from making “the exercise of the five senses” a requirement of humanity—which would deny the blind and deaf the status of human beings—to making it a condition of human flourishing—which would deny that the blind or deaf can flourish—to broadening the capability to encompass rich sensory experience from any combination of sensory modalities—which makes human flourishing available to the blind and deaf and imposes the obligation on a just society to ensure that they achieve it.

Yet every society will contain individuals whose impairments make the achievement of one or more core capabilities, however broadly framed, a practical impossibility. As Nussbaum recognizes, many severely retarded individuals, or individuals in permanent comas or persistent vegetative states, simply cannot fashion their own conception of the good life, no matter how intensive the support they receive from society. Nussbaum does not regard a society as unjust for failing such individuals; rather, she regards their incapacity as “tragic.”

This survey of how disability figures in some prominent theories of distributive justice indicates the beginnings of a more serious attempt to come to terms with disability, without identifying it with impairments or treating it exclusively as a matter of health. Increasingly, philosophers are becoming aware of the more robust models of disability and their effect on traditional arguments about the demands of justice. Yet there remain difficult and practically significant issues arising out of the interaction between justice and disability with which future theories will need to deal.

CHALLENGES TO DISTRIBUTIVE JUSTICE THEORIES

Accounts of distributive justice are a target of disability critics who see them as inherently demeaning. This change is apt for contractarian theories that exclude people with disabilities from the bargaining table altogether because of their presumed low productively or lack of capacity to form a conception of the good life. We need not consider this critique further. But disability scholars have also criticized theories that are not contractarian and aim directly at equality, variously conceived. Equality theories are also seen as demeaning insofar as they treat disabilities as individual deficits that require special resources to achieve equality, rather than disadvantages resulting from unjust social arrangements. This critique raises more serious doubts about distributive approaches, even those that pay lip service to the interactive character of disability. Can distributive justice theory adequately accommodate the radical changes in attitudes, practices, and environment that justice truly requires?

The disability critique tends to favor more procedural or relational approaches, which identify stigmatization, exclusion, and oppression as the primary sources of injustice and insist on policies aimed directly at those evils. This critique has also inspired some mainstream political philosophers to develop hybrid approaches, which acknowledge the diagnosis offered by the critique but propose a constrained distributive treatment for the underlying injustice. The specific challenges of the disability critique require separate treatment.

Social Basis for the Disadvantages of Disability

The first challenge has been mentioned several times already: Philosophers writing on justice from a roughly egalitarian basis often assume that impairments intrinsically, and dramatically, reduce subjective or objective well-being by limiting basic activities such as walking, seeing, communicating, activities essential to most life plans. The problem posed by disability, as a result, has been to find "special measures" to compensate for functional deficit, whether by Dworkin's hypothetical insurance, Daniels's unlimited resource transfer to restore normal functioning, or Sen's equalization of capability. Philosophers writing from the disability perspective, such as Anita Silvers, argue that this obsessive concern with the comparative well-being of people with disabilities is not only demeaning—since it tends to view people with impairments as defective rather than neglected—but that it also ignores the sources of inequality faced by people with disabilities, namely, the disadvantages caused by unaccommodating, stigmatizing, and discriminatory social arrangements.

Although this critique has considerable merit, it is unlikely that it goes to the heart of the overall project of "patterned" distributive justice—to identify some arrangement of welfare, resources, opportunities, or whatever that can serve as the goal of redistributive policies. On the face of it, one need only identify the full range, and sources, of social disadvantage and adjust interventions appropriately to address the range of disadvantage the theory mandates must be reduced or eliminated. As we have seen in examining the capabilities approach, a clearer appreciation of the complexity of disability will also assist in theorizing about what is often called the "currency of equality," namely, what it is that egalitarian theories of justice seek to equalize.

Distributive Justice and the Goals of Accommodation and Accessibility

As noted above, there is no theoretical barrier to a theory of distributive justice based on an interactive model of disability, one that treats the individual's social environment as responsible for the disadvantages associated with impairments. Such a theory would challenge the assumption that impairments invariably, or in isolation, lower well-being, create inexhaustible needs, or severely restrict the range of available life plans. Yet the question remains whether the current crop of distributive theories can fully incorporate the social goals of accommodation and environmental modification for accessibility. The problem is that most theories share an assumption that has historically held an iron grip on disability policy, namely, that it is always cheaper, more efficient, and publicly acceptable to provide resources to individuals than to modify the physical or social environment in which they live.

The assumption ignores the fact that privileging the "standard environment" in this way means that disability policy will always be piecemeal and ad hoc, a "special needs" policy that confirms the prejudice that people with disabilities are inferior and cannot make it in the "real world." On the other hand, however, opening up the range of interventions for distributive justice to include changes to the environment is not without theoretical and practical difficulty. First, the standard physical, social, and attitudinal environment is disadvantageous to many people in society other than those with impairments. People who are poor cannot take advantage of financial opportunities or savings that are readily available to the rich; people who do not speak the official languages of a country share with sign language users the need for translation for public communication; and children of marginalized minorities, in common with children with cognitive impairments, may require substantial accommodations to benefit from education. Second, accommodations and environmental modifications must be individualized to be useful, but changes that accommodate people with one type of impairment may be useless or worse for those with other impairments or for the unimpaired population. Finally, for these and more general reasons of cost, convenience, and efficiency, there will inevitably be trade-offs, between individuals and groups, and between areas of social participation—employment versus education, access to shopping centers versus access to public buildings or houses of worship. These trade-offs need to be resolved, but it is unclear how to do so.

Although there are large issues, it is encouraging that they are paradigmatic problems of distributive justice rather than fundamental challenges to the project itself. And indeed, some headway has been made. The theoretical underpinnings of universal design, for example, directly address all three problems. Universal design in architecture and product design insists that buildings, public spaces, and products should be designed to be usable by people with the widest possible range of functional capacities as possible. Maximally inclusive design reduces the need for difficult trade-offs among groups and individuals; by eliminating the need for retrofitting and modifying a standard building or product, such design both responds to concerns about social cost and avoids the appearance that people with impairments are being given special privileges or unfair priority over other disadvantaged groups. Much more work needs to be done, but the notion of distributive justice may not be robust enough to encompass all issues of accommodation. Yet it needs to succeed, because an approach to justice focusing exclusively on disrespect, discrimination, and disparities in power will be unavoidably incomplete.

Antidiscrimination Protection Is Enough to Secure Justice

A more comprehensive challenge, reinforced by skepticism about the adequacy of distributive approaches, is posed by so-called relational theories of justice, such as Iris Young's, which focus not on distributional outcomes but on the unjust social relationships of oppression, domination, and hierarchy. The initial appeal of relational theories for disability is that they tend to highlight precisely the same kinds of oppressive attitudes, practices, and social arrangements that lie behind what the disability rights movement has identified as the basis for social injustice, discrimination. Thus, the much admired ADA, while applying only to those with actual or perceived physical and mental impairments, clearly locates injustice in stigma and the related attitudes of devaluation that suffuse social practice. For many disability advocates, the dynamics of discrimination are all that one needs to know to understand justice in the context of disability. Pattern-based distributional theories are, therefore, of little interest.

Although the debate is far from over, a growing consensus suggests that while antidiscrimination laws and policies, fully and competently enforced, do address the core evil in the treatment of people with disabilities, as a social policy for disability, these tools—and the background relational theory of justice—are radically incomplete. In structure, relational theories of justice adopt the core assumption of the procedural approach mentioned above, namely, that as long as the laws, social practices, and institutions are fair, whatever distributional outcomes that result, even if profoundly unequal, are just. In the case of disability, this means that if we could imagine a society in which all forms of prejudice, stigma, misunderstanding, and stereotyping of impairment were absent, where oppression, domination, and exploitation were no longer in evidence, social arrangements would be completely just with respect to people with disabilities, even if the current enormous gaps between able-bodied and disabled citizens in educational achievement, income, and employment remained, or even worsened.

But, it might be asked, if oppression and domination disappear, how could inequality remain? This could happen because an enforceable injunction against discrimination does not tell us what resources are required to meet impairment needs, or how we can alter the physical and social environment to accommodate the functional limitations of impairments, or what measures are required to make the social world more accessible.

To answer those central issues of disability policy, not only do we need to identify and measure the direct effects of impairments themselves (which will remain even if socially created disadvantage is eliminated), but, more vitally, since we do not have infinite resources, we need a standard for assessing the priority of the goals of access and accommodation. This implies our ability to decide what kind of equality we are aiming toward, or what kinds of inequality we are seeking to reduce. But these are not easy issues. Should we provide resources and make social changes to the point where everyone has "equal opportunity" in one of its myriad senses; or to the point where all burdens and benefits are equalized; or to the point where all citizens are equally satisfied with their lives? These are radically different standards. Having eliminated oppression and discrimination, we will of course be committed to, for example, redesigning our educational systems and structuring jobs so as to accommodate people with limited cognitive functioning. But how do we do that? Unfortunately, the purely antidiscrimination approach gives us no guidance.

Only a theory of distributive justice can provide a sense of the practical objectives our commitment to justice demands of us.

Disability Justice, Prioritarism, and Democratic Equality

Although the antidiscrimination approach has limitations as a theory of justice, it has played an important role in refining distributive accounts. Criticism of those accounts by disability scholars has converged with, and increasingly reinforced, challenges from mainstream philosophers about two features of egalitarian accounts: (1) their acceptance of equality as the objective, although it is not attainable on almost any metric and its single-minded pursuit may compel perverse results, such as "leveling down" the better-off to reduce inequality; and (2) their adoption of comprehensive notions of well-being, which concern all or most aspects of a person's life.

Rawls's own theory was neither strictly egalitarian nor concerned with equality in any comprehensive sense. While it required equal liberty for citizens, it accepted inequalities in "social primary goods" as long as they benefited the worst-off members of society. And his list of primary goods, ranging from income and wealth to the social bases of self-respect, was intended to include assets valuable on any reasonable conception of the good, not to serve as proxies for a particular comprehensive conception. But many influential political philosophers following Rawls, such as G. A. Cohen and Dworkin, have offered accounts that are both more egalitarian and more comprehensive than that of Rawls.

In recent years, other philosophers have voiced discomfort with one or both of these features. Some, such as Derek Parfit, have pointed out that a single-minded policy of equalizing well-being—which might well involve a dramatic leveling-down to an unacceptable, but equal, minimum—ignores the moral concern for people's absolute levels of well-being. Parfit argues for giving priority to the worst off in society, rather than trying to achieve an across-the-board reduction in inequality. "Prioritarian" accounts have problems of their own (how to characterize "the worst off'"), but they represent a more general concern about theories of "comprehensive equality" that ask too much of society and seek outcomes that are either impossible or contrary to other important values.

Thus, Richard Norman has rejected comprehensive egalitarian distribution on the commonsense ground that people are unequal in countless ways, not all of which should, or even could, be remedied. Antiegalitarians may have a point when they argue that seeking equality in the face of human diversity is at best Sisyphean, at worse unimaginably oppressive. Some people are incurably shy, others form relationships easily but destroy them just as fast; others strike a balance between these extremes. Even if we could somehow redistribute emotional sensitivity (or compensate the shy or emotionally volatile), would that be a proper role for a just society? Norman thinks for these inequalities we should just say, "That's life," although they lead to inequalities in well-being. Of course, the same may be, and has been, said of impairments.

But if egalitarianism cannot sensibly require the elimination of all inequalities and disparities, what does it require? One proposal is that justice requires the achievement of "democratic equality," that is, that society should eliminate all and only those disparities in well-being that threaten to undermine basic social or political roles in status and participation. Amy Gutmann (1987), for example, has argued in the context of education that principles of democracy implicitly create a democratic distribution threshold: "sufficient resources to education to provide all children with an ability adequate to participate in the democratic process" (p. 136). This threshold is measured in part by the objective of preventing unjust relationships created when some are excluded from political processes that affect all, and in part by an appraisal of what skills and abilities are required for political participation. The threshold, significantly, does not require equality of skill and ability, only the minimum necessary for political participation. The goal is not to "level down" to the threshold, but to guarantee it for all, including children with impairments, while at the same time providing some additional resources for children with the natural abilities to exceed the threshold.

Recently, Elizabeth Anderson has proposed a similar but more general threshold of democratic equality.

Drawing from both the "patterned" and procedural approaches to distributive justice, Anderson argues that the inequality that is truly unjust is that of a hierarchy of social rankings purporting to reflect intrinsic worth (which, in turn, invariably generates inequalities in the distribution of freedom, resources, and welfare). Following Sen, Anderson argues that eliminating the social hierarchy requires redistribution of those capabilities that people require to avoid, or escape, entanglement in oppressive social relationship. Alternatively, justice requires that everyone possess the capabilities necessary for functioning as equal citizens in a democratic society. These are the capabilities required to participate in the activities of civil society, and at bare minimum, those needed to function as a human being: "effective access to the means of sustaining one's biological existence—food, clothing, medical care—and access to the basic conditions of human agency—knowledge of one's circumstances and options, the ability to deliberate about means and ends" (Anderson 1999:317–318).

With respect to disability, Anderson argues that democratic equality demands that people with disability have "good enough access to public accommodations that they can function as equals in civil society." She makes it clear that "good enough" does not require strict equality of resources (or equality of satisfaction or subjective utility), nor does democratic equality require the elimination of disparities in happiness, pleasure, or resources that are not explicitly required for equal citizenship. On the other hand, achieving (more than perfunctory, but truly) effective access to medical care (one of the preconditions for functioning as a human being) is unachievable in even the most resource-rich society. And if equal citizenship requires freedom from pain or debility, then Anderson's goal is utterly unreachable. Similar points can be made about the "basic conditions of human agency": We could spend an indefinite amount on education, training, and support for people with cognitive disabilities without achieving deliberative competence.

The problem appears to be that, motivated by the perversity of leveling down to achieve welfare, resource, or even capability equality, Anderson sets the bar at "sufficient for equal citizenship," which, in practical terms, is either too vague to be useful or utterly unachievable. Ironically, Anderson is equally open to the objection that "equal citizenship" sets the threshold too low, since it is compatible with a joyless and barren life, and too high, because the capability preconditions make a huge demand on social resources. Nonetheless, as Richard Arneson has argued, democratic equality is useful as a rough proxy for well-being, which remains a contentious notion. As is usual in philosophical theorizing, some compromise has to be found between an account of well-being that is complete enough to be intuitively plausible and one that is concrete enough to guide the evaluation, and reform, of actual societies.

CONCLUSION

There is an intriguing symmetry in the challenges facing distributive and relational accounts of justice as they apply to disability. Distributive accounts must recognize the centrality to justice of equal social and political participation, and develop metrics of individual well-being in which the capacity and opportunity for such participation figure prominently. Relational accounts, in turn, must make the notions of nondiscrimination and nonoppression sufficiently determinate to guide the reconstruction of the physical and social environment. Hybrid approaches such as Anderson's—which require that all citizens be brought up to a minimum standard for democratic participation, not to any comprehensive equality—raise hopes for a convergence between extended conceptions of distributive justice and structural accounts of discrimination and oppression.

Those hopes, however, may be illusory. Justice, as Michael Walzer, David Miller, and others argue, may be irreducibly plural. Although both distributive and relational accounts of justice appear to be guided by a principle of equal concern and respect, the former emphasize concern, the latter, respect. The two kinds of accounts focus on inequalities that, however closely correlated, may be morally distinct. The failure to take adequate account of atypical functioning in the design of the physical and social environment may be a fundamentally different kind of wrong than the treatment of people with atypical functions as inferior beings. These wrongs may require different remedies:

the former, redistribution; the latter, recognition. Perhaps, then, a single theory of justice cannot do justice to both aspects of impairments, as sources of functional limitation and as stigmatized differences. We may require both distributive and relational accounts to guide disability policy. But even if the attempt to integrate the two in a democratic threshold account cannot succeed, it provides valuable insight into the kinds of revisions we need to make in both.

K

▣ KALLIKAK, DEBORAH (1889–1978)

American subject of eugenics research

In his widely read eugenic study of 1912, *The Kallikak Family,* Henry H. Goddard introduced Deborah Kallikak as a quintessential example of "defective" heredity. At the age of eight, Deborah entered the Vineland (New Jersey) Training School after troublesome behavior marked her as potentially "feeble-minded." As Goddard and his fieldworkers gathered information on her familial background to assess the possibility of "hereditary taint," she became scientifically valuable for her relationship to a large and extended family "notorious for the number of defectives and delinquents it had produced" (Goddard 1912:16). Goddard invented the surname Kallikak from the Greek words for beauty (*kallos*) and bad (*kakos*) to indicate that the distant progenitor had produced both a *good* line and a *bad* line of descendants. In effect, Goddard's study scientifically designated Deborah, her living relatives, and her ancestors on the "bad" line as human *evidence* of the hereditary nature of feeblemindedness.

At the time of Goddard's writing, Deborah was 22 years old, but Binet tests charted her mental age at 9. Her accomplishments, however, make this diagnosis troubling. Deborah loved music, writing stories, gardening, and caring for children, but her inability to understand numbers and money, lack of abstract thought, and stubbornness convinced Goddard she was feebleminded. The most biased aspect of his diagnosis was the presumption she would lead a "vicious, immoral, and criminal" life outside an institution (Goddard 1912:12). Goddard used Deborah to exemplify the dangerous "borderline" types he designated as "morons," highly functioning but "defective" individuals who, if not properly identified and confined, threatened society with the inevitable result of producing more of their kind. Deborah died in 1978; she lived 81 of her 89 years in an institution.

▣ KANNER, LEO (1894–1981)

Austrian-American psychiatrist

Leo Kanner was one of the most influential American clinical psychiatrists of the twentieth century. He has been referred to as the "father of child psychiatry" in the United States, and his textbook *Child Psychiatry,* first published in 1935, remained a standard reference work for 50 years. Kanner is perhaps best known for his description of "early infantile autism" in 1943 as a distinct clinical syndrome. Based on his observation of 39 children with similar behavior, Kanner described a common profile whereby the children did not relate "in the ordinary way" to people or situations. Instead, Kanner (1943) described a child whose "behavior is governed by an anxiously obsessive desire for the maintenance of sameness that nobody but the child himself may disrupt on rare occasions" (p. 243). Although he was to repudiate the term (and the theory behind it) by the 1970s, Kanner also coined the term "refrigerator mother" to describe the supposed emotional frigidity of parents that he thought caused, or at least contributed to, their children's autistic behavior.

Kanner was born in Klekotow, Austria, in 1894, and received his medical degree from the University of Berlin in 1921. He moved to the United States in 1924, and from 1930 until his retirement in 1959 was on the faculty of the Johns Hopkins Medical School. Even after his retirement, Kanner remained professionally active as a visiting professor at numerous universities and maintained a clinical practice until shortly before his death in 1981 at the age of 86.

KATADA IBN DI`AMA AS-SADUSI (CA. 679/680–735/736)

Arab scholar

Katada ibn Di`ama as-Sadusi was blind from birth and had Bedouin origins. He became a learned man of the highest reputation at Basra, Iraq. Katada's renowned memory and recall led to his being often consulted on matters of history, genealogy, poetry, and Qur'anic interpretation by both rulers and scholars of his time. Evidently he prized his independence and developed a strong awareness of space and direction; it was recorded that he "used to go from one end of Basra to the other without a guide" (*Ibn Khallikan's Biographical Dictionary* 1842–1871).

KATAKORI

Katakori or *katakori kô* is a condition peculiar to Japan; the name of this condition is somewhat difficult to translate into English, but it comes closes to "pain in the neck." It corresponds generally to a combination of stiffness, tension, or pain in the neck and shoulders. Its etiology is often associated with reduced blood flow to muscle tissue. Some have suggested that it is a physical symptom that allows for medical care in the setting of Japanese stigma against psychological pain. Treatment ranges from anti-inflammatory medications to transcutaneous electrical nerve stimulation (TENS) to acupuncture.

While its history is suggestive of many comparative elements, modern medical researchers have used the status of *katakori* as a cultural-bounded syndrome to identify it and other somatic complaints as markers of depression in Japanese in cross-cultural studies. In popular culture, perhaps not unlike conditions such as anorexia, one can find reflexive affinity for *katakori,* suggested by T-shirts saying, "I ♥ *katakori.*"

KELLER, HELEN (1880–1968)

American author and lecturer

Helen Keller was born in Tuscumbia, Alabama, on June 27, 1880. At the age of 19 months, she contracted an illness, either scarlet fever or meningitis, that left her totally deaf and blind. In 1887, Anne Sullivan, a recent graduate of the Perkins Institution for the Blind in Boston, joined the Keller household as Helen's teacher. Keller learned to communicate using the manual alphabet for the Deaf. She graduated cum laude from Radcliffe College in 1904. She published nearly a dozen books as well as numerous articles, essays, tracts, and poems. Her work was primarily autobiographical, but she also wrote on such subjects as women's suffrage, women's health issues, the labor movement, and religion. She traveled widely, in the United States and throughout the world, as a lecturer and spokesperson for the American Foundation for the Blind, which she helped to found in the 1920s. She also toured on the vaudeville circuit for two seasons and appeared in several film documentaries on her life. She died at her home in Westport, Connecticut, on June 1, 1968.

For many, Helen Keller's story is the quintessential overcoming narrative. Through the sheer force of will and the self-sacrifice of her devoted teacher, she overcame her disability and serves as an inspiring symbol of the resilience of the human spirit. For this reason, her image appears on the state quarter of Alabama. By contrast, many in the disabled community, both during Keller's lifetime and today, have criticized her for the way she remained aloof from other disability organizations and causes. She angered many in the Deaf community by following the lead of her mentor, Alexander Graham Bell, and supporting auralism rather than Sign. More recently, disability studies scholars have begun to reexamine her life and work in an attempt to separate the myth from reality and gain a better understanding of her legacy.

KENNY, SISTER ELIZABETH (1880–1952)

Australian nurse

Sister Elizabeth Kenny, a feisty, opinionated, largely self-educated bush nurse, enraged the Australian medical establishment with her pioneering treatments that significantly alleviated the effects of polio. Her methods, which she developed over several years of treating children with polio and cerebral palsy in Queensland, consisted of hot baths, foments, and mobilization of paralyzed limbs with passive movements to reeducate affected muscles. She passionately asserted that the traditional procedures of splinting and bracing immobilized limbs in metal and plaster casts caused major deformities and were tantamount to torture.

Damned by no less than a royal commission of the Queensland medical fraternity, in 1940 Kenny took her treatments first to the Mayo Clinic in Minnesota and later established the Elizabeth Kenny Training Institute in Minneapolis. Gradually her work gained acceptance and she gained fame and honor throughout the United States, where she resided for 11 years.

Kenny's legacy to the disability community extended far beyond her lifetime and is evident in medical rehabilitation therapies practiced today throughout the world. People with a range of neurological conditions involving some form of paralysis, including spinal cord and head injury, multiple sclerosis, stroke, and cerebral palsy, are indebted to Kenny's vision, common sense, and conviction. Sadly, she is a largely forgotten figure in Australia, but she is still widely revered in the United States.

KERLIN, ISAAC NEWTON

(1834–1893)

American institution administrator

From 1863 until the time of his death in 1893, Isaac Newton Kerlin was the superintendent of the Pennsylvania Training School for Feebleminded Children (better known as the Elwyn Institute), located outside of Philadelphia. Kerlin himself became one of the leaders of the first generation of superintendents for the so-called idiot asylums that were emerging in post–Civil War America. In 1876, in an effort to gain professional status equal to that of the more established leaders of the older insane asylums, Kerlin invited five other fellow superintendents and the prominent educator Edouard Séguin to join him in Philadelphia to found the Association of Medical Officers of American Institutions for Idiotic and Feeble-Minded Persons (now known as the American Association on Mental Retardation). Kerlin would serve as the secretary-treasurer of this organization for the next 16 years, actively publishing and disseminating the proceedings of the group's annual meetings. With the deaths of Samuel Howe in 1876 and Edouard Séguin in 1880, Kerlin arguably became the most prominent national expert in the treatment and institutionalization of the feebleminded population and remained so until his death in 1893.

Throughout his career, Kerlin was an aggressive proponent of institutionalization of individuals with intellectual disabilities. He was earlier than many of his colleagues in abandoning the educational optimism that with skilled treatment most feebleminded children could be cured or significantly improved. Even his descriptions of "moral idiocy" (or, in later terms, "moral imbecility" or "juvenile insanity") endorsed the notion of hereditary incurability and the need for custodial institutionalization for those with normal intelligence but a defective "moral sense."

KESSLER, HENRY HOWARD

(1896–1978)

American physician

Henry Howard Kessler, a pioneer in the development of comprehensive rehabilitative services for people with physical disabilities, was born in Newark, New Jersey, on April 10, 1896. A 1919 graduate of Cornell University Medical School, Kessler earned a doctorate in social legislation from Columbia University in 1934. Inspired by Dr. Fred H. Albee, an orthopedic surgeon who practiced during World War I, Kessler became a well-recognized orthopedic surgeon, medical administrator, and international advocate for people with disabilities. He is recognized as the developer of the surgical technique of cineplasty for control of artificial arms, as for the pneumatic-operated prosthetic arm.

During his 12-year career in the U.S. Navy, Kessler served as a captain from 1941 to 1945. He was director of the New Jersey Rehabilitation Commission from 1921 to 1941. He founded the nonprofit, nonsectarian Kessler Institute for Rehabilitation in West Orange, New Jersey, in 1949 and served as its director until his death on January 18, 1978, at age 81. He considered the institute, which has long served as a model for centers for physical rehabilitation, his greatest achievement.

Kessler provided consultative services to Newark Beth Israel and Newark City Hospitals and the Federal Office of Vocational Rehabilitation of the Veterans Administration. He also directed the Rehabilitation Unit at Christ Hospital in Jersey City, New Jersey, and was clinical professor at New York Medical College.

He became internationally known for his work as a delegate to the International Congresses of Industrial Accidents and Diseases and as a consultant to the United Nations. Among his many citations and honorary degrees, most noteworthy are the Albert Lasker Award (1954) and the first President's (Truman) Award of the Committee on Employment of the Physically Handicapped (1952). His many publications include *Accidental Injuries* (1931), *Cineplasty* (1947), *Rehabilitation of the Physically Handicapped* (1947), *The Principles and Practices of Physical Rehabilitation* (1950), *Low Back Pain in Industry* (1955), *Peter Stuyvesant and His New York* (1959), and *The Knife Is Not Enough* (1968).

▣ KHALIL, AL- (CA. 710–787)

Arab scholar and teacher

Al-Khalil ibn Ahmad was a famous grammarian, prosodist, and teacher at Basra, Iraq. His son was impaired in intellect, and Al-Khalil was one of the earliest parents to record some thoughts about this issue. Once, hearing his father scanning a verse by the rules of prosody that he had invented, this lad ran out and told people his father had gone mad. Al-Khalil treated him in a kindly way and exercised patience toward other students who learned slowly or not at all. The learned scholar asked one such student to scan the verse, "If you cannot accomplish a thing, leave it and pass to another which you can accomplish." To his surprise, the student understood the politely coded message and gave up his fruitless studies. Al-Khalil reportedly lived as an impoverished scholar, with mind focused on higher things. He died after crashing into a pillar at the mosque, which he had not noticed as he was thinking about a problem.

▣ KHUJJUTTARA

Khujjuttara was the hunchbacked maid of Queen Samavati in ancient India. Converted under the Buddha's teaching, she immediately gave up her practice of stealing the queen's money. As Khujjuttara admitted her earlier thefts to the queen and explained why she had changed her behavior, she was asked to preach to 500 lady courtiers and soon attained a preeminent position as a religious teacher. This unprecedented rise from deformed female servant to teacher of the Law was endorsed by the Buddha. Khujjuttara's life is recorded to illustrate karmic retribution in the morally educational sense. In an earlier birth she had mocked a deformed holy man at Benares, and so earned a "corrective" rebirth as a hunchback herself, so that the progress of her soul should not be impeded by wrong thinking and behavior. Elsewhere, Khujjuttara played a substantial comedy role in one of the Buddha's lives, Kusa Jataka. There she took advantage of her position as royal nanny, locking up her mistress, Pabhavati, and generally throwing her weight around. She was named as Khujjuttara at the close of that story, where the Buddha identified various well-known characters.

KIRKBRIDE, THOMAS S. (1809–1883)

American psychiatrist

Thomas Story Kirkbride was perhaps the most prominent American psychiatrist (or "alienist," as psychiatrists were also called) of the mid-nineteenth century. He is best known as the creator of the "Kirkbride Plan" elaborated in his influential work on asylum design and construction, *On the Construction and Organization of Hospitals for the Insane,* published in 1854. Kirkbride was the first superintendent of the Pennsylvania Hospital for the Insane in Philadelphia, a position he held from its opening in 1841 until his death more than 40 years later in 1883. It was at Kirkbride's invitation that he and 12 of his fellow insane asylum superintendents gathered in Philadelphia in 1844 to found the organization that is now known as the American Psychiatric Association. Kirkbride's famous plan for asylum design and operation called for a linear blueprint with wings added on to a main central building. The plan also called for strict size limitations of no more than 250 residents (a principle honored mainly in the breach), with an ample, open campus surrounded by a large wall. As was the case among his early colleagues (e.g., Isaac Ray, Pliny Earle, Amariah Brigham), Kirkbride's encouragement of congregate care for the insane grew from a strong belief in the curability of the insane if they were given timely, appropriate, and therapeutic treatment.

KNOTT, MARGARET (1918–1978)

American physical therapist

Margaret Knott was born in Oxford, North Carolina, in 1918 and graduated from what is now Appalachian State University in Boone, North Carolina, with a major in physical education. In 1942, she entered Walter Reed Army Hospital to study physical therapy and, on completion of her studies in 1943, was commissioned a second lieutenant in the U.S. Army Medical Corps. After leaving the army, she became affiliated with the Kabat Kaiser Institutes (later the Kaiser Foundation Rehabilitation Center), where she gained her reputation as a physical therapist treating injured mine workers. Knott had a long collaboration with Dr. Herman Kabat as they developed the concepts and approach to patient care called proprioceptive neuromuscular facilitation (PNF), which emphasizes the exercise of muscles in specific movement patterns. The first edition of her book *Proprioceptive Neuromuscular Facilitation: Patterns and Techniques,* was published in 1956. "Maggie" spent most of her professional life in Vallejo, California, where she was a magnet for physical therapists from many nations who came to study with her. She also traveled and lectured the world over.

KŌTŌ, KUZUHARA (1813–1882)

Japanese musician and designer

Kuzuhara Kōtō lost his sight in early childhood. He studied under Kengyō Matsuno at Kyoto and became a renowned regional performer on the *koto* (Japanese zither). He had unusual spatial sense and dexterity, being credited with original designs in origami (the art of folding paper to produce decorative shapes) and living in a house that he himself designed in the city of Kannabe. In later life he made wooden printing blocks of a tactile nature for his own use, and with them he kept a personal diary for more than 30 years. The printing tools and diary are noted in Kannabe as important cultural property that is preserved for posterity.

KRAEPELIN, EMIL (1856–1926)

German professor of psychiatry

Emil Kraepelin, considered to be the founder of modern clinical psychiatry, was born in Neustrelitz, Germany, in 1856 and died in Munich in 1926. He taught in Dorpat from 1886 to 1891, in Heidelberg from 1891 to 1903, and in Munich from 1903 to 1922. His widely distributed textbook on nosology, *Compendium of Psychiatry,* published between 1883 and 1927 in a total of nine revised editions, made the symptomatic diagnosis of clearly delineated illnesses possible.

Even today's classification system, the World Health Organization's International Classification of Diseases, emerged out of the Kraepelin system. Psychiatric illness has, according to Kraepelin, a clear somatic cause; with this thesis, he relied on a psychophysiological parallelism. He did not consider psychosocial reasons, and this made him a proponent of natural scientifically oriented psychiatric doctrine. Consequently, he also subscribed to the popular theory of "degeneration." This was evident in his forensic publications.

Throughout his life, Kraepelin had a pronounced interest in clinical research. As a disciple of Wilhelm Wundt (1832–1920) in Leipzig, and with a focus on experimental psychology, he founded in 1917 the German Research Institute for Psychiatry in Munich. As a cofounder of psychopharmacology, he was influential through the end of the twentieth century.

KYŌGEN COMEDY

Kyōgen plays emerged in fourteenth-century Japan as brief comedies played between performances of the more serious Noh drama. The repertoire of Kyōgen (literal meaning, "crazy words") grew to about 250 plays recognized in later compilations. They were not standardized texts in the earlier ages. Players worked up outlines in different ways, then continued refining their acts. Disabled characters appeared in some Kyōgen plots, the audience being crudely entertained by their defects, stupidities, and abuse by the world. In Akutagawa, two travelers, each trying to hide his own impairment, gleefully expose each other's defects to mockery. In Kagami Otoko, the bumpkin's naïveté is comically revealed when a peddler sells him a mirror but is exceeded by his wife's imbecility when he presents the mirror to her. She fails to recognize the woman she sees in it, but realizes that her husband must have been dallying with this hussy. He flees before her wrath.

Better known are the Zatō Kyōgen, which are based on blind characters. More than a dozen plays fall into this group—Dachin, Dobu-katchiri, Hakuyō, Inu-hiki, Kawakami, Kikazu zatō, Kiyomizu zatō, Mari-ke zatō, Muma-kari, Nuno-kai, Saru zatō, Tarashi, Tsuki-mi zatō—but some are now obsolete. Among the best known is Tsuki-mi zatō, in which a blind man engages in the refined Japanese custom of viewing the full moon in a field. He is most appreciative of the delightful choir of insects, which he describes aloud. He is joined by a sighted moon viewer from an upper-class area. They engage in polite conversation and share some wine. Then they take their leave, thanking each other for the company. Each feels content, the blind man because he had a pleasant encounter, the sighted man because of his exercise in polite condescension. The audience then hears another thought striking the sighted man: He could exercise his talents further by sneaking back and picking a fight with the blind man, using a disguised voice. He promptly does so, bumping into the blind man, cursing the man's clumsiness, knocking him down, then running away. The irony is heightened as the blind man wails about the contrast between the nice man he met first and the hooligan who knocked him down.

This is the essential Kyōgen as now understood, crazy stuff carrying a sharp message within the slapstick, pinpointing the ambivalence of attitudes, contrasting polite hypocrisy with underlying cruelty. Yet it seems that the early Japanese Zatō Kyōgen portrayed frank ridicule of blind men who suffered farcical tricks to amuse the watchers without any irony. The plays have become more politically correct in recent centuries, with interpreters introducing moralizing elements. Parallels have been drawn with medieval European drama in which serious reenactments of religious and moral themes were relieved by comedy with satire and slapstick. A crude French farce such as the thirteenth-century *Le Garçon et l'aveugle,* about a blind man whose servant plays tricks on him, could readily be adapted to the original Zatō Kyōgen style.

LAME, THE

In the twenty-first century, the word *lame* is used primarily as slang for a poor attempt. It is rarely used anymore to refer to human gait. Perhaps this shift in vocabulary reflects the physical landscape of the twenty-first century, in which people with variant gait are increasingly rare as a result of medical technology and aesthetic norm. In contrast, "the lame" were an ordinary part of the ancient human landscape.

The image in the mind's eye of the ancient world is influenced by the legacy of the Renaissance and onward, when scholars and artists depicted perfect Graeco-Roman buildings draped with perfect Graeco-Roman bodies. In fact, any given public gathering place in the ancient world would have included people with a much greater variety of physical conditions than we see in the developed world today. Permanent "lameness" could be acquired at many different stages in one's life. Inadequate nutrition during pregnancy was a significant factor in the ancient world in terms of producing offspring with physical anomalies. Clubfoot is just one example of "lameness" that can be acquired in the womb. Because of the easy corrective procedure available today for this condition, we do not see many people with clubfoot in developed countries, but it was quite common in the ancient world; the Greek god Hephaestus (the Roman Vulcan) himself was portrayed with a condition that matches the description of clubfoot.

Children born without irregular gait could acquire it from a variety of circumstances later in life. The bones of children who are underfed do not have a chance to develop properly. Vitamin deficiencies, especially in combination with swaddling, likely led to such malformations as rickets. A simple accident, such as a fall, could have irreversible consequences for both children and adults in the ancient world. In the developed world, we take for granted that, with medical attention, even the most severe fracture will be undetectably repaired, and we assume that medical attention to a broken bone will result in perfect healing. In the ancient world, a visit from a doctor could have a range of possible results, as doctors' training was not standardized, licensed, or necessarily respected.

However an ancient doctor treated a bone injury, it was not the injured bone but rather the infection that might ensue that was responsible for extreme damage. The bone-injured person would be lucky if the bone simply healed crookedly, because every bone injury was also susceptible to infection. Untreated by antibiotics, an infection can spread throughout surrounding tissues and then the bone itself, attacking even the bone marrow. In addition to injury and infection, disease was responsible for permanent physical impairment, and epidemic diseases could leave whole groups of people with permanent physical handicaps.

Far from the embodiment of the golden mean, the ancient population included a wide variety of somatic configurations. There is no evidence that wheelchairs existed in any form, nor is there evidence that people may have propelled themselves in small carts. People with missing limbs or with other significant mobility impairments probably got around however they could, using crutches as necessary.

LANGE, DOROTHEA

(1895–1965)

American photographer

Dorothea Lange was born in Hoboken, New Jersey, in 1895. She contracted polio at age seven, which resulted in a weakened right lower leg and a visible limp. The changes in her body as a result of polio proved profound and shaped her personality and her later practice as a journalistic photographer. Her most recognized works involve pictures she took of impoverished migrant farmers during the Great Depression era in the United States. She claimed that her noticeable limp allowed her access to her subjects because it made her less threatening as a documenter of exploitation, poverty, and suffering. According to Lange: "I was physically disabled, and no one who hasn't lived the life of a semi-cripple knows how much that means. I think it perhaps was the most important thing that happened to me, and formed me, guided me, instructed me, helped me, and humiliated me" (quoted in Holland 1999). Lange paid a great deal of attention to feet in her work. During 1957, she produced more than a dozen photographs of her own disabled foot and leg.

LANGUAGE OF DISABILITY

In the new global disability universe, perhaps no more contentious debate exists than that surrounding language. Much abuse and harassment of disabled persons occurs as a matter of hate speech even as abusive acts can be covered over with euphemistic expressions and the benevolent rationalizations of professional discourse. Language study thus bears the onus of making visible the contours of disability experiences without erasing the realities behind rhetoric. Particularly since the Enlightenment (1700–1900), many philosophical efforts to explain "reason" as exemplary of what separates humans from animals derive from individuals' assessed competence with linguistic expression. In some frameworks, then, nonspeaking persons or those with communication-based disabilities may be negated as rational human beings out of an apparent lack of verbal fluency that is presumed to equate with an absence of value.

Disability historians sometimes remark that disability today constitutes a densely ramifying totality (see, e.g., Gerber 2000)—the phrase attempts to reckon with the fact that the term *disability* literally consists of conflicting investments among disciplines, sciences, and public cultures. In referencing disability in this manner, we can better understand the varied vocabulary and beliefs that inform our contemporary understanding of disability. This insight is worth picking up, given that so many professional and community interests intersect across the single figure of a disabled individual. Charity interests interpret pathos, pluckiness, tragedy, and deserving vulnerability in disabled persons. Educational interests see the difficult, special, unreachable, or uncontrollable "learner." Medicine approaches disability as a flaw to be conquered and as deviance to be overcome. Rehabilitation recognizes disability as a deficit in need of supplementation and concealment. Everywhere one finds terminology that selects the "cute ones" and conceals or gasps at the "gross ones." Thus, language becomes a barometer of the degree to which a culture openly grapples with the effort to accommodate all capacities or cater to a narrow range of abilities.

Insights from disability studies enter into this discussion in a reflexive manner, prompting us to pay closer attention to the language that filters our perspectives about human differences, particularly as a matter of grappling with the slippery metaphors and allegories that make body predicaments into emblems for cosmic, or simply social, dilemmas. Disability is rarely used to identify the realities of a life of difference—physical, cognitive, or cultural. A common, quite justifiable observation among disability scholars concerns well-placed discontent at having one's body image continually usurped into the expression of a universal motif. Economies are crippled, excuses are lame, a city council is blind to the consequences of some decision. Disability metaphors add combustion and intensity to commentary in any context; they take an expression of concern up a notch in the registers of rhetorical hyperbole. They up the ante on an atmospheric threat so that the strategic placement of a disability-based referent like *crippled* can lend a sentence the quality of an ominous threat. Horror, extremity, and tragedy are the emotions that these metaphoric equations seek—relying for their power on the premise that disability can parlay body differences into an equation with impending doom.

Because of this added punch supplied by the use of disability terminology, one crosscurrent in the field of disability poetics has been a determination to embrace the rhetorically charged references to crippled lives, akimbo limbs, lame figures of speech, cross-eyed stratagems, and limping gaits in poetic traditions. A privilege of being a practitioner of poetics, after all, is that one has permission to investigate language in all its permutations.

Disability poetics, then, assists in demonstrating that the historical language used to define, segregate, and confine people with disabilities is a rich but fraught area for research and interpretation. An encounter with this vast array of historical synonyms for physical, sensory, and cognitive "deviance" demonstrates that while we often seek a less dehumanizing vocabulary to reference disability, such a project proves difficult to achieve. In fact, the multiplicity of ways for referencing disabled lives suggests the degree to which comprehending disability constitutes a central social task in our own historical period. Even the widely accepted term *disability* denotes a form of euphemistic window dressing that cannot successfully exorcise the "barbarism" of previous terminology from which disabled people seek social redress.

Consequently, the battle over self-naming hits at the heart of language struggles themselves. Yet as one disability scholar argues in a discussion of the relationship of linguistic signs to the goals of political reform: "Rather than claiming or disclaiming any set of stigmata (or stigmatizing terminology), a successful poetics of disability would operate from a relentless skepticism of the motives and the truth-value of any sign (marks, names, labels, jargon). . . . Signs have no more an essential, autonomous existence than the categories they represent, and no sign can indelibly mark or irretrievably erase a meaning" (Jeffreys 1997:244). This "relentless skepticism" toward language fixes provides disability poetics with a more dynamic understanding of the politicized notion of language and helps to develop a less naive historical recognition that all terms become contaminated with the very ideas they seek to obliterate or refuse.

The need to develop a more protean sense of language surfaces as disability studies methodologies become increasingly prominent in academic circles. One witnesses numerous examples of critics and educators who refuse to include disability under current work on identity and minority experience. These arguments for exclusion seize on the "biological evidence" of disability as pathology in order to shore up disabled people's "real" difference from other *socially* disenfranchised groups. Within these arguments disabled people are refused a place at the table of social constructionism—they are deviant bodies, whereas other minorities have been unfairly cast as inferior. In such discussions disability poses as less of a linguistic product and more of a literal "flaw" in the mechanisms of living. In the midst of this refusal, medical labels are still assumed to offer up pure diagnostic definitions as opposed to social meanings. Within this rationale other marginal identities—such as gender, race, and sexuality—can be resignified as linguistically defined differences, but no amount of linguistic triage can put the disabled body back together again. Disability becomes a rent in the fabric of being itself rather than an adjudicator of social beliefs about biological differences.

There is a good deal of historical contingency to arguments about the celebratory nature of chosen identities such as blackness, femininity, and other culturally marginalized groupings. The capacity to embrace a historically devalued position takes generations of effort to effect, and one never absolutely arrives at the desired objective: a language free from stigma. Derogatory epithets such as *nigger, hysteric,* and *queer* still surface and, because of language's slippery properties, metamorphose into differently dehumanizing reference systems. They are the residue from historical associations of particular biologies with welfare, criminality, unproductivity, and inferior intelligence. While it proves difficult at some points in history to imagine that a group can effectively take up a despised identity as positive, such efforts are only mitigated by a repetitious history of linguistic dehumanization.

The embrace of formally derogatory language among disability groups is no different—efforts to make disability a matter of social identification rather than "flawed biology" afford an opportunity of semantic *choice* where received definition does not necessarily mean inevitability. While one cannot always choose to extricate oneself from a medicalized notion of abnormalcy projected from the outside, the "disability" rubric provides an opportunity to upend social expectations. The *choice* provided by self-designation flirts with the scandalous political potential of embracing the very identity that others believe to be inherently undesirable.

Counterdiscourse in disability studies sweeps up *crip,* for instance, into an embrace, just as gay, lesbian, and transgender studies came to flaunt *queer.* If one cannot drive away the insults of the playground, then one can take them up and repeat them as a matter of demonstrable fortitude. Such subcultural reclamations emphasize belongingness and chummy verbal communities. The counterdiscursive strategy performs one's place in language and thus exerts a modicum of control over the placement.

Depending on one's cultural location, the usage of *gimp* now results in poetic profit. For instance, the disability comedian Robert deFelice takes up the debasing terminology and turns it into a knowing affectation: "Gimp girls you have consulted with that man [the doctor] many times and look at you!" (in Snyder 1995). Such commentary suggests that strict obeisance to medical regimens of care may not prove helpful to those playfully identified as "gimpy." Likewise, the disabled performance artist Cheryl Marie Wade deploys *gnarly* and *crip* as terms of endearment for her various arts endeavors in Berkeley, California: Gnarly Bones and Wry Crip Productions. These efforts of ironic turnabout by disability performers set audiences into titillating hysteria as they adeptly expose the limits of professional definitions and linguistic assignments. Terms that seem to arrive as unalterably undesirable suddenly become points of community, camaraderie, and knowing mystery exchanged among the like-minded and like-embodied. These ruses of language reveal that labels function not as empirical descriptions of undesirable body types but rather as parameters that restrict meaning where it should be mobile. In the tongues of savvy disability commentators insulting terminology is speedily refashioned for impromptu moments of satirical reclaiming.

In the process of standing language on its head, these efforts not only set language on the run but, perhaps more important, begin to efface a lifetime of hurt for those who have borne the brunt of such abuse in school, in the doctor's office, and in the workplace. Recently a man successfully sued his employer on the basis of the fact that the metal plate in the man's head served as the opportunity for his fellow employees to call him "plate-head." The act of disarming harmful language in this manner ensures the retrieval of the individual's humanity in the face of daily language wars that would argue otherwise. It assists in exposing the violence that so often passes for "good fun" among those who take disability as a "self-evident" sign of an individual's dehumanization. Political correctness wars thus often reference disability in discussion of the ludicrous extremes to which our society will go to deny the obvious; yet, in doing so, these arguments seek to deny the degree to which the language we use shapes perceptions of those who are referenced by such terminology.

Many of today's language pundits spend time ruing the arrival of the "gerrymandering tendencies of linguistic reform movements" by using disability as the absurd example par excellence (Dutton 1996:551). As one prominent commentator argues: "Sooner or later the schoolyard finds out, and *retard* becomes the coinage of value. Everyone ought to deplore the abuse, but it is a delusion to suppose that we alter medical facts by dispensing new names, for *it is the medical condition that is the problem, not the words that describe it"* (Dutton 1996:559). Rather than deny that some persons embody a socially despised biology, the objective of disability studies, disability poetics, and the disability rights movements is to demonstrate that language debases some biologies in order to produce an environment of privilege in the cases of gender, race, sexuality, and ability. Analyses of language usage, consequently, set our sights on the contexts within which some biologies benefit at the expense of others. The object of such efforts is not to deny human difficulties, but rather to critique the idea that the complexity of any lived experience can somehow be confined to the determinism of a pathologizing medical label.

Hence the arrival of one of the more controversial issues in the history of disability language formation: person-first vocabulary. During the 1970s and 1980s, a movement of disability activists forged a social agenda in part around insistence on the phrase *persons with disability* rather than *the handicapped, cripples,* or *disabled person*—labels that were all treated as if they further consigned someone to a nonstandard, unjust future. Within such a linguistic formulation, *disability* would be backloaded as a mere adjective to the personhood of the individual described. In doing so, those who participated in such linguistic adjudications argued that disability would be an aspect of our lives but not an all-encompassing defining feature. In response, others in the same movement argued that placing *disability* last in the chain would amount to a form of denial tantamount to other euphemistic usages such as *physically challenged, special,* and *handicapper.* According to this perspective, *disabled person* is at least as acceptable as *person with disability* in that it overtly claims disability as a point of meaningful difference. Stigma is best combated, argued this language contingent, through an overt embrace of the characteristics directly affecting our lives. In formulating such discussions over appropriate terminology, disabled persons recognized language as one front in the battle for civil rights—it is not merely an adjunct or tangential issue of politically correct language policing.

In this debate, expertise once established by jargon-ridden labels developed by medical, social work, and rehabilitation professionals was challenged and, in some cases, completely overturned. Disability groups made direct claims for the necessity of developing vocabularies that meaningfully grapple with the etiologies and implications of bodily and emotional experiences that differ (or are perceived to differ) from the majority. Whereas "severe" medical vocabularies aspire to neutral description that drives out the last vestiges of freak-show provocations, disabled people deplored the objectification of their bodies that whittled them down to "conditions." Just as late-nineteenth- and early-twentieth-century freak-show performers became exotic spectacles—a man with atrophied legs metamorphosed into "the thinnest man in the world" or "the human skeleton," a woman of Mexican descent with facial hair became "the bearded lady," an African American man with scoliosis transformed into "the missing link"—the complex humanity of persons with disabilities would be usurped by a deterministic feature such as “mental retardation,” “muscular dystrophy,” or “deafness.” The goal here was expediency as opposed to clarity, and the politicized parsing of language was one vehicle of choice.

Yet in many ways some of those attentive to disability language charge that we have not sufficiently attended to the wild card of biology that operates as the point of most disabled people’s ostracization in the current political debates. According to this argument, one of the weaknesses of our current language politics is that people with disabilities cannot afford to overlook the vulnerability and “real” limitations of bodies. Often the problem with medical definitions is not that they pay too much attention to disability, but rather that they prove inaccurate as to the experience of the condition itself. Those with multiple sclerosis, for instance, would argue that a book by Nancy Mairs comes much closer to the nuances of the disorder than any deterministic medical textbook entry. In addition, others have argued that a discussion of disability that fails to take into account the social context of experience references little more than a body shorn of its environment—a corpse posing as a living condition.

Is it necessary to refuse a recognition of biological incapacity in order to establish an effective political movement? Can one not recognize the often very real limitations of the bodies that we inherit or acquire without having to give up on revising the language used to diminish the lives of persons with disabilities? In part, there exists a pressing practicality in this matter; for instance, in research one cannot locate disabled persons in history without searching the keywords by which they would appear in the dehumanizing, medicalizing, segregating, or infantilizing languages of their day. Thus, disability scholars ironically found themselves in a conundrum during the 1990s when the Modern Language Association (the largest humanities-based organization in the world) took it upon itself to excise all instances of debasing disability language from its database search engine. While the gesture proved moving as a safeguard against the use of derogatory speech, it also rendered an enormous amount of historical material invisible. The effect was to erase all written historical materials that relied on terms such as *crippled, demoniac, retarded,* and *gimp*—a sizable cache of materials, as it turned out. In a parallel example, educators might discuss research plans for studies into the future on whether or not sign language should be considered a natural language. For instance, deaf studies scholars have found themselves consternated over the discovery that American Sign Language has been classified under the rubric of “invented languages” alongside the Klingon language created by writers for the television series *Star Trek.*

Like many areas of disability, ideas about language reveal a geography of uneven development. For example, sign language poetry is currently enjoying a creative surge of interest, with international performances, an online journal, and literary prizes. Whereas a history of education for deaf individuals has made sign language usage off limits for deaf students, the effort repressed the idea that signed languages were the first communicative mode of interaction among human communities. In banning signing, then, such educational efforts privileged “voicing” as a preferred communication method in a hearing world. Work to explicitly forbid sign language forced alternative communication modes underground, so to speak, and the revival of sign language poetry attempts to reclaim the power of sign language as a rejection of such prejudicial premises. New ways of integrating the body into linguistic analyses have emerged based largely on the degree to which sign language poetry depends on the body itself as a vehicle of meaning making. The Flying Words Project performer Peter Cook and others have turned their bodies into instruments of communication that outdistance even the most articulate oral talker or writer.

Sign language analysis has also helped to unseat common beliefs that associate articulation with intelligence. Not only deaf people but many with communication-based disabilities have found themselves identified as idiotic, feebleminded, retarded, or delayed, depending on the historical period of their diagnoses. Today, difficulty in oral communication immediately earns an individual placement in special education classes, no matter how fluent he or she may be on paper or computer. Our cognitive sciences have labored long under the erroneous conception that a lack of spoken language acquisition is directly related to insufficient intellectual development where peak performance seems inevitably tied to assessments of oral fluency. To combat this prejudicial assumption, many technologies that facilitate communication have been developed to provide vehicles for communication. Such technologies serve to assist individuals who cannot speak, those whose speech is highly limited, and those who cannot point reliably. These prosthetic enhancements to communications have been widely debated with respect to the degree that they "simulate" the appearance of intelligence rather than reveal the presence of thinking individuals wielding a language of their own. However, such politicized debates only tend to demonstrate the degree to which those who oppose facilitated communication deny humanity to those with speech disorders.

Many prevalent disability clusters form around kinds of language acquisition technologies and assistance that can be readily marketed with payment assurances under different kinds of insurance reimbursement plans. Examples of this phenomenon include hearing-impaired individuals and listening devices (i.e., hearing aids, cochlear implants), people with visual impairments and reading technologies (i.e., Braille, magnification technologies, and so on), those diagnosed with developmental disabilities and various software technologies, and autistic individuals and communication hardware (i.e., portable speech boards, synthesized voicing technologies, and so on). To some extent, one may grow increasingly suspicious at the beginning of the twenty-first century that the technologies are now driving the diagnostic determinations. One will rarely find a disabled individual lacking a closet cache of useless technologies prescribed by one overzealous medical or rehabilitation professional or another. As history has demonstrated, once a technology becomes available human communities find it difficult to resist the ever-present temptation of application.

Finally, this entry will conclude with a discussion of art and advertising, which serve as key contexts for public reception of people with disabilities. The term *enfreakment* has been coined to designate the dire atmosphere of media representation that artificially generates atmospheric strangeness around disabled bodies. The most widely known examples of such phenomena can be found in the sadistic body art of Joel Peter Witkin and the deforming photography of Diane Arbus. In the work of both of these visual portraitists, disabled bodies are transformed into surreal landscapes that tend to emphasize the "grotesquery" of human differences. As one disability scholar argues, their depictions suggest that some impending calamity is about to befall their artistic subjects. Yet, as in the freak-show performances of old, these artistic endeavors consciously seek out the staging of their subjects in ways that artificially exaggerate disabilities as "oddities." Witkin's work slices, dissects, and violates the bodies of his subjects, and Arbus's photography uses alienating props such as Halloween masks, hand grenades, claustrophobic environments, and campy clothing to mock the figures depicted. Such artificial designs trade on the situation of disabled people in bizarre environments where their differences appear out of place and glaring. In all cases, debasing artwork cultivates a visual grammar that encourages viewers to participate actively in the dehumanization of disabled people. Such artwork conjures private language codes that leave art's consumers with little other than extreme emotional responses of distaste, danger, and/or discomfort.

Parallel efforts can be found in the language of charity forums such as telethons and walkathons. In these performance venues disabled people—usually depicted in a perpetually infantilized state as helpless children—are identified as fates-worse-than-death and public contributions promise to eliminate future individuals who might find themselves in the "affected" category. Almost every major disability now has its own charity "organ," and, in the case of the most renowned disabilities—such as muscular dystrophy, cerebral palsy, and "mental retardation"—a plethora of charity organizations have evolved and splintered off from each other. In order to become successful in an industry that has become increasingly competitive, charity organizations participate in the fashioning of severe and pathos-ridden language games in order to top the previous year's contributions. For instance, American telethon barker Jerry Lewis has been recorded as telling disabled people to "stay in their homes" if they do not want to be pitied by others. As this entry's opening discussion of hate speech notes, such aggravated commentary deploys language as a weapon that diminishes disabled people's lives in the midst of encouraging benevolent acts of monetary giving from viewers. Like their scientific partner, genetics, these media displays pursue discourses of prevention as the only appropriate response to unwanted human variations. In doing so, they often manage to avoid efforts at social provisions that would better allow existing disabled people to participate more fully in obstacle-ridden social contexts. Further, in "giving" of their hard-earned dollars, donors are encouraged to feel good about themselves as they contrast their more "fortunate" status with those who are described in terms that mark them as definitively "less fortunate."

By far, linguistic contexts for disability are overdetermined by detrimental ascriptions. Perhaps, as some more pessimistic analysts contend, disability is a difference that cannot be adequately accommodated within the strictures of contemporary vocabularies. At the very least, an examination of disability terminology suggests the degree to which cultures rely on perceptions of extreme human variation to test the outer limits of acceptable humanity. Language is the medium within which all bodies exist; as a result, words create the contexts, the expectations, and the imaginative possibilities for the future cohabitation of disabled and nondisabled bodies. The flexibility of our environments is greatly determined by the language we use to access and construct livable spaces. Let us hope that our language of disability can become as flexible as the bodily variations it references.

L'ARCHE

L'Arche is an international federation of communities dedicated to the service of people with intellectual disabilities. It was founded in 1964 in Trosly, a French village north of Paris, by Jean Vanier (son of General Georges Vanier, former governor general of Canada), who was born in 1928. L'Arche emerged as one individual's reaction to and attempt to address the dismal living conditions in institutions for the developmentally disabled at the time.

L'Arche began when Vanier welcomed two persons with disabilities to live with him in a small home. His desire to share his life as a brother with these individuals, Raphael and Philippe, attracted others, and soon a community of several homes and workshops grew in the same village. Later, some of those living in Trosly left to begin similar communities in other parts of the world, at the same time maintaining strong links of friendship and support with one another. In 1972, L'Arche was constituted, and by the beginning of the twenty-first century it included more than 113 communities in 30 countries around the world. The organization's name, French for "The Ark," is taken from the Old Testament story of Noah. It signifies a place of refuge, of salvation from the flood. The name was at first applied to the original home begun by Vanier; it was later given to that first community he founded.

L'Arche is distinctive in that its style of community living is based on relationships, wherein the people with disabilities, called "core members," and people without disabilities, "assistants," live in an atmosphere of trust, security, and mutual affection. The core members are valued and accepted for who they are and the gifts they bring. The people with disabilities are not viewed as "residents" cared for by "staff." Assistants do not view their role as only that of caregiver, but rather as one of sharing life *with* people with disabilities. Assistants usually commit to live in a L'Arche community for one year. Many stay longer, and some assistants have chosen to live in L'Arche communities as a life vocation.

L'Arche communities are faith based, Christian in origin, and welcome people of all faiths and religions. The communities vary in size within and among the countries around the world, having from one to eight homes per community, and they are located in both urban and rural areas. L'Arche communities celebrate each person as being of unique and sacred value and strive to create homes where faithful relationships are nurtured, based on forgiveness and celebration. The same sense of communion unites the various L'Arche communities throughout the world. Bound together by solidarity and mutual commitment, they form a worldwide family.

Although L'Arche has experienced tremendous growth over the past 40 years, this growth has been primarily organic. L'Arche does not seek to expand greatly; rather, it seeks to serve as a sign of hope to society in a divided world.

LARYNGECTOMY

Theodore Billroth of Vienna performed the first successful laryngectomy in 1873. Laryngectomy is a surgical procedure to remove the larynx (voice box), which is situated above the trachea (windpipe) and in front of the esophagus (gullet or food pipe). This procedure is often done to treat larynx cancer if chemotherapy is unsuccessful. Laryngectomies may also be performed on people with gunshot wounds, severe fractures, or other trauma.

A laryngectomy may be partial or total. In a *partial laryngectomy,* only a portion of larynx or the surrounding muscles is removed. Although the voice is not lost and the individual may retain his or her usual patterns of speech and swallowing, the voice may sound weak or hoarse. The larynx is completely removed in *total laryngectomy,* which alters breathing and communication. A permanent opening (stoma) in the front of the neck allows the individual to breathe, but speech is altered. People who have had laryngectomies are known as laryngectomees; some refer to themselves as "larries."

Laryngectomees are taught one of three alternative ways of talking to restore communication: esophageal speech, tracheoesophageal speech, and electronic speech. The goal is to learn a new speaking technique that is most comfortable for the individual.

Esophageal speech is the oldest method of voice restoration, having been used for more than 100 years. In this technique, the individual draws in air through the mouth and forces the air into the esophagus by locking the tongue. The process is similar to a controlled burp. Esophageal speech is less costly than other methods because it requires no equipment or surgery; however, the vocal phrasing and low volume of the speech that results may make it difficult for others to understand the individual.

Tracheoesophageal speech is similar to esophageal speech, but the individual uses a device to redirect air from the trachea into the esophagus. The device is inserted at the stoma site with a *tracheoesophageal puncture* (TEP): A small shunt is placed through an opening between the trachea and esophagus. A small one-way valve placed into this opening allows the laryngectomee to force air from the lungs into the mouth. This method results in a more natural voice than does esophageal speech, and voice restoration occurs within two weeks of surgery.

Electronic speech involves the use of an electronic or artificial larynx, a device first developed by Johann

Czermak in 1859 to create a clearer voice and increase vocal volume. There are two types of artificial larynxes. The *extraoral type* looks like a flashlight; it has batteries in the handle and a vibrating disk on the end that the laryngectomee presses against the outside of the upper neck. The *intraoral type* consists of a shirt-pocket-sized battery pack connected to a sound emitter by a small wire that is held in the palm of the hand.

Following laryngectomy, some people experience depression and social withdrawal due to the changes in their voices and reactions of others. A number of support groups have been established for laryngectomees (e.g., WebWhispers Nu-Voice Club, the International Association of Laryngectomees), and many find that joining such groups is beneficial. Most laryngectomees successfully return to their jobs and resume most of their usual activities.

LATINO HEALTH

LATINO ETHNICITY AND IMMIGRATION

The terms *Latino* and *Hispanic* refer to people who are of Latin American or Spanish descent. There is a great degree of heterogeneity among Latinos, as this group is made up of people from many different races, cultures, and countries of origin. Within the U.S. population, the number of Latinos is currently growing. The majority of U.S. Latinos are of Mexican descent, and most live in the southwestern region of the country. In addition, many people of Central American and Puerto Rican descent live on the U.S. East Coast and many of Cuban descent live in Florida. Growing numbers of Latinos are also immigrating to many midwestern and southern states. The majority of Latinos who migrate to the United States do so in search of jobs that will allow them to support their families, both in the United States and in their countries of origin.

INTERNATIONAL LATINO HEALTH AND DISABILITY

A major cause of underdevelopment in many countries is repeated episodes of illness and long-term disability. Poor health and disability among Latino groups in developing countries are often the consequences of infectious diseases and noncommunicable conditions such as malnutrition, perinatal conditions, mental illness, diabetes, cancer, and cardiovascular diseases. Malnutrition and the spread of infectious diseases are the results of inadequate sanitation, lack of immunization, and poverty. Poor nutrition, lack of prenatal care, and environmental toxins cause perinatal conditions. Chronic diseases such as cardiovascular diseases and diabetes are increasingly becoming major contributors to disability and mortality, both within the United States and internationally. Latinos in Latin American countries and in the United States are at increased risk for these diseases due to a sedentary lifestyle, high-fat/calorie diet, hypertension, high cholesterol, and obesity.

U.S. LATINO HEALTH AND DISABILITY

According to the U.S. Census, 15.9 percent, more than 11 million, Latinos age five years and older have some kind of disability. Data from the mid-1980s indicate that the highest rates of anencephaly, spina bifida without anencephaly, and Down syndrome in the United States occurred among Latinos. Chronic conditions are major causes of disability among Latinos living in the United States. Most often, disabled

Latinos are of school or working age. Furthermore, the U.S. population of Latinos includes 1.6 million people age 65 and older. The Hispanic elderly population is the second-fastest-growing aging population. As the population ages, the number of Latino with disabilities will grow as well. The leading causes of disability among older adults include Alzheimer's disease, arthritis, cancer, cardiovascular disease, and diabetes. More Latinos have arthritis, the leading cause of disability in the United States, and activity limitations from arthritis than do non-Hispanic Whites. The prevalence of type 2 diabetes is 10.2 percent among Latinos in the United States, a rate that is two to five times greater than that among non-Hispanic Whites, and many disabling secondary diabetes-related conditions affect Hispanics as well. Another cause of disability among Latinos is occupational injuries. It is estimated that there are more than 3 million migrant and seasonal farmworkers in the United States, the majority of whom are Latino, and large numbers of Latinos work in high-risk industrial settings as well, such as animal processing plants. Occupational injuries are not uncommon, and many Latinos do not seek treatment for fear of facing questions about their immigrant status and perhaps losing their jobs.

Prevention and Treatment

Compared with non-Hispanic Whites, Latinos in the United States are less likely to engage in preventive practices and to obtain screenings to detect chronic disease risk factors and signs of disease. That is, they are less likely to regularly obtain routine checkups, to undergo blood pressure and blood cholesterol screening, or to be screened for colon, prostate, cervical, and breast cancer. There is also evidence that rehabilitation outcomes are less successful among Latinos than among any other ethnic groups. Many social, economic, and cultural factors influence the preventive and screening health practices of Latinos.

Factors Affecting Health and Disability among Latinos

It is well established that low income, low level of education, and lack of access to health care are associated with chronic disease risk factors and mortality. Latinos in general are poorer, less educated, and less likely to have health care coverage than are members of other ethnic groups in the United States. In 1999, the per capita income for all people 16 years of age and older in the United States was $21,587, whereas among Latinos it was almost half that ($12,111). About 45 percent of Mexican Americans working full-time reported earning less than $15,000 a year. Just over half of Latinos have at least a high school diploma, whereas just over 85 percent of non-Hispanic Whites have at least a high school diploma. Latinos also have less access to health care: More than 33 percent of Latinos in the United States do not have health care coverage. Research has also shown that Latinos are less likely than members of other ethnic groups to use public aid, even if they are eligible, for reasons of pride, fear of questions about their immigrant status, and lack of awareness of the system. The negative effects of lack of resources and access are compounded for Latinos with disabilities, who experience even more difficulty with access to health care and obtaining employment. They also experience difficulty in accessing public facilities and transportation. Language barriers and cultural differences among Latinos with disabilities may also impede their access to health care, their ability to obtain assistance from service agencies, and their ability to obtain employment. In addition, it is estimated that 10,000 Mexicans cross the border into the United States every day, and little is known about the prevalence of disability among recent immigrants or about the potential barriers that those with disabilities face.

CULTURAL BELIEFS AND VALUES

Cultural values about health and disability have been shown to affect the lifestyle choices that people make, decisions to access health care, and the services that people with disabilities seek out. It is important to note that among Latinos in the United States there is a great deal of heterogeneity in cultural beliefs and values. Differences in ethnicity, national origin, gender, income, and education, as well as in religion and level of acculturation (defined as the process of adopting the beliefs, behaviors, and values of the dominant culture), all influence cultural beliefs and values.

Religion plays an important role in Latino cultures, as it does in most cultures. Religious beliefs may influence individuals' views of and attitudes toward illness and disability. Latinos may see disability or illness as a test from God, as God's will, or as a punishment. Religious beliefs can also provide a positive framework through which to view disability and illness. Many Latinos believe that prayer, pilgrimages to holy sites, and vows can aid in curing or ameliorating symptoms, and many who are ill or disabled find sources of support in faith and in organized religion. Religious leaders and fellow parishioners provide everything from emotional support to instrumental support. Research has shown that faith in God provides a higher level of support than does religion as an institution. It is common for an individual to experience an increase in faith with the onset of an illness or disability, but disability or illness may also contribute to a loss of faith.

Latino cultures in general are collectivist. They are guided by duties to the group rather than to the individual, and collectivist norms influence how Latinos perceive health and disability. The value of placing the needs of the family above those of the individual influences Latinos' view of the world. Close extended families are more commonplace among Hispanics than they are among non-Hispanic White Americans. Latinos often turn to family members for social support and advice about health. A family's beliefs and knowledge about preventing and controlling disease shape the individual members' health beliefs and behaviors.

Familial roles also influence conceptualization of disability. For example, if a person with a disability is able to fulfill his or her traditional family roles, other family members may not think of that person as having a disability. The idea of being "normal" can be related more to being able to fulfill roles and expectations than to having an illness or being impaired. A person with an impairment may be considered a unique individual rather than described as disabled. Expectations related to gender roles also influence attitudes and behaviors related to disability and illness. For example, women may deny the impact of illness or disability because of a cultural expectation of *aguantar* (a verb meaning "to endure"). *Machismo* among men may contribute to denial of disability or illness and may cause them to avoid seeking services.

Beliefs about Causes of Disability and Illness

The beliefs of Latinos vary in respect to the causes and treatment of disability, the perception of the severity of disability, and the impact of disability on life. Latinos living in the United States hold varying degrees of both medical and folk beliefs about the causes and treatment of illnesses and disability. Medical beliefs about causality are related to genetics and accidents at birth or in childhood. Folk beliefs about the causes of disability and illness include such elements as imbalance between hot and cold, flies in a home, the evil eye (*mal de ojo*), and dreams during pregnancy. Bad air, germs, and poverty are blamed for symptoms and illnesses. Psychological states such as worry, fear (*susto*), anger, and envy may be labeled as causes of symptoms and disease, as well as turmoil in the family, amorality, and ethical violations. Faith in God, fatalism (a belief that disease onset is a result of fate, and thus individuals have little or no hope of preventing or controlling disease), and *personalismo* (personal relationships) both influence health conceptualization and lead Latinos to avoid or put off seeking treatment. Some Latinos use home remedies involving herbs, purification rituals involving holy water or candles, and the services of spiritual healers to treat illness or disability before or in place of seeking medical help. One study on the cultural norms related to Latinos' delayed use of medical care when chronic disease–related symptoms are present found that the factor with the most pronounced effect on care seeking was the perceived seriousness of the symptoms.

Cultural Competence

Health professionals in the United States are increasingly recognizing that they need to be aware of the social and cultural factors that influence how Latinos perceive health and disability. To improve the health and well-being of Latinos with disabilities, research is needed to examine the diverse health-related beliefs among various Latino groups. Although it is important to be sensitive to cultural beliefs, health professionals should avoid assuming that every Latino has traditional beliefs. Culturally competent and bilingual service providers are also needed to serve this population effectively.

—Janine M. Jurkowski

LAVATER, JOHANN KASPAR

(1741–1801)

Swiss scientist and poet

Johann Kaspar Lavater was a Swiss scientist and poet who wrote in German. Lavater developed an influential science of physiognomy that linked facial countenance and bodily appearance with moral disposition. While physiognomy itself was not new—some scholars place aspects of this belief as far back as the writings of the ancient Greeks—Lavater's system sought to formalize a common practice as empirical method. His most famous book, *Art to Know the Men by the Aspect: The Physiognomy* (1775–1778), was a two-volume work that included silhouettes and illustrations of faces in profile exemplary of character traits such as greed, criminality, melancholy, miserliness, and virtue. He also included his own profile as well as those of celebrated individuals of his time whom he admired. The basis of his system of physiognomy was Lavater's belief that the body communicates the nature of the soul. Along these lines, he once argued, "Action, looks, words, steps, form the alphabet by which you may spell character." Significantly, several prominent disabled people of the eighteenth and nineteenth centuries opposed Lavater's theory on the basis of its prejudicial relation to disabled bodies. Disabled critics of this theory included the "hunchbacked" German mathematician Georg Christoff Lichtenberg (1742–1799), who mocked Lavater and other physiognomists of his time by explaining that they took their own bodies as the barometer of morality. According to Lichtenberg, "God created man in His own image, says the Bible; philosophers reverse the process: they create God in theirs."

LEADERSHIP

The term *leadership* is used to represent an office or position of leader or the ability to guide, direct, or influence people. By definition, leadership involves the holding of an elevated office or position—that is, leaders have a higher status than do those whom they are leading. Further, definitions of leadership stress that leadership is a group process that involves interaction between at least two persons as they work toward a common goal. In this way most directly, leadership has done much for the field of disability. This entry discusses types of disability leadership and their effects, which include advances for both leaders themselves and the general disability community.

TYPES OF DISABILITY LEADERSHIP

Specific to the field of disability, leadership has taken three major forms: leadership by persons with disabilities; leadership by parents, family members, and caretakers of persons with disabilities; and leadership of policy makers surrounding disability-related issues.

First, many people with disabilities have taken leadership roles themselves in a number of capacities, including in large organizations such as the American Association of People with Disabilities as well as in smaller grassroots community groups. As one example, the centers for independent living (CIL) movement began in the 1960s and 1970s due in large part to the leadership of Ed Roberts, an individual with an extensive physical disability as the result of contracting polio as a child. Roberts's leadership experience began with his advocating for his own equal access to an education and moved on to include his advocating for the rights of people with disabilities all over the United States. Another example is Deng Pufang, himself a wheelchair user, who founded the China Disabled Persons' Federation (CDPF) in 1988. The CDPF works to protect the human rights of persons with disabilities as well as promote their equal participation in society. In 2003, Deng Pufang was acknowledged with the UN Prize in the Field of Human Rights for the extensive work he has done for people with disabilities in China through legislation, programs, and activities.

Along these lines, much has been done to encourage the leadership of people with disabilities, including a number of national and local conferences that have chosen as a major theme the leadership of people with disabilities. In addition, a variety of disability leadership forums and training programs exist across the United States and the larger international community, including in places such as Illinois, Massachusetts, Michigan, Oregon, and Thailand. The majority of these projects have been designed to help youth or adults with disabilities uncover or further develop their leadership skills, sometimes in relation to a specific area, such as independent living.

Second, parents, other family members, and caretakers of persons with disabilities have also participated as leaders in the disability community. Parents of children and adults with disabilities have been responsible for beginning many support organizations, including United Cerebral Palsy, as well as networks such as the Parents Exchange, an informational, referral, and advocacy organization. Another example is the Kennedy Foundation, which grew in part out of Eunice Kennedy Shriver's experiences with her sister Rosemary's intellectual disability and continues to provide supports to serve those with mental retardation. These groups are essential to supporting people with disabilities as well as educating the able-bodied community regarding the strengths and needs of individuals with disabilities. Similar trends have been evidenced internationally. For example, in the United Kingdom a group of parents of children with disabilities formed the National Autistic Society in order to provide information and support to other family members of individuals with autism.

The third form of leadership in the area of disability has been that provided by policy makers and government agencies. For example, the National Institute on Disability and Rehabilitation Research (NIDRR) has been a strong leader in advocating for the rights of and equal services for individuals with disabilities. NIDRR has developed funding priorities that, among others, promote leadership training for people with disabilities. These priorities continue to ensure that disability remains an integral part of the research agenda in the United States. Another example of leadership by government agencies occurred in Australia during the early 1970s, when a larger community health movement took place. Under the Whitlam administration, local community health projects were made directly accountable to the communities they served. There was community involvement at every level of service development and delivery, which allowed channels of communication to open up among service providers, government officials, and consumers in areas such as disability and mental illness (among others). These types of policy initiatives provide a framework for both national and local organizations to strive to meet the needs of individuals with disabilities more effectively.

EFFECTS OF DISABILITY LEADERSHIP

Positive effects of disability leadership can be seen both in leaders themselves and in the broader disability community. First, serving as leaders can benefit leaders themselves. Much general research conducted across a variety of populations has found that helping others can have a positive impact on the person providing the help. Specific to disability, serving as a leader may benefit the leader in terms of self-determination, power, and control. For example, leadership training has been used to promote recovery in persons with psychiatric disabilities. Such training may lead to decreases in psychiatric symptoms as well as increases in self-efficacy, community living skills, and empowerment. Similarly, serving as a peer leader has been found to facilitate adjustment to a new disability among individuals with spinal cord injury. Leadership training can also open the door to further career opportunities. For example, in one leadership training program, graduating leaders had the opportunity to join local advocacy organizations on a formal basis as speakers who would advocate for effective supports for people with disabilities.

Second, leadership can also benefit the broader disability community in terms of advancements in the area of equal access and equal rights, as a catalyst toward person-directed services, and as a way to build a solid sense of disability community and identity. Perhaps the most significant impact that leadership in the disability community has had is seen in the passage of the Americans with Disabilities Act (ADA) in 1990. The development of leadership in the disability community in the United States led to the passage of the ADA, and in turn the ADA has raised the quality of life for many people with disabilities. Changes such as better access to employment, transportation, housing, education, communications systems, and public facilities for people with disabilities have all resulted from leadership in the disability community. Moreover, the passage of the ADA in the United States foreshadowed growing interest in disability rights legislation in other countries, such as Australia and Colombia.

Another example of the broader community impact of leadership is the CIL movement, which is dedicated to helping people with disabilities live independently and become productive, fully participating members of society. The National Council on Independent Living (NCIL), which was formed in 1982 in the United States, provides an excellent example of leadership for people with disabilities, by people with disabilities. The NCIL has been a leader in the disability community in terms of building local community bases as well as advocating nationally for disability rights.

Community impacts can also be seen on a smaller scale. For example, leadership training programs often foster the development of networks of individuals who have strong leadership skills. Such networks can then be effective tools for outreach and education of other people with and without disabilities about disability rights in the community.

In all of the examples presented above, leadership has facilitated the building of empowerment in the general community, which can also help new people develop as leaders in their communities, creating a solid feedback loop. Leadership serves as an effective and essential tool to effect change and advocate for a variety of rights for people with disabilities.

LEAGUE OF THE PHYSICALLY HANDICAPPED

The League of the Physically Handicapped was a grassroots organization of disabled activists that operated in New York from 1935 to 1938. In 1935, in the depths of the Great Depression, President Roosevelt established the Works Progress Administration (WPA) to provide jobs for the unemployed. However, among the groups considered "unemployable"—and thus ineligible for WPA jobs—were people with disabilities. In response to this policy, six young people with disabilities held a sit-in at the offices of New York City's Emergency Relief Bureau. At first merely aiming to speak with the bureau's director, they escalated their demands as the sit-in continued. An ongoing picket line of supporters at times swelled to hundreds, with thousands of onlookers. Six days later, when those sitting in finally met with the bureau director, the nascent group was demanding jobs in unsegregated environments and explicitly rejecting charity.

The League grew from this core of activists. Focused on employment rights, the organization engaged in picketing, public education, and meetings—often confrontational—with public officials. The group also wrote a 10-page "Thesis on Conditions of Physically Handicapped." Prefiguring later thinking, this work asserted that discrimination is the cause of disabled people's unemployment and critiqued the charity model, especially sheltered workshops.

LEARNING DISABILITY

Coming to agreement on the definition of learning disability (LD) has been a challenge since the 1960s. Various groups, such as the Learning Disability Association (LDA), provide their own definitions. However, the most widely used definition in the United States is that provided by the U.S. Department of Education under the regulations of the Individuals with Disabilities Education Act (IDEA) of 1997. According to the IDEA, the term *learning disabilities* refers to a group of neurological disorders that impact one or more of the brain's basic functions used to understand and interpret language, symbols, and gestures; such disorders are typically identified during the elementary school years. The manifestation of these neurologically based conditions can be observed in an individual's difficulty with reading, writing, listening, speaking, completing mathematical functions, fine motor skills, and even interpreting social cues and gestures. The term *specific learning disability* (SLD), which is sometimes used instead of the more general term *learning disability,* refers to a severe difficulty with one area of life and learning without any accompanying difficulty with others. For example, someone with an SLD in reading may experience great difficulty with written print but be able to complete complex mathematical computations and manipulate objects that require great dexterity.

Historically, three conditions have been considered in identifying a learning disability: (a) the presence of a discrepancy between potential and achievement, (b) the presence of intraindividual differences, and (c) the presence of average to above-average intelligence. These conditions pose a problem for professionals working in the area of LD. Most notably, procedures for determining whether a discrepancy exists are a source of great debate that centers on issues related to IQ testing and performance measures. As a result, the IDEA, the federal legislation in the U.S. that is designed to ensure that individuals up to the age 21 receive free appropriate public education that meets their needs, calls for a comprehensive, interdisciplinary assessment of strengths and needs for any student thought to have an LD. One critical factor to rule out in making a diagnosis of LD is that the problems themselves are a result of LD and not due to other disabilities or societal factors. However, LDs can coexist with nonintellectual disabilities, and in many schools it is common to find students with both LDs and emotional behavioral disorders.

More than 50 percent of individuals in U.S. schools who receive special education services have some type of LD. Adults who have learning disabilities may also go undiagnosed and thus experience great difficulties. Their undetected LDs may have negative impacts on their ability to work, engage in social relationships, and experience success. Because LDs are invisible, they pose some interesting challenges for individuals with LDs as well as their families, professionals working with them, and their peers and coworkers. An LD can affect every domain of an individual's life, and, as such, interventions designed to support success may vary greatly for different individuals.

Specific LD disorders include dyslexia, dyscalculia, dysgraphia, dysnomia, and dyspraxia, and in recent years the growing category of attention deficit disorder (ADD) has been included on this list. Individuals with the best-known type of LD, *dyslexia,* experience great difficulty understanding language and using various language-related skills, most commonly reading, writing, spelling, and speaking. This condition at times affects an individual's ability to interpret mathematical symbols to determine operations and may also influence the ability to interpret social cues (e.g., facial expressions). The next most common form of LD is *dyscalculia,* which has the same effect on an individual's learning and understanding of mathematical concepts and operations. Although the impact of this LD on a person who is in school is significant, it does not end once the individual exits the school setting. It can be observed in disorganization with balancing a checkbook, poor money management (e.g., late payments), and scheduling errors. *Dysgraphia* affects an individual's ability to develop written language and use it as a mode of communication. *Dysnomia* refers to difficulty experienced with the recollection of names, places, or specific object words. This form of LD can have a negative impact on children and youth, but it has a greater influence on adults as they attempt to communicate with coworkers, supervisors, clients, and related groups. *Dyspraxia,* the least common of the learning disabilities, is related to the manipulation of fine motor skills; it limits the individual's ability to engage in handwriting, drawing, typing, sequencing, and even daily self-care.

According to the Learning Disability Association, ADD and brain injury also fall under the category of learning disability. ADD affects an individual's ability to focus attention for any prolonged period of time; if hyperactivity is also observed, attention deficit/hyperactivity disorder (ADHD) may be diagnosed. In recent years, ADD and ADHD have become increasingly recognized. Until about 20 or 30 years ago, young people with similar behaviors were identified as hyperactive, impulsive, or disobedient. Now there is greater understanding of how this condition becomes or creates a learning disability. Given that brain injury affects an individual's neurological development, it is also considered a learning disability.

Since the 1990s, a new group of individuals has been considered as having a learning disability: individuals who are simultaneously gifted. Gifted LD individuals do not typically fit the criteria of experiencing failure, but they do meet the criteria for the presence of a discrepancy. In other words, individuals who are gifted LD may easily use their intellectual potential to compensate for their learning disabilities.

While the above description of LD conditions provides an outline of the various learning characteristics of individuals identified as having LDs, intervention options also need to be considered. Once a learning disability exists, it will not go away or be "cured" as an individual matures. The goal of intervention is to teach skills to address the challenges that are presented by the LD. Teaching the use of multiple learning modalities—visual, tactile, auditory, and kinesthetic—helps to "educate the brain," the source of this neurologically based disability. The use of assistive technology devices is becoming increasingly common among educators and employers for supporting individuals with LD. The technology that allows assistive devices to convert speech to written print, predict words, and/or read text is advancing daily. Such devices can open doors for individuals who may not be able to read or write but have excellent comprehension. They can make the difference in whether an individual with LD can access postsecondary education, participate in competitive high-level employment, and in other ways demonstrate his or her full potential.

Brain research demonstrates the neurological basis for learning disabilities and their impact on information processing, memory, and performance. However, symptoms associated with a learning disability can also be observed as a result of gaps in learning and of biased evaluations rather than the presence of a neurological condition. Consequently, there has historically been an overrepresentation of ethnic minority individuals identified as having LDs, as a result of both cultural bias and language bias. For example, professionals can easily misinterpret the characteristics of a potentially English-proficient student during the emergence of a second language as a language learning disability. However, if individuals go undiagnosed, they may experience great difficulties as adults living with undetected LDs that have the potential to limit their success in many ways.

The term *learning disability,* and the concept to which it refers, is relatively new. Learning disability was identified as a specific condition in the 1960s by a group of parents and advocates who observed unique learning styles in their children. The children in question had at least average intelligence and did not have physical or sensory disabilities. Professionals were at a loss to provide effective educational interventions for these individuals. Since that time, the recognition of this condition as a disability has extended beyond the United States and is now recognized internationally through brain research.

As with other disabilities, the presence of a learning disability has a significant impact on an individual for life. Unlike other disabilities, LDs are misunderstood as a result of their invisible nature and broad scope. Changes in the wording of legislation and subtle differences in definitions, whether theoretical or operational, can affect the diagnosis of LD. Students with LD are protected under the IDEA in the United States, but adults must use the protections of the 1990 Americans with Disabilities Act. Because of the ADA definition of disability, individuals with LD may not actually be protected unless they can prove that their disability has a negative impact on at least one major life function. In school, at workplaces, and in their communities, individuals with any type of LD are constantly pressured to perform actions that are in direct contradiction to their disability. Therefore, greater understanding of both the neurological basis for a learning disability and its vulnerability to the impacts of curriculum, poor education, and cultural bias is crucial.

LEONARD CHESHIRE

Leonard Cheshire is the largest charitable supplier of services for disabled people in the United Kingdom. It also operates globally. Founded by the World War II bomber pilot and war hero Leonard Cheshire, VC, in 1948, it greatly influenced the pattern of social care provision made for disabled people in the second half of the twentieth century internationally. This was particularly based on group living in residential institutions, which greatly restricted disabled people's opportunities to shape their own lives.

In the 1960s, the resistance of disabled people who lived in one Leonard Cheshire home, Le Court, played a major role in establishing the British disabled people's movement and the development of disability emancipatory research. The introduction of "community care" legislation in the early 1990s in Britain was intended to support disabled people to live in their own homes and neighborhoods.

In the late 1990s, the Leonard Cheshire organization established the Disabled People's Forum, which is run by disabled people and works within the organization to support disabled people's involvement and empowerment. The process of democratizing the organization, increasing the control of disabled people, improving the quality of services, and enabling disabled people to live independently, is still proving problematic, however. Leonard Cheshire's experience highlights some of the difficulties of making change from within traditional charitable organizations for disabled people.

LEPROSY

Leprosy is increasingly known by the less offensive name of Hansen's disease (HD). It was the first chronic disease to be attributed to a bacterial cause, when the Norwegian physician Gerhard Armauer Hansen identified the bacillus *Mycobacterium leprae* in 1873. There still is no clear understanding of the transmission of the causative agent, which appears to require long-term exposure and has a long incubation period. Efforts to grow the organism in a cell culture, which is prerequisite to the development of a vaccine, remain unsuccessful. Divided into localized (tuberculoid) and generalized (lepromatous) forms, the disease manifests first in skin discoloration and then in nodules, lesions, and topical anesthesia. If unchecked, it gradually spreads over the entire body, attacks the soft tissue of the nose and throat, impairs vision, and damages the nervous system. Ultimately, extremities become deformed and paralyzed, and may fall off after repeated but unperceived injuries.

The intrinsic seriousness and disfiguring effects of leprosy and, in the West, an accumulation of misnomers and misconceptions related to the disease have triggered irrational reactions that have proven difficult to overcome. Fateful changes in nomenclature began in late antiquity. The Greek category of "scaliness" (*λέπρα*), which covered a wide range of skin conditions, and the analogous Hebrew *zarã'at,* which biblical law termed unclean and cause for ritual isolation, merged into the Latin term *lepra.* The most ominous confusion ensued when the term became interchangeable with *elephantia* centuries after the Romans noted this disease as new, foreign, and presenting symptoms matching those of HD; they reported that it caused horror and that they feared the transmission of this evil.

Horror and revulsion interacted with the belief that physical deformity implied moral perversity. Deep fear persisted as long as infectiousness was misconstrued as contagiousness. The highly visible effects of the disease, together with its endemic and frequently clustered incidence, led observers—and historians—to overestimate the epidemic dimensions beyond the maximum documented ratio of patients to population. The tendency of the disease to occur in families and to strike children was confused with heredity. The steady advance of symptoms, obscuring the secondary infections that actually were the lethal threats to the weakened body, led to the assumption that death was the natural and inevitable outcome of leprosy and that, therefore, patients were beyond medical help.

The abandonment of patients found its most dramatic expression in a funeral rite that accompanied their ejection in some areas of medieval Europe, but it did not preclude continued efforts at palliative care. Similarly, in most societies, public stigmatization and exclusion coexisted with the protectiveness of families. Even official banishment failed to eliminate the victims from communal life and consciousness. HD patients have been the objects of effusive charity and the subjects of stories of miraculous healing and of heroic missionaries from the twelfth-century foundation of numerous leprosaria to the current activities of global aid movements. Nevertheless, they must still contend with discrimination and assaults on their self-esteem in addition to the physical disabilities they incurred before receiving medical treatment. After ages of unproven remedies, in which snake meat figured prominently, and high but vain expectations for chaulmoogra oil in the early twentieth century, the introduction of dapsone in 1941 brought the first effective therapy. The drug takes a toll on the kidneys, which may cause some patients to forgo their medication and others to die when dialysis is not available. In addition, emerging drug-resistant strains of *M. leprae* have necessitated multidrug therapies. These carry more side effects, and their expense impedes application in the areas of the world with both the lowest prosperity and the highest incidence. Endemic leprosy declined markedly in early modern Europe, and currently no industrialized country has more than a hundred HD patients. In the developing world, however, hundreds of thousands of new cases are diagnosed each year.

LEUPOLT, JANE (1812–1894)

British missionary and educator

Jane Leupolt, née Jane Chambers Jones, went to India in 1835 with the Society for the Promotion of Female Education in the East as a trained infants teacher. She married the Reverend Charles Leupolt in 1839 and for many years concerned herself with the education of blind children in the Orphan Institution at Sigra, Benares (Varanasi), and with local blind adults. After living in England, where she saw Moon's embossed reading materials, she returned to India in 1860 and organized formal literacy teaching of blind children with Mrs. Amalie Fuchs, a fellow missionary. By 1864 their efforts convinced the government to fund teachers for blind children. Using adapted Moon characters, Jane Leupolt succeeded in printing readers in Hindi. Light industrial work was also begun at Benares with blind youths at Raja Kali Shankar Ghosal's Asylum in this period, and Jane Leupolt's embossed books were used there from 1868 by Indian teachers whom she trained in their use. Although some earlier literacy work had begun in India with Lucas's script, Jane Leupolt was the first to organize the teaching of blind people on a larger scale and to gain government recognition. Before leaving India in 1872, the Leupolts passed the materials to the Reverend John Erhardt at Secundra Orphanage to add to the facilities of its famous printing house.

LEWIN, KURT (1890–1947)

German-American psychologist

Kurt Lewin was a German-American psychologist who profoundly influenced many fields. Lewin's environmental/contextual approaches to studying behavior and his integration of science and social change serve as cornerstones for contemporary conceptions of disability, disability research, and policy. Born in Prussia, Lewin studied and taught at the University of Berlin. In 1933, he emigrated to the United States to work at Cornell University, moving to the University of Iowa in 1935 and then to the Massachusetts Institute of Technology with the 1944 launching of the Center for Group Dynamics.

Lewin conceptualized behavior (B) as a function of the person (P) and the environment (E), expressed mathematically as $B = f(P, E)$. Person-environment interaction is key to the social definition of disability.

Lewin melded research and social intervention. His oft-quoted statement "There is nothing so practical as a good theory" characterizes his view that science and social change should be achieved simultaneously. Lewin called this combination "action research," and this approach is often used today in disability studies.

Much of Lewin's work dealt with reducing prejudice. Lewin demonstrated that nondiscriminatory policy led to decreased prejudice in mixed-race housing projects. Blacks and whites living as equals came to view each other as friends, a concept on which the inclusion efforts of disability advocates are based.

LICHTENBERG, GEORG CHRISTOPH (1742–1799)

German physicist and philosopher

Georg Christoph Lichtenberg was born on July 1, 1742, in Ober-Ramstadt in Darmstadt, Germany, and died on February 24, 1799, in Göttingen. His father, who was a minister, wrote in the church register after Lichtenberg's birth: "birth'd son who despite weakness I baptized." From the age of eight, Lichtenberg suffered from a spinal deformation combined with a hunchback that was probably caused by rachitis. With the help of a governmental scholarship, he was able to attend university. In 1769, Lichtenberg was appointed professor of physics in Göttingen. It is said that Lichtenberg could write his lectures on the board without turning his back—that is, his hump—to the audience.

For a time, Lichtenberg lived with a flower girl, Maria Dorothea Stechardt. She was his housekeeper and lover, but she died at an early age. Soon thereafter he took in a new young housekeeper, Margarete Elisabeth Kellner, who also became his lover. She bore Lichtenberg six children, and late in his life he married her.

Lichtenberg, although fond of the monarchy, was not only an outstanding physicist but also a representative of Enlightenment philosophy. He became the father of the German aphorism. Many of his witty ideas, familiar quotations, and flashes of thought—or "penny truths," as he liked to call them—were connected with his life. These can be found in his so-called *Sudelbücher* (mess books), which remained unpublished during his lifetime and became available widely only at the beginning of the twentieth century. In some of his most famous aphorisms he addressed the philosophy of disability and physical impairment. Lichtenberg's fear of people was paired with the gift for observation concerning human behavior. This also generated his polemic "Über Physiognomik; wider die Physiognomen" ("On Physiognomics; against Physiognomy"), which was published in 1778.

In 1983, an exhumation of Lichtenberg's skeleton proved that in fact no smallness in stature or "misshapenness" could be ascertained. His impairment, although descriptions of it have been handed down by his contemporaries, seems to have vanished into the air. One could take this finding as an ironic commentary on the controversies among Lichtenberg's biographers. Even today, discussions arise as to whether the philosopher endured his suffering with patience or with humor, or whether he simply went about his daily life, feeling indifferent about his disability.

—Christian Mürner

LILIANE FOUNDATION

The Liliane Foundation, located in the Netherlands, is committed to doing justice to children with disabilities in developing countries by giving them access to rehabilitation. In 1980, the Liliane Foundation started by assisting 14 children. In 2002, the foundation helped 31,982 children spread over 80 countries. As of that year, the total number of applications allocated and justified since the organization started its activities amounted to exactly 249,792.

Characteristic of the Liliane Foundation's assistance are direct contact with the child within the home situation and attention to the personal growth and happiness of the child. The key feature is "tailor-made" assistance—that is, assistance that varies according to the personality and the situation of each individual child. The guideline in the rehabilitation process is the child's individual rehabilitation plan, which sets out specific goals and describes the desired results. The final objective of the rehabilitation is the child's integration and participation in society.

The Liliane Foundation directs its efforts primarily toward children with disabilities living at home. From the start, the parents are closely involved in the rehabilitation process; this involvement (also in a material sense) is extremely important for the success of the rehabilitation.

The small-scale, direct, and person-centered assistance that is typical of the Liliane Foundation is made possible in practice through the foundation's collaboration with a worldwide network of "mediators" (local contact persons). Only representatives of nongovernmental or religious organizations can become mediators. The Liliane Foundation pursues its policy of strengthening the mediator network structurally by entering into partnership agreements with these organizations. The partnership agreements place the responsibility for the functioning and financial control of the mediators, as well as for the continuity of the work done, with the organizations.

Many mediators are social workers, physiotherapists, or nurses who work in the slums of big cities or in rural areas, where people often hardly know that rehabilitation is possible. Mediators or their coworkers arrange for the rehabilitation of the children with disabilities they come across in their work, requesting that the Liliane Foundation provide partial funding of the rehabilitation interventions needed. Because mediators and their coworkers have direct contact with these children and their families, they know the children's needs and the particulars of the local situation. They are aware of what kinds of assistance the children need most to cope better in their specific surroundings and circumstances.

The Liliane Foundation uses as many local facilities for rehabilitation as possible. Children who need surgery undergo it in the hospitals nearest to where they live and receive aftercare in the vicinity as well. Physiotherapy is provided in the children's homes or in nearby facilities, and any needed appliances are obtained locally. Children also receive education and vocational training in locations as close to their families' homes as possible.

LITERATURE, FOLLY

Folly literature is mainly a phenomenon of sixteenth-century Europe. Although the term *Narr* (fool) was used by earlier authors, it achieved its broad circulation only when Sebastian Brant (1457–1521) published the moral fiction *Narrenschiff* (*Ship of Fools*) in 1494. Shortly after the appearance of its first German edition, this book was translated into Latin, English, French, and Dutch. The passengers on the "Ship of Fools"—including the narrator himself—were fools because they were not able to conform to moral, religious, and ethical norms. The author not only criticized human sins and vices, such as drunkenness, adultery, and lavishness, but also condemned minor deviations such as the dislike of planning one's future. Brant's book became a best-seller and was a hallmark in Renaissance literature. It influenced many other pieces such as Erasmus von Rotterdam's *Encomium moriae* (*Praise of Folly*).

Besides their evident importance to moral fiction, fools played important roles in carnival plays and jest books. However, natural fools, being the main objects of interest from the disability studies perspective, were hardly ever mentioned in the *Ship of Fools* and similar fiction. In his sermons about the *Ship of Fools* in 1498 and 1499, the famous Strasburg preacher Geiler von Kaysersberg (1445–1510) explained that natural fools were fools without sins. They did not deliberately behave in deviant ways and therefore were not suitable to illustrate violations of moral, religious, and ethical norms. Instead, during the Middle Ages and Renaissance natural folly simply described a condition of essential mental difference. Natural fools were understood as differing not only from the normal but also from the mentally ill, since their condition was not a temporary, but a permanent one.

Although natural fools can be found in Renaissance literature even before the *Ship of Fools* was published, printed pieces about natural fools made up only a small segment of literature. For instance, in Wolfram von Eschenbach's thirteenth-century epic poem "Parzival," the protagonist's mother dressed his son as a fool to prevent him from becoming a knight. In doing so, the mother hoped that Parzival would return home quickly as soon as he was badly treated at court. However, as natural folly depended not only on a special costume, Parzival's princely origin could not be disregarded. In contrast, in Gottfried von Straßburg's epic thirteenth-century poem "Tristan," the hero voluntarily dressed as a natural fool when he met Queen Isolde. In this disguise, it was even possible for him to sleep at the door of his secret love. However, as natural folly was linked with asexuality, he could stick to his folly role only as long as he was not seen in bed with Isolde. Having betrayed his secret, Tristan had to escape. This plot serves as an example of high medieval German literature in which natural folly often offered a chance and disguise and dissembling.

In sixteenth-century Europe, jest books were another genre that collected anecdotes about all kind of fools. A good example of a jest book is *Schimpf und Ernst* (*Jests and Lessons*) by Johannes Pauli (c. 1450–c. 1520). Three main approaches to natural fools can be differentiated in folly literature. First, actions of natural fools were said to evoke laughter. Second, natural fools were shown as divine beings bearing messages from God. Third, natural fools were used as positive didactic examples. They were laughed at for their deviant behavior. For example, a popular anecdote told of a natural fool discovering a foal standing next to the fool's stud. The fool started to beat his horse for being a whore, and comforted the foal.

These anecdotes often had a closing statement that aimed at making the general audience laugh. The authors also understood the natural fools' deviance as divine intervention, and consequently interpreted their behavior as foretelling signs. It was Martin Luther (1483–1546) who related the anecdote about natural fool Claus Narr, who asked for water that would help him to extinguish a fire while at the same time in the distance a castle was burning. Other authors interpreted not only single episodes of a fool's life but the whole foolish behavior as a sign of prophecy or wise telling. These authors used natural folly as a didactic example for moral, religious, and ethic norms.

The German collection of 627 anecdotes of Claus Narr by Wolfgang Büttner is a prominent piece of this type of didacticism. The book was printed under the title *Sechs hundert/sieben und zwantzig Historien/Von Claus Narren. Feine schimpffliche wort und Reden/die Erbare Ehrenleut Clausen abgemerckt/und nachgesagt haben/Zur Bürgerlichen und Christlichen Lere [. . .] (Six hundred and twenty-seven anecdotes of Claus Narr. Fine and funny words and talks which honorable men noticed and retold. For civilian and Christian lessons [. . .]).* One anecdote in this book went like this: When Claus Narr saw a painted bird, he tried in vain to chase it away. Büttner interpreted this episode in a moral sense as a lesson that guests should not stay too long. Not only in everyday life, but also in the theological debates of sixteenth-century Europe, Claus Narr was presented as a model for true faith in God. For example, at one occasion he was asked about Martin Luther's future. Claus Narr answered that he was sure that the Reformation would prevail but added that his shoes and clothes became worse and worse. In his moralizing conclusion, Büttner called the fool a wise man as he foretold the continuation of the Reformation.

Until the end of the eighteenth century, Wolfgang Büttner's book was often reprinted. Other collections of jests and folly anecdotes quoted this source and continued to use the fool as a didactic example. Besides Claus Narr, who was a main source of reference in the sixteenth- and seventeenth-century folly literature, other natural fools became subjects of literature. In 1619, the Protestant preacher Philipp Cradelius printed a sermon for a natural fool's funeral. The life of the fool Hans Miesko was interpreted by him less as a sign of God but more as an object of pity. In that respect, Cradelius's sermon showed a slightly different approach to natural folly.

The various perceptions of natural folly remained in existence until the end of the eighteenth century. Until the Enlightenment, natural folly remained an object of laughter, of admiration, and of pity. At the beginning of the nineteenth century, however, the view of natural fools changed completely. They came to be classified as mentally ill. Consequently, books about natural fools such as *Claus Narr* were no longer read or understood. It is significant that in contrast to other examples of folly literature such as the *Ship of Fools* or the *Dyl Ulenspiegel,* Büttner's *Claus Narr* was not reprinted again. In the nineteenth century, the mental difference of natural fools became an object of medical and pedagogical institutions.

Literature about natural fools draws our attention to the fact that the concept of mental difference varies in history. It is therefore a fruitful source for disability studies as it serves to show the diverse constructions and functions once applied to mentally impaired people.

LOBBYING

Lobbying is relatively easy to define but less easy to explain, carrying as it does many negative connotations as well as a fairly high capacity for being misunderstood. This entry provides a definition of lobbying, a discussion of lobbying restrictions imposed by U.S. federal legislation as well as IRS regulations, and an illustration of lobbying taken from the 1998 reauthorization of a major disability law.

DEFINITION OF LOBBYING

The term *lobbying* refers to engaging in activities directed toward public officials for the purpose of influencing legislation and/or policy. Three factors are involved in a lobbying activity:

- *The government activity being targeted:* "Legislation and/or policy" in the above definition refers to an array of federal, state, and local governmental activities, such as preparation and passage of laws; adoption and implementation of rules, regulations, and policies; awarding and administration of grants and contracts; and confirmation of individuals nominated for official positions (Lobbying Disclosure Act, sec. 1602, defs. [8]).
- *The public officials being lobbied:* The title of "public official" covers a range of government-affiliated positions in the executive and legislative branches, including legislators and staff, and department and agency administrators and employees (U.S. Department of Education n.d.).
- *The method being used to lobby:* Lobbying activities include not only in-person exchanges but also written communication and background work, such as the planning of lobbying strategies, analysis of bills, and preparation of position papers (U.S. Senate n.d., sec. 3).

In essence, all attempts to influence government action, to persuade public officials of the rightness of one's position, are defined as lobbying.

LOBBYING REGULATIONS AND RESTRICTIONS

Lobbying has had a prominent presence in American government since the nation's earliest days. (In the late 1700s, veterans of the Revolutionary War petitioned Congress for reimbursement of personal funds expended on the war effort. See Byrd 1989.) As citizens of a representative government, Americans have the right to let their legislators know how they feel about laws, bills, policies, and nominees for positions in government.

That said, lobbying carries what one historian has called a "somewhat sinister and pejorative connotation" (Maskell 2001, sec. 2). Of course, this connotation has to do with improper behavior between lobbyists and public officials. Regrettably, lobbying holds a great potential to result in preferential treatment. Impropriety in lobbying has been described in the most severe of terms, including unsavory, corrupt and contaminated, and reprehensible.[1] Certainly, records provide ample documentation of lobbying abuses, describing the frequently tawdry, occasionally startling, and too-often-successful attempts of lobbyists to win favor with legislators and other public officials (Byrd 1989).

The Lobbying Disclosure Act

The U.S. Congress's answer to lobbying corruption has consistently been regulation, with the first attempt instituted in 1876 (Byrd 1989). The most recent overhaul of lobbying regulations occurred in 1995 with passage of the Lobbying Disclosure Act. This law requires lobbyists to register, disclosing such information as the organization(s) they represent and the issues they are addressing. In addition, twice a year lobbyists must file reports updating this information and adding estimates of how much money they will spend. An organization that engages in lobbying—whether using members of its staff or board of directors as its lobbyists or employing lobbying consultants—may be exempted from registration if it meets minimum thresholds related to money expended, time invested, and number of lobbying contacts made with public officials. Lobbying, it should be noted, requires serious record keeping, whether registration is necessary or not.

IRS Restrictions on Nonprofits

> This topic [lobbying by nonprofit organizations] often results in two extreme actions—some people warn that if your organization does any lobbying you risk losing your tax-exempt status with the IRS. Other people don't exercise enough caution and do put their organization at risk with the IRS because they don't understand the restrictions on lobbying that pertain to their non-profit. So what is the answer? Can we or can't we lobby? The answer lies somewhere in the middle. (Community Health Assistance Resource Team n.d.)

As the above quotation shows, lobbying by nonprofit organizations is an area in which there is much confusion and misinformation, especially for small nonprofits without the funds to hire professional lobbyists. For example, the staff at the Independent Living Research Utilization Program in Houston, Texas, have been providing technical assistance in the field of independent living for nearly 30 years, and one question they have been asked innumerable times is, "Can a center for independent living do lobbying?" One can easily replace "center for independent living" in this question with descriptions of other kinds of organizations, such as a counselor association, parent group, university, physical therapist organization, or hospital. The answer is always the same: "Yes, of course, but . . . ." And this is followed by the advice, "Be sure to run your plan of action by an attorney who specializes in lobbying."

A careful reading of the IRS rules pertaining to lobbying activities by nonprofits may reduce the confusion and misinformation to some degree. The rules make it clear that lobbying is entirely appropriate, given certain caveats such as the following:

- Federal funds may not be used for lobbying (Office of Management and Budget n.d.).
- A 501(c)(3) organization may not be involved in political campaigns (such an organization is "absolutely prohibited" from either direct or indirect participation) (Internal Revenue Service 2004).
- The lobbying activities of a nonprofit must not constitute a "substantial" portion of its total activities (Internal Revenue Service 2004).

The penalties for violating these restrictions are severe: An organization may lose its tax-exempt status, its income may be subject to tax, and penalties may be imposed against the organization's officers having complicity (Internal Revenue Service 2004).

Are there conditions under which the IRS considers it acceptable for a nonprofit to advocate strongly for its beliefs? Yes, as specified in this IRS (2004) statement:

> Organizations may, however, involve themselves in issues of public policy without the activity being considered as lobbying. For example, organizations may conduct educational meetings, prepare and distribute educational materials, or otherwise consider public policy issues in an educational manner without jeopardizing their tax-exempt status.

A POSITIVE LOOK AT LOBBYING

Much of this entry has covered the negative aspects of lobbying—as action that is morally corrupt or as action that jeopardizes the existence of an organization. There is another side to lobbying, however; lobbying is often a laudable activity undertaken by people committed to improving our way of life. The following illustration, taken from the arena of disability rights during the 1998 reauthorization of the Rehabilitation Act,[2] is provided to show how lobbying has been used to improve law, to expand opportunities for consumers with disabilities to live more independently, and to protect the civil rights of these consumers.

Background. In 1986, Section 508 was added to the Rehabilitation Act. It requires governmental departments and agencies to use accessible equipment when creating, duplicating, and sending information. This includes computers, copiers, faxes, telephones, and just about everything used in a modern office. The problem, as seen by disability rights advocates, was that Section 508 had no enforcement provisions, making it nonbinding, and compliance was not overwhelming (Association of Tech Acts Projects n.d.).

Desired changes. Members of a number of organizations active in the disability rights movement wanted to take advantage of the Rehabilitation Act's 1998 reauthorization to have Section 508 strengthened in three respects: by requiring development of standards of accessibility that all equipment must meet, by permitting individuals to file complaints and lawsuits against noncompliant departments and agencies, and by applying these two conditions to state governments.

Government activity addressed. Disability rights advocates wanted very badly to influence the writing of the law so that Section 508 would be enforceable. And just as ardently, they wanted to influence the procedure by which the compliance standards would be prepared so that the access needs of people with visual impairments, mobility impairments, and cognitive impairments would be met. And, because members of the entity given responsibility for preparing the standards (the U.S. Architectural and Transportation Barriers Compliance Board) were presidential appointees, they wanted to influence who was nominated for membership so that people who truly understood accessibility barriers would be selected.

Outcome. Under the principle of "win some, lose some," Section 508 was strengthened through the inclusion of enforcement provisions and establishment of sound access standards; however, its enforcement coverage was extended only as far as the federal government and not to state governments as disability advocates had wanted.

At the same time lobbying activity was being undertaken to address Section 508, other organizations of people affected by and/or working in the disability and rehabilitation fields were taking action to address *other* sections and titles of the Rehabilitation Act. For instance, it is likely that associations of rehabilitation counselors wanted to increase training programs under Title III, that advocates of supported employment wanted to strengthen and ensure continuation of that program under Title VI, and that researchers wanted to increase funding under Title II. (The National Council on Independent Living, for example, had its excellent reauthorization position paper written and circulated among legislators more than a year in advance.) This is the American system of lobbying at its best.

IN CLOSING: LOBBYING AND ONE'S DUTY

When considering lobbying, Americans need to remember that lobbyists are exercising rights that are guaranteed to all persons living in the United States, particularly those rights assured under the First

Amendment regarding speech and petition (Maskell 2001). Nearly a hundred years ago, the 11th edition of the *Encyclopedia Britannica* included a discussion of citizens' involvement in lobbying, observing that "people who are most intimately concerned naturally have a right to appear before the legislature or its representatives, the committee in charge of the bill, and present their side of the case." Indeed, who better to advise Congress on legislation, policies, and programs that increase opportunities for people with disabilities than those who have spent a lifetime in support of disability rights? It is the right, privilege, and, some would say, the duty of citizens to take part in the development of public policy.

—Laurel Richards and
Lex Frieden

LOHSE-WÄCHTLER, ELFRIEDE (1899–1940)

German painter

Struggles, crises, and catastrophes characterize the biography of painter Elfriede Lohse-Wächtler, whose work the Nazis condemned as degenerate in 1937 and was first rediscovered at the end of the 1990s. Born on December 4, 1899, in Dresden, Elfriede Wächtler grew up in a lower-middle-class family. During her studies at the renowned Dresdner Königliche Kunstgewerbeschule (Dresden Royal Art Academy) in the department of fashion and applied graphic arts, she moved into a studio in 1915 that became one of the main meeting spots for modern artists in Dresden. There she began to paint and draw using a variety of techniques—the beginning of work that spanned expressionism, verism, and New Functionalism. She could not survive off the income from her artwork alone, as it earned her only little money. In 1921, she married the painter and singer Kurt Lohse, and in 1925 she moved to Hamburg to be with him. The marriage was marked by frequent moves, economic difficulties, and Lohse's infidelity. The definitive break came in 1929, with the divorce occurring at Lohse's instigation in 1935 "due to incurable mental illness."

The years 1925–1931 were Lohse-Wächtler's most intense creative period and included a few public exhibitions. At the same time, her health grew increasingly worse. In 1929, she was admitted to the psychiatric state institution in Hamburg-Friedrichsberg for two months because of paranoia. After her release, she showed her portraits of fellow inmates in a successful exhibition titled Friedrichsberger Köpfe (Heads of Friedrichsberg). Isolated and impoverished to the point of homelessness, she created primarily (self-)portraits, nude studies, and milieu studies in 1930 and 1931. Without means and exhausted, she returned to her parents' house in 1931, and her father subsequently had her admitted to the regional psychiatric institution in Arnsdorf. There she was diagnosed with schizophrenia, a diagnosis that is disputed today. Although her confinement left her in a state of despair, Lohse-Wächtler continued her artistic work until she was forcefully sterilized on December 20, 1935, despite her own and her family's enraged resistance. On July 31, 1940, Elfriede Lohse-Wächtler was "transferred" out of Arnsdorf to the NS-"Euthanasia" Institution in Pirna-Sonnenstein, where she was murdered.

LÜ K'UN (1536–1618)

Chinese scholar and administrator

Lü K'un was a forward-thinking senior administrator in Northern China who worked to establish institutions that would relieve poverty and encourage self-help among aged or disabled people: "For those among the last who were not too young nor too old he prescribed training in skills like basketry or the braiding of mats" (Goodrich and Fang 1976). Lü also invested time and effort in didactic writing and publication to guide the masses toward better health and improved agriculture. He encouraged careful record keeping by physicians and government officials, so as to improve their practice. His particular concern for blind people arose from his mother's many years of blindness. "Lü ordered the officials of each city to train the blind in a profession such as music, singing, storytelling, and fortune telling" (Goodrich and Fang 1976). He had no personal faith in fortune-telling, yet he "compiled a simple textbook from which the younger people among the blind might be orally taught" (Goodrich and Fang 1976). These were innovative attitudes and practices in his time, with some parallels to contemporaneous social thinking in Western Europe.

LUTHER, MARTIN (1483–1546)

German church reformer and scholar

Martin Luther, the German church reformer, polemicist, scholar, and pastor, is linked in some disability literature with an oral suggestion about killing a severely disabled boy who was considered not human but a changeling—that is, a devil exchanged for a child (LW 54:397). The report comes from a source notorious for editing and altering some of Luther's conversations (LW 54:ix–xxiii), yet Luther's writings do underline his belief in satanic powers of deception (LW 3:244; 24:74–75; 26:190). The "changeling" idea may derive from academic constructions, mistakenly attributed to folklore. Luther's much-loved personal assistant through most of his working life was a man with mild disabilities, Wolf Sieberger. Luther strongly advocated the inclusion of deaf or disabled people in church life. He believed that their spiritual qualities are in no way impeded by their physical condition (LW 30; 54:460; 35:110–111; 45). An overview of evidence suggests that Luther's attitudes and practices toward disabled persons were largely positive, although some of his views may seem strange in the twenty-first century.

LUXEMBURG, ROSA (1871–1919)

German revolutionary and journalist

The German socialist, revolutionary, and journalist Rosa Luxemburg was born on March 5, 1871, in the province of Zamosc in Russian-occupied Poland. She came from a Jewish family. After acquiring an illness at age five, she walked with a limp. In addition, she was noticeably small. Even as a young student, Luxemburg was active in politics. After fleeing Poland, she studied economics in Zurich and received a doctorate in political science. In Zurich she also became acquainted with Leo Jogiches, who became her lifelong companion. She obtained German citizenship through a sham marriage with another man.

From 1898 on, Luxemburg lived in Berlin, where she quickly became one of the most important politicians of the Social Democratic Party of Germany (SPD) and the left-wing party's leading representative. In spite of her disability, she undertook exhaustive election campaigning, gave rousing speeches, lectured at the party school, and positioned herself as an outstanding journalist, uncompromising—although her work was eventually futile—in her stances against war and for international solidarity. During this time she was the subject of numerous personal attacks. Her opponents—as well as members of her own party—attacked her heritage and her appearance, reviling her as a "small, ugly Jew." Luxemburg spent the majority of the World War I period in prison, with her feelings fluctuating between resignation and hope. Deeply disappointed with the SPD, in 1918 she became one of the founders of the German Communist Party (KPD). Right-wing Freikorps officers murdered Luxemburg (together with her fellow KPD member Karl Liebknecht) on January 15, 1919, in Berlin during the height of revolutionary unrest. Her corpse was first discovered months later in a Berlin canal and was buried in June 1919 at the behest of a highly sympathetic populace. Perhaps the most-often quoted statement from Luxemburg's work is this: "Freedom is always and exclusively freedom for the one who thinks differently."

M

▣ MACE, RONALD L. (1942–1998)

American architect

Ronald L. Mace was a design visionary whose life as a disabled person influenced the focus of his life's work and shaped the genius of his architecture and product designs. He was a driving force behind the creation of the first accessible state building code in the United States (in North Carolina) in 1973 and in the drafting of national accessibility codes and standards. He later coined the term *universal design* to capture and promote his expanded philosophy of "design for all ages and abilities," which applies to all aspects of design—architecture, landscape, graphic, and product design.

Mace contracted polio at the age of nine and subsequently used a wheelchair for mobility; he personally experienced how inaccessible environments limit a person's ability to participate in the world. After graduating from North Carolina State University School of Design in 1966, he was the first to put a human face on access guidelines by using well-rendered, human-centered illustrations. Mace and his consulting firm, Barrier Free Environments, did pioneering work in accessible, or barrier-free, design focused on improving accessibility in the built environment so that disabled people could participate in the life of their communities. In 1988, Mace was named a Fellow of the American Institute of Architects for that groundbreaking work. He was also influential in drafting the 1988 Fair Housing Amendments Act and the 1990 Architectural Guidelines of the Americans with Disabilities Act, which require basic accessibility in the built environment for future generations. In 1992, he was honored with the Distinguished Service Award of the President of the United States for promoting the dignity, equality, independence, and employment of disabled people.

In his training of architects and designers around the United States, Mace emphasized that accessible designs make life easier for everyone—curb cuts being his favorite example. As his vision expanded, the North Carolina State University Center for Accessible Housing, founded in 1989, became the Center for Universal Design to reflect its expanded work in promoting the integration of the principles of universal design into all aspects of the design profession. Shortly before Mace's death on June 28, 1998, on the occasion of the first international conference on universal design, he was honored by designers from all over the world who had embraced his vision of designing for all people.

MACKENZIE, CLUTHA (1895–1966)

New Zealander blind activist

Clutha Nantes Mackenzie spent his youth in New Zealand as a farmhand and sailor, though his father was a senior politician and diplomat. Clutha lost his sight in 1915 during a World War I battle in Turkey. He went to St. Dunstan's in England for rehabilitation and practiced writing and magazine editing. His future wife, Doris, was a St. Dunstan's volunteer. Clutha returned to Auckland, New Zealand, and worked from 1923 to 1938 managing the Jubilee Institute for the Blind, fund-raising and campaigning for blind people to live independently. His autocratic style caused some problems, but his work was successful and he was knighted in 1935. His international career included lecturing and fund-raising across the United States, then six years in India, where he opened St. Dunstan's Center at Dehra Dun in 1943. He held a special government post to study and report on blind education and employment, and engaged in battles to determine which form of Braille would be adopted in India and internationally. In 1947, he toured China, producing a substantial report on blind people there. He advised other Asian countries, reported on blindness in Turkey in 1952, and a few years later was mobilizing services for blind people in East Africa. Clutha retired to New Zealand in 1958.

MADNESS AND MENTAL DISTRESS

While Western understandings of disability have been subjected to fundamental reassessment in recent years, the medicalized individual model of "mental illness" continues to dominate mental health policy and practice internationally. It still shapes public understandings of "mental health" and governs the lives and experience of many mental health service users. In contrast, mental health service users/survivors and their organizations are increasingly expressing their concerns about medicalized individual models of "mental illness" and framing their experience in different terms. Yet traditional "mental illness" understandings of their experience seem, if anything, to be gaining ground. They have been exported to the majority world. They have been reinforced by the introduction of a new "recovery" model for mental health services developed in the United States.

THE MAINTENANCE OF MEDICAL DOMINANCE

The number and range of psychiatric diagnostic categories continues to mushroom. These increasingly cast broad socially related issues in medicalized terms, for example, attention deficit/hyperactivity disorder (ADHD) and posttraumatic stress disorder (PTSD). The needs of a growing range of groups, notably children and young people and older people, are being framed in psychiatric terms. While making clear that it cannot "treat" them, psychiatry has also categorized a growing range of people and behaviors under the heading of "personality disorder." Some of these are closely associated with violence and homicide. This has reinforced traditional associations of mental health service users with dangerousness, which has resulted in pressure for increasing restrictions on their rights, most notably in North America and the United Kingdom.

A growing focus on and recent developments in genetics, the neurosciences, and pharmacology seem to have confirmed the ascendancy of the natural sciences in this field as the key source for understanding, interpretation, and "treatment" of "mental disorder." Doctors are still the most powerful professionals operating in this area. Understanding mental disorder in terms of physical processes fits with the large-scale use of drugs as the main and routine response to people's difficulties.

One of the consequences of the development of organizations and movements of mental health service users/psychiatric system survivors since the 1980s has been the emergence of new challenges to and new critiques of conventional medicalized understandings of "mental health." These have been qualitatively different from previous critiques of the dominant paradigm, such as "antipsychiatry" and the "social constructionism" of sociologists, which have tended to come from dissident professionals, competing professions (e.g., psychology), and related academic analysts. These new challenges have been based primarily on service users'/survivors' understandings of their own experience—their experiential knowledge.

It is important to emphasize, however, that so far, no equivalent of the social model of disability has been developed among mental health service users/survivors that could provide a systematic and philosophical basis for their activities. While it is still a focus for much debate and controversy, the social model of disability has offered disabled people just such a coherent basis for their philosophy, self-organization, and collective action, reflected in their focus on rights and independent living. The social model of disability, however, has not as yet adequately been extended to address and explain the related, but also distinct, issues facing mental health service users/survivors. Thus, while "mental health" issues and the situation of mental health service users/survivors have sometimes been incorporated in the social model of disability by its proponents, so far this model has not been accepted widely by mental health service users/survivors as providing a satisfactory conceptual framework for their experience.

It is not clear why, as yet, mental health service users/survivors and their organizations have not developed a coherent alternative to the medicalized model of "mental illness." While the latter may be the only model for understanding with which many mental health service users/survivors are familiar, there also seems to be an unwillingness on the part of many activists to develop an explicit alternative. One view is that this may be linked with fears that to do so would be interpreted from outside as an attempt to deny their difficulties or difference and lead to their being further marginalized as lacking in insight and rationality.

Mental health service user activists have tended not to challenge the dominant medicalized framework explicitly. They have themselves frequently continued to operate within a framework of terms such as *mental health, mental health problems, difficulties,* and *issues.* However, they have also shown a growing unease with the traditional medicalized model, particularly as it has been linked with an increasing emphasis on social control and the extension of restrictions on mental health service users' rights and freedom.

For a growing number of mental health service user activists, the inherent problem with a medicalized approach to "mental health"—even the descriptor is itself medicalized and value laden—is that it is based on a *pathologizing* construct. The underlying construct that dominates "mental health" policy, provision, practice, and service users is one of "psychopathology." It is possible to be persuaded that this is not the case, because terms such as *mental illness, mental disorder,* and *psychopathology* are less often and less explicitly used nowadays. But the origins and meanings of the terminology remain unchanged. The legal base that operates tends to be the same. Law and policy rest on the premise that there is something "wrong" with the person. He or she is "ill." The individual's experience, behavior, perceptions—the person *him-* or *herself*—is pathologized. This is how people also come to understand themselves as mental health service users.

DEVELOPING ALTERNATIVE APPROACHES

The lack of a clear and agreed-upon conceptual framework has not stopped mental health service users and their organizations from developing their own alternative culture, discourses, and schemes for support. These have generally been based on nonmedicalized models, highlighting a holistic, complementary approach to providing support for mental health service users/survivors. Such schemes have placed an emphasis on peer and self-advocacy, self-defined needs, self-education, self-management, and self-support. They have led to the development of self-run crisis houses and refuges, survivor-led supported housing schemes, environmentally friendly employment, training and skill exchange schemes, programs employing mental health service users as mental health workers, crisis cards and advance directives, mutual aid and self-help support groups, and peer counseling. However, the lack of a clear and agreed-upon philosophy underpinning these developments has sometimes made it difficult for service users/survivors and their organizations to avoid being co-opted and their goals and ideas subverted by dominant medicalized service systems and their agendas, with which they have frequently worked in close association.

Mental health service users/survivors and their organizations have also developed their own alternative terminology, framed in terms of "madness" and "mental distress" rather than "mental health" or "mental illness." Survivors' use of terms such as *mad* and *distress* seems to reflect a desire both to move beyond the medicalized individual understanding of their situation and experience and, in the case of *mad,* also to reclaim language that continues to be used to marginalize and demean them. *Mad* is just one of a constellation of pejorative terms used to describe mental health service users and the behaviors associated with them—a constellation that includes terms like *loony, crazy,* and *nuts.* Such terms are also still used widely in popular discussion to mean weird, frightening, outlandish, unpredictable, and irrational.

MADNESS AND DISTRESS

In different cultures and historically, madness has been interpreted and understood in many different ways. It has been associated with magical powers, the supernatural, divine intervention, possession by the devil, violence, irrationality, spirituality, and special gifts and insight. It has been seen in both negative and positive terms. If once it was treated in the West as a condition of the whole person—body, mind, and spirit—more recently it has generally been diagnosed as a disorder of the brain. Responses have been spiritual, secular, and morally based, according to the society in which madness is identified, based on both superstition and elaborate theories. It has also long had a parallel embodiment in the law, in terms of "insanity," "incapacity," and "lack of responsibility." Such legal status has served both as a basis for taking control of people's money, goods, and affairs and for the imposition of "treatment" regimes, including confinement, restriction of rights, and compulsory "treatment."

Mental health service users/survivors have yet to develop their own clear and agreed-upon definitions of *mad* and *distress,* although the terms have come to be widely used within their movement. Members of Mad Pride, a U.K. survivor network that organizes events and direct action and also produces publications, highlight their pride in being mad. This pride may be in being different, in surviving madness, in surviving the mental health system, in having unusual sensitivities or capacities, in having capacities to an unusual degree, or in having a different way of life or approach to life—an approach that may be unconventional or anarchic, open to a wider range of experiences, or experienced more intensely.

Madness can be viewed as an equivalent of "psychosis," although not all survivors would be happy with the concept's being appropriated in this way. As mental health service users/survivors discuss it, madness may have many expressions. It may be a one-off experience, episodic, or long-term. In all these cases, people may report positive aspects of their madness. They may value their experience and perceptions, discovering helpful aspects, for example, to hearing voices or learning how to live with them. They may feel that their positive qualities and abilities are linked with and inextricable from the fact that they experience madness. Such experience, however, may also be negative and costly, restricting what people can do, linked with difficult and painful thoughts and feelings and associated with crises and problems.

Mental health service users talk about both "mental" and "emotional" distress. Such distress is associated with pain, sorrow, and anguish. It is difficult to conceive of distress as a positive, although it may be seen as part of a learning process, or as a predictable human response, for example, to loss and bereavement. Anxiety and depression are two common expressions of such mental distress. Distress may be a short-term/crisis event or a long-term state. People may also experience physical distress. A distinction may need to be drawn between mental and physical distress, but it is also possible that one may be interlinked with the other.

Mental health service users/survivors have a tendency to combine the two terms *madness* and *distress* when they are seeking to offer their own conceptualizations of their identity and situation. This seems to relate to a sense that neither term adequately carries the full range of experience and meanings that they wish to convey (and that are associated with being on the receiving end of mental health services). Just as distress may not always be "maddening," so madness may not always be distressing. Thus, "madness and distress" may represent a single construct rather than two. It is important to take account of this, because there is some tendency to treat "madness" and "distress" as mirroring traditional medicalized psychiatric and psychoanalytic concepts of psychosis and neurosis.

Treating the two sets of terms as interchangeable in this way is unlikely to be helpful or accurate. One of the aims of survivors in developing new language has been to challenge rather than retain traditional categories. Treating "madness" and "distress" as distinct and separate categories is likely to reinforce existing (unhelpful) distinctions between the worried well ("us") and the mad ("them" and "other"). The terminology of mental health service users/survivors is intended to be inclusive rather than divisive. In this, it reflects the same concern as that expressed by many members of the disabled people's movement, to avoid being "impairment specific," or, in this case, to privilege diagnostic categories and to focus instead on shared concerns and common processing.

It is also questionable whether there are clear boundaries between ideas of "madness" and "distress" or "distress" and "madness" that could demarcate a distinct group of mad people or madness. The boundaries are likely to be as imprecise and socially constructed as those that relate to perceptions of physical and sensory impairment. It is also helpful to remember that the terminology of mental health service users has an underlying political purpose. The term *psychiatric system survivor* highlights this. It was developed to emphasize that what individuals in this group have in common is primarily their (frequently oppressive) experience and (hopefully) survival of the psychiatric system.

THE EMERGENCE OF A NEW SOCIAL MODEL

Mental health service users/survivors and their organizations are showing increasing interest in the social model of disability. This seems to relate to their growing focus on the barriers and restrictions to their rights they currently face. These do not seem to be diminishing significantly and in some cases are experienced as increasing. Mental health service users/survivors experience disproportionately high levels of poverty, unemployment, homelessness, and social isolation. They are subject to high levels of stigma, institutionalization, and imprisonment. In Western societies, black and minority ethnic mental health service users/survivors face additional discrimination and disadvantage. Policies of psychiatric decarceration (without the provision of adequate alternative support services) have led to political pressure internationally for the extension of restrictions on mental health service users'/survivors' rights and compulsory "treatment." This provides the context for their growing interest in a "social model of madness and distress."

The terminology of "madness and distress" provides a helpful nonmedicalized framework for a social model. Such a social oppression/barriers approach to understanding "mental health" represents a break with traditional social approaches. These have tended to focus on social factors in the generation and conceptualization of "mental health problems" rather than on social oppression. Discussion of a social model of madness and distress is still at a relatively early stage, but it has already highlighted two issues that need to be addressed. First, some mental health service users/survivors do not see themselves as having any kind of "impairment" or equivalent. They may not accept the idea of "madness" as a discrete, objective state, or they may reject the idea of it as a negative or a problem. Instead, they interpret madness as essentially a consequence of societal responses to particular people, perceptions, or situations. The view of some disabled commentators that impairment may most helpfully be understood (like disability) as socially constructed—as *perceived* impairment—may offer a helpful way of taking account of this viewpoint.

Second, some mental health service users/survivors have emphasized that psychiatric labels and diagnostic categories have traditionally been attached not only to people whose behavior is seen as pathological, defective, or different but also to those whose behavior, perceptions, or attitudes are defined as deviant, dissident, or nonconformist. Demonstrating compliance (rather than resistance) continues to be an effective way for service users to be seen as getting "better" or "recovering." It is important to note, for example, that some women's sexual behavior and the sexuality of gay men, lesbians, and bisexuals have until recently been formally and specifically identified and "treated" in the West as forms of psychopathology. This had an extreme expression in the former Soviet Union, where political dissidents were consigned to the psychiatric system.

Thinking about a social model or approach to madness and distress is still at an early stage, and it would be wrong to suggest that as yet any clear or agreed-upon definitions have been developed. Such discussion is, however, developing. Such a social model is likely to be located within the framework of a social model of disability that is extended to accommodate it. Its increased adoption is likely to have at least three significant effects. First, judging from the experience of the social model of disability, such a social approach to understanding is likely to alter the focus in mental health policy and practice and among mental health service users/survivors. It is likely to shift it from a preoccupation with individual deficiency and blame to broader social concerns. It will draw attention to restrictions imposed on mental health service users' rights and the barriers and discrimination they face—which medicalized responses have generally failed to do. It is also likely to encourage reconsideration of "mental health" issues in terms of (ongoing) support and "independent living" rather than in terms of "treatment," "cure," and "recovery."

It is also to be expected that if it is possible to develop such a social model, which carries credibility and consensus among mental health service users/survivors, it will offer them (in the same ways as the social model of disability has helped disabled people) a clearer and more consistent philosophical basis for their activities and resources. This is important given the limits of such resources and the resistance of the psychiatric system to reforming its tendency to incorporate and tokenize the efforts of service users/survivors working in partnership with it. A social model of madness and distress is also likely to strengthen links and understandings between mental health service users/survivors and other disabled people, as well as increase the sensitivity of mental health policy to social model–based disability policy. On this basis, the concept of madness and distress can be expected to have increasing currency and significance.

MAINSTREAMING

The term *mainstreaming* emerged within the educational jargon associated with the 1975 Education for All Handicapped Children Act (EHA, P.L. 94-142), the early U.S. legislation subsequently reauthorized as the Individuals with Disabilities Education Act (IDEA) in 1990. Mainstreaming was a component of the principle of the least restrictive environment (LRE) clause of the EHA, which aimed to promote the social acceptance of students identified for special educational services. However, the context was one in which students identified as needing special education services were typically removed from the general education classroom and, depending on need, reassigned to resource rooms for 21 to 60 percent of the school day or to disability-specific classrooms when student needs exceeded placement for more than 60 percent of the school day. Students with mental retardation were placed in an MR class, those classified with educable mental retardation were assigned to an EMR class, those with emotional disturbance (as per the vernacular of that era) were assigned to an ED class, those with health impairments were placed in an OHI class, and so forth. These labels—*Resource, MR, EMR, ED, OHI*—were affixed to classroom doors in much the same way other doors read *First Grade, Second Grade, Library,* and so on. In turn, this context normalized practices such as placing students beside placards that read "Resource Class," "MR Class," "OHI Class," and the like when they posed for their annual class pictures. Likewise, students became known as LD, MR, or ED students. Despite early warnings by a handful of special educators about the negative effects of the overuse of labels, most general and special educators seemingly viewed the labels as nothing more than benign markers—mere terminology formulated through the legislation of the EHA.

Decades would pass before the critical insights of scholars exposed the language of special education as a powerful mechanism that enforced subjectivities associated with assigned labels and the presumption of stigma. Although touted as a policy that guaranteed all students would have access to the least restrictive environment, this naive interpretation of the law became a controversial and contested practice by both general and special educators.

AIMS AND INTENTIONS

The vexed meaning of mainstreaming was compounded by the ambiguities of the EHA and the subsequent state and local interpretations that followed. Moreover, the EHA had unwittingly authorized the creation of two separate systems of education (which continue today), each with its own funding structures, policy and practice standards, and, most critically, distinct teacher preparation programs. In practice, the aims and intentions of mainstreaming were difficult to articulate as the goals that were established quickly proved antithetical to the everyday demands of schooling. Special education advocates urged a three-pronged approach to mainstreaming in which physical, social, and academic considerations would be merged. Thus, a disabled student would have access to receive his or her education in proximity to the *place* where other students received their education—regardless of the child's disability. *Place* was clarified as meaning the same building and same neighborhood school, regardless of its population as a preschool, elementary school, junior high school, middle school, high school, or technical school. *Social* suggested participation in the common social activities of the school in nonacademic settings, including interactions in the hallways, cafeteria, library, and playground—that is, interactions within the general social milieu of the school. The third prong of mainstreaming was specific to instruction and the general curriculum. During the 1970s, the general education curriculum was less restricted by mandates for standardization of instruction and educational outcomes than is the current curricular context. It was argued then that because students in regular classes are not all taught the same things at the same time, modification of the nature, method, rate, and procedures was commonplace for all students, and, hence, it was equally an option for students identified with special needs.

In practice, general educators rarely considered these integrative criteria, as mainstreaming proved antithetical to the everyday demands of schooling. Instead, the return of special education students to the general education setting was authorized only on the condition that the students demonstrate the "right" to return. The motivation for this approach to mainstreaming was bureaucratically driven—it was a means to ensure that general education teachers would not be stressed by the demands of disabled students who, as a consequence of mainstreaming, might jeopardize the learning of nondisabled students. A rights discourse soon emerged, but it was one that pitted the rights of the general education students against those of special education students. Fear led to educators' claims of "injustice" and imagined harm inflicted on the rest of their students as a consequence of the perceived negative impact of mainstreamed students. Moreover, citing the lack of credentials, general education teachers claimed they were ill prepared and actually unable to accept disabled students back into their mainstream classrooms. Arguing to these same ends, professional teachers' organizations warned their members to be on guard against the "hazards" of mainstreaming. In 1975, the same year the EHA was authorized by Congress, the president of the National Education Association described the "plight" of a teacher who is "suddenly and for the first time presented with a blind child, a spastic, an emotionally disturbed child—or even all three—as additions to the 40 'normal' students" (quoted in "NEA Warns" 1975). The NEA urged its members to support mainstreaming only if the plans in their districts met several specifications that guaranteed a "favorable" learning experience for both handicapped and nonhandicapped students.

Implicit within this debate was the belief that the learning problems of disabled children stemmed from individual pathology rather than from instructional or institutional pathology. For the most part, general educators held firm to the belief that despite procedural safeguards, the general education setting was not an appropriate place for disabled students, arguing, "If they can't do the work, they don't belong here."

PROCEDURES AND PRACTICES

Mainstreaming proved to be one of the many paradoxes associated with the implementation of the EHA. Because special education was mandate driven, policy heavy, and procedure intensive—and thus a highly bureaucratized approach to education—legislation, litigation, and fiscal concerns easily diverted its educational aims. Compliance with the law focused on the formulation of paper trails to document adherence to the letter of the law. Meanwhile, the spirit of the law became increasingly more illusory. Mainstreaming was a sort of no-man's land, ill defined and poorly articulated by both general and special educators, in which neither would agree to assume responsibility for the mainstreamed student. After a tremendous investment of effort toward the identification, assessment, referral, and placement of students into special education, neither general nor special education teachers were persuaded by the logic of orchestrating these students' return to general education. Once a student was identified with special education needs, he or she was removed from the general education classroom in order to receive "specialized" instruction in separate self-contained classrooms with specially trained teachers. The processes of identification, assessment, referral, and placement, although hailed within a rights discourse of "hard-won educational access," in fact often resulted in restricted access to general education. It was paradoxical that once a student was physically relocated to special education, his or her "right" to return to general education was authorized only on the condition that the student demonstrate the ability to meet the existing academic goals in place for nondisabled students.

Another related paradox emerged as educators questioned why a student would want to return to general education if his or her academic success was all but ensured in special education through the development of an individualized education program (IEP). Identified students received their education in what was often characterized in the special education literature as a "learning-intensive environment." The norm for this setting included small class sizes, specialized instruction, paraprofessional support, modified curriculum, and prescriptive technology targeted to meet individual student needs. This learner-centered setting stood in opposition to the teacher-centered general education classroom, which was neither intimate nor individualized. In fact, this was a persuasive selling point, both for the recruitment of special educators and for the parents of identified students, who tended to overlook the isolation their children would experience in separate self-contained classrooms. Moreover, because instructional remediation was predicated on a positivist approach to intervention, with treatment aligned to a medical model, it was assumed that this more "scientific" and "prescriptive" approach to learning would promote "individual" gains in ways uncommon to general education.

Indeed, the approach to learning in special education was one in which tasks were broken down into various component parts, each of which was then indexed in a hierarchy of simple to complex learning objectives. Students moved through the learning of bits of discrete knowledge on the assumption that more complete learning would result from this incremental approach. Exclusively behavioral models for learning—including task analysis, direct instruction, drill and practice, and rote memorization—formed the core of special education instruction. Accompanied by the use of reward systems and token economies, these practices reinforced the view that student learning in bits and pieces took precedence over contextualized learning within a broader holistic and emancipatory framework. The pedagogy, methodology, and learning context in special education and that common to the mainstream setting proved to be worlds apart.

Government-sponsored research on effective educational practices was another legitimating force that helped to shape the chasm between general and special education. Federal dollars allocated to university researchers privileged positivist methods over integrated and holistic approaches to learning, which in turn advanced a reductionist approach to learning and prompted calls for even greater specialization among professionals. Unwittingly, this government-sponsored research reified the belief that a "highly qualified teacher" is most capable of educating disabled students. Curiously, the link between the university-based researchers and their institutions' agendas specific to the expansion of their own teacher training programs was never questioned as a conflict of interest. The long-term effect of an overreliance on the traditional empirical research generated by many of the nation's largest academic programs in special education was the reinforcement of the beliefs that some students really *do not belong* in regular education and that some, but *not all,* teachers are responsible for all learners.

In time, this research fed the deeply entrenched attitudes that continue to divide general and special educators today. It is a belief that has proven to be one of the greatest obstacles to the inclusion of disabled students in public education. Ultimately, the goal of successfully mainstreaming identified students proved increasingly more difficult to realize as these students fell further and further behind their general education peers on both social and academic measures. The initial belief that identified students might eventually rejoin the mainstream when their learning deficits had been remediated was all but extinguished by shifting attitudes relative to who does and does not *belong* in the mainstream classroom.

MANAGED CARE

For persons with physical and mental disabilities, managed care presents both a threat and an opportunity. Persons with disabilities have much to gain from truly and responsively integrated managed care health delivery systems. However, persons with disabilities also bring atypical, complex, and, in many cases, long-term service needs that managed care organizations may be reluctant to address because of the increased clinical and financial risks these needs represent.

The origins of managed care can be traced to the late nineteenth century, when a small number of physicians in several U.S. cities agreed to provide prepaid medical care to members of fraternal orders, unions, and other associations of workers. The physicians gave the members of these organizations unlimited access to the health care services they provided in exchange for a small annual fee per member. In the early twentieth century, railroad, mining, and lumber companies organized their own medical services or contracted with medical groups to provide care for their workers. During the Great Depression of the 1930s, prepaid contracts between employers and employee associations were relatively common. Starting in the 1970s, the federal government and many large private companies began encouraging their workers to join prepaid forms of health care groups. Despite this encouragement, however, prepaid group practice grew slowly. In the mid-1980s, employers increasingly turned to managed care to contain the spiraling cost of providing health care benefits to workers. During the 1990s, managed care enrollments soared. Today, the vast majority of privately insured Americans, and a sizable fraction of those in the government-sponsored Medicare and Medicaid programs, are covered by some form of managed care.

Despite the large number of persons enrolled in managed care programs, it is difficult to define precisely what managed care is. The definition of managed care has changed significantly through time as the concept of managed care has evolved. Currently, managed care can be broadly defined as any organized system of health care that attempts to reduce or eliminate services that system representatives deem ineffective or unnecessary in order to hold down costs while at the same time maintaining high-quality health care. Most managed care is carried out in one of two basic types of health care organizations: health maintenance organizations (HMOs) or preferred provider organizations (PPOs).

Managed care organizations use a variety of methods of financing and organizing the delivery of health care to control costs. Specifically, managed care relies primarily on three strategies for success: selective contracting, innovative economic incentives, and utilization review.

To develop selective contracts, managed care organizations use health care claims data to compare the prices that different hospitals and physicians charge for the same treatments in order to identify the lowest-priced providers. In highly competitive health care markets with many providers, large managed care organizations with hundreds of thousands of enrollees can selectively contract with individual hospitals and physicians and receive substantial discounts for the provision of health care to their members. The providers are willing to give deep discounts to these organizations to avoid losing large numbers of patients. Providers also can retain or build a greater market share by giving these discounts.

Managed care organizations frequently provide innovative economic incentives to patients and physicians to encourage them to select less costly forms of health care. For example, organizations may require patients to obtain preauthorization before using hospital emergency rooms to receive care for specific conditions. They also may discourage patients from using higher-priced health care institutions such as costly teaching hospitals for routine care. To control costs, some managed care organizations, such as HMOs, put their physicians on fixed salaries. They can then adjust the salaries up or down annually based on performance, rewarding those physicians who contain costs and punishing those who do not.

To conduct utilization reviews, many managed care organizations have established their own sophisticated internal computer information systems that monitor provider prices and the quality of health care received by their enrollees. Many have also developed a variety of utilization review programs that include such elements as preadmission screenings (to determine whether a patient should enter a hospital or receive treatment elsewhere), surgical second opinions, and ongoing reviews of high-cost cases (such as patients with HIV/AIDS and those receiving complex cancer care).

Of the three strategies described above, the evidence to date clearly shows that selective contracting has been the most effective in lowering costs for managed care organizations. The evidence on innovative economic incentives is weaker, and evidence on the effectiveness of utilization review is virtually nonexistent.

Initially, managed care organizations targeted generally healthy populations, placing emphasis on maintaining health and preventing disease. Recently, however, managed care has moved into less traditional markets, including managing health care for individuals with chronic illnesses and various disabilities.

Managed care has the potential to be of great benefit to people with disabilities in comparison with traditional fee-for-service systems or typical government-sponsored programs. By its very nature, managed care tends to decrease or eliminate individuals' incentives to overuse services. It generally reduces patient out-of-pocket expenses and other financial barriers to health care. Managed care also has the potential to achieve better coordination of patient services. Given that most managed care organizations use the primary care physician to direct and structure the patient's total treatment, in theory the services provided should be more logical, customized, and prompt than they would be under other systems. Thus, under managed care, persons with disabilities should experience less frustration and confusion from splintered service provision, which can be commonplace in public programs. Managed care, through its use of internal computer information systems, also has the potential to monitor the quality of care and assess the performance of both individual patients and their physicians more efficiently. Finally, some managed care organizations provide transportation services for patients between their homes and the facilities where they receive care. These services may be vital for patients with major disabilities, especially those who live in areas without any public transportation.

Managed care also poses a number of formidable problems for people with disabilities, however. For example, managed care organizations may design and direct their marketing programs to attract only generally healthy populations. They may overtly and covertly discourage enrollment of individuals who are likely to be users of costly health care services. Because patients with disabilities may be frequent users of specialists and other high-cost medical services, managed care organizations may view them as undesirable patients.

As noted above, managed care organizations typically use primary care physicians as "gatekeepers" to control access to care. These physicians may not have the necessary experience or expertise to address the unique needs of people with diverse physical and mental disabilities. Further, they may not have the time or inclination to provide care to such patients.

With their emphasis on primary care and cost containment, managed care organizations may not provide people with disabilities adequate access to needed specialists who are qualified to diagnose and treat their special health care conditions. For example, managed care organizations may stop referrals to psychiatrists, who tend to provide more comprehensive treatment than other mental health professionals. In addition, the complexity of managed care organizations' referral procedures and complaint and grievance processes, and the materials that describe these aspects of managed care, may create tremendous barriers for individuals with cognitive or learning disabilities.

Because managed care organizations deal primarily with the needs of healthy people, they may use definitions of "medical necessity" that work against people with disabilities. For example, they may apply criteria that call for "substantial improvement" or "restoration of function" as conditions for the authorization of treatment, medication, or medical equipment. This may discriminate against individuals with certain types of physical or mental disabilities who cannot meet these standards.

Managed care organizations may have narrow short-term business perspectives that ultimately may result in decisions that harm people with disabilities. Because many of these organizations operate on a for-profit basis and so must generate an appropriate return on equity to their owners or shareholders, administrators may be under great pressure to hold down short-run costs. To do so, they may deny patients access to ongoing ancillary services, such as speech, physical, and occupational therapies, or they may withhold costly medical equipment from individuals with disabilities who truly need them. These patients may suffer in the long term because of these shortsighted decisions.

To date, no rigorous scientific evaluations have conclusively demonstrated that managed care has improved the quality of life or the health outcomes of persons with disabilities.

MATERNAL IMAGINATION

Maternal imagination is the concept that oddities in infants occur as the result of thoughts by the mother during parturition. Although the interpretation of maternal imagination as a root cause for birth anomalies does not wholly refute the idea of supernatural causation, it does signal a move toward scientific formulations of the etiologies for congenital disabilities. Any kind of parental blame spells difficulty for disabled persons, who may thus have their lives less welcomed than those of others. Maternal imagination is different, however, from the perception that corporeal differences are signs from a supernatural realm or harbingers of danger.

The theory of maternal imagination hinges on an understanding of women's bodies as highly susceptible to powerful external events, and tales about such susceptibility abound in the literature. According to such stories, a pregnant woman exposed to traumatic or highly sensitive stimuli can translate those impressions to the developing fetus. A pregnant woman who is startled by a frog, for instance, could imprint her impression onto the body of her child; that is, her child's body might manifest physical evidence of the event, such as webbed toes or fingers or a froglike head. A woman who gazes too obsessively at a portrait of Christ might be shown her excess by giving birth to a bearded child. Thus, perceived corporeal strangeness in the infant also reflects back to the mother a "lesson" concerning her affect and demeanor. Contemporary scholars discuss how explanations based in maternal imagination theory nonetheless bestow on mothers an extreme amount of control over the plasticity, form, and shape of their children's bodies. While the theory holds woman culpable for the appearance of congenital disability, it does usurp a small aspect of the patriarchal belief in the supremacy of male seed in the gestation process.

This early etiological theory of disability was most influential during the early European Enlightenment, which occurred from the late sixteenth to the early eighteenth century. Nonetheless, one can find similar theories of women's impact on parturition across histories and cultures. The early Latin story of Marulla and Cinna, who gave birth to seven monstrous children, provides a prime example of the adulterous mischief of mothers reflected in the strange aspects of their children, but it is not a matter of the sensibility or emotional experiences of a mother imprinting themselves onto a life-form. Instead, Cinna bears the blame for producing strange children by deliberately cavorting with one who is a "natural" and "black" or "red" children by crossing codes of color conformity: "Two sisters, one black, the other red, are Crotus the flautist's and Carpus the bailiff's. You would now have a troop as numerous as Niobe's, if Coresus and Dindymus had not been eunuchs."

Debates about the prevention of birth defects continue to emphasize the behavior and habits of the mother during pregnancy. Many environmental causes or congenital properties are assigned to maternal habits and modes of existence; for example, low birth weight in newborns is now frequently determined to result from maternal stress. Babies that are deemed to mix skin tones in racially polarized societies can be held out as a matter of maternal impropriety. In Third Reich Germany, German mothers of *mischling* children, whose fathers might be African, Jewish, or Romany, were publicly shamed and punished. The children themselves were frequently sent to institutions that participated in genocidal "cleansing" of the German "race."

Throughout the Renaissance and premodern period, "monstrous births" were often attributed to maternal imagination, although they were sometimes linked to other "mechanical causes," such as a narrow uterus or inappropriate sitting positions of gestating mothers. The stuff of bawdy songs and legend, such births were sensationally cataloged in publications called "wonder books." Fortuno's *Monstrum* (Italian, 1646) and Pare's *Of Monsters and Marvels* (French, 1585) contain well-known and quite remarkable examples. The wonder book collected instances of strange and unnatural occurrences for prurient audience interests in observing disability. These early Enlightenment books served to mediate between more metaphysical systems of disability interpretation implied by ideas about divine or satanic intervention in fetal developmental processes. While fanciful to a viewer from the twenty-first century, they indeed anchor developing empirical systems of medical observation. Wonder books served as transitional texts between supernatural explanations and more "naturalistic" explanations for what we recognize as congenital disability today, while unsure of any belief for supernatural purposes.

One perspective always absent from the wonder book was that of the "monstrous" individual—instead, each figured as a "marvelous" specimen. We can start to piece together a tradition of voiced commentary by subjects in dramatic and poetic traditions. In Shakespeare's *Richard III,* the protagonist contemplates his own birth predicament as "scarce half made-up." Abandoned at birth, Quasimodo, the title character in Victor Hugo's classic novel *The Hunchback of Notre Dame,* is sealed off from contact with other townspeople. In a journalistic interlude quoted verbatim by William Carlos Williams in his epic poem *Paterson,* George Washington visited a man with severe hydrocephaly to trade quips on late-eighteenth-century American politics. In each of these instances, an individual deemed a "monstrous birth" begins to give voice to a nuanced, self-reflexive perspective. Such entries in the Western literary canon also forward these perspectives as disruptive moments to competitive versions of the normalcy of a national "stock" in which early modern nations, with census taking of disabled persons, engaged.

The debate over maternal imagination as a reliable, scientific barometer for birth anomalies largely circulated around medical theorizing about the degree to which fathers could be held culpable for "disastrous" births. Marie-Helene Huet discusses these issues in detail in her book *Monstrous Imagination* (1993). If the theory of the supremacy of male seed provided masculinity with a controlling role in the course of pregnancy, then such an emphasis helped make male partners more central to procreation itself. However, such centrality in the reproductive process came with its own costs. If the birth of a disabled child was viewed as a "failure" or developmental mishap, to what degree did the male partner share the blame in such an event? Maternal imagination has been discussed as a desperate resolution to this conundrum without relinquishing men's centrality in pregnancy. A mother's influence over extreme birthing results would expand only during instances of congenital disability. In fact, as in contemporary examples of the births of disabled children, fathers often abandoned households after the births of children with medically remarkable distinctions. In this context, then, the idea of maternal imagination might be exculpatory for fathers in order to dissuade them from abandonment.

However, there have also been efforts—particularly among feminist critics—to interpret maternal imagination as an opportunity for reading women's expanding agency in their own reproductive lives. For instance, a value in the idea of inherited traits could go astray for a woman who gave birth to a child in whom a family resemblance was not forceful. This might be the situation, for instance, in cases of Caucasian women giving birth to racially mixed children or in cases of severe disability. In order to distance themselves from the social opprobrium of sex outside of marriage, women sometimes actively sought refuge in claims to maternal imagination. For instance, in one famous case, Marjorie Sheldrake, who gave birth to a "severely deformed" child in England in the mid-eighteenth century, argued against the charge that she had had intercourse with a man other than her husband by claiming maternal imagination. Given that she was scheduled to go on a trip to Australia after giving birth, Sheldrake claimed that images of kangaroos and other exotic scenes that she contemplated during pregnancy directly influenced the development of what would have been an otherwise paternally mimetic infant. While such recourse to the influence of exotic cultures may seem fraught with racial and cultural anxieties about difference, such arguments provided women with access to less severe forms of public disapproval and familial suspicion.

At root, the theory of maternal imagination developed as a reaction to widespread patriarchal suspicions that women's sexuality was untrustworthy. Because femininity's association with irrationality and embodiment led to explanations of female volatility, maternal imagination functioned as a symptom of many superficial ascriptions. An equation of failed differentiation informed these explanations. Whereas male subjectivity relies on perceptions of bodies as whole, coherent, and autonomous, women's bodies, in their many sexed differences, often appear unstable by contrast. Power structures, such as patriarchy, may directly define women's bodies as excessive, or as what Julia Kristeva (1987) has theorized as abject. Abjection is a compulsive rejection of body types that are determined to exceed acceptable mandated standards for participation in social life. They appear to espouse a refusal of normative boundaries and strict cultural assignment.

A gender theory of body difference can also be critical for assessing the different reactions to disabled bodies in culture insofar as cognitively, physically, and sensorially impaired bodies, by definition, resist normative classifications. The classic 1896 textbook *Anomalies and Curiosities of Medicine* begins with a section devoted to menstruation as the matter of a medical anomaly. Many bodies present radical challenges to Euro-American investments in the myth of a narrow bodily spectrum of variation. In this sense, maternal imagination and the often radically divergent bodies that result threaten to expose premises of bodily integrity that inform models of standardized embodiment. Pregnancy itself, harboring multiple bodies and presenting quickly growing elements, challenges boundaries of singularity and body life. Indeed, arguments about the modifications of environments that best suit pregnant bodies abound. A famous contemporary account of maternal imagining during the experience of inhabiting a multiplying can be found in Julia Kristeva's "Stabat Mater" (1987).

MAUGHAM, W. SOMERSET

(1874–1965)

British novelist and playwright

W. Somerset Maugham was born in Paris in 1874, the sixth and youngest son of the solicitor to the British embassy. His mother died when he was 10 years old, and he was sent to live with an uncle in England. After attending university, Maugham studied medicine for six years in London, qualifying in 1897 as doctor from St. Thomas' Medical School, but he abandoned medicine after the success of his first novels and plays. Maugham had considerable success first as a playwright and satirist and later as a novelist and short story writer.

Loss and disability strongly influenced Maugham's work. He had a severe stammer that left him afraid to speak. He led a double life both in sexuality and, for a brief while, occupation. He continued for many years both his marriage and his affair with an American man; he also worked as a British intelligence agent during World War I. Perhaps the most profound life event he experienced was the death of his mother when he was a child, an event from which he claimed he had not recovered some 50 years later. Themes of disability and uncontrollable longing are vividly portrayed in his classic novel *Of Human Bondage,* which was published in 1915. The protagonist, Phillip Carey, is a medical student who is embarrassed and publicly humiliated by his professors and fellow students because of his clubfoot. Carey conducts an ill-fated relationship with a selfish waitress who reappears at the end of the novel with all the signs of tertiary syphilis. The mixing of sexuality, disability, and subcultures is more clearly developed in this novel than in the works of other authors using similar themes.

McDONALD, ANNE (1961–)

Australian disability activist

Anne McDonald was born with athetoid cerebral palsy and was originally diagnosed as having profound intellectual impairment. She is unable to walk, talk, or use her hands effectively. At the age of three she was placed in St. Nicholas Hospital in Melbourne, Australia, a government institution for people with severe intellectual disabilities; she stayed there for 14 years. She later wrote:

> The hospital was the state garbage bin. Very young children were taken into permanent care, regardless of their intelligence. If they were disfigured, distorted or disturbed then the world should not have to see or acknowledge them. You knew that you had failed to measure up to the standard expected of babies. You were expected to die. . . .
>
> Nurses were discouraged from cuddling children. A crying child needed to be punished for its own good, so it would learn to accept the absence of affection and be happy. Punishment consisted of locking the crying child in a small dark storeroom. The hospital defined a happy child as a quiet child. Silence was not only golden but sullen; the nurses never saw the looks we gave them when a child was put away. (Crossley & McDonald 1980:16)

In 1977, when McDonald was 16 years old, Rosemary Crossley taught her to read and to communicate by spelling. Because of her severe physical disability McDonald needed someone to support her arm while she pointed at letters on an alphabet board. Once she was able to make her wishes known, she sought her discharge from St. Nicholas. The hospital authorities denied her request on the grounds that the reality of her communication had not been established. McDonald instructed a lawyer to take an action for habeas corpus in the Victorian Supreme Court. She won the case and was released from the hospital in 1979. In 1980, she and Crossley coauthored a best-selling book, *Annie's Coming Out,* which was made into an award-winning film of the same title (released in the United States as *Test of Love*). She later graduated from Deakin University.

McDonald's story contributed greatly to the move to community care for people with disabilities, which started with the closure of St. Nicholas Hospital in 1985 and subsequently spread throughout Australia. McDonald has been a notable campaigner for the rights of people with expressive communication impairments, helping to establish the Communication Aid User Society, the world's first organization founded by people without speech, in 1981. Her 1993 statement on the right to communicate has been adopted by the U.S. organization TASH (the Association for Severe Handicaps):

> The right to communicate is both a basic human right and the means by which all other rights are realized. All people communicate. In the name of fully realising the guarantee of individual rights, we must ensure
>
> - that all people have the means of communication which allows their fullest participation in the wider world;
> - that people can communicate using their chosen method, and
> - that their communication is heeded by others.
>
> Where people lack an adequate communication system they deserve to have others try with them to discover and secure an appropriate system. No person should have this right denied because they have been diagnosed as having a particular disability. Access to an effective means of communication is a free speech issue. (pp. 21–22)

In a 1992 address to TASH, McDonald said:

> For people without speech, talking is often dependent on the generosity of others, either in providing interpretation or facilitation or in giving up time to listen. While this is inevitable, there needs to be an irreducible right to make one's opinions known on issues concerning your future well-being. At the moment social conversation and medical consent are equal in the sight of the law, both depending on the accidental availability of communication partners with the necessary skills and commitment.
>
> There is no right to be heard. There is no right to an interpreter. There is no obligation to listen.
>
> While social interactions will always be dependent on the politeness and tolerance of individuals, it should be possible to legislate for a right to communicate in formal situations such as courts, hospitals and schools. Without such legally enforceable rights, people without speech are at the mercy of decision-makers who can arbitrarily decide to disallow communication.
>
> Communication falls into the same category as food, drink and shelter—it is essential for life, and without it life becomes worthless.

—Chris Borthwick

▣ McMILLAN, MARY L. (1880–1959)

American physical therapist

Mary Livingstone McMillan, "Molly" to her friends, was the founder and first president of the American Women's Physical Therapeutic Association, which is today known as the American Physical Therapy Association (APTA). Born in Hyde Park, Massachusetts, McMillan was raised by cousins in Liverpool, England, and graduated from Liverpool University in 1905. Her interest was attracted by the new field of physical culture and corrective exercise, which she studied along with such medical subjects as neurology and anatomy. After several years of working with polio and scoliosis patients as well as patients living with the aftereffects of industrial accidents, McMillan returned to the United States, where in 1918 she became the first volunteer to respond to the U.S. surgeon general's call for reconstruction aides to work with injured veterans at Walter Reed Army General Hospital. Later in 1918, she was asked to move to Reed College in Portland, Oregon, to organize three-month training programs for 200 new reconstruction aides needed for the war effort. This successful effort led to her recall to Walter Reed to establish an army-based education program. (The fact that she worked at the two "Reeds" has led to much confusion about McMillan's efforts and which of the two programs she founded was the first.)

After World War I, McMillan was the driving force behind the formation of a professional organization for physiotherapists. Following a meeting of some 20 women and a few physicians at Keen's Chop House in New York City, the forerunner of the APTA was founded with McMillan as its first president. The organization's structure was similar to that of the British Chartered Society of Trained Masseuses, and standards for training and ethics were important elements of the fledgling association. Along with guiding the new organization, McMillan published her book *Massage and Therapeutic Exercise* in 1921. She went on to teach at Harvard University until 1932, when she went to Peking Union Medical College to become director of physical therapy under the auspices of the Rockefeller Foundation. Caught in Manila at the outbreak of World War II, McMillan was interned at the Santo Tomas prisoner of war camp. While there, she set up clinics to treat the wounds and disabilities of combatants with whatever was on hand. Like many others, she developed severe nutritional deficiencies during her stay in the camp. Later she was transferred to the Chapei prison camp near Shanghai, where she remained until 1944, when she was repatriated on the Swedish American ocean liner *Gripsholm.*

At her death in 1959, McMillan left a large part of her estate to fund a scholarship program for all levels of education for physical therapy students. The program is administered by the APTA, which has also honored her memory with the establishment of the Mary McMillan Lectureship, which began in 1964.

MEDICAL FUTILITY

Medical futility is a term used to describe situations in which medical investigations and treatments have little or no beneficial effect on a patient. A futile treatment is one that will not cure the patient's illness or improve the patient's quality of life. When treatments are said to be futile, health professionals owe no duty to provide them to patients, and, it is argued by some, doctors can refuse to provide such treatments even when patients or substitute decision makers request them. *Medical futility* is therefore an extremely controversial term, primarily because health professionals can use it as a way of closing the debate about treatment provision and resource allocation. It is also controversial because it has proven extremely difficult to define.

ETHICAL UNDERPINNINGS OF MEDICAL FUTILITY

Concepts of futility can be found in the earliest writings on medical ethics. In the Hippocratic corpus, physicians were encouraged not to treat patients who were overmastered by disease. Similarly, in Catholic bioethics, physicians are not bound to provide "heroic" or "extraordinary" treatments—that is, treatments that are rare and expensive, that offer little hope of benefit and involve significant pain or inconvenience to the patient.

The term *extraordinary treatment* has also found its way into legislation. For example, in the Northern Territory of Australia, the Natural Death Act 1988 (NT) states that

> "extraordinary" treatment means medical or surgical measures that prolong life, or are intended to prolong life, by supplanting or maintaining the operation of bodily functions that are temporarily or permanently incapable of independent operation.

However, in the past two decades, the terms *heroic* and *extraordinary treatment* have been used with decreasing frequency. By the 1980s and 1990s, commentators began to rely more often on the term *medical futility.*

APPROACHES TO DEFINING FUTILITY

There are two main approaches to defining medical futility. One is the *quantitative* approach, by which a treatment is judged to be futile when it fails (or is known to fail) to achieve certain physiological goals. This could also include those treatments that have a very poor probability of success or that will fail to postpone the onset of death. Second is the *qualitative* approach, which looks not only at physiological success but at quality-of-life factors, such as comfort, well-being, and cognition. The simplest definition of futility using this approach is treatment that cannot return a patient to consciousness or that cannot end the patient's dependence on intensive medical care. Included in this assessment would be treatments that may have success in prolonging life but do so at a great cost to the patient's quality of life, for example, by inflicting enormous pain and discomfort. The qualitative approach therefore focuses on the ends or goals of medicine, those being primarily the absence of disease or disability. If a treatment will not be able to achieve these ends, then it can be considered futile.

PROBLEMS WITH MEDICAL FUTILITY

Clinical Uncertainty

The first problem with the concept of medical futility is that all assessments of quantitative futility are uncertain. While evidence-based medicine has improved our understanding of the success of treatments across populations of patients, it remains extremely difficult to judge the possible outcomes of treatment for individuals. Additionally, there is no consensus as to when the probability of a treatment's success will be low enough for the treatment to be classed as futile. As Kerridge, Mitchell, and McPhee (1997) point out, some doctors might think a treatment is futile when it has zero chance of success, whereas others might make the same judgment when the treatment has a 10 percent chance of success.

Discourse That Disguises Value-Laden Judgments

The assessment of medical futility, particularly of qualitative futility, is laden with value judgments about the quality of a patient's life. Physicians consider factors such as the pain that will be caused by a treatment, the level of awareness of the patient, and the patient's age. The ethical integrity of the medical profession may not provide a sufficient safeguard to prevent improper discrimination in this context.

Problems of hidden values are exacerbated in the end-of-life context, particularly in regard to decisions concerning the artificial feeding and hydration of patients in permanent vegetative states. If a person is in a permanent vegetative state, it might be argued that it is futile to continue artificial feeding and hydration because such treatment will not return the patient to sensate awareness. Nevertheless, it can equally be argued that the treatment is not futile (and in fact works extremely well) because it continues to keep the patient alive, even after the death of the higher brain. This example illustrates the fact that applying the term *futility* does not by itself resolve the underlying conflict about whether such treatment should be provided. Other considerations, such as the best interests of the patient or substituted judgment, are determinative.

Universally, common-law courts have found that artificial feeding in such circumstances is futile and have authorized its withdrawal. For example, the Supreme Court of California said such feeding was futile in *Barber v. Superior Court of the State of California* (1983). Similarly, the House of Lords found in *Airedale Trust v. Bland* (1993) that the continued artificial feeding of a patient in a permanent vegetative state served "no therapeutic purpose of any kind" and that it is the "futility of treatment that justifies its termination." Critics of these decisions have argued that the language of futility has shifted impermissibly from an examination of futility of treatment to consideration of whether the lives of the patients are futile.

RESOLVING DISPUTES ABOUT FUTILITY

Given that a purely objective and noncontroversial definition of futility does not seem to be possible, it is logical to assume that disputes about futility will continue. How are such disputes to be resolved?

If the determination of futility were limited to qualitative knowledge of medical probabilities, it might be arguable that debates about futility should be confined within the medical profession. Conversely, if the definition of futility includes consideration of factors of quality of life, medical professionals should be the only people to contribute to the debate.

Increasingly, it appears that the courts are being asked to resolve disputes about whether treatment should be provided to patients when health professionals have deemed that such treatment is futile. In the United States, much commentary was generated by the case *In the Matter of Baby K* (1994), which involved a decision by a hospital not to resuscitate a baby born with anencephaly (a congenital malformation where the upper brain, skull, and scalp are missing). The child had frequent presentations to the hospital (from the nursing home where it resided) because of breathing difficulties. The hospital believed that respiratory therapies were futile given the baby's inability ever to achieve cognition or awareness. The child's mother disagreed and insisted on treatment for the child. The court found that the hospital's decision breached the Emergency Medical Treatment and Active Labor Act, a statute aimed at ending the practice of patient dumping; the act requires hospitals to stabilize patients before moving them to other institutions.

Some commentators have seen the *Baby K* decision as an unnecessary expansion of patients' rights, so that patients (or their representatives) can demand and receive unnecessary, expensive, and unethical treatment. Others have argued that the decision is limited in scope, noting that it focuses on the narrow question of statutory interpretation and has not always been followed in later decisions.

Similar cases have arisen elsewhere. In the United Kingdom, futility arguments were raised in the case of *Glass v. The United Kingdom* (2004). In this case, doctors had decided to enter a not-for-resuscitation order on the chart of a disabled child without the consent of the child's mother. The child was also given diamorphine against the mother's wishes. The child had been treated for complications arising from surgery, and the doctors believed that resuscitation and aggressive respiratory treatment were futile. The mother disagreed with the doctors' assessment. After a fracas between the child's relatives and medical staff, the child was resuscitated and, eventually, discharged from the hospital. After the Court of Appeal of England and Wales refused to review the hospital's decision, the mother successfully sued the U.K. government in the European Court of Human Rights. That court found that the doctors' failure to gain consent from the mother or from a court meant that the family life rights of the patient and his mother had been breached. This case clearly demonstrates the problems with both quantitative (given the boy's survival) and qualitative (given the dispute between the family and the doctors about the child's quality of life) approaches to judging medical futility.

THE WAY FORWARD?

Given the failure to find an acceptable definition of medical futility, some commentators have suggested that what is needed is a process whereby disputes can be mediated and consensus can be achieved regarding the meaning of whether a particular treatment is futile. This approach has been adopted by the American Medical Association's Council on Ethical and Judicial Affairs and has also been legislatively recognized. For example, the Texas Advance Directives Act of 1999 provides for a process of ethical review of futility determinations that includes dispute resolution services when doctors and families cannot agree about whether treatment is futile.

MEDICAL MODELS

See Models

MEDICAL THEATER

The term *medical theater* refers literally to the operating room—the operating theater. More broadly, the term is also used to refer to the places and practices that surround demonstration as a method of dissemination of medical knowledge. By drawing attention to theatricality, the term *medical theater* brings into view the different agendas and power positions that crisscross medical environments.

Medical practices are not fixed; they are subject to historical changes, and they have not always been aligned with issues of visibility. In *Discipline and Punish,* Michel Foucault (1977) describes the changes in machinery and practices that influenced the hospital's move from a place of thick walls and shelter, as a place apart and out of public view, to a place characterized by a regime of visibility that allowed observation of patients, complete with theatrical spaces created specifically to allow doctors to view patients and to instruct trainees. This new regime of visibility allowed for physicians' engagement with individual patients at the same time the patients themselves became site—places within which and on which symptoms could be observed. In the history of disability representations, psychologist Jean-Martin Charcot and his performances of hysteria in the Salpêtrière in the 1870s can illustrate this point. Charcot investigated women diagnosed with hysteria, fainting attacks, or spontaneous paralyses, parading them around his amphitheater. By presenting that these women were not consciously in control, that they were not faking their attacks, Charcot established the legitimacy of psychological conditions and their effects on the physical body. The price paid for this achievement, however, was the further disempowerment of these women, who became puppets with disheveled clothes in a male-dominated theater of stares.

The original medical theaters where dissections were publicly performed were amphitheaters, architectural forms that echoed the Greek theater tradition. The architecture also echoed Greek concerns of the public sphere: knowledge circulated from the staging area to the benches, and back—the patient's body was the scene of the action, but not the action itself.

The transformation of individual bodies into "data," or into forms of knowledge, is the economy initiated in this theater. The individual patient becomes a barrier breached, the patient's life a collection of data: heartbeat, blood pressure, lines on computer monitors, relations of blood chemicals, lung capacity. These disembodied data as representations of a patient's life are familiar from medical television shows and films. In *Flatliners* (1990), for instance, the resting green luminescent line of the heart monitor signifying death becomes the central metaphor of the film. Successful television shows such as *CSI: Crime Scene Investigation* offer a narrative of the anatomy theater and dissection in stylish images, bright colors, and clean arrangements. In *CSI,* the body on display is broken down, anatomized, atomized, into microsites of narratives. Bullets are tracked through flesh; a burst vein fills the screen, zoomed into by computer graphics; skin appears under the microscope, dramatizing the story that happened outside on the streets of Las Vegas anew in the confines of the medical theater and its laboratory stages.

Within this economy of the medical theater as medical practice, the "ideal" body becomes the object of knowledge: The symptoms of the bodies on display within this theater are interesting insofar as they shed light on the general body, the nonspecific body, the universal or "normal" body. Statistics set boundaries and norms within which the body in the medical theater is aligned. In some instances, these statistical demands and their effect on aesthetics and "proper bodies" lead to strange acts: medical practices that invade bodies, often of disabled people, in order to normalize. Thus, limbs are straightened or lengthened, often under excruciating pain; ears are repositioned, fat sucked, breasts enhanced.

In art practices, the boundaries between the "diseased" and the "normal" can become unstable and can be queried. The film *Crash* (1996), directed by David Cronenberg, reconceptualizes the medical theater. In the film, which is based on J. G. Ballard's novel by the same title, traffic accidents and the unhealed flesh of survivors become eroticized. New alignments between metal and body, unnatural openings into previously "whole" bodies become the focus of the camera, identified with the central character's desirous gaze. Within the medical setting, in the hospital bed—with its paraphernalia of bandages, metal cages, and blinking instruments—sex is used as a counterpoint to death. The medical theater here is the liminal space. But disability remains negative in this economy of eroticized wounded bodies; it is the fluidity of bodies that is valued, their ability to be wounded and to heal. For disability politics, the film offers a different vision of fetishized flesh, but not a pathway to a rethinking of disability as lived reality.

The medical theater is not without an audience—Charcot's pupils eagerly drank in the sight of their powerful professor handling fainting women. In *CSI,* detectives follow action with bated breath as the stage machinery of the medical theater distills "evidence" out of the wounded and dead bodies. Historical studies of anatomy practice discuss the growing public attraction of these spectacles of medical display, and history of medicine scholars have excavated the extravagant and (to modern sensibilities) strange practices surrounding medicine in the seventeenth and eighteenth centuries. For instance, Gonzalez-Crussi (1995) describes the Bolognese amphitheater in the seventeenth century as a site of theatrical spectacle, decked out magnificently for the occasion. In these rites of knowledge and bodies, the professors appeared in long crimson robes, flanked by assistants, to take up a position on the stage next to the cadaver. In contemporary displays of the rites of the medical theater, the clothing and procession are less extravagant, but TV series such as *ER* have educated the public to the less ponderous but still strictly followed fashions and practices of the medical theater today. Within disability history, the various dramatizations of the life of the "Elephant Man" hinge on the display of John Merrick—first by the freak show and then by the medical establishment. Bernard Pomerance's play *The Elephant Man* (1979) presents the problems of seeing beyond the roles of doctor and patient, of achieving human contact within the machineries of hospitals, fund-raising, and differing class demands and life paths.

Disability culture has also embraced the medical theater as an important site of political artwork, criticism, and revolt. Many of the skits and stand-up comedy routines performed at disability arts cabarets include references to encounters between medical personnel and disabled people in the medical theater. The medical theater here becomes a performance form that is highly aware of the power differentials, the "genres," the stories and the predetermined performance scripts that surround the doctor-patient encounter. Most disabled people have intimate knowledge of these visual and performative practices of the medical theater. In particular, if they have rare congenital impairments, they might have been required to undress in front of doctors and medical students; photos might have been taken, and demonstrations held over their mute, or even their protesting, bodies.

Traditionally, the diagnostic gaze of the medical practitioner can roam freely across the displayed bodies of patients, and only rarely are its intrusive and objectifying powers acknowledged in the everyday encounter. In disability culture's revision of the medical theater, the object of the gaze speaks back or subverts the agency and power of the scrutinizing gaze. Performers such as Bob Flanagan, Mat Fraser, Angela Ellsworth, Victoria Halford, Ron Athey, and Greg Walloch have used the encounters between doctors and patients as well as the paraphernalia of the medical environment as starting points for their explorations.

MEDICINE

MODELS OF DISABILITY

In the medical and rehabilitation sciences, various models of disability have been proposed. These models help in the conceptualization of the medical aspects of disability and serve to guide research and educational efforts in rehabilitation medicine. In the United States, the Institute of Medicine of the National Academy of Science and the National Institutes of Health make use of a model that defines the development of a disability as a four-step path with three transitions. The process begins with the *pathophysiology* of the condition—that is, the basic disturbance at the level of molecules, cells, or tissues that results in clinical manifestations of disease. The presence of the disturbance itself may not result in disability and in fact may not be manifested clinically all the time. Modern medical sciences have made significant advances in understanding disease at this level, as illustrated, for example, by research into the genetic basis of disease.

When molecular and cellular alterations reach a certain threshold, the person may develop *impairment*—that is, the inability of a physiological or body system to perform the function for which it was designed. Thus, an impairment of the neuromuscular system may be manifested by muscle atrophy and weakness, and a loss of joint range of motion is a sign of an impaired skeletal system. Along the same lines, diabetics who cannot control and regulate their blood sugar levels have impaired metabolic and endocrine systems. When the impairment limits the person's ability to perform basic functional activities, such as climbing stairs, running, or jumping, a *functional loss* has occurred. Individuals need to be able to perform many functional tasks in order to be independent at home, perform the duties of a parent, work, and function in society. If a functional loss is severe enough and limits the person's ability to do such tasks, a *disability* has developed. Obviously, disability cannot be looked at from a medical or biological point of view only. In this model, disability is the final outcome, and it is defined not only by the biology of the disease or injury but, more important, by the interaction between the biology and the environment surrounding the person as well as the demands of the social and occupational activities of the person. In other words, an impairment or functional loss may not become a disability if the environment facilitates the task at hand (for example, by removing barriers to mobility) or reduces occupational demands (for example, by allowing the person to work from home). Disability is not necessarily permanent; it can be reversed if its determinants can be altered.

The elimination or treatment of factors that convert a functional loss into a disability or an impairment into a functional loss may result directly from medical intervention that limits tissue damage (e.g., thrombolysis in acute stroke) or replaces damaged tissue (e.g., joint replacement surgery). The latter, for example, eliminates pain and damaged tissue, restores joint integrity, and allows for physical therapy for the restoration of muscle strength and endurance. Thus, the functional losses and impairments are eliminated or minimized. This illustrates that the current conceptual model of disability is dynamic, and we should not assume that nothing can be done about the problem.

In this context, it is important to highlight the role that assistive technology, used in centers for rehabilitation medicine, can play in the conversion of a disability to a functional loss or in reversing a functional loss to the level of impairment. Assistive devices include mobility aids, computers to enhance communication and cognitive functions, and memory aids that can replace biological or mental functions and at least partially restore activity and participation. For example, when a person with muscular dystrophy loses muscle mass and the ability to walk, he or she may use a wheelchair to participate in community activities. In this case, the use of a device to assist in mobility replaces the functional loss and minimizes the disability.

A more recent model of disability, favored by some authors and adopted by the World Health Organization, is also based on various levels or steps but begins with the *person* as the central element. This level is roughly equivalent to the level of pathophysiology in the model described above. The person depends on having biological, physical, and psychological integrity to perform *activities* (a level roughly equivalent to the impairment and functional loss levels of the previously discussed model combined). One example of the importance of activity for disability is the beneficial effect of physical activity (e.g., walking, running) on a variety of chronic diseases. Well-conducted studies have shown that the regular practice of physical activity or exercise is associated with reduction in the incidence of heart disease, stroke, some types of cancer, diabetes, obesity, depression, and other conditions. Further, regular exercise of moderate intensity reduces mortality from many of these conditions in both men and women and, more important, delays the development of disability by several years.

Finally, it is not enough for the person to be capable of being active; rather, the ultimate objective is for the person to be a *participant* in his or her community and in society in general (i.e., for the individual to interact with the environment in performing certain tasks). Although there are important similarities between the two models, the latter model is less medically oriented and is characterized by a more holistic, participatory approach.

Independent of the model used, the important issue is that, in the practice of medicine, we need to understand the factors, biological and otherwise, that contribute to the development of disability. Medical and rehabilitative interventions must be based on this knowledge and understanding. Many of these factors are not biological or medical, and therefore many interventions must include other aspects of health.

THE INTERSECTION BETWEEN MEDICINE AND DISABILITY

An analysis of the relationship between disability and medicine is relevant for several reasons. Most obvious is the fact that the road to disability often begins with an acute illness (e.g., a stroke), injury (e.g., traumatic brain injury), or the development of symptoms and signs of a chronic illness (e.g., rheumatoid arthritis). In all of these situations, the affected person is likely to need the services of a medical professional. For many young and healthy individuals, this could be their first experience as hospital patients. Further, even those who have permanent but stable disabilities are likely to require medical services at different points in their lives. For example, disabling conditions resulting from spinal cord injury (e.g., tetraplegia and paraplegia) are associated with a high incidence of such medical complications as infections of the urinary tract, pressure sores, osteoporosis below the level of the injury, and pulmonary diseases. Persons with these conditions become regular users of the medical services available in their communities and develop relationships with health care providers. Another example is the patient with peripheral vascular disease and poor circulation who undergoes an amputation below the knee. Such a patient requires rehabilitation, including the use of an artificial limb, but also careful medical monitoring of the condition of the nonamputated leg, because many such patients develop complications during 5 to 10 years postamputation.

In any of these instances, various medical professionals with different areas of specialization evaluate the patient, establish a diagnosis, and initiate treatment and rehabilitation. These are important encounters, because medical interventions represent one of the first opportunities to control or reverse the physical and psychological conditions that, if left unattended, may lead to the development of a new disability or the worsening of an existing one. In addition, these critical opportunities represent times when professional medicine can display shortcomings. Although many medical specialists do not necessarily recognize the fact, acute therapeutic interventions can alter significantly, either positively or negatively, the pathway to disability. In other words, limiting tissue damage and disease activity in the early stages is the first step in the restoration of form and function. Medical professionals' failure to recognize this principle has led to undesirable outcomes and been the source of much criticism of the medical model of disability. On the other hand, inappropriate medical interventions can also contribute to a problem by delaying tissue healing and by imposing unnecessary restrictions on a patient's activity and community participation. History reveals many instances in which medical interventions, although well-intentioned, did more harm than good. In this context, one of the most noticeable weaknesses of the medical approach to disability has been the failure to recognize the importance of the environment as well as the psychosocial forces that define disability.

Two factors that have contributed to an increase in the prevalence of disability in recent years are worthy of attention. One of these is the success of the health care system in providing advanced medical interventions and using modern technology in acute settings. Advances in science and medicine have been published at an unprecedented rate since the middle of the twentieth century. These developments have resulted in a reduction in mortality associated with accidents, injuries, and acute and chronic illnesses. Paradoxically, the increase in survival rates, a positive outcome in and of itself, may have contributed to an increase in the incidence of disability, given that many patients now survive life-threatening injuries and diseases associated with permanent impairments and functional losses. This increased prevalence of disabling conditions requires a change in our medical practice, better educational programs for medical students and residents (postgraduate trainees), and novel research programs to generate new knowledge and successful interventions. Some of these needs are not being met, and the medical profession must make an effort to fulfill them if it intends to serve well an increasingly large segment of the population.

The dramatic demographic changes registered during the late twentieth and early twenty-first centuries have also contributed to an increase in the prevalence of disability. Increasing numbers of people survive to advanced adult age, and life expectancy is significantly longer today than in the past in all continents of the world with the exception of Africa. The World Health Organization has predicted that the aging of the world's population will continue for the next few decades, resulting in an increase in the number of people in the older age groups, particularly those older than 85, including centenarians. Further, the incidence of functional losses and disability increases with advanced age in both men and women. This is in part due to age-related physiological losses but also to the increased incidence of chronic illness in the elderly. The elderly seek health care services more than do the members of any other age group, bringing to the attention of their physicians, primary care doctors, and specialists not only their medical needs but also their functional limitations. Studies have shown that the elderly fear functional dependence more than death. This preference expressed by patients is a strong statement against the traditional medical approach of treating symptoms and diseases in isolation, without considering their functional consequences. A change in paradigm is needed to place the person's ability to participate in society at the forefront of medical interventions and to integrate the environment in the analysis of the health care and medical needs of patients.

TEACHING MEDICAL STUDENTS AND SPECIALISTS ABOUT DISABILITY

The changes mentioned above highlight the need for a health care system that is knowledgeable about and accessible to persons with disabilities. Although many medical specialties (e.g., developmental pediatrics, geriatrics, neurology, neurosurgery, oncology, orthopedics, and psychiatry) have developed an interest in disability, the only medical specialty that has included disability as a central theme in its philosophy of care, mission, educational and training programs, research agenda, and clinical services is the specialty of physical medicine and rehabilitation (PM&R, also known as physical and rehabilitation medicine, rehabilitation medicine, or physiatry). In fact, PM&R was born, to a very significant extent, out of the needs of patients with permanent disabilities caused by war-related injuries, because the other medical specialties available at the time did not offer effective therapeutic alternatives after the acute stage.

In the United States, physicians specializing in PM&R (physiatrists) must complete four years of postgraduate residency training. They learn to evaluate, treat, and rehabilitate people with disabilities using a holistic approach and are trained to pay particular attention to the restoration of form, function, and freedom to the patient. Thus, the specialty is defined by its comprehensive approach and interest in function and not by the need to attend diseases of a specific organ or body system. Furthermore, in addition to attending to the biological and physical needs of the patient, physiatrists place special emphasis on psychosocial, emotional, and vocational issues that may be important determinants of the level of disability. It is interesting that the consequent lack of identification with a specific organ or body system (unlike the identification of cardiology with the heart and ophthalmology with the eye, for example) has made the process of communicating the nature of the specialty more difficult. For those without disabilities, the concept of function may not be all too obvious.

Unfortunately, the specialty of physical medicine and rehabilitation is not very popular among medical students and is usually not included as part of the regular curriculum in most medical schools. Furthermore, conceptualization of function and disability is poorly disseminated within the field of medicine in general. Thus, standard medical textbooks such as *Harrison's Principles of Internal Medicine* do not include disability in their indexes. More frequently, disability awareness comes from firsthand experience. It is not unusual to find students whose interest in the specialty of PM&R resulted from their having lived with relatives with disabilities. Medical students interested in the field have to use some of their elective time to do special rotations in physiatry in order to learn more about it. It could be argued that this deficiency of information and knowledge about disability and rehabilitation, characteristic of many medical school graduates, explains the lack of appreciation and understanding that many physicians have in relation to disability issues. Further, more often than not, postgraduate residency training in many medical specialties fails to provide students with practical experiences in the diagnosis, treatment, and rehabilitation of disabling conditions. Nevertheless, recent data indicate that, despite the above-mentioned limitations, the medical specialty of PM&R is growing in many countries and regions of the world. Currently, there are approximately 8,000 board-certified physiatrists in the United States and 15,000 physiatrists in Europe. In addition, the numbers of medical graduates enrolled in PM&R residency training programs in the United States and Europe are 1,200 and 2,000, respectively. Greater availability of well-trained medical professionals could significantly enhance access to quality services focused on disability issues.

Another opportunity to educate physicians and other health care professionals has resulted from recent changes in the financing and management of health care systems. These changes may have the unintended consequence of enhancing the general understanding of disability and rehabilitation issues among health care providers outside the world of rehabilitation. Financial concerns with the cost of health care have forced acute care hospitals to reduce the length of the hospitalization for many diseases and surgical cases. To accomplish this goal, hospitals have begun transferring patients to other, lower-cost, facilities as soon as their medical conditions are stable enough to permit continuation of their treatment and recovery elsewhere. As a consequence, rehabilitation facilities have become important providers of subacute medical and rehabilitative care much earlier in the recovery (postinjury or postsurgery) process, and physicians and administrators in acute care facilities have been forced to learn more about the needs of people with conditions that require rehabilitation and patients with disabilities, particularly in the early stages of episodes of care.

HEALTH CARE SERVICES FOR PEOPLE WITH DISABILITIES

Modern health care systems are multicomponent organizations that integrate different levels of care across geographically separated campuses. Many patients needing multiple levels of care are transferred from one location to another, and then another, and so on. Most of the services for people with disabilities have been consolidated in entities known as *nonacute, postacute,* or *continuing care* health care systems. These systems have important distinguishing features that should be understood.

Acute medical services, including the acute hospital, an emergency room, operating rooms, ancillary services such as radiology and clinical laboratory services, and outpatient clinics, are usually available all on one campus. On the other hand, nonacute health care systems organized with the rehabilitation continuum in mind may provide services on multiple campuses, including the rehabilitation unit or hospital, nursing homes, day hospitals, and outpatient clinics, as well as in patients' homes. Acute care facilities provide important services for people with disabilities. The presence of a disability and the rehabilitation needs of the patient are sometimes important determinants of the nature and success of the intervention in the acute hospital, but most of the time they are not the center of attention. In the acute care hospital, more often than not, the need to restore form and function is a secondary consideration. The opposite is true in the various levels and facilities of care that form part of the nonacute system. In the majority of cases, people with disabilities access services in the nonacute system because of the disability, and the health care professionals make the disability and its determinants the center of attention and clinical activity. The need to include the home of the patient as a component of the system is a formal recognition of its important role in the final outcome.

An important difference between a typical acute medical intervention and treatment received in the medical rehabilitation context is the emphasis that the latter places on the interdisciplinary team. Although recently many medical specialties have begun to develop and implement versions of the team concept, medical care for people with disabilities in rehabilitation settings has always been characterized by the interrelatedness of the interventions of a large group of health care professionals. The team approach is one of the central tenets in the practice of clinical rehabilitation and the delivery of medical services for the disabled. In addition to the physician, the rehabilitation team may include individuals in all or some of the following health professions: occupational therapy, physical therapy, speech language pathology, psychology, neuropsychology, recreational therapy, rehabilitation nursing, nutrition, and social work. Fragmented medical care in which multiple specialists intervene with a patient without coordinating their services has no place in rehabilitation medicine clinics and centers or in medical programs for the disabled. The coordination of services takes place not only through daily communication among the members of the team but also through formal team meetings in which members discuss the goals and progress of the patient. In a very real sense, the patient and his or her family are also part of the team, and family meetings are held to discuss the patient's progress and to get family members' opinions on issues confronting the patient. Although some of these interactions and activities take place also in the acute care setting, they are more formally planned and executed in the rehabilitation setting.

Two of the main objectives of the rehabilitation process are the return of the person to his or her home and, if possible, the return of the person to his or her previous level of employment. To meet these objectives, medical professionals must develop a good understanding of the social and occupational environments of the patient. Such understanding may not be necessary in acute care settings, but it is almost always required in nonacute health care systems. For example, many of the rehabilitative and therapeutic interventions may have to take into consideration the architecture and physical barriers of the patient's house and the physical and psychological demands of the patient's job. Again, disability is defined by the interaction between the biological and physical domains and the environment, and even in the case of static and permanent biological dysfunctions, alterations in the environment can reduce negative impacts on function and lessen the degree of disability. In this context, it could be said that therapeutic and rehabilitative interventions should be directed toward the environment: enhancing the person's ability to overcome environmental barriers or reducing the magnitude of the barriers themselves.

THE MEDICAL RESEARCH AGENDA AND DISABILITY

Research is needed to generate new knowledge that medical professionals could use to understand the natural world and apply to the solution of clinical problems. In medicine, new knowledge is generated through research studies that can be divided into three general categories: basic science research, clinical research (including clinical trials and outcomes research), and health services research.

The goal of basic medical science research is to increase understanding of health and disease at the mechanistic level. Important basic science questions address how the human body works and what happens when a disease develops at the molecular and cellular levels. Many of these questions are relevant to a variety of clinical issues and help us understand problems at a very fundamental level even though they do not address or test immediate solutions to clinical issues.

Clinical research, on the other hand, is designed to test ideas with the potential to treat or cure disease in humans. Thus, researchers test drugs, new surgical interventions, and new technologies to assess their value in preventing illness, treating disease, and alleviating pain and suffering. This type of research is unique in that it requires the voluntary participation of human subjects. The patient or person with a disability has an opportunity to be part of the process and contribute to a better outcome. The clinical research enterprise has a solid base in areas such as cardiovascular disease and cancer but is not well developed in rehabilitation medicine. Advances in the rehabilitation of people with disabilities will depend on the establishment of a clinical trials network, so that new treatments can be tested on large numbers of individuals.

Finally, health services research deals primarily with issues related to the delivery of health care and the factors that determine the efficiency and effectiveness of health care systems. Current health services delivery models may not be adequate for people with disabilities, and more creative ways of providing services are needed. For example, new technologies such as tele-rehabilitation could help medical professionals to deliver services in patients' homes and reduce dependence on clinic and home visits.

In many ways, all of these types of research are important for persons with disabilities because many of the treatments developed in the context of acute care interventions might find application in rehabilitation centers. For example, understanding the basic events leading to brain damage after an injury or stroke could help with the development of ways to protect healthy tissue surrounding the affected area. Further, tissue engineering could potentially be used to replace tissue that has been damaged or lost due to illness or injury, as in degenerative arthritis. Stem cells that have the capability to differentiate into different types of cells represent another potential source of "new tissue."

Clearly, significant efforts in basic science are needed to accomplish these goals. Further, no discovery is incorporated in standard medical practice until appropriate clinical trials have been conducted to prove the safety and effectiveness of treatment based on the discovery. Therefore, clinical trials and outcomes research studies must also be part of the research agenda addressing disability issues. New pharmacological agents developed using this model could be effective in treating medical complications that are frequently seen in association with disabling conditions such as spasticity (a velocity-dependent increase in muscle tone) in stroke survivors and tetraplegics. Advanced prosthetic (artificial limbs) and orthotic (braces) devices for those with mobility problems and amputations, which clearly benefit consumers, are developed and tested using this approach.

Finally, the organization of a system of care for people with disabilities should take into consideration the special needs of this population; therefore, health services research is needed to help define the characteristics of such a system. This concept has been tested in the Model Spinal Cord Injury System, a network of centers in the United States dedicated to the care of patients with spinal cord injuries. These centers provide and coordinate emergency and acute medical care, rehabilitation services, psychosocial and community reintegration programs, and long-term follow-up focusing on the special needs of patients after spinal cord injury. During the past 35 years, researchers have developed and tested each of these levels of care and special programs with the needs of persons with spinal cord injury in mind. It is worth noting that these centers must integrate not only different levels of care (e.g., acute neurosurgical interventions with rehabilitation goals) but also administrative, research, and educational efforts for health care professionals, patients, and patients' families.

In general, the medical research agenda does not include enough research initiatives that have at their centers the purpose of ameliorating disability. Traditional medical research models used, for example, in acute care hospital settings are more oriented toward the biological and physical aspects of disease. These are clearly important, but in the future, the roles of environmental and psychosocial factors will have to be integrated with these two aspects. An example of this integration is the proposed future agenda for the Model Spinal Cord Injury System, which includes attempting to integrate basic science, clinical research, and health services research. This agenda, with minor modifications, could serve as an example for research agendas concerning other disabling conditions. It has been proposed that the Model

Spinal Cord Injury System centers conduct research related to the following general areas:

- Neuroscience and nerve regeneration
- Pharmacological interventions, including randomized controlled clinical trials
- Biotechnology interface projects
- Preventive health and wellness
- Subjective well-being and consumer satisfaction
- Bioethics
- Health care models
- Bioinformatics, collaborative patient, and research databases

This proposed new research agenda will take advantage of the dramatic advances in science recorded in the twentieth and twenty-first centuries and apply this new knowledge to the enhancement of the quality of life of people with disabilities. Disability should not be defined by medicine; instead, the medical profession should be considered an important partner capable of making a significant contribution to the understanding and transformation of disability.

MELANCHOLY

The word *melancholy,* which refers to a state of low spirits, sadness, and anxiety, comes from the Greek terms *melas* (black) and *chole* (bile). The historical meaning of the concept of melancholy has been superseded by modern terms such as *depression;* whereas *melancholy* is now used to refer to a state of lingering sadness, from antiquity to the development of prepsychiatric medicine the term was used to describe a medical condition.

In antiquity, the word *melancholy* referred to a medical disturbance of the mind and the soul that was contrasted with other states of madness, such as *mania,* a chronic mental disorder without fever, and *phrenitis,* an inflammation of the brain with fever. The specificity of melancholy was believed to be related to its cause in the body: black bile. Like the three other bodily humors—blood, yellow bile, and phlegm—black bile was understood to affect the body as well as the soul; in excess, it was seen as the cause not only of melancholy but also of cancer, elephantiasis, and hemorrhoids.

The Hippocratic corpus mentions black bile, but melancholy is not prominent. One of the *Aphorisms* (6.23) states that "if sadness and fear last for a long time, the state is melancholic." A treatise from the Aristotelian tradition, *Problem XXX,* which connects the melancholic state to exceptional men, was very influential. In the treatise *On Black Bile,* Galen focuses on the physiological aspects of this humor. The twofold nature of black bile—that it is both necessary to life and yet in excess so potent that it is able cause anthrax, elephantiasis, and melancholy—is clear in this text. The cure for melancholy aims at reducing black bile through purgation with white hellebore. Other authors show more doubts about the possibility of a cure. Aretaeus of Cappadocia (1856) gives a vivid account of persons suffering from melancholy:

> And they also become peevish, dispirited, sleepless, and start up from a disturbed sleep. Unreasonable fear also seizes them, if the disease tend to increase, when their dreams are true, terrifying, and clear: for whatever, when awake, they have an aversion to, as being an evil, rushes upon their visions in sleep. They are prone to change their mind readily; to become base, mean-spirited, illiberal, and in a little time, perhaps, simple, extravagant, munificent, not from any virtue of the soul, but from the changeableness of the disease. But if the illness become more urgent, hatred, avoidance of the haunts of men, vain lamentations; they complain of life, and desire to die. (pp. 299–300)

On the physical side, the skin of melancholics was said to become green-black, and they were said to have great appetites while remaining emaciated.

During the Middle Ages, the whole theory of the bodily humors was systematized, and the melancholic emerged as one of the four temperaments—that is, a type of person with characteristics, both physical and mental, determined by the melancholic humor. Robert Burton's *Anatomy of Melancholy,* first published in 1621, is emblematic for the Renaissance: The author organizes the classical sources about melancholy around scrutiny of himself. Although alternative ideas concerning the treatment of melancholy were put forward, the ancient theories were influential well into the nineteenth century.

MENTAL HEALTH

The concept of mental health has changed radically in the past decade. Mental health disabilities are no longer perceived as chronic, disabling conditions; rather, they are seen as limitations in the quality of life of affected individuals. In some nations, public policy legislation—such as the Americans with Disabilities Act (ADA) of 1990—has favored this reconceptualization of mental disability.

Despite these new perspectives in the understanding of mental disabilities, some dilemmas still are observed in this matter. In some countries and sectors of society, a disparity still exists between the perception and approaches to the management of chronic illnesses. In this regard, some chronic medical illnesses, such as diabetes and epilepsy, are treated intensively and acutely at every relapse; in contrast, this approach is not always afforded to certain chronic psychiatric disorders, such as schizophrenia. This type of discriminatory practice is also observed among countries, including the United States, where no parity exists between medical/surgical illnesses and psychiatric illnesses with respect to medical insurance coverage.

This dilemma, of course, is related to stigma, fear, and ignorance. It may not be the patient but society at large that discriminates, fears unknown illness, and feels guilty of conditions that still are not well-known. This is what has also happened in the past vis-à-vis epilepsy, leprosy, plague, and other similar conditions. Incidentally, this situation is similar to the one observed when people from different races, ethnicities, and cultures interface with people from the majority culture. In general, persons tend to be afraid of those who differ from them in religion, economic ideology, skin color, language, or culture. This type of phenomenon leads to fears, persecution, discrimination, racism, oppression, and even wars in some instances.

During the past two decades, major research advances have taken place in the field of psychiatry and behavioral sciences, particularly with respect to neurosciences and the management of mental illness. As the public begins to conceptualize many major mental illnesses as "brain diseases" instead of as the results of parenting problems or weak character, stigma is reduced. As new discoveries take place, new and promising perspectives also evolve, thus leading to progress in the way that society perceives psychiatric disorders at a worldwide level.

Mental illness ranks first in causing disabilities among many industrialized nations, including Western European countries, Canada, and the United States. In this respect, mental illnesses currently cause more disability than cancer and heart disease combined. Schizophrenia, bipolar disorders, and depression now account for 25 percent of all medical disabilities across major industrialized nations. This situation has major implications, not only from the point of view of pain and human suffering but from an economic viewpoint as well. For instance, in 1999, the economic cost due to loss of productivity as a result of mental illnesses in the United States was $63 billion. In the United States, 5 to 7 percent of adults currently suffer from serious mental disorders, and 5 to 9 percent of children suffer from serious emotional disturbances that severely disrupt their social, academic, and emotional functioning.

This situation is currently producing major public policy dilemmas in many industrialized countries. In the United States, for instance, one in every two persons in need of psychiatric treatment does not receive it, especially in inner-city and rural areas. This happens for several reasons; quality of care may be inadequate, diagnoses may sometimes be inaccurate, medication dosages may be insufficient, or the length of treatment may be too short. This circumstance is even worse with respect to ethnic and racial minority group members in the U.S. population. Stigma is definitely still a barrier to psychiatric care as well as to quality of care. Unquestionably, societal stigma and shame concerning mental illnesses lead to ostracism and discrimination vis-à-vis mental patients. Patients sometimes internalize this situation and thus develop low self-esteem and hopelessness; suicide may even result.

Despite these serious public policy dilemmas, the past decade has also seen major psychosocial research advances to complement the biological research, leading to new approaches in rehabilitation of the mentally ill, particularly the chronic mentally ill, and to major advances in the conceptualization and understanding of current mental health disability management. These new principles in psychiatric rehabilitation have shed new light on methods of intervention and have led to new perspectives with respect to early intervention and treatment of mental health disabilities.

A rehabilitation approach has recently been developed in which the patient becomes the center focus of the rehabilitation process. In this context, all key domains of the person's life—that is, the physical, emotional, intellectual, social, and spiritual needs of the person—are addressed from a rehabilitation point of view. In a well-integrated manner, all these personal dimensions are attended to from a rehabilitation viewpoint, with priority given to the rehabilitative expectations of the patient suffering from a given psychiatric illness or condition. This rehabilitative approach is geared toward involving the patient actively in the entire rehabilitation process. Active involvement also includes full patient empowerment—that is, the patient is provided with full information about the nature of the illness, its symptoms, its course, and potential sequelae.

In this context, hope becomes an inherent and essential aspect of the rehabilitation philosophy. Thus, the approach to the rehabilitation process becomes a core element with respect to the positive expectations of the patient and the outcome of his or her illness management. The whole rehabilitation process currently focuses on maximizing the patient's strengths, especially from a competence and skills point of view. Therefore, skill development, enhancement, and training are central to this new ideology.

The patient's environment extends itself to accommodate the factors that play a role in the mental health disability; thus, "limitations" substitute for "handicaps." Full focus is given to the patient's environment as a potential resource element. Possible resources include people such as the patient's family members and other persons in the environment, programs, services, and infrastructures that can play a positive role in the patient's rehabilitation process. In this regard, employers, coworkers, friends, religious institutions (e.g., churches and synagogues), landlords, and community centers all become potential resources on behalf of the patient's rehabilitative outcome.

Currently, vocational assessment of the patient is seen not as a way of coping with the mental health disability but as a way of maximizing the patient's opportunities in life; limitations in the patient's quality of life supersede acceptance of handicaps caused by the psychiatric illness or condition. Incentives for full rehabilitation opportunities aimed at helping the patient return to full- or part-time employment becomes the goal rather than the occasional expectation. The patient is offered full opportunities for maximum achievement and enhancement of his or her quality of life.

During the past decade, two new concepts have enlightened the rehabilitation process and the conceptualization of mental health disability: the concepts of *patient satisfaction* and *quality of life.* Although patient satisfaction has been addressed previously on many occasions, only recently has it come to be considered a quality indicator in the assessment of treatment outcomes. Likewise, quality of life is currently accepted as the major component in treatment outcomes. In this context, a successful and appropriate rehabilitation process has become an integral part of illness management.

The treatment of chronic psychiatric conditions depends less on the management of symptoms than it does on the intensive management of acute phases. Likewise, relapse is now perceived more as an expression of an acute phase of the illness than as a manifestation of a long-term disabling condition.

Research and educational efforts have resulted in numerous clinical advances in recent years, but further progress is still needed in this regard. Additionally, it is urgent that society face the current public policy dilemmas affecting mentally ill patients. Certainly, isolated state hospital facilities were not the appropriate answer to the need to provide humane care for the mentally ill, but neither are the streets of urban metropolises or the prison system.

MENTAL HEALTH: LAW AND POLICY

Historically, severe mental illness has been merged with global incapacity. From at least the time of classical Greece and Rome to the European Middle Ages, families were expected to control, house, and provide for those afflicted with severe mental illness or intellectual limitation, and the freedom of these individuals was subject to whatever limitations were set by their families. By the fifteenth century, however, in Western

Europe the "insane" were increasingly confined to specialized institutions, a movement that grew substantially until the mid-twentieth century. Individuals with severe mental illness might be incarcerated in such facilities indefinitely, but they were not necessarily stripped of their titles or property. However, it was generally held that during the period of "insanity"—which might be lifelong—they could not exercise many of the rights of ordinary citizens, and (if they owned substantial property) guardians were appointed to act in their stead. (One interesting distinction was made in thirteenth-century England, where the property of those born severely mentally retarded—"congenital fools"—instead reverted to the king.)

Thus, those identified as severely mentally ill were considered unable—simply by virtue of being ill—to enter into business contracts, execute wills, or otherwise control their property. The laws of the Roman Catholic Church also dealt with issues such as the effect of "insanity" on the validity of matrimonial consent and whether an "insane" person could receive church sacraments.

Perhaps because of the lack of effective treatment and the chronic nature of many severe psychiatric disorders, questions of why and under what circumstances property and civil rights should be given up by the severely mentally ill were not seriously addressed until the mid-twentieth century. Prior to that time, there was little legal oversight of the treatment of those hospitalized for severe mental illness, and virtually all such patients were hospitalized at large, state-run institutions. Beginning in the latter half of the 1950s and early 1960s, coincident with the "deinstitutionalization" of psychiatric patients and in the context of large-scale social changes that led to marked liberalization of civil rights for many groups, those identified as severely mentally ill were nonetheless recognized as having the legal ability to exercise all the civil rights (e.g., the right to vote, the right to not be subject to treatment without informed consent, the right to refuse certain treatments) accorded other citizens in the United States and several other countries. Thus, a conceptual and legal shift occurred, from status as psychiatric patient being sufficient to establish absence of legal *competence* to a more nuanced view that focused evaluation is needed to determine if and to what degree mental illness might affect an individual's specific clinical *capacity* to exercise his or her rights. Only disability severe enough to compromise such capacity could negate a person's exercise of such rights.

GUARDIANSHIP

The roots of guardianship of the estate of an incapacitated individual can be traced to classical times, as noted above. Over time, the concept of guardianship has evolved dramatically, so that in some cases guardianship of the person (for example, the power to make health care decisions) is distinguished from guardianship of property (sometimes also called *conservatorship*). Guardianship may also be general (plenary), or it may be restricted to certain classes of decisions, with the ward retaining decision-making power for others. The issue of incompetence and hence need of a substitute decision maker can be based on legal definition *(de jure),* for example, if the individual is a minor, regardless of cognitive status; in other cases, proceedings can be based on the finding of actual *(de facto)* incompetence. A ward's status of incompetence can be reversed either through a change of legal status (e.g., reaching the age of majority) or through the ward's prevailing in a "restoration" hearing.

There is still significant variability among jurisdictions in the basis for appointment of a guardian, but a shift appears to be taking place from simply equating mental illness to need for guardianship to focused evaluation of the functions the individual can (or cannot) perform, with the determination based on the degree and kind of deficits identified.

CIVIL COMMITMENT

The shift described above has played out in a number of areas of mental health law. The justification for civil commitment has in large part moved away from a *parens patriae* model, in which the sovereign, or the state, is responsible for the well-being of citizens, much as the father is responsible for his family (note the gender bias), and thus is empowered to force treatment on those judged to be in need of it. This has been supplanted in large degree by a "police power" model, in which evidence of an individual's danger to self (by self-injury or inability to provide basic necessities of life) or to others (by violent behavior) is required for involuntary hospitalization. In other words, an earlier model based on social norms of which behaviors were acceptable and which merited confinement and coerced treatment has been superseded by a model in which individual liberty, within very broad bounds, can be abridged only when evidence exists of clear and significant risk of social disruption, such as threat to the physical safety of a citizen. Less severe behavioral problems, even when accompanied by suffering and risk of lesser degrees of harm (such as financial irresponsibility or disruption of the family situation), are insufficient to justify involuntary hospitalization. Indeed, physical freedom is considered so fundamental that in *Addington v. Texas* (1979), the U.S. Supreme Court held that "civil commitment for any purpose constitutes a significant deprivation of liberty" and, hence, due process protections must be in place to ensure that "the individual suffers from something more serious than is demonstrated by idiosyncratic behavior" before his or her freedom can be abridged. Under such circumstances, because the individual disproportionately bears the cost of an erroneous determination, the state must prove the need for civil commitment at least to a standard of "clear and convincing evidence."

Often associated with this deference to physical liberty is the concept of "least restrictive alternative." First explicated in the case of *Lake v. Cameron* (1966), this principle dictates that an individual's physical freedom should be restricted as little as possible consistent with physical safety and that practitioners consider the full range of services available (such as outpatient treatment, partial hospital programs, nursing homes) before mandating inpatient treatment, with precedence granted to the setting that interferes least with physical freedom consistent with safety.

TREATMENT RIGHTS

Personal autonomy is considered a higher social good than health. Disagreeing with medical advice is not necessarily evidence of impaired judgment, and in general, the patient is free to decline treatment even when the treatment is necessary to prevent serious harm or death. Conversely, it is generally incumbent on the treatment provider to obtain permission from the patient (or the patient's substitute decision maker). For permission to be valid, the patient must be able to render *informed consent.* This concept has three components: competence, sufficient information on which to base a reasoned choice, and freedom from coercion.

Competence can be a purely legal distinction (see above); in such a case, the consent is obtained from the patient's parent or guardian. Competence can also be questioned based on, for example, the presence of mental illness. Again, however, mere presence of a mental disorder is insufficient to undermine the individual's autonomy. Under such circumstances, the legal system may either make treatment decisions or determine who should act in the patient's stead.

Specific tests differ among jurisdictions, but in general to demonstrate incompetence one must show that the individual's reason for refusal of treatment is irrational. If that is so, for most health care decisions a substitute decision maker (often but not necessarily the patient's spouse, parent, or other family member) may be employed. In some cases, the individual may have previously executed a document spelling out what treatments he or she would wish (or refuse) in the event that he or she becomes severely ill. Although such contracts may not in the end determine treatment, they may be used as part of the fact base to determine the individual's wishes.

Involuntary treatment with psychotropic medication is often (by statute) handled differently from other interventions. In that case, the court (or other fact finder) might use information such as the patient's prior experience with the medication, the patient's perceptions of its purpose and effects currently, and the preferences regarding treatment previously expressed by the patient. If the patient's refusal of treatment is considered not to be competent, generally it must be further demonstrated that the proposed treatment's benefits outweigh its risks and that the underlying condition is sufficiently grave as to merit treatment over the patient's objections.

One seeming peculiarity in regulation of involuntary psychiatric treatment is that many jurisdictions now separate issues of involuntary *hospitalization* from issues of involuntary *treatment.* The presence of a disorder, even one sufficient to cause an individual to behave dangerously, does not inherently establish that the person's ability to make treatment choices is severely impaired, although this is in fact often the case. Commitment generally requires the presence of a mental illness plus some evidence of dangerous behavior, whereas involuntary treatment requires, in essence, the individual's lack of ability to make reasoned treatment choices—two separate concepts that may require two separate judicial determinations.

It is interesting to note that there has been judicial reluctance to identify a corresponding "right to treatment," even for those involuntarily hospitalized (*O'Connor v. Donaldson* 1975). Indeed, U.S. courts have paid great deference to professional judgment, requiring only that the patient be provided safe conditions, freedom from bodily restraint, and "training or 'habilitation'" (*Youngberg v. Romeo* 1982).

OTHER COMPETENCIES

Mental illness may potentially—but not necessarily—undermine a person's ability to exercise specific abilities, such as to validly enter into a contract, marry, write a will, or testify in court. The issue becomes whether mental illness has negated some element specific to a given function. For example, to execute a will competently, one must understand that one is making a will, understand the nature and extent of one's property, and have knowledge and understanding of one's heirs ("the objects of their bounty"). Great weight is placed on the will, and generally a rather strict ("clear and convincing") proof is required to invalidate it. A rather similar analysis generally informs the judgment of competence to contract; that is, the contractor must be sufficiently aware of the contract's elements and be able to make rational decisions based on them.

CRIMINAL LAW

Analogous to civil law, within the criminal law a number of kinds of competencies are noted specifically: competence to waive certain protections (e.g., one's rights under *Miranda v. Arizona* 1965) or appeals, to enter a plea, to confess, to testify as a witness, to represent oneself, and so forth. As with civil competencies, it is necessary to evaluate specifically the impact that mental illness might have on the legal tests, which may differ substantially from jurisdiction to jurisdiction. Most fundamental is the issue of competence to stand trial. The defendant's mental status *at the time of trial* must be such that the individual has "sufficient present ability to consult with his attorney with a reasonable degree of rational understanding and a rational as well as factual understanding of proceedings against him" (*Dusky v. United States* 1960).

In practice, therefore, competence to stand trial has several components, and a number of instruments have been devised to aid clinicians in assessing them. One major domain consists of knowledge of the relevant legal facts and procedures, such as the roles of courtroom personnel; awareness of legal protections, such as right to counsel and protection against self-incrimination; the charges and their potential penalties; and potential legal strategies, such as an insanity defense or plea bargaining.

A second component is the ability of the defendant to participate meaningfully in planning legal strategy. This includes such functions as the ability to weigh alternative defenses and potential outcomes rationally, the ability to collaborate with counsel regarding trial strategy, and the ability to challenge adverse witnesses realistically. Although the defendant's ability to provide counsel with a coherent accounting of the defendant's version of events is desirable, the courts have held that amnesia for events does not equate with lack of fitness to stand trial.

The last component of fitness or competence to stand trial is the degree to which the defendant is willing and able to mount a strong defense, unimpaired by the presence of mental illness that might, for example, make him or her plead guilty to a crime out of delusional guilt. Although a high standard of proof "beyond a reasonable doubt" is necessary for conviction of a crime, a lesser standard, "preponderance of evidence," is sufficient to establish competence to stand trial. A similar standard is generally used to determine other competencies relevant to criminal law, as noted above.

MENTAL HEALTH LAW, DISABILITY, AND DISCRIMINATION

The current relationship between mental illness and the definition of disability will not be discussed here;

suffice it to say that it is a complex relationship that may vary considerably depending on the legal context in which the issue is raised.

Arguably, to date the most sweeping legislation related to the rights of the disabled in the United States is the Americans with Disabilities Act (ADA) of 1990. Many mental illnesses may be considered as disabilities under the act, primarily excepting disorders of impulse control, current substance use disorders, and certain sexual disorders (paraphilias), as well as homosexuality (which is not a mental disorder). To qualify as a disability, the disorder must substantially limit one or more of the individual's major life activities. Of note, the act states that the disability so defined need not be current, as long as the individual has "a record of such impairment; or . . . [is] regarded as having such an impairment."

Title I of the ADA deals with issues of employment, Title II with public services, Title III with public accommodations and services by private entities, and Title IV with access to telecommunications. Under Title I, the ADA specifies that a disabled individual (as defined above) who, "with or without reasonable accommodation, can perform the essential functions of the employment position" comes under the ADA's protection.

Building on Title II, in the 1999 case *Olmstead v. L.C.,* the U.S. Supreme Court held that "states are required to provide community-based treatment for persons with mental disabilities when the State's treatment professionals determine that such placement is appropriate, the affected persons do not oppose such treatment, and the placement can be reasonably accommodated." In that decision, the Court held that "unjustified placement or retention of persons in institutions . . . constitutes a form of discrimination" that the ADA prohibits and philosophically appears to have been influenced by the "least restrictive alternative" concept explicated in *Lake v. Cameron.* However, the Court deferred to the states the decision as to what community resources might be appropriate, addressing only the issue of equitable provision of existing services rather than what services ought to be available.

MENTAL HEALTH PARITY

The term *mental health parity* refers to the effort to treat mental health financing on the same basis as financing for general health services. Under the concept of mental health parity, health insurance and health plan coverage for treatment of mental illness would be equal with coverage of treatment for all other illnesses, using the same terms and conditions. Mental illness would be recognized as an issue equal in importance to physical illness.

Advocates for mental health parity, such as the National Alliance for the Mentally Ill (NAMI), believe that mental illnesses are real illnesses, that treatment works, and that there is no medical or economic justification for health plans to apply different terms and conditions to the coverage of treatment for mental illness than they do to coverage of treatment for physical illness.

President Bill Clinton signed the Mental Health Parity Act (P.L. 104-204) into law in 1996. With the leadership of Senators Pete Domenici (R-NM) and the late Paul Wellstone (D-MN), this law created a standard of parity for annual and lifetime dollar limits.

The law applies to employers that offer mental health benefits but does not mandate such coverage. Mental health advocates such as NAMI are concerned that the law allows health insurers to employ cost-shifting mechanisms, such as adjusting limits on mental illness inpatient days and outpatient visits, limiting prescription drugs, raising patient copayments and deductibles, and modifying the definition of *medical necessity.*

The U.S. General Accounting Office (GAO 2000) has found that lower limits for inpatient and outpatient mental illness treatments have continued in spite of the law, and, in some cases, insurers have actually expanded such measures to help keep costs down. The law does, however, apply to fully insured state-regulated health plans and self-insured plans that are exempt from state laws under the Employee Retirement Income Security Act (ERISA), which are regulated by the U.S. Department of Labor. Existing state parity laws are not preempted by the federal law. That is, a state law requiring more comprehensive coverage is not weakened by the federal law, nor does the federal law preclude a state from enacting stronger parity legislation. The law includes a small-business exemption for firms with 50 or fewer employees and an increased cost exemption for employers that can demonstrate a rise in costs of one percent or more due to parity implementation. The GAO also found that 86 percent of surveyed health plans are complying with the law. Noncompliance may be the result of a lack of effort on the part of state insurance commissioners, the Centers for Medicare and Medicaid Policy, and the Pension and Welfare Benefits Administration to educate employers about the new law.

Evidence shows that the effects of mental health parity laws on costs are minimal. By introducing managed care or increasing its level, insurers can significantly limit or even reduce the costs of implementing mental health parity. In plans that have not previously used managed care, introducing parity simultaneously with managed care can result in an actual reduction in costs.

Given that recent studies have shown that parity laws do not increase costs significantly, and given that extensive limits on mental health benefits can create major financial burdens for patients and their families, mental health parity represents an important way in which society can advance the concept of comprehensive health care.

—Richard Huston Sewell

MENTAL ILLNESS

Mental illness is a contentious concept. Some argue that it is a pathophysiological condition that resides in the individual, whereas others assert that it is a set of behaviors produced by and interpreted in the individual's physical, social, and cultural environment. The public health viewpoint integrates these two positions. For public health scholars and practitioners, mental illness is characterized by a set of conditions and behaviors that result from the interactions among the individual, society, and the environment.

From a medical perspective, mental and behavioral disorders are understood as clinically significant conditions characterized by alterations in thinking, mood (emotions), or behavior associated with personal distress and/or impaired functioning. Mental and behavioral disorders are viewed not just as variations within the range of "normal," but as clearly abnormal or pathological phenomena. However, a single occurrence of abnormal behavior or a short period of changes in mood does not, of itself, signify the presence of a mental or behavioral disorder. In order to be categorized as disorders, such abnormalities must be sustained over specific periods (for example, two weeks for a depressive episode) or be recurring, and they must result in some personal distress or impaired functioning in one or more areas of life.

Mental and behavioral disorders are also characterized by specific symptoms and signs, and they usually follow a more or less predictable natural course, unless interventions are made. Not all human distress is mental disorder. Individuals may be distressed because of personal or social circumstances, for instance; unless all the essential criteria for a particular disorder are satisfied, such distress is not classified as a mental disorder.

Diverse ways of thinking and behaving across cultures can influence the ways in which mental disorders manifest, but these ways of thinking and behaving are not, of themselves, indicative of disorders. Thus, culturally determined normal variations must not be labeled mental disorders. Nor should social, religious, or political beliefs be taken as evidence of mental disorder.

Two systems of classification of mental disorders are widely used for both clinical and research purposes. The World Health Organization's (1993) International Classification of Disorders (ICD-10) categorizes both physical and mental health disorders. The American Psychiatric Association's (2004) *Diagnostic and Statistical Manual of Mental Disorders* presents a classification system used only for mental disorders. Medical professionals use these two coordinated classification systems to categorize mental disorders, based on criteria sets with defining features, for diagnosis, treatment, research, and reimbursement purposes.

DIAGNOSING DISORDERS

Practitioners identify and diagnose mental and behavioral disorders using clinical methods that are similar to those used for physical disorders. These methods include the careful and detailed collection of historical information from the individual and others, including the individual's family; a systematic clinical examination for mental status; and the administration of specialized tests and investigations, as needed. Advances made in recent decades have helped to standardize clinical assessment and improve the reliability of diagnosis. Structured interview schedules, uniform definitions of symptoms and signs, and standard diagnostic criteria have made it possible for practitioners to achieve a high degree of reliability and validity in the diagnosis of mental disorders. Structured interview schedules and diagnostic symptom/sign checklists allow mental health professionals to collect information using standard questions and precoded responses. The symptoms and signs have been defined in detail to allow for uniform application. Finally, diagnostic criteria for disorders have been standardized internationally. Mental disorders can now be diagnosed as reliably and accurately as most of the common physical disorders.

PREVALENCE OF DISORDERS

Mental and behavioral disorders are found in people of all regions, all countries, and all societies. They are present in women and men at all stages of the life course. They are present among the rich and the poor, and among people living in both urban and rural areas. Recent analyses conducted by the World Health Organization (2001) found that neuropsychiatric conditions, which included a selection of these disorders, had an aggregate point prevalence of about 10 percent for adults. The WHO estimates that about 450 million people suffer from neuropsychiatric conditions, including unipolar depressive disorders, bipolar affective disorder, schizophrenia, epilepsy, alcohol and selected drug use disorders, Alzheimer's and other dementias, post-traumatic stress disorder, obsessive-compulsive disorder, panic disorder, and primary insomnia.

Prevalence rates for the disorders examined differ depending on whether the focus is on a point in time (point prevalence), a period of time (period prevalence), or the whole life of the individual (lifetime prevalence). Prevalence figures also vary based on the concepts and definitions of the disorders included in the study. When all the disorders included in the ICD-10 are considered, relatively high prevalence rates have been reported. Surveys conducted in developed as well as developing countries have shown that more than 25 percent of individuals develop one or more mental or behavioral disorders in their lifetimes.

Most studies have found the overall prevalence of mental disorders to be higher among women than among men. Much of this difference is accounted for by the differential distribution of disorders, however. Severe mental disorders are about equally common among men and women, with the exceptions of depression, which is more common among women, and substance use disorders, which are more common among men.

CATEGORIES OF MENTAL DISORDERS

The ICD-10 lists 10 major categories of mental disorders under Section F as follows:

F00–F09: Organic, including symptomatic, mental disorders

F10–F19: Mental and behavioral disorders due to psychoactive substance use

F20–F29: Schizophrenia, schizotypal and delusional disorders

F30–F39: Mood (affective) disorders

F40–F49: Neurotic, stress-related, and somatoform disorders

F50–F59: Behavioral syndromes associated with physiological disturbances and physical factors

F60–F69: Disorders of adult personality and behavior

F70–F79: Mental retardation

F80–F89: Disorders of psychological development

F90–F99: Behavioral and emotional disorders with onset usually occurring in childhood and adolescence

The ICD-10 provides clinical descriptions and diagnostic guidelines for all of these diagnostic categories. Some of the most important clinical categories are described below (these descriptions are based on those provided in World Health Organization 1993).

F00–F09: Organic, Including Symptomatic, Mental Disorders

This category comprises a range of mental disorders grouped together on the basis of their having in common a demonstrable etiology in cerebral disease, brain injury, or other insult leading to cerebral dysfunction. The dysfunction may be primary, as in diseases, injuries, and insults that affect the brain directly and effectively, or secondary, as in systematic diseases and disorders that attack the brain only as one of the multiple organs or systems of the body that are involved.

Dementia is a syndrome due to disease of the brain, usually of a chronic or progressive nature, in which there is disturbance of multiple higher cortical functions, including memory, thinking, orientation, comprehension, calculation, learning capacity, language, and judgment. Consciousness is not clouded. The impairments of the cognitive function are commonly accompanied, and occasionally preceded, by deterioration in emotional control, social behavior, or motivation. This syndrome occurs in Alzheimer's disease, in cerebrovascular disease, and in other conditions primarily or secondarily affecting the brain.

F10–F19: Mental and Behavioral Disorders Due to Psychoactive Substance Use

This category contains a wide variety of disorders that differ in severity and clinical form but are all attributable to the use of one or more psychoactive substances, which may or may not have been medically prescribed. Identification of the psychoactive substance should be based on as many sources of information as possible. These include self-report data, analysis of blood and other body fluids, characteristic physical and psychological symptoms, clinical signs and behavior, and other evidence, such as a drug being in the patient's possession or reports from informed third parties. Many drug users take more than one type of psychoactive substance. The main diagnosis should be classified, whenever possible, according to the substance or class of substance that has caused or contributed most to the presenting clinical syndrome.

F20–F29: Schizophrenia, Schizotypal and Delusional Disorders

This category brings together schizophrenia (the most important member of the group), schizotypal disorder, persistent delusional disorders, and a larger group of acute transient psychotic disorders. Schizoaffective disorders are included here in spite of their controversial nature.

F20: Schizophrenia

The schizophrenic disorders are characterized in general by fundamental and characteristic distortions of thinking and perception, and by affects that are inappropriate or blunted. Clear consciousness and intellectual capacity are usually maintained, although certain cognitive deficits may evolve over the course of time. The most important pathological phenomena include thought echo, thought insertion or withdrawal, thought broadcasting, delusional perception and delusions control, influence or passivity, hallucinatory voices commenting on or discussing the patient in the third person, thought disorders, and negative symptoms.

F30–F39: Mood (Affective) Disorders

This category contains disorders in which the fundamental disturbance is a change in affect or mood to depression (with or without associated anxiety) or to elation. The mood change is usually accompanied by a change in overall level of activity; most of the other symptoms are either secondary to or easily understood in the context of the change in mood and activity. Most of these disorders tend to be recurrent, and the onset of individual symptoms can often be related to stressful events or situations.

F30: Manic Episode

The underlying characteristics of this disorder are elevated mood and an increase in the quantity and speed of physical and mental activity. Elation is accompanied by increased energy, resulting in overactivity, pressure of speech, and a decreased need for sleep. Normal social inhibitions are lost, attention cannot be sustained, and there is often marked distractibility. Self-esteem is inflated and grandiose, and overly optimistic ideas are freely expressed.

F32: Depressive Episode

The individual usually suffers from depressed mood, loss of interest and enjoyment, and reduced energy leading to increased fatigability and diminished activity. Marked tiredness after only slight effort is common. Other common symptoms are reduced concentration and attention, reduced self-esteem and self-confidence, ideas of guilt and unworthiness, black and pessimistic view of the future, ideas or acts of self-harm or suicide, disturbed sleep, and diminished appetite.

A depressive episode may also be diagnosed when a chronic depression of mood lasts at least several years but is not sufficiently severe, or does not include sufficiently prolonged individual episodes, to justify a diagnosis of severe, moderate, or mild recurrent depressive disorder.

F40–F49: Neurotic, Stress-Related, and Somatoform Disorders

When nervousness, anxiety, and depression are persistently or episodically combined with irrational fears, obsessive thoughts, fatigue, and a number of different somatic disturbances for which no cause can be found, the condition is called *neurosis*. Stress-related disorders are characterized by the development of anxiety, dissociation, and other symptoms that occur within one month after exposure to an extremely traumatic stressor, such as death of a parent or spouse, loss of a job, or diagnosis of a life-threatening illness. The common element in somatoform disorders is the presence of physical symptoms that suggest a medical problem when, in fact, these symptoms are not explained by a general medical condition, the direct effects of substance use, or another mental disorder. An example is hypochondriasis (the preoccupation with the fear of having a serious disease based on the misinterpretation of one's bodily symptoms or functions).

F42: Obsessive-Compulsive Disorder

The essential feature of obsessive-compulsive disorder is the recurrence of obsessional thoughts or compulsive acts. Obsessional thoughts are ideas, images, or impulses that enter the patient's mind again and again in a stereotyped form. They are almost invariably distressing, and the patient often tries, unsuccessfully, to resist them. The patient does, however, recognize them as his or her own thoughts, even though they are involuntary and often repugnant. Compulsive acts or rituals are stereotyped behaviors that are repeated again and again. They are not inherently enjoyable, nor do they result in the completion of inherently useful tasks. Usually the patient recognizes this behavior as pointless or ineffectual and makes repeated attempts to resist performing the behavior.

F43: Reaction to Severe Stress, and Adjustment Disorders

This category includes disorders identifiable not only on the basis of symptoms and course but also through the existence of one or the other of two causative influences: an exceptionally stressful life event producing an acute stress reaction or a significant change leading to continued unpleasant circumstances that result in an adjustment disorder. The stressful events or the continuing unpleasant circumstances are the primary and overriding causal factor; the disorder would not have occurred without their impact.

F43.0: Acute Stress Reaction

An acute stress reaction is a transient disorder that develops in an individual without any other apparent mental disorder in response to exceptional physical and mental stress and that usually subsides within hours or days. Individual vulnerability and coping capacity play roles in the occurrence and severity of acute stress reactions. The symptoms typically show a mixed and changing picture and include an initial state of "daze" with some constriction of the field of consciousness and narrowing of attention, inability to comprehend stimuli, and disorientation. Autonomic signs or panic anxiety (tachycardia, sweating, flushing) are commonly present. The symptoms usually appear within minutes of the impact of the stressful stimulus or event and disappear within two to three days (often within hours). Partial or complete amnesia for the episode may be present.

F43.1: Posttraumatic Stress Disorder

Posttraumatic stress disorder (PTSD) arises as a delayed or protracted response to a stressful event or situation (of either brief or long duration) of an exceptionally threatening or catastrophic nature that is likely to cause pervasive distress in almost anyone. Predisposing factors, such as particular personality traits or previous history of neurotic illness, may lower the threshold for the development of PTSD or aggravate its course. Typical features include episodes of repeated reliving of trauma in intrusive memories ("flashbacks"), dreams, or nightmares occurring against a persisting background of a sense of "numbness" and emotional blunting, detachment from other people, unresponsiveness to surroundings, anhedonia, and avoidance of activities and situations reminiscent of the trauma. There is usually a state of automatic hyperarousal with hypervigilance, an enhanced startle reaction, and insomnia. The onset follows the trauma with a latency period that may range from a few weeks to months. The course fluctuates, but recovery can be expected in the majority of cases. In a small proportion of cases the condition may follow a chronic course over many years, with eventual transition to an enduring personality change.

F48.0: Neurasthenia

Considerable cultural variations occur in the presentation of neurasthenia, and two main types occur, with substantial overlap. In one type, the main feature is a complaint of increased fatigue after mental effort, often associated with some decrease in occupational performance or coping efficiency in daily tasks. The mental fatigability is typically described as an unpleasant intrusion of distracting associations or recollections, difficulty in concentrating, and generally inefficient thinking. In the other type, the emphasis is on feelings of bodily and physical weakness and exhaustion after only minimal effort, accompanied by a feeling of muscular aches and pains and inability to relax. In both types, several other unpleasant physical feelings are common, including dizziness, tension headaches, and feelings of general instability. Worry about decreasing mental and bodily well-being, irritability, anhedonia, and varying minor degrees of both depression and anxiety are all common.

F50–F59: Behavioral Syndromes Associated with Physiological Disturbances and Physical Factors

This category encompasses behavioral problems that are related to physiological factors, such as sleep and sexual disorders. Sleep disorders include insomnia, substance-induced problems with sleep, sleepwalking, breathing-related sleep disorders, and circadian rhythm disorders. Sexual problems such as pain during intercourse, aversion to sexual activity, premature ejaculation, male erectile dysfunction, and lack of sexual desire are examples of disorders that often have physiological components.

F60–F69: Disorders of Adult Personality and Behavior

This category includes a variety of conditions and behavior patterns of clinical significance that tend to be persistent and appear to be expressions of the individual's characteristic lifestyle and mode of relating to him- or herself and others. Some of these conditions and patterns of behavior emerge early in the course of development as a result of both constitutional factors and social experience, whereas others are acquired later in life. Specific personality disorders, mixed personality disorders, and enduring personality changes are deeply ingrained and enduring behavior patterns that manifest as inflexible responses to a broad range of personal and social situations. They represent extreme or significant deviations from the way in which the average individual in a given culture perceives, thinks, feels, and (particularly) relates to others. Such behavior patterns tend to be stable and often encompass multiple domains of behavior and psychological functioning. They are frequently, but not always, associated with various degrees of subjective distress and problems of social performance.

F70–F79: Mental Retardation

Mental retardation is a condition of arrested or incomplete development of the mind that is especially characterized by impairment of skills manifested during the development period, skills that contribute to the overall level of intelligence (i.e., cognitive, language, motor, and social abilities). Retardation can occur with or without mental or physical condition. Degrees of mental retardation are conventionally estimated through the use of standardized intelligence tests. These can be supplemented by scales designed to assess social adaptation in given environments. These measures provide an approximate indication of the degree of mental retardation, but the diagnosis also depends on the overall assessment of intellectual functioning by a skilled diagnostician. Intellectual abilities and social adaptation may change over time, and even an individual with very poor abilities may improve as a result of training and rehabilitation. Diagnosis should be based on the individual's current level of functioning.

F80–F89: Disorders of Psychological Development

The disorders included in this category have three things in common: (a) onset invariably during infancy or childhood, (b) impairment or delay in development of functions that are strongly related to biological maturation of the central nervous system, and (c) a steady course without remissions and relapses. In most cases, the functions affected include language, visuospatial skills, and motor coordination. Usually the delay or impairment has been present from as early as it could be detected reliably and will diminish progressively as the child grows older, although milder deficits often remain in adult life.

F90–F99: Behavioral and Emotional Disorders with Onset Usually Occurring in Childhood and Adolescence

F90: Hyperkinetic Disorders

Hyperkinetic disorders are characterized by early onset (usually in the first years of life), lack of persistence in activities that require cognitive involvement, and a tendency to move from one activity to another without completing any one, together with disorganized, ill-regulated, and excessive activity. Hyperkinetic children are often reckless, impulsive, and prone to accidents, and they frequently find themselves in disciplinary trouble because of unthinking breaches of rules rather than deliberate defiance. Their relationships with adults are often socially disinhibited, with a lack of normal caution and reserve. They are unpopular with other children and may become isolated. Impairment of cognitive functions is common in such children, and specific delays in motor and language development are disproportionately frequent. Secondary complications include dissocial behavior and low self-esteem.

F91: Conduct Disorders

Conduct disorders are characterized by repetitive and persistent patterns of dissocial, aggressive, or defiant conduct. Such behavior amounts to major violations of age-appropriate social expectations; it is more severe than ordinary childish mischief or adolescent rebelliousness and is of an enduring nature (six months or longer). Features of conduct disorder can also be symptomatic of other psychiatric conditions, in which case the underlying diagnosis should be preferred.

THE CONTEXT OF MENTAL ILLNESS

The preceding discussion has summarized the psychiatric/medical approach to and classification of mental illness. In contrast to this approach, a growing literature in the social and behavioral sciences argues as follows:

> 1. *Mental illness* is a term that refers to a broad range of conditions and behaviours. For this reason, the concept of mental illness is too amorphous to be useful except as a way of speaking about the aggregate subject matter of psychiatry.
> 2. The attribution of madness to aberrant thoughts, feelings and behaviours is not inherent to the condition but is rather contingent on the social and cultural context within which these thoughts, feelings and behaviours occur.
> 3. The attribution of madness depends not only on the setting but also on the person's personal and demographic characteristics such as race, ethnicity, poverty, age and sexual identity which accentuate or ameliorate the process of stigmatization. (Aneshensel and Phelan 1999:5–6)

Based on these arguments, scholars are paying increased attention to the study of behaviors and "normality" within specific groups and social and cultural contexts. In sum, these arguments have led Horwitz (2002) to the following definitions:

> Mental diseases are conditions where symptoms indicate underlying dysfunctions, are distinct from other disease conditions, and have certain universal features. Mental disorders include all mental diseases as well as psychological dysfunctions whose overt symptoms are shaped by cultural as well as natural processes. Finally, mental illnesses refer to whatever conditions a particular group defines as such. In contrast to the concepts of "mental disease" and "mental disorder" which have valid and invalid applications, the concept of "mental illness" refers to the actual labelling process in any group and so cannot be true or false. (p. 15)

MENTAL RETARDATION, HISTORY OF

From ancient superstition to modern science, from old to modern empires, the history of intellectual disability is largely one of expanded possibilities rather than total change. Stigma, exclusion, invisibility, abandonment, impoverishment, even systematic extermination of intellectually disabled children and adults persist today as they have throughout history. At the same time, acceptance, visibility, inclusion, support, and self-advocacy have also become increasingly available to at least some of those same individuals. Simultaneously, one can find in the current circumstances of intellectually disabled people the echoes of the worst atrocities and best achievements that history has to offer.

Like most forms of disability, intellectual disability has gone under many names. At various times, and in various countries, people judged to have some type of difficulty with learning and abstract thought have been called fools, natural fools, idiots, cretins, aments, simpletons, imbeciles, and morons; they have been described also as fatuous, feebleminded, mentally defective, mentally retarded, learning disabled, and developmentally disabled. The question arises as to whether there is something stable, something physiologically persistent, behind those terms and the historical contexts within which their usage arose and declined. Regardless of how one answers that question, the need for a history of intellectual disability that recognizes the complexity of interaction between the name and the thing being named is clear.

The history of intellectual disability, then, should include the evolution of both the concept itself and the narrative of those to whom the concept has been applied. To use a term that is now avoided but was once the professional term of choice in the English-speaking world, the history of "idiocy" (i.e., the use of the term) is different from the history of idiocy. Until recently, however, the historiography of intellectual disability has emphasized the conceptual development and programmatic innovations over the daily lives of those with the disability. As one historian has put it, the "social marginality" of people with intellectual disabilities has, until recently, been carried over into an "academic marginality" where historians seemed to feel that people who could not learn were also not worth learning about (Digby 1996:1). In part, this simply reflects the evidence that is available. For the premodern eras, for example, we have much more evidence about the conceptual developments than about what life was like for intellectually disabled people and their families. In general, we know more about what philosophers and politicians of a given era and culture proposed for definitions and policies than we do about the quotidian reality of those covered by the definition and affected by the policies.

PREMODERN ERAS

What sparse evidence there is supports the notion that intellectually disabled people have been recognized as part of societies from the earliest times. In many cases, that recognition was harsh and violent. Early laws in ancient Greece and Rome, for example, established procedures for the killing or abandonment of infants judged to be too deformed or intellectually disabled to be valued as human. At the same time, however, scholars also point to evidence of early nomadic tribes who continued to transport members of their clans even when they had congenital physical and intellectual disabilities (Goodey 1995; Scheerenberger 1983). There is also evidence that in the Greek and Roman societies some of those with intellectual—and other—disabilities who survived into adulthood became servants or slaves in the households of the ruling classes, where they were relatively well cared for compared with the majority of the poor and oppressed (Rose 2003). The Roman philosopher Seneca complained, for example, about the blind and fatuous servant his wife kept at home even as the woman's impairments became more severe. Indeed, anthropological evidence from non-Western cultures suggests that the treatment of intellectually disabled people in preliterate societies was probably tremendously varied. As one of the anthropologists who first focused on the evidence has put it, "Nothing can be more certain than the conclusion that how the mentally retarded are seen and responded to in the non-Western world is a complex and variable matter" (Edgerton 1970:537).

Throughout the Middle Ages in Europe, this variety persisted. At the same time, as disabled beggars wandered from town to town, free but unsupported, church-related hospitals developed that provided both sanctuary and care to intellectually disabled individuals abandoned by their families. While infanticide continued to receive religious tolerance, if not sanction, the court jester tradition also placed great value on having natural fools always present and cared for, but without any real location within the social hierarchy—constant outsiders. One historian of the period notes that the custom of keeping a natural fool was so popular in Germany that by the early sixteenth century, "one finds them in the household of almost any rich and powerful family" (Midelfort 1999:248). For the most part, both intellectual and physical disability were seen in the Middle Ages as part of the "hodgepodge of normality" that made up everyday society. "There was an acceptance, at times awkward, at times brutal, at times compassionate, a kind of indifferent, fatalistic integration, without ideology but also without confrontation" (Stiker 1999:65).

By the thirteenth and fourteenth centuries, legal distinctions began to appear between lunacy and idiocy. The idiot (or "natural fool") was someone incapable of abstract thought from birth, whereas the lunatic became deranged sometime after birth. Still, even with these new distinctions, the conceptual evolution of terms and explanations for intellectual disability are much less varied than was the actual treatment of people with that impairment. Consistently, from Plato to Locke, the effort was to label and exclude those who were visibly and congenitally different. Whether seen as a joke or punishment of the gods or a materialistic imbalance of the bodily humors, the birth of a child with noticeable disabilities gave permission—even responsibility—to dispose of that which was something other than fully human. However, early on, the focus was on visible difference. The changeling, for example, was the visibly disabled child of nondisabled parents. The terms of reference were many and confusing.

It is with the empiricism of John Locke, however, that the understanding of idiocy moved from a primarily visible difference associated with congenital anomalies to include those who looked "normal" but lacked the capacity for abstract or "natural" reason. The expansion was important and laid the conceptual groundwork for the subsequent emergence of a new social response based in diagnostic expertise and therapeutic efficacy. If idiocy was not always apparent or visibly monstrous, then identification through testing and intervention through training became vital for both the protection of society and the remediation of the individual.

THE MODERN ERA

As it did with other areas of human endeavor, the Enlightenment brought a wave of scientific interventionism and governmental reform to the social awareness of intellectual disability. The emerging field of psychology built on the newly empirical approaches to the mental as well as the physical to make optimistic claims of precise identification and gradual improvement. Classification typologies became increasingly elaborate, with growing emphasis on close clinical observation and physiological examination. The official social response gradually moved on the one hand from the custodial to the therapeutic and on the other hand from tolerant neglect to aggressive confinement.

Perhaps the most famous and influential "experiment" in the development of this new psychological training occurred in France at the very beginning of the nineteenth century. When a strange, uncivilized boy was captured in southern France (the so-called Wild Boy of Aveyron), a young doctor, Jean Marc Gaspard Itard, undertook to teach this "noble savage" using the careful training of the senses consistent with the radical empiricism of Condillac and other French philosophers. Although Itard ultimately regarded his experiment as a failure, because of the lack of sufficient progress by the boy he named Victor, others took over his methods and achievements to proclaim a new therapeutic regime that gave hope for the remediation or cure of at least some types of idiocy. Throughout the remainder of the nineteenth century, there was a rapid spread of specialized idiot asylums in both Europe and North America led by a new professional class of institutional psychologists who made claims of cure or dramatic improvement through early and intensive instruction and regimentation. People such as Samuel Howe and Edouard Séguin in the United States, Johann Guggenbühl in Switzerland, Carl Saegert in Germany, and William Ireland and John Langdon Down in England began congregate residential facilities for the education and training of intellectually disabled children and young adults.

By the last quarter of the nineteenth century, this wave of optimism had subsided but the institutions continued to expand. Even with this rise of institutions, most individuals with intellectual disabilities remained the responsibility of their families or the communities where they lived. Outside the walls of the new institutions, intellectual disability remained primarily an economic problem of poverty and dependence. With the progress of industrial urbanization and the need for a stable workforce, unemployable intellectually disabled people were also portrayed as a social problem: the source of the crime and degeneracy that was seen as a growing threat to the commonweal.

THE TWENTIETH CENTURY

For much of the twentieth century, emphasis remained on classification and control of the intellectually disabled rather than on education and support. Early in the century, the intelligence test developed by Alfred Binet for the Paris schools was rapidly put to use in the United States in schools and other institutions. Here finally was an operational application of Locke's definition. What came to be called IQ (or intelligence quotient) tests were efficient, supposedly objective instruments that could identify those children who were intellectually inferior even when their physical appearance was "normal" and their intellectual inferiority mild. So precise were these new tests that a new level of mild feeblemindedness could now be identified. The psychologist Henry H. Goddard coined the term *moron* to refer to these individuals, who were said to have a mental age between 7 and 12 years. *Feeblemindedness* became the generic term in the United States for all types and levels of intellectual disability.

The rapid adoption of the IQ test not only made the placement of students into the newly emerging special education classes efficient and "scientific," it also supplied more than enough evidence for eugenicists to bemoan the growing "burden of the feebleminded" as a plague on modern civilization in both moral and economic terms. The new field of psychometrics combined with the new obsession with the scientific study of heredity to produce the pseudoscience of eugenics, whose purpose was to limit the spread of feeblemindedness through incarceration in custodial institutions and involuntary sterilization. It was a practice that reached its logical extreme with the perversions of Nazi medicine, but it was pursued to greater or lesser degrees by almost all industrialized nations and continued well into the 1960s and 1970s in many countries.

Post–World War II Developments

Throughout the 1950s and the 1960s, the familiar strands of segregation and exclusion of intellectually disabled people continued to interweave with strands of community presence and family support. By the 1960s, several parent advocacy organizations had coalesced to form a national presence in both Europe and North America, lobbying for expanded educational programs and family support. By 1970, the institutional growth in the United States had crested at just under 200,000 individuals. Buttressed by journalistic exposés and lawsuits documenting patterns of institutional abuse and neglect, a slow trend called *deinstitutionalization* began to move intellectually disabled people from institutions to the community. Individuals with intellectual disabilities themselves began to organize self-advocacy groups protesting discrimination and exclusion. Programs to support the integration of intellectually disabled children and adults in home, school, workplace, and community became the official policy in most countries in Western Europe and North America. Still, by the end of the twentieth century, thousands of individuals were still living in large, segregated facilities. In the latest terminological change, *intellectual disability* has begun to replace *mental retardation* (in the United States) and *learning disability* (in Great Britain) as the term of choice.

MERCY KILLING

See Euthanasia

MICHAEL IV, EMPEROR (?–1041)

Byzantine ruler

The Byzantine Emperor Michael IV (reign 1034–1041 CE) suffered increasingly severe epileptic fits during his reign, and his attendants made efforts to hide his condition from the public. During public audiences and other ceremonies, they watched closely for signs of an impending fit and immediately let down curtains to hide him when they saw such signs. When out walking or riding, he was surrounded by guards who usually managed to conceal him if he became ill. The contemporary courtier and chronicler Michael Psellus, who described Michael IV's reign impartially and in detail, noted that the emperor recovered quickly after his fits. Michael IV came to power in very dubious circumstances and without any significant preparation, yet Psellus considered that he conducted himself well as emperor. Even with his condition steadily worsening, "he still supervised the whole administration of the Empire, just as if no illness were weighing upon him at all" (Psellus 1966).

MIDDLE EAST AND THE RISE OF ISLAM

HISTORY OF ARAB/ PROPHETIC MEDICINE

After the prophet Muhammad's death in 632 CE, a great expansion of the Arab Empire took place throughout the eastern Mediterranean. Under the Umayyad caliphate, local political structures remained intact, but by the Abbasid caliphate, the capital of the Arab Empire's administration became centralized in Baghdad (762 CE).

What is known about medicine and disability before Islam and during its expansion is difficult to summarize, as medical approaches were not monolithic but varied and often contradictory. There is a general consensus, however, that healing the sick was, and continues to be, considered in all legal schools of Islam, one of the highest forms of serving Allah (God), second only in importance to performing religious rituals. Despite medicine's high place in Arab-Islamic culture, the Qur'an itself seldom speaks directly of medicine except for references to the curative properties of honey, instructions for ways to wash for prayer when ill, and statements that the sick, lame, or blind are not inherently at fault for their disability. Muslims consider the text to embody the guidance and wisdom that restores and maintains both physical and psychological health. The Qur'an does not espouse a mind-body doctrine of the body, but it does use metaphors of disability such as deafness and blindness in references to God's decision to make some individuals struggle to reach the truth. Mostly, attitudes about and treatment of disease and disability in Islam are embedded within the historical development of Muslim political expansion and rule rather than derived from the sacred text. Following from this, the force and contributions of Islamic medicine during the medieval period were felt by both Muslim and non-Muslim residents of the Arab Empire.

The early ninth century marked the Hellenization of Islam, with translations of Greek, Syriac, Sanskrit, and Pahlavi medical texts into Arabic and subsequent commentaries and expositions by Arabic and Persian physicians. By the end of the ninth century, nearly all of Galen's writings had been translated into Arabic, reflecting the significant influence of his medicine in Arab scientific circles. As such, the Arab-Islamic medical tradition is based on the Graeco-Roman one, with humoral theory at its core.

Several physicians who wrote original treatises and compendiums on medical topics are worth mentioning due to their handling of disability and its treatment.

Al-Razi (Rhazes), a well-known Persian clinician who lived from 865 to 925 CE, wrote *Al-Hawi fi l-tibb (All-Inclusive Work on Medicine),* a 24-volume encyclopedia of medicine. Among other things, this work deals with hereditary diseases, diseases affecting women, and eye diseases. Ibn Sina (Avicenna) wrote *Qanun al-Tibb (Canon of Medicine),* a 14-volume work that investigated the contagious nature of pulmonary tuberculosis, described the symptoms and complications of diabetes mellitus, and examined various psychological illnesses. The *Canon* became the most authoritative reference book in European universities until the seventeenth century. Finally, Abu al-Qasim al-Zahrawi (Albucasis) lived in Cordoba, Spain, during the tenth century. Regarded as an expert pharmacist-surgeon, he wrote a manual on surgery called *Al-Tasrif li-man `ajaza `an al-ta´lif (Recourse of He Who Cannot Compose a Medical Work of His Own)* that included sections detailing methods for amputating limbs and removing foreign bodies. These books were later translated into Latin for widespread use in Europe.

As opposed to the formalized form of Islamic medicine, *Tibb al-nabi* (prophetic medicine) consists of popularized answers to medical issues drawn from the sayings of the prophet Muhammad and his companions in the Hadith. A popular statement of Muhammad's that is stressed in this type of medicine is, "God has sent down a treatment for every ailment." Other statements refer to the restoration of health by God's will. For instance, the question was raised in this literature as to whether or not God would, on Judgment Day, conclude that a person with an amputation tried to escape His will. Although natural causes of illness are recognized, God is said to inflict illness so as to test the individual's strength and ultimately restore his or her faithful character. As such, according to some sayings in prophetic medicine, illness has a redemptive quality to it. Other sayings, however, cite health as the means to strengthen faith and as a reflection of the blessing of God.

In prophetic medicine, prayer rituals and the physical positions they entail are said to provide physical, moral, spiritual, and psychological healing by distracting the individual from pain. They also are believed to exercise the body and ease ailments of the stomach, heart, and intestines. Such integrity of the body is central to prophetic medicine's message. Differences in medical approaches, however, sometimes exist within and between the Hadith of the two major sects of Islam, the Sunni and Shia. Despite their goal of imparting a religious value to medical practices, medical discussions of the Hadith are not considered part of sacred law. This collected medical advice, excluding magic and extensive use of amulets or charms, reflects the preventive approaches and medical treatments commonly practiced by the general population.

Throughout Islamic history, health concerns, both physical and mental, have been imbued with ethical, moral, and religious value. This social outlook has underpinned the establishment and operation of Muslim medical institutions. For example, multifunctional hospitals comprising libraries, pharmacies, and several wards were most often established by rulers, administrators, or other wealthy individuals and were managed by *awqaf* (charitable, religious endowment) foundations on land set aside for such purposes. Hospitals for specific ailments were also founded in this way. According to most schools of thought in Sunni Islam, the endower could participate in the administration of the donated property. This precept tended to encourage the proliferation of private endowments.

The first of their kind, institutions for lepers and the blind were built in Damascus under the Umayyad Caliph al-Walid (reign 705–715 CE). Guides were employed to help blind patients. Often patients were given stipends when they were discharged to help them return to work. Such treatment stands in sharp contrast to the situation in Europe, where lepers were burned to death by decree.

Islamic hospitals proliferated during the Abbasid caliphate (750–1257), especially under Harun al-Rashid, who established the first hospital in Baghdad. Men and women were treated separately. Special hospitals were established for mental patients during this time, as well as homes for orphans and older women. In addition, large hospitals included quarters for mental patients, and some used music therapy as a form of treatment. Treatment of mental illness was considered vital for maintaining one's honor and preserving a sound mind. These were thought of as fundamental rights in Islamic law that the state should protect. These institutions seem to have been inspired by earlier Christian efforts that established hostels for the insane and blind in the Middle East before and during the early medieval period.

Visiting the sick at home or in the hospital is encouraged in the Hadith, and the sick are asked to pray for others in return due to their presumed pure state of being. The ethics of medical care and visitation motivated the foundation of mobile dispensaries during the Abbasid period. These dispensaries extended accessibility to medical services throughout the countryside. In addition, it was decreed that physicians must visit jails, and physicians' services were made more accessible in general through the location of clinics near mosques.

MEDICINE IN MEDIEVAL ISLAMIC HISTORY

Prevalent Ailments and Disabilities

Blindness was perhaps the most common disability in the medieval Islamic world and the one most written about in Islamic medicine. It is discussed in a variety of medieval texts, including theological, philological, historical, legal, and literary. Discussions of the visually disabled dealt not only with questions of a physical nature but also with issues of spiritual blindness. Discussions of blindness also intersected with debates in Islam as an oral versus a written culture.

A number of words in medieval Arabic describe blindness, including *a'ma, makfuf, kafif,* and *darir.* The first of these words means complete disappearance of vision, the next two refer to someone who has lost his or her sight, and the last is the most polite, meaning one whose vision has gone or whose injury has resulted in blindness. The word *akmah* refers to those who are blind from birth and alludes to darkness, but most words for blindness point to physical covering or injury, not symbolic darkness or mental confusion.

From the time of the prophet Muhammad's death until the thirteenth century, contagious diseases such as trachoma, conjunctivitis, and smallpox most often caused visible disabilities. During the expansion phase of Islam, Arabs often contracted eye diseases while traveling, on pilgrimage or as a result of the slave trade. Blindness was also caused by old age, corporal punishment, and battle injury, as well as by marital practices of co-sanguinity. Starting in the tenth century, one way to dethrone a ruler was to blind him. Yet stories abound in the Hadith about blind men becoming devout believers, commanding men in battle, or predicting significant events. For example, Abu Sufyan, the father of the first Umayyad caliph, is said to have lost one eye at the Battle of Attayif and the other at Al-Yarmuk.

Because of the high prevalence of eye diseases, dissection of the eye was permitted as an exception for the pursuit of medical knowledge. For the same reason, specialization in and writing about ophthalmology emerged before other medical specializations. Hunayn ibn Ishaq, an early translator of Greek texts, wrote essays on ophthalmology that were collected in a volume called *Kitab al-`ashr maqalat fi l-`ayn (Book of the Ten Treatises on the Eye),* which became the basis for further research and commentary on the subject for rest of the medieval period.

Under Mamluk rule of Egypt and Syria (1250–1517 CE), the text *Nakt al-humyan fi nukat al-`umyan* by al-Safadi (d. 1361) formed an authoritative study on blindness and the blind. This biographical dictionary mentions elite blind individuals including scholars, Qur'an reciters, lexicographers, and famous poets as well as beggars who feign blindness or are truly impaired. In other types of literature of this period, blind people are treated with other physically disabled and marginal groups, referred to generally as *ahl al-ahat* (those with a physical impairment). Blindness is treated in one of two ways: as a simple difference, such that individuals who are different in this way are not excluded from society, or unfavorably, with the blind categorized along with women and beggars. Questions about the status of a blind person as a suitable witness or transmitter of the traditions posed legal controversies that ultimately stemmed from these two approaches.

The greatest concern related to blindness in Islamic legal and literary texts of the late medieval period is the problem of mobility and the dependence of the blind person on a guide's vision for description, transport, and social interactions. As Fedwa Malti-Douglas (2001) notes, such discussions point to the integration of blind individuals in society and how to best facilitate it. Another concern with similar implications is the act of eating, particularly at a communal meal. A final topic of discussion is the virility of the blind man, which is often presented in a positive, desirous light.

In addition to blindness, discussions about disability in the texts focus on such issues as disabilities of an orthopedic nature, especially in their relation to war or punishment. For instance, the Qur'an sanctions amputation for theft but exempts from such punishment a person who steals due to dire need. Crippling from stoning during battle is also noted in Islamic texts.

In general, the average life span during the medieval period was no more than 35 years, and infant mortality rates were very high. Leprosy, tuberculosis, typhus, scurvy, dysentery, malaria, and paralysis have also been chronicled during medieval Islam. Epidemics of plague also occurred at various points during this period, causing extremely high mortality rates.

Medical and Social Treatment of Disability and Disease

Before and after the advent of Islam, disease and disability in the Arab-Islamic world were treated in ways not unlike those seen in other societies of the time. In fact, the Islamic medical tradition necessarily integrated contributions of other cultures with the expansion of Arab territory. Islamic culture taught that all should be treated with justice, including those with disabilities, in order for balance in society to be achieved. Just as the balance of the humors formed the basis for the medical treatment of disability and disease, this social balance formed the moral basis for the system of charitable works and mutual responsibility in Islamic societies.

Cauterization, cupping, bleeding, setting of bones, and herbal remedies were widely used to treat disability. The populace attributed deviations from general health not only to imbalance of the humors but also to malevolent, supernatural forces or spells; this was especially the case with mental illness. On the other hand, disability was sometimes viewed as conferring luck or blessedness on a person, who could also be seen as having special insight or as being protected from the evil eye. Specific folk treatments varied according to region, ethnic tradition, and the availability of particular medicinal/magical ingredients, but they largely included amulets marked with Qur'anic passages or incantations.

Aside from the controversial issue of blindness, political leaders were generally not barred from ruling due to disability. For example, the Caliph Uthman was said to have scars from smallpox. Although others debated the point, al-Safadi claimed that prophets could be blind but not deaf, as this would hinder the central, oral character of Islamic cultural transmission. Famous poets, philosophers, and other literati were also known to have various disabilities. Records show that women cared for wounded soldiers and for those who became disabled by fighting in wars.

Mental illness is acknowledged and discussed in the Qur'an and Hadith, and during the medieval period, doctors were often appointed to visit asylums to care for patients there. Suicide is forbidden by Islamic law. Although there are no direct or explicit phrases in the Qur'an or Hadith that refer to this issue, the judgment rests on the idea that Allah created life and therefore humans do not ultimately own it. Aside from mental illness, the psychological state of a sick person should, as much as possible, be one of reservation, restraint from complaint, attempts at cheerfulness, and deference to God.

DISABILITY IN THE CONTEMPORARY ISLAMIC WORLD

With the advent of the modern period, particularly after the Napoleonic invasions of Middle East territories in the late eighteenth century, the Ottoman Empire began to accept Western medical approaches as a way to modernize the regime. This integration continued during the period of colonialism and has continued in postcolonial Middle Eastern and other Islamic societies. Still, humoral medicine and Islamic medical texts have continued to influence the treatment of disease and disability even up to the present day.

People in the Islamic world, which entails a vast territory, currently seek both biomedical and traditional folk remedies to address illness and disability. Acceptance of the disabled population varies depending on the country and the conflicts therein. For the general Muslim population, having a disability exempts one from making pilgrimage to Mecca, considered one of the five pillars of Islam.

Organized groups of disabled individuals currently advocate for greater rights and support; these include the National Association for the Rights of Disabled Persons and Youth Association for the Blind, both based in Beirut. Much of the work done on behalf of the disabled community in Islamic countries is organized, administered, and funded by nongovernmental organizations in connection with these grassroots organizations.

Disabilities that commonly exist today in the Arab world and in other Islamic countries include infectious diseases such as tuberculosis and AIDS, chronic illnesses such as heart disease and diabetes, congenital disabilities, cognitive and mental disabilities, and war-related injuries, including quadriplegia, paraplegia, and various amputations related to land mine injuries. Religious debates continue among Muslim jurists on the topics of organ transplantation and genetic engineering.

MILAN CONGRESS ON THE DEAF

See Deafness, Milan Congress of 1880 on

MINDFULNESS MEDITATION

There are two broad forms of meditation, and although one must be careful not to see them as dichotomous, most forms of contemplative practice across cultures and various traditions tend to correspond loosely to one of these two broad forms. One form emphasizes a single point of focus, excluding all other mental content. This point of focus might be an object, image, thought, prayer, or chant. This form of meditation, referred to as *Samatha* in the Buddhist tradition, emphasizes single-pointed concentration as a means of closing out all distractions and disturbances, resulting in a profound sense of tranquility and calm. The other form of meditation, referred to as *Vipassana* or "mindfulness" in the Buddhist tradition, has a very different emphasis. Mindfulness meditation involves an *inclusive* approach to one's ongoing experience and promotes insight through awareness of the present moment. This inclusive awareness occurs through one's nonjudgmental acceptance of everything that arises in the mind and body as one observes each moment as it arises and then dissipates. One accomplishes this by using the sensations of breathing as a means of staying in the present moment. The breath offers a practical means of centering oneself, as it is something that is always present; it also offers a constellation of subtle sensations and movements when experienced through careful attention.

The formal practice of mindfulness can be conducted in a number of ways, including being very still, as in the traditional sitting meditation, and in a form often called *walking meditation.* However, since not everyone can walk, and since the spirit of this method of meditation practice does not depend on walking per se, the term *walking meditation* is really a misnomer. More precisely, this form of mindfulness is *moving meditation,* in which one slowly and deliberately moves one's body (or part of the body) in space, focusing on the sensations of one's breathing and the physical sensations associated with movement. Access to such moving meditation is universal, although the nature of the movement may differ radically in form and degree among different individuals.

The body of research and theoretical literature on the relationship between meditation and health promotion has been growing rapidly in recent years. Recent interest in meditation in relation to health has focused a great deal on mindfulness meditation. This increased attention stems from the realization that an expanded conceptualization of health involves perceiving it as a multitude of experiences that are undergoing continuous change. In order to actualize such an approach to health, however, one must gain an *awareness* of the multitude of changing experiences one is a part of at any given moment. Mindfulness meditation is one means of practicing this awareness.

Methods of contemplative practice that foster self-awareness pose a universal challenge. Because the experience being fostered by any form of meditation is the *process* of attention, without a specific goal or end point, nobody, in fact, has a relative advantage. Because meditation is not based on any external criteria for “success,” it constitutes a welcome paradox in that it is an intensely personal experience that is universally accessible. Individuals who make certain types of adaptations to various meditative practices will likely encounter the same discoveries and frustrations as those who make very different adaptations. Although each person accesses the contemplative process somewhat differently, all enter onto the same path.

Meditators tend to understand, through direct experience, that when it comes to practicing a greater awareness of one’s mind and body, the challenges are similar from person to person regardless of individual differences. Whether one walks or uses a wheelchair, sees clearly or has a visual impairment, has free movement or chronic pain, the process is very much the same. As such, meditation is an inclusive process that each person must embark on for him- or herself, pursuing no goals, casting no judgments, and accumulating no achievements. It is this process of personal observation that lends meditation its “universal design.”

MIR NASIRUDDIN HARAWI

(?–1708)

Afghan Sufi

The Afghan Sufi Mir Nasiruddin Harawi, living at Burhanpur in northern India, appears among the Persian accounts of Sufism, with the usual attributes of piety, independent thinking, charitable giving, rejection of gifts to himself, and vigorous rebuttals of overtures by wealthy people. As a Sufi, Mir Nasiruddin was unusual in that he had been severely disabled since his youth, with paralysis of his legs and left arm. His right arm still functioned, and he worked as a Qur'an copyist, earning enough to keep himself alive. People revered him for his abstemious life, but Mir Nasiruddin gave them a hard time if they were among the powerful. When he denounced the governor of the province, Munawwar Khan, for greed and abuse of power, Munawwar responded correctly by asking the Sufi to guide him, but Mir Nasiruddin did not soften easily. He cited himself as an example of disobedience to Allah, which had resulted in his being crippled. This was not orthodox Islamic teaching, but his aim was to put the fear of God into the governor. He is also reported to have turned down a grant of land from the emperor Aurangzeb.

MIRACLES

Western cultural traditions historically linked with Christianity have, from an early period, associated particular classes of disability with miraculous healing: the blind see and the lame walk more readily in the New Testament than in the Old. In addition to cures of the lame, deaf, dumb, and blind, stories of miracles encompass the relief of ailments ranging from leprosy to that ultimate disability, death.

Patterns established from the earliest centuries continued through the Middle Ages and, in some cases, continue to the present. In medieval miracles, disabilities seem to have been linked to gender and status. In a sample of nearly 3,000 cases (mainly from medieval England), 20 percent of the disabilities linked to "crippling" ailments (usually of the legs) were reported by lower-class women, but only 14 percent of men of the same social level reported crippling ailments; very few upper-class women, and only 7 percent of the men of this class, reported such disabilities. A second very common disability was reported as "blindness," which affected some 16 percent of all women and 11 percent of men from the lower classes, whereas only 3 percent of upper-class pilgrims reported this ailment. This suggests that the lame and the blind pilgrims at medieval shrines were generally of the lower classes and predominantly women. This could be accounted for by the lower classes' limited access to medical treatment (which was costly), poor environmental and living conditions (cold, damp quarters; dietary deficiencies), and perhaps a tendency for more women than men to suffer conversion reaction symptoms. On the other hand, upper-class folk distanced themselves from the lower by reporting symptoms that were often quite specific (suggesting that their position enabled them to consult with doctors) or by reporting "miracles" that had nothing to do with healing; this type was reported by only 3 percent of women and 13 percent of men of the lower classes, but was claimed by 23 percent of the upper-class males.

The most common disabilities, then, resulted in afflictions of the limbs and blindness, reputedly "cured" by a saint or at a holy shrine. It should be understood, however, that the medieval concept of a "miracle" was quite flexible: a miraculous cure could be (a) partial or incomplete, (b) delayed or gradual, or (c) temporary, with succeeding relapses. Even under these conditions, the "cure" was considered a miracle and recorded as such. As for the underlying mechanisms that may explain some of these releases from disability, many of the afflictions reported seem to have been self-limiting, chronic but subject to remission, and psychogenic.

Today's reported cures from places such as Lourdes follow, in general, the same pattern as that suggested by medieval data: The element of hopeful expectation that precedes a pilgrimage, the atmosphere of heightened emotion at the holy place itself, and the sight of examples of canes and crutches left by "cured" visitors create a psychophysiological context in which some disabilities seem to be, at least partially or temporarily, relieved. Apart from the religious context, in the world of modern medicine the curative efficacy latent in the mind of the patient has come to be appreciated; accordingly, medical professionals now tend to treat the whole being while attempting to alleviate the pain and suffering of physical disability.

MOBILITY AIDS

Mobility is a fundamental human need, an important component of the achievement of other goals of independence. Assistive technology—that is, technology that assists individuals with disabilities in being mobile—includes devices that aid in ambulation, wheeled bases that provide mobility for individuals who do not use their lower extremities for ambulation, and personal transportation vehicles used in the community.

Individuals with disabilities may use devices such as lower limb orthotics to enhance their stability during ambulation. Individuals may use lower limb prosthetics if they have acquired disabilities through amputation or if they were born with partial limbs.

Stability during ambulation can be enhanced through the use of common devices such as canes and walkers. Canes are available in several designs, from a single tip to a "quad"-tip base for added stability. Different styles of walkers are also available; some have four rubber feet, whereas others have two rubber feet and two wheels to enable the user to shift the device forward more easily during ambulation. Some walkers are equipped with baskets for carrying objects and fold-down seats for the convenience of users who may need to sit and rest during the course of travel.

A variety of manual wheelchair bases are available to enable individuals to move about in the community. For decades, manual wheelchair design was dominated by heavy, chrome-plated frames, but today many lightweight options exist, with designs utilizing alternate materials such as aluminum, titanium, and composites.

Powered wheelchair frames, which are also available in a variety of styles and materials, enable users to achieve independent mobility if they can operate a standard joystick or specialized controller.

For the users of either manual or powered wheelchairs, proper seating and positioning are required to ensure the maximum opportunity to use the bases independently and without complications such as pressure sores and scoliosis. Commercially available modular seating components and custom-fabricated cushions that exactly match the contours of individual users make such proper seating and positioning possible.

Personal vehicles can also be considered devices that serve as mobility aids for individuals with disabilities. Adaptive equipment such as accelerator and brake buildups, lever controls, and steering wheel posts may be installed in automobiles to enable individuals with disabilities to operate them safely. High-tech joystick controllers may also be installed to allow individuals to operate the acceleration, braking, and turning functions of motor vehicles.

Safe restraint is important for all users of personal vehicles. For individuals who use mobility bases, the type of securement used to anchor the base to the vehicle must take both safety and independence issues into account.

Assistive technology and universal design features of public transportation vehicles also help individuals with disabilities to achieve independent mobility in the community. Examples include buses with front-end kneel-down capability and airplanes with increased clear space for maneuverability.

MODALITIES

The term *modalities,* as used in physical rehabilitation, refers to techniques of application of therapeutic heat and cold, whether by direct transfer of heat from a warmer body to a cooler or by conversion of another form of energy to heat. Direct methods of heat transfer include convection, conduction, and radiation. Examples of these methods include Fluidotherapy, hot packs, and infrared bulbs, respectively. Diathermies (from the Greek *dia,* "through," and *thermi,* "heat") are examples of heating by conversion and include ultrasound, shortwave, and microwave diathermy. Ultrasound converts a high-frequency sound wave (i.e., a longitudinal compression wave) into heat. Shortwave uses radio frequency electrical currents. Microwave is an electromagnetic wave, similar to radar, that is transmitted even in a vacuum. The direct methods of heat transfer are also direct methods of cooling, but in the reverse direction; that is, the human body, or some part thereof, is the warmer body from which heat is transferred to the cooler, as with cold water or cold packs. The latter transfers heat by conduction and, to some extent, radiation. If the cold water is moving, then all three modes of transfer are involved, especially convection.

Physiological effects of heat that may be therapeutically useful include increased extensibility of structures made from collagen, such as burn scar and joint capsular contractures, relief of muscle spasm (but not spasticity), relief of pain, and possibly increased blood flow (but see the discussion of contraindications below). Physiological effects of cold that may be useful include decreased blood flow, prevention of swelling in acute trauma (if combined with rest, compression, and elevation), pain relief, and temporary relief of spasticity. For example, an ice pack applied to the muscles in the calf may remove clonus, a manifestation of spasticity, for up to 90 minutes. This, combined with prolonged static stretch, may improve gait in patients with stroke or central cord syndrome.

Vigorous heat has the following characteristics: The highest temperature is at the site of the pathology; the temperature is brought rapidly to tolerance levels and held there for relatively long periods, such as 20 minutes. Vigorous heat is reserved for chronic processes. It can be achieved in deeply located structures only with the diathermies; however, vigorous heat should not be considered synonymous with the diathermies, as superficial structures, such as burn scar, can be heated vigorously with superficial heating agents.

On the other hand, mild heat can be used even in acute processes, because the acutely inflamed tissues are not heated to tolerance levels. For example, a hot pack can be used over lumbar musculature in spasm associated with a herniated disc because the depth of penetration of the hot pack is only a few millimeters and is not close to the pathologic area. Paraffin is particularly suitable for burn scar, as it helps soften the scar as well as make it more extensible and amenable to stretching therapy.

General contraindications to heat include lack of sensation in the area to be treated, obtundation (dulled or reduced level of alertness or consciousness) of the patient, ischemia in the area to be treated, and cancer in the area to be treated (although special oncology centers may use heat as an adjunct to radiation or regional chemotherapy). General contraindications to cold are the same, except for the cancer; safety in the latter has not been established.

Specific contraindications to shortwave and microwave include the presence of pacemakers and metallic implants. Application near the eyes should be avoided, even with shielding, which does not provide adequate protection. Ultrasound can be used in the presence of metal implants, but safety in the presence of synthetic resins has not been established. Any of the diathermies should be used only with great caution, if at all, in pregnant women.

MODEL OF HUMAN OCCUPATION

The model of human occupation is a theoretical framework developed in occupational therapy to guide services for disabled persons. It is the most widely used model in occupational therapy and is also used by other rehabilitation professionals. As its name implies, this model focuses on occupation, which is defined as the individual's engagement in work, play, or other daily living activities within his or her physical, temporal, and sociocultural context. The model seeks to explain how impairments affect the way persons engage in and experience their occupations. It focuses on how persons are motivated toward and choose what they do, how they organize their everyday behavior patterns and routines, and how performance is shaped by subjective experience.

According to the model of human occupation, the choices people make to engage in occupations emanate from a drive for action mediated by thoughts and feelings about personal effectiveness, what is important and meaningful, and what is enjoyable and satisfying to do. The model highlights how impairments can influence and resonate with a person's sense of personal effectiveness and what a person holds as important and enjoyable. It proposes that people organize their actions into recurrent patterns that are regulated by habits and roles. Habits are learned ways of doing things that unfold automatically. Roles are internalized attitudes and ways of behaving that serve as a framework for looking out on the world and for acting. The model underscores the ways in which impairments can disrupt or pose challenges to developing habits. It also calls attention to how societal attitudes can hinder access to roles. This model conceptualizes the capacity for doing things as involving not only objectively defined abilities and impairments, but also subjective experience. Thus, the model emphasizes the lived experience of impairments as a major factor in what a person can and cannot do.

The model of human occupation conceptualizes the physical and social environment as providing opportunities, resources, demands, and constraints that may affect each person's motivation, patterns of action, and performance. As with personal factors, the model underscores how the impact of physical and social environmental characteristics can be altered when a person experiences impairments. It also recognizes that physical and social environments can present significant obstacles, ranging from architectural barriers to social injustice.

More than 20 assessments have been developed (including substantial empirical validation) for use with the model of human occupation. The assessments emphasize capturing the disabled person's experience and point of view. Although some involve observation of the disabled person, most are designed to give the disabled person an opportunity to report directly his or her own perceptions, perspectives, desires, and priorities. Services based on this model do not focus on changing impairments per se; instead, they focus on how a person can be supported to achieve the kind of life he or she wants. The model emphasizes that services should be based on the client's desires and experiences. It emphasizes that achieving change ordinarily involves both physical and social environmental alterations as well as changes within the individual (e.g., changes in attitudes, habits, roles, and ways of performing).

To date, more than 300 works have been published relating to the model of human occupation. Approximately one-third of these report on empirical studies that have examined the theory and/or utility of the model.

▣ MODELS

A model is a conceptual tool. Models are useful for making sense of reality and for achieving consensus. They help us to see both the forest and the trees, and they ensure consistency of terminology and usage. In the field of disability, the debate over models and definitions has been particularly heated and long running. This entry explores why models of disability are important and then analyzes four different models, selected on the basis of their influence and significance. The final section of the entry explores how models have been applied in practice and presents recommendations about resolving the models debate.

THE IMPORTANCE OF MODELS

Disability is a complex, multidimensional, scalar concept. Whereas human beings have had impairments throughout history and prehistory, understandings and definitions of impairment and disability have varied in different societies and at different times. No universal, global definition of disability is possible, and there are many different and often incompatible approaches to the problem. Key terms—such as *impairment* and *disability*—are defined in various ways and for different reasons within individual cultural contexts, which can cause confusion. Additionally, translations between languages, cultures, and contexts contribute another layer of complexity.

Disability models are parts of a larger system of understanding and knowing the world. For example, a model is based on a set of definitions and leads to particular schemes of classification and measurement. A model is therefore a map of the relationships among concepts, a way of describing and explaining the complex phenomenon that is disability. For policy makers, a model may be part of the process of

Table 1 Definitions: Nagi's Model (1965)

Term	*Definition*
Pathology	Interruption in body processes
Impairment	Anatomical or physiological abnormalities and losses
Functional limitation	Restrictions on ability to perform normal role tasks and obligations
Disability	Pattern of behavior

distinguishing between disabled people and nondisabled people, which might be important in allocating welfare benefits or entitlement to services to individuals or in planning provision for populations. For clinicians and rehabilitation professionals, a model may be part of the process of assessing interventions, which may enable judgments as to whether a therapy or training method reduces pathology, increases functioning, and affects social roles. For social scientists, a model may clarify the causes of disadvantage, help analysis of the relationship between individuals and wider social environments and cultural contexts, and prioritize changes aimed at reducing social exclusion or disadvantage. For disabled people themselves, a model is a way of understanding the world that has implications for explaining the disability experience and hence has impacts on personal identity and political action.

To be effective, a model needs to be clear and simple. Yet clarity and simplicity make any model vulnerable to challenge. Particularly in regard to a complex and contested phenomenon such as disability, any model may be criticized for not providing a full picture. This explains why debates around models of disability are so important and sometimes so bitter. The challenge to traditional models of disability lies at the heart of the challenge of the disabled people's movement, particularly in the United Kingdom. The self-organized groups that developed among disabled people in the United Kingdom, the United States, and many other countries during the 1970s and 1980s were not just campaigning for better social provision or social inclusion, but for a radical redefinition of disability itself. In other words, the debate about models is not just an abstract academic problem of definitions and classifications; rather, it is a question of political struggle and personal identity.

NAGI'S MODEL OF DISABILITY

The dominant North American model of disability was developed by the sociologist Saad Nagi (1965) in the context of rehabilitation. Nagi's definition of impairment includes congenital abnormalities that may not be associated with pathologies and allows for variation of impairment along many different dimensions, which may influence the nature and degree of disability. Not every impairment results in a functional limitation, and functional limitation can arise from nonimpairment causes. Nagi's definition of disability, particularly as later refined (Nagi 1977, 1991), is dynamic and allows for social context. Patterns of behavior associated with disability are influenced by impairment and limitation, by the individual's own reaction to and definition of the situation, and by the reactions and definitions of others. Nagi (1991) later clarified that environmental barriers are an element in disability. Nagi's model has been used as the basis for the Americans with Disabilities Act, for almost all disability social policy in the United States, for statistics at United Nations and European Union level, and in many other contexts.

THE ICIDH

The International Classification of Impairments, Disabilities, and Handicaps, or ICIDH, was developed by Philip Wood, Elizabeth Badley, and Michael Bury for the World Health Organization in the 1970s and published in 1980. This model distinguishes among impairment (the medical problem), disability (the resulting functional limitation), and handicap (the social disadvantage resulting from impairment or disability that limits or prevents the fulfillment of the individual's social role). Impairment is a necessary, but not sufficient, cause of disability, whereas disability in turn is necessary but not sufficient for handicap. The aim of the developers of the ICIDH was to make the social context of disability clear. Previous

Table 2 Definitions: ICIDH (1980)

Term	*Definition*
Impairment	Loss or abnormality of psychological, physiological, or anatomical structure or function
Disability	Restriction or lack of ability caused by impairment
Handicap	Disadvantage for an individual in fulfilling appropriate roles

approaches had been dominated by a narrow focus on health and disease, whereas the new model used the handicap concept to emphasize social disadvantage.

It has been argued that this model, although not without its problems, has been a useful tool in assessing the social needs of disabled people. Despite the utility of the ICIDH for assessing the social needs of disabled people and situating persons with impairments in a wider social context, it has been widely contested by disability movements, particularly in the United Kingdom. The British Council of Disabled People—and subsequently other national and international movements—has rejected the ICIDH, labeling it a "medical model" or "individual model" or "personal tragedy theory." Critics have claimed that the causal relationship in the ICIDH starts with individuals and their impairments, which cause their disabilities or incapacities, which then make them vulnerable to handicaps or social disadvantages. This is seen as "blaming the victim" and as placing insufficient emphasis on the social barriers that cause problems for people with impairments. For many disabled activists, the term *handicapped* is offensive; it is associated with outdated social attitudes and organizations and is linked to the idea of begging and dependency through an association with "cap in hand." It should be noted, however, that this is a false etymology, as the term *handicap* derives from horse racing, not begging.

Although the framers of the ICIDH intended to create a social model, in practice approaches inspired by the tripartite definition tend to slip into individualist and medically focused remedies. Questions of social context and meaning are often neglected when the model is operationalized. The ICIDH has perhaps unfairly attracted and focused the generalized opprobrium directed toward traditional approaches to disability. Many disabled people have experienced negative cultural stereotypes and assumptions based on the medicalization of disability. Undoubtedly, the idea that disabled people are defined by their mental or physical deficits is a major obstacle to both self-esteem and social inclusion. But the framers of the ICIDH explicitly wanted to challenge this medicalization, and the ICIDH is not the cause of the widespread devaluing of disabled people. Opponents of the "medical model" have created a straw man that stands for medicalization, prejudice, and the devaluing of disabled people. It is difficult to find any authors who espouse such a "medical model" or deny the importance of social barriers and discrimination in the lives of disabled people.

THE SOCIAL MODEL

The social model of disability was developed by the Union of the Physically Impaired against Segregation (UPIAS), a small group of disabled people in England in the 1970s. Inspired by Marxist politics, UPIAS retained a concept of impairment (physical impairment) but stressed that disability should be defined as the relationship between people with impairments and a society that excludes them:

> the disadvantage or restriction of activity caused by a contemporary social organisation which takes no or little account of people who have physical impairments and thus excludes them from participation in the mainstream of social activities. Disability is thus a particular form of social oppression. (UPIAS 1975:14)

Disabled Peoples' International (DPI) revised these definitions slightly in 1982 as shown in Table 3.

Michael Oliver used these definitions in *The Politics of Disablement* (1990), a book that was a founding text in disability studies. However, Oliver usually used the terms *medical tragedy theory* and *social oppression theory* in preference to *medical model* and *social model.* UPIAS and Oliver—and authors and organizations that followed them—succeeded in stressing the social structures and social barriers that oppress people with impairment. Disability is an additional burden that is imposed on people with impairment. Thus, the social model soon became reduced to a

Table 3 Definitions: Social Model, DPI Version (1982)

Term	*Definition*
Impairment	Functional limitation within an individual caused by physical, mental, or sensory impairment
Disability	Loss or limitation of opportunities to participate in the normal life of the community on an equal level due to physical and social barriers

slogan: "Disabled by society, not by our bodies." Social model approaches became associated with political campaigns for antidiscrimination legislation and barrier removal. The corollary of this approach was an increase in the tendencies to minimize the significance of impairment and to make social oppression the basis of disability as a political identity.

These tendencies are responsible for several logical flaws of the DPI version of the social model. First, the definition of impairment is circular: Impairment is defined as a functional limitation caused by impairment. Second, unlike the UPIAS definition, there is no mention of impairment in the definition of disability. This leads to the difficulty that other social groups—such as people who experience racism or sexism or poverty—could be included within the social model definition, even if they do not have impairments. In the attempt to decouple disability from impairment, impairment ceases to be a qualification for being a disabled person.

The British social model is not the only version of the social approach. For example, in the United States, a focus on social oppression and social barriers is encapsulated in the "minority group model," as theorized by Harlan Hahn (1988) and others. This suggests that people with disabilities (as defined in the Nagi model, for example) form a minority group that experiences oppression. The minority group version of the social model also places highest priority on barrier removal and other social change rather than medical or rehabilitation interventions. In the Nordic countries, a "relational model" similarly situates the experience of disabled people in a broader social context.

Most disabled-led political campaigns worldwide give highest priority to the improvement of the quality of life of disabled people through the reduction of discrimination and barriers. British activists have gone further than others in actually redefining the word *disability* to refer to oppression or barriers rather than to "impairments." Whereas activists in most other English-speaking countries favor the term *people with disabilities*—to signal that functional limitation is only one aspect of a person's overall identity—Britain has favored the term *disabled people,* to signal that people are disabled by society. Representatives of the British Council of Disabled People campaigned for the world body—Disabled Peoples' International—to follow their lead in rejecting the ICIDH definitions when it was formed in 1981.

In practice, the distinction between the "barriers" and "minority group" versions of the social model is not clear. In other documents, the U.K. disability movement referred to itself as a minority group from the outset, even though the formal definitions do not include this conception. As observed earlier, without a conception of a minority group of people with impairments who face oppression and barriers, the DPI model runs into the major difficulty that it does not specify the class of people it defines. Equally, U.S. discussions of the minority group model make it clear that people with disabilities are excluded by social barriers and an oppressive social relationship, although this model is weaker than the U.K./DPI version in not defining disability as barriers and oppression.

However, the implicit combination of "barriers" and "minority group" approaches within most social models does conceal tensions. In policy terms, should political action be directed at removing structures and barriers to promote equality of opportunity, or should it be directed at benefits and protections for a disadvantaged class of individuals? In terms of identity politics, the choice is between an attempt to minimize the differences between disabled and nondisabled people and the drive to celebrate disability identity, cultural distinctiveness, and disability pride.

Conversely, the social model has been criticized for neglecting the role of impairment and personal experience, and for being difficult to apply to groups of disabled people other than the people with physical impairments by whom it was devised. Often, these criticisms have come from within the disability movement

Table 4 Terms: ICIDH and Social Model, Thomas Version

ICIDH	*Social Model (Thomas Version)*
Impairment	Impairment
Disability	Impairment effects
Handicap	Disability

or disability studies, as activists or researchers have tried to operationalize the social model or think through its implications.

Some have claimed that there is no intrinsic contradiction between the ICIDH and the social model of disability, only a difference in terminology: Where the ICIDH talks about *handicap,* the social model uses the term *disability.* In attempting to deal with the common critique that the social model ignores impairment, Carol Thomas introduced an additional level of "impairment effects" into the social model binary in her book *Female Forms* (1999). She defines these as restrictions of ability that are caused by impairment, not by social relations. Although Thomas might resist this implication, the consequence might be to generate a familiar tripartite structure, as shown in Table 4. However, "handicap" (ICIDH) is the experience of disability in a social context, whereas "disability" (Thomas) places the causal emphasis on the society or environment that excludes or oppresses the individual who has an impairment by failing to meet that person's needs by actively discriminating unfairly against him or her.

THE INTERNATIONAL CLASSIFICATION OF FUNCTIONING, DISABILITY, AND HEALTH

A recent revision of the World Health Organization approach has attempted to bridge the impasse between "medical model" and "social models" by sidestepping the definition of the word *disability.* The International Classification of Functioning, Disability, and Health (World Health Organization 2001), sometimes called the ICIDH-2 but better known as the ICF, uses *disability* to refer to the entire process rather than to any element in the chain. It is described as a "biopsychosocial model" in an attempt to offer a way forward from the increasingly sterile debate over models and definitions. The ICF sees disability as the outcome of interactions between the features of the individual and the physical, social, and attitudinal world.

As well as avoiding the "disability" controversy, this approach has the dual advantage of stressing the social context in which individuals are enabled or excluded while not ruling out the roles of bodies and medicine. No comprehensive analysis of the ICF has been conducted to date from a disability studies perspective. However, initial reaction from several authors has been skeptical, given the model's origins within the discredited ICIDH schema. Professionals, researchers, and policy makers have welcomed the ICF. More than 150 papers have been written on or about the ICF, none of which has used it as a medical classification. This suggests that the ICF avoids the problems of the ICIDH and can be operationalized as a classification of participation and environmental interaction. DPI is a full supporter of the ICF and has officially adopted it for the UN Disability Convention.

MODELS IN PRACTICE

It has been demonstrated that the debate about models is as much about politics and identity as it is about definitions. The original ICIDH model was developed by experts to help researchers and policy makers. The UPIAS model was developed by disabled people themselves as a tool for social change. For activists, the medical/social model divide stands for the rejection of traditional approaches to disability that revolve around curing or preventing impairments. The "medical model" is equated with medicalization and the prejudice that suggests having an impairment makes an individual inferior, incapable, and dependent. The social model mandates and places high priority on barrier removal and social inclusion rather than medicine or rehabilitation. Instead of special provision based on impairment, the social model suggests that barriers should be removed so that disabled people can access mainstream services. Rather than counting the numbers of people with impairment, the social model suggests that the focus should be on discrimination and prejudice.

The social model has implications for personal identity as well as for policy and practice. It has

Table 5 Disability as the Outcome of Interactions: Terms in the ICF Model (2001)

Body function and structure
Activity
Participation
Environmental factors

proved hugely effective in enabling people with impairments to move from a position in which they believe they themselves are the problem to a position in which they identify society as the problem. Psychologically, individuals move from a poor self-image based on self-pity to a strong political identity based on anger against a disabling world. For many, this is also a move from being an isolated individual to being a member of a vocal minority group, based on solidarity, resistance, and pride. The self-esteem benefits that the social model has for individual adherents help explain why the social model is an article of faith for many in the U.K. disability movement and why debates about revising or replacing the social model have been so heated and acrimonious.

UPIAS activists never denied that impairment is important. They did not argue against medical care, only against the discriminatory ways in which it is delivered. Yet the consolidation of the social model through identity politics has led some activists to express opposition to any impairment-based approach. For example, there has been rejection of medical research, therapies, and attempts to prevent impairment; opposition to surveys of the numbers of people with impairment; and rejection of mono-impairment organizations as well as services provided to people on the basis of impairment distinctions. Because the social model has become a litmus test for progressive approaches to disability, particularly in Britain, interventions based on the ICIDH definitions have been rejected. For example, a government advertising campaign to challenge prejudice against disabled people used the slogan “See the person, not the disability.” The disability movement rejected the initiative because, activists argued, the slogan should have been phrased “See the person, not the impairment.” Equally, the 1995 Disability Discrimination Act (U.K.) has been challenged by many activists because it rests on a definition of disability as a medical condition.

Yet applying and implementing social model approaches is difficult in practice, and sometimes impossible. Unless impairment is part of the definition of a disabled person, no protected class can be identified in legislation. Without counting people who have impairment, it is difficult to predict the numbers of users of services and to create adequate provision. The implementation of universal design and the barrier removal mandated by antidiscrimination legislation have led to huge improvements in environmental access. However, some argue that an entirely barrier-free world is a utopian dream, for several reasons: because the natural environment cannot be made accessible, because it is impractical to make many existing buildings or systems accessible, and because different impairments necessitate different accommodations, some of which may be mutually contradictory.

The social model has huge rhetorical power as a social critique and mobilizing force. It also has great moral power: If society has constructed disability, then it has a duty to remedy the situation and remove barriers. But the model is difficult to operationalize and implement, and it is misleading as an explanation of the social world. The ICIDH may have been more coherent, but it failed to place a high enough priority on addressing the social factors that cause problems for people with impairments. Moreover, the ICIDH was never likely to inspire political allegiance or radical action by and on behalf of disabled people. In practice, the ICIDH and similar models risk collapsing disablement back into impairment-based approaches and neglecting the broader structural causes of the disadvantage faced by disabled people.

The ICF was developed over seven years with continuing input from DPI, the European Disability Forum, and a variety of other organizations of and for disabled people. The ICF has been adopted by DPI because it highlights the role of environments, accommodations, and discriminations. To date, it appears that applications of the ICF have avoided collapsing the social aspects of the experience of disability into individual, medical explanations. Yet the social model approach remains favored by disabled people’s organizations in the United Kingdom and is influential worldwide.

Disability is a complex, multidimensional, scalar concept. As Irving Zola (1989) and many other authors have pointed out, impairment is part of the human condition. Over a lifetime, all individuals experience limitations, vulnerabilities, and permanent or transitory illnesses or impairments. Impairment per se cannot therefore be the defining criterion for a disabled person, although the presence of impairment—or belief that it is present—is necessary for a person to be defined as disabled. The category "disabled people" exists only because social definitions and thresholds have been adopted. Different definitions and thresholds will result in the category's being larger or smaller, excluding or including people with different impairments and experiences. Disability categories play wider roles in social policy, as Deborah Stone has demonstrated in her book *The Disabled State* (1984).

It should be accepted that models and definitions are relative and contingent. Disablement is always a combination of the individual and the structural, the biological and the social. Different questions—medical, psychological, social—have to be investigated at different levels of a disability model. Disabled people experience a combination of bodily restrictions and social barriers, and the two factors cannot easily be extricated from each other. Where the social model would make a polar distinction between "impairment" and "disability," in practice impairment is always already social, and impairment is always implicated in disability.

Therefore, models should not become the touchstone of progress. It may be impossible to choose one model for every situation. A model is not an end in itself, but a means to an end. Models do not matter, in themselves, but are often taken as proxies for wider political or academic affiliations and strategies. Many commentators believe that the debate over models has now become an obstacle to the development of disability studies and achievement of the equality and inclusion of disabled people. Good initiatives have been created on the basis of "medical models" and failures have resulted from "social models," as well as vice versa. Rather than using the concepts "medical model" and "social model" as ways of judging "reactionary" and "progressive," activists and scholars need to pay attention to the details of the research, policies, or provisions that are being attempted. Two fundamental questions underlie all such interventions:

1. *Will this intervention improve the quality of life of disabled people?* Rather than focusing on ideological judgments about models, critical evaluation should explore the outcomes of interventions in terms of the quality of life of disabled people. Quality of life can be improved through the reduction of pain and suffering, the improvement of physical functioning, the provision of aids and adaptations, the removal of social and environmental barriers, and the reduction of discrimination and oppression.
2. *Is this intervention targeting the most appropriate level of disablement?* This question draws attention to the complexity and multidimensionality of disablement. Difficulties arise when medical or individual solutions are offered for problems that are social and structural—and vice versa. Disablement involves medical, psychological, and social aspects, and it cannot be reduced to any one of these dimensions.

Efficiency and appropriateness are major criteria for assessing particular proposals.

—Tom Shakespeare, Jerome E. Bickenbach, David Pfeiffer, and Nicholas Watson

MODERNITY

Modernity expresses the self-definition of a generation about its own technological innovation, population makeup, and "progressive" social organization schemes. To participate in modernity is to conceive of one's society as engaging in organizational and knowledge advances that make one's immediate predecessors appear antiquated or, at least, surpassed. The eminent Victorians thus appeared old-fashioned to a new generation of "moderns" at the beginning of the twentieth century, and the motto of poets of the time was to "make it new." The ubiquitous emphasis on "newness" within modernity signaled an *epistemological break* with the certainties of premodern societies.

Modernity for U.S. and British citizenry of the first half of the twentieth century meant new formats for new thoughts—innovative ways of writing and thinking, the infusion of women's views into university life and male-dominated labor markets, short skirts and short hair, rapid urbanization, a jazz era, and silent film narratives, among other products and technologies. As William Carlos Williams, a preeminent "modern" physician-poet, put it in his poem "To Elsie" (1923): "The pure products of America go crazy." Williams thus conjoins mass production with the now destabilized institutions of family and social life that occur in the wake of the first "modern" war, World War I. The dedicatee of the poem, Elsie, was a "broken-brain" nanny who came to work for the Williams family from an institutional orphanage as an adult ward of the state of New Jersey. The poem thus invests modernity in her figure and makes her into an emblem for speed and productivity in modern America gone awry. Elsie—at least in Williams's celebrated poem—indicates the degree to which the modern age became obsessed with human "defects." Disabled people were continually represented as somehow mis-fit or displaced in the midst of a press to standardize public and private spaces. Their bodies and minds were thought to fall too far short of an idealized, albeit elusive, body—one that would be measured, weighed, surveyed, and assessed for "baseline" capacities.

Thus, the "modern era" (generally identified here as synonymous with the age of industrialization) segmented bodies into their constituent parts. This process of segmenting bodies sought to make labor power more efficient while also rendering any single body replaceable. Assembly lines for autos, such as those instituted by Henry Ford and celebrated as egalitarian mergers of human and machine by the muralist Diego Rivera, implied better practices and technologies for all. But they also further entrenched citizens within a deepening nexus of debt and consumption—conscription to labor power. Ford declared that each worker should earn the purchasing power to drive an automobile even as he would spend his workweek toiling on an assembly line to make cars for others.

Under modernity, technologies develop that yield advantages of speed or efficiency over older terms of labor and consumption that rapidly disappear on a historical horizon. These technologies result in revised workplace organization, often displacing workers with established expertise, at the same time they introduce modifications to the organization of everyday life. From movable type to steam engines, from the telegraph to the advent of photography, technological innovations alter modes of inhabiting environments and daily living for entire population groups. Such innovations also precipitate the mass exclusion of whole communities under various rubrics of inferiority—namely, immigrants, people of color, lower-class people, and disabled people. Often marginalization occurs on the basis of a mutual referencing strategy that is bound up with disability definition. In other words, individuals situated in categories of incapacitation or insufficiency to the demands of a modern world rarely find themselves referenced by only one stigmatizing category. Instead, their bodies become identified as hosting multiple insufficiencies that are often believed to be "biological" in nature.

Behind the development and introduction of technologies are the investments of an increasingly global capital that targets markets and labor pools. The marginalizing strategies of modernity ultimately sought to produce what Marx called "surplus labor pools": labor rendered "superfluous," "expendable," or "excessive" to the needs of capitalist markets. In reality, modernity oversaw strategies of worker disqualification where entire populations found themselves sidelined from the demands of labor. All "inferior" peoples of the modern period presumably shared a natural incapacity to function competitively in the labor market, and, consequently, they were relegated to segregated communities, reservations, almshouses, and workhouses, and—particularly in the case of disability—confinement in colonies, "training centers," and institutions.

To operate within modernity also means to participate in the belief that one finds bold contrast between modern conceptions of the cosmos and the worldview of premoderns or "ancients." "God is dead," declared Friedrich Nietzsche (1844–1900), a famous German philosopher of modernity, not hesitating to add that this was because his contemporaries had killed God off with their own disbelief. In the field of philosophy, premodern beliefs yield to modern dismay about how social systems, from organizations of class privilege to theories of heredity, determine a great deal of life experience for any one individual. Nietzsche himself proposed that modernity is typified by crises in systems of morality, so that once belief is crushed there can be no restoration. Of course, he discussed the fact that many of these crises in self-perception occur due to advancements in knowledge and an uncritical embrace of new technologies.

For example, Copernican proofs that the earth revolves around the sun heralded revolutions in reasoning about the universe and the not-so-central place of humans within it. Charles Darwin's (1809–1882) theories of natural selection, demonstrating as they do that a changing human species evolves among multiple shifting life forms, precipitated the arrival of a fully "modern" sensibility. The founder of modern psychoanalysis, Sigmund Freud (1856–1939), who studied states of psychological aberrance in order to expand definitions of human existence, also typifies, in his work, the displacements wrought during modernity. His proposition that an unconscious conditions human behavior and actions likewise unsettled general Enlightenment faith in human rationality. In the film *Modern Times* (1936) Charlie Chaplin spoofs the users of high-speed contraptions; herein, products "gone crazy" not only foil the ambitions of their users, they also seem to have plans for the users that mechanize all involved.

As this entry has emphasized, technologies themselves participate in this decentering of human confidence in perception and planning. Modernity as a historical coordinate, a mere marker in a chronology of named epochs, depends on the distinction between new modes of existence as well as new perceptions of a self that attends to transport, architecture, mass events, and media that quite simply replace former ways of inhabiting space and experiencing time. Thus, some scholars will even go so far as to locate modernity with the advent of the printing press and the mass circulation of print information that brings about expanded literacy in a middle class during the fifteenth century.

The most prevalently cited examples include microscopic technologies that replace the human eye as an arbiter of evaluation and laboratory heredity texts that can prove parentage with or without testimony. Often bodies themselves experience a new inferiority as they come to be outdistanced by superior visual, aural, and detective devices of modernity. All bodies might come to be perceived as increasingly inadequate without supplementation, even as methods and mechanisms of enhancement, from telephones to typewriters, increase. The camera eye, for example, can seem to capture discrete elements of an activity and therefore offer a vantage point superior to any human eye. Eadweard Muybridge (1830–1904), an early technician of camera and motion, combined scientific experimentation with photography in a series of chronophotographic demonstrations. He famously showed that a horse becomes fully airborne during a cantor. The cinematic eye can therefore improve on the human gaze, wholly delimiting its privileged gaze on reality, just as Freud's modern concept of a human "unconscious" literally undermines the stated intentions of individuals. From a disability studies perspective, it should be noted that Muybridge also did chronophotographic studies of "nonnormative" human gaits, inaugurating an entire field of analysis, known as gait training analysis, that is linked to imaging devices. Likewise, early silent films turned on the "secret" knowledge offered by a camera that showed a beggar getting up and walking away with a charitable offering after having feigned paralysis or blindness. In each instance, the powers accorded to visual recording devices sought to break down, survey, and expose the exact source of dysfunction. This form of modern mechanization shifted conceptions of the body from an "organic" to an increasingly "artificial" entity. In the process, prior ideas about the body as a sacrosanct temple gave way to a more fluid and, ultimately, disposable material being.

This lowering threshold of respect wrought by modernity can be analyzed across numerous fields of inquiry. For instance, many scholars, particularly in the wake of Michel Foucault, connect modernity to medical practices that reference human anatomy as a result of the direct observation of dissected human corpses. The practice of anatomical dissection, with its violation of sacred beliefs about bodily boundaries, neatly encapsulates a change in sensibility toward behaviors that violate sacred prohibitions with the goal of knowledge about bodily mechanics. In his lectures on the topic "abnormal," Michel Foucault locates a rupture between agrarian communities and the arrival of a modern state in its imposition of psychiatric and confinement solutions for bodies deemed pathological. In this scholarship, confinement practices, as opposed to quarantine colonies (such as those for leprosy, tuberculosis, epilepsy, and "insanity"), initiate modernity as a matter of brutal concealments, torture, and controlling technologies that take place under professional purview. Foucault traces a shift toward modern practices when an ordinary "village idiot" becomes susceptible to medical interventions, experimentation, state management, and regulation—in other words, when mere madness becomes mental illness, a modern category to be officiated, contested, recorded, and detected. If corpses can be "cut up," then all bodies become potential targets for a host of modern interventions.

Certainly this clarifies the point that little consensus exists as to when modernity begins. However, histories on and about Western Europe do concur that a modern era arrives at the end of colonial invasion and expansion across the globe, with modernity coming at the end of a chronology that proceeds from the ancient world, the Middle Ages, the Renaissance, the Enlightenment, the Age of Exploration, and the period of colonial expansion. A British writer who straddled colonial expansion and World War I, Ford Madox Ford (1873–1939), wrote a four-volume epic in order to declare that with World War I there would be "no more parades," meaning that the idea of fighting for any heroic cause had been rendered obsolete—the antiquated product of a bygone era. For Ford, wars are fought on behalf of economic interests with little effective resistance to the military conscriptions of modern nation-states. Little meaningful celebration accompanied a "victory" for the living participants who survived such violent enterprises. In short, modernity means that heroism is dead.

In modernity, governance by distant colonizing powers yields to governance by locals, and the boundaries of nation-states are perceived to reflect oversight by resident officials as opposed to colonial military powers. Occurring in tandem with the arrival of modern warfare methods, those capable of enacting genocide on a massive scale, modernity has been thought to indicate awareness of the missionary conceit that colonial settlement plans and military ventures overseas constitute sources of "improvement" for nonmodern geographies. Thus, not only were bodies deemed insufficient, but entire nations could be imagined as "damaged goods." Irish poet William Butler Yeats's dictum that "the center cannot hold" in his poem "The Second Coming" presages the degree to which modern societies seem to experience themselves as fracturing along with the bodies housed within them. As the nineteenth century came to a close, numerous cries could be heard that even the most advanced nations were succumbing to the forces of degeneration. Nations continually assessed their "wealth" in terms of percentages of nondefective bodies inside their borders. As the 1927 U.S. health propaganda film *Are You Fit to Marry?* put it: "As goes its babies so goes the nation." In order to actively improve the "national stock," moderns sought to sequester as many deviants as possible. A dream of homogeneous futures guided much action during the modern period, and social marginals found themselves increasingly under siege by a variety of improvement schemes contrived by "progressives" and other professed social do-gooders.

In 1893, Edvard Munch painted *The Scream,* a figure that is often taken as a quintessential expression of modernity. Munch himself wrote that he had experienced intense fear during a moment of isolation while on an evening walk: "My friends walked on—I stood there, trembling with fear. And I sensed a great, infinite scream pass through nature" (quoted in BBC News 2004). In the painting, wavy lines and a red sky capture the sensation of terror he describes, and Munch's effort to capture his own feelings of besiegement by emotions struck a cord of sentiment for many denizens of the time. Joseph Conrad's 1902 novella *Heart of Darkness,* which is also taken as an emblematic text of modernity, matches the psychic journeying of a European protagonist with the atrocities he recounts having encountered on a colonial venture on the Congo while he drifts in present time in a boat on the Thames. He remembers native bodies tossed aside as mere labor power now exhausted, but he also emblematizes Africa as a site of disease. This would have been so for the European journeyers, such as those who often accompanied David Livingston, who lacked immunity as adults to a common West African childhood illness such as "yellow fever." "The horror, the horror," reputed to be the dying words of the character Kurtz, may refer to the protagonist himself, his venture, or the blissful ignorance of the ultrafeminine "intended," who, as the evident manifestation of civilized society, must be protected from men's savagery at all costs.

Until quite recently, with the dissolution of the Soviet Union, modernity had been taken, more or less, as the matter of an international consensus on nation-state borders. With a growing global practice of commodity capitalism, with capital's requisite ventures to open up consumer markets, modernity now is mostly associated with ever-increasing speed, both in the transport of financial exchanges and in cross-border communications. It is important to note the fact that modernity as crisis, where "the center cannot hold," operates differently across classes and privileged parties. In that sense, modern dislocations may be heralded as opening up new possibilities for those on the periphery—those previously excluded from the spoils of empire and the opportunities of education and leisure time. Hence, women in London and Chicago, African Americans in Harlem, and many others find potential for professional development and expression in the wake of the empire's crises in epistemologies and central governance. Likewise, and particularly for groups, institutions, and colonies of disabled persons, interior pockets of self-governance or incarceration may not yield as readily as schools, churches, or principalities, for example, to oversight from nation-state governance. Thus, they are already "colonies" as opposed to under the purview of central governance.

In sum, nearly all scholars of modernity agree that scientific methods serve neatly to mark a break between modern and ancient in that research designs precisely enable a new means for testing reality—from telescopes to electron microscopes, case notes, surveys, weights, and scales, along with systems for data analysis from means deviation equations to infrared scans. Yet unlike Enlightenment thinking about scientific experimentation, often now termed a mere "faith" in Enlightenment principles, citizens in modernity are wise to the ways that scientific development results in many means for mass destruction and population control alongside material improvements in the standards of daily living. In this respect, theorists of modernity seek out means for resistance, but not necessarily revolution, no longer believing that an equitable society can be gained through military struggle or transcendent social visions. Some have mourned this surrender of revolutionary universal programs as the final capitulation to capitalist logic. The failures of communism to provide fully desirable modes of inhabiting the world inform this pessimism and indicate, themselves, the difficulty in sustaining a belief in any effective counterforce to the new global inequities wrought by venture capitalism.

Inasmuch as modernity displaces a recent past, it is often associated with forward-looking progressive social policies that include modes of social engineering. For disability, then, modernity often indicates ideologies of eugenics and the promise to eradicate certain kinds of human "suffering" and "misery" through prevention and segregation campaigns. With this emphasis underwriting the schemes of modernity with respect to "deviant" bodies, one witnesses an explicit emphasis on bodily rather than social "renewal." Rather than work to make plastic environments more flexible—and thus habitable—modernity sets its sites primarily on the enhancement of individual physicalities and minds to fit inflexible locations. If those bodies fail in such efforts, then they are effectively extracted from participation. The body winds up as the barometer for all interventions—a surface to be molded by the forces of history come home to roost. Modernity can be viewed as a rather sinister program in this respect, one that is led by innovations in manufacturing and economic venues while neglecting the needs of populations that must navigate those very locations as well as many others.

At present, modernity no longer means "modern" as exemplified by the period subsequent to modern warfare, typified by two world wars, and succeeded by postmodernism. Today, theorists of modernity look for the effects of postnationalism in the face of uneven development. The underside of a belief in the goodness of modernity is perpetual interpretation of agrarian regions as underdeveloped. Modernity thus comes to define savage inequities on a global scale; infrastructure development such as roads, plumbing, mass transportation, and labor practices; and cultural biases in the provision of public education. Today, modernity most likely means the rapid-pace movement of global capital, industries run for the profit of invisible shareholders, satellite transmission of images, and immediate transglobal communication. Part of this fluid transcultural passage of capital also entails traffic in disability technologies and policies usually designed for Western contexts. Such an export economy of disability results in absurd situations: Wheelchairs designed for paved streets literally run aground and shatter when faced with the demands of other terrains, and disability service delivery systems designed for consumption practices in one capitalist context fail of inertia in other, less acquisitive, cultural venues.

This glimpse of the underbelly of modernity has come to the fore in influential scholarship and thinking of our own time. For instance, political theorist Zygmunt Bauman (1989) sees modernity through a much darker lens when he observes that Nazi genocidal procedures toward disabled, ethnic, and sexually stigmatized populations became an "inevitable" consequence of the modern regulation of bodies and measures taken for the sake of "population" control. Bauman inflects modernity as riddled with assembly lines and population demographics. Within such regulatory labor systems, some bodies find themselves excluded almost by definition. Within modernity, the rising prominence of labor capacity as synonymous with the privileges of citizenship came to eclipse older definitions of embodied difference (such as monstrosity or marvel). In their place, disability became increasingly tantamount to "incapacity to work." In other words, modernity oversaw a transition of the power of extreme alterity by promoting a domesticating mission that tended to denote disability as a mere loss of productivity. Disability theorists then must consider the ways in which modernity actually produces disability as a matter of displaced persons.

In many ways, disability groups are directly consolidated out of shared predicaments of modernity: those persons who have been displaced from mass transit, trampled in crowd control settings, and indentured for their subsistence to welfare schemes promoting absolute dependency. One thinks of the bodies that cannot make it across moving walkways at railway stations or of buses with steep stairs at their doors, with no alternative navigation pathway in sight. Under modern management practices, categories for "special assistance" get generated in order to accommodate for "normative" patterns and expectations necessitated by policies and practices that prove exclusionary but nonetheless may be insisted upon as mandatory. Voice technology ordering at drive-through restaurants, for example, excludes those who might order by sign language, gesturing, or pointing. Those who can't push open heavy doors must wait until someone comes along who can do so. Disability politics concerns itself with modern environments, from websites to cruise ships to personal facilities, that in demanding body conformities build exclusions into their offering and, therefore, quite undemocratically create groups of nonusers.

MOLECULAR, CELLULAR, AND TISSUE ENGINEERING

Molecular, cellular, and tissue engineering is an emerging discipline that addresses the principles and development of engineering therapies for restoring the structure and function of disordered molecules, cells, and tissues. Pathological disorders occur in biological systems at the molecular, cellular, and tissue levels in response to genetic alterations and environmental stimulations induced by chemical, microbiological, and physical factors. Engineering therapies are established based on the mechanisms of pathological disorders and principles of biomedical engineering (see Langer and Vacanti 1993; Liu 1999).

Molecular disorders occur due to mutation of genes or alterations in gene activity. Gene mutation often abolishes protein expression or generates malfunctioned proteins, whereas alterations in gene activity induce an increase or decrease in protein production. These changes influence cellular activities, such as cell proliferation, differentiation, apoptosis, migration, and adhesion, inducing or enhancing pathological disorders. For gene mutation-induced disorders, such as sickle-cell anemia, mutant genes can be identified, analyzed, and manipulated through the use of genetic technologies. A therapeutic strategy for such disorders is to replace the mutant gene with a natural or engineered gene, which can be expressed to correct mutation-induced disorders. An example of such a strategy is the introduction of an engineered beta A-globin gene into hematopoietic stem cells to treat sickle-cell anemia, which is caused by the formation of abnormal hemoglobin due to a single-point mutation in the beta A-globin gene (see Pawliuk et al. 2001). For disorders due to alterations in gene activity, such as atherosclerosis, genes involved in pathogenic processes can be identified and analyzed through molecular approaches. An effective engineering approach for such disorders is to introduce into target cells with genes encoding proteins that suppress pathogenic processes induced by altered gene activities. An example is the introduction of growth inhibitor genes into atheromatous cells to suppress cell proliferation and thus to reduce the progression of atherosclerosis, a disorder enhanced by the up-regulation of growth factor genes (see Dzau, Braun-Dullaeus, and Sedding 2002).

Cell and tissue injuries or disorders occur due to physical impacts, chemical toxication, ischemia, cancerous metastasis, and/or microbiological infection, resulting in disability of involved organs. A therapeutic strategy is to identify and collect functional cells from the hosts or donors, regenerate cells in vitro, construct cell-based tissues by incorporating cells into scaffolds of biological matrix or synthetic polymers, and replace disabled cells and tissues with regenerated cells or tissue constructs. Such an engineering approach can facilitate the regeneration of injured tissues and prevent permanent organ disability. Because stem cells, including embryonic and adult stem cells, are capable of self-renewing, differentiating, and repopulating, these are preferred cells for cellular and tissue engineering. An example is the repair of bone defects with bone stem cells from the marrow stroma (see Quarto et al. 2001).

For the past decade, experimental investigations have provided sufficient information for the establishment of molecular, cellular, and tissue engineering therapies. Clinical trials have been conducted to test the feasibility and effectiveness of these therapies. It is expected that molecular, cellular, and tissue engineering will contribute significantly to the treatment of human disorders and disabilities.

MONSTERS

For most of Western history, the monster exemplified one extreme form of what is now known as disability, the departure from expected physical type. Monsters included a variety of people and animals with dramatic and obvious congenital anomalies, such as conjoined twins and intersexuals, beings with too many or too few members, and the unusually short or unusually tall. Although even in its heyday, the medieval and early modern period, the category of the monstrous overlapped only imperfectly with disability, it nonetheless shaped modern attitudes toward people whose bodies lie outside the norm.

Medieval European writers derived the word *monster* from the Latin verb *monere,* which means “to warn.” In Christian Europe, as in the ancient world, monsters were originally understood as signs of divine displeasure, by which God informed human communities of His anger at their misdeeds and warned them of misfortunes to come if they did not mend their ways. At the same time, however, the term could signal another characteristic of monsters: the fascination they engendered. “Monsters are called monsters,” one seventeenth-century writer noted, “because everyone wants to show them to each other”—a play on the Latin verb *monstrare,* which means “to show” (see Daston and Park 1998:200). Thus, at the root of the premodern understanding of monsters lay two powerful ideas: spectacle and threat.

The idea of threat was at first the most powerful. For the Greeks and Romans, as for medieval Europeans, monstrous births were one type of portent or prodigy, a category that included celestial apparitions, comets, earthquakes, and unusual meteorological phenomena. As signs of divine wrath, they evoked terror and dread. In 1317, for example, when conjoined twin boys were born in the countryside outside of Florence, the city fathers refused to look on them out of fear, and a bas-relief depiction of the boys was placed over the gate of one of the local foundling hospitals to spur the population to live in conformity with God’s will. Many such children died in infancy—the Florentine twins lived only 20 days—and some were even killed at birth out of fear that they might harbor demons; having delivered their threatening message, they had fulfilled their purpose.

Even in the Middle Ages, however, we find other, less fearful reactions to people of anomalous appearance. The English chronicler Matthew Paris recorded the arrival in 1249 of an extraordinary young man in the Isle of Wight: "He was not a dwarf, for his limbs were of just proportions; he was hardly three feet tall but had ceased to grow. The queen ordered him to be taken around with him as a trick of nature to arouse the astonishment of onlookers" (quoted in Daston and Park 1998:190). Some 250 years later, around 1500, there is evidence of commercial display; parents or guardians of monstrous children took them from town to town, showing them for money, and some cities began to issue licenses or permits for spectacles of this sort.

Over the course of the sixteenth and seventeenth centuries, this practice became increasingly common. Adult men and women displayed themselves in inns, taverns, and fairs, advertising their unusual appearances and abilities in broadsides and flyers, and became the guests of princes and nobles. Petrus Gonsalvus, a native of the Canary Islands whose face was covered with long, silky hair, was raised at the court of Henri II of France and, together with his wife and equally hairy children, was memorialized in contemporary portraits that emphasized his noble bearing and exquisite attire.

This culture of display bespoke a different attitude toward monsters than the horror engendered by the fear of divine wrath. Philosophers and popular writers referred to people with unusual anatomies in terms of admiration and appreciation, describing them as signs of God's marvelous creativity and unceasing power for innovation; those who were lucky enough to view or meet many such individuals—medical men, collectors of broadsides, frequenters of fairs and taverns—prided themselves on their connoisseurship and their ability to make fine distinctions between the merely unusual and the absolutely unique. Like works of art, these special products of divine craftsmanship were collected, both alive and dead, by rulers and wealthy elites.

By the second half of the seventeenth century, scholars and medical men also were engaging in the intensive study and description of monsters as part of an effort to untangle the natural order of the world. This effort was not new. Medieval and Renaissance physicians and natural philosophers had also offered natural explanations for the birth of people of unusual appearance. The French surgeon Ambroise Paré invoked, among other things, the presence of too much or too little matter in the uterus, the effects of maternal imagination, and the workings of chance. But late-seventeenth- and eighteenth-century naturalists—the protagonists of the intellectual movement often known as the Scientific Revolution—increasingly understood nature in a new way: as governed not by general habits or regularities, violable in both principle and practice, but as governed by inalterable laws. This new investment in natural uniformity began to deprive monsters of their scientific interest and their appeal. They were seen increasingly as embarrassing mistakes that marred the natural order and uniform beauty of the world. In a world where the physical norm—a concept pioneered by the Belgian statistician Adolphe Quételet (1796–1874)—came quickly to be identified with the ideal, people with unusual anatomies were reconceived as ugly, abnormal, even pathological.

By the nineteenth century, the fear of monsters as portents of divine wrath had gradually lost its hold, and the reaction to monsters as abnormal, even repellent, coexisted with curiosity and fascination. The freak shows that flourished from the mid-nineteenth century to the mid-twentieth century, of which the most famous example in the United States was that operated by P. T. Barnum, were similar to the displays of armless men, giants, and hairy ladies at the fairs of seventeenth- and eighteenth-century Europe with respect to the crowds they attracted and the diversity of reactions they inspired. The same might be said of some more recent daytime television talk shows. For white, middle-class nineteenth-century Americans, people with unusual anatomies—many of them of exotic birth, like the "Siamese" conjoined twins Chang and Eng and the hairy Mexican Indian Julia Pastrana, advertised as the "ugliest woman in the world"—evoked fascination with the truly different and satisfaction with their own conformity to modern, "civilized" norms.

Perhaps the most dramatic change in attitudes toward people whose appearance challenged such norms, however, came in the years after 1900, as these people became increasingly subject to medical scrutiny. Although medical men had long presented themselves as experts on human anatomy, including anatomical irregularities, they had never claimed to be able to correct such irregularities—that was beyond their technical skill. Because monstrous people were not treatable, however different they might appear from others, they were not, by definition, ill. With new developments in surgery, however—anesthesia, antisepsis, new imaging technologies—doctors not only began to medicalize such conditions, describing them in terms of medical pathology, they attempted to intervene surgically to “fix” them. Intersexuals (long referred to as “hermaphrodites”) had their genitals normalized, and conjoined twins were separated in infancy. More recently, surgical and hormonal interventions have been deployed to normalize height as well.

In some cases, such interventions have met with dramatic success, increasing mobility and social acceptance. In others, the record is far more ambiguous, as in the case of conjoined twins “sacrificed” in separation operations. There is no question, however, that the medicalization of unusual anatomies has done little to lessen their stigma. Not only have people with such anatomies been reconfigured as victims and as patients—whether or not they are subject to cure—but the unquestioned power of effective reconstructive and cosmetic surgical techniques has reduced the range of appearances deemed socially acceptable, paradoxically enlarging the ranks of people who see themselves, or are seen, as “monstrous,” despite their having anatomies that would have evoked little reaction—or even positive reaction—in earlier periods. Thus, intersexuals are no longer seen as marvelous emblems of divine fertility; rather, they are viewed as physical deviants to be fixed at birth.

In sum, neither the fear nor the fascination engendered by people with socially challenging appearances has disappeared over the course of time. Rather, the fear and fascination have taken changing forms as the meanings associated with unusual anatomies have themselves changed. No longer seen as signs of divine wrath, symbols of an admirable natural diversity, or emblems of an imperfect and exotic Other, monsters are now interpreted in terms of pathology, dependent on the doctor’s extraordinary power to both harm and heal.

MONTESSORI, MARIA (1870–1952)

Italian physician and educator

Maria Montessori was born in 1870 in Chiaravalla, Italy, and died in 1952 in the Netherlands. She is known as the founder of a pedagogical method specifically intended for children between the ages of 3 and 12 years. Montessori studied engineering science, mathematics, physics, and medicine and became one of the first female physicians in Italy in 1896. She was also an active supporter of the international bourgeois feminist movement. During her tenure at the psychiatric clinic of the University of Rome, Montessori developed an interest in disabled children. In 1899, she and Giuseppe Montesano founded the Scuola Magistrale Ortofrenica, which was both an educational institute for disabled children and a training institute for instructors. In 1898, Montessori gave birth to their son Mario, who lived in a foster family until the age of 15.

Montessori was a lecturer of disability pedagogy from 1900 to 1918 at the Regio Instituto Superiore Femminile di Magistero in Rome. In 1907, she founded the Casa dei Bambini in the working-class neighborhood of San Lorenzo in Rome. Her pedagogical convictions and stimuli for the development of her own didactic material were inspired by Jean Itard (1774–1838) and Edouard Séguin (1812–1880). Above all, she relied on the concept of sensory-based instruction as a means for developing intellectual competence. With help of the so-called prepared environment, the child should, allowing for the greatest possible independence, foster his or her own development (the child's own inner "building plan"). The didactic material, which should be available once per group, serves as a "polarization of attentiveness." Further methodological principles include the age-mixed grouping of children and instructors' stepping back as much as possible to facilitate children's self-education.

Montessori traveled extensively and presented her work—with the support of her son—in order to disseminate her ideas. In addition, the worldwide Foundation for Instruction and Apprenticeship sponsored the publication of her pedagogy. In 1928, the Regia Scuola Magistrale di Metodo Montessori was established in Rome; in 1929, the International Montessori Association emerged in Copenhagen (this organization was later headquartered in Amsterdam). Maria Montessori was nominated for the Nobel Peace Prize three times.

MOON, WILLIAM (1818–1894)

British evangelist and blind activist

William Moon, an Englishman who was partially sighted in childhood and blind in his teens, spent his life in Christian evangelism and enabling blind people to read. In 1847, he developed an embossed script based on Roman capitals that blind adults could learn to read in a few days and began a monthly magazine using the script. Moon's script facilitated the integrated education of blind children in many schools across Britain. One of his strategies was to teach sighted children to use the embossed material and then send them out to find blind people whom they would teach to read or blind children whom they could bring to school. From the 1850s onward, the script was transferred to India, China, Egypt, Australia, and West Africa by missionaries who included blind children in the schools they established and taught blind adults at home. Many of Moon's home teachers were blind men who walked great distances to serve other blind people. By 1880, Moon's annual report claimed to have reading material in 194 languages. Moon's script was the first reading system for the blind to be widely adopted across the world, but was costly to print. It was overtaken in the late nineteenth century by Braille, which was cheaper and could be produced by blind individuals for themselves. Moon's system is still used in Britain by people whose fingertips lack the sensitivity to use Braille.

MOSCOW THEATER OF MIME AND GESTURE

Founded in 1962, the Moscow Theater of Mime and Gesture (Moskovskii teatr mimiki I zhesta) was the first professional deaf theater in the world. The theater has been in continuous operation for more than 40 years and has staged more than 100 classic and modern plays by Russian playwrights and playwrights of other nationalities. It has won many Russian and international theater contests and has toured in many countries.

MULTIPLE SCLEROSIS

Multiple sclerosis (MS) is the most common demyelinating disease of the central nervous system, named for focal scars in the brain, spinal cord, and optic nerve. Myelin insulates the impulse-transmitting extensions (axons) from nerve cells and promotes fast transmission of electrical impulses. Demyelination results in slowing of impulse conduction. Clinical manifestations include sensory, motor, visual, gait, balance, bladder, speech, swallowing, sexual, mood, and cognitive disturbances, as well as spasticity, weakness, and fatigue. Ultimately, demyelination can result in axon loss, causing permanent damage. Diagnosis of MS is based on clinical presentation, nerve transmission, spinal fluid, and imaging studies.

Jean Martin Charcot provided the first clinical-histological description of MS in 1868. Since then, theories regarding the etiology of MS have included abnormal sweat suppression, toxins, poor circulation, allergy, and viruses. The prevailing theory today is that MS is an autoimmune disease—that is, the body attacks its own nervous system—that may occur preferentially in genetically susceptible people. Immune function in MS is studied in animals with experimental autoimmune encephalomyelitis.

MS most commonly affects women of childbearing age and of northern European descent. The best medical prognosis is in young women who first present with sensory symptoms and whose disease is relapsing-remitting (i.e., periods of exacerbation alternate with periods of improvement) rather than chronically progressive. Pregnancy does not affect long-term outcomes. MS does not alter lifespan. Psychological stress is suspected to exacerbate symptom severity.

Pharmacotherapy for MS includes medications to manage spasticity, pain, bladder dysfunction, sexual dysfunction, and fatigue, as well as corticosteroids to reduce exacerbation severity. In the 1990s, chemicals that modulate the immune system (immunomodulators), thought to alter the course of MS, were developed. Immunomodulators are used widely today, despite possible debilitating side effects. On the horizon are neuroprotective agents, stem cell transplants, and gene therapies.

The course of MS is highly variable. MS can result in a range of disability, from nearly none to the inability to write, speak, and walk. Physical therapy, occupational therapy, adaptive devices for ambulation and function in the home and workplace, and psychological and social supports are critical components of overall care.

As young adults adjust to new careers and families, those with MS must also adjust to loss of body function and the social stigma and losses of self-esteem, job opportunities, family time, and independence that come with it. Unpredictability of disease course makes acceptance and coping particularly difficult, both for the individual with MS and for the primary caregiver. Community support networks can help individuals with MS and their families adapt to disruptions in social, family, and work life, and can help to maximize both functional status and quality of life. In recent years, the Internet has increased the accessibility of individualized information on MS, clinical trials, and support networks.

Currently, there is no cure for MS. Its etiology—and whether more than one etiology could result in the clinical picture characterized as "MS"—has not been definitively determined. In the future, increased understanding of interactions among genes, immunity, central nervous system damage, clinical manifestations of disease, and psychosocial well-being will allow medical practitioners to provide maximally effective individualized treatment programs.

MURPHY, ROBERT FRANCIS

(1924–1990)

American anthropologist and disability scholar

Robert Murphy was one of the most influential scholars in the field of disability studies. His work proved critical to the disciplinary beginnings of disability studies as a field that challenged the medicalization of human differences as pathology. In 1976, at the age of 52, Murphy was diagnosed with an inoperable spinal tumor and later became increasingly paralyzed. At the time, he was already an established anthropologist at Columbia University and had spent many years (along with his wife, Yolanda, who was also an anthropologist) in the Amazon among the indigenous peoples. His most significant contribution to disability scholarship is the autobiographical work titled *The Body Silent,* in which Murphy takes up his experience with disability outside of more traditional narrative modes such as the first-person overcoming story. In doing so, he transforms disability into a journey of cultural discovery. As Murphy himself characterizes his efforts, "Since it is the duty of all anthropologists to report on their travels . . . this is my accounting." *The Body Silent* presents Murphy's accounting with the zeal of a field anthropologist investigating an unknown landscape or culture. Murphy thus successfully shifts the understanding of disability from a tragic encounter to one of profound intellectual value. His work moves disability out beyond an individual experience and into a profound analysis of societal and historical investments in bodies that exist outside of aesthetic and functional norms. Ultimately, Murphy's work transforms the disabled body from a socially bequeathed silence into a vehicle of social exposé.

MUSCULAR DYSTROPHY

The neuromuscular diseases (NMDs) are disorders of muscle or of the peripheral nervous system that cause generalized muscle weakness or paralysis but either mildly affect or completely spare the brain. The weakness most commonly results in inability to achieve or loss of independent ambulation, scoliosis (childhood onset), respiratory complications (which are generally preventable), and occasionally heart failure.

Before the French physician N. Andry's attribution of NMDs to muscle pathology in 1743, it was believed that they were caused by bony lesions. In 1853, the French physicians Duchenne and his colleague Jean Cruveilhier distinguished between generalized weakness due to muscle pathology and "paralysis" denoting muscle dysfunction on the basis of neurological disease. Duchenne described these disorders as resulting from febrile illnesses that affect the spinal cord (later called *poliomyelitis*), from syphilis, and from heavy metal toxins, and both paralyses and muscle diseases (from "impaired circulation or nutrition") could lead to fatty transformation of muscle. The most common and most rapidly progressive NMD has become known as *Duchenne muscular dystrophy.* However, it was not until 1868 that Duchenne distinguished muscular dystrophy, primarily a muscle disorder, from other NMDs. This was 16 years after the English physician Meryon's (1852) classical description of this condition and

32 years after its initial description in Italy (Conte and Gioja 1836).

Meryon (1852) described how a patient died at 16 years of age from acute respiratory failure during a febrile episode with "profuse secretion of mucus from the trachea and larynx" (quoted in Archibald and Vignos 1959). All NMDs cause death by respiratory complications due to weakness of inspiratory, expiratory, and throat (bulbar-innervated) muscles. Inspiratory muscle weakness can result in coma and death from carbon dioxide narcosis. Expiratory (essentially abdominal and chest) muscle weakness results in pneumonia and respiratory failure due to airway secretion encumberment from an ineffective cough. Bulbar muscle dysfunction results in death from massive aspiration of airway secretions; however, this is seen only in advanced bulbar amyotrophic lateral sclerosis (Lou Gehrig's disease) and virtually never in muscular dystrophy or other NMDs. In the case of myopathic disorders, heart muscle weakness (cardiomyopathy) can also result in death.

The inability to find very effective medical treatments or cures for any of these conditions and the failure to appreciate how respiratory muscles can be aided has resulted in therapeutic nihilism (see Dubowitz 1977). However, effective means of preventing or limiting musculotendinous contractures, prolonging ambulation, preventing scoliosis, and increasing limb function are now available; the use of specially designed robotics and computers can prevent morbidity and death and help to maintain a good quality of life for individuals with NMDs (see Bach 2004). The use of inspiratory and expiratory muscle aids can consistently and indefinitely prevent death from respiratory causes (see Bach 2002b), and effective regimens of cardiac medications have been developed that can prolong effective cardiac function for patients with myopathies (see Ishikawa and Bach 2004).

Respiratory muscle aids are devices and techniques that involve the manual or mechanical application of forces to the body or intermittent pressure changes to the airway to assist inspiratory or expiratory muscle function. The devices that act on the body include body ventilators that create atmospheric pressure changes around the thorax and abdomen and exsufflation devices that apply force directly to the body to mechanically displace respiratory muscles. Negative pressure applied to the airway during expiration or coughing assists the expiratory muscles as forced exsufflation just as positive pressure applied to the airway during inhalation (noninvasive ventilation through mouthpieces or nasal interfaces) assists the inspiratory muscles (see Bach 2002b). Despite the extraordinary efficacy of respiratory muscle aids in preventing hospitalizations, resort to tracheotomy, and death (see Gomez-Merino and Bach 2002; Bach et al. 2002; Bach 2002a), respiratory complications continue to cause death for the majority of patients with NMDs (Bach 2002b). This is because of a general lack of awareness of the availability of these aids and the medical community's low level of interest in helping patients with rare conditions that cause severe disabilities.

▣ MUSIC

Ethnomusicologists have long understood that music can be the focus of highly autonomous cultural units whose rules and rituals—including their constructions of (dis)ability—may vary considerably from those of their host communities. What constitutes disability or impairment may differ greatly between a musical "world" and its extramusical environs. For example, in Japan and Ukraine of bygone eras, blindness was far from disabling for professional minstrels. In contrast, deafness, while regarded as a cultural identity rather than a disability by the Deaf, renders participation in music ("musicking") difficult. Nonnormate hand function typically regarded as minimally significant—left-handedness, small hands, single-finger mobility impairment (such as that experienced by composer Robert Schumann)—may be disabling for musicians. Addiction, epistemologically complex as regards disability, becomes exponentially more challenging taxonomically in music, where substance abuse may be regarded as a rite of passage, identification badge, or hearing (that is, musicking) aid.

Mobility impairments mandate either accommodations to facilitate normate musicking or at least nonnormate strategizing. While challenges to musicking with a disability are, ultimately, socially constructed, they may be formidable. Many remain unaddressed.

CLASSICAL MUSIC

Perhaps Western classical music's greatest advocate for disability accommodation was pianist Paul Wittgenstein. After losing his right arm in World War I, Wittgenstein commissioned five one-hand piano works; the concertos by Ravel and Prokofiev became standard repertoire, mostly for two-handed pianists. That compositions originally intended to accommodate Wittgenstein's disability have entered the twentieth-century canon—few modern concertos have—exemplifies universal design principles.

Ambulatory impairment barely impedes classical musicking, significantly affecting only instruments with pedals—keyboards and harp. Mobility-impaired conductors James DePriest and Jeffrey Tate use high stools on the podium. Renowned violinist Itzhak Perlman walks with crutches and performs seated; a colleague carries his instrument onstage. Recent improvements in concert stage/backstage accessibility are said to owe much to Perlman's prominence.

The most famous disabled classical musician was composer Ludwig van Beethoven (1770–1827). Gradual, ultimately profound hearing loss forced the composer to abandon instrumental performance and conducting. Contemporaneous biographical accounts take notice of his use of the adaptive technologies of his day, ear trumpets and conversation books. Many of the latter have been preserved, providing an exceptional biographical reference. Beethoven's compositional prowess was surely undiminished by his deafness. Whether some of his stylistic preferences were shaped by his hearing loss is a matter of speculation.

Contemporary Scottish percussionist Evelyn Glennie also has significant hearing loss. She eschews disability/Deaf identity. Her public statements could be interpreted as anti–Deaf culture; her official website (http://www.evelyn.co.uk) is inaccessible. She is a supporter of the Alexander Graham Bell Foundation, widely perceived as opposed to Deaf culture and a major advocate of orality and cochlear implants.

The late Canadian pianist Glenn Gould (1930–1981) was noted for his musical and personal eccentricities and abandonment of concertizing in favor of an exclusively recording career. His hypochondria and psychological dependence on prescription medications, which Gould obtained in great and often contraindicated variety and in large quantities by going to several physicians who were unaware of what others had prescribed, has been reliably documented. It is widely and exceptionally convincingly speculated that Gould had Asperger's syndrome, a high-functioning condition on the autistic spectrum and a diagnosis virtually unknown at the time of the pianist's death. Whatever Gould's cognitive differences and whatever the affect on his health and quality of life, it is precisely the iconoclasm of his music making—doubtless related to his unique cognitive makeup—that remains highly cherished.

POPULAR MUSIC AND JAZZ

Probably the most disabling aspect of Americanist global popular culture is the insistence that artists be exceptionally physically attractive by normate standards, particularly in youth popular music, where prominent figures with visible disabilities are virtually unknown, with such minor exceptions as late-disabled, established figures like Curtis Mayfield and Teddy Pendergrass, whose careers certainly declined postdisability. (Hidden conditions such as Karen Carpenter's anorexia and the substance addictions of Jimi Hendrix, Janis Joplin, Jim Morrison, Kurt Cobain, and others are common.)

More (under)class conscious musicians have been somewhat more accepting of artists with apparent disabilities. (Alt-)country has produced prominent singers whose impairments, although obvious, do not impede their performance: Vic Chesnutt (paraplegia) and Mel Tillis (speech disfluency).

Important jazz musicians have also been noticeably, although not musically, disabled. They include Benny Goodman band trumpeter Wingy Manone (amputee), pianist Michel Petrucciani (small stature, brittle boned), and blues singer-guitarist Brownie McGhee (mobility impaired). Others, including Charles Mingus (ALS) and Ella Fitzgerald (double amputee, owing to diabetes), were late disabled and continued to work.

Several jazz artists' physical impairments are incorporated seamlessly into their uniquely virtuosic styles. Pianist Horace Parlan, well-known for his work with Charles Mingus and also as a sideman for jazz legends Dexter Gordon, Archie Shepp, and Rahsaan Roland Kirk, had polio that left his right side affected, in particular his right hand, the fourth and fifth fingers of which cannot play at all. Parlan was fortunate that at age eight, piano teacher Mary Alston encouraged him to develop a uniquely personal technique rather than dismissing his musical aspirations. It is interesting to compare the careers of classical pianist Wittgenstein and jazz pianist Parlan. Wittgenstein's disability compelled him to commission a whole new one-handed literature, which, however, provided him only a minuscule repertoire. Parlan, working in an idiom whose essence is flexibility and improvisation, knew no such limits. He is able to play with his unique technique the entire jazz repertoire alongside legendary players.

Even more remarkable than Parlan was Roma guitarist Django Reinhardt. Badly burned at the age of 18, Reinhardt lost most of the use of the fourth and fifth fingers of his left hand. (The left hand uses fingers 2–5 to fret the strings, often simultaneously, when chords are played.) Even less able than Parlan to play with the conventional technique of his instrument, Reinhardt is known for having invented the single-string jazz guitar solo and revered as one of the greatest jazz guitarists of all time.

Singer Jimmy Scott, Billie Holiday's favorite, has Kallmann's syndrome, a hereditary hormonal condition that inhibits growth and prevents the male voice from deepening at puberty. Known for his work with Lionel Hampton, his newly revived career is currently at its peak, with international tours, recordings, and a recent biography.

MUTUAL ASSISTANCE AMONG MUSICIANS WITH DISABILITIES

The notable achievements of individual musicians with disabilities do not justify the lack of technological and other accommodations that would enable more universal musical participation. Organizations of disabled musicians in Canada and the United States provide important models.

Founded in 1988, the Vancouver Adapted Music Society (VAMS) is devoted to facilitating, through the development and commissioning of highly sophisticated technologies, musicking by people with "significant disabilities," mostly mobility impairments. Much of the new technology emphasizes composition and sound synthesis, although real-time performance aids have also been developed. VAMS views music making as inherently valuable rather than therapeutic or rehabilitative. Program participants tend to be avocational, rather than professional, musicians. In 1993, the organization's showcase band, Spinal Chord, recorded an all-original CD titled *Why Be Normal?*

Founded in 1986, the Long Island–based Coalition of Disabled Musicians (CDM) is concerned primarily with professional music making: Several members have acquired workplace disabilities that mandated career changes. CDM advocates and disseminates information about adaptive technologies, typically simpler if no less effective than those developed at VAMS, as well as nontechnological accommodations such as “tag-team performance”—that is, the use of several musicians in alternation as a strategy for dealing with fatigue issues. Like VAMS, CDM has a featured band, Range of Motion.

Organizations like VAMS and CDM have tremendous value for the advancement of music making by people with disabilities. In particular, the development of technologies for composition and sound synthesis and the emphasis of real-time performance address the needs of potential musicians with mobility impairments.

MUSIC AND BLINDNESS

Blindness usually presents no obstacle to music making; indeed, the blind are often regarded as exceptionally musical. Nations have even reserved classes of musical employment for the blind, and blind musicians have often formed unions.

Blind musicians flourish where musical praxis is predominantly oral. Western classical music’s reliance on notation creates difficulties for blind musicians, and conductors present another problem. Still, notable blind classical musicians include composer-organists Francesco Landini, Louis Vierne, and Jean Langlais, and composer-pianist Joaquin Rodrigo. Louis Braille, inventor of tactile writing and music notation for the blind, was an accomplished organist.

FRANCE

Pierre-François-Victor Foucault (1797–1871) was a blind professional hornist in postrevolutionary Paris and husband of blind author Thérèse-Adèle Husson (1803–1831). Foucault and Husson were partially supported by Quinze-Vingts hospice for the blind, sponsored by French royalty since the thirteenth century. An 1825 census shows that 34 of 225 hospice members were professional musicians, including 9 women, most of Quinze-Vingts’s working blind. While music was considered a suitable occupation for the blind, Foucault’s colleagues defied hospice authority by serving as the house orchestra for the questionably reputed Café des Aveugles (Blind People’s Café), a manifestation of the tendency for the blind of Paris “to form a support network beyond the reach of an institution” (Weygand and Kudlick 2001:140), a transgression likely disapproved by hospice administrators. Braille entered Quinze-Vingts within a year of Foucault and Husson’s departure.

UKRAINE

Since at least the fifteenth century, Ukraine hosted a folk bardic tradition, with singers accompanying themselves on *kobza* (a lute that later evolved into the bandura) or *lira* (hurdy-gurdy). Blindness was obligatory for minstrels, and minstrelsy was reserved as a profession for the blind; artistry was a secondary consideration. Evidently, blind female minstrels sang a cappella and sang a repertoire different from that sung by men. Musical instruction was nearly universal for the blind, perhaps for all otherwise unable to work. Minstrels were associated with the Orthodox Church, but their social position was ambiguous; they were respected as workers and compensated as beggars.

Minstrels’ “remarkably democratic and egalitarian” guilds trained, protected, and policed the profession

(Kononenko 1998:xii). Apprenticeships included musical training as well as training in life/social skills and a secret language. Most guild members owned homes and raised families. Unlike most peasants, they traveled extensively. Minstrels hired sighted child guides, often with disabilities, who typically later became instrument builders, a skill acquired from their blind masters.

In 1939, Joseph Stalin convened a minstrel conference in the Ukraine. Fearing nationalism in minstrels' lyrics, he had all in attendance shot, nearly ending the tradition.

JAPAN

Japan's *biwa hōshi*—blind "lute-priests"—bear remarkable parallels to the minstrels of Ukraine. Even more than in Ukraine, in Japan the art and patronage of mendicant bards were religion based, with Indian and Chinese Buddhist antecedents perhaps as early as the sixth century BCE. The repertoire of the *biwa hōshi* syncretized Buddhism, Shinto, earlier local folk religion, historical narrative, and popular culture.

The principal function of the *biwa hōshi* evolved from spirituality to entertainment. Japanese attitudes toward blindness were complex and ambivalent, combining ancient beliefs that the blind have powers of divination and "extraordinary ability in communicating with invisible, yet very powerful, natural forces" (Matisoff 1978:30) and the Buddhist association of disability with negative karma. Disability was considered an opportunity to accumulate merit for future incarnations, fueling numerous morality tales in art and folk genres. Legendary *biwa hōshi* Semimaru has been described as "an archetype of the performing arts in Japan . . . a virtual 'patron saint'" (Matisoff 1978:6), inspiring stage works for Noh, Bunraku (puppet theater), Kabuki, and Butōh. Semimaru's status rose from local Shinto deity to bodhisattva, Buddha incarnate. The power that the *biwa hōshi* had over important popular narratives advanced his social position.

In the fourteenth century, *biwa hōshi* Akashi Kakuichi founded Tōdōza (the Proper Path Guild), which was eventually recognized by the government as a regulatory agency for blind lutenists. Tōdōza classified members "according to a system of four graded titles, divided into sixteen ranks" (Matisoff 1978:43). Beyond direct government control, the guild assumed the authority of "a country of the blind" (Matisoff 1978:43). Tōdōza was abolished in 1871, early in the modernist, pro-Western Meiji era.

The unionization of blind musicians in Ukraine and Japan implied broad societal consensus that certain categories of musical employment were apt and thus reserved for the blind, owing as much (or more) to extraordinary ability as to disability.

UNITED STATES

American democracy and market economics render impossible the existence of exclusivist guilds of blind musicians such as those established in Japan and Ukraine. The principal achievements of blind American musicians have been in forms of music with African American roots (although some notable blind exponents of these genres are neither American nor African descended). This is likely owing to the prevailing orality of African musical cultures and African American aesthetic preference for deeply personalized interpretation, often including improvisation. One ramification of the high value placed on individuality is that artists shape their interpretations around whatever idiosyncratic musical techniques emanate from their bodies, including vocal range, tone color, level of virtuosity, and the shaping force of a physical disability. African American music has produced distinguished musicians with a variety of impairments, including blindness.

Blindness has been particularly associated with the blues, especially older, acoustic varieties, the institution of the blind bluesman (blind blues musicians are apparently exclusively male) having nearly vanished in electric blues bands. Best known include Blind Lemon Jefferson, Blind Blake, Blind Willie McTell, Blind (or Reverend) Gary Davis, and Sonny Terry—the only one of this group whose sobriquet does not include "Blind." Although many acoustic bluesmen of this era were not blind, playing the blues appears to have been recognized as a suitable calling for blind musicians. Some, like Blind Lemon Jefferson, achieved considerable financial security and social status from their music making.

Although jazz makes greater use of notation than does blues, its prevailing orality/improvisation has made it an expressive medium for numerous blind musicians (not all African American), some of whom are acknowledged masters. They include pianists Art Tatum, Marcus Roberts, and George Shearing; pianist-vocalists Ray Charles and Diane Schuur; and saxophonists Rahsaan Roland Kirk, Lenny Tristano, and Eric Kloss. Among Motown's most illustrious performers and composers is Kennedy Center honoree Stevie Wonder. One of the best-known gospel groups in the United States is the Blind Boys of Alabama. Somewhat more removed from African American roots are folk musician Doc Watson and Latino vocalist-guitarist José Feliciano. Harder to characterize stylistically and largely forgotten musically but vital to disability history is composer-pianist "Blind Tom" Bethune (1849–1908), whose life is chronicled in three volumes by Geneva Southall (1979, 1983, 2002).

ELSEWHERE

Since the 1930s, the Royal New Zealand Foundation of the Blind has operated a program of music education and performances that has its origins in the pre-mainstreaming residential school system. A tradition of blind mendicant street ensembles, reminiscent of Japan and Ukraine, resides in Cuzco, Peru. The award-winning, extensively toured Light and Hope Orchestra of Cairo, made up entirely of women, is the world's only blind symphony orchestra. The South African Blind Musicians Association, which receives federal funding, performed at that nation's South African Music Week in 2002. The "blind-musicians" Listserv (blind-musicians-subscribe@yahoogroups.com) has worldwide subscribership.

Organizations of blind musicians have existed for centuries on nearly every continent. Blind leadership appears to be the rule in such organizations.

MUTATION THEORY

Mutation theory joined two seemingly opposed traditions of evolutionary thought at the beginning of the twentieth century. First, its practitioners accepted the primary contention of saltationist theory, which argues that new species are not formed, as Darwinism holds, through the gradual accumulation of variation over vast epochs, but instead are produced during sudden and unexpected shifts in the constitution of elemental species (a process referred to as *sports*). Second, unlike saltationists, who argue that some organismic variations are inherently undesirable, the first mutationists tended to hold the stricter Darwinian line that all differentiation is for the good of the organism/species. This argument was premised on the belief that more variation provides better opportunities for adaptation to a variable environment. This second emphasis has often escaped the reasoning of evolutionary theorists, many of whom have appeared to be perplexed that mutationists have claimed a Darwinian lineage (see Gould 2003:443). This important dovetailing of seemingly antithetical traditions made mutation theory one of the vanguard movements in twentieth-century evolutionary and, ultimately, genetic theory.

The first self-acknowledged theorist of mutation was the Dutch botanist Hugo de Vries. In his breakthrough two-volume work *The Mutation Theory (Die Mutation Theorie),* de Vries (1909) stubbornly insisted that he was first and foremost a Darwinian in spite of the fact that mutation functions as an expression of what the eugenicist Sir Francis Galton called *sports.* De Vries held that new species arrive suddenly and without prior precedent through the process of mutation, which he defined as "the change of one species into another [due to the formation of] a new center of analogous variations" (pp. 66–67). Rather than simply argue that species are discontinuous from each other—as in the case of neo-Lamarckism—mutation theory originated the idea that variations themselves are discontinuous, as in the cases of "dwarfism," "giantism," and "albinism." In the *O. Lamarckiana* species of plant that de Vries studied, these new species came into existence fully formed and viable while lacking all defining characteristics of the parent generation. Thus, de Vries's analysis focused on the creative force of discontinuity as a prime explanation for the origins of new species. This argument attempted to address a key lack in Darwinian analysis with respect to the incompleteness of the fossil record. Rather than insist that knowledge of the fossil record is insufficient to identify transitional stages in the gradual accumulation of incremental variations over time, de Vries's mutation theory insisted that no such gaps in the genealogical trees of organisms existed. Thus, what appeared to be absences in the fossil record could be marshaled as evidence in favor of a Mendelian and saltationist-based theory of evolution.

Mutationist theories developed after de Vries's work, such as Richard Goldschmidt's (1933) "hopeful monsters" and Gould and Eldredge's (1977) "punctuated equilibrium" theories, not only remained faithful to the saltationist basis for new species formation but also championed de Vries's devotion to the pure Darwinian belief that all variation proves beneficial, including above and below the organismic level. In doing so, mutationist theories have recognized alternative, viable organismic formations (often labeled "disabilities" at the human level) as examples of the creative force of new species coming into existence through mutation. This interpretation flies in the face of eugenicist—and geneticist—assertions that some mutations are monstrosities or organismic abominations. Those who have taken up this stance in favor of productive readings of mutation have been readily critiqued by a discourse that remains faithful to its investment in designating some organismic expressions "unnatural."

Rather than try to settle this dispute of more than 100 years' duration here, we need to ask this question: Why are efforts to embrace rather than malign the existence of recurrent forms of mutation so routinely banished from the theoretical canon of evolutionary and genetic traditions?

MUWAFFAK AD-DIN MUZAFFAR (1149–1226)

Egyptian philologist and poet

Muwaffak ad-Din Muzaffar was a blind Egyptian philologist and poet. Ibn Khallikan remarked that Muzaffar's treatise on prosody "testifies, by its excellence, the acute intelligence of the author." He quoted a little of Muzaffar's verse, in which the poet commented, rather wearily, on how strange sighted people found it that he could be in love: "You are in love, and yet you are blind! You love a dark-eyed nymph with rosy lips, yet you never saw the charms of her person; you cannot then say that they captivated your imagination." In a later era, the puzzled questioners might have listened to the radio and had the experience of falling in love with someone's voice; thus Muzaffar's reply, "I love through the medium of my ears," which Ibn Khallikan expanded with similar thoughts from earlier blind poets. The skills of memorizing and expounding Arabic literature, and expressing well-worn ideas about female beauty in neatly turned verse, continued in the thirteenth century to provide an opportunity for a few capable blind men to take part, without much disability, in the literary and courtly life of their times.

MYASTHENIA GRAVIS

Myasthenia gravis (MG) is a syndrome of fluctuating skeletal muscle weakness that worsens with use and improves with rest. Eye, facial, oropharyngeal, truncal, and limb muscles may be involved in varying combinations and degrees of severity. MG occurs throughout the world at any age from birth to the tenth decade. Today's overall annual incidence is 20 new MG cases per million individuals, with a remarkable increase with age. Current point prevalence rates of MG are in the range of 100–200 per million population.

The etiology of MG is varied, divided initially between those rare congenital myasthenic syndromes that are genetic and the bulk of MG that is acquired and caused by the body's own immune system attacking itself (autoimmune). The autoimmune conditions are divided into those that possess measurable levels of an antibody to a substance that allows communication between nerves and muscles (acetylcholine receptor, or AChR) and a smaller group that does not. The latter includes those MG patients who have antibodies to a chemical critical to normal muscle function (MuSK).

General treatment measures include rest, high-potassium diet, and avoidance of infections and drugs that exacerbate MG. Except for some of the congenital myasthenic syndromes, drugs that help overcome the diminished communication between nerves and muscles (anticholinesterases) are usually effective for temporary treatment of MG symptoms. Short-term immunological treatments for autoimmune MG emergencies such as breathing difficulties (crisis) include filtering the blood, plasmapheresis, and/or intravenous immunoglobulin. For long-term immunological treatment, therapies differ for early-onset MG, late-onset MG, and MG associated with tumor of the thymus gland, thymoma. Thymectomy is often effective for early-onset MG (before age 50). Drugs that suppress the immune system, including corticosteroids, are useful for late-onset MG and for MG associated with thymoma (following thymectomy). Most MG patients can be treated effectively, but more specific therapies are still needed.

MYOFASCIAL PAIN

DEFINITION AND SYMPTOMS

Myofascial pain is a chronic regional musculoskeletal pain syndrome characterized by the presence of trigger points, which are discrete areas of focal tenderness within a muscle that reproduce the patient's pain and have a characteristic referral pattern when palpated.

The characteristic symptoms of myofascial pain may begin after a discrete trauma or injury or may be of insidious onset. Patients note localized or regional deep aching sensations, which can vary in intensity from mild to severe. The myofascial trigger points of each muscle have their own characteristic pain patterns. Often associated subjective symptoms are present, such as abnormal sweating, vasomotor/ temperature changes, paresthesias ("pins and needles" sensation), edema (swelling), joint stiffness, impaired muscle coordination, decreased work tolerance, fatigue, and weakness.

CAUSE

Although many theories have been developed, no absolute answer has been reached concerning the cause of myofascial pain syndrome. The recent medical literature demonstrates that excess release of acetylcholine (the chemical responsible for communication between the nerve and muscle at the neuromuscular junction) may result in chronic muscle shortening, relative ischemia (diminution of local blood flow), and reduction of energy supply to the muscle.

In addition, in this chronic pain syndrome, neurochemical changes occur at higher-level pain-processing centers in the spinal cord and brain, rendering the nervous system more sensitive to pain. This results in a hypersensitivity to both painful and normally nonpainful stimuli.

PHYSICAL EXAMINATION AND TREATMENT

A comprehensive medical, neurological, and musculoskeletal physical examination is performed to identify underlying structural causes of regional pain, such as sciatica, bursitis, or tendonitis. Thereafter, careful palpation of the painful region is necessary to search for trigger points. Trigger points feel like ropy bands of muscle and are painful when pressure is applied. Pain is often referred distally (away from the area). Pain recognition by the patient is important to confirm that the trigger points are indeed the cause of relevant pain.

The treatment of myofascial pain may be either pharmacological (involving the use of medications) or nonpharmacological. *Pharmacological* treatments may include anti-inflammatory medications (for example, ibuprofen) to help treat any associated bursitis, tendonitis, or other inflammatory condition. Several different types of muscle relaxants are useful as well. Low doses of antidepressants have demonstrated utility in reducing pain even in the absence of clinical depression. In severe cases, botulinum toxin may be injected in the painful musculature. *Nonpharmacological* options include massage, ice, heat, acupuncture, and relaxation training. Trigger point injections are reserved for recalcitrant cases.

Rehabilitation and Exercise

Physical therapy is indicated both to provide local treatment and, most important, to ensure that the patient is educated in appropriate exercise, including stretching, graded strengthening, and aerobic exercise to decrease pain and improve function. An occupational therapist can be helpful in educating the patient on proper body mechanics and improving workplace ergonomics. Reinforcement of appropriate posture, stretching, and relaxation training can be helpful components of rehabilitation.

FUNCTIONAL OUTCOME AND DISABILITY

To date, few outcome studies have examined myofascial pain and its treatment. One research study found improvements in life satisfaction and coping skills as well as decreased sick-leave time after rehabilitation. Growing evidence suggests a link between arm pain and physical risk factors in the workplace. Therefore, possible ergonomic solutions may be forthcoming. No studies have yet been conducted regarding myofascial pain and disability.

MYOPATHY

Myopathy is a general term referring to a disease of the muscle. Myopathies can be subdivided into hereditary and acquired variants. The hereditary myopathies include the various forms of muscular dystrophy, congenital myopathies, metabolic myopathies, and some mitochondrial myopathies. The acquired myopathies include a group of diseases known as the inflammatory myopathies, toxic myopathies caused by drugs or other chemicals, and myopathies due to endocrine dysfunction. All myopathies cause skeletal muscle weakness, which can cause disability.

The hereditary myopathies come from genetic defects affecting the expression of a protein, enzyme, or other structure within muscle. With the explosion of molecular genetics, many of these genetic defects and gene products have been identified. The three most common hereditary myopathies are all forms of muscular dystrophy: Duchenne dystrophy, myotonic dystrophy, and facioscapulohumeral (FSH) dystrophy. Both myotonic and FSH dystrophy are inherited in an autosomal dominant fashion, meaning that an affected parent has a 50 percent chance of passing the disease on to a child. The congenital myopathies are further classified by abnormalities seen on muscle biopsy. In the past, they were also distinguished from the dystrophies by nonprogressive weakness; however, it is now recognized that weakness does progress in some of these disorders.

The metabolic myopathies are caused by abnormalities in glycogen or fat metabolism in muscle, producing weakness, early fatigability, and muscle cramping. Mitochondrial myopathies are caused by abnormalities in the mitochondria, the energy source for cells. Unfortunately, there is no effective pharmacological treatment to reverse weakness caused by the inherited myopathies. However, the use of rehabilitation strategies limits the disability and handicap produced by these diseases.

The acquired myopathies are often treatable with medications. The inflammatory myopathies (dermatomyositis, polymyositis, and inclusion body myositis) are the most common acquired myopathies, with an incidence of 1–2 per 100,000. Dermatomyositis and polymyositis are autoimmune diseases, which can be treated with drugs that modulate the immune system (e.g., steroids). Inclusion body myositis does not respond well to pharmacological treatment. The endocrine myopathies can be treated through correction of the underlying hormonal imbalance, such as hypothyroidism or hyperparathyroidism. The toxic myopathies can be reversed through elimination of the responsible drug or the offending toxin (e.g., alcohol).

The disability associated with myopathies is caused by muscle weakness. Depending on the particular disease, the limb, trunk, breathing, chewing and swallowing, and ocular muscles can all be involved. Some of the myopathies have an abrupt onset with rapid development of weakness (e.g., dermatomyositis), whereas others present with gradual weakness (e.g., some cases of FSH and myotonic dystrophy). Onset can occur in childhood or adulthood. Disability and impairment due to limb muscle weakness can be minimized through the provision of appropriate assistive devices, braces, and alternate modes of mobility (scooter, wheelchair). Respiratory muscle weakness is often managed through the use of noninvasive ventilation and through assistance with coughing. Speech therapists can teach patients compensatory strategies to minimize swallowing and speech difficulties caused by bulbar muscle weakness. In some myopathies, cardiac muscle is involved as well as skeletal muscle, producing another source of disability, which may be managed through medications and/or pacemaker placement.

In the near future, advances in molecular genetics that have identified the causes of many of the inherited myopathies may translate into effective treatments that will reduce the disability caused by these diseases. Likewise, ongoing research on the pharmacological treatment of the inflammatory myopathies may reduce disability from these diseases.

N

NARCISSISTIC PERSONALITY DISORDER

Although prevalent in human society since the beginning of recorded history, narcissistic personality disorder has attained prominence as a distinct disability only in the past quarter century through the work of psychoanalysts. The disorder is characterized by most of the following: extreme sensitivity to slights, a grandiose sense of self-importance, a great need for admiration accompanied by a personal lack of empathy, a sense of being so special or unique that only high-status people or institutions are worthy of association, a sense of entitlement (unreasonable expectations of especially favorable treatment), and arrogance.

Rather than seeing them as people who were overly indulged growing up, contemporary psychoanalysts view such persons as having been partly arrested in their emotional development at a stage of early childhood. Seeking the parents' validation and a sense of personal specialness is within normal developmental bounds at age two or three. When such emotional supplies are not adequately provided to them in childhood, the inappropriate seeking of them well into adulthood is the hallmark of people with this disability. Treatment rests on the psychotherapist's tolerance of their self-centered behavior without gratifying it and promoting insight into the patient's exaggerated vulnerability to empathic lapses by the therapist and others in their world.

NATIONAL ACTION PLANS IN NORWAY

See Norway: National Action Plans

NATIONAL CENTER FOR MEDICAL REHABILITATION RESEARCH (UNITED STATES)

The National Center for Medical Rehabilitation Research (NCMRR) has primary responsibility for medical rehabilitation research that is supported by the U.S. government's National Institutes of Health (NIH). The center's professed mission is to foster development of scientific knowledge needed to enhance the health, productivity, independence, and quality of life of persons with disabilities. Research is emphasized that addresses the health-related problems of people with disabilities and that has implications for enhancing their daily functioning. The center pursues its mission principally by providing multiyear grants-in-aide to investigators located in universities, medical schools, and other institutions throughout the United States.

The *Research Plan for the National Center for Medical Rehabilitation Research* (National Institute of Child Health and Human Development 1993) describes a conceptual framework for identifying research that the NCMRR supports. Seven priority areas are the following:

Improving functional mobility

Promoting behavioral adaptation to functional losses

Assessing the efficacy and outcomes of medical rehabilitation therapies and practices

Developing improved assistive technology

Understanding whole-body system responses to physical impairments and functional changes

Developing more precise methods of measuring impairments, disabilities, and societal and functional limitations

Training research scientists in the field of rehabilitation

The NCMRR's annual expenditure in 2002 for research and research training was $57,659,000. The bulk of those funds supported research grants that originated with unsolicited, investigator-initiated applications for funding that then were submitted to peer review. A small percentage of applications were funded in response to solicitations that were announced by the NCMRR on topics of special importance to the center.

Established by legislation passed by the U.S. Congress in 1990, NCMRR is a component of the National Institute of Child Health and Human Development (NICHD), a part of the NIH. That legislation established two other entities, the National Advisory Board on Medical Rehabilitation Research, and the Medical Rehabilitation Coordinating Committee. The Advisory Board consists of 12 scientists and clinicians in medical rehabilitation, 6 people with disabilities who have been recipients of medical rehabilitation services, and 17 ad hoc members from government agencies that fund research or service programs of relevance to medical rehabilitation. Its principal functions are to recommend research initiatives that it believes the center should undertake and to advise the directors of the NIH, NICHD, and NCMRR on matters and policies relating to the center's programs. The Coordinating Committee is charged with making recommendations to the directors of the NICHD and NCMRR regarding the center's research plan and its activities that are carried out in conjunction with other organizational entities within the NIH and throughout the federal government.

The NCMRR's efforts are organized in terms of three programs. The Biological Sciences Program promotes basic research to provide the scientific underpinnings of clinical rehabilitation. Research supported by this program strives to understand the mechanisms of recovery from, and adaptation to, injury and disease. The Clinical Practice Program applies scientific findings to improve clinical practices in rehabilitation. Work supported in this area includes development of new therapeutic interventions, clinical trials of new interventions, and clinical studies to improve and validate existing rehabilitation practices. The behavioral science portion of the Behavioral Science and Rehabilitation Engineering Program supports research that is relevant to the development or redevelopment of individuals' emotional, cognitive, and behavioral functioning. The rehabilitation engineering component encourages applications of engineering and bioengineering principles to promoting the habilitation or rehabilitation of people with physical disabilities. Examples include research on various forms of assistive technology, including prostheses and devices for wheeled mobility.

—Marcus J. Fuhrer

NATIONAL INSTITUTE ON DISABILITY AND REHABILITATION RESEARCH (NIDRR) (UNITED STATES)

The U.S. National Institute on Disability and Rehabilitation Research (formerly the National Institute on Handicapped Research and hereafter referred to as NIDRR) was established in 1978. The U.S. Congress adopted the Rehabilitation Comprehensive Services and Developmental Disabilities Amendments of 1978 (Public Law 95–602), which removed the engineering and training programs previously administered by the Rehabilitation Services Administration (RSA) in the U.S. Department of Health, Education, and Welfare and placed them in NIDRR located in the newly reorganized Department of Education under the Office of Special Education and Rehabilitative Services. The institute's name was changed to NIDRR by the 1986 amendments to the Rehabilitation Act. The mission of NIDRR is to contribute to the independence of persons of all ages who have disabilities by seeking improved systems, products, and practices in the rehabilitation process.

NIDRR is an old program. The official role of the U.S. government in vocational rehabilitation, prosthesis research, and other disability-related research dates back to the 1930s and 1940s. Much of the groundwork for the current system of rehabilitation research was laid in the 1940s by the National Academy of Sciences and the armed services response to the postwar needs of veterans. A large share of the initial research was conducted by the Department of Defense and the Veterans Administration (VA) on prosthetic devices. The Interagency Committee on Rehabilitation Engineering, a working group composed of representatives of the National Science Foundation, National Bureau of Standards, National Aeronautics and Space Administration (NASA), VA and other agencies, and the Senate Committee on Labor and Human Resources, was responsible for NIDRR's initial long-range plan. The Interagency Committee for Disability Research, which is coordinated by NIDRR, is responsible for reviewing proposed research projects and for identifying areas that overlap with ongoing projects.

NIDRR's initial research plan focused on functional areas of research needs including mobility, communication, function, education, employment, recreation, and activities of daily living. Using a competitive grant process, NIDRR program mechanisms included the following: rehabilitation research and training centers (RRTCs), rehabilitation engineering research centers (RERCs), spinal cord injury rehabilitation centers, centers for deafblind youths, and coordination with international rehabilitation research centers.

After the passage of the Americans with Disabilities Act in 1990, NIDRR increased its emphasis on research related to independent living and community integration. The most recent long-range plan for 1999–2003 was issued in 2000. The disability paradigm, which provides the value framework for the plan, maintains that disability is a product of an interaction between the individual and the environment. The plan listed the following research agenda areas: (a) employment outcomes, (b) health and function, (c) technology for access and function, (d) independent living and community integration, and (e) associated disability research areas such as statistics. The plan also listed priorities for related activities in knowledge dissemination and utilization and capacity building for rehabilitation research. RRTCs and RERCs continued to receive the largest percentage of NIDRR's resources with 22.8 percent and 10.78 percent, respectively, of the $70 million appropriated to NIDRR in fiscal year 1996.

In an enumeration of research and administrative accomplishments from 1993 to 2001, NIDRR identified both administrative reforms and research outcomes. Administrative reforms include reinvigorating the Interagency Committee on Disability Research, overhauling its peer and program review processes and implementing a Center of Excellence model that balances scientific rigor with consumer relevance. Research accomplishments include the following: (a) establishing the first RERC on telerehabilitation, (b) continued decrease of decubitus ulcers and other secondary complications of spinal cord injury, (c) expanding the Traumatic Brain Injury System and initiating a system in Burn Rehabilitation, (d) research support for the accessibility features in the Windows operating system, and (e) initiating voting research.

NIDRR has been involved in a number of science and technology policy issue areas and initiatives during this period including the President's Executive Memorandum on Technology Transfer, the President's Information Technology Advisory Committee and Section 508 and electronic accessibility in the workplace, and signing cooperative agreements with federal laboratories. NIDRR unleashed new international initiatives that included the Web Accessibility Initiative within the World Wide Web Consortium (W3C), and the establishment of an RERC on land mines.

NATIONAL THEATRE OF THE DEAF (UNITED STATES)

The National Theatre of the Deaf (NTD) is the world's first professional deaf theater company and the oldest continually producing touring theater company in the United States. NTD's influence is widespread and renowned: The company has trained most of the deaf theater artists working today, and a number of its alumni have started their own deaf theater companies across the United States and abroad. NTD has also educated generations of hearing audiences about American Sign Language and Deaf culture and provided intercultural experiences that bring both deaf and hearing audiences together. Despite the company's successes, some deaf audience members have criticized the company for gearing productions to primarily hearing audiences.

NTD was conceived and eventually founded by a hearing medical professional and several high-profile, hearing theater artists. Dr. Edna S. Levine, an expert in deafness and psychology as well as an ardent attendee of Deaf amateur performance events, originally conceived the idea for NTD in the late 1950s and early 1960s. She garnered the support of actor Anne Bancroft, who had consulted Levine for research about deafness for her role as Anne Sullivan, the visually impaired teacher of deaf and blind Helen Keller, in Broadway's version of *The Miracle Worke*r. Broadway directors Gene Lasko and Arthur Penn and Tony Award–winning Broadway set designer David Hays also lent their support. Early efforts foundered when the federal government turned down two different grant applications. Hays and Levine continued to pursue funding with the assistance of faculty at Gallaudet University; hearing administrator Mary Switzer of the Department of Health, Education, and Welfare; and deaf and hearing administrators of the Vocational Rehabilitation Administration.

This persistence and networking paid off in 1965 when NTD earned its first federal grant for the 1966–1967 season. Along with federal grants, NTD is supported by corporate donors and ticket revenue. The company's first home was the Eugene O'Neill Memorial Theatre in Waterford, Connecticut, moving to Chester, Connecticut, in 1983, and moving to its current home in Hartford, Connecticut, in 2000. Throughout its history, NTD has collaborated frequently with Gallaudet University faculty and students.

NTD's repertoire includes adaptations of canonical dramatic literature (both Western and non-Western), children's literature, poetry, letters, novels, and fables. The work has appeared on stage, film, and television. The company strives for cultural diversity, a goal furthered by exchanging company members with international deaf theater companies and the regular inclusion of international artists in their professional training programs. In addition, NTD has collaborated with hearing theater luminaries such as Peter Brook, Arvin Brown, Colleen Dewhurst, Bill Irwin, Marcel Marceau, Chita Rivera, Jason Robards, and Peter Sellers.

In addition to its theatrical productions, NTD has included a professional actor-training program (Deaf's Actors Academy, its earliest incarnation founded in 1967), a touring theater for young audiences (Little Theatre of the Deaf, founded in 1968), workshops for deaf playwrights (primarily active from 1977 to 1982), and educational outreach programs. NTD has performed in all 50 of the United States and on five continents.

To appeal simultaneously to both deaf and hearing audiences, NTD has developed a unique theatrical style, a seamless hybrid of corporeal and spoken languages in which audiences "see and hear every word." Because of his background and training as a set and lighting designer, David Hays recognized that the sculptural qualities of sign language theater had the potential to revolutionize theater aesthetics as a whole. In contrast to traditional Western theater's focus on spoken text and realistic acting styles, NTD's performance style emphasizes the spatial and dance-like qualities of human communication. The resulting style blends the spoken word, American Sign Language, sign-mime, invented theatrical sign language, music, and stylized individual and ensemble movement. A hallmark of NTD's style is the creation of visual scenic elements using only the actors' bodies, a few suggestive props, music, and unusual sound effects. NTD employs both deaf and hearing performers. Deaf performers most often portray main characters with hearing actors located on the stage's periphery voicing the main characters' lines, a technique called *shadowing*. Sometimes hearing actors play minor characters as well.

The NTD's performance style and repertoire have not succeeded without controversy. During its early years, while the company was in the process of inventing its theatrical vocabulary, deaf audiences complained that the American Sign Language used in the productions was unintelligible to them. They complained that the signing was performed too quickly and invented signs were cryptic. Furthermore, deaf audiences felt that the material was more often than not geared toward hearing audiences and that Deaf cultural issues went unexplored. Deaf audiences also tended to be suspicious of a company whose leadership was almost entirely hearing. To address these concerns, NTD began developing original work for deaf audiences about Deaf culture. As deaf theater artists became trained and experienced, they moved into leadership positions within the organization and took on more directing and design assignments. Complaints from the deaf community about the productions' unintelligibility have quieted as well. Audiences may have simply become accustomed to NTD's theatrical vocabulary as it has become more conventionalized and used by numerous companies. While the majority of NTD's audiences remain hearing (about 90 percent), over the years the company has dedicated portions of its season to work by, for, and about the Deaf community.

NAZISM

Disabled people have faced both neglect and oppression within different cultures and political systems, throughout history. Yet the period of Nazi control in Germany (1933–1945) is notorious for genocidal policies toward disabled people. In the postwar period, the magnitude and cruelty of the "Final Solution" or Holocaust of the Jewish people has overshadowed the parallel exterminations of disabled people, homosexuals, Gypsies, Communists, Jehovah's Witnesses, and other minorities. Reclaiming the story of the Nazi eugenic and euthanasia program has been an important part of the disability studies project and the political development of the disability movement. Where neo-Nazi groups have been resurgent in America and Europe in the late twentieth century, disabled people have been targeted for abuse, attack, and sometimes murder, showing the continued need for awareness of Nazi ideology.

THE NAZI VIEW OF DISABILITY

Social Darwinism—the application of Herbert Spencer's idea of "the survival of the fittest" (it was English philosopher Spencer who first used the phrase)—was widely accepted and promoted in the Germany of the 1920s. Adolf Hitler's political manifesto, *Mein Kampf*, adopted a strongly social Darwinist approach: "The strongest asserts its will; it is the law of nature" (quoted in Gallagher 1995, p. 21). One of his perennial concerns was with the biological basis of the German race. This took the form of perorations against Slavic or Jewish intermarriage with Germans, and the threat of "mongrelization." It also led Hitler to express prejudice against the weak, sick, and disabled. Thus, he expressed admiration for the Spartan city-state of classical times: "The exposure of the sick, weak, deformed children, in short their destruction, was more decent and in truth a thousand times more humane than the wretched insanity of our day which seeks to preserve the most pathological subjects" (quoted in Gallagher 1995, p. 21).

In his speeches and policies, Adolf Hitler negated both the Christian and humanist traditions, by explicitly promoting militarism and putting the good of the nation above the rights of individuals. For example, he claimed: "Nature is cruel; therefore we are also entitled to be cruel. When I send the flower of German youth into the steel hail of the next war without feeling the slightest regret over the precious German blood that is being spilled, should I not also have the right to eliminate millions of an inferior race that multiplies like vermin?" (quoted in Fest 1974, pp. 679–680).

Mein Kampf is full of prejudice against disabled people and expresses the view that disabled people should be prevented from reproducing. However, these views were not unique to Nazi ideologues: Beliefs about race and fitness had been popular since the late nineteenth century in German science and medicine. Old ideas were reinforced and emboldened by the development of the Nazi movement. During the 1930s, and especially after the takeover of power in 1933, propaganda against disabled people became more common. For example, the film *I Accuse* featured a husband who killed his wife, who was suffering from multiple sclerosis. This idea of mercy killing was to become a major element in the Nazi approach to disability. Other terms used in propaganda posters and films to describe disabled people included "useless eaters," "ballast existence," and "life unworthy of life."

NAZI ACTIONS AGAINST DISABLED PEOPLE

After 1933, eugenic laws were passed in Germany, which prohibited marriage for certain individuals and mandated sterilization for some. These laws were comparable to equivalent legislation in the United States and the Nordic countries. After the advent of war, a covert euthanasia program (T4) was authorized by Hitler, which led to the murder of 70,000 disabled people in six killing centers, largely by gassing them. The main targets for murder were individuals who lived in institutions, particularly people with learning difficulties or mental health problems. After complaints and concerns were raised among the public, the official euthanasia program was halted. However, it was replaced by other measures to murder disabled people and also people with tuberculosis and other diseases, particularly as the German army took over territory to the East—"wild euthanasia" as it was called. The technicians of the T4 program moved on to staff the new extermination centers, which murdered Jews and other minorities. Meanwhile, a children's euthanasia program murdered thousands of disabled children in hospitals, via starvation or lethal injection: this program continued until 1945.

The motivation for euthanasia was largely economic: In the context of war, it was an attempt to save money and resources by eliminating dependent people. The aim of racial purification was often subsidiary to the financial motive; for instance, disabled people outside institutions were less likely to be killed.

As well as official and unofficial euthanasia, disabled people were subjected to medical experimentation, particularly in the concentration camps such as Auschwitz. During the Nazi era, such research was conducted with little or no regard for the rights of the subjects, or concern for the origins of the medical specimens that were used. Corpses or body parts were sent to scientists from residential institutions, killing centers, and concentration camps. For example, Julius Hallervorden, working at the Kaiser Willhelm Institute for Brain Research in Berlin—now the Max Planck Institute—received more than 600 brains from institutions. He was very prominent in the field of neurology and gave his name to Hallervorden-Spatz disease. While the means and values of Nazi science may have been reprehensible, not all the findings can be dismissed as bad science. For example, alongside the eugenic and euthanasia programs, public health physicians were making major discoveries about the causes of cancer, linking tobacco to lung cancer for the first time.

This raises important questions about the extent to which all these developments should be attributed to the Nazis themselves. Hugh Gallagher (1995) argues that "although this program was authorised by Hitler and carried out under the auspices of the National Socialist government of the Third Reich, it would be a mistake to call it a Nazi programme. It was not. The program was conceived by physicians and operated by them. They did the killing. While many of these physicians were Nazis, many more were not. The program's sponsors and senior participants were the leading medical professors and psychiatrists of Germany, men of international reputation" (p. xv).

Nor was eugenics solely a Nazi ideology. In the United States, the Nordic countries, and across the world, involuntary eugenic sterilization was widely used during the twentieth century. However, in adopting official and unofficial euthanasia programs, the Nazi regime went further than any other.

It should be noted that the eugenic and euthanasia programs, although authorized by Hitler and carried out under the National Socialist government of the Third Reich, were largely conceived and carried out by senior medical professionals, not Nazi storm troopers or party ideologues. However, medical professionals were undoubtedly the professional group with the highest percentage of members of the Nazi party (approximately 50 percent). Many Nazi doctors escaped postwar prosecution, and some continued to take a leading role in German and international medical science after 1945.

THE NAZI ANALOGY

Referring to the eugenic and euthanasia programs carried out against disabled people during the Nazi era has rhetorical force in contemporary political arguments. For example, it is not uncommon for disability activists to label modern genetic research or screening services as "Nazi." Individuals who take positions that appear threatening or hostile to disabled people—such as the bioethicist Peter Singer—have been tarred with the "Nazi" epithet.

Equally, advocates of particular screening policies have used the Nazi example as a way of distinguishing between their own ideas and the discredited notions of eugenics that predominated prior to 1945. Distinctions between "bad science" and "evil eugenics" versus "good science" and "reproductive choice" are used to exonerate governments, medical professionals, and families from having immoral motivations or actions. Yet, on closer examination, freedom of choice is not always a reality, and the attitudes of doctors may sometimes sound implicitly or explicitly eugenic.

The descriptor "Nazi" has huge power, and it should be deployed with care and accuracy, not simply as a way of dismissing others with different views. Equally, when arguments about saving money by preventing the birth of disabled people—or about putting the interests of society above those of the individual—are being used by scientists and policy makers, then it is important to remember the past contexts in which these arguments were deployed. Understanding how the abuses of the Nazi era came about—and guarding against similar measures in modern medicine or social policy—remains vital in the twenty-first century, in democracies as well as in less liberal regimes.

NESBITT, MURROGH DE BURGH (1889–1959)

South African independent living pioneer

Murrogh de Burgh Nesbitt lost his legs at 13, falling from a train on which he hitched a ride at Jagersfontein. The next 30 years of activity and adventure, overcoming physical obstacles and attitudinal barriers in others' minds, appeared in his much-reprinted autobiography, *The Road to Avalon* (1944), where Nesbitt also sketched his dream of a rural center for self-help rehabilitation, run by disabled people. The dream was realized in 1946, after publication of his first book. A further book (1958), including many descriptions and first-person accounts of people overcoming disabilities, described how the center "Avalon" was built and developed by Nesbitt, his wife Fraan, and a few companions, near Tulbagh in the Winterhoek Mountains, with fundraising and control vested in a committee of like-minded people at Johannesburg. However, by 1951, with Avalon in full swing, the original committee had largely been replaced, and the Nesbitts were ousted from Avalon. They moved to farming in the Orange Free State, living among the Basuto people. Murrogh Nesbitt was years ahead of his time in implementing ideas of self-help, mutual therapy, and the importance of disabled people as leaders and role models.

NEURAL ENGINEERING

Neural engineering refers to a new discipline that has emerged by combining engineering technologies and mathematical/computational methods with neuroscience techniques. The objective is to enhance our understanding of the functions of the human nervous system. Neural engineering also holds promise to improve human performance, especially after injury or disease. As befits such a broad definition, the field is multidisciplinary, in that it draws from neurological sciences (especially neurobiology and neurology) but also from a diverse range of engineering disciplines, including computer sciences, robotics, material sciences, neural networks, signal processing, and systems modeling and simulation.

While the potential applications of neural engineering are very broad, the discipline offers particular opportunities for improving motor and sensory function after major human central nervous system illnesses such as stroke, traumatic brain injury, or spinal cord injury. In these illnesses, the new technologies can be applied to help reroute neural signals around damaged areas of brain or spinal cord, or to substitute one type of neural signal for another type that is lost after the injury.

A particularly innovative example relating to the descending control of muscle actions in spinal cord injury relies on the application of multi-electrode recording techniques to enable long-term, simultaneous recordings from clusters of neurons in the motor cortex during the performance of skilled voluntary movement tasks. These cortical signals can be used to drive assistive devices, to program electrical stimulation of muscles (functional electrical stimulation or FES), or to interact directly with computers as communication systems.

Leading investigators in this area are Andrew Schwartz (2004) from the University of Pittsburgh, John Donoghue (2002) from Brown University in Rhode Island, and M. A. Nicolelis (Patil et al. 2004) at Duke in North Carolina. Each group has developed impressive animal models that involve recordings from various cortical areas during normal voluntary behaviors. These neural signals are usually filtered and processed to allow them to be used to instruct computers, to control simple robotic devices, or to activate electrical stimulators to control limb muscles. Exemplar approaches includes studies in which primates can be trained to use cortical neuron discharge to control simple planar robots, or they can be used to activate neural stimulators to excite muscles and move joints.

Alternative approaches allow signals from skin or other sensory areas to be routed around damaged areas and to be delivered to the cerebral cortex by other means. For example, sensory signals from the eye or from skin can be detected by a range of electronic sensors then delivered to the cortex in the form of electrical stimulus trains.

Other potentially helpful applications of neural engineering include the development of novel recording systems to allow long-term recording from small groups of nerve fibers in peripheral muscle or skin nerves and the development of implantable stimulators for use in promoting recovery of walking in individuals with spinal cord injury or for the restoration of motor function after cortical damage sustained as a result of stroke. Neural cuffs placed around nerves innervating the foot sole can be used to sense foot contact during walking or to detect other phases of locomotion, allowing accurate programming of muscle nerve stimulation.

Clinical applications of neural engineering are increasing rapidly in number, and there will certainly be many new practical applications emerging over the next few years.

NEURASTHENIA

Neurasthenia literally means nerve weakness. Although the New York neurologist and electrotherapist Georg Miller Beard may not have coined the term, contemporaries certainly considered him to be the father of neurasthenia. Beard's publications on neurasthenia appeared from 1869 until 1883, the year that he died. His most influential books were *A Practical Treatise on Nervous Exhaustion (Neurasthenia): Its Symptoms, Nature, Sequences, Treatment* (1880), and *American Nervousness: Its Causes and Consequences* (1881). A German translation of *A Practical Treatise* already appeared in 1881; a French translation followed in 1895. In the meantime, the neurasthenia concept had become widely known on both sides of the Atlantic, including Russia and Italy but also in, for example, the Dutch East Indies. From the early twentieth century onward, the diagnosis would also be introduced in countries such as Japan and China.

The label of neurasthenia was applied to a whole range of physical and mental symptoms, varying from anxiety, despair, phobias, and insomnia to inattention, extreme fatigue, palpitations, migraine, indigestion, and impotence, among others. Neurasthenic symptoms were attributed to a lack of nerve force, stemming from excess demands on the brain, the digestive organs, and the reproductive system. These demands, in turn, were thought to result from the fast pace of modern, urban life. Beard had presented neurasthenia as a truly American disease that was more or less the acceptable by-product of American civilization, but in the European context, next to modernity, heredity and degeneration also figured as explanatory concepts.

The therapeutic repertoire included treatment with electricity; visits to spas, seaside resorts, or the mountains; psychotherapy in combination with a stay in a sanatorium of (mental) hospital; or the rest cure of the American physician Silas Weir Mitchell, consisting of seclusion, bed rest, electrical treatment, a nutritious diet, and massage.

Neurasthenia acquired many different faces, geographically, socially, and through time. Not only was neurasthenia appropriated in many different ways, its popularity as a diagnosis also varied significantly, as did the popularity of its various therapies. Beginning as an affliction of the elite and the educated classes, neurasthenia was later "democratized" to a certain extent, by including ordinary people. Male neurasthenic patients tended to constitute the majority. In America and Europe, neurasthenia's heyday continued into the first decade of the twentieth century. From the early twentieth century onward, neurasthenia shifted from a somatic into a psychic diagnosis. After World War I, the diagnosis of neurasthenia gradually became outdated, although it by no means disappeared, as witnessed by its inclusion in the 10th revision of *International Statistical Classification of Diseases and Related Health Problems* (*ICD-10*) and the fourth edition of *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-IV*). Conditions similar to the ones that used to be called neurasthenia now tend to be labeled as chronic fatigue syndrome. In eastern Asia, neurasthenia is still a preferred diagnosis, presumably because of its somatic rather than mental connotation.

NEUROLOGICAL IMPAIRMENTS AND NERVOUS DISORDERS

Neurology is the study of human neuromuscular system, including the brain, spinal cord and roots, peripheral nerves, junctions between nerves and muscles, and the muscles themselves, in health and disease. Neurological impairment arises from an alteration of function in any of these structures and can result from a wide variety of etiologies, from inherited genetic conditions to obstructed blood flow to a particular part of the nervous system. Common neurological symptoms and related disabilities include problems with memory, attention, concentration, speech or language (aphasias); sleep disturbance; visual changes; dizziness or vertigo; fatigue; weakness; involuntary movements or muscle rigidity; pain; loss of sensation or abnormal sensations; and problems with coordination or gait.

Neurology has a long history, and knowledge of the structure and function of the nervous system, along with conceptions of neurological impairments and their related disabilities, can be roughly divided into three phases: the preclassical, classical, and scientific phases. During the preclassical period, from antiquity until the early nineteenth century, medical scientists described several neurological syndromes, including epilepsy (the "sacred disease" or "falling sickness"), migraine and cluster headaches, hemorrhagic stroke (apoplexy), paralysis, and a variety of psychiatric disorders. Anatomical knowledge during this period was largely limited to the gross anatomy of the brain, spinal cord, and peripheral nerves. Concepts of the nervous system's function were correspondingly guided by structural appearance, so that peripheral nerves were believed to be conduits for the flow of animal spirits or nervous fluid; or by extrapolation from simple observation or experimentation, such as the notion of reflex action. With a relatively short human lifespan, limited knowledge of the structure and function of the nervous system, and the absence of effective medications or interventions, neurological disability during the preclassical era frequently involved chronic pain, paralysis, social stigma, and institutionalization.

The classical period of neurology, from the early nineteenth century to the mid-twentieth century, witnessed a dramatic growth in knowledge about the structure and function of the nervous system, and detailed clinical descriptions for dozens of neurological disorders along with their underlying pathology. During this period, neuroanatomy advanced beyond the surface structure to the microscopic descriptions of the nervous system, including individual nerve cells (neurons) and their connections, and provided a foundation for the understanding of normal function and pathophysiology. Physiological concepts were still closely tied to general concepts of nerve impulses and reflex action, but were integrated with psychological notions of inhibition, association, and representation. Many neurological disorders were first described during this period, including the aphasias or disorders of language (Paul Broca, Carl Wernicke, Ludwig Lichtheim), several brainstem stroke syndromes, general paresis and tabes dorsalis (syphilis of the brain and spinal cord), movement disorders such as Parkinson's and Wilson's diseases, multiple sclerosis (Jean Martin Charcot), hemi-transection of the spinal cord (Charles Éduoard Brown-Séquard), and muscular dystrophy (G. B. A. Duchenne).

Although several anesthetics, aspirin, and potent anticonvulsants (phenobarbital and phenytoin) were also developed during the classical period of clinical neurology, disability was still largely related to the progressive or fixed paralyses, chronic pain, and institutionalization, with the addition of traumatic brain lesions resulting from war injuries and generalized syndromes related to combat and advancing technology ("railway spine," neurasthenia, shell shock).

The scientific phase of clinical neurology, dating from the early twentieth century until the present, has produced an explosion of detailed knowledge about the structure and function of the nervous system. Several innovations made this rapid evolution possible, including the development of information theory, storage, and analysis; techniques for molecular and genetic analysis; structural imaging of the nervous system from magnetic resonance imaging (MRI) of the entire brain to electron microscopy of individual neurons and their connections; and techniques for studying brain function such as electroencephalography (EEG), positron-emission tomography (PET), and functional MRI. Knowledge of the different organizational levels of the nervous system (genetic, molecular, membrane, cellular, and functional systems) is now integrated to provide a detailed account of many neurological disorders.

These techniques have also produced new concepts such as neurodegenerative disorders, autoimmune syndromes, disease-modifying drugs, and critical time periods for therapeutic intervention. Indeed, recent decades have seen the development of highly effective symptomatic treatments for many neurological disorders, as well as agents that alter the natural history of neurological diseases. Neurological disability has been likewise transformed by our ability to diagnose neurological disorders at earlier stages, detect and manage risk factors for stroke, alleviate the paroxysmal pain of migraine as well as the chronic pain of peripheral neuropathy, delay the progression of conditions such as Parkinson's and Alzheimer's diseases, and provide technologically advanced treatment or life support for patients with life-threatening neurological conditions.

Examples of common neurological disorders, their associated impairments, and treatments in Western medicine follow:

Movement disorders. Parkinson's disease, the most common movement disorder, involves three cardinal features, namely, tremor, rigidity, and bradykinesia, but it is frequently associated with fatigue, cognitive changes, and sleep disturbance. Medical therapy with carbidopa/levodopa and other dopamine agonists (medications that stimulate dopamine receptors) have significantly reduced these symptoms and their associated disability. Surgical treatment with deep-brain stimulators is available for severe cases.

Headache. Migraine is one of the most common headache syndromes and is frequently associated with severe pain, visual changes, dizziness, nausea, and vomiting, requiring several hours of rest for symptomatic relief. Development of a novel class of neurochemicals (serotonin agonists, or triptans) and the use of antiseizure medications to prevent migraines has significantly reduced the frequency, intensity, and duration of attacks.

Epilepsy. Recurrent seizures involve unpredictable lapses of awareness and are frequently associated with either subtle automatic movements or violent jerking movements of the entire body. They pose significant risks of bodily injury or death. In addition, personal and social activities including driving, employment, and interpersonal relationships are restricted in many cultures. Over a dozen new antiepileptic agents developed over the past 20 years have resulted in significantly fewer medication side effects and some improvement in seizure control. Epilepsy surgery for refractory cases has excellent prognosis in select patients.

Stroke. Temporary or permanent interruption of blood flow to an area of the brain typically can produce a variety of neurological symptoms including aphasia, weakness, visual problems, difficult swallowing, or paralysis, in addition to long-term neurological and medical complications. Recovery of neurological function is highly variable and depends on several factors. Acute intervention with thrombolytic agents (“clot busters”) or revascularization strategies can produce a significant improvement in neurological outcome, but these techniques are underused and limited to a very brief time window after the onset of symptoms.

Demyelinating diseases. Multiple sclerosis is a progressive, disabling autoimmune syndrome that typically affects young women and involves inflammatory lesions in the brain or spinal cord. Typical symptoms include cognitive difficulties and poor memory, loss of eyesight, weakness, incoordination, a decline in gait, incontinence, and prominent fatigue. New chemicals that modulate the immune system reduce the number of acute attacks, but their impact on long-term disability (i.e., average years before a patient is a wheelchair user) is not yet clear. Other medications can alleviate symptoms of profound fatigue and incontinence, improving the disability associated with these symptoms.

Dementia. The most common form, Alzheimer’s-type dementia, is increasing in both incidence and prevalence and typically involves loss of memory and higher intellectual abilities. Symptoms include a progressive loss of memory, difficulty with basic activities of daily living, loss of autonomy, and institutionalization in severe cases. Anticholinesterase agents mildly slow the progression of disease.

Radiculopathies. Symptoms of weakness, muscle atrophy, and numbness in the arms of legs commonly result from compression of a spinal cord root compressed by the bones of the vertebral column, osteoarthritis, or displaced vertebral discs (herniated or “slipped” disc). Physical therapy, anti-inflammatory agents, or surgical decompression or stabilization provide effective symptomatic relief.

Neuropathies. Injury to the peripheral nerves is most commonly produced by chronic disease (diabetes mellitus), toxins (alcohol), infection (leprosy, hepatitis), or repetitive mild trauma (carpal tunnel syndrome). Neuropathies can produce a loss of sensation in distal extremities, abnormal burning or lancinating pain, weakness, and a decline in gait. Minor trauma due to numbness in the feet can lead to major complications such as infection of the bone (osteomyelitis) or destruction of a joint (Charcot joint). Medical treatment of any underlying conditions producing nerve damage and the use of various medications for symptomatic relief can minimize related disability.

Motor neuron disease. Amyotrophic lateral sclerosis (ALS) is a relentlessly progressive disease typically affecting males in the fifth and sixth decades of life that involves symptoms of weakness and spasticity. Disability is typically associated with loss of use of the arms and legs, requiring the use of a wheelchair, as well as progressive weakness of the muscles of speech, swallowing, and breathing. Physical therapy is helpful in managing symptoms of muscle cramping and spasticity but does not have an impact on the overall disability or course of disease.

This brief list of neurological conditions highlights the variability of neurological symptoms and their extraordinary impact on human function, life, and culture. A historical view of neurological conditions and impairments also illustrates the evolving interaction between medical knowledge, technology, practice, and therapeutics across history.

NEUROPATHY

Neuropathy is a loss of the function of nerves. Symptoms depend on which nerves are damaged. The main motor symptom is weakness, whereas common sensory symptoms are numbness, paresthesias (abnormal sensations such as pricking, tickling, burning, or tingling), and pain. Neuropathy is a common neurological disorder resulting from damage to the peripheral nerves and thus is more often called peripheral neuropathy. Peripheral nerves include the nerves branching off the spine, nerves innervating the head and neck area, and the autonomic nerves regulating functions such as blood pressure and motility of the intestines.

Historically, in the eighteenth and nineteenth centuries, neuropathy was not recognized as a separate disease, but rather diagnosed as progressive paralysis together with many other diseases. In the nineteenth century, many different forms of neuropathy were described as ascending or descending according to the direction in which the disease progressed, because the common thought was that nearly all disorders of the nerves were based on inflammation. A second diagnosis often used was progressive muscular atrophy (degeneration). Due to the work of great nineteenth-century French neurologists such as Jean Martin Charcot and G. B. A. Duchenne, many new diseases were split from this general category of progressive muscular atrophy: various diseases of the muscles, the spinal cord, the brain, and the many diseases of the peripheral nerves, the neuropathies.

Neuropathies can be classified into mononeuropathies when one restricted area is damaged, polyneuropathies if there is damage of the nerves in more areas, and symmetric neuropathies with bilateral manifestations. Another classification is according to which type of nerve is involved. Sensory neuropathies account for damage to nerves carrying sensory information and motor neuropathies for those innervating the muscles.

Common causes of neuropathy are diabetes and alcoholism. Other causes include mechanical pressure such as repetitive strain injuries, direct damage, toxic substances, certain medications, inflammation, autoimmune disorders, and endocrine and hereditary diseases. Recent diagnostic DNA tests have greatly increased our understanding of the complexities of hereditary neuropathies.

Although there is a wide range of causes, the type of damage to the nerves is limited. The nerve is composed of a cell body and a fibrous extension (axon), which conducts electrical nerve impulses. Isolation cells (myelin sheath), which facilitate electrical conduction, surround most of the axons. In toxic or metabolic injuries (e.g., diabetes) the axons and the myelin degenerate, resulting in a numb feeling in the area, the so-called sock or glove hypesthesia. Degeneration of myelin can be due to hereditary, inflammatory, or autoimmune factors and usually shows patchy damage to the myelin sheath.

Treatment of neuropathies involves eliminating or regulating the causes. Surgery can help when a nerve is entrapped; optimizing drug treatment is required in the case of diabetes. Some drugs are prescribed to relieve symptoms such as burning sensation, pain, and painful contractions of muscles. Physical therapy and splints can also relieve the burden of muscle contractions. Some complementary therapies ([electro]acupuncture) can be useful in alleviating symptoms such as pain.

Most hereditary and autoimmune neuropathies are incurable and often show a gradual deterioration leading to a lifelong use of a wheelchair or chronic pain. The impairment of sensory neuropathies, such as those of diabetes or leprosy, can lead to secondary injuries, infection, gangrene, and limb amputation. Providing the means to increase quality of life and improve self-image and providing emotional support are critical for dealing with the disabilities of neuropathy.

NEUROPSYCHIATRY

Neuropsychiatry is a nonboarded subspecialty of the medical discipline of psychiatry that focuses on the treatment of persons whose psychiatric symptoms appear to be most related to *documented* brain disease or brain injury. The term *neuropsychiatry* refers to psychiatrists who have had one or more years of postresidency training in a neuropsychiatry fellowship program or who have had some neurological experience. The qualification, *documented* brain disease, restricts the field of neuropsychiatry and limits the overlap with other related subfields of psychiatry, such as biological psychiatry, in that biological psychiatry attempts to define the biological abnormalities that correlate with mental illness in the otherwise normal brains of psychiatric patients. Because of this difference, patients treated by neuropsychiatrists not only have documented neurological disease but are often under the care of a neurologist as well.

The overlap with the subspecialty of neurology called behavioral neurology is therefore the strongest for neuropsychiatry. However, the differences between these two fields are more significant than their overlap. Behavioral neurologists diagnose and treat the cognitive and behavioral disturbances that correlate with the patient’s documented brain lesions. Neuropsychiatrists view these same brain lesions in the context of the patient’s total psychosocial context and also within the context of the remaining healthy part of the patient’s brain function, that is, the patient’s emotional reaction to his or her brain impairments. In this regard, neuropsychiatry overlaps to some extent with the medical field of physiatry, or rehabilitation medicine, and the psychological subspecialties of neuropsychology and neurorehabilitation.

Neuropsychology is more concerned with the precise measurable characterization of both cognitive and emotional symptoms of brain impairment using standardized testing materials and structured interviews to give as complete as possible a cross-sectional view of the patient’s function. Neurorehabilitation concerns itself with the application of new technologies to promote recovery of brain function or limit the progression of brain disease. Because the neuropsychiatrist has the larger psychosocial picture of the patient in mind and follows the patient longitudinally with relatively frequent follow-up visits, the final integration of the multifaceted care of the brain-impaired patient often falls into the hands of the neuropsychiatrist, which triggers an overlap with the legal and ethical aspects of medicine as a whole.

Therefore, the questions of medical as well as financial competency often arise in the course of the neuropsychiatrist’s longitudinal care of the patient as well as forensic issues related to legal state of mind during impulse dyscontrol in patients with disinhibition due to the progression of their brain disease. This is particularly true in the treatment of older patients who suffer from progressive dementias, and this triggers another overlap with the psychiatric subspecialty of geropsychiatry. Unlike neuropsychiatry, geropsychiatry is a fully established board-accredited subspecialty of psychiatry that specializes in the psychiatric care of older patients who may or may not have documented brain disease but do have psychiatric symptoms.

In the process of treating psychiatric symptoms of brain-impaired patients, both positive symptoms of delusions and hallucinations and negative symptoms of apathy and neglect, as well as mood symptoms such as hypomania and depression and dysexecutive symptoms such as poor judgment and impulse dyscontrol, neuropsychiatrists attempt to make use of the most recent work in integrative (clinical and basic) neuroscience. This includes neuropsychopharmacology, neuroimaging techniques such as single-photon-emission-computed tomography or brain SPECT, magnetic resonance imaging or MRI with its specialized techniques of functional imaging, magnetic resonance angiography, and diffusion tensor imaging, as well as positron-emission tomography or brain PET imaging, with radioligand binding, electroencephalography including EEG (electroencephalographic), MEG (magnetoencephalographic), QEEG (quantitative EEG), and EPs (evoked potentials), clinical neurogenetics, neural network theory, and medical informatics databases. In using these sources of clinical information, the neuropsychiatrist must rely on the expertise of the established practitioners, such as the neuroradiologist and the electrophysiologist, but because the neuropsychiatrist knows the larger history and psychosocial context of the patient and has generally spent more time with the patient in the clinic, it becomes his or her responsibility to make optimal use of this information in guiding the overall treatment plan.

The following are some examples of clinical problems that might be managed by a neuropsychiatrist: (1) a Parkinson's patient with delusions and hallucinations on high doses of dopamine-enhancing medications, (2) a Huntington's patient exhibiting violent behavior and personality changes, (3) a developmentally disabled patient exhibiting self-injurious behavior, (4) a dementia patient who is causing behavioral and social disruptions, (5) a postoperative neurosurgical patient with delirium and speech impairment, (6) a seizure patient with psychosis and/or depression, (7) a patient with recurrent seizures, (8) a patient with chronic fatigue syndrome and decreased cognitive function, (9) a patient with a traumatic brain syndrome with an unstable mood and cognitive impairments, (10) a poststroke patient with apathy, (11) a patient with both schizophrenia and dementia, (12) a patient with Tourette's syndrome and severe obsessive-compulsive disorder, and (13) physical violence in a patient with known brain disease.

A major contribution of neuropsychiatry has been the management of the violent patient with known brain disease. Neuropsychiatrists have been active in treating patients who exhibit patterns of violence related to different types of brain lesions. These include (1) violence related to hypomanic or manic behavior after right parietal stroke, (2) impulsive aggression in the setting of congenital brain abnormality or diencephalic injury, (3) reflexive aggression to transient environmental stimuli in patients with dementia, (4) violence emanating from a dysexecutive syndrome due to prefrontal cortical disease, (5) violence related to deepened affect or delusive ideation in patients with temporolimbic epilepsy, and (6) violence in childhood abuse victims who have experienced traumatic brain injury. Carefully crafted combinations of beta-blockers, anticonvulsants, antipsychotics, serotonin re-uptake inhibitor antidepressants or SSRIs, and psychostimulants have been used to enhance cortical control of limbic circuits for these patients. Decreasing the frequency and intensity of violent behavior in these patients is essential to effective nursing care and rehabilitation as well as outpatient management.

Neuropsychiatrists have helped to significantly reduce morbidity in stroke patients. Stroke is the third leading cause of mortality and morbidity in North America. More than 20 percent of stroke victims become severely depressed, greatly complicating their rehabilitation. Neuroimaging studies suggest that infarction of the left anterior cortex as well as left rostral prefrontal cortex and left rostral caudate area carry the greatest risk for poststroke depression. Vascular dementia is also receiving the attention of neuropsychiatry with extensive use of psychoactive agents especially anticholinesterase inhibitors to enhance cognitive function. Early treatment of stroke and vascular dementia patients with antidepressants and psychostimulants can substantially increase their success at rehabilitation. Also, since the psychiatric symptoms in vascular dementia can often be more disabling than the cognitive deficiencies, the neuropsychiatrist can play a substantial role in improving the patient's overall function. Neuropsychiatrists are also taking an active role in the treatment of other dementias particularly Lewy body dementia, which often presents with delusions and mood instability, and frontotemporal dementia, which frequently presents with anxiety, obsessions, and delusions. The patient's quality-of-life issues with these dementias often depend on the effective control of their psychiatric symptoms.

NEUROPSYCHOLOGY

Neuropsychology is the study of brain-behavior relationships. Clinical neuropsychology is an applied science dealing with the behavioral manifestation of brain dysfunction. Neuropsychological evaluation therefore entails assessing the various psychological/behavioral functions governed by the brain. Evaluations are useful in differential diagnosis among similarly appearing neurological disorders or between psychiatric and neurological conditions. Neuropsychological assessments often serve as the nucleus of rehabilitation and educational intervention plans and are instrumental in the evaluation of their effectiveness.

As with all psychological evaluations, neuropsychological assessment involves a process of answering clinical questions and responding to unique clinical situations that vary somewhat from patient to patient and across practice settings. The clinical application of neuropsychological principles can be used to determine the etiology and behavioral consequences of disabling conditions, as well as provide medical, rehabilitation, and psychiatric treatment recommendations. Treatment intervention is also an important and developing area within the specialty of neuropsychology.

Lezak (1995) delineated four knowledge areas important for neuropsychological practice: (1) clinical psychotherapeutic and assessment skills, (2) psychometrics, (3) neuroanatomy and functional neuroanatomy, and (4) neuropathologies and their behavioral effects. A fifth important knowledge area is a theoretical understanding of how the previous four content areas interrelate and interact. Such a conceptual framework helps the neuropsychologist integrate the historical information, medical material, current cognitive abilities, and general psychological functioning; provide an accurate description of a person's cognitive strengths and weaknesses; arrive at correct diagnoses (etiological conditions and anatomic location); outline the implications of the results for that person's functional living potential; formulate prognostications; and make clinically useful recommendations or design appropriate treatment interventions.

NEUROPSYCHOLOGICAL ASSESSMENT

There are three general reasons for conducting a neuropsychological evaluation: differential diagnosis, patient care, and research. The first step in the assessment process is defining the questions that need to be answered to meet particular clinical needs. Next, the neuropsychologist must determine what information is required and how best to obtain it. Neuropsychological testing might be only one of several methods used. In fact, a psychological test is simply a sample of behavior obtained under controlled or standardized conditions. Other methods of obtaining information about a person's past and present behavioral capabilities include the case history, clinical interview, mental status examination, direct behavioral observations, and reports of other people who are involved with the patient (e.g., spouse, children, friends, employer, and other professionals such as nursing staff or rehabilitation therapists). If testing is to be conducted, then test selection must be competently addressed. Structuring the testing session, administration procedures, scoring, and clerical issues also are important factors in the overall competent completion of the data collection phase of the evaluation process. Following data collection are the interpretation and application phases of the evaluation process.

A wide variety of cognitive and intellectual abilities are typically assessed during a neuropsychological evaluation. These include attention and concentration; learning and memory; sensory-perceptual abilities; speech and language abilities (sometimes including academic skills such as reading, spelling, and math); visuospatial and visuoconstruction skills; overall intelligence; executive functions (such as abstraction, reasoning, problem solving, behavioral self-monitoring, response discrimination, selection, inhibition, and mental-processing efficiency and flexibility); and psychomotor speed, strength, and coordination. Included are measures of sensory-perceptual input, the two principal central processing systems (verbal-language and nonverbal-visuospatial), executive organization and planning, and response output (motor abilities). Underlying them all are attention, concentration, arousal, and motivation. Although this list of cognitive functions might be organized or labeled differently by different neuropsychological schools of thought, these behaviors would generally be evaluated in most comprehensive neuropsychological evaluations. Frequently, aspects of psychological functioning (i.e., psychopathology, behavioral adjustment, and interpersonal issues) also are included in a neuropsychological evaluation.

Neuropsychological evaluation differs from other neurodiagnostic procedures such as computed tomography (CT) or magnetic resonance imaging (MRI) scans that examine the anatomical structure of the brain. With a neuropsychological evaluation, cognitive capabilities, from which inferences about the brain and its function can be derived, are examined. In this regard, it is similar to neurodiagnostic tests that assess other functional capabilities of the brain. For example, the electroencephalogram (EEG) and event-related potentials (ERPs) measure the electrical activity of the brain, and positron-emission tomography (PET) scans or single-photon-emission-computed tomography (SPECT) scans assess anatomical patterns of cerebral blood flow or metabolic activity. Among these, the neuropsychological evaluation is the only neurodiagnostic procedure that can evaluate how a person cognitively and behaviorally functions in real life. Neuroimaging studies may review a location of dysfunction, but two people with damage in the same brain region may have different behavioral manifestations of that damage. Neuropsychological examinations can identify and quantify those differences.

Neuropsychologists must be aware of the anatomic considerations and behavioral sequelae associated with various etiological conditions in the evaluation and interpretation of data. For example, some cognitive functions depend on well-defined anatomic structures (e.g., lower-level sensory-motor skills and even higher-level perception such as recognition of familiar faces dependent on functions of the sensory-motor strip and bilateral basal occipital-temporal regions, respectively). Other abilities (e.g., new learning, abstract reasoning, and speed of information processing) are diffusely organized or rely on complex interacting cortical and subcortical networks. The effects of brain injury can result not only in deficits in various cognitive abilities but also in the emergence of new behaviors or symptoms such as perseverations, unilateral neglect, or confabulations. Furthermore, congenital conditions (e.g., hydrocephalus, renal disease, William's syndrome) can result in similar deficits that result in learning disability and attentional disorders manifested in infancy and childhood.

NEUROPSYCHOLOGICAL INTERVENTIONS

In addition to neuropsychological evaluations, many neuropsychologists also provide intervention services. The neuropsychologist is informed by general psychological principles and knowledge of adjustment issues and mental health disorders, as well as by the influence of brain-behavior relationships on psychological and behavioral functioning. Treated patient populations include the spectrum of medical, neurological, and psychiatric disorders. Interventions often focus on adjustment, coping, and adaptation issues but may also involve attempts to remediate the adverse cognitive or psychological effects of various neurological disorders. Treatments include adjustment counseling, cognitive-behavioral therapy to deal with the emotional and psychological consequences of various neurological or medical conditions, cognitive rehabilitation therapies designed to enhance recovery or adaptation to cognitive limitation from various disorders, or family/marital therapy.

DIFFERENT PRACTICE SETTINGS

As the field of neuropsychology has grown, practice settings have diversified. Neuropsychological evaluations historically have been used to help determine lesion location in neurology and neurosurgical settings. That function has decreased in importance with the advent of such neuroradiological procedures as CT and MRI scans. However, evaluations remain a frequently requested procedure to help identify the pattern and severity of deficits associated with various brain lesions or neurological conditions. Neuropsychological evaluations are often an important factor in helping medical staff, patients, and families make decisions about treatment issues and placement after hospitalization. They are also important in educational planning and treatment planning for children with developmental and other disabilities. The assessment contributes to the diagnosis of subtle disabilities and clarifies the nature of any cognitive problems underlying learning disabilities.

In rehabilitation settings, neuropsychologists are most typically asked to detail and quantify a given patient's cognitive deficits, as well as explain how these deficits may affect the patient's daily life. Neuropsychologists help identify deficits that would be amenable to treatment and identify behavioral capacities that remain relatively intact and potentially useful in a compensatory fashion for other impaired cognitive functions. Finally, the neuropsychologist is asked to make treatment recommendations. These recommendations are typically for immediate treatment purposes (e.g., while the patient is in the rehabilitation treatment facility) as well as more long-term issues (e.g., are the deficits likely to improve, can the patient drive safely, can the patient return to work or school). In educational settings, neuropsychological evaluations can be important in identifying different learning disabilities, serve as an important ingredient in designing treatment and/or educational plans and in setting realistic goals, and help evaluate the effectiveness of various treatment interventions.

Neuropsychological evaluations continue to play an important role in the differential diagnosis between neurological and psychiatric conditions that may appear clinically similar (e.g., dementia vs. a pseudodementia secondary to depression or anxiety) but that have different prognostic implications and require divergent treatments. Finally, neuropsychological evaluations are appearing with increasing frequency in forensic settings where they are used to help document the presence or absence of behavioral impairments secondary to injuries (personal injury or medical malpractice cases) or in helping to evaluate issues of diminished capacity or disability and competency.

NEUROSIS

Sigmund Freud's early work with neurotic patients was in a population that was totally disabled and dependent on others for care. Conversion hysteria was reportedly rampant in Europe at the end of the nineteenth century, and Freud's work as a neurologist exposed him to a large number of cases of total disability where no clear-cut organic etiology was evident. Neurotic patients with phobias, conversion symptoms, hysteria, obsessions, repetition compulsions, and inhibitions then and now range in functional level from highly successful to very disabled. The most severe cases are totally dependent on others for care and are still seen in long-term care facilities. Neurotic patients overlap with patients with personality disorders, and symptoms usually have a greater effect on the individual than on his or her friends and family. Some cases of conversion hysteria are still seen and may be more common in certain cultural settings. These patients, as a hundred years ago, are dependent on others, often family, for basic care and are disabled without clear evidence of depression or psychosis.

The extent of disability due to neurotic illness is difficult to quantify as the concept of neurosis has been replaced by a more descriptive diagnostic system. In the past, anxiety neurosis or panic attacks would have been seen as clearly disabling neurotic illness. For example, students who are unable to succeed due to neurotic issues often may end up underemployed rather than fully disabled. Adaptation to other illnesses is also an area where degrees of neuroticism may increase disability. Pseudo-seizures are a condition in which the patient usually unconsciously feigns a very realistic seizure episode witnessed by others. They continue to be a cause of diagnostic confusion and often are found in patients who suffer from genuine organic-based seizures. Disability post-myocardial infarction is also increased in patients with depression and preexisting neurotic illness. Currently, much of organized psychiatric research has focused on treatment and disability prevention in psychotic states and mood and anxiety disorders, and fewer resources have been devoted to the issue of neurotic illness. However, cognitive-behavioral approaches to anxiety, phobia, and dysthymia have led to good symptom improvement and time will tell if the associated disability will diminish with treatment. Also the improvement in anxiety phobia and dysthymia seen with the newer antidepressant medications suggests that neurotic illness may also share an organic substrate with the mental illnesses. Psychoanalysis continues to be used to treat a variety of neurotic illnesses especially when less intense and demanding treatment strategies have failed.

NIETZSCHE, FRIEDRICH

(1844–1900)

German philosopher

Friedrich Nietzsche, the *enfant terrible* of Western philosophy and culture, is usually hailed as the greatest forerunner of twentieth-century intellectual innovations, from psychoanalysis to postmodernism to cultural critiques of various stripes. Reared in pre-Bismarckian Germany, he quickly became its most vociferous critic and exile. His public debut began with an *éclat* over *The Birth of Tragedy out of the Spirit of Music* (1872) that cost him his reputation as the rising young star of classical philology at Basel. Thereafter, he drifted off into increasingly unruly and shrill philosophical and cultural writings, but never found much of an audience until shortly after his death. Once the darling of the Right, he remains the darling of the Left and an inspiration to all counterculturalists.

His writings are treacherous things, open to misreading and misappropriation. As in other matters (such as questions of race, gender equality, power, and violence), so too here Nietzsche can easily be taken to task for his merciless indictments of human disability. After all, doesn't he declare the better part of humanity shriveled and impaired, both psychologically and physically, and for that reason unworthy of life and hence worthy of extermination? And wasn't he from the first happy to view ugliness and deformity as sure signs of degeneracy—as, for instance, in his lifelong crusade against Socrates, that "monstrosity *per defectum*"? In that case, one would have to attribute to Nietzsche not only a distasteful prejudice but something like a pathological obsession. Max Nordau's ([1892] 1993) inclusion of Nietzsche in his gallery of European degenerates seems all too justified.

Nevertheless, several factors tell against these conclusions. First, Nietzsche's true meaning is notoriously hard to locate amid the polyphony—or cacophony—of his writings. Second, much of the time disability, like disease and weakness, seems to be a metaphor for culture, not a reference to the empirical body or to nature. "Nothing is beautiful" or "ugly" intrinsically, "there is no health as such [*an sich*]," and even the infirm demonstrate a will to life and to power that has to be affirmed and admired, yet everyone alive is diseased. How stable is Nietzsche's apparent indictment of disability and disease? If his prescriptions were taken seriously, the entire human race would have to be eradicated. A likelier conclusion is that Nietzsche is embarrassing, not perpetuating, a widespread cultural idiom, by bending it back upon itself. To be sure, this does nothing to erase the prejudice from his texts, although it does a lot to emphasize its untenability.

—James I. Porter

NIRJE, BENGT (1924–)

Swedish activist

Bengt Nirje is internationally known for his work in promoting self-determination among people with intellectual disabilities. Born in Sweden and educated in comparative literature, law, and philosophy, Nirje's first work with people with disabilities was with the Swedish Red Cross and later with the United Nations where he was a welfare coordinator. As director of the Swedish Parents' Association for Mentally Retarded Children (1961–1971), he formed social clubs for persons with intellectual disabilities. These social clubs gave people with intellectual disabilities opportunities to exercise control over their leisure activities, including the right to take risks and make mistakes.

Nirje was deeply concerned with the lack of power and participation in normal community life experienced by people with intellectual disabilities. His work to formalize the principle of normalization led to the first English publication on the principle in 1969. This paper was highly influential throughout the Western world, particularly with respect to residential care and treatment of people with intellectual disabilities. Nirje's legal advocacy has resulted in the enactment of progressive legislation and policies reflecting the concept of normalization throughout Europe and North America. Nirje is one of the founders of the self-advocacy movement.

NONTI NATAKAM (TAMIL CRIPPLE DRAMA)

The *nonti natakam* (cripple drama), also sometimes *ottraikkaal natakam* (one-legged drama), is a genre of Tamil drama or street theater originating in southeastern India in the seventh century or earlier, having a lame rogue as hero. The protagonist becomes obsessed with a prostitute, engages in crime to fund the habit, is caught stealing a horse, and is punished by amputation of a leg (sometimes also an arm). Next he comes under the influence of a holy man, renounces evil, and regains his limb(s) by intervention of the god Subramaniya (Murukan). This provides a serious frame while lending itself to bawdy, slapstick, and farce as the hero hops about on one leg recounting his sexual and criminal adventures. Disability is clearly portrayed as a consequence of wrong conduct, from which repentance leads to healing. There are also nonti natakam giving Muslim or Christian accounts of similar themes in southern India. These minor dramas can also be linked to broader themes of bandit heroes and kings with physical deformities in Tamil literature, as well as with East Asian and European medieval farce.

NORMALITY

Defining normality has presented a puzzle to medicine and society for decades. Health and normality remain obscure concepts particularly in the medical field, which is historically reductionistic and its practitioners trained to recognize and treat pathology. Constructing concepts of normality requires philosophic inquiry as well as experience with general populations of people rather than those presenting only for treatment. As public policy has developed around concepts of disability, the implications for definitions of normality are profound.

The word *normality* derives from the Latin word *norma*, which referred to a tool used to show a square angle and by extension to mean a rule, standard, or principle. Over time, the definition of normal came to mean ordinary, usual, or "naturally occurring." Interestingly, if one applied the "naturally occurring" definition, many individuals born with "anomalies" or "birth defects" or with behaviors different from mainstream could be considered normal. But most societies did not take this definition. Instead, a departure from the typical physical or behavioral characteristics was usually seen as abnormality or deviance.

Although terms such as *normal* and *normality* serve some purpose in medicine and the study of human behaviors, they also perpetuate labeling and discrimination. The utility of the normality concept can be seen in how it benefits or contributes to the well-being of and services to the full range of human beings. Several attempts at defining normality are worth reviewing to examine examples of traits felt to be abnormal. Two different models to normality relevant to disability are the medical and social. Both have merits as well as limitations; attempts at integrating these models would be useful.

Offer and Sabshin (1980) reviewed four perspectives on normality, originally designed for purposes of examining mental health. These perspectives are rooted primarily in the medical model but allow an attempt at integration with the sociological. In their first definition, normality as health, normality is seen to exist in the absence of disease in terms of noticeable pathology and corresponds to medicine's concern with treating patients with observable signs and symptoms of illness. Such a perspective tends to be binary and reductionistic: One is either normal or has a disease. This view obscures the continuum of physiology and functionality that exists in almost every human physical and mental attribute. More important, this view does little to advance the principles of prevention or early intervention in the pathological progression of an altered physiological state.

A good example of the weakness of this approach is seen in the evolution of fetal alcohol syndrome (FAS) in the past two decades. Physicians first diagnosed that condition by a set of criteria including appearance (small head/body, certain facial characteristics), behavioral disorder such as attention deficit, heart defects, sight/hearing problems, and joint anomalies. Useful as this diagnosis is, it did not draw sufficient attention to the fact that maternal alcohol use can be hazardous to the developing fetus. In fact, low levels of maternal alcohol intake, below that seen in typical FAS, can cause milder problems for the fetus and newborn child.

Vitamin deficiency is another good example in which a disease state (e.g., scurvy from the absence of vitamin C) obscures the wide variation in vitamin C intake and blood levels, some of which are dangerously low and interfere with optimal functioning, but not to the extent of meeting the criteria for disease. Clinical medicine sometimes recognizes this problem by employing the term *subclinical* disease, again trying to use categorical distinctions rather than a continuum model, which would show the range of vitamin C levels and note the points within that range where various symptoms of pathological processes may emerge.

A second perspective is normality as utopia. Offer and Sabshin (1980) date this idea back to Sigmund Freud, who wrote, "A normal ego is like normality in general, an ideal fiction." This perspective highlights the ideal form and being, and it recognizes the diverse, interrelated mechanisms that define functionality.

A third perspective is the one most commonly used in medicine today: normality as average, based on the principle of the bell-shaped distribution around a central point where the greatest number (median) or average (mean) of findings (e.g., height, weight, IQ) occur. Various statistical measures further define *deviance* from this center point with boundaries that encompass various percentages of population (e.g., 2/3, 98 percent). By such methods, one can look at the "tails" or outliers in this normal distribution as being so many standard deviations away from normal. If one measures vitamin C intake as an example, this method captures disease state but also reflects subclinical deficiencies.

While there are many limitations to normality as average, there is also inherent value over other definitions of normality. Using this definition and applying it to medicine can define illnesses such as coronary artery disease, obesity, and blindness better than simply deciding when one has it or does not. For example, using a continuum model, we can see that adolescents start depositing plaque on their arteries and that this process continues through life. This allows intervention at any level as well as monitoring for later intervention. Similarly, an individual did not become *morbidly obese* (defined as twice one's "ideal weight") overnight. There was a progression, likely started in childhood, whereby the individual gradually gained weight to the point of severely limiting mobility and causing added health risks. Similar examples of this continuum of a trait can be found for vision, blood sugar levels, intelligence, movement, height, and many other traits that appear first in "normal" form before becoming pathological.

A variation on normality as average is to consider two bell-shaped curves, one representing the distribution of a characteristic, for example, hearing acuity of individuals with known hearing impairment, and compare them with a representative group from the general population without known or perceived hearing loss. The hearing-impaired group will have a narrower curve that will overlap with individuals in the general population on one end of the curve. This overlap consists of a group of individuals who may not be diagnosed as having hearing loss, but indeed show the common characteristic of hearing reduction with age. An interesting part of this example is that such hearing loss with age is considered part of "normal aging."

The continuum method allows for interventions and prevention as can now be seen with worldwide attention to the diets of children in Western countries and its relationship to adult obesity. However, when certain conditions or traits are congenital or currently irreparable (e.g., Down syndrome), intervention or prevention to a more "normal" state is not always possible, and using this as a benchmark might be damaging to a disabled individual.

A final perspective is normality as a transactional system that recognizes that behavior or traits cannot be examined by themselves but only in the context of other systems. It also implies that culture and context help determine what we define as normal: How and what we consider normal varies over time and space, with values shifting according to culture, gender, ethnicity, national origin, and age.

The social model of disability holds that it is society that defines, stigmatizes, and discriminates against the disabled by setting norms for and values on physical appearance and behaviors. This reasoning leads to the conclusion that it is not the physical aspects of the person, per se, that lead to damage. Rather, when a society or culture labels disabled bodies as inferior or diseased, it leads to reduced self-worth as well as devaluation and marginalization in society. The social model conceives of bodies as bearers of differing value as defined by society that acknowledges and distributes economic and social capital depending on these values. People with speech impediments, for example, are made to feel inferior, which directly affects their social interactions, often reduces their capacity to get around in the world, and clearly limits their employability. Social practices from genetic testing and subsequent abortion to devaluations of disabled people throughout childhood and adult life reflect a social definition of normality that can marginalize disabled people and reduce their sense of self-worth.

The social model is critical of the medical model, which is seen as objectifying and reducing the body to objects and conditions to be analyzed, diagnosed, treated, and rehabilitated along with prognostications that often emphasize the negative. What the social model often lacks, however, is a view of how the individual interacts with changing societal values and how technology, medicine, and changing social norms interact to determine the extent to which disabled people can navigate through society and the extent to which they are viewed as "normal." In different times and cultures, individuals with auditory or visual hallucinations have been viewed as having distinct talents and have been seen as healers or savants. At other times, these individuals have been viewed as dangerous and valueless to society. Similarly, people with seizure disorders have been seen as having special gifts and vision; conversely, such people also have been viewed as incapable of the most basic tasks including driving.

The industrialization and urbanization of society also affect the view of disabled people as normal or abnormal increasing the requirements for social maintenance and employment. Individuals with schizophrenia reportedly do better in developing nations and agrarian areas in part because these societies have roles in which the person can fit and provide some sense of belonging and utility within their community.

Three features of human existence are frequently the subject of controversy and labeling: physical characteristics, cognitive/learning capacity, and behavior. One common characteristic that illustrates the many uses and misuses of normality is weight. What is viewed as ideal or normal body size has shown tremendous variation over time and place. In Western society, being "stout" or obese by current standards was formerly a sign of good health and wealth. Since access to a good food supply had been for millennia a sign of one's status in many societies, appearing too lean suggested poverty or ill health. Today in Western society, "thin is in" to the point of encouraging youth to be anorexic and to where liposuction to remove fat is very big business. While this culture of starvation applied primarily to women over the past three decades, it now also affects men. However, in many non-Western societies women are desired for being more full bodied, and there is likely a relationship between this and fertility. Chinese society has been characterized as being very tolerant to the point of extolling the virtue of fatness in men as they age; recent studies show that in China this is also true for women and interestingly, obese men and women among elderly Chinese have lower rates of depressive symptoms. Morbid obesity carries considerable stigma and prejudice in many countries. It is also associated with varying disability such as decreased ambulatory capacity, and when the morbidly obese person enters into health care their providers frequently mirror these societal attitudes.

Cognitive capacity, particularly as measured by intelligence testing, has survived a storm of attacks based in part on how we measure and react to definitions of normal intelligence. The concept that intelligence could be or should be tested began with a nineteenth-century British scientist, Sir Francis Galton, who had training in both biology and early forms of psychology. Galton was strongly influenced by the revolution caused by the 1859 publication of Charles Darwin's *The Origin of Species*, which examined the relationship between heredity and human ability or disability. The general attitude of the time held that the human race had a very small number of both geniuses and idiots, while the vast majority of the human race comprised equally intelligent people. This thinking is typical of the binary method of medicine, which divided the population into disease or normal with the variation of adding "supernormal" or geniuses in this case. Galton believed that mental traits are based on physical factors—inheritable traits—the same as eye color or blood type. With the help of a statistician, Galton discovered the concept of normal distribution or the bell-shaped curve, with most of the population falling between two extremes. He published his ideas on hereditary intelligence in a book titled *Hereditary Genius*, which is recognized as the first scientific investigation into the concept of intelligence. James McKeen Cattell, a student of Galton's, led a brief and intense period of intelligence testing in the United States; this testing quickly fell into disfavor when it was shown that scoring high on the Galton test did not predict whether a student would do well on schoolwork. In France, Alfred Binet devised tests of intelligence and used them to compare "average" students with known "mentally handicapped" students. He found that certain tasks could distinguish the two. Binet calculated the normal abilities for students at each age, resulting in a tool to identify the developmental age of each student.

The idea that a test could determine a child's "mental age" became extremely popular. Just before World War I, German psychologist Wilhelm Stern suggested a better way of expressing results than by mental age. Stern determined his results by finding the ratio between a subject's chronological age and mental age. A 10-year-old scoring one year ahead of chronological age (110) would be less significant than a 5-year-old scoring one year above her chronological age (120) would. Later an American psychologist, Lewis Terman, coined the term *intelligence quotient* (IQ), identifying 100 as average. This method of IQ testing was first put to mass use in placing draftees in World War I in the United States. After the war, many companies and most school systems in the United States began using some form of IQ testing.

The designers of IQ testing had reservations on the potential misuse of testing. As early as 1922, a well-known social commentator, Walter Lippmann, wrote: "One only has to read around in the literature of the subject . . . to see how easily the intelligence test can be turned into an engine of cruelty, how . . . it could turn into a method of stamping a permanent sense of inferiority upon the soul of a child." With the beginning of the civil rights movement, the potential misuse of IQ testing for racist purposes became apparent initially with African Americans and later Latinos. Questions about the reliability and validity of testing and the role of heredity versus environmental enrichment and language curtailed the widespread usage. However, school systems still use IQ testing as one factor in determining the need for special education. Such usage might be valuable, but the stigma associated with the testing implies that students placed this way are innately less intelligent and, more critically, may never be capable of being "mainstreamed" back to regular classrooms.

The concept of intelligence and its measurement has continued to evolve, despite problems and testing misuses. In 1983, Howard Gardner argued that "reason, intelligence, logic and knowledge are not synonymous," setting forth a theory of multiple intelligences. Gardner defined seven distinct intelligences: logical-mathematical, linguistic, spatial, musical, bodily-kinesthetic, intrapersonal, and interpersonal intelligences.

The concept of multiple intelligences helped broaden the idea of intelligence from a mathematical and verbal understanding to one where many inherent abilities of humans may be considered and valued. Implicit in this approach is that disability in one area of intelligence may not be associated with other areas, or more practically, individuals with certain mental disability may also have rich, useful, and enriching capacities in other mental areas.

Classifying behaviors as abnormal poses a very difficult problem for sociologists, anthropologists, and cross-cultural psychologists, and it again begs the question of the value of such classifications. Within most cultures, there are individuals who are so out of sync with the accepted range of behaviors that they pose a threat to themselves or others. Inherent in the act of classifying behaviors is the use of taxonomy of behavioral descriptions as an instrument to define and therefore punish, exclude, or incarcerate a group whose behaviors constitute a threat to the status quo or to the local governance.

For example, homosexual behaviors were frequent parts of polytheistic and pagan ceremonies, and it is likely that homosexual practices were condoned in early societies. The ancient Greeks welcomed homosexuality along with other hedonistic behaviors, though marriage and producing children held higher value, making it "normal" only as an occasional activity for young boys or for older men after they produced children. Interestingly, the Greek military viewed homosexuality as positive in that it encouraged morale and camaraderie. However, men who were exclusively passive partners in homosexual encounters were stigmatized and even banished from the military as having become women. By the sixth century, the popularity and power of Christianity led to condemnation of homosexuality as well as prostitution and other hedonistic activities, although little was done to enforce this code even among priests and monks. Tolerance of homosexuality continued in most of Europe in certain circles until about the thirteenth century. The Inquisition and the Protestant Reformation resulted in strong penalties in different European countries including castration, imprisonment, and death. The death penalty for "sodomites" was imposed in the United States by the military as early as the eighteenth century, a sentence that Thomas Jefferson changed to castration in 1779.

By the close of the nineteenth century, medicine, including the newly developed field of psychiatry, was competing with religion and law over which had jurisdiction over sexuality in general and homosexuality in particular. As with the medicalization of alcoholism, this was progressive, as a "sick person" was better than a sinner or criminal.

Some forces within psychiatry were more liberal in their view of homosexuality. In 1901, Havelock Ellis considered homosexuality to be inborn and therefore not a disease. He also recognized the contribution homosexuals made to society. Sigmund Freud saw all humans as innately bisexual and their sexual preference was made according to experiences in early development. While he advised acceptance, he noted that homosexuality stemmed from arrested development. In his "Letter to an American Mother" (1935), Freud, in keeping with his view of psychoanalysis toward promoting mental health through self-understanding, wrote about homosexuality:

> If [your son] is unhappy, neurotic, torn by conflicts, inhibited in his social life, analysis may bring him harmony, peace of mind, full efficiency whether he remains a homosexual or gets changed.

Psychiatry and psychoanalysis did not always follow Freud's more accepting view. In the 1940s to the early 1960s, these fields developed complex developmental theories explaining the pathological development leading to homosexuality. Alfred Kinsey's empirical studies of sexual behaviors of Americans revealed findings that could not be discerned by clinicians working exclusively with individuals seeking their services. His studies revealed that a significant number of his research participants reported having engaged in homosexual behavior to the point of orgasm after age 16 and that 10 percent of the males in their sample and 2 to 6 percent of the females (depending on marital status) had been more or less exclusively homosexual in their behavior for at least three years between the ages of 16 and 55.

The *Diagnostic and Statistical Manual of Mental Disorders*, second edition (*DSM-II,* 1968) of the American Psychiatric Association (APA) listed homosexuality as a disorder, but the *DSM-III* (1975) did not. This change in thinking was supported by insiders within the APA but also was in response to growing numbers of gay and lesbian advocates who protested and disrupted the APA through the 1960s and 1970s. In 1973, the APA removed homosexuality from the *DSM.* However, to permit payments for treatment by insurance companies, the *DSM-III* included the category "ego dystonic homosexuality" and listed the criteria as (1) a persistent lack of heterosexual arousal, which the patient experienced as interfering with initiation or maintenance of wanted heterosexual relationships, and (2) persistent distress from a sustained pattern of unwanted homosexual arousal. While this had impact on American opinion, it did not change the values and rules of much of the larger society including the American military, which has continued to discharge homosexuals from service. These considerations strongly influence psychiatric views of the criteria for mental illness and normality as will later be demonstrated. The World Health Organization's classification, the International Classification of Diseases (ICD), in its diagnostic manual used in much of the world, continued to list homosexuality as a diagnosis until 1992 with the publication of ICD-10.

An example from the former Soviet Union demonstrates the misuse of psychiatry to serve a government's purposes in a more striking way through its implicit authority to determine normal versus pathological behavior. By the early 1960s, one of the most prestigious psychiatric institutes in the Soviet Union added a criterion for schizophrenia very different from any previously proposed: "dissident behavior" and coined a new type of schizophrenia, which was called "sluggish schizophrenia." Using this criterion and diagnosis, a number of radicals were hospitalized in psychiatric institutions and given treatments with severe side effects under the auspices of curing them of their "illness." Many Western counties and human rights watch groups made challenges to this diagnostic method and practice. However, this policy continued for more than two decades when, with a more open emigration policy in the Soviet Union, the practice was discontinued. Unlike the case of homosexuality where psychiatry was used to bolster general public opinion, the mislabeling of dissidents as schizophrenics was not in concurrence with society but was enforced by the existing regime.

Psychiatry's role in defining normal behavior is part of the larger ways in which society and culture define what are its shared beliefs and behaviors and the "proper" way an individual conducts himself or herself within a society and family. Many aspects of social behavior are usually considered including dress, posture, hairstyle, smell, gestures, facial expression, and use of language. Cultures also have specific codes for the context within which behaviors are appropriate so that different behaviors are condoned depending on gender, age, privacy, work, home, family, friends, and strangers, for instance. Some cultures while having very strict taboos on behavior also include special days of celebration (e.g., Mardi Gras, Halloween, New Year's Eve) in which behavioral norms are deliberately flouted. Some very restrictive cultures may place an onerous burden of conformity on certain demographic groups such as women, so that any deviation from these "normal" role expectations is seen as deviant and deserving of punishment.

As psychiatry and the social and behavioral sciences consider normality, they are increasingly addressing the context of behavior. Delusions, for example, are a criterion for many psychotic disorders. However, Western psychiatry has included in the definition of delusion that it be a "false and fixed belief" and also that it is a belief not commonly held by other members of the individual's cultural group. This added definition allows many unique cultural-religious views of the world without labeling them as psychopathology. Individuals who feel they have been "bewitched," possessed by an evil spirit, or that God is punishing them for their sins are no longer diagnosed as psychotic if these thoughts are consistent with the beliefs of their cultural or religious background. Likewise, hallucinations, defined by Western medicine as a sensory experience without sensory input (e.g., hearing voices or seeing things), has usually been seen as one sign of a psychotic experience. It is now recognized that "normal" individuals partaking in religious experiences with or without hallucinogens can have hallucinations that are not part of a larger psychiatric disorder.

Beyond questions of psychiatric disorders, there are more common behaviors related to disabled individuals that are sometimes considered abnormal in a manner that threatens their dignity. These behaviors include drooling, incontinence, and being physically and cognitively dependent on others. These acts are sometimes incorporated under the heading of "activities of daily living" and if an individual cannot perform them, it is assumed he or she does not have a good quality of life or is not "normal." Rehabilitation aims to improve or restore function on all levels possible. While it is hard to reject maximizing each person's potential, dwelling on a failure to reach a certain level of performance or function perpetuates the stigma attached to disabled people. Likewise, as elderly persons lose the capacity for performing these activities they are often seen in Western society as pathological and a burden, a factor that can be associated with increased interest in euthanasia. For disabled people, as well as other marginalized groups, the political revolution they are likely to lead is one in which difference is not labeled as deviance or abnormal.

NORMALIZATION

Normalization, or the normalization principle, has been the most significant driving force in the ongoing closure of state-run or state-funded institutions for people with a disability, especially those with a developmental disability in the Western industrialized world.

Its influence is also permeating the policies of developing countries that are increasingly embracing human rights principles. For instance, the normalization principle resonates closely with the UN Standard Rules for the Equalization of Opportunities for People with a Disability.

Possibly the first reference to the concept of normalization was by the Committee for the Partially Able-Bodied, established by the Swedish Government in 1943. This committee was appointed to create better opportunities for the productive ability of partially able-bodied persons, who, because of physical or mental occupational impairment or social affliction, can be expected to have more difficulty than others in acquiring and maintaining employment. This goal was consistent with Sweden's development of modern social services to replace the earlier philanthropic and public protective interventions that were seen as inadequate. In particular, segregated services, such as institutions for people with disabilities and social disadvantage, were being rejected. The committee's report, published in 1946, stated that "this 'normalization' of conditions of life, education, employment exchange etc. of the partially able-bodied must be a great achievement."

These developments in Sweden in the 1940s concentrated specifically on people with limited impairments but had little impact on those with more severe developmental impairments. Many of this population were placed in large institutions. However, in the 1950s and 1960s the normalization principle, as presented by the Committee for the Partially Able-Bodied, was frequently cited as a principle that should also be applied to persons with intellectual and other developmental disabilities. The immediate effect was a restructuring of the institutions toward a more normal life for their residents, but this did not lead to increased contact between persons with a disability and those in the local community.

Historically, for the institutional population, the scene shifted to Denmark where a strong advocate for people with an intellectual disability, Niels Erik Bank-Mikkelsen, was instrumental through his support for parent advocacy groups in achieving an act of Parliament that used the term *normalization*. This act supported the creation of situations for people with disabilities as near as normal as possible, irrespective of whether it occurred entirely or partially within an institution or in the general community.

While the act was strongly supported by large numbers of families who wanted their child with a disability living closer to home or at home, it attracted hostility from vested interest groups, including professional staff, who feared a loss of their jobs. It was significant that the enactment of the act was helped by the ever-improving Danish economy.

When Bank-Mikkelsen spoke of normalization, he was not inferring that people with disability were abnormal and nondisabled people were normal, nor did he want to imply that the special nature of people with disabilities should be made "normal." To him, the goal of normalization was not to normalize these people but to normalize their living conditions.

Undoubtedly, Bank-Mikkelsen's passion for strong advocacy for disadvantaged people was significantly influenced by his experiences during the German occupation of Denmark in World War II. He was imprisoned for his activities in the resistance movement. Bank-Mikkelsen's work soon had an international impact. In 1962, U.S. President John F. Kennedy established an advocacy committee on mental retardation, members of which visited Denmark and other Nordic countries. Bank-Mikkelsen contributed one of the chapters of the President's Committee's final report released in 1969. He also strongly supported an international conference held in Copenhagen in 1964, which saw the formation of the International Association for the Scientific Study of Mental Deficiency (IASSMD; now the International Association for the Scientific Study of Intellectual Disabilities, IASSID).

He also played an important role in the Legal Aspects of Mental Retardation symposium held in Stockholm, Sweden, in 1967 and sponsored by the International League of Societies for the Mentally Handicapped (ILSMH; now Inclusion International). The results of this symposium strongly influenced the 1971 UN Declaration on the Rights of Mentally Retarded Persons.

Through his travels to countries including Australia, the United States, Japan, and Saudi Arabia, Bank-Mikkelsen promulgated the tenets of normalization, with particular reference to the appalling conditions he witnessed in institutions for people with an intellectual disability.

The second significant person to contribute to the development of the principle of normalization was the Swedish scholar Bergt Nirje. Nirje, whose background was in the law and humanities, was deeply influenced by the work of Bank-Mikkelsen, whom he visited in 1963 as a preamble to speaking at a Nordic conference held in Oslo in that year. The theme of this conference was "institutions for mentally retarded persons." Nirje related that he was struck by the words in the Danish law that stated "to let the mentally retarded obtain an existence as close to the normal as possible."

Positions with the Swedish Red Cross and the UN High Commissioner for Refugees that involved visiting Hungarian refugee camps in the aftermath of World War II profoundly influenced Nirje's mission to oppose large "mass managed" institutions. He too contributed chapters to the report of the President's Committee on Mental Retardation.

As ombudsman and executive director of FUB, the Swedish Association for Persons with Intellectual Impairment (1961–1970), and coordinator of training and program planning in the Ministries of Health and Community and Social Services of the Government of Ontario, Canada (1971–1978), Nirje had the opportunity to develop his conceptualization of the principle of normalization. In 1967, in a paper presented to the First Congress of IASSMD held in Montpellier, France, he introduced the concept of the "normal rhythms of life," a concept that became embedded in the eight core facets of life that became the essence of his conceptualization of normalization. To Nirje, normalization means a normal rhythm of the day; implies a normal routine of life; means a normal rhythm of the year; calls for normal developmental experiences of the life cycle; calls for the valuing of individual choices; means living in a bisexual world; means applying normal economic standards; and calls for living, learning, and recreating in facilities similar to those others in the community enjoy.

Nirje (1969) summed up these elements into his overall definition of the normalization principle that "means making available to the mentally retarded patterns and conditions of everyday life which are as close as possible to the norms and patterns of the mainstream of society" (p. 181).

In 1985, Nirje refined his definition: "The Normalization Principle means making available to all persons with disabilities and other handicaps, patterns of life and conditions of everyday living which are as close as possible to or indeed *the same as* the regular circumstances and ways of life of society" (p. 67). He further elaborated this statement by pointing out that

> the normalization principle rests on the understanding of how the normal rhythms, sequences and patterns of life in any cultural circumstances relate to the development, maturity of life of the handicapped, and on the understanding of how these patterns apply as indicators for the development of proper human services and actions. (p. 67)

Integration in society, Nirje maintained, is based on the recognition of a person's integrity, meaning "to be yourself among others—to be able and to be allowed to be yourself among others."

The next significant figure to contribute to the principle was Wolf Wolfensberger, who together with Robert Kugel, then chair of the President's Committee on Mental Retardation, edited its final report published in 1969 (Kugel and Wolfensberger 1969). Wolfensberger (1972), drawing on deviancy theory, proposed a reformulation of the definition of the principle as follows: "Utilization of means which are culturally normative as possible, in order to establish and/or maintain personal behaviours and characteristics which are as culturally normative as possible" (p. 28). He specifically indicated that this definition was for purposes of a North American audience, and for broader adaptability to the general area of human management. He suggested that the normalization principle is culture specific and what may be typical in the Scandinavian environment would not necessarily apply in other cultures. Wolfensberger's elaboration was more detailed in its recommendations to service providers and facility managers than was Nirje's approach.

Wolfensberger became closely involved with the deinstitutionalization movement in North America, as did Nirje in Sweden and Canada. However, whereas Nirje concentrated on those structures that primarily affected the day-to-day lives of the person with the disability, Wolfensberger developed a quality control system that was directed specifically to program management. He devised two instruments for this purpose: The Program Analysis of Service Systems (PASS) and Program Analysis of Service Systems' Implementation of Normalization Goals (PASSING).

In the 1980s, Wolfensberger (1983) further elaborated the principle of normalization, subsuming and replacing it with the theory of social role valorization (SRV). In his earlier formulation, deviancy theory was the driving force, but this was replaced by social role theory. He defined SRV as "the enablement, establishment, enhancement, maintenance, and/or defence of social roles for people–particularly those at risk . . . by using, as much as possible, culturally valued means" (p. 234). He suggested people's roles can be enhanced by improving both their competencies and their social image.

Normalization, in its various interpretations, is a social science theory that has had a profound positive effect on the lives of people who were once removed and segregated from society. It remains relevant for the twenty-first century as thousands of people remain in institutions across the world. However, there are forces emerging that could see a return to institutional solutions to social problems.

NORSE SAGAS

Norse sagas are prose narratives written in Old Icelandic between 1190 and 1230 (the last years of the Icelandic Free State) mostly by unknown authors, concerning the lives of Norwegian kings, prominent Icelandic families, and legendary Norse figures as well as stories translated from Latin saints' lives and continental romances.

The Icelandic Family Sagas are set in tenth-century Iceland and are structured on a pattern of conflict (of honor or property) and revenge. The secondary literature on origins, structure, and plot themes such as feuding largely overlooks the great number of characters with impairments and disfigurements.

In the saga world, impairments were often acquired as Viking occupational hazards. That people with such impairments as blindness or the loss of a limb or eye were regarded as disabled was a social construct that related not to the denial of civil rights but to one's ability to acquire and defend property and dependents against aggressive neighbors. The measure of an Icelandic saga hero was in how he negotiated his impairment to obviate its disabling aspect. Impairments are thus the mark of outstanding characters—they were never sentimentalized.

The saga world regarded as impairments not only the loss of a faculty or limb but also sexual and temperamental quirks and foreign ethnicities. Of the three best-known and -loved eponymous saga heroes, Njál was never able to grow a beard, Egil was seven feet tall and swarthy, and Grettir was inarticulate and had a very small penis. Among the several saga heroes who are skaldic poets, Kormák looks Irish and is sexually dysfunctional, Björn the Hítárdalur Champion appears to be homosexual, Gunnlaug Snake's-Tongue suffers serial leg impairments, and Thormód Kólbrún's-Skald has a crippled right arm and stammers. Virtually all the Family Sagas include minor characters who are blind or have peg legs, and the simpleton is a stock character frequently made to play the fall guy. Women are not usually said to have any impairment other than blindness, and deaf characters do not appear.

The saints' lives treat impairment as an opportunity for a miracle cure, while legends and romances exploit impairment for fantastical prostheses or magical means to induce or cure dumbness. A subgroup of the Family Sagas, the so-called Contemporary Sagas set in the thirteenth century, describe impairment even more frequently, though this is usually the result of extra-juridical mutilation, and here we see impairments first associated with moral deficiencies, as came to be standard in modern times.

NORWAY: NATIONAL ACTION PLANS

Action plan is a term used in many countries and in many languages, typically referring to a package of objectives and activities that are intended to combine in ways toward accomplishing a larger goal. As in many other countries, Norway has had a series of action plans in many areas of sociopolitical life. One arena where Norwegian national action plans have received much national and international attention is in the area of disability. The national action plans for disabled people refer to three sequential four-year plans, covering a total period from 1990 to 2002, and with a general goal of improving the situation of disabled people. The first two plans were written by Norway's national Ministries, whereas the third and most recent one was also acted on by the Parliament and exists in the form of a white paper (*Stortingsmelding nr 8:1998–99*).

BACKGROUND AND CONTEXT

As a follow-up to the UN International Year of Disabled Persons (1981) and the subsequent Decade of Disabled Persons (1983–1992), Norway produced a national plan with the aim of working toward the newly formulated international goals of full participation and equality for disabled people. This first plan included a set of objectives and activities, but these were formulated in quite general ways and with unclear political commitment. While the government never admitted that this plan was unsuccessful in terms of its actual accomplishments, the first four-year plan of action (1990–1993) was in part a result of the fact that very few of the intended actions in the plan for the 1980s had actually been implemented. It was noted that there was a need for a more specific description of the intended actions, as well as a clearer and more binding political commitment. It is these two elements of concreteness and commitment that have shaped what became known as national action plans.

In Norway, all services for all citizens are the responsibility of the public sectors, with primary coordination at the local municipality level (*kommune*). Action plans for the disabled are not limited to activities in the area of health and social services, but include all spheres and sectors of public life. It is the national government that provides direction and guidelines, as well as having a monitoring role. Action plans could be interpreted as a signal that the Norwegian government is taking the social and political situation of disabled people more seriously, or at least is taking the actualization of stated goals more seriously.

USER INVOLVEMENT

Participation and influence of disabled people have consistently been a central principle in these action plans. Concretely, this involvement has occurred in two ways. First, the plans themselves are developed in cooperation with disabled people and their organizations, both through direct participation and also through a series of consultative hearings. The National Union of Disabled Peoples Organizations (Funksjonshemmetes Fellesorganisasjon) and the National Council for the Disabled (Statens råd for funksjonshemmete), which includes members from disability organizations, have also been involved in the drafting of these plans. The second way that disabled people are involved has to do with the actual actions stipulated in the plans, where user participation is mandated in a number of ways. One example is that research and development activities require user-collaboration as a prerequisite for receiving funding.

PLAN CONTENT

The content of these plans for action has been twofold. The first part is more principled in nature and describes overriding sociopolitical goals and general guidelines. The second part is the actual plan of actions to be carried out, containing the concrete activities and arrangements that the government is expected to implement, usually including specified sources and mechanisms for funding. The list of actions has been quite diverse in regard to purpose, form, and scope, and the number has increased with each plan. The 1990–1993 plan had a list of 53 actions, the 1994–1997 plan had 90, and the third had nearly 150 actions to be taken. While the range of types of listed actions to be implemented is rather diverse, they can be summarized in the following major categories: specified (earmarked) funding, incentive funding, innovative efforts, research and development work, and information projects.

Examples of activities receiving economic incentives include extending the range and type of respite services available to families with a disabled family member and smaller actions such as economic support for the production of "talking books." Examples of innovative actions are the establishment of a competence center to assist those with rare diagnoses and their families and smaller projects such as sign language theater. In the area of research and development, action plans have financed a range of projects, including a national research program on disability, one on the living situations of intellectually disabled people, and a number of smaller projects. Examples of information activities include projects aimed at improving access to information, such as sign language and subtitles on television. Other types of information projects are efforts aimed at informing public servants and the general citizenry about disability issues, especially those involved in local administration and community planning.

TIME LIMITED OR PERMANENT?

The activities stipulated in these action plans were intended to be time limited. However, many of the actions were deemed as successful and have been expanded or developed into permanent arrangements. Examples include the right to have a user-controlled personal assistant and functional assistants to assist at one's place of employment. In this way, action plans can be said to be vehicles for initiating and trying out different arrangements, as experimental steps as part of a longer-term strategy and goal.

EVALUATION

While several of the larger projects resulting from these action plans have been externally evaluated, the process of action plans itself has not been assessed. However, after the first two plans, the government Ministries reviewed results and experiences and emphasized in their conclusions that action plans made it easier to start up new initiatives. In addition, many actions and arrangements might not have taken place at all were it not for the framework of guiding principles and priorities described in the plans. The dual focus on concreteness and binding commitment was also seen as important.

However, there are some likely limitations to the "action plan approach" as a way of improving the situation of disabled people. First, disability politics risks becoming something outside of, or at least alongside, mainstream public sector policy. Having a special plan for a certain group of citizens reinforces their separateness and differentness. Another limitation might be that the overall effort behind these plans has been so all-encompassing and yet so detailed that the smaller bits may be easier to implement than addressing the larger, overarching challenges. Furthermore, there have been problems at local levels in joining the various actions together into a coordinated, comprehensive strategy. There is then a risk of increasing the gap between the societal goals of full participation and equality and the vast range of specific actions to be implemented. While it is difficult today to judge the overall effect of these national action plans, the hope that the various actions and activities would somehow combine toward a larger common effort remains to be realized.

"NOTHING ABOUT US WITHOUT US"

The expression "Nothing about us without us" has become one of the rallying cries of the international disability rights movement (DRM) and disabled people's organizations (DPOs). First coined in the early 1990s, the slogan's power derives from its location of the source of many types of (disability) oppression and its simultaneous opposition to such oppression in the context of control and voice. "Nothing about us without us" was adopted as a leading slogan by Disabled Peoples' International because it resonates with the philosophy of the disability rights movement. As Ed Roberts, one of the leading figures of the international DRM, has said, "If we have learned one thing from the civil rights movement in the U.S., it's that when others speak for you, you lose" (quoted in Driedger 1989:28).

"Nothing about us without us" can be considered a demand for self-determination. Self-determination is the essential theme that runs through all the work of the international DRM, regardless of political-economic or cultural differences. Control has universal appeal for DRM activists because the needs of people with disabilities and the potential for meeting these needs are everywhere conditioned by a dependency born of marginalization saturated with paternalism. The condition of dependency is presently typical for hundreds of millions of people throughout the world. Only in the past 25 years has this condition begun to change. Although little noticed and affecting only a small percentage of people with disabilities, this transformation is profound. For the first time in the thousands of years of recorded human history, politically active people with disabilities are beginning to proclaim that they know what is best for themselves and their community. This is a revelational claim aptly capsulized in "Nothing about us without us."

Since the late 1990s, the expression has become very popular and has been used by a variety of disability groups in trainings, articles, slogans, and titles.

NOVEL, THE

"His wound gives him his narrative power." Arthur Frank is speaking of Tiresias, the ancient seer, who was blinded by the gods that he might "see" the future more clearly. Procne weaves the story of her sister Philomela's rape by King Tereus into fabric, her tongue having been cut out to prevent her telling the tale. Homer may have been blind, the better to remember the tale of the tribe and translate it into heroic dactyls. Such examples from classical literature suggest that the art of storytelling is intimately linked to a narrator's disability. Frank speculates that, at some fundamental level, the figure of the "wounded storyteller" may represent a "common bond of suffering that joins bodies in their shared vulnerability." But the wound may also extend to the story itself, a tale that is often of self-inflicted blindness (Oedipus), hubris-generated madness (Lear), and socially redemptive suffering (Quasimodo, Tiny Tim). Although disabled figures seldom appear as main characters, they often appear in cameo roles as grotesques or exotics necessary to the novel's plot. Given the preponderance of disabled figures in fiction, what is the relationship between the body of the story and the story of the body?

This question has been crucial for disability studies in the humanities. Disabled figures appear in many novels, such as Melville's one-legged Ahab, the invalid narrator of Charlotte Perkins Gilman's "The Yellow Wallpaper" and the limping Baby Suggs in Toni Morrison's *Beloved,* and most novels touch, in some way, on themes of illness, disfigurement, and mental illness. Certain genres—mysteries, Gothic novels, science fiction—are built around nontraditional bodies and extreme psychological states. We may not think of Milly Theale's lingering illness in James's *Wings of the Dove* or of Bertha Mason's madness in *Jane Eyre* as disabilities, but once we do, we begin to see the extent to which novels rely on a figure of bodily infirmity or cognitive incapacity. This linkage has spawned a considerable interest in the novel within disability studies. Foundational works such as Lennard Davis's *Enforcing Normalcy* (1995), Rosemarie Garland Thomson's *Extraordinary Bodies* (1997), Diane Price Herndl's *Invalid Women* (1993), and David Mitchell and Sharon Snyder's *Narrative Prosthesis* (2000) address not only the prominence of the disabled figure in fiction but also the cultural meaning of disability in a genre founded on an ideal of verisimilitude and fidelity.

Many critics see the novel emerging in the eighteenth century as an extension of Enlightenment rationality, a vehicle for chronicling the emergence of a new middle class. The novel's ability to represent ordinary people in ordinary circumstances made it a significant genre for validating a certain type of average individual, *l'homme moyen sensuel*, as the Realists called it. But as Lennard Davis has observed, *l'homme moyen* was also a product of medical and positivistic sciences that emerged in the early nineteenth century and that reinforced certain ideas of bodily or cognitive normalcy and excluded others. The sciences of eugenics, comparative anatomy, psychoanalysis, and phrenology provided a host of new (often suspect) diagnostic methods for analyzing various types of bodies and mental states for which the new technologies of photography and film provided visual support. This nineteenth-century "hegemony of normalcy," as Davis calls it, required a nontraditional or disabled body that could serve as a negative version of the statistical average. Often the disabled figure annexed other forms of deviance—racial, sexual, political—that threatened projects of imperialism and national consolidation. Thus, the disabled figure in fiction was a site for social anxieties within modernity for which there was as yet no name.

A key optic for regarding disability in nineteenth-century fiction is through gender. As women participated more forcefully in the public sphere, they found themselves portrayed as threats to patriarchal institutions, commonly represented in terms of irrationality and hysteria (the madwoman in the attic) or physical frailty (the invalid woman). Novelists such as Nathaniel Hawthorne, Émile Zola, and Gustav Flaubert often represented women as limited by their biology or subject to "female maladies" such as hysteria and neurasthenia. To some extent, this focus on female biology and psychology was prompted by scientists who were diagnosing women's illnesses and prescribing cures, the most famous of which was S. Weir Mitchell's "rest cure." As Diane Price Herndl (1993) points out, many nineteenth-century novels are centered around an invalid or dying woman whose representation reinforces female passivity and pathology at a moment when many women were gaining political and social power. But this passivity performs a critical function, as Herndl points out, because the invalid woman can serve as a challenge to representation itself. Invalidism, whether in the historical Alice James or the fictional portrait of Milly Theale, may offer women "a coherent and simple role in a world where multiple and conflicting roles are threatening or disappointing" (Herndl 1993). The unnamed narrator of Gilman's "The Yellow Wallpaper" uses her status as invalid to question the scientific definition of female biology offered by her doctor husband.

In the modernist novel, disability often serves as a sign of lack or absence, a figure for alienation in a world dominated by instrumental reason and commodity capitalism. In Ernest Hemingway's *The Sun Also Rises,* Jake Barnes suffers from a mysterious "wound" that has rendered him impotent. Edith Wharton's protagonist in *Ethan Frome* is a man who becomes seriously disabled in a suicide attempt in response to his arid, sexless life with a disabled wife. In *Lady Chatterley's Lover,* Clifford Chatterley is in a wheelchair, the result of a war wound that has rendered him, like Jake Barnes, impotent. In William Faulkner's *The Sound and the Fury,* Benjy Compson is mentally retarded, his broken, discontinuous narrative rendering the loss of family property but also the fragmentation and commercializtion of the American South. These modern texts thematize male inadequacy through disability that is a synecdoche for larger issues of world war, urbanization, and gender uncertainty.

Contemporary novelists have used disability to question the integrity of the unitary subject whose invention had been the focus of much previous fiction. Recognizing that the "normal" body is a variable fiction, novelists have represented the disabled body as a site of stigma but also of social critique. From William Burroughs's science fiction cyborgs—part technology and part human—or Katherine Dunn's carnival freaks in *Geek Love* to Toni Morrison's one-armed Nan in *Beloved,* disabled characters challenge certain humanist definitions of identity. Burroughs's cyborgs reveal the proximity of bodies to technology in the postwar era; Dunn's chemically altered grotesques expose the fictive nature of family and social institutions; Morrison's disabled African American women call attention to bodies that have historically been marked as other, culturally ostracized within racist culture. Rosemarie Garland Thomson (1997) notes that such representations in Morrison "enable [her] . . . to represent a particularized self who both embodies and transcends cultural subjugation, claiming physical difference as exceptional rather than inferior."

The pervasiveness of disability in the novel has produced several influential theoretical studies of narrative. David Mitchell and Sharon Snyder (2000) have suggested that not only do many novels feature a disabled character, such a figure provides a kind of "narrative prosthesis" for novelistic coherence itself. On the analogy of the prosthetic limb that provides an illusion of physical wholeness for the amputee, the disabled figure provides an illusion of textual embodiment that the novel must produce. And just as the wounded hero must be "cured" or brought back to health, so the disabled figure must be eliminated for the social body to be restored. The one-legged Ahab, whose megalomaniacal pursuit of the white whale for taking his leg, must be eliminated so that Ishmael's more recognizable humanist narrative can triumph. Physical and cognitive differences are the text's "cultural other" that must be brought under control by the narrative act. In Mitchell and Snyder's theory, the interrogation of the body's materiality coincides with an interrogation of the novel's materiality, its ability to complete a story that has a wound at its center.

Lennard Davis (1995) has argued that this wound is a historical phenomenon. He notes that theories of the novel that focus on its response to material conditions of emerging capitalism fail to recognize the impact of these conditions on the materiality of the body. Davis sees the modern novel as constructed around a dichotomy of normal-abnormal identities, one reinforced by positivist science in service to a national imaginary of typicality. For Davis, the disabled figure is foundational for undermining this imaginary. Since anyone can become disabled, the ideal of an average, typical, national body is suspect. The disabled figure "dismodernizes" the modern novel, establishing its formations in modernity but recognizing its deconstructive function in relation to the modern subject produced therein.

NURSING

Competent nursing has been central to the care of people with disabilities for many centuries. Up until the nineteenth century, people who were sick or disabled because of old age, mental illness, or physical disability were usually cared for by their families at home. For the poor sick and destitute, institutional care existed in local charitable guest- or poor houses. Professional nursing care by skilled nurses who were paid for their work, either in these institutions or through visiting nursing associations, grew during the nineteenth century. At that time, patterns of living and the provision of health care changed as a result of broader social changes, such as industrialization, urbanization, and changing work and gender relationships.

NURSING ORDERS

Nurses' role in care for the sick and disabled originated in religious orders, founded at the time of the Reformation and Counter-Reformation. Women and men who joined religious orders actively devoted themselves to poor relief and care for the sick. They viewed the care they provided as part of their religious practice and learned nursing skills through apprenticeship. With the foundation of the Daughters of Charity in France in 1633, cofounders Vincent de Paul and Louise de Marillac set a remarkable example of organized nursing care by lay women. The Daughters of Charity gained enormous social respect. Religious calling and spiritual commitment to God legitimized their role. So strong was the example that Roman Catholics and Protestants alike adapted to this model, and charitable nursing orders spread over Europe and North America through the next centuries, reaching a peak in the Evangelical and Missionary religious revival movements in the late nineteenth and early twentieth centuries.

Within a broader nineteenth-century humanitarian reform movement, previously unspecified groups of socially marginalized poor and disabled people were differentiated into distinct categories. Separate institutions emerged, for example, for the care of the sick and incurables, for insane persons, and for prisoners. In the new capitalist and industrial world, the emerging middle classes became concerned about the growing numbers of poor, which they perceived to be a source of social instability, fueled by fears of dirt, poverty, and contagious disease. In the New World, massive immigration created its own problems. Reform-minded middle-class citizens sought new and supposedly more effective ways to help the poor through rational control and scientific efficiency. Establishing good nursing care was one of them. Numerous associations for care of the sick emerged, who involved themselves with care of the sick in institutions, but some also provided care for people in their own homes.

Modeled after Roman Catholic sisterhoods and brotherhoods, the Protestants revived the function of the deacons and deaconesses. In 1836, Pastor Theodor Fliedner established one of the most well-known associations for care of the sick and dependent, the Deaconess Institute in Kaiserswerth, Germany. Within the protected structure of a motherhouse, the institute trained both nurses and teachers to work in its facilities. The work of deaconess nurses was not limited to care of physically sick or disabled people. People with mental illness were also included in the charitable effort. Within decades of its founding, the Kaiserwerth Institute included hospital care, a school for infants, an orphanage, and an asylum for women with mental ailments.

NURSING AS A PAID PROFESSIONAL OCCUPATION

The Kaiserswerth Institute served as an important inspiration to Florence Nightingale, who spent some time there in the mid-nineteenth century. She had an influential role in spreading and transforming the disciplined religious hospital apprentice training for nurses into a nonsectarian model that was fundamental to the emergence of nursing as a paid professional occupation. Most well-known for her work in the Crimean War, Nightingale fundamentally influenced the direction of nursing and nursing education in modern hospitals. Her authority evolved against the backdrop of a profound change in the public role of middle-class women.

The nineteenth-century humanitarian impulse that generated a new concern about the well-being of the poor provided a context for new caring roles for women. Their work and education became a matter of public debate, and an expanding economy created new work opportunities for middle-class women. They actively joined the humanitarian effort to uplift the poor and to help create a respectable working class. In this way, women not only created resources for a more meaningful life, but their philanthropic activities helped them to articulate the value of women's work in asserting a moral and ethical social influence, in fighting for temperance, for example, or in reforming hospitals and asylums. Based on a middle-class domestic ideology of women's special inclination for caring work, the new opportunities for women were considered an extension of women's traditional role in their families. Teaching, nursing, and social work became new areas of paid professional work for women. The women's movement, which obtained a more organized form in the late nineteenth century, provided a context for transforming a hitherto religious legitimization for women's work into a secular one. The idea that women had a special moral capacity and compassion, and the right characteristics such as devotion, sensibility, and sacrifice for caring work in a paid capacity, complementary to public roles of men, was a deeply gendered notion, reflecting the gendered beliefs of the time.

The projected image of the middle-class woman, trained in care of the sick, who brought order, cleanliness, and discipline to the unordered environment of large urban hospitals was a powerful one, and especially attractive to reform-minded physicians, who had their own interest in hospital reform. Influenced by the ideals of science, they sought to expand the application of medical therapeutics and technology. They had an interest in enhancing their research and teaching on hospital wards and valued the assistance of trained nurses who could help them to implement new therapies and maintain order on the wards.

NURSING EDUCATION AND WORK

The expanding demand for women with training in care of the sick grew from various sources, a boosting economy, the rise of a middle class that could afford to pay for private nursing, and the expansion of hospital care for a growing urban community and industrialized workforce that could no longer be cared for in their own homes.

Physicians sought to improve the image and reality of public hospitals and asylums alike, which traditionally had a poor reputation as stigmatizing places of last resort. In making hospitals attractive to a growing middle (and reputable) working class, the civilizing role of respectable nurses, for which high social regard had already been established in nursing orders and associations for care of the sick, became an inspiration to reform-minded doctors. The slight difference was that they were particularly interested in training these women themselves and bringing the nursing staff under their own control.

Initially, their interest matched feminist attempts to create work opportunities for women. The combined efforts of doctors, hospital administrators, and respectable ladies to reform hospitals resulted in the introduction of hospital-based training schools of nursing, a highly attractive model of nursing education that spread throughout the world, attracting large numbers of young, middle- and working-class women. The arrangement was that the women lived and worked on the hospital grounds, their reputations carefully protected through a disciplined system of supervision and regulations, in return for a nursing diploma after initially two, but later three, years of training. Doctors taught them the medical knowledge deemed appropriate and necessary, and usually a nurse superintendent oversaw the management of the school under the authority of the medical director of the institution. Soon, however, nurses expressed awareness of the challenges associated with a hospital-based program of education. Work conditions of the new student nurses did not differ much from their counterparts in domestic servant roles in terms of pay and working hours. The work nurses took up in private duty upon graduation was largely unprotected. This situation prompted nurses to organize themselves into professional associations and seek legal and social protection from the state through registration laws and licensing regulations.

NURSES AND CARE OF THE MENTALLY ILL

The introduction of diploma-based nursing education forcefully continued the cultural connection between nursing work and care of the sick and disabled. The introduction of trained nursing in asylums forms a salient example. Institutional care for the mentally ill became firmly established in the industrializing world in the nineteenth century. However, despite initial optimism about the improvement new institutions would bring, asylums soon grew into overcrowded, lower-class institutions for indigent insane and their social reputation was very poor.

When scientific psychiatry grew as a medical field in the late nineteenth century, psychiatrists had a vested interest in enhancing the status of asylums and introducing new therapies such as bed rest and hydrotherapy. They began to model the asylums after the influential example of the general hospital. A crucial factor in this transformation was the availability of competent personnel who could assist them in making the new therapies work. Inspired by the impact of the role of middle-class women in hospital reform and the effect of hospital nurse training schools, asylum physicians also began to argue for the establishment of mental nurse training. Nurses, trained in care of the sick, began to provide day-to-day care of the mentally ill, and asylums opened their own mental nurse training programs.

The care of large groups of mentally ill patients with difficult and often unpredictable behavior remained a burdensome task, however, and the limitations of high turnover of personnel and demanding work conditions characteristic of the general hospital nursing workforce were probably even more prominent in the asylums. At the turn of the twentieth century, a large part of the asylum population consisted of demented elderly, for example, who came to the asylum in the last years or last months of their life. Behavior of demented, confused, or agitated patients was difficult for nurses to handle, and communication with this population was a complex matter. Patients in a delusional, manic, or agitated state could be dangerously violent or unpredictable in their behavior. Asylum work was strenuous and not without risk. More stable patients, however, usually took part in hospital work and made an extensive contribution to the asylum economy. A gradual decrease in mortality rates, as in Dutch asylums, likely indicated that to some extent mentally ill patients did benefit from more competent and compassionate care, although generally circumstances in asylums remained challenging, reflecting the broader social difficulty of caring for the mentally ill.

Although the disadvantages of large institutions did not disappear with the introduction of systematic training of personnel, nursing work provided an opportunity for a decent social position for large groups of middle- and working-class women and men. The popularity of this training model for nurses may indicate that it served first and foremost as a new way to staff institutional care for the sick and disabled. This model of combined nursing education and work gradually changed in the second half of the twentieth century, as nursing education and work increasingly began to be separated and the necessity of a more advanced education for nurses became essential for expanding health services in the second half of the twentieth century.

PUBLIC AND MENTAL HEALTH MOVEMENTS

The devastating impact of World War I, with its aftermath of labor unrest and economic depression, combined with widespread tuberculosis and high infant mortality rates, reinforced the idea that in a democratic society basic needs of citizens had to be taken care of independent of the ability of individuals to pay for health services. Starting in the nineteenth century and expanding in the first half of the twentieth century, Western industrialized nations began to provide more consistent protection of its citizens through state regulated security and insurance plans for unemployment, old age, sickness, and disability. Although models and programs varied between countries, some form of regulated health insurance financed through private or public funds became the norm and had a permanent impact on the provision and development of health services and disease prevention.

Closely related to this idea was the belief that science, generating more effective and efficient ways to manage the social problems created by dependency, provided the foundation on which social policies and solutions should be based. The public and mental health movements arising in the first part of the twentieth century were a case in point. They reflected the growing confidence that professional and scientifically based efforts to enhance the health of the people, physically and mentally, would ultimately result in a productive and healthy population. Nurses took up an essential role in these movements, expanding and re-creating more independent careers in public and mental hygiene work, such as children's bureaus and vaccination programs, school health programs, visiting nursing societies, tuberculosis prevention, child guidance clinics, but also in factories, insurance companies, and boards of health and education.

CHANGES FOLLOWING WORLD WAR II

Following World War II, a growing health agenda originated from various sources. Increased international economic and social collaboration in health matters was reflected in the foundation of the World Health Organization (WHO) in 1948. The WHO noted that "health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (Howard-Jones 1981:472). The new availability of antibiotic drugs fueled increased confidence in the advancement of medical knowledge and technology. Increasing national wealth provided an economic basis for expanding health programs. In the mid-twentieth century, hospital and medical care insurance legislation facilitated an enormous growth of hospitals and medical care services and generated an unprecedented demand for health care personnel.

During the 1940s and 1950s, every industrialized country faced an enormous shortage of nurses. As a more acutely ill patient population filled hospital wards, traditional patterns of staffing hospitals by continuously turning over nursing student personnel no longer matched required levels of care and clinical observation. More graduate nurses became employed in the hospital, while continued demand for more caretaking personnel was also filled through new diversification of the nursing workforce. As of the 1960s, academically based nursing education became more widespread, while new programs for nurse assistants and licensed practical nurses were also established to complement the work of the traditionally registered nurses. Nursing homes emerged for the care of chronically ill and disabled people, and the lower-qualified group of nurses became the workforce of choice in these new institutions.

While nursing adapted to increased demand, coming to terms with the new diversity in educational preparation of nurses was a complicated process. Through national and international nursing organizations, such as the International Council of Nurses (ICN), nurse leaders sought to establish minimal educational guidelines for professional nurses and expand nurses' role in health service, policy, and research, while seeking to maintain control over a continuously expanding nursing workforce. The higher complexity of nursing care required for a patient population that experienced new illnesses for which in the past no medical treatment had existed was not always well understood among health policy makers. Moreover, as health care advanced, chronic illness and permanent disability rendered new demands for skilled long-term care. The gendered context in which professional nursing emerged during the nineteenth century had generated beliefs that made it persistently difficult to articulate at a social level the essential value of nursing care in all of these situations.

Defining the responsibilities of the nurse, which had been a long-standing matter of debate within nursing organizations, regained relevance as the function of the nurse had to be articulated in new twentieth-century contexts. Virginia Henderson (1969:50), an influential nursing leader in the United States and a clinical nurse researcher, developed a powerful and influential statement that captured the essential role of the nurse in the assistance of dependent and disabled individuals:

> The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or its recovery (or to a peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge.

Her view, articulated in *Basic Principles of Nursing Care,* became the basis for the ICN's vision on nursing and was translated into 12 languages, serving as a guide for nurses around the world.

PRIMARY HEALTH CARE

Not only the view on health and health services changed profoundly during the twentieth century but also the perspective on sick and disabled people themselves. Health is increasingly considered a basic human right. Moreover, health consumers now actively participate in health care politics, raising awareness and advocating for equal access and improvement of service. A strong consumer movement now advocates for consumer rights, resources, and responsibilities.

Demographic changes and a rapidly growing elderly and chronically ill population have shifted the emphasis of health services from merely disease prevention to health promotion. The argument that hospital-based care and medical services alone are not enough to maintain people's health gained momentum as of the 1970s. An emphasis on primary health care has emerged, in which community-based care and promotion of a healthy lifestyle have obtained central stage, enhancing an active role of people in maintaining their own health. Primary health care is a broad-based approach to health services in which promotion, prevention, cure, rehabilitation, and palliative support are equally valued. Nurses, both in staff positions and in specialized advanced practice roles such as clinical nurse specialist or nurse practitioner, have an essential role in patient advocacy and in bringing about the primary care philosophy.

CURRENT AND PERSISTENT CHALLENGES

Currently, nurses consider enhancing the integration of people with disabilities in the community and improving their quality of life essential tasks. As part of their academic education, nurses have gained knowledge and expertise in research and policy development. Nursing research is now a fundamental component of nursing practice. Over the past decades, nurses have made substantial contributions to knowledge of chronic illness and disability, supporting people with disabilities in improving their health and living conditions. Both nurses, as providers, and persons with chronic illnesses and disabilities, as consumers, experience the unrelenting reluctance of society at large to value the public need of basic care. As a nursing shortage once again is looming around the world, largely as a result of the profound effects of cost-containment and restructuring of health care during the 1990s, which eliminated thousands of nursing jobs, the persistent difficulty as much as the profound necessity of finding a balance in evaluating the cost and value of nursing care remains a prominent health care issue.

O

OBESITY

Obesity is a condition characterized by a larger-than-average amount of body fat (excess adipose tissue). While fatness has been associated with wealth and prosperity in historical contexts where continued existence was predicated on access to food, *obesity* is a medical term used to pathologize the fat body in a context of abundance of resources. In contrast to overweight, which is a Body Mass Index of 25–29 (BMI, or weight in kilograms divided by the square of height), obesity is a BMI of 30 or greater. (BMI problematically does not consider muscle mass and is only a crude measure of weight.) Obesity is considered a public health crisis/epidemic in the affluent West in the early twenty-first century, with more than one-third of all adults and one in five children categorized as obese. There was a huge jump in National Institutes of Health estimates of the prevalence of obesity in the United States from the 1960–1980 period, when 15 percent of adults were obese, to over 30 percent in the 1980–2000 period. However, the federal government's lowering of the baseline of standards for obesity made 35 million people who had not been considered fat before suddenly very much so.

The management of obesity fuels a multi-billion-dollar diet and fitness industry, extensive pharmaceutical research and development, lobbying for taxes and advertising bans on certain foods, efforts to improve nutritional labeling, and other interventions aimed at slimming down the public. The medical establishment links obesity to a host of health problems, including high blood pressure, diabetes, heart disease, stroke, gall bladder disease, and cancer of the prostate, colon, and breast. Sedentary lifestyles and increased consumption of inexpensive, fatty, processed foods are typically hailed as contributing factors, though heredity and genetic factors are thought to play some part as well. However, much medical research conflates obesity with these factors, further suggesting a causal relationship between obesity and the aforementioned health problems. Critics point out that the correlation is far too often misinterpreted as causation, and they propose instead that the stresses resulting from living in a society that stigmatizes fatness as unhealthy, immoral, and disgusting may in fact be the cause of ill health.

Since the early 1970s, members of several U.S. size-acceptance organizations, most prominently the National Association to Advance Fat Acceptance (NAAFA) and the Fat Underground, have been working to change the way society perceives of fatness, to cast off its stigma, and to combat discrimination. Their actions have been instrumental in the inclusion of obesity in the Rehabilitation Act of 1973 and the Americans with Disabilities Act of 1990. Fat Americans are legally protected against discrimination so long as their condition substantially limits at least one of their major life activities or is perceived as doing so. Nonetheless, controversy abounds about whether the condition of obesity, over which individuals are usually thought to have some personal control, should be protected, and very few anti-obesity discrimination cases have been successfully argued. Several places in the United States have taken the plight of fat people who suffer discrimination more seriously, with Michigan, Washington, D.C., and Santa Cruz and San Francisco, California, offering anti-size discrimination statutes for protection.

OBSESSIVE-COMPULSIVE DISORDER

Obsessions or compulsions, or more commonly both, are the hallmark of obsessive-compulsive disorder (OCD). Obsessions are recurrent and persistent ideas, thoughts, impulses, or images that are intrusive and inappropriate and cause marked anxiety or distress. Common obsessions include fears of harming other persons or sinning against God. Compulsions are repetitive, purposeful, and intentional behaviors or mental acts performed in response to obsessions or according to certain rules that must be applied rigidly. They are meant to neutralize or reduce discomfort or to prevent a dreaded event or situation, even though the sufferer generally knows the irrationality of these acts. Obsessions create anxiety, which is relieved by compulsive rituals such as checking, washing, counting, confessing, hoarding, and rearranging objects with symmetry and precision. These symptoms can cause functional disability as severe as psychosis and can make it virtually impossible to function at work or at home.

To receive a diagnosis of OCD, a person must have either obsessions or compulsions that cause marked distress, consume more than one hour daily, or significantly interfere with the person's normal routine, occupational functioning, or usual social activities and relationships. The person must recognize that the obsessions and compulsions are unreasonable. Many psychiatrically normal individuals—particularly children—have occasional obsessional thoughts or repetitive behaviors, but they tend not to cause distress or disability. Many people double-check locks or avoid stepping on cracks. These rituals are viewed as acceptable and desirable and are easily adapted to changing circumstances. To the obsessive-compulsive person, however, rituals are a distressing and unavoidable way of life. Data indicate that as many as 2–3 percent of the general population meet criteria for OCD at some point during their lives. Men and women are equally likely to develop OCD, although men have an earlier onset.

Recent developments in the treatment of OCD have improved outcomes and instilled a greater sense of optimism. The mainstays of treatment are pharmacotherapy and cognitive-behavior therapy. Behavior therapies, which tend to be more successful for ritualizers, emphasize exposure paired with response prevention. Proponents of behavior therapies state that 60–70 percent of the patients who persevere with the treatment improve markedly. New generations of drugs work well at relieving both obsessions and compulsions in nearly 75 percent of patients. Treatment is long term because patients tend to relapse when the drug is discontinued, often within weeks. Patients who complete a course of behavior therapy are less likely to relapse.

OCCUPATION

In the context of disability and rehabilitation, the term *occupation* is most widely used and discussed in the field of occupational therapy. While various definitions exist, occupation generally refers to engaging in work, play, or activities of daily living. Work refers to activities (both paid and unpaid) that provide services or commodities to others, such as ideas, knowledge, help, information sharing, entertainment, utilitarian or artistic objects, and protection. Activities such as studying, practicing, and apprenticing improve abilities for productive performance. Thus, work includes activities engaged in as a student, employee, volunteer, parent, serious hobbyist, and amateur. Activities of daily living, play, and work interweave and sometimes overlap in the course of everyday life. Play refers to activities undertaken for their own sake. Examples of play are exploring, pretending, celebrating, engaging in games or sports, and pursuing hobbies. Play is the earliest occupation, persisting throughout life. Activities of daily living are the typical life tasks required for self-care and self-maintenance, such as grooming, bathing, eating, cleaning the house, and doing laundry.

Occupation is recognized as a basic human need and as a determinant of well-being. This need is reflected in the strong drive to do things and the fact that people flourish by engaging in practical, productive, and playful pursuits. The need for occupation entails the urge to do things, to discover, to exercise capacity, and to experience oneself as competent. It is considered to be the product of an evolutionary process in which the complex nervous system of humans gives them a pervasive need to act.

The term *occupation* derives from the Latin *occupare* and connotes taking hold of (i.e., occupying) time and place. Modern discussions of occupation highlight the fact that occupations are how persons fill their time. Humans mark the passage of temporal cycles by what they do. Such terms as *mealtime*, *playtime*, and *workweek* illustrate how the patterns of time and doing are intertwined. Human awareness of the future also means that much of what people do in the present is aimed toward some state of affairs they wish for at a future point. Therefore, occupations not only fill and mark time but also shape the course of people's lives over time. To a large extent, people engage in their occupations so as to locate themselves in an unfolding narrative with an eye toward a particular direction or outcome for that life story.

Occupation is also how persons make their place in the social world. Most of the occupations that people do are conducted among and with others. Occupations express and maintain the social fabric since they not only follow normative ways of doing things but also serve to perpetuate those same social patterns they reflect.

Occupation, disability, and rehabilitation were historically linked in the moral treatment movement of the seventeenth century. Moral treatment saw mental illness as a result of persons' loss of connection to the occupations that made up the mores or folkways. This perspective presaged contemporary views of disability as an interruption of a person's participation in life activities. Moral treatment emphasized using occupations (i.e., work and leisure activities) as ways to encourage and enable people to reconnect with the social world around them. The idea of using occupation as a therapeutic tool has continued in occupational therapy and other disciplines that use activities as a means of habilitation and rehabilitation.

OCCUPATIONAL THERAPY

Occupational therapy is a health-related profession that primarily serves persons with disabilities. It is concerned with the well-being of persons in their everyday occupations (i.e., work, play, and daily living tasks). The profession sees occupation as a necessary aspect of life, contributing to physical, emotional, and cognitive well-being. Occupational therapists work with individuals whose participation in occupation is threatened or hampered by impairments and/or environmental barriers.

The origins of occupational therapy are the eighteenth-century moral treatment approach. Moral treatment was a European movement that saw mental illness as a form of demoralization emanating from disruption of a person's connection with the mores or customary activities of society. Moral treatment consisted of inviting and supporting participation in everyday activities as a means of "remoralizing" individuals by reintegrating them into ordinary routines of living. Moral treatment exported to North America and practiced in the eighteenth and early nineteenth centuries. In the mid-1800s, overcrowding and underfunding of state hospitals led to its virtual demise.

In the early 1900s, a diverse group of people (architects, physicians, nurses, and leaders from the settlement movement and industrial arts) began developing a form of treatment that used participation in work, crafts, leisure activities, and self-care as a form of therapy. These early leaders included the psychiatrist Adolf Meyer and social activist Eleanor Clarke Slagle. William Rush Dunton, another psychiatrist and a descendent of Benjamin Rush (a physician and statesman who introduced moral treatment to the United States), was responsible for introducing and spreading literature and concepts from European moral treatment into occupational therapy. The early practice of the field (which quickly spread from application with persons who had mental illness to a variety of other impairments) focused on helping patients reclaim function and achieve satisfying everyday lives through active participation in work, self-care, and leisure tasks during their rehabilitation.

In mid-twentieth century, the field became more closely aligned with medicine and the medical model. As a consequence, more attention was paid to remediation of underlying impairments that contributed to disability. In the 1970s and 1980s, this emphasis on impairments was increasingly criticized from within the field. Consequently, leaders sought to return occupational therapy to a more holistic practice centered on the client's participation in everyday life occupations.

The contemporary focus of the field is, therefore, on the client's challenges or difficulties with participation in occupations. Occupational therapy services seek to enhance individuals' performance and satisfaction in work, play, and activities of daily living through reducing impairments and through personal and environmental adjustments. Services are offered to clients who range from preterm infants to the very old and to persons with any type of physical, sensory, cognitive, or emotional impairment. More recently, services are offered to persons whose work, play, and activities of daily living are disrupted by war, poverty, violence, and other social injustices. Occupational therapists are also increasingly involved with providing services to promote wellness and prevent loss of function.

Since the aim of occupational therapy is to enable persons to have satisfying and productive engagement in occupation, occupational therapists are trained to understand and address the interrelated biological, psychosocial, and environmental factors that contribute to occupational problems. The common denominator of occupational therapy practice is involvement of persons in occupations as a means to enhance their well-being. The profession is based on the premise that when humans engage in occupations using their physical and mental powers, they can positively affect their biological and psychological status. Consequently, occupational therapy focuses on empowering clients to actively influence their own rehabilitation process and outcomes, but selecting their own objectives for the kind of lives clients want to lead.

Occupational therapy ordinarily consists of one or more of the following elements. First, therapists provide direct opportunities for clients to perform occupations with an aim toward achieving personal change (e.g., development of new skills, learning to compensate for a permanent impairment, increasing self-confidence, and discovering new ways to achieve satisfaction in performance). The occupations that are used as therapy can include a wide range of activities (e.g., sensory-motor play, crafts, work tasks, group projects, leisure activities, school/classroom tasks, and self-care activities such as dressing or bathing).

Second, occupational therapists provide and train clients in the use of various technical devices that extend limited capacity or compensate for lost capacity. This technology ranges from simple adaptive equipment that has been modified to accommodate motor limitations to complex, computer-based equipment that is used for communication and environmental control.

Third, therapists help clients remove barriers to engaging in occupations by modifying how tasks are completed or through modifications of the environment. Tasks are modified through such strategies as simplifying steps, providing special sensory or memory cues, or altering expectations for outcomes. Environmental modifications include such things as removing architectural and structural barriers in the physical environment and changing attitudes of others toward disabled persons in environments where the person carries out occupations (e.g., home, school, and workplace). More recently, occupational therapy has increasingly included advocacy for social and policy change as a strategy for removing environmental barriers.

Fourth, therapists may enable persons to engage in occupations through counseling and problem solving that encourage the client to choose and participate in occupations. Because occupational therapy is based on the client's active involvement in doing things, the field pays particular attention to the client's perspectives and experiences in order to facilitate this involvement. Client centeredness is an important theme in occupational therapy.

In addition to working with individuals, many therapists have agencies, organizations, and entire communities as their clients. They may provide consultation services on program design, optimal environments, training and development of staff and families, prevention programs for workers, and education programs for community members, all within the context of maximizing occupational functioning of the target group.

There are occupational therapists practicing in more than 60 nations worldwide. Education ranges from occupational therapy assistants who earn two-year associate of arts degrees to therapists who earn professional doctoral degrees. In the United States, a graduate degree will be required for entry into the profession in 2007, but the most common educational background worldwide is the bachelor's degree. The World Federation of Occupational Therapists is a major international body that recognizes educational programs, although most countries have their own credentialing of educational programs and qualified therapists.

O'CONNOR, FLANNERY (1925–1964)

American author

Flannery O'Connor was born in Savannah, Georgia, the only child of a devout Catholic family. This background, as many critics have argued, shaped her later fiction writing as part of the southern grotesque. Her father was a realtor and her mother was a member of a prominent political family (her grandfather had been mayor of Milledgeville, Georgia, for many years). She graduated from Georgia State College for Women in 1945 and then attended writer's workshops at the University of Iowa. In 1950, she experienced her first bout with lupus—a debilitating blood disease that she inherited from her father. O'Connor used crutches for mobility from 1955 onward.

From the beginning, O'Connor's work demonstrated a somewhat perverse relationship between religious and disability themes. In her second novel, *The Violent Bear It Away* (1960), the main character, Francis Marion Tarwater, becomes a minister in his youth and later baptizes and drowns Bishop, the "idiot" son of his uncle. The act is performed in eugenic-like style as one of mercy to save the cognitively disabled character from Satan's temptations. Likewise, in her famous short story "A Good Man Is Hard to Find," a malignant criminal named "The Misfit" explains that the easy expendability of human life was brought about by Christianity when Jesus was raised from the dead. This miraculous act precipitated attitudes of false reverence for death and afterlife as mere inconveniences that can easily be overcome. In the story "Good Country People," the female protagonist dons an artificial leg as the result of a hunting accident. When she tries to sexually engage a country Bible salesman named Manley Pointer, he runs off with her prosthesis as punishment for her "licentiousness." Thus, O'Connor spent much of her writing career demonstrating the degree to which humans will torture, injure, and kill each other as an expression of their investments in religious "morality."

In the 1950s, she reflected directly on the social fate of disabled children by arguing that sentimentality expressed toward them—that which would deny their difficulties and suffering in a hostile world—is akin to beliefs that sent individuals to the gas chambers during the Holocaust. Furthermore, O'Connor insisted that the parents of disabled children would hesitate to dismiss such a comparison of cultural attitudes toward disability even though her parallel may seem extreme to many. In making this argument, the disabled author identified sentimentality as a key antagonist of disabled people with respect to more meaningful engagements with the experience of impairment. O'Connor died in 1964 at the age of 39 following an ill-fated surgery that reactivated her lupus.

ONTARIANS WITH DISABILITIES ACT OF 2001 (CANADA)

The recognition that people with disabilities are entitled to full citizenship and that government has an obligation to take steps to make that vision a reality is a relatively recent development in Canada. It reflects a transition from the view that people with disabilities are inadequate and require charity and beneficence to an acknowledgment that the obstacles for full inclusion are barriers that prevent people with disabilities from fully participating in all aspects of society.

The Charter of Rights and Freedoms provides constitutional protection to persons with disabilities by prohibiting discrimination on the basis of disability. Provincial and federal human rights legislation also prohibits discrimination on the basis of disability in a number of key areas including employment and the provision of goods and services to the public. However, the charter and human rights legislation require individual complaints to be filed for each act of discrimination and involve a lengthy legal proceeding. While human rights legislation may allow for systemic litigation and proactive approaches to prevent and remove barriers, the lack of a comprehensive barrier-removal statute was identified as an important deficit preventing the full participation of persons with disabilities. Requiring individuals to file complaints is difficult where people are afraid to disclose that they have a disability.

Between 1995 and 2001, the Ontarians with Disabilities Act committee, a province-wide coalition of people with disabilities and organizations representing people with disabilities, was formed to lobby for comprehensive barrier-removal legislation in Ontario.

Legislation was introduced in November 2001 and went into effect on September 30, 2002. It requires the provincial government, municipal governments, hospitals, educational institutions, and public transit organizations to develop barrier removal plans within one year. The plans must set out how organizations intend to identify existing barriers, how they plan to remove those barriers, and how they intend to prevent the creation of new barriers. There is no specific obligation in the legislation to remove a certain number of barriers or types of barriers within any time frame. The plans are to be developed in consultation with people with disabilities. The plans must be filed with the newly created Accessibility Directorate and will be available to the public. The legislation does allow the government to develop regulations and guidelines on the plans, but to date none have been developed. As of January 2003 the enforcement provisions of the legislation had not been proclaimed.

The legislation also permits the government to extend its application to the private sector, but again, this has not been done. The government is seeking voluntary compliance by the private sector. There are a number of other obligations placed on the provincial government, such as ensuring that all of their websites meet accessibility standards.

The legislation does not create an independent body, but it does enshrine in legislation the Accessibility Directorate as a part of the public service. It also creates a provincial Accessibility Advisory body, as well as requires municipalities of more than 10,000 people to create their own advisory councils.

The legislation specifically states that it does not in any way diminish or affect the rights of people with disabilities under the Ontario Human Rights Code.

The definition of *disability* in the Ontarians with Disabilities Act is inclusive and specifically includes mental disability and brain injury. The definition in the Ontario Human Rights Code was amended to be consistent with the definition in the Ontarians with Disabilities Act.

The legislation also requires that people with disabilities and other stakeholders must be given an opportunity to consult on any proposed regulations developed under the act. It allows for the development of guidelines and standards, although there are no timelines in place for them to be developed.

In a provincial election held in October 2003, the Ontarians with Disabilities Act was raised as an issue with the new government promising to strengthen the legislation within its first year in office. Consultations started in January 2004, and the legislation was passed and went into effect in 2005.

OPPRESSION

Oppression occurs when individuals are systematically subjected to political, economic, cultural, or social degradation because they belong to a specific social group. In 1970, Paulo Freire argued that the experience of oppression is marked by dehumanization, conquest by the oppressed group, dividing and ruling by the oppressed group, manipulation, cultural invasion, "forcing the oppressed group to adopt the beliefs of the oppressors," exploitation, marginalization, power inequities, and violence.

OPPRESSION AND THE COMPLEX DISABLED PERSON

Oppression is often a topic when minority groups and the dispersion of power are discussed. In the African American civil rights movement, the women's movement, anti-apartheid movements, and many civil and human rights movements globally, oppressed people have sought to redistribute power and increase equality, all citing a common theme of oppression.

Many parallels have been drawn between the black community and the disability community in North America. The idea of the minority model being applied to both groups is anchored in the social model that has flourished in British and American disability studies. This model argues that social attitudes rather than physical or mental inabilities are the primary source of problems confronting disabled people. In addition, disability theorists argue that many aspects of the physical and social environment are determined by public policy and that policy is a reflection of pervasive societal attitudes and values. This may have a distinct impact on those who have intersecting identities that may be targets for oppression.

Consider, for example, a black woman who is disabled as defined by Western disability theorists. Persons such as this, who are members of more than one minority group, often experience tension, and they rank their membership in such groups in terms of the characteristics they consider most appealing and most central to their identity. What is appealing to a person is often dictated by the culture that the individual identifies with. Often, even within minority groups, the dominant culture influences beliefs about what characteristics are of value. Cultural invasion is a phenomenon discussed by Freire (1970) where the invaders, "persons outside of the oppressed group," penetrate the cultural context of another group, disrespecting the latter's potentialities. In this invasion, the invaders impose their views of the world—right and wrong, good and bad, inferior and superior—on those whom they invade, and they inhibit creativity by curbing expression of the less powerful group. Those invaded are then expected to pick up the values of their oppressors and accept them as their own. Many disabled blacks have internalized the views of the dominant group concerning both race and disability.

Oppression is expressed in the above instance by locating the sources of oppression within the body of the disabled person, thereby blaming the individual for experiences of oppression, because his problems are housed within him. This is done in an attempt to remove societal responsibility for barriers that may be placed on the oppressed group. The internalization of race hatred has been argued well; however, less theorized is the acceptance of dominant cultural views concerning disability status and the effect this has on the experience of oppression for persons who hold multiple minority status.

It is not enough that the skin is a culprit; now the biological traits beneath the skin have been targeted. Such an argument is not new to blacks as it was seen in the measuring of black skulls to prove innate inferiority and a lack of humanness in an effort to legitimize mistreatment of blacks based on race. Over the years, black theorists and scientists have taken up this argument to disprove it, but the same has not been successfully done for disability, and blacks have not openly recognized this similarity in a way that would spark revolution as it did in race politics. In turn, the dominant culture's ideas of the "normal-functioning body and mind" have become mainstream in black communities, and these ideas lend themselves to inadvertent oppression from a group that is familiar with the trauma of daily oppression.

Although incorporation of dominant beliefs toward the disabled has occurred, it is not an absolute within the black community. Blacks are also influenced by a historic ostracism based on race, and they have learned to accept a wider range of difference as normal and acceptable. Thus, disability oppression is often seen enforced on those whose differences lie outside the range that blacks have carved out as normal and functional, and it places those on the fringes at high risk for "majority norm enforcement."

If ethnicity complicates disability, then adding gender to the equation can certainly offer an additional dimension. Rosangela Berman Bieler, a Brazilian disabled woman, argued in 1998 that in spite of the similar discrimination that disabled men and women face, there is a point where they differ; that difference is seen in the cultural norms accepted by majority society concerning sexuality and affection in regards to disabled women. In a society where body defines you, the black and disabled female finds her body on the lowest stratum of beauty in terms of the dominant culture's standards.

Women of color with disabilities are not unique in their struggle to fight the stereotypes of asexuality and abnormality concerning the disabled female body, but an ethnic female does face the added stigma of being an "other," already considered less than the dominant culture's acceptability for beauty. Thus, not only does the disabled black woman receive societal messages that she is less than female because of her disability, she also receives the message that she is less than female because she is black. As a trinity, disability, blackness, and femaleness represent a union of oppression that is focused on the body of an individual who can be devalued from many angles. Her image is tarnished by her triple minority status, and it is acceptable to treat her as less than human.

THE UNIQUENESS OF DISABILITY OPPRESSION

Though oppression based on race and gender has similarities to oppression experienced by those who are disabled, disability oppression is unique in some respects: People are born black, or female, but can become disabled at any time in their lives. There is a fear associated with the unknown, and to distance oneself helps to keep a separation between what one currently is and what one does not want to be. This distance is seen in North America and also globally, and the fear of becoming disabled helps to keep disability oppression grounded in many cultures. The establishing of oppression based on the fear of a shift in social category separates disability-based oppression from race-based oppression; in other words, people do not wake up after 20 years of being white and suddenly possess the characteristics of blackness.

An additional unique characteristic of disability-based oppression is the need that a disabled person may have for personal assistance. This opens doors of oppression in different ways than does race or gender. Consider an individual who needs daily assistance with bathing or dressing. If the personal assistant refuses to help, or is late and services are not rendered, the disabled person is in a situation of less power, of less authority, of "dif-ability," and is thus oppressed based simply on the need for personal assistance. These occurrences are specific to those who have disability status.

CONCLUSIONS

When grappling with the existence of oppression, we must be informed by our surroundings, by the oppression that others have experienced and navigated through, while also being aware of the nuances that are present in oppression experienced in the context of disability. Oppression is not just an experience but also a social phenomenon that has been globally expected. There is always a group that assumes a subordinate position. The disabled community faces multiple levels of the expression of oppression, because disability inhabits locations that cross and encompass gender, race, socioeconomic status, disability type, lifestyle, age, religious beliefs, and nationality. It must be realized that disability oppression is not housed in genetics but lives in the cultural norms that have been accepted as mainstream beliefs in the societies in which we live. Mainstream cultural norms concerning disability must be altered in ways that will help eliminate disability oppression as a standard experience for the disabled.

ORALISM

Oralism refers to one of the two principal approaches to and philosophies of teaching language to the deaf; it is contrasted with manualism. Oralism assumes that speech is the most evolutionarily advantageous form of language and that the ability to use and/or understand spoken language is what separates humans from lower species. Thus, oralism devotes considerable attention to teaching deaf and hearing-impaired people not only how to produce speech but also how to read lips. Manualists take the opposite position, regarding sign language (in its various forms, from American Sign Language to Signed English, and their national variants) as "natural" languages, possessing all the important characteristics of any language, such as morphology, syntax, and markers for semantic and rhetorical intensifiers and connotations. In its earliest years, manualism also carried with it an evangelical mission, as a way of spreading gospel to those ordinarily considered excluded from its transmission.

In the nineteenth century, when the great debates between oralists and manualists first took shape, one of the most famous proponents of oralism was Alexander Graham Bell, whose invention of the telephone was in part a by-product of his work on creating communication systems for the deaf (Bell was married to a deaf woman). His father, Alexander Melville Bell, a famous teacher of elocution, developed a system called "Visible Speech," designed to assist in teaching deaf people how to acquire spoken language. The Alexander Graham Bell Association, a foundation named after him, continues today and is committed to furthering Bell's conviction that the proper way for deaf and hard-of-hearing (their term) people to communicate is through spoken language.

There were eugenic and racist elements to the oralism versus manualism debates, as well. Bell, for example, believed that manualism needed to be done away with in large part because it encouraged inbreeding between deaf people, thus leading to a greater possibility (in the case of hereditary deafness) of the continuation of deafness, since manualism allowed deaf people to remain segregated from the hearing. Also, by the end of the nineteenth century, it was the case that there was a racial gulf between oralists and manualists, and only people of color were being taught exclusively through manualist approaches (presumably because educators either believed them incapable of learning through oralist methods or because they did not see the reason for nonwhites to have the skills they associated with spoken language).

Oralism also became a platform for the development of the teaching of deaf people as a form of "women's work" in the United States: Because of the American Civil War, men, who were the principal teachers up until that time, were called to battle, and women took over some of these roles. After the war, the lowering of the age at which deaf children began to receive instruction and the economic advantages of assigning such work to women helped increase the role of women in this arena.

In recent decades, as deaf people became Deaf (i.e., assumed a cultural identity that involved pride in their status), oralism has become once again a more criticized approach to language education. Such larger educational movements as mainstreaming and inclusion are often seen as vestiges of or returns to the precepts of oralism, in that they do not create a space for Deaf people to enact their own linguistic culture and that they privilege speech over sign. Similarly, more recent debates over cochlear implant surgeries, particularly for children during their most sensitive years for language acquisition, revives the binary division between speech and sign that oralism raised almost two centuries ago.

ORTHOPEDICS

The practice of orthopedics has a long history. From its first inception in France in 1741 to the present, orthopedics is a specialty that has evolved to fit the changing nature of disabling conditions with the rise of technology.

Despite its long history, prior to the nineteenth century very little orthopedic surgery was performed. Generally, orthopedics was confined to the correction of deformities by means of external apparatus, reduction in the case of dislocation, and amputation. With developments in other spheres such as anesthetics, antiseptic techniques, and X-rays, more surgical means were at the disposal of orthopedists. In the nineteenth century, orthopedics began to formally establish itself as a specialty, particularly in the United States. The American Orthopaedic Association was founded in

1887, its German counterpart in 1901, and the British Orthopaedic Association was established in 1918.

Specialist hospitals and clinics such as the Boston Orthopedic Institution and Fracture Clinics in Manchester and Liverpool were established in the late nineteenth and early twentieth centuries. While new techniques were created, such as surgery for open reduction of congenital dislocation of the hip and bone lengthening with direct skeletal traction, it was during World War I that orthopedic surgery came to the fore. Orthopedic surgeons' skill prevented permanent disability from skeletal injuries, halted deaths from gas gangrene through amputations, and mediated highly complex procedures on nerves and tendons. The need was so great that American orthopedists were imported even before the United States entered the war in 1917.

After the war, the orthopedic surgeons' focus concentrated once more on civilians. Hospitals that had housed disabled ex-servicemen were turned into institutions for disabled workmen and children. Surgery was conducted on tubercular joints so prevalent in Britain and other disabling conditions such as clubfoot. In the United States, until the development of vaccines in the late 1950s, orthopedists treated those who had contracted and recovered from paralytic polio with a variety of methods. As previously mentioned, discoveries in other spheres have had an impact on orthopedics; for instance, the development of sulphonamides and penicillin in the late 1930s and 1940s decreased the risk of bone infection in compound fractures.

The late 1950s and 1960s were a time of great change in orthopedics. Although artificial joints had been designed and implanted since the late nineteenth century, it was in the late 1950s that Sir John Charnley, at the Wrightington Hospital in Wigan, England, perfected his two component combination plastic and stainless steel hip replacement. His new procedure changed much of the focus of orthopedics to implanting devices that replaced worn joints affected by osteoarthritis. This innovation was taken up around the world, and other artificial joints were designed. Successful replacement knees were first inserted in 1968 and were followed by the shoulder, elbow, ankle, and hand. In Switzerland, the AO (Arbeitsgemeinschaft fur Osteosynthesefragen; Association for the Study of Internal Fixation) revolutionized fracture care, rejecting plaster casts for surgical intervention with a system of screws and plates. New materials have been developed for joint replacement surgery including titanium, combination alloys, and ceramics. High technology now plays an important role in joint replacement with new techniques such as minimally invasive surgery (MIS), which usually results in a shorter recovery time for the patient. These innovations have created even more specialization in orthopedics, which now includes approximately 12 specific areas of subspecialization including sports medicine and arthroscopy, trauma, tumor, and metabolic disease. Manufacturers play an important role in the marketing and promotion of orthopedic products, a multi-billion-dollar business.

OSTEOPOROSIS

Osteoporosis (porous bone), named in the 1820s by Alsatian pathologist Jean Georges Chrétien Fréderic Martin Lobstein "the Younger," is characterized by low bone mass and deteriorated bone tissue, causing fragile bones and increased risk of fracturing. Bone compression or fracturing most frequently affects the hip, spine, or wrist and causes loss of height and/or kyphosis (dowager's hump). Persons with severe osteoporosis may experience spontaneous and/or traumatic bone breakage; pain; mobility limitations; physical, emotional, or psychological disabilities; or death.

In 1940, Fuller Albright, a Boston endocrinologist, discovered a link between estrogen loss at menopause and "thin bone." Albright initiated estrogen treatments to osteoporotic women. Its use became widespread only in the mid-1960s when Robert A. Wilson, a Brooklyn gynecologist, promoted estrogen therapy, newly available in pills, as a cure for all menopausal deficits in popular and medical media. Researchers in the late 1970s associated estrogen treatment with reproductive system cancers, and its use declined. Osteoporosis remained obscure until 1984, when a Consensus Conference through the U.S. National Institutes of Health declared estrogen and calcium standard treatments.

Historically, osteoporosis was mostly associated with older women, but others at risk include aging men, persons with eating disorders, pregnant teenagers, and female athletes. Men generally have higher bone mass, lose bone density at a slower pace, and develop bone loss at older ages. Controversy remains about whether osteoporosis is a disease or a natural concomitant of aging.

Genetic, behavioral, and environmental factors and their interactions contribute to osteoporosis. All racial groups are susceptible, although incidence varies. Peak bone mass (PBM), the amount of bone tissue attained by adulthood, is a major determinant of fracture risk. Smoking, excess alcohol, excess caffeine, lack of or excess exercise, and lack of sunshine deplete bone tissue. Secondary osteoporosis may result from other illnesses (e.g., end-stage kidney disease), medical treatments and practices (e.g., removal of ovaries, institutionalization), specific drugs (e.g., long-term steroid use), and other hormonal and nutritional deficiencies (e.g., vitamin D, calcium, parathyroid hormone, calcitonin, and fluoride).

Bone densitometry proliferated during the late 1980s; campaigns to promote screening to measure bone mineral density (BMD) of older women further increased recognition of this "silent" epidemic and the estimates of persons affected. Definitions of osteoporosis and osteopenia (borderline low bone density) based on BMD criteria established by the World Health Organization resulted in the diagnosis of millions of asymptomatic patients. More than half of all women and about one-third of all men over age 50 are predicted to experience osteoporotic fractures during their lives. Incidence and cost estimates are widely employed by commercial, medical, and advocacy interests to influence governments and consumers.

Since the late 1990s, nonestrogenic drugs (e.g., bisphosphonates) have been widely prescribed to prevent and repair bone loss. In 2003, in the United States, the Women's Health Initiative clinical trials indicated increased risk of cancer and heart disease from use of estrogen with progestin. Postmenopausal women with osteoporosis are now advised to avoid long-term hormone replacement therapy.

Despite widespread bone densitometry testing in North America, many cases go undiagnosed, even when serious bone fracturing has occurred. Science cannot yet accurately predict which individuals with low BMD will develop fractures or become disabled, but geneticists and molecular biologists are pursuing subcellular studies. Programs to prevent falls play an important role in reducing incidence of broken hips, which often lead to disability and/or death in seniors.

North American patient activists and medical experts established voluntary agencies (e.g., National Osteoporosis Foundation, Osteoporosis Society of Canada) in the 1980s, which lobby governments, educate the general public, and provide services for persons with osteoporosis.

OUTCOME MEASURES

Functional disability and quality of life are key outcomes that influence patients' demand for care, as well as their compliance and satisfaction with treatment. Over the past few decades, there has been a shift from traditional physician-focused assessment, with its dependence on physiological and radiological measurement, toward methods based on the belief that patients can provide accurate and meaningful assessments of their own health. Such measurements have found a natural home in the field of disability, where clinician-based assessments can give only a limited picture of the impact of illness on individuals. Indeed, clinical assessments have tended to overestimate the adverse effects of disability on self-reported quality of life. For example, in one study over 80 percent of patients with spinal cord injury anticipated average, or better, quality of life, while less than one-fifth of those treating them rated their potential health state so positively. Such a mismatch in perceptions of the impact of disability means that appropriate outcome measures must be developed that assess what is important to patients in terms of their own health-related quality of life.

Results from studies of patients with disabilities have often shown that they view their health in a positive way and that their self-reported quality of life is often very comparable to similarly aged people not reporting any disabilities. Manifestly, however, the impact of disability can also have dramatic negative consequences for patients, and appropriate outcome measures can be useful to assess patients' reactions to treatment and therapy. For example, the quality of life of stroke patients has been found to decrease over time, despite clinical assessments remaining stable. In trials of interventions, patient-based outcome measures can be used to assess their efficacy, and they provide an important addition to clinical assessments.

The increasing use of subjective health indicators has been reflected in the number of research papers reporting aspects of subjective health status or *health-related quality of life*. This reflects a growing interest on the part of physicians and health researchers in using the patient's viewpoint in formulating treatment plans and monitoring the quality of medical care outcomes. As more of the population experience the limitations of aging, chronic illness, and disability, due to increased lifespan, a need has developed for a more humanistic form of health care that incorporates a systematic assessment of the patient's perceptions.

Interest in subjective patient-based assessment accords with the World Health Organization's (WHO) now classic characterization of health, which incorporates autonomy and physical, mental, and social well-being and not merely the absence of disease. Health-related quality of life is a concept that attempts to encompass the spirit of the WHO definition of health by incorporating both personal health status and social well-being in assessing the health of individuals and populations. Although there is no agreed-on single definition of health-related quality of life, researchers for the most part concur on the components that should be included, such as general health, physical functioning, emotional state, subjective well-being, and social support.

Indicators of health-related quality of life typically incorporate patient views gained from interviews and/or focus groups. It is essential that, once a set of questions has been identified, the instrument has good psychometric and statistical properties. An instrument that evaluates outcomes of treatment must measure reliably and accurately what it purports to measure. Minimally, outcome measures should manifest the following attributes.

1. *Reliability.* The instrument should produce the same, or very similar results, on two or more administrations to the same respondents, provided, of course, there is good reason to believe that the health status of the patients has not changed. The difficulty with such a method of validating a questionnaire rests on the uncertainty of whether results that may indicate a questionnaire is unreliable are in fact an indication of real change in health status. Due to the potential difficulties in gaining an accurate picture of reliability in this way, many researchers adopt the Cronbach's alpha statistic, to determine internal reliability. Internal reliability refers to the extent to which items on a scale are tapping a single underlying construct, and therefore there is a high level of interitem correlation. Assuming that such high levels of interitem

correlation are not a product of chance, it is commonplace to assume that a high alpha statistic indicates the questionnaire is tapping an underlying construct and hence is reliable. However, due to many potential sources of variability, high internal reliability reported in only a single study should be viewed cautiously.

2. *Face validity.* Face validity refers to whether items on a questionnaire appear to make sense and can be easily understood. An instrument that contains ambiguities or illogical response categories is very unlikely to either be reliable over time or manifest high levels of internal consistency. In studies that are undertaken cross-culturally, it is essential that translations of an instrument have been validated and that translations of items should retain the original meaning.

3. *Content validity.* This refers to the choice of appropriate items in a questionnaire. Items included in a measure should reflect the underlying domain being measured.

4. *Criterion validity.* This is the ability of an instrument to correspond with other measures. However, finding a "gold standard" instrument is rare, and only really possible in instances where a shorter-form measure is being created from an established longer instrument. For example, results of the eight-item SF-8 have been compared with results from the 36-item SF-36 Health Survey.

5. *Construct validity.* This refers to the ability of an instrument to reflect previously hypothesized patterns of data. For example, physical health typically deteriorates with age, and any questionnaire designed to measure this should reflect this pattern in its results.

6. *Sensitivity to change.* Measures must be responsive, that is, sensitive to meaningful change. When evaluating health care interventions, responsiveness is a crucial aspect of a measures utility. It is possible, for example, to have measures that are reproducible and valid but not responsive. Gordon Guyatt and colleagues (Guyatt et al. 1989) give the example of the Sickness Impact Profile (SIP) in a controlled trial of different strategies for managing back pain. They found that while many parts of the SIP were useful in evaluating change, others were not. For example, they found that no respondent, either at baseline or at follow-up, endorsed the item "I do not feed myself at all, and must be fed," which produced results that are clearly reproducible but not informative in the context of that particular trial. Such unresponsive items cannot prove useful in detecting changes over time as a function of treatment. Consequently, when selecting a measure for inclusion in an evaluative study, researchers should select instruments that contain appropriate items for the patient group and that are likely to detect changes.

7. *Interpretability.* It is essential for measures to provide meaningful data. For example, in terms of change scores a number of instruments provide guidelines for interpreting changes that are important to patients, rather than simply being statistically significant. Minimally important differences (MIDs) are those changes that patients themselves have judged as being small but meaningful. These MIDs can be useful both for interpreting results of longitudinal data, and calculating sample sizes for trials.

The most commonly used measures are generic instruments that have been designed for use in any illness group, population, or sample, for example, the SF-36 and SIP. Such measures have gained widespread use, and consequently substantial amounts of data exist on reliability, validity, and sensitivity to change. Furthermore, data from general populations exist, enabling comparison of results with normative samples. Any given disease-specific measure is, by its very nature, less widely used but more likely to reflect concerns typical of the specific illness group for which it was designed.

P

PAIN

Chronic pain may well be the most common cause of recurrent and permanent disability in the developed world today. According to a 1999 Gallup survey, 89% of Americans suffer from pain at least once a month, and 43 percent—some 83 million—report that pain frequently affects their participation in some activities. More than 26 million (15 percent) describe their recurrent monthly pain as severe. Pain accounts for an estimated 20 percent of health care visits and 10 percent of prescription drug sales. Yet less than 1 percent of the U.S. National Institutes of Health's budget supports research into the mechanisms and management of pain.

Pain is classified as chronic rather than acute when it persists beyond the normal healing period for any illness or injury and appears likely to recur or continue indefinitely. The insurance industry defines three months as the minimum for chronicity, but a period as short as two or three weeks can establish a chronic condition in many instances. Several organic diagnoses such as arthritis, cancer, diabetes, and herpes are associated with severe chronic pain.

Many Americans suffer, however, from disorders defined by the pain alone. These include migraine and other forms of chronic headache; low back pain; abdominal and pelvic pain; temporomandibular joint disorder; trigeminal neuralgia, an intense stabbing pain throughout the facial area, triggered by the fifth cranial nerve; fibromyalgia, defined as widespread musculoskeletal pain, often accompanied by fatigue; phantom limb pain; carpal tunnel syndrome (repetitive strain); and the causalgiform disorders (in current terminology, chronic regional pain syndrome [CRPS]). The latter are characterized by persistent burning pain, usually located in an extremity, which may be referred elsewhere in the body; allodynia, or painful sensation in response to an innocuous stimulus (such as light touch); and hyperesthesia, or severely painful sensation in response to a mildly painful stimulus (pressure or pinprick).

Regardless of its specific location and nature, chronic pain often takes over the sufferer's life. The individual finds it difficult and tiring to work, exercise, and participate in normal activities; withdraws from other people; and becomes both anxious in expectation of severe pain and depressed by its unrelenting persistence. Although many treatments are available, there is no one therapy that works in all cases, and many patients become angry and frustrated at what they perceive as the indifference or ignorance of the medical profession.

HISTORY

Nineteenth-century British, German, and French physicians were the first to recognize the problem of chronic "pains without lesion" and attributed them to a functional disorder or persistent irritation of the nervous system. Johannes Müller's concept of *Gemeingefühl*, or "cenesthesis," an individual's ability to correctly perceive internal sensations, was another of the creative etiologies proposed. S. Weir Mitchell, the American neurologist who observed many Civil War soldiers afflicted with causalgia, phantom limb pain, and other painful conditions long after their original wounds had healed, wrote movingly of their suffering. He described classic causalgia (the burning pain following a nerve injury) as "the most terrible of all the tortures. . . . Under such torments[,] . . . the most amiable grow irritable, the soldier becomes a coward, and the strongest man is scarcely less nervous than the most hysterical girl." Despite the odd and often hostile behavior of his patients, Mitchell was convinced of the reality of their physical suffering.

However, by 1900, specific diagnostic tests and signs had redefined the practice of neurology, leaving little room for unexplainable chronic pains without other physiological symptoms. At the same time, practitioners of psychiatry and the new field of psychoanalysis found that "hysterical" pains offered potential insights into mental and emotional disease. The contributions of neurophysiologists such as Charles Sherrington supported the concept of *specificity:* that "real" pain was a direct, one-to-one response to a specific harmful or noxious stimulus (although Sherrington himself insisted that the central nervous system integrated neural response from the periphery). The corollary of specificity theory was that individuals who reported pain in the absence of an evident cause were delusional, neurotically obsessed, or malingering (often the conclusion of military surgeons or those treating workmen's compensation cases): Their pain was "in the brain." As John Homans wrote of causalgia-like disorders in *The New England Journal of Medicine* in 1940, "That there is something basically at fault about the nervous system of certain of the individuals affected, is probable. Some . . . have grudges against the world, or are perhaps stupid, or even criminal."

This disparaging attitude toward patients with chronic pain persisted well into mid-century. A few researchers and clinicians—the surgeons Rene Leriche and William Livingston, the neurologists Alfred Goldscheider and Rafael Lorentè de No, and the anesthesiologist Emery Rovenstine—proposed alternatives to specificity theory or attempted new treatments before 1940. In the 1890s, Goldscheider endorsed Sherrington's insistence that the central nervous system integrated inputs from the periphery and proposed that pain was a result of the brain's recognition of spatial and temporal *patterns* of sensation. Leriche, based on his work with injured men during World War I, suggested that a nerve injury that damaged the myelin sheath surrounding the sympathetic nerves might create some kind of artificial synapse between these and contiguous sensory nerves, leading to sensations of pain in response to normal stimuli and internal physiological activity. Livingston, who worked with patients with industrial injuries in the 1930s, diagrammed a feedback loop within the nervous system, which he termed a "vicious circle," theorizing that continuing severe pain over a period of time led to functional and organic changes in the nervous system, producing a chronic pain state.

These ingenious ideas were largely ignored until World War II, when, for the first time in history, organized teams of clinicians had the opportunity to observe and treat large numbers of men with similar injuries. Henry K. Beecher, a Harvard anesthesiologist serving in Europe, was startled to realize that soldiers with serious wounds seemed to be in much less pain than surgical patients recovering consciousness in the recovery room. The GIs were slow to request morphine and often appeared quite relieved by a cigarette. Beecher theorized that, whereas pain for the surgical patient meant disruption of normal life and fears of serious illness, the soldier's painful wound meant his release from the battlefield to a hospital and increased chance of survival. The human experience of pain, he suggested, had to result from the fusion of a physical sensation and a cognitive and emotional "reaction component." The assumptions of specificity theory, based on laboratory experiments in which the reaction component was relatively neutral, could not be applied therefore to the understanding of clinical pain.

At Madigan Army Hospital in Washington state, the young anesthesiologist John Bonica participated in regular lunchtime discussions with colleagues—a neurologist, an orthopedist, and a psychiatrist—about the difficult pain disorders they encountered. He left army service with the conviction that interdisciplinary collaboration in both clinical and basic research would be essential to improving medical understanding of pain. Both Bonica and Livingston, who called the war years dealing with nerve injuries at Oakland Naval Hospital "the most exciting and productive of my life," founded multidisciplinary pain clinics at their home institutions in 1947. In 1953, Bonica brought together much of the current state of knowledge in his magnum opus *The Management of Pain.* One of the important points made in this book, paralleling Beecher's work, was that all clinical pain included both physiological and psychological components.

The Dutch neurosurgeon Willem Noordenbos extended the theory of pain as an integration of multiple inputs into the nervous system in his short but classic 1959 book, *Pain.* His model of a multisynaptic afferent system was "an extremely complicated nerve net in which, within limits, everything synapses more or less with everything else." His ideas appealed to the Canadian psychologist Ronald Melzack (who had been Livingston's fellow) and the British physiologist Patrick Wall, two self-described iconoclasts who met at MIT in the late 1950s. They drew together Goldscheider's, Livingston's, and Noordenbos's ideas with the available research evidence, rethought the problem, and proposed the gate control model of pain in their now iconic paper, "Pain Mechanisms," in 1965. Although the theory itself proved to be incorrect, the implication that laboratory and clinical observations together could demonstrate the physiological basis of a complex neural integration mechanism for pain perception inspired and challenged a young generation of researchers.

THE PAIN FIELD

Drawing on the upsurge of interest in pain generated by Wall and Melzack, John Bonica organized a meeting of 300 researchers and clinicians at an isolated convent in Issaquah, Washington. Under his leadership, this conference gave birth to an interdisciplinary organization, the International Association for the Study of Pain (IASP), and a new journal edited by Wall, *Pain*, marking the emergence of pain science as a professional field. National chapters of the association have been organized throughout Europe and Latin America; in Asia, Australia, and New Zealand; and in several African countries. The American Pain Society (APS) was founded in 1977. In 2003, the IASP had more than 6,700 members, representing more than 100 countries and 60 disciplinary fields. The next 30 years saw much new research on the problem of pain, stimulated by the availability of a dedicated research journal and by regular professional meetings and opportunities for interdisciplinary discussion between clinicians, neurophysiologists, biochemists, pharmacologists, molecular biologists, and psychologists.

Two major findings have emerged from this research. First, severe pain from an injury or other stimulus, if continued over some period, can alter the neurochemistry of the central nervous system, creating a sensitization of the central nervous system and significant neuronal changes that will endure after the initial stimulus is removed and that is perceived by the individual as chronic pain. Gary Bennett and Xie Yu-Kuan demonstrated this phenomenon dramatically at the National Institutes of Health (NIH) in 1989, using a rat with a constricted sciatic nerve. In 2004, Min Zhou and a team at Washington University in St. Louis identified two enzymes in the forebrain, adenylyl cyclase 1 and 8, that play an important role in central sensitization.

The second finding is that pain perception and response differ with gender and ethnicity and with learning and experience. Women appear to suffer pain more often and with greater emotional stress than do men, but some evidence shows that they may cope with severe pain more effectively. African Americans show a higher vulnerability to chronic pain and a higher level of disability than do white patients. These observations are borne out by neurochemical research; for example, Jon Levine and Christine Miaskowski at UCSF found in the early 1990s that males and females have differential analgesic responses to different types of opioid drugs.

In another set of experiments at NIH in the late 1990s, M. A. Ruda and her colleagues showed that animals that experience pain when very young show neuronal changes at the molecular level and appear more sensitive and hyperesthetic as adults. The clear inference of these studies is that no two individuals experience pain the same way. The clinical observations of Mitchell, Beecher, Livingston, and others are thus borne out by research evidence. Pain is in the brain after all, but in a physiological as well as psychological sense.

TREATMENT

Effective treatment of many chronic pain disorders remains problematic. There are more options than in the early 1900s, when opiate drugs or disabling surgery were the only alternatives, but no one method seems to work in all cases. Morphine and its relatives, including oxycodone, hydropmorphone, meperidine, propoxyphene, and codeine, remain the most consistently effective analgesics known. Since the introduction of the World Health Organization (WHO) analgesic ladder in 1986, an international group of pain specialists and policy advocates, led by Jan Stjernswärd, Mark Swerdlow, Robert Twycross, Kathleen Foley, Vittorio Ventafridda, David Joranson, and June Dahl, has campaigned for the removal of legal and attitudinal barriers to opiate use in severe chronic, particularly cancer, pain. But many patients and clinicians associate these drugs with an unacceptable loss of mental clarity and control. Drug regulatory authorities in most countries fear diversion to the criminal market and restrict and discourage the prescription of opiates. In the late 1990s, the diversion and illegal recreational use of Oxycontin, a slow-release formulation specifically designed for use in chronic pain, prompted a new outburst of public and regulatory concern in the United States.

Surgeons have progressively refined sympathectomies and other techniques—ligature, resectioning, or crushing of the nerve fibers—for blocking the transmission of pain signals to the spinal cord and brain since the 1870s, but in the 1920s, a few pioneers, including Leriche and Livingston, advocated the use of serial anesthetic blocks as a more humane therapy for intractable chronic pain. Livingston found that multiple injections of procaine, sometimes as many as eight over a period of two years or more, often ended the “vicious circle” and resulted in permanent remission. These methods were refined by Rovenstine, Bonica, Swerdlow, and other anesthesiologists and became the staple practice of pain clinics in the United States and the United Kingdom in the 1950s.

The search for pharmaceutical alternatives to the opiates has continued. Although many morphine derivatives were isolated by the 1960s, none had been found that combine analgesic efficacy with a complete lack of addictive potential. Clinical observations in patients with depression meanwhile had demonstrated that the tricyclic antidepressants, such as amitriptyline and imipramine, could relieve headache, postherpetic neuralgia, and other types of persistent pain. More recent research has suggested a number of new pharmacological strategies to develop drugs that will block or inhibit specific steps in sensory, inflammatory, or sensitization neural pathways: These include COX-2 inhibitors and N-methyl-D-aspartate (NMDA) antagonists.

Psychologists have developed alternatives to drugs for the treatment of chronic pain, based on learning and behavioral theory. Soon after the publication of the gate control model, Richard Sternbach argued that an individual’s perception of and response to pain were learned from prior experience—and, by implication, could be relearned. In the early 1970s, the psychologist Wilbert Fordyce and his colleagues at the University of Washington developed a therapeutic program based on operant conditioning, which helped chronic pain sufferers to work their way back to normal functioning by gradually increasing levels of activity. This method has often proved successful but is expensive and requires significant time investment. Cognitive-behavioral therapy, a related modality that emphasizes the teaching of self-management skills, emphasizes the patient’s own agency. The individual who has learned to cope effectively with his or her pain, using relaxation, distraction, and controlled exercise, is able to function better, may suffer less from anxiety and depression, finds the pain less intensive and less disabling, and discovers ways to lead a productive life. Yet some observers have criticized these learning-model programs for shifting so much of the therapeutic responsibility to the patient.

PAIN IN THE TWENTY-FIRST CENTURY

As the twenty-first century begins, pain has increasing salience as a scientific and health problem. In the late 1990s, the American Pain Society (APS) popularized the use of "Pain as the Fifth Vital Sign," and a campaign led by June Dahl prompted the Joint Commission for the Accreditation of Health Care Organizations (JCAHCO) to include pain assessment as a required standard. The U.S. Congress declared 2000–2010 the "Decade of Pain Control and Research" as a result of strong advocacy by pain professional groups, such as the APS and American Academy of Pain Medicine, and patient support groups, such as the American Chronic Pain Association. The Pain Care Policy Act, reintroduced in 2005 as H. R. 1020, would establish a new National Center for Pain and Palliative Care Research at the National Institutes of Health and a national awareness campaign within the Department of Health and Human Services.

Yet most medical students still learn little about pain; many medical specialists, in fields such as cardiology, oncology, gynecology, and gastroenterology, still pay relatively little attention to their patients' pain, and despite its high prevalence and debilitating effects, there is no definitive and completely effective treatment for chronic pain.

PALLIATIVE CARE

The term *palliative care* describes an orientation to the care of persons with life-limiting illness that encompasses physical, social, psychological, and spiritual dimensions. It is closely associated with the development of hospice services and is a model of care that has operated beyond the narrow confines of the formal health care system to involve local communities, charitable and philanthropic giving, and the efforts of volunteers. Palliative care services have considerable potential to serve the needs of people with disabilities with advanced illness, although so far and in most cases, they have tended to focus on the care of those with malignant conditions, to the exclusion of those with other needs.

The World Health Organization (WHO) first defined the term *palliative care* in 1989. The most recent definition of palliative care to appear from the WHO, published in 2002, states that palliative care is an approach that improves the quality of life of patients and their families facing the problems associated with life-threatening illness, through the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychosocial, and spiritual. Palliative care provides relief from pain and other distressing symptoms; affirms life and regards dying as a normal process; intends neither to hasten nor postpone death; integrates the psychological and spiritual aspects of patient care; offers a support system to help patients live as actively as possible until death; offers a support system to help the family cope during the patient's illness and in their own bereavement; uses a team approach to address the needs of patients and their families, including bereavement counseling, if indicated; will enhance quality of life and may also positively influence the course of illness; and is applicable early in the course of illness, in conjunction with other therapies that are intended to prolong life, such as chemotherapy or radiation therapy, and includes those investigations needed to better understand and manage distressing clinical complications.

There is a global need for improved end-of-life care. Around the world, more than 1 million people die each week. It is estimated that 60 percent of these could benefit from some form of palliative care. Yet at the moment, only a tiny minority of dying people ever receive the support of hospice and palliative care services. Palliative care is hugely underdeveloped in most resource-poor countries, and it is still significantly constrained in many countries with otherwise "advanced" health care systems. There is a significant shortage of political leaders and "product champions" with an interest in palliative care and a dearth of national and international policies to promote its development. The creation of a trained multidisciplinary workforce to deliver clinical care, educational programs to support them, and an evidence base to highlight both unmet need and the efficacy of existing provision are all additional challenges. It is estimated that hospice or palliative care services now exist or are under development on every continent of the world—in around 100 countries. The total number of hospice or palliative care initiatives is in excess of 8,000, and these include inpatient units, hospital-based services, community-based teams, day care centers, and other modes of delivery.

The first attempt to develop a modern approach to hospice and palliative care was led by Dr. Cicely Saunders at St. Christopher's Hospice in South London, which opened in 1967. Based initially around an inpatient unit, soon followed by a home care service, it also delivered education programs and undertook research into the care of terminally ill people. From the outset, ideas developed there were applied differently in other settings. Within a decade, it was accepted that the principles of hospice care could be practiced in many locations: in acute and oncologic hospitals, in home care and day care services, and through ambulatory, outpatient, and "drop-in" services. Such approaches brought the new thinking about dying into the very heartlands of acute medicine and into domiciliary and long-term care settings.

Professional recognition of this emerging area of expertise was necessary if the work was to spread and the influence of hospice philosophy was to go beyond the confines of the voluntary hospice movement. Some claimed that specialization, the integration of palliative care into the mainstream health system, wider "coverage" of services, and the development of an "evidence-based" model of practice and organization were crucial to long-term viability. Meanwhile, others mourned the loss of early ideals and regretted an emphasis on physical symptoms at the expense of psychosocial and spiritual concerns. During the 1990s, there were claims that forces of medicalization and routinization were at work and even that the putative "holism" of palliative care philosophy masked a new, more subtle form of surveillance of the dying and bereaved in modern society.

At the same time, two forces for expansion were also clearly visible. First was the impetus to move palliative care further "upstream" in the disease progression and to make it available to those at earlier stages of a life-threatening illness, thereby seeking integration with curative and rehabilitation therapies and shifting the focus beyond terminal care and the final stages of life. Second, there was a growing interest in extending the benefits of palliative care to those with diseases other than cancer, to make "palliative care for all" a reality. So far, there has been greater success in the first of these; palliative care has found its way into the curriculum of health care professionals working in many settings, its services are delivered alongside and sometimes closely integrated with mainstream provision, and the palliative care "approach" is being fostered in many settings. Too often, however, access to specialist palliative care is confined to those with a cancer diagnosis.

Health and social care staff working in palliative care require training in the particular needs of people with disabilities in relation to advance health care planning, options for hospice and palliative care, and special concerns in consenting to care. People with disabilities, as well as their family members, companions, and surrogates (where applicable), require information and guidance on their rights to make informed health care decisions and on the availability of hospice and palliative care to manage pain and distressing symptoms, as well as psychosocial and spiritual distress in the context of advanced illness.

The lack of engagement between disability studies and studies in palliative care is striking. Yet both fields reveal some of the properties of social movements. In their early decades, modern hospice and palliative care services in the West were supported by wider forces: consumerism and increasing calls for autonomy among the users of health and social care; demographic trends, which created substantial numbers of individuals able to volunteer their labor in local hospices; and greater affluence, which led to an increase in charitable giving. This movement may well have contributed to a new openness about death and bereavement that was in evidence in the late twentieth century (in Britain, for example, the first person ever to be seen to die on television was in the care of a hospice). Inspired by charismatic leadership, the hospice movement condemned the neglect of the dying in society, called for high-quality pain and symptom management for all who needed it, sought to reconstruct death as a natural phenomenon rather than a clinical failure, and marshaled practical and moral arguments to oppose those in favor of euthanasia.

Hospice care and palliative care have a shared and brief history. The evolution of one into the other marks a transition that, if successful, could ensure that the benefits of a model of care previously available to just a few people at the end of life will in time be extended to all who need it, regardless of diagnosis, stage of disease, social situation, or means.

PANIC DISORDER

Panic disorder (PD), a commonly observed mental disorder affecting up to 3 percent of the general population, is one of the most disabling conditions among the so-called common mental disorders. Approximately 60 percent of people suffering from PD show a severe or moderate level of disability and reduced quality of life, with relevant difficulties in important areas such as work, social relationships, marital life, and leisure. Disability related to PD may be due to several factors. First, the nature of symptoms themselves can result in overwhelming anxiety that impairs functioning, as can the fear of recurrent attacks and the presence of "anticipatory anxiety" (i.e., the anxiety related to the expectation of a new attack). Second, the frequency of "comorbidity" with other disabling anxiety or depressive disorders, particularly agoraphobia, complicates up to two-thirds of PD cases. Agoraphobia is characterized by anxiety about being in places or situations from which escape might be difficult or embarrassing (i.e., open or restricted spaces, crowded places, travelling in a bus, etc.) and by avoidance of such situations, with a consequent, often marked, restriction in lifestyle of people affected. Major depression is a frequent consequence of untreated panic disorder, and this adds to the symptom picture and adds considerable social-occupational disability. Finally, the chronic or recurrent nature of the disorder (up to 70–80 percent of cases) often leads to suicide attempts and to reduced self-esteem, which compounds the disability.

PARALYMPICS

The Paralympic Games or the Paralympics are the international multisport competitions for athletes with disabilities, which take place every two years, alternating between summer and winter sports. Roughly 4,000 athletes from around 140 countries compete in approximately 20 sports in the summer Paralympics, while roughly 500 athletes from around 40 countries compete in approximately four sports in the winter Paralympics. The *Paralympic movement* is a term that refers to the collective parties who contribute to the worldwide development of sports for persons with a disability, from developmental to the elite sport level. Historically, the idea stems from the use of sports for rehabilitation, but due to the increased participation and recognition of sports for persons with disabilities, the Paralympics and the Paralympic movement now play a vital role in facilitating sporting opportunities for all persons with disabilities and contribute to changing societal attitudes and perceptions of individuals with disabilities. In the past 50 years, this movement has seen a significant increase, and today, thousands of athletes participate in more than 300 international competitions every year.

HISTORY OF THE PARALYMPIC MOVEMENT

In 1944, Sir Ludwig Guttmann promoted sport as a form of recreation and rehabilitation therapy for World War II veterans with spinal cord injuries in Stoke Mandeville, England. In 1948, he organized a sports competition for athletes with disabilities, and with the gradual inclusion of other countries into these competitions, the Paralympic movement began. Olympic-style games for athletes with disabilities were organized for the first time in Rome in 1960. A number of different disability groups were merged in competition in 1976, and in the same year, the first Paralympic Winter Games took place. The number of participating athletes has consistently increased at every event since.

The Paralympic Games are multidisability, multisport competitions and have become the second largest sporting event in the world, only after the Olympic Games. The Paralympic Games have always been held in the same year as the Olympic Games, and since the Seoul Games (summer, 1988) and the Albertville Winter Games (1992), they have also taken place at the same venues. In 2001, an agreement was signed between International Olympic Committee and the IPC under which the city chosen to host the Olympic Games will also host the Paralympics. The Italian city of Turin will host the 2006 Olympic and Paralympic Winter Games, and in the summer of 2008, both the Olympics and Paralympics will be held in Beijing.

The word *Paralympic* was originally a pun combining *paraplegic* and *Olympic,* but with the inclusion of other disability groups and the close associations with the Olympic movement, it now relates to *parallel* and *Olympic,* to illustrate how the two movements exist side by side. Most sports at the Paralympic Games are the equivalent to the Olympic sports, but four sports are unique to the Paralympic Games (boccia, goalball, powerlifting, and wheelchair rugby). For current information about the Paralympic sports (summer and winter), please visit the International Paralympic Committee (IPC) website at www.paralympic.org.

To create a level playing field, Paralympic athletes are classified into one of six disability groups. The six disability groups are amputee, cerebral palsy, intellectual disability, visually impaired, spinal injury, and *les autres* (conditions that do not fit into the traditional classification system). In some sports, athletes compete in a class according to functional ability, for example, in Swimming. This means that an athlete who uses a wheelchair for mobility may compete not only against other wheelchair athletes but also against amputees or those with cerebral palsy, if they have the same or similar functional ability. In Athletics, however, classification is disability specific. This means that the disability groups only compete against other athletes with the same disability, for example, amputees against amputees.

As athletic opportunities have expanded and sport for persons with disabilities has matured, so have the number of participants at all levels of competition and the individual accomplishments of athletes with disabilities. Outstanding performances by athletes at Paralympic events are often only slightly behind those of able-bodied athletes and constantly improving.

THE INTERNATIONAL PARALYMPIC COMMITTEE

The IPC is the international representative organization of sport for athletes with disabilities. It supervises and coordinates the Paralympic Games and other multidisability competitions such as the World and Regional Championships as well as developing sporting opportunities around the world for athletes of all levels.

The IPC was founded on September 22, 1989, as an international, nonprofit organization formed and run by around 160 National Paralympic Committees (NPCs) and 5 disability-specific international sports federations (IOSDs). The organization has a democratic constitution and structure, made up of elected representatives. The current president of the IPC is Phil Craven, a former Paralympian and former president of the International Wheelchair Basketball Federation.

The IPC has a number of objectives and functions. Overall, the IPC aims to promote, without discrimination, the practice of sports for people with disabilities and to seek the expansion of sport opportunities for people with disabilities from a developmental to an elite level. To achieve these aims, the organization must coordinate the calendar of international and regional competitions, liaise with the IOC and other international sports bodies, and develop and encourage educational programs, research, and promotional activities. The IPC also currently serves as the International Sports Federation for 13 of the 26 sports. Other sports are either governed by independent sport federations or are part of a disability-specific IOSD program. All of these activities allow the IPC to achieve its mission: “To Enable Paralympic Athletes to Achieve Sporting Excellence and Inspire and Excite the World.”

Until 2005, the IPC was composed of the General Assembly (its highest decision-making body); the Executive Committee; the Management Committee; the Headquarters in Bonn, Germany; and the various standing committees and commissions. In 2005, the IPC underwent some structural changes; the Executive Committee was replaced by a Governing Board, and all members of the Governing Board are now directly elected by the General Assembly. There are four advisory councils in addition to several standing committees and commissions. They are governed under a new IPC constitution and a new electoral system. This will lead the 13 IPC sports toward more self-sustainability and eventually independence from the IPC. In addition to the NPCs and IOSDs, the sports and regional bodies will also become full members of the IPC. It is hoped that these changes will allow the IPC to lead the Paralympic movement more effectively and consistently in the future.

PARALYSIS

Paralysis, the relative absence of intentional movement of a part of or the whole body, has an impact on the social order. As Harold Garfinkel teaches, the entire social world, including the built environment, is based on an upright, bipedal, mobile body, with eyes in the front of the skull. Garfinkel illustrated this to his students by taking them to Rancho los Amigos, a hospital specializing in the rehabilitation of patients with spinal cord injuries. The objective was to learn the changed spatial perspective of the patients.

There are many causative conditions leading to paralysis. Among these conditions are stroke, spinal cord injury, a wide variety of congenital and neuropathic conditions and diseases, brain injury, and a host of other causes.

Paralysis is highly variable. Some people have a contracture in the shoulder and cannot move an arm. Others may suffer arthritis in the hip and cannot use a leg. Still others suffer from systematic neurological disease or injury and are totally dependent on others for movement, eating, toileting, cleaning, communicating, and, in some cases, breathing. For the most part, those who are totally dependent on others are the focus of this entry, which details the social impact of living within a paralyzed body. First, conversation and gaze will be topicalized. Second, lack of mobility will be discussed. Finally, the hope of practical sociology will be elaborated on behalf of paralyzed subjects.

This entry focuses on the interactional difficulties that have devastating economic consequences for totally and dependent paralyzed people. Most dependent paralyzed people lose their jobs and company or institutional medical insurance. The income stream plummets. People have to sell their homes and draw down their financial assets. Then, they move to apartments, often publicly assisted, and change to public medical insurance. These apartments are far from family support and lead to a sense of isolation and acute depression.

Families of dependent paralyzed subjects, who suffer the evaporation of financial resources, are extremely fragile in the United States. There is a frequent expression of resentment and cruelty toward paralyzed subjects. Some family members deal with their feelings by ignoring the subject, even when the subject requests assistance. Some declare ignorance as an excuse for not assisting in the care of paralyzed subjects. The care often falls on the parent or spouse. These caretakers are isolated within their family and suffer from the absence of psychological help and physical help.

CONVERSATION AND GAZE

General Properties of Being Voiceless

Paralysis of the voice and sound-making muscles radically distances the subject from participating in the social world. The paralyzed subject cannot solicit and maintain the attention of others by making sounds. Since the majority of social institutions are accomplished by speech, the paralyzed subject is routinely left out of these collaborative enterprises (e.g., conversations, parties, family, medical care, employment, organizations, friendships, banking and investment, and a host other everyday routines).

Here are some examples. In the daily flow of domestic activity in a house or apartment, the body without a voice quickly gets routinized as an object with no social reference. No one informs the body without a voice what is going on in the other parts of the dwelling and what people are doing. People will pass by, their eyes averted, and not address the voiceless. Questions about activities in the house, communicated by alternative means, are treated as pesky and are not answered. The subject without a voice soon comes to see himself or herself as treated like a piece of furniture.

Not only is the paralyzed subject removed from the ongoing interaction in the house, but the voiceless is subject to actions that are determined by others and not sanctioned by the voiceless. The voiceless subject will be moved, told "you are crooked," and then quickly and sometimes violently moved into the caretaker's perceived appropriate position. This will happen regardless of whether the voiceless subject is comfortable.

The caretaker(s) will frequently substitute their own judgment for that of the voiceless subject. The subject will be told he or she is fine and in no need of action, when in fact the subject is in immediate need of action. The words "you are fine" are often uttered in the face of an apparent request for action. Substitution of judgment can take many permutations, with people speaking and acting for the paralyzed subject without permission. The result is a decrease in the subject's autonomy.

If the subject demonstrates any displeasure with the failure to take proper action, such as getting red in the face or shaking the few working muscles, the caretaker will often infantilize the protest. The subject will be told, "You are not being a good boy." Caretakers will collaborate in characterizing the subject as "not a good boy" in endless rounds of conversation.

Adverse characterizations of the subject or patient are frequent in caretaking but routinely overlooked. Caretakers' utterances of phrases such as "you would be better off dead" or "death will be a gift" are not infrequent. Subjects' wives, husbands, children, and extended family members are not immune from getting involved with the talk of death, uttering phrases such as "why don't you just die!"

This kind of talk and reflexive attitude can infrequently lead to violence against and even the death of the paralyzed subject. Violence is usually written off as a result of stress, and there is certain stress within the family of the paralyzed subject. However, the focus on stress misses the widespread ambiance of the rhetoric of resentment, burdenship, and anger. Beyond the family and friends, this rhetoric of denunciation and violence seems widespread in general American culture.

Conversation

Sometimes, conversations are essential and cannot be avoided. If the paralyzed subject is lucky enough to be employed, most often in his or her preparalyzed position, the work product is produced by communication. Those who use the strength of their bodies are disqualified from employment as soon as they become paralyzed. Truck drivers, construction workers, repairmen, waiters, professional athletes, restaurant cooks, and others are out of luck if they become paralyzed. Only knowledge workers can continue to be employed after paralysis.

Knowledge workers, or those who are not employed in positions of physical labor, produce and distribute knowledge. Such work requires attending meetings and engaging in conversational interaction with others. The work is often computer based. Subjects with spinal cord injuries who can talk are able to do most of this work. Spinal cord injuries, especially at a lower level in the spine, do not affect the ability to carry on conversations. Those who suffer from neurological diseases or conditions that more generally affect movement in the body, including speech production, face a predicament in the information business. They cannot enter into conversations, produce utterances, or verbally acknowledge what they are told.

Conversation is a series of sequentially arrayed turns at talk. The turns are temporally tight, meaning there is no gap between them. The lack of a gap is a mutually read indication that each speaker is referring to the last turn or a formulated previous turn. The pace of natural conversation presents a huge problem for those who rely on computer-assisted speech and the few who use lipreading as their form of communication. Most people see computer-assisted, synthesized speech as a panacea for people with damaged speaking abilities. First, the person cannot type fast enough to keep up with the pace of conversational turn taking, with the exception of "yes" or "no." Any elaborate response cannot be formulated quickly enough to be designed to the previous turn at talk.

Some suggest that responses to verbal exchanges can be designed in advance. But stock answers do not respond to the particular verbal formulation of a questioner. Stock replies do not have built-in recipient design: The formulator of a question or a turn in conversation can easily anticipate the next turn at speaking, an answer built specifically to the previous turn at speaking, or to the inquiry. Preformulated turns at talk cannot adapt to the particular words used and to the specific setting of a verbal exchange. These predesigned turns at talk feel like heavy weights, encumbering natural conversation.

The ability to type is variously affected by paralysis. Some have full use of their arms and hands and can type as quickly as they are able. Such individuals have fewer problems keeping up with the pace and reference of a conversation. Others, including those who have neurological diseases or brain injuries, have more impaired arm and hand-finger movement.

Typing may be limited to a single finger input, to a scanning of words or letters. An orally held stick that is pushed onto letters on a keyboard may be used as a typing device. Head movement can be used to input letters; blinking of the eyelids can be used to input letters. There is a growing amount of technology that comes to the communicative aid of paralyzed people.

Still, despite these advances in technology, alternative computer input devices are painstakingly slow and cannot keep up with the pace of natural conversation. These devices, as cleverly engineered as they are, are frustrating to use because the conversational pace moves so quickly: By the time the computer speaks, the interlocutors have lost the specific turn at talk, and the reference of the comment is tapped out by an alternative device.

Finally, there are those paralytics who rely on lipreading to communicate. Lipreading is not fast but offers the maintenance of mutual gaze between conversationalists and the expression of facial gestures, intensifying the communication and slowing down the transition to the next turn at talk. Lipreading requires a lip-signer and a lip-reader, a person who assembles words or letters into sentences and then speaks the sentences on behalf of the lip-signer. This person is usually called a translator and is a side participant in the ongoing conversation. The translator can often connect the paralyzed subject's slowly formulated turn at talk to a previous turn at talk, to which the paralyzed subject designed his or her response. The role of an effective translator is difficult because the translator has to keep track of the ongoing conversation and translate what the paralyzed subject wants to say at the same time.

Translators can be great facilitators of communication, but it is also possible for translators to interfere with what the paralyzed subject intends to say. Once the translator becomes familiar with the subject's thought patterns, phrases, and vocabulary, the translator can and often does answer inquiries posed to the subject without getting input directly from the subject. This often leads to charges leveled by the subject that translators are speaking for him or her, saying things not intended. Control of communication is a continuing issue for paralyzed subjects.

MOBILITY

Paralysis is a big problem in a world constructed on mobility: in houses, offices, educational institutions, markets, planes, trains, motor vehicles, and social relations. As mentioned earlier, the whole constructed world is based on an upright postured and bipedal individual. Paralyzed subjects face a deficit in this world.

The paralyzed subject in a wheelchair, as well as his or her caretakers, becomes cognizant of every surface feature—for example, sand, grass, up and down hill angles, steps, rugs, step-downs and step-ups, uneven sidewalks, ice and snow, oil, curbs, edges of sidewalks, and other terrain. All of these details constitute hazards to safe wheelchair transportation. Nearly every wheelchair occupant has experienced being dumped out of the chair, landing violently on the concrete.

Just as automobile drivers are of varying quality, wheelchair pushers are spread out along the quality continuum. There are some pushers who regularly go over curbs and sidewalks, letting the wheelchair turn over. Others appear to have a spatial perception problem, regularly driving the paralyzed subject's knees and feet into walls and tables.

Often, those who push wheelchairs lack the American middle-class sense of personal responsibility and may repeatedly push the paralyzed subject's knees into solid objects. Wheelchair pushing often becomes an instrument of cultural and class differences.

Because the paralyzed subject cannot move, transfers are another area of danger for the subject and those who perform the transfer. The sites where transfers commonly take place are from wheelchairs to bed, from wheelchairs to the shower and toilet, and from wheelchairs to easy chairs. Paralyzed subjects frequently are dropped, and those facilitating the transfers hurt their backs and joints. Fortunately, there are mechanical lifts that help those who perform transfers to avoid the danger of injury. However, not all people can afford mechanical lifts.

Difficulty in movement contracts the spatial and social world. Previous routines of shopping, going to the bookstore, seeing a movie, going on vacation, and going to parties, barbecues, supermarkets, and meetings are seen as gigantic achievements. As such, they are avoided personally and perceived as an avoidable drain on caretakers. Despite this trend to avoid the above social situations, the paralyzed subject may desire to go to parties, for example. However, invitations are few, and when they come, they have the caveat, "I have steep steps to get into my house." Nevertheless, there are certainly enjoyable occasions at wheelchair-accessible houses and at hotels. But for the most part, there is a perceivable decline in invitations to social events. If the paralyzed subject had been a partygoer before, a feeling that one's social life has collapsed is inevitable.

The cure for feeling isolated and estranged from social life is to open one's home to parties and family social gatherings. Assuming the house has been modified to the requirements of a disabled, paralyzed person, it is a wonderful place to enjoy the fruits of social gatherings. However, remodeling houses for the disabled takes significant amounts of money. Few paralyzed subjects have access to these financial resources.

PRACTICAL SOCIOLOGY

Paralyzed subjects are great practical sociologists. They quietly and repeatedly observe the everyday routines of their households and of the individuals who are their caregivers. They are absorbed by these routines and family activities because they can interfere with getting attention. It takes attention and regard to participate in social settings. Getting this attention and participation is often problematic for paralyzed subjects.

Most paralyzed subjects did not realize before paralysis how much household activity is repeated in the same way, even institutionalized. This includes the routines of going to the toilet, preparing and eating food, reading the daily newspaper, cleaning rooms, going to bed and waking up, and the various tolerable limits in being called by the subject. There are certain times that are off limits, when the subject cannot call a caregiver, such as sleeping, no matter how many hours, and eating, showering, toileting, and free time.

Even gaze patterns are socialized. For most people, gaze is embedded in the project at hand because people have limited peripheral vision. Peripheral vision is developed through circumstantial training, such as hunting or operating a small sailboat. Paralyzed subjects notice how directed gaze is to the task at hand. They experience repeated frustration with signaling and maintaining mutual gaze. They attempt to set a behavioral code, such as the violent shaking of the head, as a solicitation for mutual gaze. However, this code is frequently overridden by emerging circumstances. The code is practically useless.

The situational opportunity for paralyzed subjects to develop into practical sociologists provides some hope and an instrumental sense of life. From observation and memory, they can anticipate problem settings and instruct their primary caregivers to ensure successful participation. They can also communicate what not to do. These "not to do's" have to be communicated neutrally and in a gingerly fashion, avoiding any sense of personal attack.

Although not every paralyzed subject has the patience and sense of a growing base of knowledge, practical sociology is the best way to avoid and repair most of the dire circumstances described here. Practical sociology does not require formal education in sociology, but it assumes a contemplative attitude. However, paralysis is often the harbinger of contemplation.

PARENTAL ADVOCACY

An advocate is defined as "one that pleads in another's behalf" and is often compared to a lawyer (*American Heritage Dictionary of the English Language* 1992).

In the case of parental advocacy for children with disabilities or special needs, the advocate is often responsible for pleading on behalf of a child from multiple perspectives. A traditional perspective would assume that the parent is responsible for "pleading on behalf" of the child in tandem with professional therapist(s) (e.g., the assumption being that there is only one perspective to consider, that of the child's success and "cure"). Current approaches through the field of disability studies allow for the incorporation of multiple perspectives on a "cause." By promoting parental advocacy, we can ensure that perspectives on the individual as a child, a family member, and a student or learner, as well as a person with a disability, are respected.

The treatment of children with disabilities has long been an issue requiring parental advocacy but has only recently been legitimized through public policies relevant to education and quality of life. Reading historical documents serves as a reminder of just how recently individuals with disabilities were stigmatized, and significant assumptions were made regarding future capabilities and life trajectories, based on initial status at birth or diagnosis at a young age. Parents were often encouraged to "give up" on their young children with disabilities and to "cut their losses" by institutionalizing children. A growing realization on the part of both parents and educators that such programs often were not in the best interests of the child and family has resulted in legislation that guarantees a "free and appropriate" education "in the least restrictive environment" to children age three and above and encourages states to identify high-risk children and children with disabilities from ages zero to three as well.

The growing fields of disability studies, special education, and child development/developmental psychopathology have all begun the process of researching how one determines the best educational programs for children across a wide range of developmental concerns and disabilities, but there is much work to be done in documenting which programs work for whom and how different programs meet the specific concerns of children and their families in terms of both educational and functional success. Within this cultural context (a relatively new area of study, with limited data on program success), what is the best way for parents to advocate for children and families?

PARENTAL ADVOCACY NEEDS

For any advocate to plead one's case, he or she needs information. This applies to parents of children with special needs in a broad variety of arenas. We compiled the following list of *some* types of information required by parents to be effective advocates for their own child and family:

Disability-specific information (the ability for parents to get such information will vary dramatically based on their child's identified special needs, as well as the age of the child. In some cases, diagnoses of children will not be made until the grade school level, if at all, making appropriate information-seeking difficult if not impossible.)

Knowledge of public policies and the child and family's legal rights, as well as the changes with age (Section 504 or the Rehabilitation Act; the Individuals with Disabilities Education Act [IDEA] and its components, including Individualized Educational Programs [IEPs]; Least Restrictive Environment; the Family Education and Privacy Act [FERPA]; most recently, the No Child Left Behind Act [NCLBA] and its implications for special education students; and potentially many other relevant policies dependent on the child's disability)

School district–specific information (within the legal parameters of the policies mentioned above, what are the offerings of the family's home school district? What is the range of possible placements? How do they change from pre-K to primary to middle and high school? How does the school district deal with behavioral or discipline issues for children with IEPs? How are children made eligible for special services within the district? How are school year programs extended through the summer to provide continuity? How are school or program transitions handled within the district? What types of assistive technologies are available?)

Statewide policies (statewide assessment, qualifications for state funding and special education initiatives)

"Out-of-the-box" information—Many types of "suggested" programs for children with special needs

(particular types of massage, yoga, or physical therapy for motor-related disabilities or regulation disorders; particular listening therapies for sensory or auditory processing disorders; etc.), as well as general programs of enrichment (music, fine arts, etc.), may be useful. Parents need information both about offerings of these programs, as well as data on effectiveness/actual effectiveness, and whether any data are available.

"Impact" and networking information—Finally, parents often find it useful to know about supportive services and resources in their own community (e.g., parent support networks) and more nationally (informational websites or chat groups).

As should be obvious from above, there is an overwhelming amount of information required to be an effective parental advocate for a child with special needs. Making the job even harder are some of the emotional issues regarding parental advocacy. Most parents did not expect to be raising a child with special needs, and there is a significant adjustment period required to cope with discovery of the child's needs. When one seeks information or services for a child with special needs, one suddenly enters a world of experts, from varying disciplines, with much jargon. Many parents are afraid of asking the "experts" questions, either because of potential reprisal (perhaps the district or private professionals will not treat my child nicely if I am seen as a "difficult" parent) or due to discomfort with feeling or being perceived as "stupid." Through parent information and support groups established throughout the country and funded by the federal government, parents are learning how to share information about their child with special needs, ask questions of professionals and school personnel, and bring relevant and important information about their child to the table.

Parents play a key role in providing information about the child's abilities, strengths and weaknesses, and interests. They have a unique expertise with regard to their own child and his or her role in their family. Parental insights complement information obtained by the school or the service provider and provide a broader picture of the child's capabilities and needs. Identifying specific ways for parents to be involved in the process is essential for developing a good educational program. The importance of collaboration on the part of parents and professionals, as well as key advocacy roles for both groups, cannot be overemphasized.

WHEN ARE PARENTAL ADVOCACY EFFORTS NEEDED?

Although parenting and advocating for a child is an ongoing process, there are certain distinct times when particularly intense efforts are needed. For example, two such times are (1) the period during which identification or "diagnosis" of a child's special needs occurs and (2) the yearly review or IEP meetings that document a child's educational progress and form plans and goals for the coming educational year. In addition to these two times, there is the ongoing supervision of the child's program, in terms of both meeting the child's educational and experiential goals, as well as the effect of the program on the child and family.

IDENTIFICATION OR DIAGNOSIS

In some cases, identification of special needs occurs at or prior to birth. In other cases, there is a growing realization either on the part of the parent or in an initial preschool or primary school experience that something is just "not right." Many parents discuss having gnawing levels of concern regarding specific behaviors, only to be reassured by pediatricians or other medical specialists. This is in part due to the very broad range of behavior in early development, which makes more subtle variations that may be indicative of special needs harder to detect. Most special educators, parents, and textbooks dealing with this issue recommend that in a "gray" instance, primary care professionals refer parents to early intervention specialists who can conduct evaluations and either reassure parents or provide needed services.

It is also the case that the reverse can happen—professionals at school or medical professionals can notice possible areas of developmental delay or learning differences and raise concerns to parents who have not yet been concerned (anecdotally, many parents of firstborn children with special needs mention this and state they had no "barometer" on which to judge their child's differences).

Once a developmental delay or other learning or social, emotional, or behavioral issue has been identified, parents are likely to be provided with a referral for evaluation. Key components of the parents' job at this point are twofold: (1) coordinating all needed evaluations and (2) providing accurate and complete information as part of the evaluation process. In general, gathering reliable data from children can be difficult; this is true for typically developing children and even more so for children with special needs. Indeed, the more profound the special need, the more potential for misinterpretation of child behavior and communication attempts. This makes the parents' role as "data provider" all the more essential. A good evaluation should include a parent interview both regarding the child's general abilities (birth history, meeting of developmental milestones, etc.) as well as a sense from the parent of just how typical the child's behavior has been during the evaluation and whether the child has demonstrated his or her true abilities, knowledge, and learning styles.

YEARLY REVIEW/IEP MEETINGS

Once a child is "in the system" (e.g., has received a detailed evaluation and been determined eligible for services), an initial IEP meeting will be held to create the child's program for the current or coming school year. In subsequent years, annual reviews and/or IEP meetings will be held to document progress toward educational goals and to form plans for the coming year. Parents must be notified about this meeting and may make plans to attend along with any key individual or individuals they would like to bring.

For most parents, IEP meetings are among the most stressful places they find they must advocate for their child. Anecdotally, many parents cite as particularly stressful the "litany" of data about their child and the technical format, focused primarily on weaknesses rather than strengths, given that the purpose of the meeting is to define need for services. Many parent information centers offer training on preparing for a meeting, particularly on the art of representing your child and family, as well as the importance of asking questions and getting accurate information. In addition, websites and information centers provide detailed checklists for preparation for IEP meetings, as well as reinforcing particular aspects of the family's rights (e.g., timing of information and receipt of reports, ability of parents to attend a meeting but withhold signature until all information is satisfactorily available for the child's program, etc.).

In summary, this entry merely scratches the surface for key factors underlying the necessity of parental advocacy in forming appropriate educational and quality-of-life goals for children with disabilities. Key needs of parents for information and support are discussed, as well as key times when parental advocacy efforts may be most important. An additional critical factor to be considered is the importance of advocacy and collaboration from other sources, such as the school and the community. A critical factor in future efforts should be the collection of evaluative data, both by individual and group methods, to ensure that we are all advocating for the best possible start for our children.

PARENTAL NARRATIVES

Mrs. Merrick explained that the appearance of her son, known as "The Elephant Man," was the result of her being frightened at a Victorian circus; Carry Nation explained that her husband's drinking led to their daughter's many health problems; Michael Bérubé explained that his son's Down syndrome was determined by the random replication of chromosomes at his conception. In all eras, parents of children with disabilities have explained. They have written and spoken their explanations as parental narratives, a genre somewhere between autobiography and biography, between memoir and witness. It is an enduring genre, often sharing shelves with adoption stories, mourning parent stories, and other vernacular efforts to recall the process of loving a child through unusual or difficult circumstances.

Several categories of parent narratives of disability can be identified. Inspirational or sentimental narratives are generally upbeat, intended to comfort and encourage others, especially other parents but also a more general readership, which may account for the frequent success of such books. A classic in the category, Dale Evans Rogers's *Angel Unaware,* published in 1950, was a best-seller for years; its frankly religious tone can strike many readers today as heavy-handed, but the book's ultimate message—that Robin Rogers's short life was worthwhile, her presence in the home a joy to her parents—countered medical advice and even other parents' more tragic constructions of disability in mid-twentieth-century America. The latter category, the parent confessional or pathographical narrative, is personal to the same degree as sentimental narratives but with the intent of warning other families and sharing grief. Heartbreaking accounts of learning the child's "hopeless" diagnosis are characteristic of this genre, for example, in Pearl Buck's *The Child Who Never Grew* (1950) or Michael Dorris's *The Broken Cord* (1989). Other parents take a more practical how-to approach to their story, attempting a more neutral voice as they pass along advice to a readership of new parents. Charles R. Callanan's *Since Owen,* from 1990, is among these works. Finally, more and more, some parents use their experience with a disabled child as a springboard toward exploring broader social or philosophical issues. Kenzaburo Oe's (1995) *A Healing Family* and Michael Bérubé's (1996) *Life as We Know It* are two recent exemplars of this approach. All these categories share the underlying impulse to say what others cannot or will not about disability and its effect on family life.

Such testimonies are not universally embraced. They are dismissed as unreliable evidence or, at best, anecdotal, imprecise, and self-serving documents. The ethical problem of consent is raised: Is the disabled child capable of giving informed consent for very personal details of her or his life to be revealed in print? And if so, is the parent's role too powerful, the relationship too emotionally fraught, to allow that consent to be given freely? Other critics fear that such narratives will be taken as sufficient substitutes for firsthand accounts of disability. Still others find that, by the time a parent is ready to write a memoir, his or her advice may no longer be useful to a new generation of parents encountering a much-changed landscape of laws, programs, and social attitudes.

Others, however, see parent narratives of disability as serving an array of useful functions. As Rapp and Ginsberg (2001:543) point out, because "the knowledge of what is entailed in caring for such children remains absent from the mainstream discourse, underscoring a sense of social segregation or stigma," parental narratives may bridge a destructive gap in common awareness. Parental narratives written in or recalling earlier times may work as a record of past conditions, valuable to historians but also to policymakers seeking models or measuring change. Parents themselves often report that the writings of other parents are more accessible, supportive, and relevant to their day-to-day decision making and coping than other formats, and parental narratives have historically encouraged, or even (in the case of *Angel Unaware*) directly funded, parent advocacy on behalf of social inclusion and community-based programs. As parental narratives are often (but not always) written in the context of developmental disability, they may add to a literature otherwise short on vernacular accounts.

The parental narrative literature is well developed in the United States and seems to continue growing: In 2002 alone, at least a dozen new parental narratives were published by American presses. Furthermore, online support groups are inviting millions of connected parents to tell their stories to each other, through listserv posts and web pages, unmediated by editors or publishers. What is less common is the parental narrative written in a non-Western cultural context (Kenzaburo Oe's work being a notable exception here); parents in emerging economies, finding their traditional sources of support lost without a strong system of alternatives in place, cannot access a rich array of published narratives for making sense of their circumstances. A wider range of cultural stories would also work to place existing Western narratives in a broader context than is now fully possible. Another opportunity for comparison is beginning to emerge in narratives written by adult children about their parents' disabilities (for example, Alzheimer's), a reversed situation that may produce an equally intense literature. The dimensions of intimacy, caregiving, and power inherent in family life, as they are experienced in the presence of disability, will thus long remain a fertile, complicated, and ethically challenging source of personal narrative.

—Penny L. Richards

▣ PARENTING

A common misconception is that there are relatively few parents with disabilities. This assumption appears to perpetuate social obstacles—a lack of appropriate and accessible resources for parents with disabilities and their families. In fact, in the United States, parents with disabilities represent 15 percent of all parents of children younger than age 18. However, 24 percent of single parents, 18.7 percent of African American parents, and 16.3 percent of Hispanic parents have disabilities.

There is an overall lack of detailed national, regional, or local data on U.S. parents with disabilities and their children. Targeted national disability surveys, such as the National Health Interview Survey, focus primarily on the impact of the adult's disability on major life activities—such as work, education, managing a home, or personal care—but do not investigate the impact on parenting activities. As a consequence, national disability statistics provide only broad estimates of the numbers of disabled parents but little detail about their family lives. In addition, disabled parents and their children remain invisible in most public and private data systems' tracking services to parents or disabled adults in the United States. As a result, the need for specialized or accessible services for parents with disabilities tends to be underestimated.

An analysis of the 1993 Survey of Income and Program Participation, U.S. Census Bureau data by Linda Toms Barker and Vida Maralani, distinguished disabilities in parents as 40 percent sensory, 26 percent physical, 24 percent psychiatric, and 16 percent cognitive. The literature on parents with disabilities reflects a tendency to overgeneralize about them, often in a pathological direction. That is, negative assumptions about parents with emotional, psychiatric, or cognitive disabilities are generalized to parents with physical disabilities. Concerns about parents with acute disabilities such as a recent spinal cord injury are generalized to parents who have long-term stable disabilities, with coping skills and resources that have developed over many years. A focus on variation in disability issues should not obscure the profound effect of cultural, environmental, and psychosocial issues in the lives of parents with disabilities.

Unfortunately, parents with disabilities and their children face many social obstacles: Public policy and appropriate resources lag far behind the social changes that have led to the apparent increase in the numbers of parents with disabilities. The largest study on parents with disabilities to date was done for Through the Looking Glass by Maralani and Toms Barker and yields data from a national sample of 1,175 parents with disabilities. Although participants in the study tended to have more education, employment, and income than most individuals with disabilities, 23 percent had household incomes under $15,000 and 43 percent under $30,000. The many social obstacles and the lack of public resources mean that parents with disabilities and deaf parents in the United States face more out-of-pocket costs than other parents, while their incomes are lower.

In the national survey, transportation was cited by 83 percent as a problem for them as parents. Problems in housing accessibility was another key area that affected parenting. Another access problem was identified regarding adaptive parenting equipment, such as adapted cribs. Such equipment is still essentially unavailable on the market and is seldom reimbursed by public or private health or disability funding systems. Of the 240 parents answering what prevented them from obtaining such equipment, around half did not know how to find information about such equipment and had no way to pay for it. During pregnancy or childbirth, 62 percent of parents had found a lack of disability expertise on the part of professionals, attitudinal problems, and/or interference in the right to become a parent.

Deaf parents also report social obstacles. Ninety percent of deaf parents have hearing children and face significant communication problems with their children's schools, as well as a lack of culturally and linguistically appropriate services for their families.

Mothers with disabilities may face more complex social obstacles. Research by the Center for Research on Women with Disabilities (CROWD) at Baylor College of Medicine found that women with disabilities in the United States are more likely to remain in abusive relationships due to dependency. They report longer durations of physical and sexual abuse compared to women without disabilities and different forms of abuse, such as the withholding of personal assistance or adaptations. Intervention programs report that trauma and abuse experiences are particularly prevalent in mothers with intellectual disabilities. Despite these problems, CROWD research found that traditional shelters and agencies for battered women were generally not accessible for women with disabilities. Specialized services for mothers with disabilities in the United States seldom effectively address trauma issues.

In the U.S. survey of parents with disabilities, it was particularly concerning that 16 percent of these predominantly physically disabled, well-educated middle-class parents reported efforts to remove children from their custody. The literature on parents labeled with developmental disability cites a 25 to 60 percent rate of removal of their children. While 28 percent of adults labeled with "developmental disability" or "mental retardation" have children, only 14.4 percent of these adults have children living with them, apparently reflecting this high removal rate.

Through the Looking Glass's National Resource Center for Parents with Disabilities has identified significant problems in family courts and the child protection system for parents with disabilities. In child protection systems, there has been a tendency to assume that parents with cognitive or emotional disabilities cannot parent or benefit from services, based solely on their diagnoses. In family courts, there is often the assumption that marital custody by a parent with a physical or vision disability is "not in the best interest of the child," even when the primary relationship is between this parent and child. Both systems often do not evaluate actual parent-child interaction (or do so inadequately) and are unaware of disability adaptations, community supports, and relevant research. These problems are compounded by the lack of disability-appropriate preventive intervention in the United States. Similar problems in practice have been described by Gwynnyth Llewellyn in Australia (see McConnell and Llewellyn 200) and Tim and Wendy Booth in England (see Booth and Booth 1994).

The National Task Force on Parents with Disabilities in the United States has identified additional underlying social obstacles. Policies, programs, and funding streams tend to focus only on the parent or the child, rather than emphasizing the family as a unit. Relationships and interaction between parent and child should be more of a focus in research, evaluation, and services. Personal assistance services (PAS) usually only serve the individual with the disability but will not provide any assistance related to care of an infant or child. Both PAS and the availability of parenting adaptations are affected by the lack of inclusion of baby care or parenting as an "activity of daily living."

Since parents with disabilities are faced with so many social and environmental obstacles, adaptation emerges as a theme in their everyday family lives. In the 1980s, Through the Looking Glass documented the natural reciprocal adaptation process between parents with physical disabilities and their babies. This research evolved into a number of studies focused on developing and evaluating the effect of baby care adaptations for parents with physical disabilities. The studies found that such equipment can have a positive impact on parent-baby interaction, in addition to reducing difficulty, pain, and fatigue associated with baby care. By reducing the physical demands of caregiving, the equipment can be instrumental in preventing secondary disability complications. Prevention of secondary injuries prevents additional stress on the parent-child relationship. The equipment has also appeared to have a significant role in preventing or alleviating depression associated with postnatal exacerbation of disability, such as in multiple sclerosis. The research and clinical experience with parenting adaptations makes it clear that one cannot assess the potential of a relationship between a parent with a significant physical disability and an infant without first providing whatever adaptive techniques and equipment make it possible for interaction to occur and the infant-parent relationship to develop.

The incorporation of cognitive adaptations into prevention services for parents with intellectual disabilities has also been clinically documented as crucial to effective practice. Adaptations in communication are essential when evaluating or intervening with parents with cognitive or learning disabilities, visual disabilities, and deafness. Without adapted communication, parents may be mislabeled as "unable to benefit from services" and therefore vulnerable to loss of custody. Inappropriate and disrespectful services can create rather than resolve problems in parenting by individuals with intellectual disabilities. The Booths have eloquently described such problems with practice in England (Booth and Booth 1994).

Adaptations can remove disability obstacles to fair evaluation and effective services for parents with disabilities and their children. Disability-appropriate early intervention can achieve positive outcomes even in the most stressed families.

Parents with disabilities and their children demonstrate resilience and adaptability in the face of considerable social obstacles. However, parents with disabilities and their children are much more alike than unlike other families; parenting is about loving, guiding, caring, and nurturing, disability status aside.

PARKINSON'S DISEASE

Parkinson's disease (PD) was described in 1817 by James Parkinson, a London physician, whose "Essay on the Shaking Palsy" reported his observations on six patients. It is a disease of the brain characterized by degeneration of nerve cells (neurons) in an area of the midbrain known as the substantia nigra, which produce the neurotransmitter dopamine and transport it to the basal ganglia. The latter are paired groups of nerve cells in the base of the brain involved with movement. Parkinson's disease typically begins between ages 55 and 60 years. It is a common disease, affecting 1 to 3 percent of those older than age 60, and each year, between 5 and 25 new cases per 100,000 population are diagnosed.

The diagnosis is made be observing the characteristic signs described by James Parkinson. The classic triad includes slowness of movement (bradykinesia or akinesia), a slow tremor of the hand at rest, and a ratchety-like resistance when a limb is passively moved, known as cogwheel rigidity. Additional features include small handwriting (micrographia), a flexed posture, decreased facial expression, a soft-monotone voice, shuffling gait, and, as the disease advances, impaired balance with falls.

The cause of most cases of PD is not known. Approximately 5 percent of patients have PD on a primary genetic basis. These include an autosomal dominant gene, which codes for the protein α-synuclein, among others, and the *parkin* gene, which causes autosomal recessive, young-onset PD. Yet, most cases of PD are sporadic, and genes appear to play a contributory role but are not directly causal. Epidemio logic studies have demonstrated that environmental factors, such as being raised in a rural environment, drinking well water, having a prior head injury, and exposure to pesticides, are putative risk factors for PD, but none has been shown to be directly causal.

The treatment of PD is based on the deficiency of dopamine in the basal ganglia. The mainstay of therapy is levodopa, which is converted to dopamine by the remaining nigral neurons. It is combined with carbidopa to prevent nausea. As PD advances, the response to levodopa diminishes, and many patients no longer have a smooth transition between dosages, leading to fluctuations. During periods when levodopa is working, there is relative freedom of movement, alternating with times when levodopa does not work, characterized by an exacerbation of symptoms, including immobility. These fluctuations, known as "on-off," are further complicated by periods when there is an exaggerated, unwanted response to levodopa, producing excessive twisting movements known as dyskinesias.

In addition to levodopa, a number of other therapies can either be used alone or as adjuncts to levodopa. Dopamine agonists work directly on the dopamine receptor and, like levodopa, are often used as initial therapy. Anticholinergics are the oldest agents used for PD and help restore balance in the basal ganglia between dopamine and another neurotransmitter, acetylcholine. Amantadine is an antiviral agent, which was discovered serendipitously to have antiparkinsonian activity. Other medications are available to enhance the effectiveness of levodopa. When the symptoms of PD, particularly movement fluctuations, cannot be controlled adequately with medication, surgery is an option for selected patients. This involves inserting a permanent electrode into the basal ganglia and connecting it to a battery, a procedure know as deep-brain stimulation.

With modern therapy, most people with PD live a normal or near-normal lifespan. Yet, disability increases as the disease advances, while its rate and degree vary greatly among patients. There are currently no treatments that slow progression, but that is one of the most active areas of research. Throughout the course of PD, medical and surgical therapies are enhanced by rehabilitation directed at improving strength, flexibility, endurance, gait and balance, speech, swallowing, and the activities of daily living.

Although motor problems and their treatment are the main focus of managing PD, equal attention must be paid to the psychological and cognitive well-being of patients, as well as the needs of caregivers. Depression is very common in PD and is considered to have an organic basis and not simply a reaction to disability. With advancing disease, many patients develop cognitive impairment and often frank dementia, further contributing to disability and caregiver distress. The diverse and progressive symptoms and signs of PD emphasize the importance of a multidisciplinary approach for successful management.

PARTICIPATION

Participation has become a core concern of disabled people and disabled people's organizations because of the discrimination, barriers, and segregation that historically they have experienced and seek to overcome. Disabled people's political participation can only adequately be understood within a broader understanding of ideas of participation. *Participation* is a complex, ambiguous term without an agreed-on definition, to which disabled people have added their own meanings. Disabled people internationally have developed three particular focuses for their participation. These are as follows:

> participation in the support they receive, to ensure it meets their needs and is consistent with, rather than restricts, their human and civil rights (this aim is embodied in the disabled people's development of the international independent living movement);
>
> participation in society more generally, to ensure that disabled people are able to live in mainstream society on equal terms with nondisabled people, with equal access to mainstream employment, education, health, and other services and opportunities, instead of being segregated in separate structures and provision;
>
> political participation, to afford disabled people the same democratic rights as nondisabled people and equal opportunities to influence and take part in public life. These concerns are reflected in the rights-based approach of the disabled people's movement and its emphasis on disabled people's rights and responsibilities based on equal citizenship.

THE NATURE OF PARTICIPATION

Participation implies active involvement in the public and social sphere and refers to a range of involvements that individuals and groups may have in organizations, institutions, and decisions affecting them and others. There are many approaches to and understandings of participation and involvement. These have most often been framed in terms of the degree of involvement people have—from zero to control; from tokenism, through consultation, to a primary say in decision making. This was notably expressed in Sheri Arnstein's (1969) "Ladder of Citizen Participation." Participation is crucially judged by the extent to which people can exert influence and bring about change.

The concept of *public participation* developed in the context of land-use planning in the 1960s, became a key concern of community development, and is central in a growing number of discussions and developments, including the emergence of new social movements, postmodernism, public policy and services, the rekindling of interest in citizenship, "human need," "social exclusion," and the search for a new more participatory politics.

Because participation is an inherently political concept, it is contentious, without a clear or agreed-on definition. There is also no consensus about terminology, with different words used, including *citizen participation, self-advocacy,* and *consumer involvement,* sometimes synonymously, sometimes to impart different meanings.

COMPETING APPROACHES TO PARTICIPATION

Generally framed in terms of "consumer" or "user involvement," the idea of participation reemerged internationally toward the end of the twentieth century as a key idea, policy, practice, and goal, particularly in the fields of public policy, health, and welfare. This renewal of interest in participation relates to two frequently opposed and broader developments. First is the development of increasingly powerful and influential movements of disabled people and other long-term recipients of health and social care, with their own democratically constituted local, national, and international organizations and groupings. Second has been shifts in ideology and economics, which have resulted in a expansion of interest in the market and individual responsibility, linked with the philosophy and rhetoric of consumerism, highlighting individual choice and involvement.

This has resulted in two competing understandings of user involvement, which are often confused—the first from the disabled people's and related movements, committed to people speaking for themselves and securing and safeguarding their human and civil rights, choices, and quality of life, and the second from states and service systems, including private providers, reflecting consumerist concerns of improving the efficiency, effectiveness, and economy of services. The first approach starts with people's lives, the second with the concerns of service systems. These two approaches to participation—the "democratic" and the "consumerist"—do not sit comfortably. One is managerial and instrumental in purpose, without any commitment to the redistribution of power or control; the other is liberational, with a commitment to empowerment.

They are also associated with different strategies for participation. The consumerist preoccupation with service user feedback is reflected in an emphasis on consultation and data collection exercises focusing on the planning, management, and market testing of specialist services. The frequent experience of disabled people is that such exercises have very limited effects on improving their lives and support while making significant demands on them. Their concern is with bringing about direct change in people's lives, through collective as well as individual action. The disabled people's movement bases its approach to participation on the social model of disability, using both constitutional and direct action. It has prioritized independent living, civil rights legislation, and the provision of adequate support for organizations controlled by disabled people themselves.

DISABLED PEOPLE AND PARTICIPATION

Participation makes possible the negotiation of different, often competing interests. Participation is also an idea inseparable from issues of power and inequalities of power. As a constituency, disabled people are still relatively disadvantaged, in terms of income, class, status, and power. This is one reason why it is helpful to consider *who* is being involved, when exploring the policy and practice of participation. The equal inclusion of people in participatory developments has so far been a major and unresolved problem. The evaluation of participation is still at an early stage. Different approaches to participation also frame people in different categories. Thus, public policy initiatives have generally been framed in terms of "public participation"; regeneration, community, and international development initiatives have been framed in terms of "community" involvement; and health and welfare initiatives have been framed in terms of "user" and "patient" involvement. Typically, disabled people have not been equally included as members of the public and communities and therefore may not be equally represented in such categorization. Thus, policy for participation can reinforce the broader exclusions and discrimination that disabled people face.

Disabled people, like some other new social movements, have developed an approach to participation based on identity. They also emphasize participation in their own self-organization, highlighting their local, grassroots, and "bottom-up" approach to collective action. In their self-organization, they have generally developed their own representative structures to ensure accountability, but they also emphasize and prioritize the role of direct democracy in their broader collective action and campaigning.

While participation is generally associated with the public sphere, it is also affected by people's circumstances and responsibilities in the *personal* sphere. This can limit the participation of many groups, notably women, because of the care and support responsibilities that continue to be placed on them disproportionately and disabled people, if they are denied appropriate personal support or their access requirements are not met.

Two components are essential if disabled people are to have a realistic chance of participating and all groups, regardless of the nature of their impairment, are to have equal access to involvement. These are *access* and *support.* Both are essential. Experience indicates that, without support, only the most confident, well-resourced, and advantaged people and groups are likely to become involved, while without access, efforts to become involved are likely to be arduous and ineffective. Access includes equal and ongoing access to the political structure at international, national, regional, and local state levels and to other organizations and institutions that affect people's lives. Support includes increasing people's expectations and confidence; extending their skills; offering practical support such as child care, information, advocacy, and transport; enabling people to get together in groups; and ensuring that women, minority ethnic groups, and others facing discrimination can get involved on equal terms.

PARTICIPATION IN CONTEXT

While participation is generally presented in positive terms, it also has a regressive potential. Participatory initiatives can frequently serve to obstruct rather than increase people's involvement. They are sometimes used to tokenize and co-opt people, delay decisions and action, and legitimate predetermined agendas and decisions. This has been identified as a major problem in international development, where indigenous involvement sometimes serves to put a participatory gloss on policies imposed from outside, beyond local control. This relates to a more general and fundamental tension that exists when arrangements for participatory or direct democracy exist in political structures based primarily on a system of representative democracy. So far, little work has been done to explore if and how these two approaches to political participation may be reconciled. As a result, some disabled commentators see participation as a necessary but not sufficient condition for their liberation, arguing for an emancipatory, as well as a participatory, politics.

PASSING

Although passing originally defined any form of pretense concerning identity, its meaning today refers increasingly to identity disguise motivated by social injustice and oppression. Passing is one strategy for managing what Erving Goffman (1963) calls the stigma of spoiled identities—those identities discredited by law, opinion, or social convention. For example, when in the minority and powerless, Jews pretend to be Christians, blacks pass as white, gay and lesbian people masquerade as heterosexual. Similarly, people with disabilities find ingenious ways to conceal their impairments and to pass as able-bodied. Disabled people who pass are often accused of leading an existence that endorses deception, accommodation, and betrayal, despite the fact that passing is necessary only because of the inequality and injustice of society. They supposedly deceive society at large, acquiesce to its injustices for personal gain, and betray other disabled people who are unwilling to pass. A more complex consideration of disability passing, however, focuses on the psychological and physical price paid by those who pass as well as on the knowledge they have acquired about the organization of human society. On one hand, to free themselves from curiosity, prejudice, economic disadvantage, and violence, disabled people develop sophisticated tactics designed to help them blend into society, but these tactics may also exact a heavy toll on individuals both mentally and physically, leading to psychological crises and secondary health problems. On the other hand, passing represents a vivid understanding of everyday life and its conventions. Those who pass treat social situations that others consider natural and normal as calculated, artificial, and subject to manipulation, thereby demonstrating their knowledge about social organization and human perception. Passers are skillful interpreters of human society. They recognize that in most societies, there exists no common experience or understanding of disability on which to base their identity. For where a common acceptance of disability exists, passing is unnecessary.

Passing is one strategy useful to manage the loss of self created by the oppression of people with disabilities. Temporary passing is empowering, producing brief moments of freedom from the prejudice and morbid curiosity often found to surround disability. Pretending to be able-bodied is one way of performing normalcy, of inserting oneself in society and escaping the alienating experience of being disabled. In the long term, however, disabled people who try to pass may feel guilty or become depressed about constructing their acceptance by society on the basis of pretense. They also internalize prejudices against disability, seeing their hidden identity as wrong, lacking, or shameful. For both the physically and mentally disabled, passing often requires overcompensation that exacerbates already existing conditions. A woman with chronic fatigue or post–polio syndrome may extend herself to the limits of endurance to maintain the appearance of able-bodiedness, but the result will be a worsening of her condition, sometimes permanently. The college student with a learning disability may discover that passing adds levels of unbearable stress to an already difficult classroom situation. Moreover, those who pass often find that keeping their secret requires solitude. Passing is a solo experience for most people. The feelings of relief that accompany coming out as disabled often derive from the discovery that one is no longer alone and that other disabled people exist on whom one may depend for acceptance, friendship, and love.

Passing requires a working knowledge of human society often unavailable to the majority of people. It entails a conscious engagement with and obedience of social rules, creating the impression of being able-bodied by close attention to the details of everyday life. Passing also requires individuals to make quick calculations in unexpected situations to avoid exposing their identity. Those who pass have a gift for dealing with unstable social situations from which we all might learn; they create a zone of comfort that blankets disability with the appearance of normalcy, making an art of helping nondisabled people feel more comfortable with the presence of disability. Passing also depends on special insights about the ways that human society and perception are organized. A blind woman pretends that she can see by giving the impression that she is sighted. Her role-playing is intentional and precise and will be successful only if she has both acute knowledge of the behaviors that define sightedness and the capacity to reproduce them. Sighted people need not pretend to see and would not be able to do so if required because the knowledge of seeing is unnecessary to their existence. A deaf boy may pass by asking questions to which he already knows the answer and by attending to subtle cues about how he should react in conversation, while a hearing person has no need to learn such nuanced behaviors. Passing involves playing roles, but its essential character is less a matter of deception than of an intimate knowledge of human ability and its everyday definition. Those who pass understand better than others the relation between disability and ability in any given situation. As careful strategists of social interaction, they know what sightedness looks like, though they may be blind; they know what conversation sounds like, though they may be deaf.

The limits of disability passing are often thought to rely on the visibility of an impairment. People with visible disabilities do pass, however, and often with relative ease because a common knowledge of disability does not exist in many situations. Both this ignorance about disability and the general anonymity of modern life produce opportunities for passing. People in public, disabled and nondisabled alike, prefer not to be noticed, with the consequence that disabled people may pass as able-bodied simply by obeying the unconscious laws of anonymity. Moreover, people with disabilities are often recognized by their tools rather than their impairments. A power chair of unusual design may not present as a wheelchair. A blind person without a white cane or whose guide dog is not the expected breed may not be perceived as blind. Similarly, when people with disabilities make their behavior conform to expectations about disability and then reverse these expectations, their status as disabled is placed in doubt. The individual who enters a bookstore in a wheelchair but stands to take a book off a shelf will confuse those who lack knowledge about disability. Passing demonstrates that the visibility or invisibility of an impairment is a less significant factor in the recognition of disabled people than the fact that a common experience of disability is rarely available in society.

Disabled people who pass understand more vividly than others that society possesses no common experience of disability. The lack of common knowledge underwrites passing, for widespread understanding and acceptance of disability would render passing not only impossible but unnecessary. While people with disabilities who pass have an understanding of both disability and its able-bodied counterparts, able-bodied people often have little idea of the conventions shaping either their own abilities or the disabilities they shun. The sighted are blind to blindness, and the hearing, deaf to deafness. When the able-bodied attempt to pass as disabled, for example, they rarely succeed, producing unconvincing versions of disability recognizable only by their exaggeration, and yet disabled persons are able to pass where the nondisabled fail. Disabled people who pass have a double experience of the oppression of disability from which both disabled and nondisabled people might learn. Like all disabled people, those who pass experience the oppression of disability on a daily basis, but they also have an intimate knowledge of just how little the habits of everyday life relate to disability. If their knowledge of human society were more widespread, disabled individuals tempted to pass might move from the desire to pass to the desire to unlearn passing and call upon others to recognize and accept their disabilities.

PATIENT-PROFESSIONAL RELATIONSHIPS

Patient-professional relationships involving disabled people and their health care providers is an area characterized by diverse perspectives. Research has shown that patients' relationships with professionals are critical to the outcomes of their health care. In addition, these relationships often influence patients' willingness to return for health care should the need arise. A number of theoretical models have been developed and used to build and maintain positive patient-provider relationships. These include models of patient-provider communication, interactive reasoning models, and client-centered models, among others. According to these models, key elements of the patient-provider relationship include the necessity for rapport, empathic understanding, mutual trust, empowerment, and reciprocal communication. However, models of the patient-provider relationship tend to differ with respect to the degree to which they emphasize a directive versus a nondirective or client-centered approach to interaction.

In directive approaches, the professional assumes the role of expert, and his or her role is to provide an informed viewpoint, structure, and direction to the treatment process. Providers who favor a directive approach also tend to favor a problem-solving, logical-deductive approach to treatment. Client-centered or empowerment-oriented approaches tend to be less directive and less structured. Professionals in favor of these approaches tend to seek the patients' views about the presenting concerns and encourage patients to control and direct their own care.

For disabled people, the nature of their relationships with health care professionals is critical. The attitudes and emotions that accompany these relationships, as well as the settings in which these interactions take place, affect the degree to which health care is viewed as relevant, useful, and ethical. A number of researchers, educators, and activists have examined and critiqued relationships between disabled people and health care professionals. Some of the more prominent voices in this analysis include Ian Basnett, Sally French, John Swain, John McKnight, Susan Wendell, Susan Lonsdale, Barbara Altman, and Peter Coleridge, among numerous others. Existing literature from this perspective includes testimonials and research reports that highlight the negative aspects, weaknesses, and areas for improvement within patient-professional relationships. These reports range from expressions of marked dissatisfaction with professionals to analyses and discussions of injustice, stigmatization, and victimization by professionals toward disabled people.

Like many relationships, the evolution of patient-professional relationships has involved a number of interacting variables. These include the personal characteristics and individual differences among and between professionals and patients. Larger contextual forces are also involved that address the societal norms of power, control, and hierarchy characteristic of the medical model of care. This model focuses on treatment or cure of damaged or failing body parts or systems. The implication of such an approach for disabled individuals is that body parts or systems that do not function as well as those of the nondisabled need to be remediated or fixed. If the impairment cannot be fixed, then the individual is somehow lacking or not whole.

Examples of these experiences are provided by number of writers and researchers, including but not limited to Susan Wendell (1996) and Susan Lonsdale (1990). Susan Lonsdale has interviewed a number of disabled women and found that they related many harmful experiences of hospital treatment and medical care. Visits to health care professionals were described as frightening in childhood. Women recalled being asked questions that were experienced as inappropriately personal and insensitive. They recalled being photographed unclothed and being pressured to walk naked in front of medical students. Peter Coleridge (1993) believes that the self-image of many disabled people has been damaged from their frequent involvement with professionals. This harm occurred particularly during childhood when necessary experiences of play, enjoyment, and discovery were attenuated or altogether replaced by stress, medical exams, and rehabilitation programming.

The negative impact resulting from objectification of the body and the medicalization of disability is also experienced by individuals with fluctuating or broadly defined chronic illnesses, such as arthritis, lupus, and multiple sclerosis. Individuals with these conditions, which are sometimes referred to as emergent or invisible disabilities, have been labeled as being depressed, anxious, or otherwise neurotic. Because their symptoms do not fit into neat diagnostic slots, professionals opt for psychiatric diagnoses of their secondary concerns and do not accurately assess the underlying disability. This invalidation is also evident in the early diagnostic labels given for less visible disabilities. For example, multiple sclerosis was once referred to as malingerer's syndrome or housewife's syndrome. Similarly, people with difficult-to-diagnose or poorly understood conditions, such as chronic fatigue syndrome, chronic pain, and fibromyalgia, have often faced ridicule, misdiagnosis, denial of care, and other stigmatizing attitudes and behaviors from professionals. For example, individuals with invisible disabilities have described a number of difficulties obtaining social services. Caseworkers with no knowledge of these conditions have denied benefits based on judgments that these conditions are not legitimate disabilities. These problems have a sharp impact on patient-professional relationships and can harm patients at a time of great vulnerability. Yet, it is not simply that professionals deny that these are disabilities or refuse services, important though those are. The larger issues of how disabilities are recognized and legitimized for treatment by society and the health care professions are relevant. To some extent, professionals reflect the societal awareness at the time. This is a problem since society can delay in understanding and recognizing emergent disabilities, especially ones that are not readily visible such as chronic fatigue syndrome. Thus, professionals are not the only individuals who bear the responsibility to address and correct this process.

For example, on average, individuals with chronic fatigue syndrome and fibromyalgia have seen 10 or more physicians, and it has taken five years or more to obtain a diagnosis. Many with these conditions have been told erroneously that their conditions were due to stress, mental illness, or lifestyle. The implication of these messages is that that the person's experience of his or her condition is not valid, that the individual is to blame for his or her condition, and that it is the responsibility of the individual to overcome it. As a result of these experiences, many people with poorly understood disabilities have developed a tendency to mistrust and doubt their health care providers. Discrimination is often multiplied for disabled people of lower socioeconomic status, as well as for those who are considered members of racial and ethnic minority groups.

As a support group facilitator, the second author has had many conversations involving the same recurrent theme—mistrust of health care providers. One individual with fibromyalgia commented, "Doctors don't know what they're doing. . . . Every time I ask my doctor something he has to pull out a book and look it up, or, says I don't know, or that's a bad idea!" A law enforcement officer with an invisible disability related during one physician's appointment that he asked his doctor about an alternative medicine therapy. The physician remarked, "I think you're reading too much." Another person related that three separate physicians are treating her because she does not believe any one physician knows how to help her.

Moreover, patients report that health care providers are often not aware of the physical and logistical challenges they face, including challenges involving mobility and transportation, limited or absent health care insurance, job schedules, and economics. Failure to arrive at scheduled appointments on time is often not tolerated or is interpreted by professionals as selfishness, disorganization, or noncompliance with treatment recommendations without appreciation of challenging complexities in the environment.

In addition, a number of disabled individuals have encountered paternalistic attitudes in their relationships with health care providers. Many report not being asked for input or concerns about health care or service needs. The professional reviews the patient's situation, makes a determination, and sets a plan of action. Then the patient is directed to follow a protocol. Another example of paternalism is evidenced in attempts by professionals to protect patients by failing to provide them with complete information about their condition or by deliberately excluding them from involvement in key decisions. For example, some patients have learned by accident that health care providers or legal advisers have "sugarcoated" or hid the severity or consequences of a situation because they felt that they (the professionals) knew what was best for the person. For example, a disabled woman was going through a difficult divorce. Her attorney insisted on closed-door negotiation with her ex-husband, his parents, and his attorney but advised the woman not to attend because he thought the situation would be too stressful for her because of her disability. Years after the divorce was finalized, this woman is still discovering the adverse consequences of her lack of direct involvement in these negotiations. Many of these consequences involve economic issues.

Medical perspectives that grow out of societal attitudes toward persons with disabilities can have a negative effect in patient-professional relationships. Contemporary writers argue that pejorative and misinformed notions of disability, often characterized as the tragic view (or personal tragedy view) of disability and impairment, have been reinforced by health care professionals. This view and its reinforcement have developed through health care workers' professional training, through their traditional approaches to practice, and through their biased interactions with disabled individuals. Health care professionals' contact with persons with disabilities is often limited to times when disabled individuals are most recently injured or acutely ill.

This tragic view holds that disability is something that should be avoided, reduced, rehabilitated, eliminated, or normalized by adopting as much of the lifestyle and behavior of a nondisabled person as possible. This view of disability is so prevalent that it has affected decisions and values about birth and the right to life. Writers have argued that the abortion of impaired fetuses is not commonly challenged within the United States. Gynecologists are now being sued if they do not appropriately screen for and detect impairments and abnormalities, including having one extra finger or toe. Physicians and society as a whole put pressure on women to undergo prenatal screening and to terminate pregnancies in which medical pathology has been detected. Notwithstanding considerable scientific evidence to the contrary, the idea that disabled people and their parents cannot sustain a joyful, fulfilling, or adequate quality of life is prominent within the tragic viewpoint.

RESEARCH

Individuals writing from the perspective of disabled people are not alone in their observations. Similar observations have been made in a smaller body of research and writings documenting the attitudes and behaviors of health care professionals. The literature indicates that the power imbalance that characterizes the medical model of care may, in part, contribute to the injustice, dominance, and delegitimization experienced by disabled people in their relationships with health care professionals. Writers and researchers such as Sally French, John Swain, and John McKnight have defined and discussed extensively the elements of power that are central to patient-provider relationships. The first involves the power of knowledge and skills possessed by professionals by virtue of their education and training. Professionals possess the power to evaluate the impairments that disabled people have and label their problems and needs based on their own perceptions of those needs. They also recommend specific treatments and evaluate the compliance and effectiveness of those recommendations.

According to Heather Coates and Alan King (1982), the professional's observations are often viewed as accurate, objective, and therefore superior, whereas the patient's perceptions are viewed as subjective and therefore inferior. Professionals not only possess power when working as individuals within clinical settings, but some groups, particularly physicians, also possess power collectively in that they are viewed as a high-status and economically and politically influential group within society. Professionals are more often consulted in the process of making public policy decisions that have a wide range of social and economic implications, including decisions involving abortion, genetic and stem cell research, cloning, and the sale of tobacco, alcohol, and other products, just to name a few. Professionals, rather than patients, are also called upon to make decisions that help insurance companies decide whether a patient deserves benefits or whether that patient is capable of returning to work.

As observed by Barbara Altman, Sally French, and others, practices that involve professional power encourage, maintain, justify, and enforce the dependency of disabled individuals on professionals and professionally driven institutions. Nursing homes, residential facilities (such as those for foster children or individuals with chronic illness, mental illness, or developmental disabilities), and day care programs, many of which provide specialized forms of transportation, embrace rigid treatment protocols, structures, and routines and fail to involve consumers meaningfully in daily decisions, and operations serve to foster and reinforce this dependency. These structures can encourage dependency, resentment, or both within patient-professional relationships. Systems and practices that are set up to encourage dependency have secondary effects on some disabled people. These consequences may involve internalized oppression in which the disabled person accepts his or her role as a dependent, disempowered individual. Ultimately, this process makes it more difficult for the recommendations made by professionals to be successfully embraced, and it makes it more difficult for the disabled person to achieve independence.

Over the past four decades, there have been efforts to counteract existing social norms through movements such as the disability rights movement, the independent living movement, and the patient power movement. These social movements are covered elsewhere in the encyclopedia.

WORK IN PROGRESS

Disability advocates and progressive health care educators and providers have formed a number of initiatives to improve patient-professional relationships. Values emanating from these movements and from client-centered models of care emphasize nonhierarchical, egalitarian relationships between consumers and professionals in which the role of the professional is limited to providing the patient accurate and balanced knowledge and information. Key decisions pertaining to health care, treatment, and participation in all other domains of life are within the control of the patient. Other recommendations to improve patient-professional relationships that have emerged from these movements and have been put in place to some extent include training health care professionals to understand the broader psychological, social, and economic influences of health and disability outside the health care system. For example, health care professionals from all disciplines have benefited from increased understanding of the role of physical aspects of the environment that prevent access to full participation in community and occupational settings. A final contribution that has emerged from these movements is the recommendation and practice of employing more disabled individuals in the roles of health and social service professionals.

One significant step toward incorporating these recommendations into real-world practice has involved the establishment of centers for independent living and other centers that embrace peer-facilitated models of care and the empowerment of disabled people by disabled people. Many disabled people prefer professionals who treat them as partners in their health care, legal situations, and in their search for social services. Many patients take the time to learn as much as they can about their disability, legal issues, treatment advances, and research updates. The most empowered patients expend the energy to learn about disability-related social services and attend self-help or support groups.

It appears that the most satisfied patients are the ones who feel empowered and know how to advocate for themselves in their relationships with professionals. Relationships with professionals work when disabled individuals have health care providers, legal advisers, and social service advocates who not only appreciate these qualities but also promote them. Individuals fortunate enough to find such relationships discover that they can have useful and relevant conversations with the various professionals in their lives. They can express their ideas and concerns about their situations in a trusted atmosphere without fear of being ridiculed.

In general, advocacy groups promote the value that patients take charge of their disabilities and become an integral component of their health care. In sum, health care professionals can occupy an important role in the lives of disabled individuals, and the way in which they regard and choose to relate to disabled individuals inevitably affects their well-being in emotional, social, economic, and political arenas. Well-intended professionals can provide valuable services that are nonetheless useful in the context of asymmetric relationships. There are some circumstances and cultures in which people may not be ready or accepting of an egalitarian or empowering approach. In sum, professionals who are sensitive to these issues and able to custom-tailor their approach to the client's needs may share in the most positive outcomes with their clients.

PATIENTS' RIGHTS

When people with disabilities enter a hospital setting, they expect to be talked over, around, and about based on a perception by medical staff that they, by the virtue of their disability, are not capable of thinking or talking for themselves. This behavior on the part of medical staff is historic and reflects society's attitude about disability and infirmity. As a practical matter, rehabilitation hospitals present less discrimination than acute hospitals because rehabilitation settings are more used to dealing with people with disabilities.

People with disabilities and the organizations that represent them have been working over the past 40 years to change people's attitudes about disabilities. One of the major methods of choice has been to use the law to improve wheelchair accessibility, to eliminate discrimination in employment, to provide equal access to services to all people with disabilities, and to ensure communications access throughout the new electronic world. Unfortunately, we as a society were not able to reduce discrimination against people with disabilities without resorting to the use of the law, but that is how it is getting done. In what follows, I offer several examples of legal and institutional documents, which enumerate patients' rights in a disability context. Together they suggest a range of societal reactions motivated to protect the rights of those with disabilities both in a medical setting and in society at large.

When Americans with disabilities think about their legal and civil rights, they consider two milestones in federal law related to services and nondiscrimination. The two milestones are Section 504 of the Rehabilitation Act of 1973 and the Americans with Disabilities Act (ADA) of 1990. The Rehabilitation Act affects only recipients of federal funding, including most hospitals. The law, with respect to services, states that

> no otherwise qualified individual with disabilities . . . shall, solely by reason of his disability, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving federal financial assistance. (29 USCA § 794, Section 504 of the Rehabilitation Act of 1973, as amended)

The regulations provide further clarification.

The kinds of discriminatory acts prohibited include actions that

> (1) directly or through contractual, licensing, or other arrangements, on the basis of disability:
>
> (i) Deny a qualified person with disabilities the opportunity to participate in or benefit from the aid, benefit, or service;
>
> (ii) Afford a qualified person with disabilities an opportunity to participate in or benefit from the aid, benefit, or service that is not equal to that afforded others;
>
> (iii) Provide a qualified person with disabilities with an aid, benefit, or service that is not as effective as that provided to others;
>
> (iv) Provide different or separate aid, benefits, or services to persons with disabilities or to any class of persons with disabilities unless such action is necessary to provide qualified persons with disabilities with aid, benefits, or services that are as effective as those provided to others;
>
> (v) Aid or perpetuate discrimination against a qualified person with disabilities by providing significant assistance to an agency, organization, or person that discriminates on the basis of disability in providing any aid, benefit, or service to beneficiaries of the recipients' program or activity;
>
> (vi) Deny a qualified person with disabilities the opportunity to participate as a member of planning or advisory boards; or
>
> (vii) Otherwise limit a qualified person with disabilities in the enjoyment of any right, privilege, advantage, or opportunity enjoyed by others receiving an aid, benefit, or service.

In addition,

> In determining the site or location of a facility, an applicant for assistance or a recipient may not make selections (i) that have the effect of excluding persons with disabilities from, denying them the benefits of, or otherwise subjecting them to discrimination under any program or activity that receives Federal financial assistance.

In 1990, the ADA built on Title V of the Rehabilitation Act of 1973 and declared that regardless of funding, the provision of services available to the general public could not discriminate against people with disabilities. The ADA states the following:

> No individual shall be discriminated against on the basis of disability in the full and equal enjoyment of the goods, services, facilities, privileges, advantages, or accommodations of any place of public accommodation by any person who owns, leases (or leases to), or operates a place of public accommodation. (42 USCA §12182(a), Americans with Disabilities Act of 1990)

And through regulation:

> (a) Prohibition of discrimination. No individual shall be discriminated against on the basis of disability in

> the full and equal enjoyment of the goods, services, facilities, privileges, advantages, or accommodations of any place of public accommodation by any private entity who owns, leases (or leases to), or operates a place of public accommodation.
>
> (b) Landlord and tenant responsibilities. Both the landlord who owns the building that houses a place of public accommodation and the tenant who owns or operates the place of public accommodation are public accommodations subject to the requirements of this part. As between the parties, allocation of responsibility for complying with the obligations of this part may be determined by lease or other contract. (28 CFR 36.201, DOJ, Nondiscrimination on the basis of disability in places of public accommodation)

Many states have a "Patient's Bill of Rights," applicable to both patients with and without disabilities, which builds on the Rehabilitation Act and the ADA. As an example, the Massachusetts "Patient's Bill of Rights" follows the subsequent concepts.

MASSACHUSETTS GENERAL LAWS, CHAPTER 111, SECTION 70E

"'Facility' shall mean any hospital, institution for the care of unwed mothers, clinic, infirmary maintained in a town, convalescent or nursing home, rest home, or charitable home for the aged, licensed or subject to licensing. . . ; any state hospital. . . ; and any private county or municipal facility."

"The rights established . . . shall apply to every patient or resident in said facility. Every patient or resident shall receive written notice of the rights established . . . upon admittance into such facility. . . . In addition, such rights shall be conspicuously posted in said facility."

"Every . . . patient or resident . . . shall have, in addition to any other rights provided by law, the right to freedom of choice in his selection of a facility, or a physician or health service mode."

"Every . . . patient or resident . . . shall receive from a person designated by the facility an itemized bill reflecting laboratory charges, pharmaceutical charges, and third party credits and shall be allowed to examine an explanation of said bill regardless of the source of payment."

"Every Patient or Resident of a Facility Shall Have the Right:

(a) upon request, to obtain from the facility in charge of his care the name and specialty, if any, of the physician or other person responsible for his care or the coordination of his care;
(b) to confidentiality of all records and communications . . . ;
(c) to have all reasonable requests responded to promptly and adequately within the capacity of the facility;
(d) upon request, to obtain an explanation as to the relationship, if any, of the facility to any other health care facility or educational institution insofar as said relationship relates to his care or treatment;
(e) to obtain from a person designated by the facility a copy of any rules or regulations of the facility which apply to his conduct as a patient or resident;
(f) upon request, to receive from a person designated by the facility any information which the facility has available relative to financial assistance and free health care;
(g) upon request, to inspect his medical records and to receive a copy thereof, the fee for said copy shall be determined by the rate of copying expenses;
(h) to refuse to be examined, observed, or treated by students or any other facility staff without jeopardizing access to psychiatric, psychological, or other medical care and attention;
(i) to refuse to serve as a research subject and to refuse any care or examination when the primary purpose is educational or informational rather than therapeutic;
(j) to privacy during medical treatment or other rendering of care within the capacity of the facility;
(k) to prompt life-saving treatment in an emergency without discrimination on account of economic status or source of payment and without delaying treatment for purpose of prior discussion of the source of payment unless such delay can be imposed without material risk to his health, and this right shall

also extend to those persons not already patients or residents of a facility if said facility has a certified emergency care unit;

(l) to informed consent to the extent provided by law;

(m) upon request to receive a copy of an itemized bill or other statement of charges submitted to any third party by the facility for care of the patient or resident and to have a copy of said itemized bill or statement sent to the attending physician of the patient or resident; and

(n) if refused treatment because of economic status or the lack of a source of payment, to prompt and safe transfer to a facility which agrees to receive and treat such patient."

"Any person whose rights under this section are violated may bring in addition to any other action allowed by law or regulation, a civil action."

The Massachusetts statute also establishes patients' rights in the doctor-patient relationship that mirror those enumerated above.

As a result of the various state and federal laws defining "patients' rights," hospitals have made public, through postings and pamphlets, their own patients rights policies. A typical policy, developed by the Spaulding Rehabilitation Hospital in Boston, is set forth as follows.

SPAULDING REHABILITATION HOSPITAL PATIENT BILL OF RIGHTS

"Spaulding Rehabilitation Hospital is committed to providing you with quality care and respecting your rights as a patient. The hospital completely supports the law known as the Massachusetts Patient's Bill of Rights. The following are your rights as a patient, established by the provisions of that law.

"Every patient or resident shall have the right:

- Upon request, to obtain from the facility in charge of his/her care the name and specialty, if any, of the physician or other person responsible for his/her care or the coordination of the care;
- To confidentiality of all records and communications to the extent provided by law;
- To have all reasonable requests responded to promptly and adequately within the capacity of this facility;
- Upon request, to obtain an explanation as to the relationship, if any, of the facility to any other health care facility or educational institution insofar as said relationship relates to his/her care or treatment;
- To obtain from a person designated by the facility a copy of any rules or regulations of the facility that apply to his/her conduct as a patient or resident;
- Upon request, to receive from a person designated by the facility any information that the facility has available relative to financial assistance and free health care;
- Upon request, to inspect his/her medical records and to receive a copy thereof in accordance with Chapter III, Section 70, of the Massachusetts General Laws, and the fee for said copy shall be determined by the rate of copying expenses;
- To refuse to be examined, observed, or treated by students or any other facility staff without jeopardizing access to psychiatric, psychological, or other medical care and attention;
- To privacy during medical treatment or other rendering of care within the capacity of the facility;
- To prompt, life-saving treatment in an emergency without discrimination on account of economic status or source of payment, and without delaying treatment for purposes of prior discussion of the source of payment unless such delay can be imposed without material risk to his/her health, and this right shall also extend to those persons not already patients or residents of a facility if said facility has a certified emergency care unit;
- Upon request, to receive a copy of an itemized bill or other statement of charges submitted to any third party by the facility for care of the patient or resident and to have a copy of said itemized bill or statement sent to the attending physician of the patient or resident;
- If refused treatment because of economic status or the lack of a source of payment, to prompt and safe transfer to a facility which agrees to receive and treat such patient. Said facility refusing to treat such a patient shall be responsible for ascertaining that the patient may be safely transferred; contacting a facility willing to treat such patient; arranging for transportation; accompanying the patient with necessary and appropriate professional staff to assist in the safety and comfort of the transfer, assure that the receiving facility assumes the necessary care promptly, and provide pertinent medical information about the patient's condition; and maintaining records of the foregoing.

The physician shall provide every patient or resident in the facility essentially the same rights."

There is a relationship in a rehabilitation hospital between dignity and rights. It is often said that one must "check one's dignity at the door" when checking into a hospital. The personal privacy of people in the hospital setting is frequently compromised during the provision of hospital services. Respecting the dignity of people in the hospital setting, through the exercise of courtesy, confidentiality, compassion, and the empowering of patients to make informed choices regarding their treatment, is essential in ensuring the rights of all people in the rehabilitation setting.

PEDAGOGY AND CURRICULUM DESIGN

Across the United States, disability studies courses continue to multiply in academic departments within institutions that have established disability studies programs and those in which program development is not currently a goal. Course offerings are found in the humanities, the social sciences, medicine, applied health and rehabilitation sciences, psychology, philosophy, architecture, law, policy, and business. Until recently, disability-related content was the exclusive domain of medicine, education, and the social sciences. Infused by the current wave of disability studies in the humanities, disability is now more likely to be understood as a product of cultural rather than purely biological forces. Recent course offerings include the following: Disability and Literature; Disability in American History; Cultural Studies/ Body Studies; Extraordinary Bodies; Disability and Culture: Race, Gender, and Sexuality; Women and Disability; Disability in Film; and Crip Cultures & Disability Studies. Judging by the titles alone, this sample evidences a strong bias toward the cultural branch of disability studies, but undoubtably, titles can be deceiving.

ACADEMIC COURSES AND PROGRAMS

In many universities, the process for new course creation can impede the development of new courses if it threatens existing, state-approved, or professionally sanctioned content. However, courses can be updated with little or no fanfare and pasted into an existing course title. For example, Normality, Abnormality, and Society, offered in the philosophy department at the University of Hawaii, Hilo, is suggestive of the first wave of disability studies when professionals set the parameters for inquiry into disability informed by a prevention/treatment/remediation paradigm. However, despite its retrograde title, the course, taught by Ron A. Amundson, a philosopher of science and a wheelchair user, is described in the course catalog (2002–2003) as

> a philosophical study of how human diversity interacts with social norms. Topics include health and illness, disability, gender, and sexual orientation. Perspectives from biology and the social sciences are included in a study of how beliefs about normality vary between cultures, change through time, and affect human relations.

The course is not included in a special disability program, nor is it part of a cluster of course offerings designed to provide a closer examination of disability informed by a disability studies. Like many of the new disability studies courses that dot the academic landscape, this course stands alone in a traditional academic department.

Where efforts are under way to develop disability studies programs, course offerings are plentiful and more diverse. Community Planning and Public Policy for Disability, offered through the Department of Environmental Design at the University of California, Berkeley, explores what society and local communities can do to address the needs of citizens with disabilities specific to policies, programs, and local planning. Although the content is shaped by cultural awareness and more progressive interpretations of disability, the course has as its foci the economics of disability and the politics of producing change, with special attention to transportation, housing, public facilities, independent living, employment, and income policies, with content that reflects the perspectives of disabled and nondisabled members of society. Although the disability studies concentration to be offered at the undergraduate level in American studies at the University of California, Berkeley has yet to be finalized, a wide range of interdisciplinary courses already exist. Because Berkeley shares a long history of involvement with the disabled community, many courses were offered well in advance of the recent efforts to create an undergraduate minor in disability studies.

INFLUENCES ON PEDAGOGY AND CURRICULUM DEVELOPMENT

In the example of disability studies, two significant influences on pedagogy and curriculum design are (1) the perspective on disability offered and (2) the context in which the course is offered. When the perspective on disability is informed by cultural criticism and theory, it is useful to consider its relationship to women's studies, African American studies, and queer studies, particularly as each emerged in the era of civil rights movements. However, arguing against the impulse to add disability to the "roster of the disenfranchised," Lennard J. Davis (2002) contends that because the category of disability is porous, it poses a significant challenge to identities that seem fixed. Thus, increasingly disability studies scholarship has moved away from particular claims to status as "another other," opting instead to unsettle fixed identity categories through a more complicated critique informed by disability studies.

GOALS AND OBJECTIVES FOR DISABILITY STUDIES CURRICULA

In its most simple statement of purpose, the goal for a disability studies curriculum is to unpack inadequate representations of disabled people wherever they exist. At the center of many new courses in academe are efforts to disrupt pity, fear, loathing, and overly romanticized and uninterrogated inspirational depictions of disability. Course descriptions are peppered with terms such as *excavate, examine, explore, investigate, interrogate, probe, appropriate,* and so on. Moreover, when the content is organized according to the strictures of cultural studies as a "strategic practice," risk taking and discomfort are likely to follow, according to the critical theorist, Lawrence Grossberg—in short, to radicalize rather than romanticize the content. Demands for authenticity remain a critical feature of the evolution of disability studies curricula. As a consequence, it is not uncommon to find disclosure as a unique feature of the pedagogy of disability studies in academe—with both sides weighing in on the issue. An early framing of the disclosure issue appeared in the *Chronicle of Higher Education* in 1999, when Leonard Cassuto posed the question, "Whose Field Is It, Anyway? Disability Studies in the Academy." The essay sparked a healthy debate among scholars relative to the issue of disability insider/outsider status and who is qualified to speak about disability. It was a timely exchange that provided the occasion to map disability studies as a field and, more subtly, to foreshadow a few of the ruptures in academic traditions likely to follow. Among the most challenging disruptions within the academy at the practice level include those relative to hiring and promotion, instruction, publication, student services, and physical plant design and construction.

In less than three years, issues of pedagogy and curriculum development have become increasingly more complicated and turbulent. The recent publication of *Disability Studies, Enabling the Humanities* provided the occasion for Georgina Kleege and Brenda Brueggemann to consider their own classroom context and their teaching of disability content as professors with visible disabilities. Kleege voiced resentment over the assumption that her own personal experience "augments" her teaching and, more pointedly, that there is pedagogic power in exposing her disability to nondisabled students. Her refusal turned on the unintended effects of naive or well-intentioned approaches that cast her as the "goodwill ambassador sharing the quaint beliefs and customs of my alien world." It is also through her candid exchange with a student depicted in this essay that Kleege articulates the development "over time" of her own disability identity. The impulse to incite activism within a disabled community was revealed to be a latent issue—an insight that only insiders can substantively debate—and one with important implications for K–12 curriculum development. In a variation on us/them positioning still erupting in academe, Brueggemann turns the issue on its head to reveal that the "sword cuts both ways." Initially exasperated by students in her freshman composition class and their resistance to get "in" her disability content, Brueggemann recounts her own resistance to get "in" their abilities. Acknowledging the pedagogic tensions and reflecting upon them, both Kleege and Brueggemann informed their own practices and raised new points to debate as a field.

Arguing against the tradition of silence on the issue of pedagogy among cultural studies theorists, Henry A. Giroux (1995) cited academic elitism, the rewards of disciplinary policing, reluctance to cross academic borders, careerism, and competitiveness as the some of the barriers to probing the relationship between pedagogy and cultural studies. Composition studies, Giroux contends, is one of the few fields in the humanities to seriously contend with pedagogy. However, it is clear that many disability studies scholars have broadened the debate of what is political at the heart of pedagogy and curriculum development. Particular claims to postdisciplinary knowledge is not the ultimate goal for disability studies, at this juncture; there remains too much to be learned from the lives of real people articulating and renarrating lived experience *within* rather than outside history.

DISABILITY STUDIES AND THE PEDAGOGY OF INCLUSIVITY

As academic courses continue to develop and programs gain in popularity, sustained success turns on the pedagogy of inclusivity as the catalyst to sustain explorations into disability studies; to encourage enactment of policies that affect enrollment, hiring, access, and course offerings; and to foster the continuous examination of what counts as knowledge. At the present, those institutions that embrace a pedagogy of inclusivity herald disability studies as more than academic antics in pursuit of another other; rather, these institutions recognize the importance of reimagining the ways disability affects all our lives. In contrast, institutions that practice a pedagogy of exclusivity endorse traditions whereby elitism, entitlement, exclusion, and privilege prevail. Knowledge is more likely inherited rather than interpreted, leaving little appreciation for reflection on the recent ideological shifts that inform disability studies. That is not to say that disability studies courses would not, on occasion, appear in such institutions; novelty or fad-driven courses advance the economic interests of all institutions. But it is to remind us that there are real and measurable political implications for offering disability studies in the first place. Disability studies will be greatly undermined as a viable academic pursuit if institutions fail to simultaneously engage rigorous self-examination of existing policies relative to access and the inclusion of disabled people in the academy regardless of their status as faculty, student, staff, or visitor. A pedagogy of inclusivity would pursue fair representation of disability not only in the curriculum but throughout the university: indeed, no minor undertaking.

DISABILITY STUDIES IN THE CONTEXT OF K–12 EDUCATION

In K–12 educational settings, where disabling constructions are manufactured and conveyed through pedagogy and practice institutionally endorsed by local, state, and federal mandates, the context is thick with a pedagogy that pathologizes difference. Despite the growing legitimization of disability studies in higher education, many teachers are unfamiliar with the field and its implications for K–12 education. Were this encyclopedia entry written 10 years into the future, it would include samples drawn from K–12 school-based curriculum projects in which disabled youth spliced together lived experience, dreams, desires, and reflections on their subject positions in schools. The goal would be nothing short of locating students' experience *within* rather than outside history and, as a consequence, substantively reshaping the extant curriculum.

Given that education, health, and human services are the primary service providers for the disabled community and in schools, an important concern for professionals might be to address why the most recent wave of disability studies has emerged from within the humanities and outside the professions. Or, how can this new wave of disability studies inform and shape the education and training of future educators and school-based professionals? More to the point, how might this scholarship influence disabled students in K–12 educational settings to locate themselves in the curriculum in ways that have yet to emerge? Given that the professions have a high stake in preserving status quo assumptions about disability as pathology, it is highly unlikely that such questions will be considered in the absence of rigorous self-engagement with interdisciplinary disability studies and collaborative planning initiatives. The National Endowment for the Humanities (NEH) has taken the lead to provide funding for such initiatives discussed below.

Emerging K–12 Initiatives

Recognizing the value of cross-disciplinary and interdisciplinary scholarship, the NEH has previously sponsored focus grants and summer institutes for higher education faculty and for secondary educators that focused on disability studies. Although these are quite recent initiatives, it is clear at this stage that efforts to import coursework from academe into K–12 contexts will prove challenging unless the disjuncture between these two competing contexts is explored toward ends that promote reciprocal gains. *A Collaborative Inquiry on Understanding Disability in Secondary and Post-Secondary Settings* (2000) attempted to identify intersecting interests toward the realization of reciprocal goals, but what became apparent was how much a difference disability can make depending on one's context. K–12 teachers work in contexts in which disability is more than a theoretical concern, and although many are unaware of disability studies scholarship, their instructional context continues to include greater numbers of disabled students. This distinction served to complicate the project of articulating shared goals as most universities are situated at the exact opposite extreme and enroll far fewer disabled students—and, for the most part, only those likely to succeed.

"Integrating Disability Studies into Secondary Education," a five-week summer institute for secondary teachers, was cosponsored in 2003 by the University of Illinois, Chicago and the National Endowment for the Humanities. Both general and special educators were treated to a rigorous course of study that stood quite a field from the usual technicist fare that drives in-service "training" for teachers. Exposure to new ways to imagine the lives of their disabled students, informed by a broad survey of humanities content and interactions with disabled artists and performers, led many of the participants to confront, for the first time, the obvious contradictions in K–12 education as it currently exists. For these teachers, five weeks of interactions with wholly new content that, without malice, served to underscore the inadequate representation of disability in their teaching and daily practice was just a beginning. Once these educators returned to their schools, the hard work began as they continued to deconstruct and critique disability in the schooling context. Again, what became apparent was that pedagogy and curriculum development relative to disability studies in the instance of K–12 settings are quite distinct from that in postsecondary settings. Working in isolation to reassemble new images of disabled people and their own students to reflect newly acquired political understanding of disability proved a formidable challenge. Embedded in relationships with content, processes, and policies over which they exert little authority, K–12 educators face an incredible responsibility when attempting to dissolve the boundaries between schooling and popular culture, inherited social scripts, and the limits of their own professional knowledge base. Only through persistence and a long view of the change process can K–12 educators advance disability studies in their everyday practice. Educators' attempts will be greatly enhanced if postsecondary faculty maintain outreach to K–12 contexts as a necessary component of academic disability studies.

PEDIATRIC REHABILITATION

The term *pediatric* refers to medical aspects of children and *rehabilitation* to the medical field of helping people with disabilities acquire greater function. Both are terms of professionalization, in which a field of training, research, and patient care has been assembled by its practitioners and recognized by society at large. As a consequence, this entry refers primarily to the profession, which cares for children with disabilities using medical techniques, following a primarily first world, modern model. In other cultures and at other times, care for children with disabilities has been provided.

In a formal sense, pediatric rehabilitation is comparatively young. It falls against the backdrop of the development of pediatrics from the mid-nineteenth century and the development of rehabilitation largely over the last two-thirds of the twentieth century.

Western medical systems have identified the unique aspects of pediatric conditions of disability from their inception. Certainly, case examples of children with disabilities and the adults they became exist from at least ancient Egypt. Hippocrates, Galen, Soranus, and other ancient authors identified certain conditions of a disabling nature in children and offered interventions appropriate to the time. In the Middle Ages, hydrocephalus, or swelling of the head, in newborn infants was recognized and treated by surgeons. With the earliest texts devoted exclusively to children's medical disorders, disabling conditions were identified and explained, and cures were suggested from Thomas Phaire's *The Boke of Chyldren* (1544) onward. However, it was not until the aggregation of children's care in a coherent way, at the beginning of the nineteenth century, that Western medicine began to identify and react to challenges peculiar to children with disabilities in an articulated fashion.

For much of its history, pediatric rehabilitation was closely related to institutions of chronic, "inpatient" care. In Paris, for example, the Hôpital des Enfants Malades, founded in 1802, was the first hospital dedicated to sick children, using the medical model. In this way, it was distinct from other institutions, which cared for abandoned, poor, or orphaned children. Within its walls, children with acute conditions were gradually separated from those with chronic conditions. Among the latter, those with conditions such as spinal tuberculosis, paralyses, Huntington's chorea, and skeletal anomalies gradually received medical care intended if not to cure then to improve the quality of the child's functional life.

Clearly, part and parcel of the institutionalization process was segregation, social control, and stigmatization. Children with chronic conditions, deemed amenable to intervention, were taken off the streets and away from begging for charity. In this sense, state-sponsored charity for children supplanted spontaneous, private intervention. But the impact on the children, including separation from able-bodied peers, enforced perception of difference; usually, isolation from family was nearly complete. From within the field of pediatric rehabilitation, these effects have been historically downplayed in comparison to the described benefits of concentrated resources, efficiency, and opportunities for learning. Collecting such children together in inpatient and outpatient settings fostered the growth of expertise in their medicalized conditions and care. Thus, pediatrics, pediatric orthopedics, pediatric rheumatology, pediatric neurology, pediatric neurosurgery, pediatric psychiatry, pediatric rehabilitation, pediatric occupational and physical therapy, and other specialties were born and grew.

In the United Kingdom, as in France, figures such as William John Little identified conditions such as cerebral palsy with more or less clinical coherence. This process of medicalizing conditions—identifying a constellation of signs and symptoms and then tracking the natural history of those signs and symptoms from origin to conclusion under a medical rubric—allowed physicians to gain control of knowledge about the children with these conditions. Similarly, conditions from meningomyeloceles to traumatic brain injuries to learning disabilities have been identified, catalogued, and allocated medical resources for intervention and research.

The multidisciplinary growth of the care of children with disabilities is exemplified by figures who wrote pioneering works on their conditions. As well as English surgeon William John Little, in Germany, orthopedist Jacob von Heine (1800–1879) worked with children with paralyses and poliomyelitis, writing on their conditions in 1860; in Vienna, psychiatrist Sigmund Freud (1856–1939) worked with children with cerebral palsy (1897) prior to developing psychoanalysis; and in the United States, the seminal figure in internal medicine, William Osler (1849–1919), wrote an observational study on children with cerebral palsy (1889) and later became the fourth president of the American Pediatric Society. Beyond the frame of medicine proper, other parts of society in other countries followed the French government in allocating central resources to the care of children.

In the United States during the 1920s and early 1930s, the White House advanced elements of a children's agenda; the presidents both convoked symposia for policy creation and created a "Children's Charter" (1928) to begin to identify the needs of children with disabilities, under the auspices of physicians interested in their care. Following his own bout with poliomyelitis, Franklin D. Roosevelt helped create the private philanthropy, the National Foundation for Infantile Paralysis (NFIP), later to become the March of Dimes. From its inception in 1938, the NFIP helped fund both care and research into pediatric rehabilitation. The impact of sequential epidemics of polio continued to bring the care of children with chronic conditions to the attention of reformers, government agents and agencies, and health care practitioners.

In 1947, physical medicine and rehabilitation (PM&R) as a field was formally recognized with its own certification board. Dr. George C. Deaver, commonly identified as the first pediatric physiatrist, influenced training, certification, and philanthropy to aid in the care of children with disabilities from his professorship at New York University and the (Rusk) Institute of Rehabilitation. In 1946, he organized the Advisory Council to the National Easter Seal Society. In these early stages, Deaver was joined by specialists from child neurology (such as Bronson Crothers), neurosurgery, orthopedics, and pediatrics to form the American Academy for Cerebral Palsy (later the American Association for Cerebral Palsy and Developmental Medicine) in 1947. Deaver and others subsequently fostered fellowships in pediatric rehabilitation in the 1950s. In these early years, training was often received as much from the therapists working with the children directly as from the senior physicians "directing" their care.

With further disparate developments in funding, research, and care models, the fields of pediatrics and PM&R began to establish joint residencies in the 1970s on an ad hoc basis. Similarly, PM&R programs created one-year fellowships for those trained primarily in adult PM&R to specialize in the care of children. By the 1980s, numbers of physicians identifying themselves as primarily pediatric rehabilitation specialists reached sufficient levels to form a Pediatric Rehabilitation Special Interest Group (SIG) in the American Academy of Physical Medicine & Rehabilitation (AAPM&R).

Over the past 30 years, pediatric rehabilitation has become a more formalized endeavor. Today, in the

United States, for example, one can enter pediatric PM&R from more general training in PM&R (largely adult) or a dual background in pediatrics and PM&R. Professional political movements over the past 20 years have resulted in a subspecialty examination process begun in 2004 under the aegis of the American Board of PM&R and with the acceptance of the American Board of Pediatrics. Other countries vary from this model, sometimes markedly.

From the point of view of the trappings of professionalization, pediatric rehabilitation is a comparative newcomer to the world of medicine. The first journal confining itself to the topic is in its eight-volume *Pediatric Rehabilitation.* No formal and independent organizations exist solely to sponsor pediatric rehabilitation, although there are professional organizations devoted to individual conditions, such as the American Academy of Cerebral Palsy, or sections of umbrella organizations that address pediatric issues, such as the Pediatric SIG of the AAPM&R.

Providers of pediatric rehabilitation include physical, occupational, and speech language therapists, nurses, social workers, play therapists, teachers, physicians, and others. In many of these fields, some formal training in pediatric rehabilitation is provided, but "specialization" occurs with experience and clinical setting. For physicians, that specialization previously occurred with similar on-the-job training and inclination. However, increasing recognition of the specific nature of such work has promoted certification in many fields. As in all matters with economic consequences, supply and demand in the marketplace change the value of certification. In the United States, while there are fewer children overall with rehabilitation needs compared to adults, there are far fewer specifically trained providers. Those with partial training are still very much in demand.

While there is a core of conditions generally treated by pediatric rehabilitation professionals, concentrating on physical disabilities, practitioners often apply rehabilitation concepts to almost any condition, which might consequently be improved. Conditions traditionally falling under the purview of pediatric rehabilitation include cerebral palsy, neural tube defects (e.g., spina bifida or meningomyeolocele), traumatic brain injuries, amputations, burns, congenital conditions, strokes, neuromuscular disorders, cancers, and a variety of others; in addition, many pediatric conditions, including those related to sports, are treated in outpatient clinics by rehabilitation personnel. There is much room for growth, quite apart from patient numbers.

As in many specialties, pediatric rehabilitation, as a concept, may be effectively applied to many conditions not now generally using it. Thus, standard treatments do not apply full rehabilitation models to children recovering from cardiac surgery as they would in adults. Newborns with complex conditions are only rarely specifically targeted for coordinated rehabilitative care beyond the intensive care unit. But expectations and market forces are gradually changing these limits. Similarly, rehabilitation as a field grew out of therapeutic associations often viewed as "marginal" in the late nineteenth century. As a medical specialty today, it often is amenable to alternative forms of treatment. This is particularly true as conditions treated by rehabilitation practitioners rarely have "cures."

Pediatric rehabilitation uses tools—including rehabilitation; physical, occupational, and speech-language therapies; gait analysis; casting; bracing; orthoses and protheses; electrodiagnosis; physical modalities; pharmaceuticals; and injections—to assess and improve the overall function of children. While the tools are similar to those of rehabilitation physicians for adults, the perspective is often different. In part, this is because of the neurodevelopmentally moving target of the child. Unlike adults, whose physical, mental, and sensory development has plateaued in a gross sense, children are still actively, often aggressively, changing in those respects. Thus, an adult with a low-level cervical spinal cord injury would learn to operate a wheelchair, transfer himself or herself, and so on. For a child, depending on his or her age, this might at first be difficult, but then increasingly possible, and then be complicated by growth and the shifting proportions of the child's body parts. Pediatric rehabilitation providers have to take account of such changes.

In addition, that children are still being educated by society—in a formal school setting—requires that pediatric rehabilitation providers interact with teachers in a fashion that their adult counterparts usually do not have to do. In one sense, this is a salutary symbiosis, as the educational program can be changed to take account of static or evolving impairments. On the other hand, it adds a layer of complexity onto a rehabilitative plan.

Families also play a huge role in pediatric rehabilitation. While parents can sometimes need as much support as the child, they are usually extremely strong advocates and caregivers. In current clinical models, the pediatric rehabilitation specialists are supportive partners to the child and family rather than directors of care. Siblings, like their parents, also need attention, which can be hampered by the physical and emotional demands of a child with a disability.

Research into exclusively pediatric rehabilitation conditions and settings is only slowly growing. Health services research, for example, has been struggling to identify care delivery mechanisms designed specifically for this sector despite exclusion by adult modeling. Clinical research also has met challenges. Since the numbers of children involved are fewer than adults and the reimbursement for their care, at least in the United States, is less consistent, research has sometimes lagged. As is true for its adult cognate, pediatric rehabilitation has also struggled to identify means to measure outcomes of children treated with rehabilitation techniques. A further challenge is the relative infrequence of such pediatric conditions. Low numbers make it difficult to generate statistical proof of treatment efficacy. Nevertheless, taking advantage of related basic sciences, pediatric rehabilitation internationally continues to doff its empirical roots and to seek out theoretical underpinnings for functional intervention and evaluations of outcomes. In this goal, pediatric rehabilitation is following the paths of previous specialties from ophthalmology to adult rehabilitation.

PEER SUPPORT

Peer support involves a process of giving and receiving help among individuals who are in similar situations. A peer can be defined as a person of equal standing with another—someone who is equal to another person in some important respect such as age, social class, or experience. A peer can also be defined as a friend or companion. Peer support can vary greatly from one circumstance to another, but central to peer support is the ability to understand someone else's situation because of some shared experience. Through this common understanding, peers are able to share stories, exchange information, and often, once the relationship has become solid enough, challenge each other when they are in conflict. Peer support stresses experiential and not professional knowledge. The very value of peers is that they do not have professional training or use professional jargon: They speak from their experience and from a similar status.

The relationship between peer support and disability involves discussing the history of peer support;

how peer support occurs across types, structure, and settings; and the benefits and conditions necessary for peer support to be effective.

HISTORY OF PEER SUPPORT

The concept of peer support in the United States can be traced back to the establishment of Alcoholics Anonymous in 1935, which was formed under the assumption that persons who experienced and overcame alcoholism would be most effective in assisting others who were trying to do the same. The concept of peer support inherently allows individuals to be seen as resources. Specific to the area of disability, peer support offers an alternative to traditional ways of viewing disability as a deficit or problem in need of treatment. Because of societal discrimination, disability can often be an isolating social status. The availability of peer support can provide an antidote to stigma through affirming the very characteristic for which individuals with disabilities have often been disrespected. Furthermore, peer support can be an empowering experience for those who have faced discrimination and marginalization. Such a relationship can provide a positive and/or critical alternative way of looking at the world. For these reasons, peer support has emerged as a central guiding force in many disability-related organizations and services. Peer support relationships involve people with disabilities or family members or caretakers of people with disabilities.

Peer support has grown most visibly through the formation of a number of disability-related organizations across the United States. For example, peer support has been the foundation of the self-help movement and, more specifically, organizations such as Recovery Incorporated, a nonprofit peer-based organization that began facilitating weekly support group meetings for people with mental illness in 1937. As another example, United Cerebral Palsy was created as an organization in 1949 when two families with children with cerebral palsy came together to create a network to allow families to stay together and improve the lives of children with disabilities. Support groups have been a core service of this organization as they strive to help families share resources.

In the United States, the revolutionary thought of the 1960s continued to foster ideas related to peer support, as a rise in service delivery by paraprofessionals and nonprofessionals increased interest in the concept of peers supporting each other. An excellent example of this is the Center for Independent Living (CIL) movement. Led by Ed Roberts in Berkeley, California, a group of students with disabilities organized to pressure the University of California at Berkeley to become more accessible and to provide more supports for students with disabilities. In 1972, the Berkeley Center for Independent Living was founded as a community-based organization, with peer support as one of its central values. Today, more than 400 CILs exist around the United States, and peer support remains a core service for most local chapters.

During the 1980s, peer support continued to make its mark, as seen through the development of the Mood Disorders Association, a nonprofit, peer-based organization that was started in 1982 by and for mental health consumers. As another example, Americans Disabled for Accessible Public Transit (ADAPT) was founded in 1983 to promote advocacy in the disability community through civil disobedience to achieve the goal of public accessibility. Many other large organizations for people with physical disabilities, such as the National Spinal Cord Injury Association and chapters of the Paralyzed Veterans of America, have made peer support one of their major activities.

Peer support has been a strong component of independent living organizations around the globe. For example, independent living organizations in Sweden and Canada have used peer support as a mechanism for bringing people with disabilities closer to independence. Similar to the United States, international peer support developed strongly in the 1960s and 1970s. For example, in 1962 in the United Kingdom, a group of parents of children with disabilities formed the Society for Autistic Children, which later became the National Autistic Society, and includes a telephone support service for parents of children with autism. In Australia, peer support was part of a larger community health movement during the early 1970s. During this time, under the Whitlam administration, local community health projects were directly accountable to the communities they served. There was community involvement at every level of service development and delivery. This involvement opened channels of communication among service providers, bureaucrats, and consumers in areas such as disability and mental illness. Founded in the 1970s, GROW is one example of such organizations that flourished and presently runs peer-led groups for those with mental illness in many countries. More recently, peer support has reached other nations such as Thailand, where, in 2000, people with disabilities were trained as peer counselors. Thai individuals with disabilities have continued with training that focuses on how to establish and maintain an independent living center.

TYPES OF PEER SUPPORT

Peer support can take multiple forms, including peer support provided on an individual basis and that provided in a group setting. Individual peer support can include peer education, peer counseling, and peer-mentoring relationships. These relationships may involve sharing similar experiences and offering advice based on these experiences. As an example, individuals with newly acquired spinal cord injuries may serve as mentors to new patients, so that both can share emotional experiences as well as information regarding resources they have attained since their injuries.

In contrast to individual approaches, peer support groups are often composed of people with disabilities who have common difficulties. Created around common core issues, these groups then meet regularly to discuss their problems and strategies to deal with them. To provide an example, one peer support group among people with psychiatric disabilities announced that their group had two goals: serving as a source of friendships for participants and seeing that interpersonal skills learned via the group process would generalize to other relationships beyond the group.

STRUCTURE OF PEER SUPPORT

Across these forms of peer support, the structure of peer support relationships can also vary. Relationships can range from formal to informal and can occur across or within diverse programs. Regular contact between the supporter and supported can occur face-to-face and may involve educational or recreational activities. Contact can also be less frequent and may involve a simple phone call whereby the supporter is simply “checking in.” Last, support can be shared over the Internet in the form of listservs, chat rooms, and other online communities. Online support can be a particularly valuable resource for people with disabilities who face barriers regarding physical accessibility, transportation, and personal attendant care (for example, those who live in rural communities). One peer-mentor program had a variety of mentors “on-call” for consumers to contact as needed. In contrast, one peer support group was more formally organized, as the group included two meetings each week. One meeting was structured by the group. It included both time for each member to talk and also a facilitated discussion around some issue. The second weekly meeting was a recreational activity.

SETTINGS OF PEER SUPPORT

Peer support in its many forms and with its many structures can also be incorporated in a number of environments, including educational settings, employment settings, rehabilitation hospitals, independent living centers, health promotion centers, and supported living/supported housing settings. For example, one peer-mentor program, set up with individuals with violently acquired spinal cord injuries, is based in the rehabilitation setting. This program consists of, among other things, recreational activities, including wheelchair basketball, camping, and sailing. As another example, one supported housing program for individuals with HIV involved a series of groups. These groups were developed to focus on specific needs, such as cooking, emotional and addiction recovery support, information sharing about opportunistic infections, treatment protocols, and medication and alternative holistic therapies. Needs were identified in the group setting, and all community members were asked to contribute to solving them.

BENEFITS OF PEER SUPPORT

The little research that has been conducted to evaluate peer support programs has found positive results. Broadly, peer support seems to benefit the people being supported, those doing the supporting, and the broader community. In terms of individuals being supported, a number of psychological effects have been demonstrated. First, peer support in general seems to promote a sense of empowerment among the group of people with disabilities. When people are faced with a stressful situation, especially when they acquire a new disability, they prefer the company of those facing the same stressful event. Peer support helps people feel validated when they are able to share emotional reactions with others having similar experiences. Furthermore, people are given the opportunity to learn from the peer providing support. They are given the chance to develop skills that have proven effective for someone else in their life situation. They can also learn to advocate for themselves and may experience enhanced feelings of self-worth because someone similar cares about and understands their situation.

Peer support may also help the peer doing the supporting. In general, research conducted across a variety of populations has found that helping others can help you. Specific to disability, peer supporters can experience a heightened sense of self-worth as they are able to share their valuable knowledge and presumably help someone else in the process. They may also feel and explicitly acknowledge a strength of their disability (perhaps for the first time), as it has given them the tools to assist someone else through a difficult time. Furthermore, peer supporters often feel great satisfaction knowing they are helping someone else. This experience has also been cited as a catalyst toward career development.

Finally, the broader community can benefit from peer support in a number of ways. First, peer support can demonstrate to the community a positive contribution that peers with disabilities can provide. Furthermore, it seems to be a mechanism for building capacity for change. When people are sensitive to and aware of common needs and common rights, they have the opportunity to make appropriate social change; they can work together to develop appropriate solutions to complicated social issues and problems. For example, advocacy groups can be built based on common interests and can evolve from peer support relationships and groups. Advocacy groups facilitate change in certain areas.

As an example of the variety of benefits that peer support can yield, one peer support program among persons with psychiatric disabilities reported that participants maintained their independent or semi-independent living and increased their use of community resources. The participants also experienced greater social support networks and social and leadership skills. Furthermore, their likelihood of hospitalization decreased, and they reported high satisfaction with the program.

Benefits include that peer support is more cost-effective than that provided by professionals. Peer support also allows more people to receive assistance more frequently: Assistance becomes a part of individuals' natural networks rather than something they receive only when going to see a professional in an office.

Though advantageous in many situations, effective peer supporters require adequate support themselves to avoid burnout. Often, a strength of peer support is that peers have not been formally trained as clinicians or practitioners and therefore speak to their peers from their own experience. This strength also presents a limitation in that they need to be supported in dealing with others' problems, as this can be an overwhelming burden. Support can be provided to peer supporters in a number of ways, from structured contact with professionals to more informal contact with other peer supporters.

It is imperative that peer relationships, whether individual or group based, are comfortable for all involved and that they make individuals feel that it is acceptable to talk about their problems or sources of stress. A supportive environment is key to an effective peer support relationship.

Given the hundreds of millions of people with disabilities in the world and the limited number of professionals, peer support is a vital resource for people with disabilities. Peer support helps people with disabilities cope with everyday concerns, enabling them to validate their strengths and to move forward to improve their lives. As this review as shown, peer support can take many forms, yield many benefits, and lead to the development of advocacy efforts.

PEOPLE FIRST®

People First® is an international self-advocacy organization with chapters all over the world. People First® groups are run by and for people with intellectual disabilities to work on civil and human rights issues. People First® groups are always led by people with intellectual disabilities. They have four guiding principles:

1 Speaking for ourselves
2. Solving problems—making decisions
3. Knowing our rights and responsibilities
4. Contributing to our community

Most People First® groups elect officers to run their meetings and have facilitators or advisers who assist group members. Facilitators help the group without taking control. People First® groups work on a wide variety of issues, including closing institutions, housing, employment, voting, and sexuality and social relationships. People First® groups fight prejudice and discrimination against people with disabilities. They also combat overprotection by parents and professionals. Those who participate in People First® find that their lives are enriched. They have more friends and colleagues to socialize with and help them to solve problems and meet individual goals.

PEOPLE FIRST® HISTORY

In 1968, a meeting was held in Sweden at a parents' organization for children with developmental disabilities. The organization had a motto—"we speak for them," meaning the parents spoke for their children. However, people with disabilities who attended the meeting wanted to speak for themselves. They started their own self-advocacy group. Similar groups quickly spread to England and Canada.

In November 1973, individuals with disabilities living at the Fairview Hospital and Training Center in Salem, Oregon, attended a conference in British Columbia, Canada. The conference was organized and run the British Columbia ARC. The conference was for people with disabilities, but it was run by professionals. The group from Oregon wanted to start a self-advocacy group by having a similar conference, but they wanted it to be organized and run by people with disabilities. They wanted support from professionals only when it was requested. During a meeting on January 8, 1974, they discussed how to name their group. Everyone disliked being called by negative labels such as "retarded," so they decided to call themselves "People First."

In October 1974, the first People First® Convention was held in Oregon. It was attended by 560 people.

Within five years, Oregon People First® had 1,000 members. People First® groups also began in Nebraska, Kansas, California, and Washington state. Self-advocates from 42 other states were seeking help in starting their own groups. The first international self-advocacy conference was held in Tacoma, Washington, in 1984. International conferences have since been held in London, England (1988); Toronto, Canada (1993); Anchorage, Alaska (1998); and Northampton, England (2001).

CONCLUSION

As of 2004, there are People First® and self-advocacy groups in 43 countries with an estimated 17,000 members. It has been estimated that there are more than 800 self-advocacy chapters in the United States with a national organization called Self Advocates Becoming Empowered (SABE). Although not all self-advocacy groups choose to call themselves People First®, this group continues to be a dynamic and visible arm of the international self-advocacy movement.

PERL, OTTO (1882–1951)

Author and cofounder of the Self-Help Alliance of the Physically Handicapped

Otto Perl was a German author and cofounder of the Selbsthilfebund der Körperbehinderten (Self-Help Alliance of the Physically Handicapped) (1919–1931), the first emancipatory self-help organization representing the interests of the physically disabled in Germany, which was also called the "Otto Perl Alliance." He was born on October 19, 1882, the son of a small farmer, in the state of Saxony. With nine siblings, he grew up in rather simple rural circumstances.

From the age of 13, he suffered from a stiffening of joints. In 1898, he began an odyssey through German so-called invalid institutions and cripple homes. In 1919, he became part of a small circle of founders of the Self-Help Alliance for the Physically Handicapped in Berlin. From 1922 until 1924, he was acting deputy of this first organization to represent the interests of people with birth defects and physical disabilities in Germany. After completing his studies at the gymnasium in 1919, he studied philosophy and economics in Berlin. In 1926, he lived in his own room for the first time in his life, in an institute in Nürnberg, and published his book, *Krüppeltum und Gesellschaft im Wandel der Zeit* (*Crippledom and Society in Changing Times*). He fought against institutionalization and demanded the right for self-determination. However, he limited his demand for education and job training to the "mentally normal" but physically handicapped person, in contrast to the "mentally handicapped," and already in 1926, he showed a thinking that alarmingly coincided with the Nazi ideology for selective care.

In 1946, a year after the end of the National Socialist regime, he described himself as a victim of Nazi encroachments, yet in 1935, he had demanded the separation of the "mentally sound" and the "mentally degenerate" and unmistakably applauded the National Socialists for their measures to control hereditary biological problems. Otto Perl died on October 17, 1951, at the Kaiser-Friedrich-Siechenhaus (Kaiser-Friedrich-Institute for the Invalids) in Wittenberg.

PERSONAL ASSISTANCE AND DIRECT PAYMENT

Personal assistance services are the most critical services for individuals with disabilities and are often considered to be one of the individualized supports essential for community life. Personal assistance is defined as one person assisting another with the tasks that individuals would normally do for themselves if they did not have disabilities (Litvak, Zukas, and Brown 1991). Personal assistance services are founded upon principles of universal access; information access, including for children and youth; community access; empowerment; and opportunities for full lives (Racino and Litvak 1999). In the United States alone, personal assistance services affect the lives of more than 9.6 million citizens with disabilities.

The 1991 Resolution on Personal Assistance Services, passed at the International Personal Assistance Symposium, upholds the basic human and civil rights to full and equal participation in society called for in the Americans with Disabilities Act (1990) and the United Nations Universal Declaration on Human Rights. Personal assistance services "shall enable users to exercise their rights and to participate in every aspect of sociocultural life including, but not limited to home, school, work, cultural and spiritual activities, leisure, travel and political life" (Litvak and Kennedy 1991). The right to these services is part of what it means to be without discrimination based on color, race, creed, gender, religious background, income and social class, cultural or ethnic origin, geography, or sexual orientation (World Institute on Disability 1991).

Personal assistance services (PAS) are consumer-directed services (Heumann and Racino 1992; Flanagan and Green 1997), and their growth has indicated a need for development based on the individual and for models that take into account unserved or underserved groups or populations. These groups may include people who need technological assistance and those with mental retardation and physical disabilities, brain injuries, psychiatric disabilities, and other cognitive disabilities (Racino 1993, 1995a, 1995b), in addition to youth and those who belong to cultural and ethnic minorities (Egley 1994). Adaptations may vary substantially by disability field, in part due to the organization and funding of services in countries such as the United States. Leaders internationally in PAS by field include Boston University's Center for Psychiatric Rehabilitation and Judi Chamberlin, as well as consumers such as Lori Stewart, one of the independent living leaders who is a psychiatric survivor. Personal perspectives were shared internationally through the 1991 symposium (Weissman, Kennedy, and Litvak 1991).

Critical aspects of personal assistance services are that it must be available up to 24 hours a day, 7 days per week, to people of all ages, and with access to governmental payments (independent of marital status and not as a disincentive to employment). In addition, selection of personal assistants must be the choice of the service user and include family members (World Institute on Disability 1991). Agency models of assistance, while supported, are more expensive and offer far less user control of services. More than 30 specific services have been surveyed in the United States, including personal, household, cognitive, transportation, and short-term (respite, emergency) services (Egley 1994), and they have been reviewed in the context of specific population groups (e.g., on issues such as involuntary care). Models of assistance include work site support (e.g., supported employment and worker-directed PAS) and have been approached through the individual life course theory (Kasnitz 1993), among others (e.g., Beach Center on Families, University of Kansas, lifespan theory, consumer empowerment theory).

Personal assistance services have been studied and investigated over the past decade, including through a congressionally funded U.S. Center on Personal Assistance Services, based at the World Institute on Disability. Original nationwide work in the field was conducted by Simi Litvak, Hale Zukas, and Judith Heumann (1987) in the report *Attending to America,* based on the independent living paradigm developed by Gerald DeJong, a supporter of personal assistance in long-term care (DeJong, Batavia, and McKnew 1992). The centers also developed from their international roots (e.g., Judith Snow and circles of support [Canada]) with national support, such as the Consortium of Citizens with Disabilities (e.g., Marty Ford of the Arc), state-level field models in severe disabilities (O'Brien 1992), the aging and university communities (Heumann and Racino 1992), and local/ state independent leaders throughout the United States.

New models of youth personal assistance services include peer-to-peer support; self-determination; career development; in-school support; youth lifestyles, including dating; and social relationship facilitation, if desired. Program models of PAS for independent living have been identified as varying based on the degree of consumer choice, often involving variations of state administration in relationship to the service user (Egley 1994). Among other findings (e.g., costs of PAS), "available data have indicated that different models do tend to serve different population groups, but offer no evidence that models and populations are closely or inherently linked" (Egley 1994:18). Major systems concerns in the United States revolve around systems coordination, eligibility, access, service limitations, assessment, workforce, liability, service quality, and long-term services coordination.

Through the past decades, PAS leaders have reviewed the development of the diverse fields (e.g., community integration, supported housing and living) and led national policy at the level of their relationships with organizations such as the National Council on Disability. Margaret Nosek, at ILRU-Texas at the Baylor College of Medicine, has assessed independent living programs on the basis of program age, consumer control, and budget; framed PAS in the community integration context (Nosek and Howland 1993); and supported U.S. and worldwide PAS development at the public policy levels (e.g., Nosek 1991). Leaders such as Ed Roberts have provided the inspiration for the continued development from the independent living movement's early roots.

Direct payments to service users have been the theme of funding in the field of independent living (Brown 1993), while other fields have pursued cash subsidies as part of service packages (Bradley, Knoll, and Agosta 1992 [family support services]) and explored the options of direct payments (Ridley and Jones 2003 [mental health]). In addition, major efforts nationwide in the United States have been placed on modifying public sources of funding for Medicaid, especially for community services (Doty, Kasper, and Litvak 1996; Racino 2000a, 2000b). In the field of mental retardation and developmental disabilities, individualized funding tied to the person has been the major focus in reform for the past several decades (see also Racino 2000a, 2000b; Lord and Hutchinson 2003). In the United Kingdom, direct payments to people with disabilities to purchase their own support services were attributed to importation from the United States and Canada (Maglajlic, Brandon, and Given 2000).

Debates by the late 1990s moved on the services front to privatization in the context of supporting the individual person (vouchers, grants, and service choice; Glover 1999) and less so to the family-user-government relationships. By 2000, the first international conference on individualized funding and self-determination was held in Seattle, Washington, and the Internet hosted sites worldwide on the topic (e.g., European Network on Independent Living, Centre on Human Policy, Syracuse University, Instituto Universitario de Integración en la Comunidad in Spain, the Australian Society Association for the Study of Intellectual Disabilities, Community Living Society of Canada, and Hester Adrian Research Centre in the United Kingdom).

International models of personal assistance services, which were also presented in 1991 at the International PAS Symposium, include housing and personal assistance services in Sweden (Tucker and Kleinman 1990), especially the Stockholm Cooperative Model for Independent Living (Ratzka 1991). Service brokerage with a component of individualized funding began in Canada (Salisbury, Dickey, and Crawford 1987), which has strong proponents for individualized funding and support approaches and links easily with the United States and United Kingdom (Centre for Research and Education in Human Services 1993). Independent living has been pursued in diverse parts of the world, from Japan and South Africa to Norway and New Zealand, and these roots are critical for the future development of PAS.

Today, the support and empowerment paradigm has influenced the development of PAS, including "model variation" based on community membership, person-centered and support approaches, the continued expansion to and from other population groups (e.g., HIV-AIDS), systems reform of state-federal-local financing, and diverse contexts such as those of abuse and rights abridgements. Personal assistance services, with its roots in the independent living movement, has reached new generations and holds a promise beyond its beginnings for personal and community futures in the years yet to come.

PERSONAL CARE ATTENDANTS

Personal care attendants (PCAs), also referred to as personal assistants, are individuals who provide help to people who have difficulty performing, or are completely unable to perform, daily living activities by themselves due to a disabling condition or injury. Until recently, the use of PCAs was associated with only the most severely physically disabled population (e.g., people with paraplegia or quadriplegia). However, PCAs are increasingly employed to assist other populations who require extensive supervision or help with daily living activities, such as people with cognitive impairment and frail elderly individuals who are at risk for nursing home placement.

While historically, the majority of PCAs were untrained independent direct care providers, a rising demand for workers who provide assistance services has led to the development of training programs by community colleges and other organizations that certify paraprofessionals in the health care field. The duration of such programs may be from several weeks to several months. In many programs, the titles *PCA* and *certified nursing assistant* (CNA) are synonymous. Like CNAs, PCAs are hired by home health agencies and nursing homes, although many certified PCAs retain independent status.

PCAs are central to the "personal assistance service (PAS)" model of providing help to people with disabilities in the home setting, a mainstay of the independent living movement. The PAS model is in contrast to the home health agency-based model of home care delivery historically associated with the aging service system.

The PAS and agency-based models represent different and incompatible philosophies of service delivery. Proponents of PAS view home health agency-based workers to be part of the medical model of service delivery, in which health care providers define, direct, and deliver services to the individual. Agency supervisors hire, train, pay, and, if necessary, fire the home health aide or homemaker who is the direct provider of care. Under the medical model, the service recipient assumes the passive role of patient, with little input into the nature of services provided and little control over the direct provider of care. Activists and supporters of the independent living movement argue that the medical model entails the sacrifice of personal control as a condition of service receipt. Thus, this model is perceived to foster dependency, which is antithetical to the concepts of empowerment and independence—major goals of the independent living movement.

In contrast, control resides with the service recipient, termed *consumer* or *client,* in the PAS model of service delivery. Under this consumer-centered model, the person with disability interviews, hires, trains, manages, and, if necessary, fires the direct provider of services, generally a PCA. While the title "personal care attendant" is still widely used, members of the independent living movement and its broader counterpart, the disability rights movement, perceive the word *care* to hold connotations that are more appropriate to a medical model approach. *Personal assistant,* on the other hand, conveys a broader role that encompasses assisting consumers to meet work-related and social needs.

The duties of the PCA, or personal assistant, in the PAS model are defined by the consumer in accordance with his or her needs. Payment is either out of pocket or from third-party payers to the consumer who, in turn, pays the assistant, thus reinforcing that accountability is to the consumer in a clearly defined employer-employee relationship.

In general, two features of the PAS model increase the likelihood that service recipients will have their needs met over the more traditional agency-based model. First, the job of the PCA is defined by the consumer, not an agency, and redefined according to the consumer's changing needs. Control over job description such that the highly specific needs of the individual are met empowers the person with disability to participate in life's activities to a far greater extent than the more limited agency-based model, in which tasks performed by the PCA are fixed and typically confined to the client's home.

A second beneficial feature of the PAS model is the additional amount of coverage allowed by the organizational structure of the program. The elimination of administrative overhead associated with agency-directed services results in cost savings that can then be used to purchase additional hours of PCA service delivery.

The majority of third-party funding for PCAs is through states' Medicaid personal care optional benefit. Currently, only 28 states have this option available, although recent emphasis on community care for people with disabilities has heightened interest in expanding the Medicaid personal care option. An obstacle to expansion of this option is concern regarding the feasibility and desirability of the PAS model for elderly persons with disabilities. Advocates argue that the principles of autonomy, control, and independence are appropriate for older as well as younger individuals who need help with tasks essential to everyday life. Furthermore, an alliance of the two constituencies could greatly enhance opportunities for political action in securing the expansion of long-term community-based services in a manner that maximizes the potential for community rather than institutional living, as well as participation in the mainstream of community life.

For some elderly people who need extensive help, PCAs are a feasible and not prohibitively expensive alternative to nursing home placement. However, there is no doubt that some elderly people lack enthusiasm for the personal assistance model, generally because of discomfort with assuming the role of employer or supervisor. In response to this discomfort, many independent living centers offer training to people with disabilities on how to manage their PCA.

Other concerns that have served to impede widespread use of PCAs are fears of client safety, exploitation, and even abuse. Such fears stem from the fact that independent PCAs often lack the training that agency-based workers are required to receive as a term of their employment. In addition, attendants are often hired in response to newspaper ads placed by clients and consequently are not subject to background checks. Despite these potential drawbacks, several large-scale studies comparing the personal assistance model to the agency-based model have found no difference in the instances of abuse, exploitation, or adverse consequences associated with lack of training reported by consumers of the two models of service delivery. In fact, several studies conducted to date have concluded that clients of PAS are more satisfied with care arrangements than are clients of agency-based services.

Another unique feature of the PAS model of care, as offered under the Medicaid personal care option by a number of states, is that family members of the person who requires help are eligible to serve as PCAs. Studies have shown that people with disabilities who employ family members as their personal assistants are most satisfied with the quality of the job performed. This finding has allayed fears among Medicaid program administrators that family members will take advantage of a personal care benefit, by receiving payment for a service they would have performed anyway. Research has shown, however, that payment to family members enables them to stay out of the workforce, assisting their loved ones in performing daily tasks while still earning much-needed income.

Other labor issues associated with the PCA position include low pay and few or no benefits. However, a survey of Medicaid PAS programs conducted by the World Institute on Disability in the 1980s revealed substantial variation in wages and benefits offered to attendants, with independent PCAs in some states earning more than agency-based workers in other states.

With the aging of the population and increase in life expectancy for people with disabilities, it is likely that the demand for PCA services will increase in the near future, particularly by frail elderly people who desire to "age in place" despite disability. As this profession evolves, it is likely that associated wages and benefits will improve, as will its stature in the health care field. An adequate supply of PCAs will be essential to fuel current trends toward the development of home-based alternatives to nursing home care.

PHANTOM LIMB PAIN

The term *phantom limb* has been used since the 1870s largely to describe the experience of pain and other sensations from a limb that has been removed, although it has also been applied to sensations seemingly coming from dead tissue. American Civil War surgeon and physiologist Silas Weir Mitchell coined the term after working with amputees in Philadelphia but was not the first person to write about the phenomenon. Early descriptions of phantom limbs appear in the works of Ambroise Paré (mid-1500s), René Descartes (mid-1600s), Charles Bell (early 1800s), and many others. The historical literature even reveals a self-description of a phantom limb by William Porterfield, a highly regarded Scottish physician who described his illusory sensations in 1759.

Different people living at different times had different motives for writing about this disorder. For Paré, a Renaissance barber-surgeon, the important thing was not to be fooled by "false" sensations. His fear was that sensations from dead tissue might dissuade well-meaning surgeons from performing life-saving amputations on riddled, gangrenous limbs. For Descartes, the great French philosopher, phantoms were used to argue that sensory information can be grossly misinterpreted and that the human soul receives information from the brain. Bell, in contrast, used phantom sensations of limbs in various positions to support a sixth sense, his muscle or proprioceptive sense. From his studies of sensation and movement, he became convinced that the brain not only sends messages to the muscles but also must receive feedback from those muscles to manipulate the limbs effectively.

As for Silas Weir Mitchell, he was both a surgeon and a humanist. He viewed phantoms an all-too-common horror of war that demanded compassion from the public and considerably greater understanding by the medical community. He even presented a fictional case involving a wounded medical officer in a popular magazine, hoping that "George Dedlow's" plight would move people to take the mental consequences of amputation more seriously.

Much was learned about phantom phenomena even before the twentieth century, including the fact that phantoms can follow amputations of more than just limbs. Descriptions of phantom breasts and even penises can be found in the early literature. So can recognition of the fact that phantoms can be brought on by loud noises, changes in the weather, emotional turmoil, and physical (including electrical) stimulation of the nerve trunk. Perceived changes in the size and position of a missing part have also been studied, as has the time-since-amputation factor.

The literature on phantom limbs now encompasses hundreds of papers and many books. These writings describe a multitude of treatments that have been tried, often with only temporary success. They include nerve resection, cauterization, narcotics, anesthetics, nerve blocks, acupuncture, and more radical amputations. Like Paré, Descartes, Bell, and Mitchell, people today are still trying to understand the relative contributions of signals from remaining nerve stumps, the roles of associative learning and memory, and the actions of the creative brain in this perplexing disorder. The hope is that, with more knowledge, there will be more effective treatments.

PHYSICAL ACTIVITY

An important aspect in improving the health of people with disabilities is to encourage higher levels of physical activity. Not only is physical activity important from the standpoint of promoting a higher quality of life by reducing secondary conditions and maintaining functional independence, but it is also essential in terms of reducing health care expenditures. Several reports have noted that a sedentary lifestyle can precipitate functional decline in people with disabilities and that physical activity must be a targeted health priority to prevent a progressive loss in health and function.

TERMINOLOGY IN PHYSICAL ACTIVITY

Physical activity involves all forms of bodily movement produced by contraction of skeletal muscle that substantially increases energy expenditure. Subcategories of physical activity include leisure-time physical activity (LTPA), which is a broad descriptor of the activities one participates in during free time, based on personal interests and needs. A structured form of physical activity is generally referred to as *exercise*, which is different from other forms of physical activity by its well-planned, structured, and consistent body movements and repetitions. Other kinds of physical activity include work-related activity or household activity. Gardening, cleaning, and working in physically demanding jobs (e.g., construction, janitorial) are all considered forms of physical activity. Among people who have a disability or are injured, therapy or rehabilitative exercise could also be considered a form of physical activity.

Physical Fitness. Physical fitness is defined as a set of attributes that people have or achieve that relates to the ability to perform physical activity. Components of physical fitness include cardiorespiratory endurance, muscular strength and endurance, flexibility, body composition (ratio of lean muscle mass to body fat), balance, and respiratory function. Certain individuals with disabilities will require a greater amount of each component depending on the various secondary conditions that may be associated with their disability. For example, persons with post–polio syndrome may require respiratory exercises to maintain the strength of the pulmonary musculature. Individuals with multiple sclerosis often have difficulty with gait and balance and would benefit from an exercise training program that targeted these areas.

Exercise. This is a subset of physical activity that is planned, structured, and consists of repetitive bodily movement that is done to improve or maintain one or more components of physical fitness. Examples of structured exercise that people with disabilities often participate in are chair aerobics, swimming, and handcycling, among others.

Moderate-Intensity Physical Activity. This term is used in the *Healthy People 2010* document to describe any type of physical activity requiring three to six times the energy required at rest. Since the definition has been developed for young individuals without disabilities, it is not clear if a "moderate" level of physical activity would be different for persons with disabilities.

Vigorous Physical Activity. This term is also used in the *Healthy People 2010* document to express any physical activity requiring seven times the energy required at rest. Similar to the definition for moderate intensity physical activity, this definition has been established for younger populations without disability.

Many activities that people with disabilities perform require a higher level of energy expenditure (i.e., transfers, walking with crutches or pushing a wheelchair, carrying various items). It is possible that moderate or vigorous physical activity has a different connotation for people with disabilities and does not fall in the same range that describes these activities for the general population. For example, carrying a bag of groceries from the store to the car may be considered a "moderate" activity for the general population but a "vigorous" activity for someone with reduced gait efficiency. More research is needed to evaluate the intensity level of various instrumental activities of daily living and general physical activities in persons with various types of physical, cognitive, and sensory disabilities.

PUBLIC HEALTH INITIATIVE IN PHYSICAL ACTIVITY

As a result of several landmark studies that have shown a graded, inverse relationship between physical activity/fitness and the incidence of morbidity and mortality, public health officials and federal agencies are recommending that all Americans, including persons with disabilities, engage in a minimum of 30 minutes a day of moderate aerobic exercise. The American Heart Association, National Institutes of Health, Centers for Disease Control and Prevention, Surgeon General's Office, and the American College of Sports Medicine have all developed position statements that call for Americans to achieve a higher level of physical activity. One of the historic documents published by the Surgeon General's Office in 1996 was a report titled *The Surgeon General's Report on Physical Activity and Health.* This report emphasized that physical inactivity is a major contributor to heart disease, adult onset diabetes, and colon cancer and that the risk from inactivity is similar to that of smoking. Today, physical activity has been recognized by numerous public health organizations as an important vehicle for improving the health of the U.S. population.

Despite strong endorsements from the Centers for Disease Control and Prevention (CDC), National Institutes of Health, Surgeon General's Office, and American College of Sports Medicine, most Americans are still not obtaining the recommended amount of physical activity that is necessary for maintaining health, and the level of physical inactivity among persons with disabilities is significantly higher than that of the general population. This represents a significant public health issue for people with disabilities.

OVERVIEW OF PHYSICAL ACTIVITY AND DISABILITY

For close to a half century, exercise has been promoted as one of the most powerful health promotion strategies for reducing chronic disease (i.e., heart disease, diabetes) and functional limitations. The first 25 years of research in exercise physiology contained only a handful of studies that investigated the effects of exercise on people with disabilities. Several of these studies were conducted on children with cerebral palsy and other neuromuscular disorders, primarily in Sweden and other Scandinavian countries. It was only until the mid-1980s that a growing number of researchers began to investigate the effects of exercise on people with disabilities in both children and adults.

The research literature on physical activity, exercise, and disability continues to expand. Exercise-related studies are being conducted to determine the effects of various interventions using cardiorespiratory, strength, flexibility, and balance training to enhance overall health and function. While there are numerous short-term studies demonstrating the positive effects of exercise on improving various health outcomes in people with disabilities, longitudinal studies are still lacking.

Low Physical Activity Participation among People with Disabilities

Federal officials and members of the public health community are growing increasingly concerned that as persons with disabilities age, they will have increasing difficulty performing activities of daily living (ADL) (i.e., dressing, showering) and instrumental activities of daily living (IADL) (i.e., ambulation, doing laundry, grocery shopping) at a much earlier rate than the general population. Persons with physical disabilities are often faced with various environmental challenges (i.e., navigating ramps and curb cuts, performing transfers) as a result of their impairment (i.e., paralysis) and/or associated secondary conditions (i.e., spasticity, weakness, pain, fatigue). The high incidence of physical inactivity observed in persons with disabilities, combined with the natural aging process, presents a greater risk of premature physical decline and accentuates the importance of physical activity in maintaining health and function.

Despite calls for higher levels of physical activity from major federal and private agencies, the vast majority of persons with disabilities are not obtaining the recommended 30 minutes a day of physical activity necessary for conferring health benefits and preventing or mitigating secondary conditions. Several reports have noted that people with disabilities have a disproportionately higher incidence of physical inactivity compared to people without disabilities. The *Healthy People 2010* document reported the prevalence of physical inactivity among people with disabilities to be substantially higher than in people without disabilities, 56 percent versus 36 percent. And in data collected at the National Center on Physical Activity and Disability (NCPAD), very low levels of physical activity were reported among various subgroups of disability. As noted in Figure 1, individuals with stroke, type 2 diabetes, and arthritis were significantly below the recommended 30 minutes a day of moderate exercise recommended by the CDC and other federal agencies.

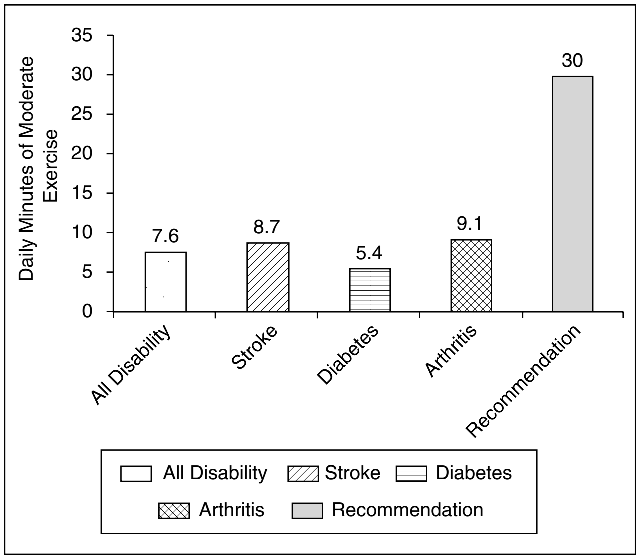

Figure 1 Daily Physical Activity Reported by People with Disabilities

Physical Activity and Reduction of Secondary Conditions

Numerous laboratory and field-based studies have quantified the many health and fitness benefits associated with physical activity. Among studies with disabled populations, benefits of endurance and strength training include reduced fatigue, reduced pain, improved fitness, and general well-being. Implicit in these reports is the notion that the health and fitness benefits associated with physical activity most likely follow a dose-response relationship. Most experts agree that any amount of physical activity is beneficial and that even minimal amounts of physical activity are better than no physical activity at all, and increasing amounts of physical activity accrue greater health benefits provided it is done safely. Vigorous physical activity performed in excess amounts (usually greater than one hour) increases the risk of injury. Physical activity must be conducted in a manner that allows maximum benefits at the lowest possible risk. Given the progressive nature of certain disabilities (i.e., multiple sclerosis) or physiological changes that occur after injury (i.e., spinal cord injury), greater attention must be provided by exercise specialists to ensure that the program is safe and effective in enhancing overall health. Shoulder injuries are common in chair users and have prompted researchers to develop alternative ways to exercise that will reduce the stress on joints and muscles that are used for ambulation.

Physical Activity, Functional Status, and Disability

Given the empirical evidence linking physical activity with functional status and overall health, as well as the fact that impaired health and functioning can impede participation in physical activity, one can postulate a downward cyclical pattern in both health and functioning that results from prolonged physical inactivity. The onset of disability often results in greater effort required to engage in physical activity, thereby causing persons with disabilities to remain sedentary. Physical inactivity over prolonged periods results in the development of secondary disabling conditions and further functional loss, which in turn results in greater effort to participate in physical activities.

The relationship between physical functioning and physical activity is a reciprocal one; physical functioning provides the individual with the capability to engage in physical activities, whereas physical activity helps to maintain and, in some cases, improve physical functioning. This reciprocal relationship, coupled with the high prevalence of physical inactivity among persons with disabilities, has profound implications for rehabilitation practice, especially in evaluating intermediate and long-term outcomes of clinical practice. For rehabilitation to play a role in the long-term maintenance and enhancement of physical functioning among persons with disabilities, monitoring of physical activity by both rehabilitation professionals and individuals with disabilities must be part of the recovery and maintenance process. The development of a standardized tool for assessing physical activity levels of people with physical disabilities can serve the purpose of monitoring physical activity patterns at both the individual (clinical application) and population levels (public health surveillance level).

Barriers to Physical Activity Experienced by People with Disabilities

Despite the plethora of evidence supporting the benefits of regular physical activity for improving health and function, people with disabilities are not engaging in physically active lifestyles at the same level as their peers. This may be due, in part, to the many environmental barriers to physical activity that people with disabilities are often confronted with, including inaccessible equipment and programs, transportation difficulties, limited income, unsafe neighborhoods, and a variety of personal barriers such as chronic health conditions and beliefs that exercise will not benefit their health.

Accessibility of fitness and recreation programs and facilities is a critical issue affecting the participation of persons with disabilities in fitness and leisure activities and ultimately affects their ability to improve their health and quality of life. A common barrier in the disabled population is the lack of attention given in promotional campaigns to the needs of persons with disabilities. Public health messages encouraging people to become more physically active usually recommend walking a minimum of 30 minutes a day most days of the week. Unfortunately, this recommendation is unattainable by many people with disabilities and chronic health conditions who are unable to walk (i.e., spinal cord injury, multiple sclerosis), have difficulty walking (i.e., back pain, obesity, heart condition, arthritis, frailty), live in neighborhoods where it is unsafe to walk, or are not allowed to walk without supervision. Campaigns to increase physical activity must present a more inclusive image by providing people with disabilities greater opportunities to improve their health besides walking. For this to occur, personal and environmental barriers must be eliminated so that access to various types of physical activity can be engaged in by a significant percentage of the disabled population.

Resource on Physical Activity and Disability: NCPAD

Through a grant from the CDC and the National Center on Birth Defects and Developmental Disabilities, the National Center on Physical Activity and Disability (referred to as NCPAD) was established in 1999. This information and resource center offers people with disabilities, caregivers, and professionals the latest information on fitness, recreation, and sports programs for people with disabilities. NCPAD's aim is to collect and synthesize various types of information on physical activity, rehabilitation, and disability and to disseminate this information to fitness and health professionals. With advances in technology, the NCPAD website at http://www.ncpad.org contains various types of readily accessible information on exercise and disability. The center also publishes a monthly electronic newsletter and sends out monthly features via e-mail on new topics and information related to physical activity and disability.

SUMMARY

The evidence concerning the benefits of physical activity is compelling. Among people in the general population, participation in habitual physical activity extends life, prevents multiple chronic conditions, and has beneficial effects on many systems of the body. Physical activity epidemiologists have noted that approximately 250,000 deaths in the United States annually can be attributed to a sedentary lifestyle. It is considered one of the leading preventable causes of death in our society.

It is unfortunate that most, if not all, of the physical activity longitudinal research has been conducted on nondisabled populations. While there is good evidence from short-term clinical studies demonstrating the benefits of physical activity among various subgroups of disabled populations, there is a dearth of longitudinal data on the long-term effects of physical activity in this cohort. Future longitudinal studies must be conducted on various subgroups of individuals with disabilities to determine the magnitude of health benefits that might be accrued from a physically active lifestyle.

PHYSICAL MEDICINE AND REHABILITATION

Until the beginning of the twentieth century, people with disabilities were generally scorned, pitied, demeaned, and, in some societies, killed. As recently as the 1950s, they were "imprisoned" without trial in places such as "The Home for the Incurables" and custodial facilities. Even when kept at home, they were often isolated and "hidden" from outsiders. Still, "custodial care" too often is considered first, before placement at home.

There were isolated instances of medical people who showed an interest in "cripples," but they were rare. In general, medical students and others were taught that it would be uninteresting and demeaning, if not futile, to be involved in the care of such people (as well as the elderly and chronically ill).

The main thrust toward the organized care of people with disabilities came because of (1) the great drama of polio, a sudden event (paralyzing and sometimes fatal) affecting a president, Franklin D. Roosevelt, and very frequently children, and (2) World Wars I and II. In both instances, the nation decided that care must be given and that there should be an attempt to reintegrate people with disabilities into the community.

This idea of allowing people with disabilities to participate and contribute in the community was not entirely original at that time. At the beginning of the twentieth century, bureaucracies were intended to facilitate employment of people with disabilities, especially if they had been in the military.

In most wars, relatively few numbers of disabled people had returned home; however, with the discovery of antibiotics and better trauma care, more veterans of World War II survived, and there was a national outcry that these people, these heroes, should not be "discarded."

In military hospitals, some physicians took it upon themselves to develop a system to help these veterans (largely men). It was soon discovered that it would be necessary to deal with issues of functional loss and frequently with overwhelming psychological and sociological issues. Social work, nursing, and other allied health personnel were found to be necessary in carrying out this work as a collaborative effort.

A solo physician could not address these needs alone, so "collaborative medicine" practices were developed to unite the physician with a team of medical consultants as well as nurses, physical therapists, social workers, speech pathologists, occupational therapists, vocational counselors, and various technicians. The approach had to be nonautocratic and non–male chauvinistic.

At the same time, the Veterans Administration (VA) system was developed, and most of its 172 hospitals included this potential for a rehabilitation system.

In the meantime, celebrity status was given to polio, especially because of the effect it had on Franklin D. Roosevelt, and huge amounts of money were raised as a bulwark for a national effort to provide care for this population.

These movements required physicians able to practice physical medicine and rehabilitation (PM&R), so the demand grew.

At about this time, a philanthropic couple in New York, Mary and Albert Lasker, became very interested in health. At some point, Albert Lasker decided that although he and his wife could contribute large sums of money to worthy causes, they could multiply this amount hundreds of times by "lobbying" in Washington, D.C., to get the government more involved in health.

Their main contribution to society was providing the impetus for the formation of the National Institutes of Health. They discovered that in Washington, D.C., there was a small agency headed by Mary Switzer that attended to some aspects of people with disabilities, especially vocation. Switzer was an intelligent, charming, and convincing woman with New England force and directness blended with Irish charm.

The Laskers also discovered an extraordinarily capable and charismatic man, Dr. Howard Rusk, who had built a rehabilitation center in New York at the NYU Bellevue Medical Center on 34th Street. He was an internist but had helped invent the techniques of PM&R and promulgated its principles. He had built the rehabilitation center at Jefferson Barrack Hospital in Missouri during the war. Dr. Rusk and Switzer, united by the Laskers, mesmerized the Congress and generated millions of dollars for Switzer's agency.

Mary Switzer's agency developed a mandate to deal with disability very broadly—educating a whole nation about people with disabilities. At that time, few hospitals or medical schools had shown much interest in people with disabilities, but their interest was piqued when money appeared on the horizon. Not only did Ms. Switzer supply funds for programs to train residents in the specialty of PM&R (physiatrists), but she also offered funding for stipends for medical students to train. Training residents made it possible to send physiatrists where there were few or none, and good and early care could be made available. Even now in the United States, if someone becomes disabled, he or she may go to the person considered the best doctor in town and find that the doctor has never seen a similar case and has no knowledge of rehabilitation. Switzer's impact on medical students started with her mandatory summer fellowship. Eventually, mandatory rehabilitation rotations were added for students in medical school.

Switzer also established regional research and training centers, which became very important, and some eventually evolved into centers for spinal cord injury and stroke. In each of these instances, a grant went to a comprehensive center and gave it status along with the obligation to have links to other states and to spread knowledge about aspects of disability beyond the original centers.

All of this made PM&R much more visible—to the medical and lay communities. Progress has been slow in coming, however, partly because physiatrists have not made an effort to explain who they are, what they do, and what their background and education are. Many physiatrists will not even use the word *physiatrist* but will simply say they care for the disabled. This does little to spread the word about the field of PM&R.

EARLY EFFORTS IN REHABILITATION MEDICINE

The first major thrust toward thinking about bringing people with disabilities into the mainstream of society was accomplished by Jeremiah Milbank, a wealthy 30-year-old New York lawyer who had been interested in helping the "crippled beggars" in the streets of New York. He allied his thinking with ideas from Germany, Canada, and France. Even before World War I, he had joined a few pioneering thinkers who were pushing to create self-sufficiency. They decided to create a rehabilitation facility in New York: the Red Cross Institute for Crippled Soldiers and Sailors. (It opened just after the war began.)

At the same time, the Army Surgeon General was encouraging growth of allied health assistance. Soon before World War I began, the American Occupational Therapy Association was formed. Milbank developed a program to educate the country about the potential of people with disabilities by providing medical/vocational assistance, training professionals, publishing literature, and establishing media contacts.

In about 1920, the state of Ohio created an organization to work with crippled children, and the Shriners opened hospitals for the care of these children.

Simultaneously, care providers saw a growing alliance in care among medical, surgical, and vocational/psychological/sociological health care providers, which set the stage for progression toward the collaborative approach of physiatry. Nonetheless, by 1920, there were few people in the field of rehabilitation.

Physical therapy began to develop and became recognized by physicians as vital to their team. In 1926, Dr. John Stanley Coulter pioneered PM&R in the United States and became assistant professor of physical therapy at Northwestern University Medical School.

In 1928, President Hoover established a "Children's Charter" highlighting the need to attend to the needs of crippled children.

In 1929, Dr. Frank Krusen established a Department of Physical Medicine and Rehabilitation at Temple University. He then joined the Mayo Clinic in 1935, organizing and directing the Mayo Clinic Graduate School of Medicine's first three-year fellowship in physical medicine.

In 1935, Dr. Henry Kessler wrote about the absolute necessity of the development of the rehabilitation movement around a comprehensive medical, sociological, psychological, and vocational model. He built a center in New Jersey and published eloquent reports and papers.

Dr. Kessler objected to the Workmen's Compensation Program, which made it more profitable to neglect the disabled than to restore them to activity and productivity.

In 1936, the American Academy of Physical Medicine & Rehabilitation was founded, and Dr. Krusen was elected as its first president. He wrote definitive texts, and his trainees were the first doctors trained to care for the disabled.

In 1942, Dr. Howard Rusk started the Army/Air Force Convalescent Center at Jefferson Barrack Hospital in Missouri. The plan was that "convalescent time" could be "rehabilitation time." In New York, Dr. Rusk learned how to proceed from the Milbank Institute for the Crippled and Disabled and was able to broaden physical medicine in his burgeoning "convalescent program." In the meantime, Dr. Krusen was a consultant in PM&R to the U.S. Army. He also continued to stress the need of education in PM&R.

In the war years, Bernard Baruch established the Baruch Committee on PM&R. He laid the groundwork for a great expansion in rehabilitation. Mr. Baruch gave grants for educating individuals and established major centers in research and patient care at Columbia, the Medical College of Virginia, and NYU. Concomitantly, the number of occupational therapists and physical therapists continued to grow and receive acceptance as key personnel in military hospitals.

The collaborative approach was even more firmly demonstrated through the founding of spinal cord injury centers at Hines VA (Illinois), the Bronx (New York), and Van Nuys (California). Dr. Paul Magnuson, who became the second medical director of the VA system, was first in charge of education and research and then headed the Dean's Committee System, which linked VA hospitals to academic centers. He later founded the Rehabilitation Institute of Chicago.

In 1947, the denouement in officially recognizing PM&R occurred with the approval of the American Board of Physical Medicine & Rehabilitation by the American Medical Association (AMA). The first three certificates of specialization went to Dr. John Coulter, Dr. Walter Zeiter, and Dr. Frank Krusen.

THE PM&R FIELD TODAY

The vision statement for the Academy of Physical Medicine & Rehabilitation, the major professional organization for physiatrists, is as follows:

> The American Academy of Physical Medicine and Rehabilitation will be the leader in assisting PM&R physicians to acquire the continuing education, practice knowledge, leadership skills, and research information needed to provide quality patient care, and to represent the best interests of patients with, or at risk for, temporary or permanent disabilities.

The distinction of the field of PM&R lies today in its ability to deal with the technical issues involved in diagnosing and treating disabilities/functional loss in ways that can in great breadth affect the quality of life of the individual patient. The training of physiatrists gives them a unique ability to unite in consideration of the basic pathology, the psychology of the patient, the social environment and the effects of existing attitudes allied to the patient, and what might appear to be a "new identity."

They have particular skill in bringing together all the facts at hand and being able to turn to members of the coalition who are best equipped to explain and deal with these matters. It is understood that there must be a sense of equality among members of the team and universal, mutual respect for the talents of all involved. Citizens in the United States are well aware of the need for "coordination" in health care and certainly in the case of people with disabilities; good care cannot be given without such talent available. In all health care, these premises are valid.

> Life is short, the art long, occasion sudden, experience fallible and judgement difficult. Not only must the physician show himself prepared to do what is needed, he must make the patients and attendants and the surrounding circumstances cooperate with him. (Hippocrates, 1st Aphorism)

—Henry B. Betts

▣ PHYSICAL THERAPY

Physical therapy is a health profession serving persons of any age or health status with compromised physical functioning or the desire to improve their current physical functioning. Typical clients are persons with compromised quality of life as a result of impairments, functional limitations, and disabilities caused by disease or injury. Physical therapists complete an examination of the individual and work with the person to determine goals that are reached primarily through exercise prescription and functional training to improve movement. A key component of patient management is education to promote physical health and to prevent injury and disability caused by abnormal posture and movement. Other problems such as pain may be addressed with treatments, including mobilization of soft tissues and joints, electrotherapy, and other physical agents.

Although the use of exercise as part of a healthy lifestyle is ancient in its origins, modern physical therapy developed in response to the needs of injured soldiers. The first physical therapists in the United States were trained to work with soldiers returning from World War I and were called "reconstruction aides." Some worked in hospitals close to the battlefields in France to begin early rehabilitation of wounded soldiers. Typical patients were those with amputated limbs, head injuries, and spinal cord injuries. As the field developed in the early part of the twentieth century, physical therapists also attended to the movement needs of those affected by polio epidemics. In this instance, strength was impaired by damage to cells that activate muscles to create movement. For these clients, physical therapists developed programs to strengthen muscles when possible and helped patients learn how to use the remaining musculature to accomplish functional mobility activities.

Physical therapists now practice in a wide variety of settings, including private practices, hospitals, rehabilitation centers, nursing homes, public schools, and home health agencies. In all of these settings, therapists work with the other members of the health care team toward common functional patient goals. Typical clients are individuals with back pain, elderly persons with arthritis or balance problems, injured athletes, infants with developmental disabilities, and persons who have had severe burns, strokes, or spinal cord injuries. For all of these individuals, physical therapists are the experts in examining and treating musculoskeletal and neuromuscular problems that affect how people move and perform physical functions such as standing up, walking, and lifting. Persons whose endurance for movement is affected by heart or lung problems or other illnesses are also helped by exercise and education to build activity tolerance, improve muscle strength, and move efficiently during functional activities. Individuals with limb deficiencies are taught to use prosthetic replacement devices.
