Examination of the individual begins with identifying the client's perceived problems with functional activities and his or her movement goals for reducing disability and improving quality of life. Adults with the types of impairments and functional limitations described above can be taught how to recover or improve movements impaired by disease and injury. On the other hand, infants born with developmental disabilities are helped to learn movements they have never done before, with an emphasis on functional mobility for satisfying participation in family and community activities.

New areas of practice are continually developing. For example, the scope of practice of a growing specialty in women's health includes concerns of women such as incontinence, pelvic/vaginal pain, prenatal and postpartum musculosketelal pain, osteoporosis, rehabilitation following breast surgery, lymphedema, and education for prevention, wellness, and exercise. All females across the lifespan, from the young athlete to the childbearing woman to the menopausal and elderly woman, can benefit from physical therapy.

In addition to working with individuals and their family members, many physical therapists have agencies or organizations as their clients. In the role of consultant, they perform services such as advising clients on preventing back injury in workers or designing workplace environments to prevent repetitive use injury. Physical therapists also teach in higher education institutions, specialize in areas such as the training of high-performance athletes, consult with public school teachers to educate children with disabilities, and provide consultation to fitness centers on developing workouts for clients who already know they have joint or back problems.

Physical therapists (also called physiotherapists) are at work in countries all over the world. The World Confederation for Physical Therapy is a nonprofit organization consisting of 82 national physical therapy associations. The confederation represents 225,000 physical therapists worldwide. In the United States, the American Physical Therapy Association represents 64,000 physical therapists and physical therapist assistants. The organization's mission is to further the profession's role in the prevention, diagnosis, and treatment of movement dysfunction and to enhance the physical health and functional abilities of the public.

The Commission on Accreditation in Physical Therapy Education accredits educational programs for physical therapists who are trained at the master's or doctoral level and for physical therapist assistants who complete a two-year associate's degree program. Physical therapy professional education involves grounding in basic sciences such as anatomy, physiology, and movement science followed by clinical science courses on the musculoskeletal, neuromuscular, cardiopulmonary, and integumentary systems. Education for the profession culminates in clinical fieldwork training involving internships of various lengths up to about a year. Although a graduate-level college degree and state licensure are required for practice in the United States, physical therapy education in many countries takes place in polytechnical institutions.

PHYSICIAN-ASSISTED SUICIDE

Defining physician-assisted suicide might initially appear a straightforward task, as it is an expression that concatenates three terms, each of whose meanings are clear and uncomplicated. However, even the most basic etymological exploration reveals a concept that sustains an inherent contradiction that is only the beginning of the problematization of what remains likely the single most critical issue in biomedical ethics. Said contradiction lies between the notions of "suicide," the killing of oneself, and "assistance," the implication of another in that killing, which by definition renders the assistant an agent and, at times, depending on the circumstances of that killing, even the sole agent in homicide, which may or may not be regarded as justifiable. In the simplest and most literal terms, then, *assistance* and *suicide* combine as—or at least approximate—an oxymoron, although one whose practice, whether legal or illegal, is far from unknown. Furthermore, moving only slightly beyond the most basic sort of definition, physicians are universally known to be admonished to "do no harm," a responsibility that is necessarily, at the very least, difficult to reconcile with deliberately putting a "patient" to death.

A major complication in defining physician-assisted suicide is that it is frequently conflated and even regarded as being synonymous with euthanasia or "mercy killing." The terms are (obviously) not (entirely) synonymous. The former assumes as an absolute given the agency of a medical doctor. The latter does not, and this has often been borne out in practice. While it is customary to presume that both terms assume the consent and even the explicit request of the person who is killed, there is neither anything inherent in the notion of euthanasia to safeguard that presumption, nor in the case of either term is it possible to arrive at an unproblematic definition of consent given the abject vulnerability of a person whose circumstances lead to an intentional death being contemplated.

In practice, those seeking assistance in suicide typically do so either because their physical impairments are such that they render the act of self-killing impossible and/or they are unable to legally and/or easily procure adequate quantities of toxic substances that would facilitate a relatively painless demise. Generally, "patients'" motivations fall into two, often overlapping, categories: (1) those whose impairments are so significant that they find the activities of daily living impossibly difficult without substantial, though possibly unavailable, assistance and (2) those who find their physical/emotional pain unbearable.

How any society responds to the question of physician-assisted suicide provides an important window into how it prioritizes the value and quality of life of its individual members, one that forces an examination of praxes of family units, health care delivery systems, educational programs, and social service networks. The desire to die is often the ramification of the unavailability of entirely feasible if currently/apparently unavailable enhancements to the quality of life, including disability accommodations, educational and professional opportunities, emotional and logistical support, and palliative medical and/or psychological care. In that context, the provision of and advocacy for the alternative of a quick, easy, and economical death as a solution to life's challenges requires the utmost scrutiny.

Laws regarding physician-assisted suicide are sometimes ambiguous. In the United States, the practice is legal only in the state of Oregon. It is also a lawful practice in the Netherlands, Belgium, and Switzerland and was permitted for nine months in the Northern Territories of Australia, ending in 1997. The practice is legal, though, owing to social opprobrium, practically nonexistent, in Japan. Whether physician-assisted suicide is right or wrong, its availability anywhere implicates medical doctors and biomedical ethicists who condone the practice.

In the United States, physician-assisted suicide achieved its greatest notoriety through the infamous "Dr. Death," Jack Kevorkian, a pathologist who claims to have illegally assisted in dispatching over 130 "patients," many obviously and almost surely treatably depressed, others with conditions such as fibromyalgia, which threaten neither life nor general health and for which palliative treatment is frequently available. Since 1999, Kevorkian has been serving a 10- to 25-year prison sentence for second-degree murder, the result of his participation in an assisted suicide.

PINEL, PHILIPPE (1745–1826)

One of the founders of modern psychiatry

Philippe Pinel is considered by many to be the father of modern psychiatry. After the French Revolution, he was appointed physician to the infirmaries at the Bicetre Hospital, which at that time housed 4,000 criminals, pensioners, and the sick, including many with syphilis. Pinel focused his attention on the ward housing 200 mentally ill men where he instituted a strict nonviolent, nonmedical management of patients that became known as "moral treatment." Although he gave due credit to his mentor, Jean Baptiste Pussin (1745–1811), who had freed patients from their shackles and invented the straightjacket, it was Pinel who was credited for the improved management of the mentally ill. After he moved to the Salpêtrière Hospital, he worked to assure that the shackles were removed from patients there. Pinel also put an end to the bleeding, purging, and blistering "therapeutic" interventions for the mentally ill. He focused his energies on careful diagnosis developed through close contact, observation, and extensive conversations with patients. He kept careful notes on his patients, which served as the basis of his book, *Traité medico-philosphique sur l'alienation mentale; ou la manie* (1801), translated in English as *Treatise on Insanity* (1806). In 1795, he was appointed to the chair of medical pathology, which he held for 20 years, and was also named chief physician of the Salpêtrière, which he kept until his death.

Pinel created an inoculation clinic at the Salpetriere, where the first vaccination was given in Paris in 1800. In 1798, he published *Nosographie philosophique ou methode de l'analyse appliquée à la médicine,* which was, for the time, an authoritative classification of diseases. He was elected to the French Académie des Sciences in 1804 and to the Académie de Médicine in 1820. His treatise on mental illness has had a long lasting influence on French, English, and American psychiatry. He has been immortalized in paintings, prints, and by a statue situated outside the Salpetriere.

—Claude Wacjman

▣ POETRY

Poetry seeks to explore and validate the lived experience of moving through the world with a disability. Sometimes referred to as crip poetry, disability poetry embodies a disability consciousness; it is informed by and contributes to disability culture.

Like the rest of the disability arts movement, crip poetry rejects the view of disability as a shameful, pitiable, tragic, and individual phenomenon. Fundamental to crip poetry is an understanding of disability as a social construction. This is not a denial of the pain and functional limitations that may come with impairment—in fact, disability poetry is often informed by a heightened awareness of those aspects of impairment. But crip poetry is also sharply aware that a major part of the impact that disabilities have on lives results from the ways those human differences are interpreted culturally and responded to by society, so often with prejudice, marginalization, and discrimination. Lynn Manning's poem "The Magic Wand" explicitly addresses this point when it describes the transformation the persona undergoes, "from black man to blind man," through the simple act of unfolding his white cane.

Disability poetry can be characterized by several characteristics: a challenge to stereotypes and an insistence on self-definition; foregrounding of the perspective of people with disabilities; an emphasis on embodiment, especially atypical embodiment; and alternative techniques and poetics.

One of the major impulses of crip poetry is to resist stereotyping and the limits of the socially imposed "handicapped" identity through a process of self-definition. Disability poetry often explicitly rejects social pressure to pursue a forever-elusive "normality" and instead finds value and strength within disability experience, not *in spite of* impairments but *because of* and *through* them. This can be seen in Cheryl Marie Wade's "I Am Not One of The," in which the persona forcefully rejects the labels that are applied to her.

The speaker of this poem rejects the euphemistic labels applied to her by a world that would prefer to not discuss disability and rather simply stereotype her. Instead, she articulates an identity for herself. She claims a kinship with disabled people through history, including those hidden away, left to die, even executed for their disabilities. Each time she rejects the euphemism, she replaces it with images that confound common expectations for people with disabilities—images of strength, of action, of sexual attraction and pleasure. The poem situates people with disabilities not in the margins but in the center of human experience ("I'm the first cell divided," "I've been forever I'll be here forever"). By the end of the poem, she has claimed negative terminology ("gimp," "cripple," "crazy") for her own, transforming the terms with the final, triumphant assertion: "I'm the Woman With Juice."

Disability has typically been described by nondisabled people. Another characteristic of disability poetry is that not only is it situated within the lived experience of disabled people, but it specifically comes from the perspective of people whose bodies and minds have been deemed anomalous. Whether from wheelchair height or through impaired eyes or ears, crip poetry foregrounds an alternative perspective. Sometimes, that alternative perspective is specifically addressed in the poem, as in "Harvest" by Stephen Kuusisto, when the speaker seeks to "admire the white moon of the morning, / even if my eyes tell me there are two moons."

Embodiment is another characteristic of disability poetry. Crip poetry demonstrates an awareness of and sensitivity to the body, which may not be unique to poetry within a disability aesthetic but is certainly present. This is not to suggest that disability poetry is simply participating in a larger poetics of embodiment, which centers the body as the source of artistic production but also expects bodies to conform to nondisabled expectations. Instead, with its attention to alternative ways of being in the world, crip poetry seeks to redefine what it means to have and be a body in the world. In Mark O'Brien's poem "The Man in the Iron Lung," the speaker describes his dream life in "the body electric," which "inserts itself in the map of my mind." As it "whooshes beautiful lies of invulnerability," it forces its way not just into his lungs but into his sense of who he is. Eli Clare describes a far different anomalous embodiment in "Learning to Speak": "I practiced the sounds *th, sh, sl* / for years, a pianist playing endless / hours of scales. I had to learn / the muscle of my tongue."

Because of this emphasis on exploding the limits of acceptable bodies in the world, embodying poems through performance is an important part of disability poetry. Disability is centrally about bodies, how they look and act, and how they are construed, so this embodiment is a crucial strategy. People with disabilities are often told to disregard their flawed, unsatisfactory bodies; paying the attention that poems evoke and reward is a powerful antidote, one that is intensified and multiplied through performance. And, as with other disability arts, events that include the performance of crip poetry are an important site for the continuing development of disability culture.

Alternative poetics can be found in disability poetry as well. Anomalous ways of moving through the world can lead to formal differences in poems; for example, using a respirator to breathe has significant potential to influence rhythms and use of the line. Cerebral palsy had a significant impact on the poetry of Larry Eigner, including the length of his poems—it was difficult for him to put a new piece of paper in his typewriter—and his distinctive use of space on the page. It is important to note that alternative embodiment, cognition, and rationality do not guarantee alternative poetics, but anomalous ways of encountering the world seem likely to influence a disabled writer's poetry.

POLIO

Although forgotten by many, polio was during the past centuries one of the most widespread and devastating diseases, leaving many persons with residual functional limitations. The disease is not completely eradicated, however, with a few new cases in some countries in Asia and Africa during recent years. The major health problem is the late effects of polio with reduced muscle functions and other symptoms leading to increased disability decades after the initial period.

DISEASE AND PREVALENCE

Polio (or poliomyelitis) is a virus-spread disease whose only known host is man. There are three types of polio virus (1, 2, 3), which is spread mainly through fecal-oral infection, usually through the water system. Polio has been accompanying man for a long time, and archaeological dig-outs from Egypt have identified skeletons with changes after polio, from more than 13,000 years B.C., and there are hieroglyphic stones with persons seemingly affected by polio. It has been an endemic disease, but with increased hygiene, epidemics started. Large epidemics occurred in Scandinavia, North America, and Australia in the 1940s and later. The virus has a seasonal variation, with a start in late summer and continuing during fall and declining in midwinter. The typical picture of a polio case starts with an initial infection with slight upper respiratory infection, general malaise with slight fever, fatigue, or gastroenteritis. The disease could stop here (so-called abortive polio), but often within a few days up to a week, the meningitis would start. Fever occurs with headaches and a stiff neck. While the fever is still rising, the paralysis starts to occur, and after a few days, the fever goes down but usually the paralysis stays. The paralysis is characterized by flaccid, asymmetric paresis. The most common form is spinal polio, where the legs often are involved and the breathing muscles are often affected, giving reduced pulmonary function. Cranial polio could affect the facial nerves but also the lower cranial nerves. The so-called bulbar polio results in paralysis of the throat and eventual paralysis of the swallowing process, with the gathering of secretion in the throat and lungs, eventually suffocating the patient. The centers for breathing and circulation in the brainstem could also be affected. Cerebral polio is similar to other types of encephalitis, with a drowsy-person "slow cerebration," but could lead to coma and death. The start of the vaccination era halted this.

The first vaccination was developed by Dr. Jonas Salk, who developed a vaccine that was a mixture of the three virus types, which were killed with formalin. Vaccination trials started, and the vaccine was available in 1955, which ended the epidemics in the Western world. A new vaccine developed by Dr. Albert Sabin (approved for use in 1961), which was made of weakened virus strains and given orally, gained popularity and is now the dominating vaccine in the world.

During 2002, around 500 confirmed cases were reported to the World Health Organization (WHO), and polio was still present as an endemic in Pakistan, Afghanistan, India, Nigeria, Niger, Egypt, and Somalia, with a few cases in Ghana and Lebanon. The number of persons who have had polio and are thereby at risk for late effects of polio is not known, but WHO estimates that there are up to 20,000,000 survivors in the world today. The risk for developing post–polio syndrome is not known, with reports ranging from around 25 percent up to 75 percent. This means that 5,000,000 to 15,000,000 persons might need to be in contact with the health system now and in the next 50 years for problems due to the late effects of polio.

CONSEQUENCES OF POLIO

Polio survivors may experience different types of health problems. Dominating are new or increased muscle weakness, general fatigue, pain in muscles and joints, and, for a smaller group, breathing problems. There may also be reduced tolerance to cold.

The muscular symptoms are connected to the initial loss of nerve cells in the anterior part of the spinal cord. During the recovery, after the initial infection, there is a more or less pronounced reinnervation by terminal sprouting from still-functioning motor units—a motor unit is the nerve cell, with its nerve and nerve branches and the muscle cells (fibers) connected to that nerve cell. In that way, one of the same nerve cells may have innervated several times the normal number of muscle fibers. This process leads to recovery of muscle function, which even could become normal or near normal in a polio-affected muscle. Besides that, the other compensatory mechanisms are increased size of the muscle fibers (hypertrophy), which can be double the normal cross-sectional area in muscles used in daily life. Over time (often 20–30 years after the initial polio infection), these compensatory processes may not maintain the muscle strength. This may be due to several factors, as further loss of nerve cells in the spinal cord (aging and/or overload) and less efficient reinnervation. Still, there is evidence of an ongoing reinnervation also at that age, with motor units that may contain five or even more times the normal number of muscle fibers. There may also be immunological factors involved in the deterioration of function.

Fatigue is a common symptom and can be muscular due to muscular overload or reduced physical fitness due to a low level of activity; it can also be of a central origin, to which damage in the central nervous system by the polio affection may contribute. Pain may be due to overload of muscles or joints and connected to physical activity. Persons with previous affection of respiratory muscles may experience further breathing problems.

These impairments may lead to different levels of activity limitation, especially mobility, as the lower limbs are usually more commonly affected than the upper limbs. This may then lead to limitations in activities in household work, work, leisure time, and so on. The person will suffer an increasing amount of disability. This situation has been named post–polio syndrome and is especially defined by increasing muscle weakness.

HEALTH CARE

This new or increased disability situation requires medical analysis to understand the background factors for that particular person and the possibility to give symptomatic help. Pain relief is important. Physical training may have positive effects on muscle strength and general fitness. Still more important is advice about the proper level of physical activity in daily life to facilitate adaptation to a new life situation. Technical aids are important for some persons, especially mobility aids such as canes, crutches, wheelchairs, or adapted cars. Orthoses may be given or renewed, especially in some cases of reconstructive orthopedic operations. Screening for reduction in breathing function is important since some persons may require assisted ventilation. Some people have been dependent on ventilators since the initial infection; others need night ventilators. There may also be psychological crises connected to the increased disability situation.

Although acute polio occurred quite recently in the Western world, knowledge about care for acute disease has disappeared, and the teaching in medical schools about the late effects is scarce. Therefore, not many health professionals have knowledge about the disease and the effects that might come with time. For polio survivors, this can be a frustrating experience when changes are occurring in their bodies and they seek advice. This can lead to unnecessary contacts with different specialists in the health care system and might prolong the correct diagnosis. Special clinics have therefore been created to handle the late effects of polio.

POLIO SUPPORT

In many countries, there are support groups available for polio survivors. They can serve many purposes: They give emotional support to the polio survivor and next of kin, provide information about the disease, help the polio survivor obtain health professionals who are knowledgeable about the disease, and lobby for more interest in the polio disease. The support groups are also involved in trying to get a more accessible society and provide information about disability rights in the society where they are active. Polio support groups have also been of great value, and the “polio-movement” is considered strong in many Western countries. However, new cases have appeared in several developing countries in the later decades, and it may be expected globally that there will be a large number of polio survivors with medical and disability problems for another half century.

POLITICAL ECONOMY

The political economy of disability seems like an arcane topic until we realize that the inexorable growth and aging of the world population, particularly those with physical and mental disabilities, is putting enormous strains on governments, economies, and political systems in the developing and industrial worlds. Who will take care of these people? What systems can be put in place to deal with the problem? Who will pay for this and how? What will the burden be on our children and grandchildren? Disability is an issue that forces people to reassess their values and make painful decisions on how to allocate scare resources.

DEFINITION

Political economy is a perspective used in analyzing how money and politics shape behavior in social institutions such as health and welfare systems. Political economists emphasize that studying the interdependent operation of government and the economy is essential for understanding the survival and growth of a nation and the configuration and operation of its institutions. Political economists are equally concerned about how the demands of citizens influence government and economic institutions such as the National Health Service in the United Kingdom, splintered capitalistic health care systems in the United States, and government-run, public health–oriented systems in Cuba. Interestingly enough, the vast disparities in per capita expenditures across nations do not seem to have similar large effects on health outcomes as measured by mortality, morbidity, and disability. In fact, the most expensive system of all, the United States, leaves more than 60 million citizens totally uninsured or dramatically underinsured and does not produce longer life expectancy than that of many other countries. Differences between these systems can be explained by differences in values and economic and political systems. At the root of the issue lie different decisions on how to identify and manage risk, how to allocate scarce resources to those in need, and whether to believe in some sort of safety net. The tagline always is, What do people need? What do they want? Who is going to pay for this? And how much? The consequences of these decisions are far reaching because they speak to idealism, values, quality of life, and cross-generational responsibilities.

THE STATE

Because of global urbanization and changing values, people less often are living in extended family systems where the family as a unit cares for the weak and vulnerable. Consequently, the elderly and disabled are increasingly being thrown to their own devices and become more a concern for the state. In the microcosm of Cook County, Illinois, for example, more than half of the 4,000 current inmates of the county jail are judged to have mental illnesses, often complicated by the dual diagnosis of alcohol and drug addiction. In this case, the justice system is being used as a “dumping ground” for those with serious mental illnesses because their families are unable or unwilling to care for them, and there is no county or state mechanism for dealing with these people in the existing mental health system. In Africa, AIDS has become a similar unmanageable problem for families and governments with meager resources to prevent the problem or care for those with a prevalent, deadly condition. Where AIDS used to be a condition that killed rather quickly, modern treatments and drug regimens have extended life expectancy but often in a disabled condition. These HIV-positive individuals lose their capacity to work and parent, thus requiring constant care and medical attention. The burden on families is enormous. In those regions where HIV prevalency is at or above 40 percent, entire generations are being decimated, with dire consequences for the oldest and younger generations. These examples are illustrative of an international phenomenon. While responsibility for caring for the vulnerable is being transferred from the family to the state, the political and economic systems of most countries are not prepared to deal with these problems. People are living longer, and the numbers of disabled people are growing. Individuals typically have not saved enough for old age or anticipated disability. Families often do not have the resources or are not willing to pay for the care of their older and disabled members and do not want taxes raised in any form to do so. All of this leads to a crisis in the welfare state of industrial countries and insurmountable pressures on the economies of developing countries. As populations age and the number of young workers paying taxes decreases, something has to give. Savings and taxes must go up or the type, quality, and amount of services decrease.

VALUES

Disability exacerbates the pressures put on social institutions by aging and vulnerable populations; raises difficult ethical issues such as abortion, euthanasia, and physician-assisted suicide; and questions the basic values of a society. Disability symbolizes the debate over quality of life for individuals and their relatives and questions judgments about the lived experience of disabled persons. Is living with a disability an unbearable experience to avoided at all costs? Should individuals or their relatives be able to end their lives? If so, under what conditions, and who is to decide? What values and principles underlie these decisions? These are questions that disquiet individuals, family, and the state. For all of the espousal of family values and respect for elders, adult children are not eager to care for elders in their own homes and are reluctant to pay for expensive assisted care living. The trend in North America and other industrialized, urban countries is for more elders to live by themselves or in institutions, particularly if they are disabled or at the end of life.

Research studies complicate these discussions. There is growing evidence that many individuals with persistent and severe disabilities report a good or excellent quality of life even though external observers might judge otherwise. Many disabled people are as happy and enjoy life as much as those without disabilities. Like anyone else, they have no desire to be discounted, be left alone to fend for themselves, or die. Given the aging populations in the world, the trend is that more people will live longer with disabilities exacerbating the existing problem and placing more strains on families and welfare systems. Faced with these issues, disabled people are becoming better organized and more vocal. They are joining forces with the elderly to exert more political pressure on the state to address their needs. Almost every disability group has an organization that lobbies for their cause, be it Alzheimer's disease, multiple sclerosis, arthritis, asthma, depression, or intellectual disabilities. It is also clear that these people do not want to be made dependent. They want to make or at least actively participate in decisions that affect their quality of life and future.

These issues directly address the values of human life and to whom. Utilitarian philosophers have examined these problems through the lenses of an individual's worth to society and contribution to the common good. Economists have spent considerable time assessing the economic value of human life based on age, sex, education, ability to participate in the labor force, and capacity to pay for and consume goods and services. While both of these approaches are informative in exploring disability in society, the political economy of disability adds to the discussion by analyzing the interrelationship between disabled people and political and economic institutions. This is important because the political and economic institutions and values that undergrid them will determine how disabled people are treated in a society.

Political economic values and institutions vary from state to state. In the United States, considerable emphasis is placed on rugged individualism, capitalism, "free markets," and an "American" form of democracy. As a consequence, American funding for and support of disabled people is generally related to an individual's ability to work and be economically productive. In this sense, men are favored over women and children. American pundits say that American health insurance is wonderful as long as you do not have a serious or persistent health problem. This is really true for disabled people. Health insurance companies and the government try to limit the numbers and types of disabled people they cover. This is euphemistically called "cherry picking." The disability system is disjointed and often profit driven or risk aversive. Since there is no integrated "safety net," disabled people frequently fall between the cracks and have to rely on family and friends, live in an institution, or live alone poor. Investigations after the incredible loss of life among the elderly and disabled in the recent, severe summer heatwaves in Chicago and France indicated that thousands died because they were living alone, no one checked in on them during this dangerous time, they were unable or afraid to go out for help, they did not drink enough water, and they did not have fans or air-conditioning. In France, this occurred during the national vacation time when the vulnerable elderly and disabled were left alone. These problems are intensified because these vulnerable citizens are usually poor, so they cannot purchase assistive care if the family is not present. Disabled people are either poor to begin with or the loss of work and cost of dealing with their health and disability problems deplete their resources. These dynamics illustrate the dilemma that citizens face. Either they must care for their elderly and disabled in the family, or there must be an effective state system to do so.

Absent either solution, these vulnerable populations will suffer and even die as in the case of the Chicago and French heatwaves.

THE MARKETPLACE

On the other hand, because there are large numbers of disabled and dependent elderly people, private insurance money, public funds, and personal resources to pay for health care and rehabilitation goods and services, a large industry has developed to define and respond to this multibillion-dollar annual market. Historically, disabled individuals received benefits if they or their work were important to the national economy: members of the armed forces, merchant seamen, railroad workers, miners, and members of the government. More recently, disability benefits were expanded to a much larger population through social security, social welfare programs, and employer-based private insurance. As a consequence of extended coverage, demand for disability-oriented health care and rehabilitation goods and services grew enormously. A massive health care market niche for rehabilitation was created.

In the past, families, local communities, and charitable organizations cared for disabled people. Now, disability has become part of the capitalistic, free-market system where health care and rehabilitation goods and services have become commodities for sale, frequently at a profit. This increasing commodification and privatization of goods and services enabled remarkable growth in the hospital, medical goods, pharmaceutical, insurance, and rehabilitation industries from the 1980s to the present. Not only are these industries some of the fastest growing in the world's stock markets, but they are also among the most profitable. As health care and rehabilitation goods and services became privatized, industry focused on forming companies to serve a need and to make a profit. At times, it is unclear which goal predominates. Certainly, the size of corporations has grown through mergers and acquisitions, expansion of the market through advertising, and development of new products. Concurrent with the privatization of health and rehabilitation care has been the corporate abuses of the past 10 years. Executives of large health care companies have been accused and convicted of accounting irregularities, fraud, questionable marketing practices, and overpricing. The corporate jet, multimillion-dollar salaries, stock options, and golden retirement "parachutes" have become staples in the health care corporate world. HealthSouth is an example of such a multi-billion-dollar company.

While the corporatization of health and rehabilitation care has resulted in remarkable advances in health care and rehabilitation, it has driven up the cost of care to unprecedented heights, creating an expanding chasm between those who can afford these goods and services and those who cannot. These forces raise fundamental questions about capitalism and democracy. What should be expected for all citizens as a minimum standard? Should there be a social safety net? Should health care and rehabilitation be for profit industries in the private sector funded by government and private insurance? How will access for all and equity be effected? The critical issue concerns who will protect the vulnerable populations of any nation.

FUNDING AND RESPONSIBILITY

While the issues are becoming clearer, their solution is not. The problems of an aging population and increases in the numbers of disabled citizens are apparent. How to structure a system that deals with these issues and pays for them is not. It is clear that the very wealthy can afford to pay for their own care. What to do about those who cannot pay for this care out of pocket affects every nation in the world. The existing models are no system (e.g., Sudan, Cambodia), national health insurance (e.g., Canada, United Kingdom, France, Sweden), mixed systems (e.g., Switzerland and Japan), and a strong public health and primary health care system with family support for the elderly (e.g., Cuba). Of those countries with some sort of system to deal with the elderly and disabled, each has attractions. The most attractive in terms of national policy are those that provide universal coverage at some minimum level. This is clearly the most equitable solution, but the problem is funding. Who will pay for it?

The funding issues immediately raise questions of responsibility. Whose responsibility is the care of the elderly and disabled, and how should it be financed? While this is a contentious issue in many societies and raises unavoidable cross-generational tensions, there are but a limited number of solutions. Resolution of the problem will probably involve a combination of strategies. Expectations will have to be lowered. People will not receive services that they and/or the nation cannot afford. Expectations of what constitutes a materially "good life" will have to diminished—hence current attention being given to "simplifying life" and spirituality. Taxes to support an adequate welfare system will need to be increased. The age of retirement will need to be increased as populations age into their 80s and 90s. Social security and retirement systems were designed during a time when life expectancy was in the early to mid-60s. These systems cannot sustain early retirement and life expectancies projected for an additional 30 years. Immigration will continue to be a "hot button" issue. As populations age, more young people will be needed to work, pay taxes, and provide the goods and services required to sustain the elderly and disabled population. Since birth rates are unlikely to increase dramatically, permitting the immigration of healthy, skilled young workers is the likely outcome. This, in turn, will make societies more multicultural and intensify tensions between race/ethnic groups.

Rationing of health and rehabilitation care is inevitable. Today, rationing occurs through the use of health maintenance organizations (HMOs), managed care organizations, queuing in National Health Insurance systems, and copayments for diagnostic and surgical procedures and for drugs. As costs of these goods and services continue to increase, more intense rationing will occur. The heated debate that will ensue will be over universal health coverage, inequities in the access to care and the rationing system, what constitutes minimum standard care for all, and how much care is enough. The economics of the situation will dictate limits on demand.

INFRASTRUCTURE AND STEWARDSHIP

Here the expressed the rights, needs, desires, and demands of the individual collide with the greater good of the community and all the citizens of the state. Sometimes, these perceived needs and demands are in concert; other times, they are not. In ethical terms, should the needs and wants of the individual supersede those of the larger community? The debate is tinged by value systems. In the United States, great emphasis is placed on the rights of the individual, whereas in European and Asian societies, more relative importance is given to the primacy of the community. Hence, the discussion will be framed differently in different countries.

These issues of demand for and allocation of scarce resources in society further lead to discussions of infrastructure and stewardship. The quality of life of elderly and disabled people is contingent on their access to care, ease of use, appropriateness of treatment, and cost of care (particularly pharmaceuticals). The present U.S. and national health care systems of most countries are not constituted to meet the increases in demand of elderly and disabled people. Consequently, they must be restructured. More physicians and health care workers knowledgeable with geriatrics, physically accessible facilities, transportation to and from places of care, home care services, redesigned accessible living quarters, and affordable drugs and assistive devices are needed. These adjustments need not cost more money, but they do require a reallocation of resources. For example, new buildings, homes, apartments, and health clinics can be constructed with a universal design in mind. Social support systems for these populations who can often be isolated need to be encouraged through more family involvement, community activities, friendship networks, and community-based home visiting programs.

Finally, the disabled and aging populations of the world suggest the problem of stewardship. If citizens want to leave the world a better place for having been there, they will have to rethink how they treat their physical and social environments and the people they leave behind. There are many communitarians and community leaders who are calling for a renewed emphasis on respect for our physical and social environments and other people. This requires a rethinking of how we use precious resources and deal with our families and neighbors. All citizens of the world have an obligation to be trustworthy stewards of their own worlds and social lives.

POLITICAL PARTICIPATION

Grassroots political activism by people with disabilities formed the basis of the disability rights movement in the United States, leading to the passage of the Americans with Disabilities Act and other important laws. Despite these policy gains, however, recent research indicates that people with disabilities remain underrepresented in the political process, raising concerns that their needs and interests are often neglected and ignored by politicians and elected officials. The lower levels of political involvement can be largely explained by economic and social disparities faced by people with disabilities, which often create barriers that make political participation more difficult but can spur some people to become disability activists. While there has been only limited research in this area, several studies shed light both on overall political participation among people with disabilities and on disability activism.

OVERALL POLITICAL PARTICIPATION

Overall levels of political participation among people with disabilities are significantly lower than among nondisabled individuals in the United States. In addition to being less likely to vote (for further information, see the Voting entry in this encyclopedia), people with disabilities are also less likely to work with others on community problems; write or speak to public officials; attend political meetings; contribute money to political causes, parties, or campaigns; write letters to newspapers; participate in political protests or demonstrations; or otherwise work to change government laws or policies. The following comparisons come from nationally representative surveys conducted in the United States in 1998 and 2000 (see Table 1).

Table 1 Comparison of U.S. Political Participation by People with and without Disabilities

	People with Disabilities	*People without Disabilities*
Number of political activities in the past year (0–9 scale)	1.86	2.33
Political activities (in percentages)		
Voted	61.9	70.9
Written or spoken to elected representative or public official	31.2	41.4
Worked with others on community problem	22.1	29.0
Contributed money to organization trying to influence government policy or laws	16.9	24.3
Attended political meeting	13.1	16.6
Contributed money to political party or candidate	13.2	17.4
Written letter to newspaper	8.2	8.9
Otherwise worked with groups or on one's own to change government laws or policies	15.3	19.4
Participated in protest or march	4.0	5.5

Women with disabilities have slightly but not significantly lower levels of overall political participation than do men with disabilities, reflecting economic and social disparities due to gender as well as disability. Nonetheless, they are about as likely as men with disabilities to vote, write letters to newspapers, and work with others on a community problem and are actually more likely to take part in political protests or marches.

Many people with disabilities face considerable barriers, such as the lack of accessible transportation, stigma, and discrimination, that discourage them from taking part in political activities. At the same time, however, such obstacles motivate others to become and remain politically active, particularly on disability rights issues. The factors affecting political participation in general can be divided into three categories: resources, recruitment, and psychological engagement. Resources include money, education, time, and civic skills that facilitate participation—for example, the ability to speak in public or write an effective letter to a public official. Recruitment networks expose people to requests for participation, and psychological engagement includes interest in political issues, feelings of political efficacy, and other psychological factors.

People with disabilities tend to have fewer resources, including lower average levels of income, education, and civic skills, which help account for their lower levels of political participation. They are also less likely to have vehicles they can drive, which curtails their ability to engage in many types of political activity outside the home.

People with disabilities are also less likely to be recruited for political activities, reflecting their generally greater social isolation. This is due in part to transportation constraints and to the fact that people with disabilities are more likely to live alone and are less likely to have jobs, socialize with friends or family, attend religious services, or regularly attend groups where recruitment can occur.

Less than half of people with disabilities are employed, and these low employment levels contribute to their low levels of political participation. Employment provides not just income and recruitment opportunities that increase participation but also opportunities for developing civic skills through activities such as leading meetings, giving presentations, or participating in decisions at work. There is, in fact, no political participation gap between employed people with and without disabilities, and the particularly low participation level of women with disabilities is partly explained by their especially low employment levels.

Regarding psychological factors, there is mixed evidence on whether people with disabilities express the same general level of interest in political issues as people without disabilities. People with disabilities are more likely to express interest in public health care issues and to identify with the Democratic Party but have a similar average score on a liberal to conservative scale. When asked how disability has affected their political views, about half of people with disabilities say that it has had no effect. Among those who say it has affected their views, about half say it has increased their interest in disability-related issues, while smaller percentages say it has made political participation more difficult, has made them more cynical and antigovernment, or has made their political views more liberal.

The psychological impact of living with a disability can be especially strong in the first few years after onset, as individuals undergo a major life transition and learn to cope with disability-related problems and their new status. This can be exacerbated by the often greater demands on time, energy, and financial resources during this period and helps explain why political participation is particularly low in the first few years after disability onset.

Feelings of political efficacy are another important psychological factor that helps explain the lower political participation levels among people with disabilities. Compared to people without disabilities, they report lower average levels of both internal political efficacy (the belief that one is competent to participate in politics) and external political efficacy (the belief that the political system is responsive to people such as oneself). The lower levels of internal efficacy are largely explained by lower levels of education and employment, but the lower levels of external efficacy are not explained by other factors and appear to be directly related to the experience of living with a disability. Individuals with disabilities are also much more likely to report that people with disabilities do not receive equal treatment from public officials or have equal influence in politics. Combined with their low external efficacy levels, these responses indicate that people with disabilities tend to feel that the political system is not responsive to their interests. Such perceptions may result from internalized "social constructions" of disability, which are popular images of disability that are shaped by public policies that send negative messages (for example, by stereotyping people with disabilities as dependent and needy).

Low levels of political efficacy can be part of psychological responses to the experience of living with a disability. Among the variety of responses that individuals can have to disability, Renee Anspach (1979) and other writers have described how some people with disabilities have a negative self-concept and respond to stigma, discrimination, and other disability-related problems by developing an attitude of fatalism and helplessness. This discourages political involvement and can lead people to withdraw from society.

Other psychological reactions to disability do not discourage political participation. Some people react to the experience of living with a disability through "normalization"—trying to emphasize their similarity to people without disabilities while ignoring or minimizing stigma, discrimination, and other disability-related difficulties. Such people accept society's devaluation of people with disabilities and try to maintain a positive self-concept by de-emphasizing their disabilities. An extreme form of this response is characterized by "role distance," where people with disabilities try to separate themselves as much as possible from others who have disabilities and only associate with nondisabled people. Those who normalize may engage in standard political activities such as voting but avoid political activities directly related to disability issues.

DISABILITY ACTIVISM

While the experience of living with a disability leads some people to retreat from society or practice normalization, it motivates others to become politically active in an effort to end discrimination and improve conditions for people with disabilities. The percentage of people with disabilities who said they took some sort of action on a disability-related issue in the course of a year is shown below (based on U.S. national surveys in 1998 and 2000):

Political activity on a disability issue (as part of one or more of the political activities listed earlier)	10.1 percent
Took action against private organization on a disability issue (e.g., talking to business owners, filing lawsuits)	8.6 percent
Either of above	14.8 percent

(Note: This does not equal the sum of the two previous activities because overlap has been eliminated.)

Four basic perceptions appear to be linked to disability rights activism. First, there must be recognition of the importance of disability-related problems. This is undermined by normalization where people minimize or rationalize such problems. Second, in contrast to people with a fatalistic response, activists believe that many disability-related problems are not an inherent part of living with a disability and can be eradicated. They also perceive that their problems are widely shared and have a strong sense of identification with others who have disabilities. Finally, activists perceive that many disability-related problems require political, rather than purely individual, solutions. They emphasize changing policies, practices, and laws, rather than relying on self-help strategies such as developing a "positive attitude" or learning how to put nondisabled people at ease.

People who become politically active on disability issues are more likely to meet regularly with disability groups. Such groups can provide members with role models, education on disability issues, recruitment networks for political activities, and a supportive environment for the development of a sense of identification with others who have disabilities. It is important to note, however, that not all politically active people who work on disability issues work through groups. Some people are politically active on their own, engaged in private struggles to change laws or policies as a result of discrimination or other negative experiences they have had.

Disability activists are more likely than other people with disabilities to say that they have directly experienced disability discrimination. This partly reflects a broader definition of discrimination. For example, activists tend to define discrimination not just in terms of intentional behavior but also in terms of policies or practices that have discriminatory effects, such as architectural standards that create inaccessible buildings. Disability activists also express greater life satisfaction and a greater sense of control over their lives and have higher levels of internal and external political efficacy than other people with disabilities. At the same time, they are less likely to believe that people with disabilities get equal respect from public officials, which helps motivate their activism.

The most committed activists have lived with their disabilities for a longer period of time on average, consistent with findings on the psychological impact of disability onset. While some people describe becoming activists after being galvanized by a particular experience (for example, an act of discrimination or denial of needed services), others describe going through a slow process in which they gradually learn to come to terms with living with a disability, fully accept themselves, and identify with others who have disabilities. Early in this process, they may go through stages of fatalism, role distance, and/or normalization but then learn to develop broader views of disability and discrimination, as well as an appreciation for the value of political action.

Those who have become leaders in the disability rights movement, in particular, have learned to reject the medical definition of disability in favor of a sociopolitical definition that views environmental and attitudinal barriers as helping create disability. Some people originally join disability groups for nonpolitical reasons (for example, for recreation or needed services) but become politically active after being exposed to new issues and meeting politically active people who serve as role models. The gradual politicization of many activists suggests that there are no apparent prerequisites for who can become active in disability rights politics and that circumstances—the types of groups, information, and opportunities that are available—often play a large role in politicization.

In conclusion, overall political participation is lower among people with disabilities than among the general population. This disparity is accounted for by factors such as lower resource levels, fewer recruitment opportunities, and lower political efficacy levels. The barriers that discourage many people with disabilities from fully participating in political life, however, also motivate others to become politically active on disability issues. While some people view their disability-related problems only as personal matters, many others perceive political dimensions in the problems they face. Disability groups can play a particularly important role in this respect by providing role models, building group identification, and increasing exposure to political information and opportunities for participation. Overall political participation among people with disabilities can also be encouraged by policies that decrease social isolation and increase resource levels—for example, by creating better educational and employment opportunities. Greater political and civic participation among people with disabilities will help them achieve equality, ensure that their voices are heard, and strengthen our democratic institutions.

POLITICS OF DISABILITY: INTERNATIONAL

The politics of disability refers to the ongoing debates over how disability definitions and programs shape what constitutes disability, who is identified as being disabled, and what resources a society will allocate to disabled people. Disability politics have come to the forefront as increasing demands are made on state welfare systems and as nations experience serious problems in coping with their aging and disabled populations.

This entry conceptualizes the politics of disability internationally and in a social and cultural context. First, at the fundamental level, the very existence of disability as a category of knowledge should be clarified. This is important in an international context because the social and cultural context in which disability is framed has political consequences. Several authors report that the distinction between disabled and nondisabled people is not known in certain social and cultural contexts and hence of no political consequence. Second, in the study on the politics of disability, one would want to know how a person gets categorized as disabled (i.e., the process by which one is assigned and confirmed a label of disability and through which one acts as a disabled individual in a cultural and social context). Third, given the social existence of disability, the next level of analysis is to explain how the very distinction between disabled and nondisabled people, through processes of socialization and social exclusion, is maintained. This is a question of control and/or tolerance for change. Fourth, the politics of disability consists of the development of an ideology of thought, as found in the formulation of the social model of disability, and the building of coalitions to overcome the historical distinctions between disabled and nondisabled people. In processes of identity formation, cultural development in the so-called culture of disability, and social movement, power is used to redefine disability and the relations between disabled and nondisabled people. From a disability studies perspective, the question here is about the contours of a disability model that pertains to different cultures.

The questions above are directed with the goal of recontextualizing a Western perspective on disability. The intellectual benefit is to clarify meanings of disability in other cultures as well as providing directions of studying and practicing the politics of disability internationally.

THE POLITICS OF THE VERY EXISTENCE OF DISABILITY

The very existence of disability cannot be understood without taking into consideration the particular ways in which Western society has separated people with certain characteristics from the overall group, through defining a certain status as human beings, with rights and entitlements, and the right of society to take certain decisions. *Disability* as a linguistic term is a composite; it comprises people with a large variety of unrelated characteristics, yet through processes of separation and practices of defining society's responsibility to those who have been separated from the rest. This is, however, not a universal process. For example, Holzer (1999) observed that in Juchitán, Mexico, the distinction between disabled and nondisabled is not known. Such ethnographic examples may, however, make clear how the distinction *is* made in other cultural contexts.

The category of disability has taken form over the centuries. In the English language, the term *cripple* first took on connotations of designating *all* people with identifiable disabilities. But it is undoubtedly the notion of "handicap" that is perhaps best known for being able to apply a particular ideology to a group of people with varying types of disabilities, namely, the ideology of equal chances. This ideology was first developed in the United States, in the context of building a modern, industrial society. The term *handicap* appeared in public discourse around the turn of the century (e.g., in the *New York Times* in 1905). From the United States, the ideology of equality (through many different transformations known as integration or, more recently, as inclusion) reached most, if not all, societies in the world. The ideology of *handicap* reached Europe in the 1950s. However, it appears in legal texts much later (e.g., in Belgium in 1967). In France, the year 1975 constitutes the essential moment of putting in place the politics of *handicap.* From that moment on, *handicap* serves as a unified field of intervention that figures among other social politics. While *handicap* is no longer in favor in the United States and has largely been replaced by the term *disability,* at least in professional and legal language, the term *handicap* survived in many other countries. Because of the many shifts in language, the use of terminology in a text has become an object of careful explanation for many writers, as a matter of political consciousness.

THE PROCESS OF ACQUIRING PEOPLE BY A LABEL

Social scientists have studied the process by which people are enlisted by a label and the consequences of this enlistment for society. Perhaps the most early and well-known studies are in the area of mental retardation. According to one definition of mental retardation, the number of people who could be identified as mentally retarded could be as many as 16 percent of the U.S. population. The identification of people as mentally retarded evidently has direct consequences for the provision of services and the spending of public funds. Labeling people as mentally retarded added also to the stigmatization of people. This was the case with a disproportionate number of ethnic minorities identified as mentally retarded. This issue put into perspective the cultural inadequacies of tests and, more generally, the politics of testing.

The politics of testing in Jordan is put into perspective by what is being tested and what is left out. According to Turmusani (2003), the only national survey ever conducted in Jordan (in 1979) used a definition of disability based on the concept of visibility of impairment, meaning that persons with nonvisible or hidden impairments would not be perceived as disabled. The consequences are both positive and negative since they would not be discriminated against but also not be entitled to services. The political consequence at the national level would, however, be that disability would remain low on the public agenda.

In *The Disabled State,* Stone (1984) describes how the medical profession achieves and exerts power as the gatekeeper in the process of entitling a person with a particular label, thus giving way to a certain treatment by society. In many cases, the relation between society and disabled people is here defined in terms of employment as a contribution to society. Nonemployment can result from not being able to work, which can in turn be the result from a contribution to society. The distinction between "deserving" and "nondeserving" plays an important role in the determination of entitlements.

In a broader framework of the relationships between society as a governing body and disabled people, one can speak of a political economy of disability, which aim it is to explain the occurrence and the magnitude of the existence of disability. In such a perspective, societies are producing disability and disabled people. Disability in this perspective is the very outcome of historical, economic, and political processes that regulate.

At the more intermediate level, Barral et al. (2000) ask what social form do various organizations take that operate in the field of disability. What are the structural or psychological characteristics of the politics in which they are engaged, the status that is given to individuals who are active within these organizations and in the movements that intend to represent disabled people? By investigating the laws in different countries, one can glean at the ways in which "the national obligation" takes place. In France, this takes the form of a mission of prevention, follow-up, and rehabilitation to which private initiative and public action can be associated. On the other hand, it becomes necessary for the French state to install a way of controlling private initiative so that disabled individuals are given a republican guarantee.

THE DISABILITY MOVEMENT

The politics of disability transcends all times and societies. Indeed, the very existence or nonexistence of the category of disability is the result of a negotiation process among individuals in society, a political process with social consequences. However, in recent decades, a disability social movement has arisen in the aftermath of human and civil rights consciousness throughout the world. This development was both spurred by the aftermath of World War II and the development of the United Nations, as well as by the civil rights movements in the United States. In the early developments of the disability movement, Scotch (1984, 1988) researched how disabled people could define themselves as a minority and how a disability movement could emerge in view of its own historical past. In many countries, the movements have accomplished the passing of civil rights legislation, such as the Americans with Disabilities Act in 1990. In particular in the United States, the independent living movement became a strong advocacy and practically oriented means to implement the ideas of the disability movement. The prominence of disability advocacy and the passing of antidiscrimination legislation evolved differently according to the social and cultural contexts. In the United States, it is clearly connected with the civil rights movement and the prominence of individual development. In most of Europe, the development of a disability movement was less strongly developed, in part as a result of strong social security systems. Lee (2002) argues, mainly in reference to Great Britain, that the disability movement has been rather unsuccessful in reaching out to the disabled population as a whole. Moreover, the movement has been dominated and fueled by a very particular constituency, notably those with strong physical and sensory impairments, who are both relatively active and relatively young. On the other hand, the social disability movements in Southern African countries became strongly developed in conjunction with the struggle against apartheid. In still other countries, the (lack of) prominence of the disability movement could be clearly connected to military and government regimes (for examples on Asian countries, see Charlton 1998). The disability movement was supported by some slogans that intended to express the required attitude changes (e.g., "ability, not inability," "no pity," and "nothing about us without us"), expressing wide disparities in the political demands. Following Oliver (1990) and Lee (2002), it can be supported that the disability movement ought to be characterized as a new social movement. It is indeed internationalist, aims at empowerment and consciousness raising, offers a critical evaluation of society, lies at the periphery of the conventional political system, and can be seen to focus on the quality of life of a particular section of society.

The academic and theoretical framework in support of the social movement of disabled people and the emergence of what became known as "disability studies" has been the "social model of disability." This model was first launched primarily by sociologists and political scientists, some of whom had themselves disabilities and engaged as both advocates and academics. This model was usually defined in opposition to either an individual or medical model of disability. In terms of knowledge, an overall focus on the social construction of disability became central. In Britain, the social model of disability has been supported by Marxist ideas that explained the material conditions and the oppression faced by disabled people. In the United States, the social model became more readily interpreted in the analysis of ecologies (i.e., adaptations between people and their environments) and grew into increasing attention to the discriminatory impact of systems and of language use. This also grew into considerable attention to representations of disability in media, history, literature, and visual arts.

During the 2003 European Year of Disabled People, the key emphasis was on the ways disabled and nondisabled people could work together and on the issues of physical, social, and informational accessibility. Such a European perspective therefore frames disabled people as a political entity to be taken into account and also pushes attention to the politics of the environment as the source of disability. In particular, as a follow-up to the International Year, the European Union maintains its goals of achieving equal treatment in employment and adds goals such as reinforcing mainstreaming of disability issues in relevant policies and accessibility for all.

The proliferation of difference in postmodern times has led many groups to claim their own identities and social movements. For disabled people, this has consequences as such proliferation leads at first glance to "forgetting" the difference. Lee (2002) argues that as the environment becomes the focus, it is suggested that differences can simply melt away. This is a politically dangerous idea since it minimizes the necessary social care and accommodations that disabled people require. The difference of disability is equally challenged by the intersection with other groups, such as women, elderly people, and ethnic minorities. In many cases, coalitions with other groups appear to have political implications (for an example, see Iris 2003).

A future disability model that pertains to different social and cultural contexts and to the impact of globalization will have to respond to the fact that various forms of modern society are found throughout the world. In such modern societies, disability is understood with different degrees of emphasis on religious, biomedical, and social-political components. Such a future model could be called "cultural" in the ways it can integrate existing dichotomies that dominate the current understanding of disability. A cultural model would equally emphasize certain universal characteristics of the world today (such as the importance of information and the media) and of disability (such as its challenge of existing cultural orders and therefore its potentially transforming impact on society). Last, a cultural model would be sensitive to our modes of communication as these are affected by historical and cultural developments in the use of spoken and written language, visual imagery, technologies, and aesthetics. Research on the politics of disability that is steered by such a cultural model of disability would continue to emphasize how new modern societies create orders by overcoming old categories and developing new ones that once again produce disability.

POLITICS OF DISABILITY: POLICIES AND PROTEST

DISABILITY AND POLITICAL ACTION

People with disabilities frequently occupy marginalized social, economic, and political positions in contemporary societies, positions that are only likely to change through effective political action. In recent decades, people with disabilities have increasingly sought to participate collectively in decisions about public policy, both specifically about disability issues and more generally about issues related to participation in governance and the distribution of power. While people with disabilities are almost universally constrained by stigma and limited resources, their political status varies considerably across societies, according to how disability is socially constructed.

In the medical model of disability, which has been predominant in Western culture since the nineteenth century, disability is considered an individualized attribute dispersed across the general population rather than a commonly held position and thus is perceived as not naturally forming the basis for collective political activity. Many disability issues are nominally apolitical, as disability is viewed as inextricably linked to impairment and more a matter for professional treatment than for political action.

Within this construct, whether one has a disability has important consequences, and gatekeeping, the definition of who is and is not considered to have a disability, is considered to be a scientific interpretation linked to impairment and thus is typically managed by medical and rehabilitative professionals. People with disabilities themselves often are not considered to have an appropriate role in public debates over who is entitled to claim public benefits or other entitlements attached to the disabled status.

However, there are considerable political implications within the medical model of disability. Within this conception of disability, the primary question within the politics of disability is reallocative—to what extent public resources should be devoted to medical and rehabilitative services for treatment and to benefits accorded to maintain people with disabilities, who are judged incapable of self-sufficiency. Since disabled people are also considered to be incapable of self-advocacy within this context, such disability politics are typically engaged in by nondisabled advocates rather than by people with disabilities themselves. Thus, in many historical accounts of disability policy debates, people with disabilities are rarely characterized as major political actors, either individually or as an organized interest group. (A prominent exception is the case of disabled veterans, who typically self-identify primarily as veterans who have earned the right to social assistance through their service, rather than as people with disabilities who have needs related to their impairments.)

Taking the lead, rather, are organizations *for* rather than *of* people with disabilities—often charitable organizations or professional service providers led by nondisabled individuals. Political initiatives of this variety frequently emphasize the incapacity associated with disability, as well as the moral blamelessness of "deserving" disabled people, unable to help themselves, whose conditions have been acquired through no fault of their own. Such political discourse frequently features tales of woe about people, particularly children, whose lives will be ruined by their impairments unless help is given.

Many public officials are reluctant to appear insensitive to appeals by those perceived as helpless and blameless, and such political appeals have often been quite successful. At issue in such political discourse is often the moral entitlement of those who are "afflicted," which is based on their impairment being based on random victimization rather than their own choices and behavior. Thus, political debates over disability benefits frequently involve questions of moral entitlement. With the gatekeeping role usually taken by medical professionals, efforts have been made to medicalize a number of conditions to entitle those who have them to a flow of benefits and services earmarked for the "deserving" poor. Questions of personal responsibility may arise, with debates over public funding benefiting people with chronic conditions widely considered to be morally questionable, such as HIV/AIDS, psychiatric disorders, addiction to alcohol or illegal drugs, or learning disabilities.

Nonmedical models of disabilities are associated with quite different political forms, issues, and dynamics. A sociopolitical model of disability conceptualizes disability as a social and political construction that is the result of interaction between physical or mental impairment and the social environment. Technology, architecture, and spatial organization all reflect concepts of what is "normal" and how "normal" people function, as do cultural attitudes and institutional processes. These social characteristics help to define who is “disabled” and who is “normal,” as well as what constitutes an appropriate social response to those who have a disability.

The politics of disability takes far different forms within the sociopolitical model than would be expected in the medical model. Political issues are not simply reallocative, although disputes over resources are found here, too, but may also include conflict over what social roles can appropriately be played by individuals who have disabilities and how the state should support or restrict those roles through its policies. A sociopolitical model of disability would lead one to expect political conflict over issues such as the appropriate role for people with disabilities in education, employment, public services such as transportation, economic development, and participation in civic life. Organizations composed of people with disabilities are prominent in such political activities, groups whose membership and leadership are individuals who themselves have disabilities.

By characterizing the social isolation and enforced dependency of people with disabilities as the result of social choices rather than as inevitable results of impairment, the sociopolitical model suggests analogies between the social status of people with disabilities and other marginalized groups such as racial and ethnic minorities, women, or gays and lesbians. Within this political framework, disability politics can encompass disputes over civil rights (in the American context) or human rights (in the European context and in non-Western societies around the world). Similarly, politics encompasses conflicts over the role of disabled people collectively in the governance of service systems and other institutions addressing the disability community and the role of individuals with disabilities in shaping and controlling the services they receive.

In recent decades, as the dominance of the medical model has diminished, the sociopolitical model has become more prevalent. In such a sociopolitical model, people with disabilities may be grouped together into common medical, educational rehabilitative, human service, and custodial systems, but the establishment of such systems and the definition of who is to be considered disabled vary across cultures and historical periods. Gatekeeping under a sociopolitical model of disability is not solely the province of medical and rehabilitation professionals but can be contested by many within society, particularly by people with disabilities themselves.

DISABILITY IDENTITY AND POLITICAL REPRESENTATION

Disability politics increasingly involves advocates who have disabilities, although individuals with disabilities do not necessarily share the political perspective held by the majority of people with disabilities within a society. The label of having a disability may be taken or rejected by individuals with impairments as well as by others. In some instances, vanguard groups have celebrated their identity as people with disabilities, promoted disability culture, and embraced a belief in “disability pride.” For others, stigma is perceived as associated with disability. People may be reluctant to self-identify as disabled; they may seek to hide their impairment or to portray its effect on their lives as minimal. Even people with significant impairments that interfere with important life functions may not consider themselves to be in a similar situation as others with the same impairments, let alone with quite different ones, and may be unwilling to be visibly associated with them.

Even when individuals self-identify as disabled, having a disability does not in itself inevitably lead to participation in collective political action with others who have disabilities. Many political constituencies form on the bases of spatial propinquity and/or out of already socially cohesive groups. Because impairments are spread spatially and demographically throughout the general population, people with disabilities may not find themselves in naturally occurring communities of their peers; they typically grow up within families of people who do not share the experience of disability and must seek out others like themselves. Thus, while some disability advocates commonly refer to the “disability community,” those who actively identify with this community may include only a portion of the substantial number of people with disabilities in any society.

One issue that often arises within disability politics is that of who may legitimately represent the broader disability community, which is diverse in terms of impairments, demographics, socioeconomic status, and cultural perspective. This dilemma is reduced when diverse people with disabilities representing a variety of constituencies are engaged in politics, rather than a few token individuals purporting to represent a single disability community. At the high end of representation, for example, a total of approximately 47,000 Ugandans with disabilities serve in the country's governing bodies, including 40,000 who have been elected at the village level.

This strong national presence of persons with disabilities is unique, but increased political participation by people with disabilities has occurred in many nations around the world, often in accordance with growing democratization and concerns about representation of diverse minority interests. In the Soviet Union, along with a number of other political organizations founded in the wake of the Helsinki Accords in the late 1970s, the Action Group to Defend the Rights of the Disabled in the USSR was founded in 1978 to advocate for legal rights for Soviets with disabilities. In the Philippines, a national political party was recently established to represent the interests of disabled persons.

Many individuals with disabilities have challenged the legitimacy of political representation by anyone but those who themselves have disabilities. These advocates question whose interests actually are advanced by nondisabled service providers and contend that only people with disabilities should speak on their own behalf. Such issues of representation have been applied to parents or other family members of disabled individuals; some contend that parents should be viewed as a part of the "disability community" and allowed to represent that community in political forums, while others strongly disagree. These questions become even more complex when applied to individuals with severe cognitive or psychiatric impairments who may have difficulty articulating their own interests in political discourse. However, whenever disability is created as a social category, particularly through public policy and the provision of health and social services, those defined as having a disability have the potential to become a distinct political interest group that may become capable of mobilization and political action.

There are numerous examples of people with disabilities engaged in protests or forming organizations on their own behalf. In the past four decades, political activity by individuals with disabilities and organizations of disabled people has particularly increased, and much of that activity has been directed toward the goals of equal access, community integration, and independent living. Among the explanations that have been offered for this increase are emerging medical and assistive technologies that have supported independence for many people with disabilities, changing ideologies of treatment that have encouraged noninstitutional service strategies, and the models of other minority movements in the 1960s and 1970s that advocated for inclusion and social change.

LEGAL ADVOCACY

Some efforts to redefine the social position of people have occurred through legal advocacy in the courts, particularly in the United States. Enabled by the distinctive American constitutional and legal framework and building on the civil rights advocacy that fought racial segregation through federal lawsuits in the post–World War II era, a number of class action suits were successfully pursued in the late 1960s and 1970s on behalf of children denied public school education because of their disabilities, people with disabilities receiving inappropriate treatment in residential institutions, and others denied fair treatment because of their disabilities. These lawsuits were often the product of advocacy groups representing parents of children with disabilities working in partnership with public interest law centers.

Key judicial rulings have helped to establish legal protections for disabled people and foster the growing disability rights movement in the United States. In the American disability policy context, with its emphasis on civil rights, legal advocacy has been a crucial component in ensuring that broader public policies are applied appropriately to individual cases. Legal organizations such as the Disability Rights Education and Defense Fund and the Bazelon Center for Mental Health Law have been valuable resources in the protection of individuals with disabilities. Yet in the absence of more broadly based political advocacy, litigation-based political strategies tend to be episodic and non-self-enforcing and may have a limited capacity to effect institutional change. Such advocacy is most effective when it is part of a wider political mobilization of people with disabilities on their own behalf, a process that requires both social solidarity and collective action.

ELECTORAL POLITICS

Participation in electoral politics is a potentially important avenue for people with disabilities to secure their political voice, yet Americans who have disabilities are much less likely to register and vote than are nondisabled individuals. For example, in the 1994 election, 56 percent of people with disabilities were registered to vote, as compared to 71 percent of nondisabled individuals; only 33 percent of people with disabilities reported voting, as compared to 54 percent of nondisabled individuals.

While there has been little research on possible explanations for this pattern, one factor may be accessibility of the polling place, where individuals with disabilities may encounter a variety of architectural barriers. Another issue is the receptivity and responsiveness of election officials. At times, election officials may become sufficiently frustrated with meeting accessibility needs, so they urge the disabled voter to vote absentee, although some individuals with disabilities view absentee voting as an inferior form of participation. People with mental retardation, blindness, or deafness are sometimes subjected to challenges or have to encounter election officials who are uninformed about their accommodation needs or who resist taking the necessary steps to make the voting process or polling place accessible.

In addition to these physical and attitudinal barriers, policy barriers may affect participation. In the United States, 44 states disenfranchise some individuals with cognitive and emotional impairments, and England's Representation of the People Act 1983 disenfranchises people who have been involuntarily admitted to mental hospitals. Similarly, the constitution of Albania prohibits voting by individuals who have been adjudicated incompetent.

PEOPLE WITH DISABILITIES AS POLITICAL CANDIDATES AND ELECTED OFFICIALS

Persons with disabilities hold or have held elected offices in several countries, and this may help to shape the electorate's response to people with disabilities and the problem of disability. These include Joshua Malinga of Zimbabwe, who was mayor of Bulawayo; Joseph Sinyo of Kenya, a member of the national parliament; Kalle Konkkola, who has served on the city council of Helsinki, Finland; Midori Hirano, of Japan, who was elected in 1998 to the Kumamoto Prefecture; a Philippines congressman, Ernesto Herrera; and several individuals with disabilities who have served or are serving in the national parliament of South Africa.

Informal observations of U.S. politics indicate that disability is often an issue in campaigns, particularly contests for the presidency. In the 1996 American campaign, for example, the Republican Party candidate, Senator Robert Dole, was a World War II veteran who had lost the use of his arm from an injury sustained in combat, whose disability was labeled a badge of honor. The Democratic Party candidate, Bill Clinton, is not disabled, but the Democratic national convention featured an address by Christopher Reeve, an actor who had become quadriplegic after a riding accident. Reeve, a controversial figure in the U.S. disability community, issued a plea for funding for research to cure paralysis. In neither of these instances was civil rights for people with disabilities a major focus of the campaign message, although in both parties' campaigns, disability rights was a minor emphasis.

Because they tend to be less affluent than nondisabled individuals, people with disabilities around the world are less likely to have the wherewithal to contribute money, time, or other resources to political candidates. To the extent that these circumstances make their voice less likely to be heard in the electoral process, people with disabilities will be disadvantaged in democratic governance.

LOBBYING AND PRESSURE GROUPS

In addition to participation as elected officials or through political parties, disabled people in many nations have formed organizations whose purpose is to represent the disability community and influence governmental bodies responsible for the enactment and implementation of public policy. While there is a long history of political activity by and on behalf of people with disabilities, disability politics has become far more widespread in the post–World War II era, particularly in the last three decades of the twentieth century, building on the example of similar movements for self-determination and inclusion by other politically marginalized social groups around the world.

In recent decades, a number of umbrella organizations have been formed to coordinate political activity and speak with one voice on behalf of the disability community. In Great Britain, for example, the British Council of Disabled Peoples (BCODP) formed in 1981 to represent 80 organizations and approximately 200,000 Britons with disabilities. In the United States, the American Coalition of Citizens with Disabilities was organized in 1975, with 19 constituent groups. In Canada, the Coalition of Citizens with Disabilities (CCD) was founded in 1976 with affiliates from most Canadian provinces. In Denmark, De Samvirkende Invalideorganisationer (DSI) has been active for decades in promoting the integration into Danish society of Danes with disabilities.

Parallel to the formation of these national coalitions has been the creation of cross-national coalitions. Some international groups have organized around specific disabilities, such as the African Union of the Blind, founded in 1987, whose activities have been supported by the Norwegian Association of the Blind and Partially Sighted. In 1981, Disabled Peoples' International (DPI) was formed, an international cross-disability coalition of more than 110 organizations, including many from developing nations in Latin America, Africa, and Asia. DPI has been particularly active in advocating for disability rights in international governmental and particularly nongovernmental activities, as well as in supporting the development of organizations of people with disabilities around the world. Pelka (1997:103) quotes Joshua Malinga, a former DPI chairperson from Zimbabwe, who remembered the 1980 organizational meeting of DPI in Singapore: "It was at this meeting that most of us from Africa first understood what was meant by a 'disability rights movement.' We had never thought about disabled rights as a cause, to the disabled community as a community. . . . It was a shift from looking at disability as a health issue, to looking at it as a human rights issue."

Perhaps the most established political role for disability advocates has been in the United States, where a number of organizations maintain active lobbying roles in Washington and many state capitals. Representatives of disability organizations in the United States played an extensive and significant role in disability policy development in the 1970s and 1980s. In Scandinavian nations, disability policies have been shaped by disabled representatives of community-based disability organizations. Organizations of people with disabilities in many other countries, including Canada, Singapore, England, Ireland, and the Netherlands, have participated in the reformulation of outdated disability policies.

Most American disability policies since the mid-1970s, including the landmark Americans with Disabilities Act, have been drafted with the active participation of representatives of organizations of disabled people, and in the 1990s, many appointed government officials responsible for making and enforcing government disability policies were recruited to their posts from organizations of people with disabilities. In a number of instances, the prior connections among government appointees from the disability movement have meant that the long-standing absence of communication and cooperation among competing public bureaucracies has been overcome.

While access to positions of power and influence has had many important benefits for the disability community, it has often created dilemmas for those holding them, who must balance their loyalties to their constituencies with the practical considerations of public policy making. Nevertheless, since so many aspects of life for people with disabilities are shaped by public policy, institutionalized participation in policy debates within government appears to have incorporated the experience of disability into many policy decisions. Where regular participation does not occur, however, disability advocates may need to turn to more contentious nonelectoral political action to represent their own interests.

PROTEST POLITICS

Disability protestors have been willing to confront public officials, block traffic, occupy public places and government offices, or be arrested for their causes. In 1972, for example, members of the cross-disability group Disabled in Action blocked traffic in the New York financial district. In 1981 in Canada, coordinated national protests were organized by the Council of Canadians with Disabilities to advocate for a Human Rights Amendment to protect the civil rights of Canadians with disabilities.

Through much of the 1980s, members of ADAPT (originally Americans Disabled for Accessible Public Transit) chained themselves to buses and disrupted meetings of the American Public Transit Association to protest inaccessible public transportation. Following the enactment of the Americans with Disabilities Act, ADAPT changed its name to Americans Disabled for Attendant Programs and has conducted numerous protests against the unnecessary institutionalization of people with disabilities in nursing homes. In 1988, deaf students at Gallaudet University in Washington, D.C., forced the closure of their campus for a week, demanding that a deaf person be hired as university president. British organizations of people with disabilities have engaged in similar disruptive tactics; Gooding (1994:160) cites a 1993 *New Statesman* report of a national register maintained by the Direct Action Network of more than a thousand disability activists willing to take part in civil disobedience.

Typically, protests involve not just short-term objectives but also a sense of shared purpose based in a vision of an alternative to existing social arrangements. The goal of an inclusive, barrier-free society may motivate disability activists beyond the specifics of an exclusionary policy or demeaning practice. It is such a vision that will increasingly serve as the basis for disability politics.

POOR LAWS (UNITED KINGDOM)

The English poor laws consist of the parliamentary legislation, as well as subsequent practice, related to the public relief and control of the impoverished, including the disabled poor. The period from 1531 to 1834 is known as that of the *old* poor law, with an emphasis on parochial, predominately noninstitutional, provision (outdoor relief). From 1834 to 1929, the *new* poor law involved national supervision and extensive use of workhouses.

Responding to concerns about the social order and influenced by Christian humanism, the sixteenth-century elites passed legislation initially to punish vagrants but later to identify and relieve needy paupers. In 1572, England became the only country in Europe to permit parish authorities to regularly levy poor rates (compulsory property taxes). In 1598 and 1601, further legislation *required* parishes to levy rates, to punish vagrants, to provide outdoor relief (usually a pension) for those disabled to work, and to provide work for the able-bodied. Further legislation included a 1662 act establishing settlement laws limiting migration and providing a way for paupers to establish a right to relief in their "home" parish (usually where they were born), with the right to appeal to local justices of the peace.

In the seventeenth century, the system spread in practice throughout the country, and pension numbers and levels grew substantially. Disability to work was the test in practice, with the elderly, those disabled on the job, the feebleminded, and war widows given priority. Medical care was provided. Institutions were increasingly established (almshouses, workhouses). From 1593 to 1679, thousands of disabled veterans were relieved via a statutory, county-based pension system administered by county justices and paid for by taxes (after 1679, the central government took over this responsibility).

From 1700, workhouses increasingly included infirmaries that provided medical care. It has been argued that the sick and disabled had more control over their lives and bodies on out-pension (noninstitutional) than in-house (institutional). Others argue that the infirmaries provided much-needed medical attention for those with disabling conditions such as syphilis. "Out relief" continued, with relief manipulated by employers to top up and consequentially depress wages.

The costs of the poor law came under increasing scrutiny, with many assuming the poor were unwilling to work. In 1834, a new poor law was enacted that created a uniform national system, with parishes joining together in unions running workhouses controlled by Boards of Governors. Outdoor relief was significantly curtailed. The disabled had to be prepared to enter the workhouse to be relieved. Conditions within some of the workhouses were appalling.

In 1929, the Local Government Act officially abolished the Boards of Governors and workhouses, although many related aspects of the poor laws continued to be implemented for some time.

Throughout the history of the poor laws, the actions of the disabled poor themselves were an important factor in the growth of the system, as well as changes in practice, particularly at the local level. The disabled increasingly felt entitled to relief and negotiated as best they could to that end.

—Geoffrey L. Hudson

POPE, ALEXANDER (1688–1744)

Eighteenth-century English poet

Alexander Pope, eighteenth-century England's most celebrated poet and his generation's most frequently portrayed celebrity, dominated the emergent literary marketplace as the first self-supporting, nonplaywriting professional author while fascinating his audience as a spectacle of deformity. Characterizing the career of a wit as "a warfare upon earth" and complaining in his *Epistle to Arbuthnot* of "this long disease, my life," this master of the heroic couplet endured a war between an exceptional mind and a body lambasted as "at once resemblance and disgrace" of humanity's "noble race." Barely four and a half feet tall when grown—in Voltaire's words, "protuberant before and behind" (speculation as to the cause of his deformity has ranged from tuberculosis of the spine contracted from a wet nurse, to trampling by a cow, to excessive study)—and socially disenfranchised for his Catholicism, Pope transformed his marginality into a vehicle for self-reflection, self-representation, self-possession, and self-legitimation. His life's work was the ultimate couplet of deformity and poetic form. Mocked early on as "the ladies' plaything" for a best-selling translation of Homer appealing to a nonaristocratic and female audience (a serious attempt at post-Miltonic epic refracted in his mock-heroic mirror *The Rape of the Lock*), at his career's close, the Tory satirist cast himself as a hypermasculine epic hero embodying moral integrity in an age of beautiful hypocrisy. Radically conservative in his final nostalgic critique of British economic and imperial progress, innovative in his exploitation of the literary marketplace, Pope embodied, negotiated, and redefined the ambiguities of his age. When the curtain falls at the end of *The Dunciad* and "universal Darkness buries all," Pope's couplet art concludes triumphantly by envisioning art's destruction.

POSTCOLONIALISM

Only recently have scholars in both disability studies and postcolonial studies attempted to explore the intersections between these two areas of scholarship. Disability studies' scholars have ventured into global contexts to explore the intersection of disability and culture in comparative perspective and/or have explored the impact of globalization on disabled people internationally. However, they have only very rarely situated these same discussions within the political space of postcoloniality—a space that postcolonial scholars would argue provides a very different analysis of the global.

Postcolonialism, in its broadest representation, foregrounds the effects of imperialism and exploitation as a result of the colonization of specific cultures and societies, but this representation has itself been widely contested. While on one hand, the term *post* in *postcolonialism* clearly highlights a historical dimension to the discussion (i.e., "after" colonialism), this position has been contested by other postcolonial scholars who argue that colonialism has become transhistorical because the effects of imperialism and exploitation continue to affect the former colonies via the neoliberal policies of globalization. Other postcolonial scholars have broadened this focus to include discursive analyses of postcolonial culture that foreground contradictions, ambiguities, ambivalences, and ruptures. In this case, the *post* in *postcolonial* foregrounds a more nuanced discourse that supports "going beyond" materialist analyses of contemporary culture to foreground radical possibilities of movement, fluidity, and mobility that produce hybrid (postcolonial) subjects.

It is in engaging Otherness that scholars in both postcolonial studies and disability studies find common ground, especially in their deconstructive analyses of how representation, hegemony, and normativity produce both the postcolonial and the disabled Other. For example, postcolonial studies scholars have described how the colonized body has been constituted as the abject Other when situated in opposition to the “civilized, civilizing, [and] normal” body of the colonizer. Similarly, disability studies scholars have also demonstrated how the Western paradigm of knowledge has produced specific ideological representations of the “normate” through a series of exclusions that constitute the disabled Other as outside the purview of rights-bearing humanity.

These ideological representations of the colonized and disabled Other often draw on the presumed interrelationships between physiognomic factors and social/geographical environments. For example, even though John Langdon Down (Jackson 1999) recognized differences between those he termed “mongoloid idiots” and the “real Mongols,” he still saw what he claimed were unmistakable similarities and considered these combined physical and mental features of this ethnic group as pathognomonic of a distinct and prevalent class or type of idiocy. Even though this was refuted in later years, the racial assumptions inherent in his study continue to persist such that, on one hand, “mental defectives” became metaphorically as well as literally “a race apart,” and at the same time, the racialized Other was seen as “mentally defective” and in dire need of civilization via colonialism. As a result, just as it was imperative that attempts be made to tame the savage racialized Other in the colonies, the minds and bodies of the “idiot,” the “imbecile,” and the “feebleminded” were also to be subdued and domesticated in the segregated internal colonies of state institutions.

The oppressive interrelationship between disability and colonialism was epitomized in the freak show, a popular form of entertainment that had its heyday in the United States from 1840 until about 1940. Of particular interest to this discussion are those “freaks” who were exhibited as the exotic mode. This was a mode of presentation that accentuated the culturally strange, the primitive, the bestial, and the exotic. Promoters of the shows claimed that their exhibits came from mysterious parts of the world—darkest Africa, the wilds of Borneo, a Turkish harem, and an ancient Aztec kingdom. Many of these exhibits were non-Western people with demonstrable physical differences who were exhibited in the exotic mode by emphasizing their anomalies as well as their “strange ways,” and though they were nondisabled, they were exhibited alongside native-born Americans with disabilities. One of the most famous examples of such an exhibit was the “Hottentot Venus,” whose enlarged labia and buttocks were accentuated to foreground her savage sensuousness and mark her as measurably different from the European woman. Moreover, in another blatant distortion of presentation that brought together both disability and colonialism, native-born Americans with disabilities were misrepresented as savage foreigners (e.g., Ohio-raised dwarfs as the “Wild Men from Borneo”; African Americans with microcephalus from Alabama as members of the Ituri—a head-binding African tribe). While such exhibits at the freak shows were arguably presented as entertainment, at the same time, they also provided a quasi-scientific basis for the justification of both slavery and colonialism by depicting the nonwhite world as childlike, barbaric, and dangerous and therefore in desperate need of the civilizing influence of the West.

A critique of Western science and its devastating effects on both the disabled and the colonized Other is yet another commonality shared by both postcolonial and disability studies scholars. According to postcolonial scholars, Western medicine, armed with an enormous battery of tests and discursive practices that focused specifically on the physical and mental constitution of the colonized body, extended its reach beyond mere scientific interest to explore and use its knowledge to further the authority, legitimacy, and control of the colonial state. Describing a similar history of the asylum on Robben Island, South Africa, postcolonial scholarship describes how the racial superiority of the white settler over the African native was codified in the science of ethnopsychiatry. Unlike the European “madman,” whose insanity was seen as physiological, the African “madman’s” insanity was attributed to his racially determined incapacity to cope with the stresses of urbanization and civilization and was therefore provided physical rather than psychological therapy, with the therapeutic purpose of introducing the African to civilization. Such examples demonstrate how Western science used specific ableist and racist discourses to justify European control of its colonies even in the face of Enlightenment ideals of universal humanity.

With this oppressive context as their historical backdrop, postcolonial subjects have attempted to distance themselves from what they perceive as a stigmatizing context of disability and, in doing so, have failed to realize the emancipatory possibilities of forging a political alliance with disabled people. In fact, postcolonial scholars, for the most part, almost never recognize disability as a political construct and, as a result, seldom include disability in their analyses of difference. When disability does appear in their analyses, it is often used as a metaphor to describe the colonized condition.

For example, postcolonial analyses have explained how, under the censorship of Japanese colonialism, Korean writers often drew on the trope of disability to create characters who lacked freedom in bodily function and movement. Casting their literary work in metaphorical terms as the textual body impaired by the violence of colonialism, these writers overturned traditional views of disabled people as abject citizens by recasting them along with the colonized (disabled) nation-state as a bearer of rights. The silencing of these writers by colonial censors also represented a shared critical relationship with disability such that just as the physically disabled were constituted as objects of colonial hygiene and social control, these intellectuals were also constituted as objects of thought control and censorship. In this way, Korean writers produced literature that was encoded with anticolonial and anticapitalist messages of protest by using disability as the discursive means to articulate various positions of their colonial destiny, ranging from internal critique and self-criticism to objection of their unfree colonial situation.

The radical potential of disability in postcolonial literature is also echoed by various postcolonial literary critics. According to these analyses, because the postcolonial subject is forced to enter into a multiple symbolic order (e.g., colonial, native, and postcolonial/neocolonial contexts), he or she is forced to go through (as per Lacanian psychoanalytic theory) multiple castrations to achieve wholeness and, as a result, experiences symbolic deformity—entering into a condition, sometimes problematically described as “disability.” At the same time, some scholars also realize the radical possibilities for the “disabled” postcolonial subject in this context as it enters into a combat over meaning by using one cultural/symbolic system against another. This space where disability and postcoloniality intersect has been described as the “third dimension,” where the Self can no longer be contained within the simplistic binary of Self/Other, thereby producing an identity that is both ambivalent and muted. Located now at the point of slippage between identity categories, the disabled postcolonial subject appears as the “evil eye”—the figure that resists the image of totality that is critical in the myths used by both the colonizer and the colonized. However, some scholars have been quick to point out that postcolonial authors often fail to capitalize on this radical potential of disability in their novels and have instead characterized the disabled body as a docile body against which nationalist tensions can be arbitrated and against which a rationalist ideology can pull “a collection of disparate peoples into a self-identified nation” (Lacom 2002:141). In this way, national identity is consolidated so as to maintain the differentiation of the national “us” from aliens within and without. Unfortunately, such efforts fail to serve the interests of both the postcolonial and disabled subjects because they continue to support oppressive representations invested in tragedy and exoticism.

Just as postcolonial scholars have used disability as a metaphor to represent their oppression under colonial rule, disability studies’ scholars have also appealed to the metaphor of colonialism to depict and explain the social oppression of disabled people. For example, some scholars describe the harsh and delimiting educational segregation of students with disabilities in U.S. public schools as mimicking the historical trajectory of colonialism. Others point out that just as emerging European states drew on particular notions of normality to support their project of imperialism, these same states looked inward at the human variation among their own people and produced a form of internal colonization that supported a dehumanizing view of disability. In educational contexts, in particular, these oppressive beliefs about disability have resulted in disabled students experiencing a “pedagogy of control” that, according to authors, mirrors the forced labor and absolute confinement that was experienced by those living in the colonies. In addition, scholars have likened the struggles for equal schooling for disabled students as a decolonization effort that has sought to challenge the social hierarchies that have reduced disabled students to the status of defective and dependent citizens.

What is apparent in the previous examples is that the metaphoric representations of both the colonized and disabled Other hold emancipatory possibilities for each other. At the same time, these metaphoric discourses of Otherness sometimes fail to account for and/or describe the actual experiences of disabled postcolonial subjects living in the former colonies that constitute the so-called Third World. Already living in impoverished conditions in nation-states incapable of providing an economic safety net for even their nondisabled citizens, disabled citizens living in postcolonial contexts continue to struggle for survival amid conditions of abject poverty; unemployment; lack of adequate medical care, education, and assistive technology; and the denial of basic human rights.

These conditions have been exacerbated in recent years by the neoliberal policies of the World Bank and the International Monetary Fund, which support economic austerity measures to be implemented by countries that had defaulted in their payment of debts incurred as a result of more than a century of colonial economic exploitation. These austerity measures, called structural adjustments policies (SAPs), are specifically designed to cut public spending in the areas of health, education, and public welfare in an attempt to support sustained economic growth and eventually lead to a reduction in poverty. However, as a result of these policies, there has been a drop of 10 to 25 percent in average incomes, a 25 percent reduction in spending per capita on health, and a 50 percent reduction in spending per capita on education in the poorest countries in the world—material conditions that set the stage for the social construction of disability. In addition, the World Bank uses the concept of the DALY (disability-adjusted life years) to prioritize health interventions by calculating their relative cost-effectiveness measured by the number of DALYs saved through each intervention, where the cost of each intervention is weighed against the person's potential "productivity' (i.e., contribution to economic growth). Here postcolonial disabled citizens who are unable to work are awarded zero value and therefore have little or no entitlement to health services at public expense. In this context, postcolonial conditions are seen to once again support the oppression of disabled citizens.

POSTER CHILD

Poster children are persons with disabilities portrayed in the media (e.g., newspaper, television, and publicly displayed posters) to encourage the public to donate money to organizations set up to help persons with disabilities. Most of the general population views disability as a statistical tragedy and often is not familiar with anyone who has a disability. In portrayals of poster children, the emphasis tends to be placed on the difficulties these individuals face, and the language tends to be negative, referring to the persons with disabilities as victims and sufferers who spend their life waiting for a cure. Poster children tend to be children because it is easier to portray children than adults as innocent victims. The vivid portrayal of the "tragedy" of an adorable child with a disability touches the emotional hearts of the viewers by eliciting feelings of pity and guilt, which in turn stimulate individuals to donate money to help these "helpless" individuals.

Throughout the past century, the media have used poster children to collect large sums of money. During the nineteenth century, religion-based charities often took on the responsibility for persons with disabilities. The concept of the poster child was invented at the beginning of the twentieth century, when volunteer organizations were developed that depended on donations. In 1919, Edgar "Daddy" Allen, a businessman from Ohio, founded the Society for Crippled Children, today's Easter Seals, and during the 1920s, Franklin D. Roosevelt inspired the March of Dimes. Today, when 99 percent of families own televisions, telethons have become a popular method for reaching large numbers of potential donors. The telethons portray the struggles of persons with disabilities, most of them cute disabled children, and their families (e.g., Jerry Lewis's Muscular Dystrophy telethon on Labor Day).

Although these organizations are set up to help persons with disabilities, an increasing number of disabled individuals, including former poster children, criticize them. Common criticisms include the following: these organizations have developed into million/billion-dollar enterprises, which have lost sight of their original goals; the organizations exploit poster children; primarily nondisabled individuals run the organizations; and disabled people are not consulted on how the money is used. In fact, many disabled individuals oppose using contributed money for various types of therapy (e.g., surgery and physical therapy), preferring instead that it be used to provide disabled individuals with necessary aids to live full and productive lives and to make built environments more accessible. The organizations tend to deny the various criticisms or insist that the protestors' opinions are not representative of larger groups.

The portrayals of poster children may have a negative impact on disabled children, especially those without disabled adult role models, because the children may learn to view their disability as a defect that needs to be cured. By overemphasizing the struggles in their lives, the children may reject (this part of) themselves. This rejection in turn can lead to insecurity, depression, anxiety, or other types of psychopathology, thus affecting disabled individuals into adulthood. The portrayals can affect children directly, by being poster children or seeing the portrayals, and indirectly, by interacting with members of society who have seen these portrayals and adopted the perspective that disability is a defect.

—Ingrid C. Hofmann

POSTTRAUMATIC STRESS DISORDER

A person's life can be interrupted by sudden, unexpected, and uncontrollable events involving death, injury, inflicted pain, or threat to self-integrity. Such events are very distressing. With time and appropriate support from others, distress and sorrow subside in most survivors, leaving scars but no open wounds. Some, however, do not recover and develop prolonged and disabling mental conditions. Posttraumatic stress disorder (PTSD) is the prototype of prolonged psychological disturbance that follows a stressful event.

Known since ancient time and masterfully described following World War I, PTSD was formally delineated in a classification of mental disorder in 1980 (*Diagnostic and Statistical Manual of Mental Disorders,* third edition [*DSM-III*]). The definition was further refined in the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-IV*). Some PTSD symptoms are directly related to the triggering event. These include reliving the traumatic experience through distressing and intrusive flashbacks, nightmares, heightened sensitivity to reminders of the event, and fearful avoidance of places, situations, or mental representations of the traumatic event. Other PTSD symptoms resemble depression and anxiety: loss of interest in previously pleasurable activities, restriction of one's emotional life, irritation, trouble falling or staying asleep, jumpiness, and constant vigilance.

For PTSD patients, therefore, the traumatic event is ever present and extremely demanding. A war veteran with PTSD may feel that the war "never ends." Combat scenes may continue to intrude into his or her consciousness, and he or she might experience an overpowering need to remain vigilant and defensive (e.g., scan building roofs for potential snipers). Survivors of terrorist attacks will, similarly, feel that another attack is imminent and behave accordingly. Rape survivors with PTSD might find it difficult to freely engage in sexual activity—even with known and beloved partners. As in other anxiety disorders, PTSD patients are well aware of the irrational nature of their fears but are trapped and overpowered by them.

Because many PTSD symptoms evoke the traumatic event, a prevalent theory explains the disorder as an inappropriate acquisition of fear responses during the event. Specifically, it has been argued that those brain areas that mediate fear responses (such as the amygdala) come to control and dominate PTSD patients' emotional and cognitive life. Brain-imaging research has shown that trauma survivors with PTSD tend to activate the brain's alarm system whenever confronted with novelty or challenge.

PTSD does not develop in every survivor. Inherited vulnerability and lifetime exposure to trauma increase the risk of developing PTSD. Adequate support and a nurturing recovery environment in the aftermath of traumatic events help protect survivors from developing the disorder. PTSD symptoms can be alleviated by pharmacological agents from the family of selective serotonin receptor inhibitors (SSRIs) and by psychological treatment (such as cognitive or cognitive-behavioral therapy).

Some writers have challenged the validity of this syndrome, arguing that PTSD is an artifact that reflects skewed social perception of normalcy and pathology. Clinicians are well aware of the suffering of PTSD patients and, while admitting that the definition of PTSD might be imperfect, use this diagnosis and the related research findings in the best interest of their patients.

POVERTY

A family is considered poor when their monthly income is less than the income threshold set by the particular country's census bureau. Poor families do not have adequate income to cover their basic needs, including food and shelter. People living in poverty are more likely to be unemployed, have limited education, and are more likely to lack health care. An increasing number of people with disabilities, including children and adults, live in poverty.

Poverty is both a cause and consequence of disability. Several reports have found a strong correlation between disability and poverty and have described them as being cyclical in nature. First, living in poverty has implications for being at increased risk for developing a disability. Pregnant women living in poverty are less likely to receive prenatal care and are at higher risk for having low-birthweight babies and birth complications that place them and their offspring at a higher risk for experiencing disabilities. Also, people living in poverty are more likely to have either insufficient or unhealthy nutrition and live in conditions that put them at high risk for exposure to malnutrition, hazardous working conditions, and unhygienic living conditions, increasing their likelihood of developing impairments. Second, having a disability can lead to poverty. It is estimated that people with disabilities are three times more likely to live in poverty than the population as a whole. Individuals with disabilities experience additional stressors and expenses related to daily living. These include expensive assistive devices/adaptive equipment for increased functioning, home modifications expenses, health care attendant costs, special services (e.g., interpreters), extra transportation expenses, and health care costs.

Individuals with severe disabilities are more likely to experience difficulty seeking and maintaining employment. They are more likely to receive welfare benefits and less likely to have health insurance. All of these difficulties, combined with the marginalization from community and social activities, increase the likelihood of leading a life of poverty. According to the 2001 census data for the United States, only 48 percent of citizens 25 to 64 years old with severe disabilities have health insurance compared with 80 percent of individuals with nonsevere disabilities and 82 percent of nondisabled Americans.

In the United States, at least half of the adults with disabilities who cannot work because of a chronic disease or disability receive federal cash benefits under Social Security Disability Insurance (SSDI) and Social Security Insurance (SSI), and some may qualify for Medicaid and Medicare. The paperwork and bureaucracy involved in receiving this income are complex. Even if an individual successfully obtains these supplements, the small monthly income is often not sufficient to cover living expenses. In brief, having a disability has three different types of consequences that increase the likelihood of experiencing poverty for the individual and the immediate family. These consequences include (a) the income lost due to incapacity and discrimination; (b) the direct cost of treatment, access, and accommodations; and (c) the indirect costs to family caretakers who are not necessarily directly affected by the disability. Caregivers may have to quit their jobs or accept only part-time jobs so that they can care for the family member with a disability.

Women with disabilities in general are also more likely to live in poverty than men. Disabled women, compared with men with disabilities, are likely to have fewer years of formal education, less likely to have health care and to be employed, and, if employed, likely to be earning less income. A similar outlook has been reported for the elderly with disabilities worldwide. It has been reported that the proportion of the elderly with disabilities living at or below the poverty line, with limited health care, limited income to meet their daily needs, and limited access to attendant care, transportation, and assistive devices, is higher than younger adults with disabilities.

Adults are not the only ones affected by the relationship of poverty and disability. Children living in poverty are particularly at risk for having a disability. For example, in 2003 in the United States, it was estimated that about 28 percent of children with disabilities were living in poor families compared with 16 percent of all children. Poverty affects a child's development and learning, and in turn, the presence or onset of a disability exacerbates poverty. Children living in poverty have a higher incidence of malnourishment and exposure to environmental toxins; furthermore, poverty contributes to other factors such as parental stress and reduced exposure to a healthy and safe learning environment. Children with disabilities living in poverty are more likely to be neglected and malnourished and are more likely to die young than nondisabled children. Antipoverty programs need to closely examine the needs of families with children with disabilities who may experience emotional and material hardships.

Researchers have also highlighted the relationship between race, poverty, and disability in the United States. Minorities with disabilities (including

Hispanics, African Americans, and Native Americans) are more likely to live in poverty than nonminorities with disabilities. Researchers have called this "triple jeopardy" or triple discrimination of race, poverty, and disability that increases social inequalities. Minorities with disabilities are at a higher risk for being discriminated against when looking for jobs compared to Caucasians with disabilities. They are likely to have less formal education, to be less integrated into the fabric of society, and to be more often marginalized from societies' social and economic life than are Caucasians with disabilities.

It has been shown that, worldwide, people with disabilities are poorer as a group than the general population and that people living in poverty are more likely than others to be disabled. Individuals living in developing countries in poor conditions are more likely to experience poor nutrition, dangerous work environments, limited access to vaccination programs, limited preventive health care and maternity care, poor hygiene and sanitation, war and conflict, and natural disasters that can cause disability and impairment.

In communities around the world, people with disabilities are among the poorest and most vulnerable of all groups. Individuals with disabilities are often stigmatized and abused and less likely to have social security and health care. Furthermore, the housing and environmental conditions in which poor people live and work make them and their children more vulnerable to mental and physical impairments.

According to the World Health Organization (WHO), it is hard to obtain an accurate estimate of the number of people with disabilities in the world. Disability rates may vary by the type of country, type of disability, and age group. Nevertheless, the percentage of disabled persons ranges from 0.2 to 20.9 percent of the population in a given country. It is estimated that more than 500 million individuals in the world have a disability, and about 80 percent of these individuals live in developing countries. The fact that developing countries have such a high number of people with disabilities is due, in part, to the large number of people who live in poverty. Many international efforts are under way to address poverty and disability. For instance, the Action on Disability and Development (ADD) and the Chronic Poverty Research Centre (CPRC) attempted to understand the relationship between poverty and disability and are sponsoring a multitude of efforts to address these issues. These efforts have included economic development initiatives to create new and safer jobs, campaigns to eradicate polio and other childhood diseases through appropriate vaccinations, campaigns to prevent malnutrition in small children, and educational campaigns about appropriate handling of hazardous materials.

A worldwide effort is led by WHO to eradicate polio and other preventable childhood diseases with vaccinations. Much of the WHO efforts are also concentrated in Asia and Africa. In addition, the Department for International Development is sponsoring numerous programs through the United Nations in developing countries to improve sanitation and the water supply, as well as decrease exposure to environmental hazards. More research needs to be done to address policy issues and examine the impact of current international efforts. Research endeavors also need to focus on practical strategies for reducing the poverty that people with disabilities face, instead of continuing to gather data to reaffirm the well-known link between poverty and disability. It is important to increase the inclusion of people with disabilities in policy and social change efforts concerning poverty and disability. Inclusive and participatory research is needed to empower people with disabilities during the process of gathering data and information, to assess progress, and to challenge the exclusion and marginalization that help perpetuate the link between poverty and disability.

PREMATURITY

Prematurity, as defined by the World Health Organization, includes infants born at < 37 weeks gestational age (GA). The prematurity rate varies between 5 and 7 percent in Europe and Canada, whereas in the United States, it is 8 to 10 percent in white and 16 to 18 percent in African American women. Despite improvements in obstetric care, the prematurity rate has not declined in the past 40 years. Prematurity remains the leading cause of mortality and morbidity worldwide and accounts for between 60 and 80 percent of deaths among infants without lethal congenital malformations.

Survival of preterm infants is directly related to the degree of immaturity and birthweight. Although only about 1.5 percent of all infants are of very low birthweight (VLBW, < 1500 g), this group accounts for a disproportionately high mortality and morbidity. Neonatal survival improves dramatically with increasing GA; currently, the survival is more than 50 percent at 25 weeks and more than 90 percent at 28 or 29 weeks GA.

Although recent advances in the care of infants have resulted in a significant improvement in survival, they have not been associated with a parallel decrease in the rates of subsequent neurosensory sequelae, which include cerebral palsy, mental retardation, blindness, and deafness. The rates of cerebral palsy for infants < 1500 g birthweight are between 13 and 90 per 1,000 live births, which is nearly 40 times higher than the rate of 2 per 1,000 in the general population. The rates of blindness for infants < 1000 g are between 2 and 8 percent. The current estimate is that 1 in 2 extremely low birthweight (ELBW, < 26–28 weeks GA) survivors will have a neurodevelopmental disability; the most immature infants often have multiple disabilities.

At mid-childhood, additional problems such as behavioral difficulties, inattention, and learning disabilities may emerge. Children who were ELBW have mean IQ and achievement scores that are 9 to 13 points below the normative mean. Nearly half of the ELBW cohorts require special educational assistance and/or repeat a grade. These difficulties have been shown to persist to mid-to-late adolescence. Even children who are normal neurologically and have intellectual scores within the average range do not perform as well as their term birthweight peers. Thus, there is an economic burden for remedial assistance over and above that for term infants. However, by self-report, adolescents born with ELBW placed a high valuation on their health-related quality of life, despite recognition of their disabilities.

In terms of general health, the high prevalence of recurrent illness and hospitalization in early childhood appears to decline as the children born prematurely grow older. However, although there is some catch-up growth, overall, ELBW survivors have lower growth attainment at adolescence and early adulthood. Disturbances in growth in the intrauterine and postnatal period may have long-term implications in terms of metabolic derangements, hypertension, and cardiovascular disease in adulthood.

It is important to emphasize that the morbidities described are more prevalent in the least mature infants. By and large, infants weighing >1500 g at birth or born above 32 weeks gestation do substantially better but may still have minor disabilities. Thus, prematurity is a major public health problem. The high disability rates are often compounded by psychosocial disadvantage.

To date, medical efforts to prevent premature birth have been largely unsuccessful.

PRENATAL TESTING

Disability plays a major role in prenatal testing. This entry focuses on the principal diagnostic categories that contribute to risk of disability in prenatal testing and the major technologies that are used to assess prenatal and preconceptual risk of disability; full discussion of the social contributors to prenatal testing is beyond this brief essay. Prospective parents seek prenatal or preconceptual testing to determine specific anatomic or genetic diagnoses with which to assess risk of disability in their fetus or yet to be conceived fetus. Individual parents generally seek to optimize the chances of a "normal" (i.e., nondisabled) child. As access to prenatal information concerning fetal anatomic and genetic characteristics has increased, the gap between accurately predicting fetal anatomy or genetic mutations and predicting childhood disability has widened. This widening gap leaves parents to define the limits of hope for their offspring individually, based on heterogeneous information and experiences. In many industrialized countries, socioeconomically advantaged parents act on these risk assessments in decisions to terminate pregnancies. Some parents who have a specific disability and are faced with a relatively certain fetal diagnosis of the same disability (e.g., achondroplasia) will opt to continue the pregnancy based on their own life experiences. Alternatively, parents faced with a similarly certain but life-limiting disability (e.g., Tay-Sachs disease) may opt for pregnancy termination.

The major diagnostic categories in prenatal testing associated with a significant risk of disability are genetic, anatomic, infectious, and environmental. Genetic diagnoses include cytogenetic abnormalities (too many, too few, or malformed fetal chromosomes, e.g., Down syndrome) and inherited genetic diseases (e.g., cystic fibrosis). Diagnosis of either category of genetic disease requires access to fetal cells or DNA through amniocentesis, cordocentesis, chorionic villus sampling, or embryo biopsy. Anatomic diagnoses are established by antenatal ultrasound and include major birth defects (e.g., congenital heart disease or spina bifida) and prematurity. These diagnoses can also lead to the prediction of childhood disability (e.g., cerebral palsy in premature infants). Fetal infections (e.g., rubella or German measles) can be diagnosed using either maternal or fetal blood samples or amniotic fluid and can lead to the prediction of significant pediatric disability. Finally, fetal exposure to specific teratogens through maternal or paternal environmental exposure discovered through a careful medical history can increase the risk of childhood disability (e.g., fetal alcohol syndrome or birth defects due to paternal exposure to organic solvents). Each of these categories includes many conditions with widely varying outcomes in disability. This biologic heterogeneity in outcome can complicate parental understanding of disability risk.

The two most frequently used diagnostic methods for prenatal testing are antenatal ultrasound and amniocentesis. After ultrasound technology was developed during World War II to detect German submarines, early ultrasonographers in the United States began to visualize the fetus in "black and white pictures of things that looked like the clouds seen in hurricane reports," according to Lewis H. Nelson, president of the American Institute of Ultrasound Medicine. With rapid advancements in technology, accurate anatomic evaluation of individual organs (e.g., hearts or spinal cords) in fetuses as early as 8 weeks gestation has become commonplace. However, antenatal ultrasound has significant false-positive and false-negative rates. In addition, the anatomy of a fetus may not predict the disability of a child. For example, with enlarged chambers in the fetal brain midway through a pregnancy (hydrocephalus), the likelihood of adverse neurodevelopmental outcome (e.g., seizures, inability to read or talk, blindness, or deafness) is significantly increased. But some children with this finding are "normal," and the ultrasound test cannot distinguish those who will have from those who will not have disabilities.

Amniocentesis, or the removal of a sample of amniotic fluid from the womb, was first developed in 1950 by a Uruguayan obstetrician to measure pressure changes in the womb during labor. This procedure transformed obstetrics from an exclusively maternal discipline to a medical specialty that included prenatal testing for fetal chromosomal composition around 16 weeks gestation. Recent advancements now permit fetal chromosomal evaluation at less than 8 weeks gestation (by chorionic villus sampling) or prior to implantation in the womb of an embryo (by embryo biopsy). Diagnosis of disabling chromosomal and genetic conditions in the embryo or fetus prior to the legal definition of viability is feasible (24 completed weeks of gestation in the United States). However, like antenatal ultrasound, the biologic continuum of many genetic diagnoses plus the socioeconomic status of different families may lead to different degrees of disability in children with similar fetal genetic diagnoses. For example, children with trisomy 18 are frequently born with life-limiting birth defects that lead to death within hours to days after birth. However, some of these children survive for years. Parents faced with a fetal diagnosis of trisomy 18 may choose to terminate or carry the pregnancy depending on their perceptions of the disability these children develop. These techniques also provide access to fetal DNA that can be used for molecular diagnosis of specific gene defects. When unambiguous evidence is available correlating a specific gene mutation with disability, parents use this information to make decisions about the management of the pregnancy and the child. However, the ability to predict disability based exclusively on genetic information is limited due to the biologically complex interactions among gene mutations, environmental conditions, and genetic backgrounds (e.g., different ethnicities). For example, in Tay-Sachs disease, the neurodevelopmental progression of the disease is invariable and life limiting. In cystic fibrosis, while the diagnosis is equally precise, the disability outcome may be quite variable, with many affected individuals surviving and being productive well beyond age 30.

Preconceptual testing for predicting risk of disability in future children has also become increasingly commonplace. Using careful review of family histories of both parents and DNA testing for many different gene mutations, preconceptual testing attempts to reduce the risk of conceiving children who will be born with disability or become disabled. For example, if there is a strong family history of spina bifida or anencephaly, folic acid is recommended for prospective mothers prior to conception and for the first three months of the pregnancy. Epidemiologic studies have shown that this inexpensive nutritional supplement can reduce the risk of spina bifida and anencephaly by 75 percent. A more difficult problem with newer DNA technologies is the ability to predict the risk of disabling adult diseases (e.g., Alzheimer's disease, Parkinson's disease, or breast cancer) prior to conception. Available genetic testing technologies permit the identification of genetic predisposition, and risk can be reduced with strategies such as the selection of a genetically determined low-risk sperm or egg donor. In some conditions, pharmacologic, behavioral, or monitoring strategies can also be used to reduce the risk of disability.

Prenatal and preconceptual testing leaves parents with a conundrum that they must resolve based not only on test results but also on personal values, prior experiences, and, ultimately, hope. Parents use the input of medical providers, religious advisers, family members, financial consultants, the media, the Internet, and cultural expectations differently and selectively. Frequently, mothers and fathers differ in their perception of disability based on prenatal testing, and this difference will lead to conflict concerning consideration of pregnancy termination. Some parents will choose to rely on hope that their child will be less disabled than predicted, on hope that technology advancement will offer their child new strategies to reduce the impact of disability, or on faith that their child's disability will be a leavening factor in their lives. Other parents will choose to terminate a pregnancy rather than subject a child to multiple painful medical interventions without reasonable hope of the ability to overcome disability. While technology offers impressive anatomic and genetic precision for fetal evaluation, the biologic continuum of disability outcome associated with specific fetal anatomic and genetic findings, parental perceptions of disability risk, and the timing during pregnancy of the diagnosis all contribute to decisions that may alter significantly the population-based frequency of specific disabling conditions.

Prenatal and preconceptual testing provides a battery of powerful medical tools to predict risk of disability. Prenatal testing also provides an area for disability research to improve the capability of prenatal testing to predict disability, to identify strategies to understand mechanisms of disability, and to improve outcomes of specific disabilities. Such research is critical to ensure that parents optimize their children's futures rather than choose their future children. Prenatal testing must be viewed as information for parents that will help them decide wisely about their pregnancies, not simply make wise decisions prompted by medical providers. Given the significant contributions of genetic, environmental, anatomic, and infectious causes to risk and severity of disability and the substantial amount of prenatal testing provided to parents, the opportunity for improved understanding of disability has never been greater.

PRESSURE ULCER/SORE

Pressure ulcer/sore (PU) is a severe soft tissue breakdown most commonly reported in individuals confined to an unaltered body posture such as sitting in a wheelchair due to mobility impairment or staying in bed due to illness. Unrelieved pressure squeezes tiny blood vessels, which supply the skin with nutrients and oxygen. When skin is starved for too long, the tissue dies and a PU forms. The most frequently affected body locations are where soft tissue is overlying a bony prominence and where body weight is supported, such as the ischia and tailbone for sitting posture and the hip bone, back of the head, shoulder blades, spine, ankles, and heels for supine posture.

Persons with impaired nervous systems are not able to sense the need to change posture for pressure relief. Those in bed may get PU after as little as one to two hours, while those who sit in wheelchairs can get PU in even less time because the force on the skin is greater.

A number of factors predispose an individual to a high risk of PU. External factors include interface pressure, shear and friction, time remaining in a fixed posture, temperature, and humidity. Internal factors (i.e., sensory impairment, vascular disease, previous history of pressure damage, malnutrition, and dehydration) determine the level of loading tolerated by the tissue before damage occurs. In practical situations, these factors interact with each other, making an individual more vulnerable to PU formation. Increasing the time that pressure is applied without relief and the loss of muscle bulk and tone all make the tissues more liable to be damaged by a given level of pressure.

Among the above-mentioned factors, pressure, which is more concentrated over bony prominences, has been considered the single most important etiologic factor in PU formation. High pressure leads to impaired lymphatic circulation and hypoperfusion in the compressed tissue, resulting in an accumulation of toxic intracellular materials and a compromised blood flow, which further lead to tissue hypoxia, acidosis, interstitial hemorrhage, and cellular death. Both duration and intensity of pressure affect the amount of damage. Reestablished tissue perfusion after a long period of high loading will result in ischemic/reperfusion injury, which has been implicated in tissue damage. Studies have shown that muscle is highly susceptible to localized compression, eventually leading to tissue degeneration in the form of a deep PU that progresses toward the skin surface.

If pressure is relieved periodically, higher pressures can be tolerated for longer periods. This forms the basis of pressure relief regimens used in clinical practice, which involve regular turning, pushing up from the support surface, and the use of alternating pressure support systems. Short-term loading generally produces elastic deformation and rapid elastic recovery, whereas long-term loading results in marked creep and requires significant time for complete tissue recovery.

It is suggested that skin inspection be performed regularly and the frequency determined in response to changes in the individual's condition. Patients who are able and willing should be informed and educated about PU risk and prevention strategies.

PREVENTION

Prevention: (noun) 1. action that stops something from happening; e.g., prevention of crime. 2. something that acts to prevent something: an action or measure that makes it impossible or very difficult for somebody to do a certain thing, or for something to happen.

In everyday language, the word *prevention* refers to stopping something bad or unhealthy from happening. *Promoting* or *encouraging* are the antonyms—actions that facilitate or help something to happen. The two ends of the spectrum are generally associated with negative outcomes, on one hand (prevention), and positive outcomes, on the other (promotion).

PUBLIC HEALTH PREVENTION

The traditional public health meaning of prevention refers to efforts to eliminate a negative health condition. For example, infants are immunized early in life to prevent certain childhood diseases. An overwhelming percentage of infants in the United States are now immunized, and this is clearly a public health triumph—one that few would question. Traumatic injuries, another example, are associated with several negative health outcomes, ranging from long-term limitations in activities to death. Public health interventions to prevent injuries include seat belt protection, swimming and diving safety, and bicycle helmet programs. Research has shown that a large percentage of neural tube defects could be prevented if women of childbearing age take 400 micrograms of folic acid each day by a combination of nutrition, food fortification, or vitamin supplementation. Obesity is another significant problem in the U.S. population, resulting most often from a combination of poor diet and lack of physical activity. Major public health programs have been implemented to prevent each of these—childhood illness, traumatic injuries, birth defects, and obesity through population-based programs—through immunizations, automobile safety, folic acid consumption, and appropriate diet and exercise.

"Prevention," as it pertains to disability, is a more complicated topic. Disability, by public health definition, is a negative health outcome to be prevented. Disability prevention is perceived by many in the disability community, therefore, as an attempt to prevent the person with a disability from existing. This interpretation can create an adversarial relationship between public health and the disability community—one that need not be present.

Public health does not inherently disrespect the experience of disability. In the pursuit to improve the health of the public, in the context of the history of public health, it is easy for public health professionals to forget that no accumulation of public health activities will eliminate all conditions that limit people's activities. Public health can, therefore, inadvertently frame messages designed to help prevent behaviors associated with disabling conditions so that they disrespect the human experience of disability—and those living with a disabling condition. Those messages, for example, proclaim the need for safe driving while showing someone in a wheelchair. The explicit connection disrespects the experience of disability and draws an inappropriate connection. Disability, then, is presented as equated with illness. To the extent that public health messages, in an effort to prevent the conditions associated with disability, equate illness with disability, they unwittingly demean people living with a disability.

People with disabilities can also contribute to an adversarial perspective. In their pursuit for inclusion, people with disabilities may believe that public health prevention activities are implicitly (or explicitly) trying to prevent them from being. Seeing the emphasis placed on primary prevention often leads those with disabilities to conclude that all public health activities are focused on trying to keep them from existing. Past experience is not balanced with current reality—the reality that public health emphasis on improving the health of people with disabilities is growing. There is no inherent conflict between primary prevention interventions that try to reduce disabling conditions and maintaining and improving the health of individuals who experience disabilities. Those who experience disabling conditions often have fallen through the primary prevention net—that is, all the public health activities did not prevent them from experiencing the disabling condition. They live with disabilities related to birth defects, developmental disabilities, injuries, chronic illness, or aging.

Primary prevention messages are equally important for people with and without disabling conditions. This is a crucial perspective for public health professionals, as well as individuals with disabilities and their families. Individuals with disabling conditions are just as vulnerable to cancer or heart problems, for example, as the rest of the population. Screening for breast or prostate cancer or cardiovascular problems should be a part of clinical preventive services for all of the population. Cancer research comparing women with and without disabilities show that women with disabilities are diagnosed later and treated less intensively than the general population. Even though they might see medical professionals more often, people with disabilities often do not receive these preventive services as routinely as the general population.

Part of the problem might be that clinical preventive services (e.g., shots, prostate or breast cancer screenings) are usually completed in the offices of family physicians or internists. Many individuals with disabilities use specialists as their primary care physicians. The specialists may be less aware of, familiar with, and sensitive to the need for clinical preventive services.

In addition, there are times when public health messages should be tailored specifically to reach people with disabilities. This is particularly important when people with disabilities could be at particular risk. For example, people with mobility limitations are at greater risk for weight gain than the general population due to their often reduced physical activity and poor nutrition. In fact, national data suggest that people with disabilities report significantly more obesity and less physical activity than the population without disabilities. Few public health messages, however, focus on this at-risk group.

Prevention and the Environment

There is another kind of public health primary prevention activity relevant to people with disability—environmental factors. Dramatic improvements in the health of the public have come about as a result of environmental changes. It is clear, for example, that more improvement in the health of a population occurs because of clean water and hygienic waste removal than because of any other contributors. Improvement of the health of the public has often been intimately tied to such environmental improvements. Changes in environmental conditions have been estimated to account for an overwhelming percentage of decreased mortality during the first half of the twentieth century. That is, environmental improvements have been primarily responsible for the increase in lifespan from 45 years in 1900 to 72 years in the year 2000. Toxic air, water, or food can decrease quality and quantity of life for the population, including those with disabilities. In addition, however, environmental factors such as a lack of curb cuts, negative attitudes of society, and government policies can dramatically affect the health and well-being of people with disabilities.

PUBLIC HEALTH PREVENTION PROGRAMS

Programs to implement primary prevention activities associated with disability were officially begun at the U.S. Center for Disease Control and Prevention (CDC) in 1988. The program focused on disability prevention using the traditional public health model—identify the condition, generate interventions to control or prevent the conditions, identify those at risk for the condition, and intervene. This approach has been used universally by public health agencies to protect the health of the world. Unfortunately, emphasis on primary prevention of conditions associated with disability has been the major focus but is only a small part of public health's responsibility related to disability. Many conditions are not prevented from occurring despite the best public health effort. Children are born with sensory, physical, and cognitive problems. Throughout our lives, we may experience traumatic injuries anytime, and chronic illnesses develop for many individuals as they age. Vernon Houk, a public health physician and CDC leader, speaking to one of the early disability prevention meetings, suggested that "people with disabilities form the only minority group to which anyone may join at any time with no intention to do so." Prevention of conditions associated with disability is one, albeit important, set of public health activities. Public health also has responsibility to people who live with disabilities.

SECONDARY CONDITIONS

The term *secondary conditions* is relatively new to the lexicon of public health and disability studies. While the term has created some confusion—in part because it is new and in part because the definition continues to be refined—the distinctions it creates are essential to the lives of people with disabilities. "A secondary condition is *any* condition to which a person is more susceptible by virtue of having a primary condition" (Lollar 1999). The concept of secondary condition does not reflect its importance but rather its temporal quality—that is, a secondary condition occurs after a primary condition.

There are fundamental distinctions between comorbid conditions and secondary conditions. Often, the science of public health addresses individual conditions in terms of risk, prevention, and intervention, as if those experiences occurred in isolation. That is seldom the case, of course. In some situations, conditions occur as comorbid health conditions—that is, they are unrelated; there is no association. An older person with macular degeneration (an eye disease) might also have arthritis. There is essentially no relationship between these two conditions, although the combined effect may be significant in terms of mobility and quality of life. In other cases, one condition creates risk for another. A person with paralysis, for example, may be at risk for pressure sores. One follows the other. An important characteristic of a secondary condition is that it can be prevented. Prevention strategies to avoid pressure sores would include shifting weight, repositioning, or having a good seating system. Some secondary conditions are unique to people with disabilities, while some are not. For example, because of a disability and its consequent isolation, a person might become depressed. An individual without disabilities may be depressed as well, though the underlying causes may differ. Common secondary conditions include depression, chronic pain, joint and muscle pain, sleep disturbance, obesity, fatigue, contractures, and lack of conditioning.

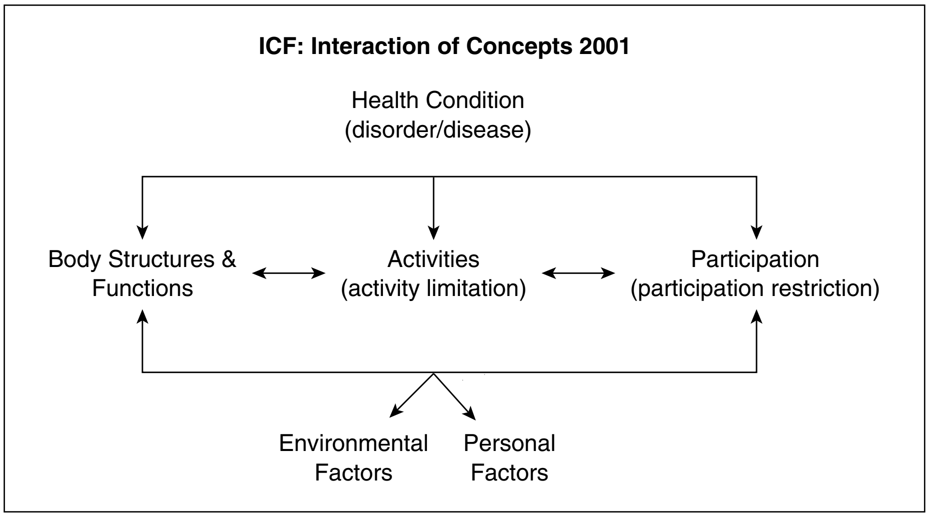

Figure 1 ICF: Interaction of Concepts 2001

The concept of secondary conditions, however, is now regarded as broader than associated impairments to include activity limitations and participation restrictions. Recently, the concept of secondary conditions has expanded: "Secondary conditions can create significant impediments to an individual at the level of *body system* dysfunction, *activity limitations* or *participation restrictions*" (Lollar 1999). This expanded notion of secondary conditions emerges from efforts over the past 25 years to reconceptualize the lived experience of disability. Until recently, the so-called medical model dominated how disability was described. The essential notion was that a problem at the body system level created inherent limitations in function—for example, the ability to pronate or supinate the hand. The medical model relies on an accurate diagnosis that allows problems to be "fixed." However, in disability, people's lives go on—"fixed" or not—and individuals generally demonstrate remarkable capacities to make do with what they have. The ability of individuals to deal with adverse circumstances and go on is mediated by many factors in addition to restoring function. One's financial resources, the kinds of activities one performs, and the supportive nature of the environment, as well as one's own resilience, may have more to do with quality of life and social participation than restoration of function. Thus, in recent years, scholars and advocates in disability have attempted to portray the multidimensional characteristics of disability as a way to understand how people carry out their lives or how they might be more successful in pursuing meaningful activities. This effort is described as a social model of disability.

This more dimensional portrayal of disability embraces the complex relationships of human experience and illustrates the potential impact of secondary conditions. The World Health Organization developed the *International Classification of Functioning, Disability, and Health* (*ICF*) as a companion to the *International Classification of Diseases* (*ICD*). The *ICF* creates a framework to "map" human experience. It is not designed to be used exclusively to model disability. The *ICF* creates a taxonomy to portray the relationship of human experience in related domains—body, person, and society. Health condition describes disease, injury, or disorder at the at the person level. Health conditions may result in changes of body structure and function. These can be described and measured; for example, macular degeneration occurs at the cellular structure of the macula, and its effect can be measured in altered acuity and central loss of visual field. Activities describe the things people do: walking, lifting, reading, driving, and preparing meals. And participation deals with the social roles that people carry out—going to school, working, voting, and having friends and relationships. The multiple arrows of Figure 1 illustrate the multidimensional characteristics of the concepts of the *ICF.*

For example, a disease or injury may create changes in body function and structure that, in turn, may or may not affect the performance of activities, which, in turn, may or may not affect social roles. In this model, the environment plays an important mediating role insofar as the environment can serve as either a barrier or a facilitator. An example helps to make these relationships substantially clearer. A person with macular degeneration (an eye disease) experiences changes in the structure of the macula. These changes can be measured in terms of visual acuity, that is, function. As a result of macular degeneration, then, a person may have difficulty reading print, driving a car, getting around in dimly lit environments, or recognizing faces at a distance. These are all activities. As a consequence of these activity limitations, a person with macular degeneration may be less inclined or less able to go out to dinner with friends. The print on the menu might be too small to read, steps could create hazards for falls, and an individual may not be able to get to the restaurant unless someone picks her or him up. These relationships are not inevitable or predictable. This model suggests multiple places where interventions may reside. For example, medical treatment may mitigate the effects of macular degeneration, low-vision services (technology) may improve function, and rehabilitation services might improve the performance of various activities (say, using a cane to detect steps). Moreover, the environment can have a major influence in reducing the negative outcomes of macular degeneration for the individual. For example, a robust transportation system would likely solve the problem of getting to the restaurant. Better light at the steps might improve safety and mobility, and a large-print menu might ease the difficulty and anxiety of ordering. Also, helpful and patient restaurant staff could make the entire outing more pleasant. In the *ICF,* the concept of environment has to do not so much with the built characteristics of the environment as with the environment as it is defined by social attitudes and public policy.

While the *ICF* allows us to map the course and dimensions of disability, the conceptual framework also helps to understand the role of secondary conditions in a complex system defined by our lives. The definition of a secondary condition emphasizes *any condition* that creates significant impediments to individuals at the level of body system dysfunction, activity limitations, or participation restrictions. Therefore, if we map potential secondary conditions against the *ICF* model, we can see that there may be secondary conditions at the body structure or function level (say, pressure sores or contractures), a secondary condition may occur at the activity level (e.g., personal care might be limited due to a fall), or secondary conditions can occur at the participation level if one is socially isolated or cannot get a job.

Consequently, the prevention of secondary conditions is embedded in more responsive clinical care. For example, physicians should routinely ask about weight, exercise, and pain among patients with disabilities, and broad health promotion activities should include or target people with disabilities in health messages. The prevention of secondary conditions may evolve from improved technology, for example, as wheelchair design and improved seating systems reduce contractures, pain, and skin abrasions. And secondary conditions related to social isolation and social roles (e.g., work) can be mediated by changes in the environment, as the built environment becomes more accessible, transportation systems more robust, and employers more welcoming.

—Donald J. Lollar and John Crews

PRIVATIZATION

Starting in the late 1970s and continuing today, there has been a worldwide movement by countries to privatize government-owned industries and state-provided services. Starting with Prime Minister Margaret Thatcher, the rightist governments in the United Kingdom and the United States (under President Ronald Reagan); labor governments in Scandinavia, New Zealand, and Australia; socialist governments in Spain and Mexico; and the governments in the countries of the former Soviet bloc have all implemented privatization programs. This unprecedented growth in privatization will likely have profound and long-term impacts on the type, cost, and quality of social and health care services that individuals with physical and mental disabilities receive.

Privatization (or liberalization, as it sometimes is called) has strong political, technical, strategic, and ideological dimensions. It has been proposed as a strategy to meet an almost limitless set of objectives, from shrinking the overall size of government, to raising funds and lowering taxes, to enhancing the technical efficiency of specific public-sector services. For some, privatization is an end in itself; for others, it is the means to other valued outcomes.

The privatization movement raises a number of important fundamental public policy questions that governments and citizens must address. These questions include the following: How large of a role should governments play in their nation’s economies? What are the basic realms and responsibilities of governments? What specific tasks should governments perform for their citizens? Which tasks are best performed by the private sector? What role should governments play in regulating functions best implemented by the private sector?

The term *privatization* first appeared in the business and management literature in the early 1970s. Economic and social theorist Peter Drucker is credited with inventing the word. Since it was coined, numerous definitions of privatization have been proposed. Some of them have been very broad and vague, while others have been very narrow and specific. All of the definitions, however, have two common elements: a movement away from the reliance on government agencies to provide goods and services and a movement toward the private sector and market forces.

Privatization can take on a myriad of forms. They include governments: contracting with organizations in the private sector to purchase goods and services; providing grants and subsidies to individuals and organizations to encourage them to provide needed items; charging consumers fees for the use of particular services; encouraging volunteerism so that charities and other organizations assume a larger portion of the social burden; encouraging self-help services by individuals and groups; granting franchises to private organizations to provide particular services within specific geographic areas; issuing vouchers to consumers, authorizing them to purchase specific goods and services from government-approved private-sector companies; totally withdrawing from the provision of existing services; selling assets, such as land holdings, to the private sector to generate revenue or to spur development; and deregulation, the weakening or total elimination of legislative rules and regulations governing certain private-sector industries.

In the United States, most privatization to date has occurred at the local and state levels of government. Much of it has been through increased contracting with private-sector companies to provide such services as trash collection, fire protection, public health laboratory services, and the operation of correctional facilities. Also, several cities and states have established school voucher programs enabling students in public schools to enroll in private charter schools. Recently, however, there have been a number of proposals to partially privatize the nation's Medicare and Social Security programs.

Outside of the United States, privatization has taken place mainly at the national level and primarily through the sale of assets and the withdrawal of services. Many countries have concentrated their privatization efforts in the areas of telecommunications, energy production, and health care and community services. For example, Sweden, the world's traditional exemplar of the welfare state, has privatized much of its health care system, selling many of its formerly state-owned hospitals to private corporations.

Views about privatization's virtues and pitfalls vary widely. In most cases, the views are fundamentally ideological and political in nature. Conservatives in general and businesses in particular tend to advance positive arguments, while liberals in general and labor unions in particular are strongly opposed to any form of privatization.

Proponents of the privatization of health care argue that it enhances individual choice, fosters innovation, and reduces inefficiencies. They state that selling off government-owned hospitals brings much-needed money into state, county, and regional coffers. And privatizing local clinics removes their operating costs from public budgets. Proponents argue that private companies, or groups of physicians, who purchase these medical facilities can run them more efficiently, increase patient access, and provide better quality care. They also indicate that privatization can "free up" scarce government resources to provide services for the poor, to the extent that those individuals who are willing and able to pay for health services seek care outside the public sector.

In sharp contrast, opponents of privatization argue that although some health care programs may have serious problems and need attention, privatization is not a general solution to them. Critics say that privatization erodes the very principles of universality and social equity in the delivery of health care services. It creates an inappropriate "multitiered" health care system where the provision of care is based on the ability to pay, rather than on need. Such a system decreases the access of underprivileged groups to care and ultimately worsens health outcomes. Also, important preventive care and community public health services such as immunizations, which are generally not profitable, tend to be neglected. Critics further point out that privatization interferes with real accountability to consumers. Last, they argue that privatization hurts health care workers because it threatens their job security, pay and benefits, working conditions, and career opportunities.

Despite the large number and types of privatization programs implemented in countries throughout the world, it is notoriously difficult to assess their impacts. There have been few evaluations of the programs in terms of their stated objectives. Even in crude terms such as the number of privatized firms, the proceeds of sales, or the share of gross domestic product coming from the private sector, it is very difficult to get hard data and an overall picture. Many of the privatization programs have been implemented haphazardly and often with little consistency across different regions of counties. Furthermore, because every industry is different and because countries have their own unique cultures and traditions, no two acts of privatization are ever identical.

The effects of privatization on health care services and patient outcomes are also very difficult to assess. In several countries, privatization appears to have adversely affected the health of its citizens. For example, in Russia, after the collapse of communism, many former state-owned hospitals and clinics were privatized. Some of these private for-profit facilities offer the latest medical technology and high-quality health care but, unfortunately, at prices that few Russians can afford. At the same time, state-owned facilities are critically short of money and medicine, equipment and buildings are crumbling, and physicians and nurses earn near-poverty wages. The decline of these facilities has resulted in a rise in Russia's overall mortality rate and a decrease in average life expectancy unparalleled among developed nations in recent peacetime history.

Rural health care in the People's Republic of China is reported to have suffered because of privatization. As China moved toward a free market system, an increasing number of state-owned clinics have contracted out services, and a large number of privately owned for-profit clinics have been established. The for-profit clinics charge their own rates, which many of China's hundreds of millions of poor rural citizens cannot afford. The private clinics have also led to the decline in community public health services. Because it is not profitable, clinic physicians no longer trek to distant villages to vaccinate children or to exhort women to obtain prenatal care.

The health care system of Mozambique also appears to have suffered from privatization. After independence, the Mozambique government established a national primary health care system. The system was so successful that the World Health Organization considered it a model for other African nations. To undertake various development projects, Mozambique borrowed funds from the World Bank, the International Monetary Fund, and other international financial institutions. These institutions pressured the nation to adopt free market policies. Many local private organizations and foreign agencies began providing health care services. As a result, Mozambique now has a two-tiered health system where poor people continue to seek care in an underfunded, understaffed, demoralized government-run system, while a small group of largely urban, rich elites receives services from private for-profit clinics.

In summary, it is not clear how individuals with physical and mental disabilities have fared under these and other privatization programs. It is clear, however, that all privatization efforts must address the special and unique social and health care service needs of those with disabilities. To protect them and other disadvantaged groups, governments must maintain a safety net of services that they alone can provide. Last, although empirical studies do not provide clear evidence on the costs and benefits of privatization, public perceptions and pressures to improve government efficiency and hold down taxes will keep proposed privatization programs on present and future government agendas.

PROFESSIONS

Professions are a special type of occupation. The sociological study of professions examines the social forms taken when work is organized and controlled by experts. According to Freidson (1970a, 1970b, 2001), work ("the practice of knowledge") is best understood by constructing three ideal types (or conceptualizations) of work: free market, bureaucratic, and professional. Each ideal type represents a different form of control over work: (1) the consumer/buyer (free market), (2) managerial (bureaucratic), and (3) occupational (professions). In turn, each has its own characteristic ideology: the market in consumerism (or what Freidson terms "popularity generalism"), the firm in managerialism ("elite generalism"), and professionalism in "specialization." Freidson also identifies five "critical contingencies for establishing and supporting professionalism": (1) an esoteric body of knowledge requiring "considerable discretion"; (2) control by the occupation over its own division of labor, (3) its own labor market, and (4) its own training program; and (5) "an ideology serving some transcendent value." For Freidson, a major sociological question of our time is the "status of professionalism in advanced industrial society." However, and as noted by Abbott (1988, 2001), the concept "profession" is distinctly Anglophone, with the term having no direct translation in either French or German. Professions trace their early roots to the guild system in England. The general form, as we know today, emerged in the early to mid-1800s in England and the United States, with medicine serving as the prototypical profession. Studies of the historical evolution of medicine as a profession generally point to a period of rapid growth from the mid-1800s into the early 1900s, followed by a period of consolidating professional powers and privileges that lasted until the late 1960s. Beginning in the 1970s, traditional professional groups came under sustained attack by rival occupational groups seeking their place under the professionalism sun, a growing consumer rights movement, increasing encroachment by the state, and the aforementioned arrival of a for-profit marketplace. Social theorists in the 1950s and 1960s envisioned a groundswell of professionalism that would neutralize the evils of political authoritarianism and capitalistic exploitation—a vision that has not materialized.

AN EVOLVING SOCIOLOGICAL INQUIRY

Analysis of professions has undergone its own evolution. Early works such as Carr-Saunders and Wilson (1933) adopted a functionalist approach to social analysis, an analytical framework that reached its zenith in the 1950s and 1960s with the theoretical writings of Talcott Parsons. In 1970, Eliot Freidson published two watershed volumes, *The Profession of Medicine: A Study in the Sociology of Applied Knowledge* and *Professional Dominance: The Social Structure of Medical Care.* Freidson sought to critique the functionalist emphasis and to explain the rise of professional dominance and autonomy—with allopathic medicine serving as Freidson's occupational template.

Works critical of the "professional dominance approach" quickly followed. Notable was work by Margali Larson (1977), Paul Starr (1982), and Andrew Abbott (1988). Alternative theoretical frameworks included "deprofessionalization" (Haug 1973), "proletarianization" (McKinlay and Arches 1985), and "corporatization" (Light and Levine 1988). A vigorous decade-long debate between Freidson and his critics ensued, as insights into the nature of professions were extended to occupational groups other than medicine and to a more nuanced cross-national understanding of professional work (Hafferty and McKinlay 1993). Most recently, Light (2000) has extended his earlier work on corporatization into a more robust theory of "countervailing powers."

THE "REDISCOVERY" OF PROFESSIONALISM BY ORGANIZED MEDICINE

The failure of the Clinton Health Plan in 1994 occurred in the midst of what would be the United States' longest running bull (stock) market, thereby unleashing a deluge of investor dollars into a number of new corporations and corporate sectors—health care being one. What had once been defined almost solely by the pharmaceutical industry quickly came to include new market sectors such as “health care services,” “physician practice plans,” biotechnology, and, most recently, “genomics”—as purchasers and providers alike quickly staked out territory in a new “medical marketplace” (itself a new way of thinking and talking about medicine). The arrival of “managed care” and the development of varied strategies to alter both physician and patient behaviors were greeted with fear and distrust by organized medicine. Editorials, commentaries, and articles began to appear in authoritative medical journals (e.g., *JAMA, New England Journal of Medicine, BMJ*) about the “inherent conflict” between medicine’s “culture of professionalism” and the marketplace’s “culture of commercialism” and medicine’s loss of public trust. In turn, a number of medical organizations ranging from trade groups (e.g., Association of American Medical Colleges) to specialty societies (American Board of Internal Medicine) to accrediting agencies (American Council of Graduate Medical Education) began to call for a rededication to the principles of professionalism, for a more explicit presence of professionalism in medical education, and for the development of licensure and accreditation standards for professionalism. Similar efforts appeared in England and Canada.

MEDICINE AND THE "NEW PROFESSIONALISM"

This mingling of medicine and Wall Street, along with other social changes, brought about another call to professional arms, this one for a “new professionalism” or for a “reformulation” of old professional ideals. Traditional professional values or organizational forms such as a “autonomy,” “monopoly,” “hegemony,” and “hierarchy” were deemed “lacking” and/or “inappropriate” in a “new medical era.” Instead, the physician and patient were being cast as a “partnership of equals.”

MEDICINE AND THE SHIFT FROM IMPAIRMENT TO DISABILITY

The evolution of disability as a social form follows a somewhat similar path to that of professions and the sociological analysis of expert work. The growth of medicine as a scientific enterprise was both a cause and a consequence of a broadly based effort to “objectify” disease and to extend the influence of a distinctly biophysiologic account of “normal” and “patho” physiology. Behaviors and/or attributes that had been seen as personal shortcomings and/or moral weaknesses became markers of disease, a process sociologists refer to as “medicalization.” This increasing encroachment of medicine over domains of social life was not without detractors (Illich 1976). Nor were they without negative consequences, as advances in medical science seemed to be doggedly shadowed by the rise of treatment side effects, iatrogenic disease, and an appalling rate of fatal medical errors. Organized medicine, operating within an insular cocoon of elitism and arrogance, rebuffed criticisms. Earlier promises to place the patient’s welfare ahead of its own (e.g., altruism) slowly morphed into a less stringent promise that medicine would act in the best interests of the patient (paternalism). Organized medicine had become less responsive to the needs and concerns of patients.

A FUNDAMENTAL TENSION BETWEEN PROFESSIONALISM AND DISABILITY

The emergence of “disability” as a unique social form, distinct from that of “impairment,” reflects the emergence of a “social” versus a “medical model” of disability. This growing recognition of the barriers faced by people with physical and/or cognitive conditions was not defined solely by pathophysiology or rooted within the individual but could (and did) involve elements of social organization. This recognition, however, with its underlying recognition of a form of expertise rooted within the lived experience of disability, stands in conflict with professionalism—and not just “medicine’s version” (grounded in scientific expertise) but sociology’s as well (with its focus on “expert work”). Of the two, the conflict between the disability and medical professionalism is more stark. Sociological professionalism, on the other hand, is not so much “antidisability” as it is likely to view disability as part of a broader consumer rights movement than as a countervailing example of expertise grounded in knowledge.

Recent calls for a "patient-centered" medicine rooted in egalitarian notions of a "partnership among equals" have served to heighten this tension between traditional medical authority (e.g., the physician as expert—the patient as the object of that expertise) and the physician-patient relationship as a partnership of authoritative equals. The rise of genomics and the search for the "root causes" of disease also stand to re-excite tensions between the individual-medical and the social-discriminatory models of disability. While individual physicians may profess or "play at" partnering, the prevailing belief system within medicine is that medicine believes itself to be a "culture of no culture" (Taylor 2003) and therefore a domain where knowledge is neither relative nor culturally determined but rather exists as "fact" and therefore outside the relativizing presence of time, place, or social arrangement/forms. This cult of science, with its ideology of "objectivity," is not so much disdainful of the lived experience of patients with disabilities as it is truly uncomprehending about how "subjective experience" can be anything more than a source of distortion and bias. All of this is taking place within an occupational arena (medicine) that itself is currently undergoing a fundamental value shift via the "evidence-based medicine" movement. In this latest iteration of scientific objectivity, "truth" is to be based on "evidence" *rather than* "experience," whether that experience is the clinical type of practitioners or the "lived" expertise of patients.

The identification of disability as residing in social arrangements and structures (as opposed to individuals) also allows medicine to disavow expertise and authority in this later arena and thereby delegate "those problems" to other health care or social service workers, all the while maintaining occupational control over what medicine considers to be the defining issue—physiologic or cognitive impairment. While any such unbundling may invite other types of "experts" into the fray, it does not, necessarily, acknowledge patients as an *alternative and legitimate source of expertise.* As noted above, the sociological definition of professionalism stresses "esoteric knowledge" and "considerable discretion" with respect to its work. This stands at odds with the notion of physician and patient as equal partners or, better still, "equal experts." Patients may constitute competing sources of authority—"the market" for individuals with disabilities (as consumers) and professionalism for physicians—but this does not elevate experience to expertise.

However, as Western industrialized nations face the tsunami of an aging population, so will medicine and sociology face the conjoint social fact that age is more than a biological marker and that lived experience may well come to represent a new type of social authority.

—Frederic W. Hafferty

▣ PROGRESSIVE ERA WOMEN IN SPECIAL EDUCATION

While special education has taken significant advances in recent decades, throughout the world, its history did not begin in the 1960s. Generations earlier, reformers, often women, were beginning to establish the underpinnings of pedagogical and therapeutic approaches to children whose disabilities seemed to require alternative means of education, as well as the bureaucratic and professional cultures that have developed to provide those alternatives. These women worked in various national contexts, from a wide array of motives and backgrounds; they shared an era of innovation and unprecedented opportunity for women's participation in policy making and the development of theory.

The numbers of women activists who took a role in Progressive-era beginnings of special education are impressive and may be explained by several factors. Reformers in the Progressive era were often especially drawn to the problems of children in cities, immigrant children, and other young people in apparent crisis. Through the settlement movement and similar ventures, reform-minded women's groups sought reforms that some term "maternalist" because they imposed middle-class notions of femininity, hygiene, and domestic relations on the working-class objects of their charity. While many of these reforms seem uncontroversial today—child labor regulation, milk safety, kindergartens, urban playgrounds, and parks—others cast grave suspicions on families that could not easily conform to the domestic ideals proposed. And among the latter were measures to identify and segregate children with special educational needs, especially those associated with eugenic "defect."

Meanwhile, newly opened opportunities in medicine, education, government, and law gave some individual women professional credentials and expertise for establishing programs. Women working in the public schools as teachers and administrators saw the need for separate classes and methods for educating "misfit" students; women with medical training working in such positions as health inspectors, home visiting nurses, and clinic doctors saw the children unserved by public schools on account of their disabilities and the ways they might be otherwise educated. As the field of special education was new, it held great potential as a niche where professional women might gain positions of significant authority, without encountering resistant, entrenched networks. In addition, the specialties of pediatric medicine, public health nursing, and eugenics research were unusually accepting of women's expertise, with the added assumption that any endeavor that involved children or health appealed to a "natural" talent inherent in the female sex.

Among the many women whose names appear in the era's history of special education, only a few can be mentioned here. Italian doctor Maria Montessori (1870–1952) is best known today as a pioneer in early childhood education, but she derived many of her theories during her stint as director of the State Orthophrenic School in Rome, where she performed direct teaching with "feebleminded" children as well as developing a teacher training program. In London, Mary Ward (1851–1920) was a novelist from a literary family when she became involved in philanthropy, founding the Passmore Edwards Settlement (now the Mary Ward Centre); among its offerings, beginning in 1898, was an innovative model day school for children with disabilities. A year after the English school opened, Elizabeth Farrell began teaching an ungraded class of boys in the New York City public schools, using a self-developed curriculum that emphasized individualized, practical skill building. Farrell, who would eventually found the Council for Exceptional Children, was part of a cluster of socially active women centered around public health nurse Lillian Wald (1867–1940), who founded the Henry Street Settlement and mentored Lina Rogers (the first public school nurse in the United States) and Margaret Sanger (the birth control activist). Meanwhile in Providence, Rhode Island, two medical doctors, Mary S. Packard and Ellen Stone, conducted a summer camp in 1907 for children with tuberculosis, which would develop into school-year programming in specialized classrooms to serve students with special health needs. These stories must stand for those of many other women in the early twentieth-century history of special education.

PSYCHIATRIC DISORDERS

Psychiatric disorders are estimated to affect 20 percent of the adult population in America in any given year. Although less well developed for children, epidemiological studies estimate an annual prevalence rate of 20 percent for this population also. With more than 40 million persons affected annually by mental illness in the United States, it is likely that very few individuals have not had contact with a person with a psychiatric disorder. Psychiatric disorders exist along a spectrum from the very mild, with little or no evidence of disability, to the very severe, with profound disruptions in all areas of functioning, leading to severe, disabling consequences.

Based on functional impairment, it is estimated that 9 percent of the adult population has severe mental disorders. Prevalence rates in childhood are not predictive of adult prevalence rates. Many children with psychiatric disorders will recover from their disorders. Many adults with psychiatric disorders have their initial onset as young adults without a prior premorbid psychiatric disorder in childhood. Although prevalence rates in adult and child populations approximate each other, the numbers are not in and of themselves predictive of how psychiatric disorders impair or disable over the life course of an individual within a population as the correlation between symptoms and disability, while positive, remains weak. Some individuals can function well with severe symptoms, and others are genuinely disabled with few symptoms.

It is estimated that approximately 20 million adults in the United States have psychiatric impairment. Of this number, 4.5 million adults have persistent mental disorders that, by virtue of the severity of their symptoms, significantly disrupt or impair their ability to carry out activities of daily living (ADLs). ADLs include maintenance of personal care and hygiene, maintenance of school or job tasks, maintenance of household duties and responsibilities, and maintenance of interpersonal relationships. When these functions are disrupted by a psychiatric disorder, an individual is said to have a psychiatric disability. By understanding and measuring disruptions in ADLs, the extent of the disability can be measured quantitatively and qualitatively.

It is well documented that individuals with psychiatric disabilities manifest limitations in everyday functioning. In interpersonal situations, social cues are misinterpreted, yielding inappropriate responses to social situations. Minor stressors can lead to catastrophic emotional responses. Individuals can experience poor concentration, poor memory, lack of initiative, lack of affective expression, and indifference to socially appropriate expectations. These symptoms place the individual with a mental illness at a disadvantage in a society where cognitive and interpersonal skills are highly valued. In developing and agricultural societies, the World Health Organization (WHO) has shown that individuals can enjoy higher functioning in the presence of more severe psychiatric illness.

The World Health Organization's *International Classification of Impairments, Disabilities and Handicaps* has stated that psychiatric disability is a predictable consequence of having chronic severe mental illness. With disability, there are always quantifiable restrictions and lack or loss of the ability to perform specific roles and tasks.

PSYCHIATRIC DISORDERS

The fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-IV*) is the official diagnostic manual used in the United States for diagnosing psychiatric disorders. The content of the DSM-IV is exhaustive and far exceeds what can be covered in this review. It is an excellent reference text, comprehensive in its scope and readily available to anyone seeking a comprehensive text describing diagnostic criteria used to diagnose all psychiatric disorders.

Disorders that occur with the greatest prevalence and are likely to be associated with disability are the anxiety disorders, mood disorders, schizophrenias, and substance abuse disorders. The *DSM-IV* provides a comprehensive listing of diagnostic symptoms for each disorder listed.

As a group, anxiety disorders represent the most common psychiatric disorders. Symptoms include a subjective feeling of nervousness or fear in conjunction with specific physical symptoms. Physical symptoms include heart palpitations, shortness of breath, sweating, muscle tension, sleep disturbance, fatigue, urinary frequency, diarrhea, sensation of having a lump in the throat, and dilated pupils. These symptoms typically manifest themselves when an individual comes into contact with a specific object or situation. Persons with anxiety disorders frequently report avoidance as a means of symptom management. Although not fully understood, it is believed that this category of psychiatric disorders is caused by a dysregulation of the brain chemicals norepinephrine, serotonin, and gamma amino butyric acid (GABA).

Generalized Anxiety Disorder (GAD). Excessive worry and anxiety in addition to some of the physical symptoms listed previously characterize this disorder. The anxiety, worry, or physical symptoms are severe enough to cause impairment or distress in the individual's ability to carry out social or occupational functions.

Panic Disorder. Individuals with this disorder frequently report a sudden feeling of impending disaster or doom. Patients frequently report symptoms that resemble those reported by heart attack victims. These include but are not limited to palpitations, shortness of breath, dizziness, sweating, lump in throat, numbness or tingling in fingers or around the mouth, and chest tightness. Symptoms generally peak within 10 minutes. Chronic symptoms can lead to significant impairment in functioning as the individual attempts to avoid those situations psychologically linked to the panic attacks' occurrence.

Specific Phobias. This group of disorders is characterized by excessive fear of specific objects (simple phobia), situations that expose the person to the possibility of judgment or ridicule (social phobia), or situations where escape may be perceived as difficult by the patient (agoraphobia). This group of disorders constitutes the most common of all psychiatric disorders according to epidemiological catchment area (ECA) data. The avoidance or distress that occurs as a consequence of phobia can be debilitating.

Obsessive-Compulsive Disorder (OCD). This disorder is characterized by persistent and recurrent thoughts, impulses, or images that are experienced as unwanted or intrusive (obsessions). The person attempts to alleviate these thoughts and the associated anxiety by engaging in repetitive nonsensical behavioral rituals (compulsions) such as avoiding stepping on cracks in the sidewalk or excessive hand washing. Obsessions can impair concentration and thus lead to disability. Compulsions likewise can lead to incapacitating disability as the person's time is consumed by the performance of the ritualized behaviors.

Posttraumatic Stress Disorder (PTSD). This disorder typically follows exposure to a traumatic event that is life threatening, leading the person to experience intense fear, helplessness, or threat of losing one's physical integrity. The traumatic event is then reexperienced in a manner that is intrusive, occurring as flashbacks or recurrent dreams. Avoidance of events or places that may trigger memories, increased arousal (decreased need for sleep), or enhanced startle response are additional associated features. In its most severe forms, this disorder causes significant disability.

MOOD DISORDERS

This category of psychiatric disorders includes those disorders that have a disturbance of mood as the primary symptom. The mood may appear as excessively sad, as seen in depression, or as excessively happy, irritable, or grandiose, as seen in mania. When a patient experiences episodes of depression alternating with a single or multiple episodes of mania, the individual is said to have bipolar disorder. Prevalences for major depression and bipolar disorder in the general population are 4.4 percent and 1.2 percent, respectively.

The etiology of mood disorders is hypothesized to be related to a dysregulation of neurochemicals in the brain (norepinephrine and serotonin).

Major Depression. This condition refers to a mood disorder in which the patient experiences sadness, loss of interest, or loss of pleasure daily for a period of two weeks. During this period, the patient might experience crying spells, decreased or increased need for sleep, decreased or increased appetite, agitation, loss of energy, loss of sex drive, and thoughts of death. Untreated, this disorder can lead to significant time away from work and an inability to carry out ADLs, as well as result in suicidal behavior or completed suicides.

Manic Depression or Bipolar Illness. This disorder is characterized by recurrent episodes of depression alternating with mania. The depressive episodes are synonymous with the major depressive episodes described previously. Mania is characterized by persistent elevated expansive or irritable mood lasting at least one week or shorter if hospitalization is required. Other accompanying symptoms include inflated self-esteem, decreased sleep, engagement in high-risk behaviors, increased speech production, and goal-directed behavior. A variant of this disorder (Bipolar I), in which symptoms of mania are decreased in their intensity, is known as Bipolar II mood disorder. Both disorders can lead to significant disability if treatment is not accessed.

Dysthymia. This is a disorder that is experienced by the affected person as a subjective experience of a continuous low-grade form of sad mood lasting a minimum of two years but not meeting threshold criteria for the diagnosis of major depression.

Cyclothymia. This disorder is an attenuated form of bipolar illness. In this disorder, episodes of mania alternate with episodes of subsyndromal depression. Although less severe than Bipolar I, it is associated with significant disruption of social functioning and can lead to disability if undiagnosed and untreated.

SCHIZOPHRENIAS

This group of disorders includes a spectrum of disorders characterized by the presence of "psychotic" symptoms. The term *psychosis* is generally used to indicate a state of impaired reality testing, leading to severe impairment of social, personal, and occupational functioning. Whether schizophrenia is a single disorder or a series of disorders occurring along a continuum is unresolved. This disorder has a prevalence of 1 to 2 percent in the general population. It is characterized by symptoms that are referred to as "positive" and "negative." Positive symptoms include hallucinations, delusions, and bizarre associations. Negative symptoms include decreased motivation, decreased attention, and social isolation.

Although the cause of the disorder is unclear, it is believed to be due to a disruption of function of a main neurochemical known as dopamine. Dopamine interacting with serotonin, GABA, glutamate, and acetylcholine in such ways as to enhance the effects of dopamine on neuroreceptors appears to play prominent role in the etiology of this group of disorders. Environmental and genetic cofactors appear to play a significant role in determining who gets these disorders. Of all psychiatric disorders, the schizophrenias carry the highest level of morbidity and psychiatric disability as a group.

SUBSTANCE ABUSE DISORDERS

These disorders represent some of the most prevalent and psychiatrically disabling disorders known. Alcohol abuse and dependency affect 15 to 17 percent of the general adult population. Alcohol or another drug of abuse is involved in 50 percent of homicides and 33 percent of suicides recorded in the United States.

Substance abuse or dependency is typically seen as a comorbid condition in all of the major psychiatric diagnostic groups. Schizophrenia, bipolar disorder, and anxiety disorders are all associated with significant levels of comorbid substance abuse or dependency. Substance abuse contributes to the morbidity of psychiatric disorders by precipitating psychiatric disorders directly (e.g., substance-induced mood or anxiety disorders) or by exacerbating a pre-existing disorder in an individual. Failure to diagnose and treat substance abuse in patients results in treatment noncompliance, treatment failure, overutilization of mental health resources due to recidivism, and increased rates of suicide.

Typical substances abused by today's adolescent and adult populations include alcohol, cocaine, marijuana, ecstasy, heroin, and PCP. All have addictive potential, but addiction is not a prerequisite to these substances having a profound impact on the course and outcome of psychiatric disorders.

SUMMARY

When thinking about psychiatric disorders associated with disability, one should keep in mind specific characteristics held in common by all that can lead to functional impairment.

Many psychiatric disorders, when severe (as defined by the presence of psychotic symptoms), have symptoms such as hallucinations, delusions, disordered thoughts, poor concentration, and loss of reality testing. These symptoms can interfere with the patient's ability to make decisions, process information, problem solve, or follow instructions. Occurring singularly or in combination, it is not a stretch to ascertain that impaired functioning can be a consequence.

The life course of a psychiatric disorder may reveal the presence of intermittent or constant symptoms. Psychiatric symptoms can result in a person experiencing low self-esteem, loss of confidence, emotional fragility, and feelings of helplessness and hopelessness. The consequence of these symptoms can be a lack of initiative, lack of motivation, loss of confidence, and lack of pleasure, which can impair one's ability to perform tasks, function in required roles, or carry out the daily activities of living.

Because psychiatric disorders typically have their onset for many in the most productive years of life, many individuals experience interruptions in social and interpersonal development that lead to impaired social functioning, interpersonal dependency, and arrested achievement.

Many individuals with psychiatric disorders are in a double bind. On one hand, they have an illness that can profoundly impair them emotionally, interpersonally, and professionally. On the other hand, the stigma attached to mental illness prevents some individuals from accessing mental health systems where help is available that could reduce the disabling consequences of living with a psychiatric disorder.

It is not unusual for individuals with psychiatric disorders to have lower socioeconomic status, to experience social isolation and rejection, to have lowered expectations from family and friends, to have increased rates of substance abuse, or to have increased levels of homelessness and crime victimization. Clearly, morbidity associated with mental illness is significant and requires the collective efforts of our nation's health care system to find treatment strategies that are accessible, affordable, and tolerable, whether pharmacologically, psychotherapeutically, or psychosocially based.

Psychiatric disorders are treatable, and the cost in both financial and personal terms of not treating them can be monumental. It is estimated that more than $100 billion in direct (associated with treating psychiatric disorder) and indirect costs (associated with loss of productivity and other sequelae of being mentally ill) is spent yearly. Not treating these disorders can lead to major disruptions in interpersonal relationships, diminished socialization, loss of educational opportunity, and failure to maximally participate in society and make significant contributions.

Activities and interventions directed at reducing the potential for disability in at-risk individuals need to focus on those factors that can reduce the effects of psychiatric disorders as they are diagnosed or reduce the long-term effects of the disorders once an illness manifests itself. Thus, activities that focus on prevention by educating at-risk populations to seek mental health services can be effective. Education of the public at large that reduces stereotyping and stigmatization of those with psychiatric disorders can further enhance reduction of potentially disabling symptoms of mental illness by encouraging and promoting early diagnosis and treatment. It is not enough for those with mental illnesses to simply avail themselves to treatment; they must also comply with recommendations made by physicians and other mental health care workers if treatment is to be successful. Reduced morbidity or disability defines success in this case.

Many communities have underdeveloped mental health networks that can lead to reduced availability of mental health services. Inadequate funding, lack of qualified mental health professionals, and absent rehabilitation services can contribute to the disabling effects of mental disorders over time. Improved awareness by citizenry may lead to improved availability as citizens lobby their government officials for increased expenditures for the creation of more mental health service networks.

Even when available, mental health services are often underused. Access issues related to affordability of mental services can create opportunities for disability. For the working poor and minority communities, lack of adequate insurance coverage can prevent individuals from gaining access to treatment, thus contributing to the potential for disability. Stigma associated with having a psychiatric illness may also negatively affect access to psychiatric services.

Providing improved ways of funding services and educating the public on the importance of accessing these services can reduce disability. Addressing mental health availability and access issues through increased funding and education in conjunction with efforts to make mental health services more sensitive to the specific cultural needs of those being serviced will likely improve utilization. Improved utilization of mental health services offers the best possibility for preventing and controlling the disabling effects of psychiatric disorders, thereby improving outcomes for many with these disorders.

PSYCHIATRIC SURVIVORS MOVEMENT

The psychiatric survivor movement consists of a loosely affiliated coalition of individuals who have used the psychiatric system and found it extremely lacking. Most members portray their experiences as harmful and disempowering and therefore have adopted the term *survivor* to indicate that fact. Reflecting a diversity that is characteristic of the nature of the movement, various factions may use different terminologies to describe themselves such as "ex-patients," "ex-psychiatric inmates," "consumers," "service users," and "psychiatrically labeled."

Because self-definition is a central theme within the survivor/user movement, it is accepted that participants will define themselves as appropriate, as opposed to having a medical authority "diagnose" their condition. Those who use terms such as *survivor* and *inmate* emphasize their militancy by taking up a decidedly antipsychiatric orientation, while those who prefer the term *consumer* may be less critical of psychiatry and more attentive to improving the quality of services. Even given these differences, a sense of the mental health system as broken and in need of repair infuses the whole movement. While the method and degree of repair may be somewhat controversial, the innate value of user input and control is an integral foundational belief for all factions.

A largely North American development of the late 1960s, the psychiatric survivors movement was heavily influenced by this era's emphasis on individual choice and civil rights. Its membership was collectively energized by negative experiences at the hands of the psychiatric system while incarcerated as patients; the survivor movement is rooted in self-advocacy. It is an important principle of the movement that practices that induce discrimination toward those labeled with a mental illness diagnosis must be changed so that a psychiatric diagnosis has no more impact on a patient's choices and rights than a diagnosis of arthritis or heart disease. Challenging their stigmatized status in society, the movement promotes the values of self-help and collective action while rejecting forced treatment of any kind. While it would be incorrect to characterize the survivor/user movement as antipsychiatric, it does negatively critique the dominant medical description of mental illness and demands a more holistic view of mental health disability or, as some survivors might say, "extra-ordinary mental experiences." As one pioneering survivor put it, "Because psychiatric ideology mystifies people's difficulties into 'illness' that only experts are thought capable of treating, we are all rendered a little less human" (Chamberlin 1990).

While there are overlaps in social and developmental histories, the relationship between the psychiatric survivors movement and the disability rights movement is a complex one. Kept separate by a theoretical and medical taxonomy applied to physical and mental impairments as if people were either "apples" or "oranges," interpretations of disability as different types of personal tragedies worked to draw attention away from shared situations and shared needs. In addition, some disabled people may have difficulty viewing psychiatric survivors as disabled because their impairment is not evident and may fluctuate. Alternatively, survivors may not consider themselves disabled because they reject the medicalization of their experiences.

STAGES OF DEVELOPMENT

Driven by their perception that the psychiatric system damaged its users, the psychiatric survivors movement began when clusters of ex-patients spontaneously gathered in small local venues. These early years were exciting but tiring times. Like other disabled people, psychiatric survivors were geographically and socially dispersed, suffering from economic hardships, accessibility issues, and stigmatizing social forces. Many people with psychiatric labels were still in state hospitals or on strong psychiatric medication. Promoting healing through consciousness raising, survivor groups worked to move themselves from the static position of victim/survivor to the active role of providing mutual support and advocacy. Common goals included fighting for patients' rights, eradicating stigma, ending economic and social discrimination, and creating peer-run support services. Out of these seemingly disconnected efforts, coalitions began to form, leading to regional associations in Oregon (Insane Liberation Front, 1970), Northern California (Network Against Psychiatric Assault, 1972), New York (Mental Patients' Liberation Project, 1971), and Massachusetts (Mental Patients Liberation Front, 1971). Early advocates such as Judi Chamberlin, Howie the Harp, Sally Zinman, Leonard Roy Frank, and Su and Dennis Budd staged civil disobedience actions, chaining themselves to the gates of psychiatric facilities and picketing American Psychiatric Association meetings.

Sponsored by a nonpatient professor and the New York City–based Mental Patients' Liberation Project, the first Conference on Human Rights and Psychiatric Oppression was held in 1973 at the University of Detroit. Fifty people from the United States and Canada, many working together for the first time, met to develop philosophical guidelines. True to the movement's core belief in self-advocacy and leadership, by 1976, the conference was limited to only patients and ex-patients.

The Madness Network News first went to press in 1972. Begun in San Francisco as a simple newsletter, it evolved into a newspaper that perpetuated and connected the growing survivor efforts in North America and throughout the world. *The Madness Network*

News existed solely on subscriptions and volunteer efforts yet became the voice of the ex-patients' movement, publishing a wide range of material that included personal experiences, art, and factual reporting. It ceased publication in 1986.

In the late 1970s, the federal government began to support the movement's efforts with small grants. The Community Support Program was developed within the National Institute of Mental Health to increase the involvement of users in the development of psychiatric services. Projects such as the "Alternatives" conference were begun with its assistance. The first national Alternatives conference was held in 1984 and has been held annually ever since. Offering workshops related to self-help and self-determination, the Alternatives conference is a great success, bringing together national and international leaders in the survivor/user movement with an annual attendance often exceeding 1,500.

Many of the early pioneers in the survivor/user movement were angry, promoting the complete abolishment of the psychiatric system. By 1980, some individuals were identifying themselves as "consumers" and had begun organizing self-help advocacy groups and promoting peer-run services. While still sharing many fundamental beliefs, consumer groups differed from earlier militant groups in that they preferred reform over abolishment, believing certain traditional services were necessary. Increasingly, these consumer groups have gained access to mental health policy-making and advisory committees. Many such groups have incorporated and now receive direct funding to provide peer-run services. These have proven to be effective, and the "consumer-driven" model is now generally accepted as key to the provision of mental health community services.

The California Network of Mental Health Clients (CNMHC) is an example of a mental health consumer organization. In 1987, it received funding from California's Protection & Advocacy agency. In 1989, CNMHC produced *The Well-Being Project: Mental Health Clients Speak for Themselves* (Campbell and Schraiber 1989), which included groundbreaking research on mental health services developed and implemented by mental health clients themselves. They went on to produce what some consider the movement's self-help bible, *Reaching Across: Mental Health Clients Helping Each Other* (Zinman, Harp, and Budd 1987). Today, user/survivor groups in California have a strong public position, and members sit on mental health–related planning boards and advisory councils throughout the state.

In more recent times, consumer/survivors have moved into paid jobs as "peer specialists" in their state-funded consumer organizations or as case managers in the mental health system itself. (*Prosumer* is a new term that attempts to capture the liminal position of those providing a service within the mental health system while receiving or having received services.) States may require boards that receive federal or state mental health funds to include consumer/survivors. Many states now have an Office of Consumer Affairs, which is headed by a psychiatrically labeled person. This infusion of survivor/user perspective can be attributed to the pioneering efforts of the psychiatric survivors movement, with its core belief in the importance of self-determination and the essential humanity of psychiatric system users.

The Bazelon Center for Mental Health Law was founded in 1972 by a group of committed lawyers and professionals in mental health and mental retardation who attempted to affect mental health service provision through individual and class action suits. In 1980, a group of these lawyers formed the National Association of Rights Protection and Advocacy (NARPA). One-third of NARPA's board of directors must identify themselves as current or former recipients of mental health care. Dedicated to promoting the preferred options of people who have been labeled mentally disabled, NARPA is committed to the abolishment of all forced treatment.

There are some disadvantages to this infusion of federal funds and the growing coalition with community mental health agencies. Many "consumer" groups have become dependent on state or federal money, while independent organizations have faded as volunteers are drawn to paid positions in publicly funded projects. A split has formed between "consumers" and "survivors," with the more radical groups, which relish their independence, warning against "sleeping with the enemy." While some say the independent psychiatric survivors movement is over, a few radical groups continue to directly challenge the fundamental principles of the psychiatric medical model. In 1988, leaders from several grassroots psychiatric survivor groups formed the Support Coalition International. Now an alliance of nearly 100 groups in 14 countries and known as the MindFreedom Support Coalition, it works to defend the rights of psychiatric survivors and to promote empowering treatment alternatives. The coalition has produced a journal since 1987. Originally known as the *Dendron News,* it advocates the global networking of "free minds."

HISTORICAL AND PHILOSOPHICAL ROOTS

Although the psychiatric survivors movement began in 1970, the earlier efforts and writings of former patients in the late nineteenth and early twentieth centuries challenged society's views on insanity and the use of asylums. A good example is the Alleged Lunatic's Friend Society, formed in England by ex-patients in 1847. Another example would be Mrs. Elizabeth Packard, who began publishing books and pamphlets that detailed her forced commitment in the Jacksonville (Illinois) Insane Asylum in 1868. Though she later founded the Anti-Insane Asylum Society, it never gathered significant public attention or support. At the same time, Elizabeth Stone worked in Massachusetts to change public opinion about mental states and to stop the incarceration of those unjustly labeled as insane.

With rapid and expansive industrialization, and as medical science became more elaborate and readily available, more people were given mental illness diagnoses while asylum populations mushroomed. At the dawn of the twentieth century, there were approximately 126,000 patients in 131 state hospitals, yet by 1940, there were 419,000 patients in 181 state hospitals. By the mid-1950s, New York state alone had 93,000 inpatients (Grob 1994). By 1943, with a U.S. patient-doctor ratio as strained as 277:1, a hospital could become more holding tank than medical treatment center. In 1908, Clifford Beers wrote *A Mind That Found Itself,* chronicling his own incarcerations in public asylums. Speaking out against mistreatment and neglect within the system, Beers founded the National Committee of Mental Hygiene, an organization that persists in its current incarnation as the National Mental Health Association.

Another landmark moment in the history of mental health advocacy occurred in 1961 with Erving Goffman's (1961) publication of *Asylums: Essays on the Social Situation of Mental Patients and Other Inmates.* Goffman emphasized that institutionalization created the role of "mental patient" and challenged the central importance of diagnosis in predicting outcome. Many psychiatric survivor leaders continue to credit Goffman's work as significant in expanding the understanding of how a dependency on long-term institutionalization creates an inherently disempowering system of psychiatric care.

By the 1940s, invasive procedures such as insulin coma therapy, Metrazol convulsive therapy, electroconvulsive therapy (ECT), and prefrontal lobotomy had become popular treatments in psychiatric hospitals. These often damaging treatments created a tide of criticism among users and some professionals. Ken Kesey depicted these modes of treatment in a decidedly negative fashion in his 1962 novel *One Flew Over the Cuckoo's Nest*—a book he claimed to have modeled on his actual experiences as an orderly at the San Mateo Mental Facility. The 1970s movie rendition won five Academy Awards and strongly influenced the general public's view of the psychiatric system while fueling the antipsychiatry and psychiatric survivors movements.

In the 1950s, in response to the excessive and violent intervention plans developed in the field of psychiatric care, a critical analysis of psychiatry also began from within, among a small number of practitioners. This insider critique, most literally, authorized the knowledge base for what is recognized today as "antipsychiatry." Charging that the medical model attended almost exclusively to pathology, antipsychiatry accused the field of leaving its patients powerless and isolated. Antipsychiatry practitioners stressed the value of difference, attempting to reconfigure normalcy and deviance.

In 1965, R. D. Laing, Aaron Esterson, David Cooper, and supporters founded the Philadelphia Association, devoted to the creation of therapeutic communities that valued agency and experience as integral components of psychosis. In his influential

The Politics of Experience (1961), Laing declared that normality entailed intrinsic hidden losses, while madness, if we allowed it to unfold instead of subordinating its power beneath an array of medication and psychiatric technology, harbored potential benefits. As an alternative to medical intervention, he recommended initiation and guidance.

Current participants in the antipsychiatry movement also often reference *The Myth of Mental Illness* by Thomas Szasz. Szasz's popular work, although originally published in 1961, is still controversial and continues to be used as a focal point for the antipsychiatry movement. Remaining active, Szasz consistently proposes that psychiatric patients are not ill but are instead social misfits who receive poor treatment and eventually find themselves placed improperly in asylums.

In sum, a more radical faction of the psychiatric survivors movement eventually affiliated with antipsychiatry—both share critiques of a profession and systematically expose historical violence that occurred under its purview. The more moderate consumer groups reject the complete denouncement of the medical model, feeling some portion of traditional treatment to be helpful. They would emphasize the fact that many who have been diagnosed with mental illness relate experiences of real and terrible suffering that both psychiatry and community treatment ultimately helped to alleviate.

—Pam Wheelock

PSYCHIATRY

Psychiatry is the field of medicine that is devoted to the scientific study of mental illness and the evidence-based treatment of mental disorders. A physician must complete a four-year course of postgraduate training after college and medical school to qualify as a psychiatrist. Psychiatry is a board-certified medical specialty. The concept of mental disorder currently used in American psychiatry is defined in the fourth edition of the *Diagnostic and Statistical Manual of Mental*

Disorders (*DSM-IV*). It states that a mental disorder is a clinically significant behavioral or psychological syndrome or pattern that occurs in an individual and that is associated with present distress, such as a painful symptom, or a disability, such as an impairment in one or more important areas of functioning or with a significantly increased risk of suffering death, pain, disability, or an important loss of freedom. The *DSM-IV* recognizes approximately 386 distinct mental disorders, each of which can be characterized by a set of criteria. Many other conditions may be included in subsequent editions of the *DSM* as their criteria become empirically validated. This current classification of mental disorders can be divided into broad categories that include dementias, cognitive disorders, mood disorders, anxiety disorders, dissociative disorders, personality disorders, eating disorders, sexual disorders, sleep disorders, developmental disorders, attention deficit disorders, and substance use disorders. Physicians who graduate from four-year residency training programs in psychiatry develop a high interrater reliability in assigning a *DSM-IV* diagnosis to a given patient and also in assigning a similar score on the Global Assessment of Function Scale (GAF), which provides a standard measure of symptom severity and degree of functional impairment for a given patient. This scale score, in conjunction with the multiaxial diagnostic system, provides a criterion-based approach to the measurement of progress of any therapy chosen for the treatment of the patient.

Mental disorders can be severely disabling and can be measured in terms of missed employment, accommodated employment, and full disability; approximately 20 percent of the U.S. population will experience some form of psychiatric disorder with related disability. By far, the disorders that account for the greatest impact on employability and workplace accidents are alcohol abuse and dependence, with a lifetime prevalence of 13.8 percent. Phobia, with a lifetime prevalence of 14.3 percent, and generalized anxiety disorder, with a lifetime prevalence of 8.5 percent, are also major factors in the workplace. Major depressive disorder and substance abuse and dependence have a prevalence of about 6.2 percent each. Other mental disorders that significantly account for psychiatric disability are dysthymic disorder, with a lifetime prevalence at 3.3 percent; obsessive-compulsive disorder, at 2.6 percent; antisocial personality, at 2.6 percent; panic disorder, at 1.6 percent; schizophrenia, at 1.5 percent; and bipolar disorder, at about 0.8 percent. A major concern for school-age children is attention deficit hyperactivity disorder, which has a prevalence rate of between 3 and 5 percent. Absences and suspensions from school have been positively affected by the widespread use of psychostimulants such as methylphenidate, which are effective in 70 to 80 percent of children with this disorder.

Historically, modern psychiatry grew out of the need for those who superintended the large asylums and mental hospitals (alienists) to develop common principles of care at the beginning of the nineteenth century. First in Europe, then North America, then spreading throughout the world, associations of asylum directors began to meet on a regular basis to discuss management and treatment issues and gradually assumed the name of psychiatrists (from *psyche* [mind] and *iatros* [physician]). At the beginning of the nineteenth century, psychiatry focused primarily on the social and psychological factors that were thought to underlie mental disorder such as immoral behavior, unrestrained ambition, or political and religious enthusiasm. This trend led to the formulation of moral therapy as the fundamental mode of treatment. During the second half of the nineteenth century, the pendulum shifted toward biological and brain-related causes of mental disorder, with the disease of neurosyphilis serving as the paradigm mental disorder. The two Nobel prizes specifically given for the treatment of mental disorders were awarded for fever therapy for neurosyphilis, developed by Wagner von-Jauregg, and psychosurgery for intractable psychosis, developed by Egaz Moniz during this era.

By the early twentieth century, the pendulum had shifted back in the direction of psychological causes of mental disorders with the success of the Austrian psychiatrist Sigmund Freud's psychoanalytic theories. This trend, also attributable to French psychiatrist Pierre Janet, culminated in the latter half of the twentieth century with an appreciation of the role of psychologically traumatic experiences, stemming from child abuse, adult trauma, and wartime experiences, as causes of mental disorder and led eventually to the addition of the category of posttraumatic stress disorder to the psychiatric nomenclature. However, with the advent of the psychopharmacology era in the 1950s, as well as the development of chlorpromazine as the first specifically antipsychotic medication and imipramine as the first specifically antidepressant medication, the pendulum began to swing back in the direction of brain-related research for mental illness. The research field of neuropsychopharmacology, which studies the mechanisms of action and brain circuits that underlie the efficacy of psychopharmaceuticals, paralleled the growing field of biological psychiatry, which studies brain circuitry thought to underlie the major mental disorders of schizophrenia, anxiety disorders, and bipolar mood disorder. By the 1990s, brain circuit and neural network models of mental disorders were proposed and tested both in animal studies and in human brain neuroimaging.

The success of the psychopharmacological revolution in psychiatry fueled the trend toward deinstitutionalization, which was further accelerated with the advent of the community mental health movement in the 1960s. In 1955, when chlorpromazine was introduced into the United States (following its introduction in Europe), there were approximately half a million psychiatric inpatients in public and private facilities. By the mid-1990s, that number had dropped to approximately 20,000. The treatment of three major mental disorders—schizophrenia, mood disorders, and anxiety disorders—all received a specialized psychopharmacology based on drug receptor theories unique to each area. Thus, for example, in the treatment of schizophrenia, high-potency phenothiazines such as fluphenazine and haloperidol replaced the first generation of antipsychotics because they were more potent blockers of dopamine. Since antipsychotic potency appeared to correlate with the degree the pharmaceutical blocked certain dopamine receptors in the brain, it was proposed that an excess of dopamine stimulation caused schizophrenia. These receptor theories have proven to be oversimplifications of the etiology of psychiatric disorders.

Despite these advances in the psychopharmacological area, the drawbacks of side effects such as tardive dyskinesia (embarrassing involuntary movements of lips and tongue), the lack of compliance due to cognitive slowing and restriction of affective tone, and treatment resistance led to a new wave of pharmacological innovation. Attempts at molecular engineering, to produce a safer congener of the pharmaceutical clozapine, which had superior efficacy and tolerability in the treatment of schizophrenia, produced a new family of atypical antipsychotics. These newer antipsychotics were better tolerated and had less potential of producing tardive dyskinesia. The additional features of blocking the 5HT2 serotonin receptor and the histamine receptors also proved effective in the treatment of the negative symptoms of schizophrenia not satisfactorily addressed in earlier generations of antipsychotic medications. The negative symptoms of schizophrenia, such as decreased intensity of pleasure or anhedonia, social isolation, affective flattening, poverty of speech and thought, inattentiveness, apathy, and negative behavior, are very disabling. How positive and negative symptoms link up over the natural course of schizophrenia and which brain circuits are involved in their production are questions currently under intensive psychiatric investigation in the area of schizophrenia research.

Comparable progress has been made in the psychopharmacology of mood disorders. Efforts to target the serotonin transmitter system in the brain and to avoid potential overdose lethality from a toxicity point of view led to the development of a generation of serotonin reuptake inhibitors (SSRIs) as well as norepinephrine reuptake inhibitors (SNRIs), both classes of which showed greater specificity in the enhancement of the synaptic concentration of these vital neuromodulators. Despite showing no greater efficacy in treating the fundamental symptoms of major depressive disorder than that possessed by their predecessors, the tricyclic antidepressants, the removal of histamine, and acetylcholine blocking characteristics liberated these newer psychopharmaceuticals from the bothersome side effects of excessive sedation, weight gain, and dryness of the mouth.

Diminution of these side effects was especially important in considering the use of different combinations of these medications, which is often necessary in severe cases of mental disorder and was virtually impossible with the older medications because of cardiac and other toxicities. Where the dosage of the primary drug has been optimized without full remission, then the choice of the second or third medications must be based on the likelihood of enhancing therapeutic effects while, at the same time, diminishing possible side effects and harmful drug-drug interactions. This problem is especially acute in the treatment of bipolar mood disorder, where a refractory patient may require more than one mood stabilizer, one or more antidepressants, and one or more antipsychotics. Added to this problem is the issue of comorbidity, both medical and psychiatric. The psychiatrist needs specialized expertise to effectively treat a patient who has multiple medical conditions requiring medical and psychiatric drugs with overlapping side effect profiles, if a patient has multiple psychiatric diagnoses requiring medications with overlapping side effect profiles, or if the patient is abusing an illicit substance while requiring a complex medical and psychiatric pharmacological regime. Also, if the patient is a member of a vulnerable age group at either end of the spectrum or belongs to a class of imperiled medical patients—for example, those with cancer, AIDS, or other chronic illness—then the choice of psychopharmaceutical agents becomes highly constrained by many physiological considerations. These problems have further reinforced the need for several psychiatric subspecialties such as child and adolescent psychiatry, consultation-liaison psychiatry, addictions psychiatry, neuropsychiatry, and geriatric psychiatry.

Despite these advances in psychopharmacology, psychiatrists are trained in several forms of psychotherapy. Psychotherapy is essential to psychiatry because even those mental disorders that respond reasonably well to psychopharmacological interventions require supportive psychotherapy as well as medication management to sustain patient compliance. No psychopharmaceutical is curative in the most complete sense, and all mental disorders have a psychological as well as a social aspect. The psychotherapies most used by psychiatrists include psychoanalysis, psychodynamic psychotherapy, cognitive therapy, cognitive-behavioral therapy, interpersonal psychotherapy, integrative psychotherapy, dialectical behavior therapy, psychoeducational therapy, group therapy, and brief dynamic psychotherapy. Certain mental disorders require mainly psychological and psychosocial treatment such as addictive disorders, eating disorders, personality disorders, dissociative disorders, developmental disorders, and the group of sexual disorders termed the *paraphilias.*

In diagnosing and treating the whole range of mental disorders, psychiatry, more than any other medical specialty, incurs an obligation to the greater society to protect those who might be injured as a result of a person acting under the influence of a mental disorder. This duty takes many forms depending on the mental health laws of the country or state in which the psychiatrist practices. The basic principles include involuntary hospitalization for endangerment to self or others, duty to warn a potential victim of a patient's homicidal tendency toward him or her, and duty to inform child protective services of probable child abuse. On the other side of the issue, the psychiatrist has a duty to protect a person who has allegedly committed a crime but who was acting under the influence of a mental disorder. In most criminal codes, this is an important mitigating factor. Because persons with mental disorders can be found in all walks of life and in all institutional settings, psychiatrists can be found in most large institutional concerns. Some of these subfields of psychiatry include forensic psychiatry, or psychiatrists who work primarily with the court system; prison psychiatry, an area of growing importance; military psychiatry, psychiatrists who handle issues of fitness for service; Veterans Administration psychiatry, psychiatrists who treat not only military posttraumatic stress disorder but also the entire spectrum of mental disorder; academic psychiatry, those charged with training the next generations of psychiatrists; and research psychiatry, psychiatrists who are funded by government or pharmaceutical companies to perform research on mental disorders.

PSYCHOLOGY

Although psychology did not emerge as a discipline centering on the study of disability, its development as a field dedicated to the understanding of the human mind and behavior has inevitably led to the involvement of psychology in work with individuals with disabilities. Initial psychological models of understanding disability borrowed from the medical paradigm, which emphasizes individual-level factors, pathology, and abnormality. Thus, persons with disability have traditionally been defined as those possessing deficient physical and mental characteristics. Definitions of disability have evolved as historical events such as the World Wars, the eugenics movement, and the disability rights movement both shaped and have been shaped by the involvement of psychology in disability issues. Contemporary models of working with disability are progressing toward a focus on the role of environment in disability issues and an understanding of disability in terms of "differently abled" rather than as deviant from "normal" human functioning. In addition, current psychological practice and research seek to apply an interdisciplinary approach in work with persons with disabilities as a means to address disability issues in their entirety. Overall, psychology's role in disability work continues to generate new roles and responsibilities for psychologists in the areas of research, practice, and training. Doubtlessly, psychology will continue to experience the mutual influence of the changing zeitgeist as it relates to disability issues.

EARLY CONTRIBUTIONS

Much of the work that established psychology as a valid science simultaneously produced both theory and research methods that have aided in psychology's study of disability. In the late 1800s, experimental psychologists Hermann Ebbinghaus, Wilhelm Wundt, and Gustav T. Fechner developed observational methods of measuring psychological processes, including rudimentary forms of learning and sensory experiences. Fechner's work directly contributed to modern sensory screening. In fact, Fechner's techniques of testing vision and hearing are the same that are used in contemporary screening tests. Also, the work of Ebbinghaus, Wundt, and Fechner provided a basis for developing measurement techniques that aid in identifying intellectual, emotional, and other forms of mental disability.

When psychology surfaced as a new field of study, evolutionary theory was guiding much of the intellectual thought of the late nineteenth and early twentieth centuries. Consequently, evolutionary theory had great implications for psychology, which led to a focus on heredity and genetic superiority. In 1865, Sir Francis Galton observed that children of geniuses were more likely to be geniuses themselves than were other children and asserted that through controlled breeding, the human race could develop into one with superior intelligence. In the early 1900s, the development of intelligence tests provided psychologists with an apparently valid method of assessing an individual's intellectual functioning, thereby creating a means of identifying those whose propagation was less desired. It was at this time in the United States that the use of intelligence tests and the eugenics movement in the United States were growing.

PSYCHOLOGICAL TESTING AND THE EUGENICS MOVEMENT

The work of Alfred Binet in France established a standardized measure of intelligence based on average mental levels for various age groups. With this measure, a person would receive a score and be placed in a category according to his or her intellectual functioning. Henry Goddard further developed these categorizations by labeling each group. He is responsible for the term *moron,* which referred to adults who had scored similarly to 8- to 12-year-old children. According to Goddard, this category of individuals, though not the most severely intellectually disabled, posed a threat to society as they were more likely to survive and procreate than were those of lower intellectual functioning. Goddard proposed control of these individuals through strict monitoring and institutionalization.

Goddard continued his assistance of the eugenics movement by developing group testing procedures for the army during World War I. Through such testing, men were identified as having high or low intellectual functioning and accordingly assigned to "appropriate" positions. Men with lower intellectual functioning were systematically assigned to the front lines, as their likely deaths were not considered as great a loss as the death of an individual with higher intellectual functioning.

Henry Goddard's interest in eugenics coincided with the increased institutionalization of people with a number of physical and mental disabilities. In addition, in 1907, sterilization laws, requiring the sterilization of people with disabilities, were put into effect. Beginning in 1910, these laws were challenged by discoveries in genetics. Yet the momentum of the eugenics movement was not immediately slowed, and people with disabilities continued to encounter the effects of the movement for years.

POSITIVE CONTRIBUTIONS OF PSYCHOLOGY

The early 1900s was not merely a time in which psychology provided a scientific basis for discrimination against people with disabilities. Psychological testing did produce a standardized method with which disability could be assessed accurately, one that has remained useful in contemporary psychological research and practice. Moreover, the physician Edouard Séguin, produced work with individuals with developmental disabilities and demonstrated the learning capacity of these individuals. Thus, he directly contributed to the development of special education programs and influenced developmental psychologists' work with persons with disabilities.

VOCATIONAL REHABILITATION

In 1912, neuropsychologist Shepard Ivory Franz developed a training program for persons with brain damage, conducting some of the first disability work that provided evidence of reversing the psychological effects of brain damage. Franz's work marked an important shift toward applied psychological work with people with disabilities. However, the major impetus for psychology's involvement in applied work came at the end of World War I, when veterans with disabilities acquired during the war returned to the United States. Increased need for rehabilitative services for veterans prompted the 1920 passage of the Vocational Rehabilitation Act to "provide for vocational rehabilitation of persons disabled in industry or otherwise and their return to civil employment." This legislation marked the formal beginning of federal support for vocational rehabilitation in the United States.

The early to mid-1900s continued to be an era in which psychologists' primary role in disability was rehabilitative, and with World War II, the need for vocational rehabilitation increased. In 1943, the

Vocational Rehabilitation Act was passed and expanded services to include persons with intellectual and psychiatric disabilities as well as those with physical and sensory disabilities. This act helped to establish additional rehabilitation settings, such as schools and mental institutions, in which psychologists provided services to people with disabilities. Over time, many psychologists became involved in the National Society for Crippled Children and Adults. Founded in 1919, this broad-based organization, now Easter Seals, provided psychologists an arena in which they could discuss disability issues with people with disabilities, family members, and other professionals. Psychology's role in disability grew and led to the formation of a special interest group during annual conferences held by the American Psychological Association (APA) in the 1950s. By 1956, a new division of APA was originated, which focused on rehabilitative work with persons with disabilities. Division 22 was originally named the National Council on the Psychological Aspects of Physical Disability and exists today as Rehabilitation Psychology.

THEORETICAL DEVELOPMENT

While rehabilitation work was at the center of psychologists' involvement with disability during the first half of the twentieth century, concurrent developments in psychological theory provided a framework to guide psychologists' understandings of individuals with disability. These theories are based in the medical model, are individually oriented, and often focus on the individual's emotional and/or behavioral characteristics. Clinical and counseling psychologists have used them extensively in their work with people with disabilities, and their influence continues today.

Among the most influential of these theories is Freud's psychoanalytic theory, which originated in 1910 and was widely known and accepted by the 1920s. The theory was developed to explain and aid in the treatment of neurosis and thus emphasized abnormality. Psychoanalytic theory has undergone much criticism and reform since its origination. Psychologists whose practice is guided by this framework have maintained a focus on treatment of abnormalities, which has influenced clinical and counseling services provided to people with disability. Specifically, persons with psychiatric and emotional disabilities are considered to possess a deficiency that must be treated, much as a physical illness is treated by a medical doctor. Currently, individual adjustment to a disability is largely understood as the stages of coming to terms with an object loss. Because of its focus on individual limitations, critics of the psychoanalytic framework claim that this approach overlooks other important aspects of the person and his or her disability, including both abilities and environmental issues. Conversely, psychoanalysis provides helpful insight into a person's needs and motives, which enables a greater understanding of the individual experience of the psychiatric and emotional disability.

Other theories that arose at this time have a similar focus on individual characteristics and seek to influence the behavioral and mental processes associated with disability. Edward Thorndike's law of effect and B. F. Skinner's operant learning theory provided a theoretical basis for applied behavioral analysis. Applied behavioral analysis focuses on the careful use of rewards to develop specific desirable behaviors. It has been used to help develop many behavioral abilities of people with a variety of disabilities, especially including autism and other intellectual and emotional disabilities. These abilities include speaking, relating to others, and reducing self-injurious acts such as head banging. Applied behavioral analysis has been criticized for its narrow focus on a limited number of behaviors, its occasional use of punishment as well as rewards, and its inability to develop skills that can be used across many situations. More recently, applied behavioral analysis has been used as part of larger interventions to help youth and adults with physical, learning, and other disabilities accomplish educational, employment, and independent living goals.

In mid-century, Albert Ellis's rational emotive therapy and Aaron Beck's cognitive therapy emerged and have been widely used in clinical and counseling practice. These methods aim to challenge unhealthy thoughts and beliefs that are thought to cause emotional or psychiatric disability. These approaches have also been used in work with individuals with other forms of disability, particularly when the individual's stance toward his or her disability is a primary issue. In this case, the psychologist understands that the person's difficulty with disability stems from an unhealthy manner of thinking about his or her disability. According to these approaches, when these beliefs are challenged and replaced with healthy beliefs, individuals with disabilities are more able to think constructively about their impairments. Similar to criticisms faced by psychoanalytic theory, these approaches have been criticized for failing to address possible environmental issues that may contribute to a person's disability.

By the end of the 1950s, psychology's role in service to individuals with disabilities was established as one that incorporated testing, counseling and psychotherapy, and rehabilitative work. As these services were established, the political context within the United States was marked by an increasing awareness of and struggle against discrimination and the injustices that it produced.

PSYCHOLOGY AND THE DISABILITY RIGHTS MOVEMENT

With the *Brown v. Board of Education* ruling of the U.S. Supreme Court in 1954, separate schools for African Americans were declared unconstitutional, and the modern civil rights movement began. By 1964, the Civil Rights Act was passed, outlawing discrimination on the basis of race and consequently providing a model for disability rights legislation. Four years later, the Architectural Barriers Act, requiring access to federally funded facilities, became the first disability rights legislation in the United States.

Meanwhile, psychology was evolving with the changing political climate. Psychologists from various areas of specialization were becoming involved in advocacy efforts for minority groups, which evidenced a shift from a focus on solely individual characteristics to greater attention to environmental factors in the understanding of individual experience. In addition, there was more interaction between psychologists and individuals from other disciplines, further influencing psychological methods of service. Specifically, psychologists began seeing a need to merge traditional research and practice with newly emerging advocacy roles. A number of psychologists organized such efforts by developing the Division of Community Psychology, Division 27 of the American Psychological Association. This division (now the Society for Community Research and Action), among others, helped legitimize the role of psychologists as advocates by establishing a mission that emphasized psychologists' responsibility for promoting social justice.

During the 1970s, the disability rights movement gained momentum and continued seeking legislative protection for the rights of people with disabilities. The movement centered on concepts of the inclusion and autonomy of people with disabilities. In 1972, the Center for Independent Living originated in Berkeley, California, launching a widespread independent living movement. Legislation, such as the Rehabilitation Act of 1973 and the Education for All Handicapped Children Act in 1975, promoted antidiscrimination efforts by explicitly specifying the rights of people and students with disabilities, which aided in developing future legislation.

Psychologists were able to support the disability rights movement during the 1970s and 1980s by supplying empirical evidence for the necessity of inclusion and autonomy as well as develop techniques that would facilitate such inclusion. For example, psychologists produced methods of skill instruction to people with disabilities to aid in community living. They also created assessment tools to measure individual skill levels for people with disabilities. They conducted research that provided evidence of the benefits to both individuals and society when persons with disabilities lived in the community versus in institutions. Furthermore, the 1970s saw some of the first conferences on the psychological aspects of disability, which aided psychologists in working together to develop and implement beneficial services to people with disabilities.

The work of psychologists and other disability right activists in the 1970s laid a foundation for work in the 1980s. Much of the legislation that was passed during this time built on prior legislation. While psychologists continued to be involved in disability rights, other changes that society experienced in the 1980s further influenced how psychologists were involved in disability work.

CONTEMPORARY PSYCHOLOGICAL PRACTICE AND THEORY

A primary influence on psychology's role in disability in the 1980s was the progress in medical technology. Such progress led to a greater number of individuals surviving serious head injuries and other medical conditions and thus a higher need for psychological services. Neuropsychologists who had been trained in the new medical technology became involved in rehabilitation services with these individuals. Today, neuropsychologists continue to contribute to services for people with disabilities by studying the connections between the brain and behavior for those with disabling conditions. Knowledge acquired through these studies enables other psychologists and individuals from other disciplines to provide more appropriate services to these individuals.

In addition to the contributions of neuropsychologists, other clinical and counseling psychologists sought to enhance their methods of serving individuals with disabilities. Specifically, psychologists, such as Beatrice Wright and Hanoch Livneh, developed theory and practice that would address specific disability issues. They drew first on existing individually focused theories of personality and counseling and applied them to their psychological rehabilitation approach to help persons with disabilities. Building on the ecological tradition of Roger Barker and the socially relevant social psychology of Kurt Lewin and Tamara Dembo, Wright later called attention to the importance of improving societal attitudes toward and acknowledging the strengths of people with disabilities. She encouraged rehabilitation professionals to recognize that people with disabilities are not passive and should be actively engaged as "comanagers" of their own rehabilitation and affirmed as in charge of their lives more generally. These approaches incorporated both psychological and social aspects of disability. They explained how the interaction of these components could either promote or inhibit a healthy adaptation to disability. Carol Gill has advanced a positive view of the development of disability identity that describes how individuals with disabilities constructively come to terms with their limitations and engage society based on their own strengths. These developments in practice and theory have guided contemporary methods of counseling and psychotherapy services with people with disabilities.

Psychological views of family members of individuals with disabilities have also evolved. The blaming models of mid-century, such as Bettelheim's "refrigerator mothers" who purportedly caused autism, have been replaced by the more positive views underlying the work of Tamar Heller, Marty Krauss, and others. They recognize the substantial care and support provided by mothers and other family members to children and adults with intellectual disabilities. They are documenting the stress, coping, satisfaction, and fulfillment that can be part of living with and supporting family members with disabilities.

From the area of social cognition, Ronnie Janoff-Bulman, Shelly Taylor, and others have examined the important role that assumptions may play in how individuals respond to major life changes such as becoming disabled. "Positive illusions" can be a coping resource, for example. They also show that major traumatic events can affect views of the world by challenging long-held assumptions such as "The world is a benevolent place" and "I am a worthy person." They suggest that highly emotional events are of great importance in shaping the thoughts persons have about the world.

In their now-classic article on the social model of disability, Michelle Fine and Adrienne Asch recommended questioning the social attitudes and arrangements that limit the opportunities of people with disabilities. They suggest viewing people with disabilities as a minority group whose disabilities are not a matter of shame but a reality to address and who can contribute meaningfully and valuably when given equal access to education and employment and independent living. In that spirit, psychologists have also continued to work as researchers and advocates. In 1990, the U.S. Congress passed the Americans with Disabilities Act (ADA), which provides greater legal protection for the civil rights of individuals with disabilities. Psychologists were active in providing testimony in support of ADA and were influenced by its passage. Currently, psychologists have a responsibility to understand legislation protecting the rights of people with disabilities so that psychological services, research, and advocacy respect, examine, and build on this important legal foundation.

FUTURE DIRECTIONS IN PSYCHOLOGY AND DISABILITY

While psychology has progressed for more than a century and thereby has become a field more knowledgeable about and responsive to disability issues, criticisms of current psychological practice have pressed the field to further develop its involvement with individuals with disabilities. Specifically, some psychologists are challenging traditional definitions of disability, which have significant implications for current psychological practice.

Newer ideas of disability have stemmed from the social model of disability, which conceptualizes disability on a dynamic continuum. That is, the degree to which a person is considered disabled may fluctuate from day to day or from situation to situation depending on the interaction of environmental and/or individual factors. For instance, an individual who uses a wheelchair experiences the disability differently depending on whether he or she is attempting to enter a building that is wheelchair accessible or inaccessible with a wheelchair that can or cannot climb stairs. In essence, the lack of fit between the individual's abilities and the environmental characteristics creates an inaccessibility that becomes a part of the disability. The new social paradigm of disability has begun to influence psychology in the areas of training, assessment, research, and practice. For example, the nature, extent, and role of social support in the lives of persons with disabilities are emerging as areas of research interest with implications for community-based interventions.

Furthermore, although there has been an increase in studying individuals with disabilities, reform efforts suggest that there is also a need for an inclusion of persons with disabilities in areas of psychological study that are not particularly directed toward understanding disability issues. Similarly, psychological training programs are being challenged to address disability issues across the curriculum to enhance disability competence within the field. These methods of including disability issues in broader psychological practice have been recommended to ensure that the perspective of those with disabilities will be considered. This consideration will lead to better informed psychological practices for individuals with disabilities and to greater knowledge about the human condition more generally.

PSYCHOSIS

The term *psychosis* refers to an array of symptoms that relate to disturbances in how the brain processes perceptions and thoughts. A narrow definition of psychosis focuses on a cluster of phenomena known as positive symptoms. Positive symptoms include hallucinations and delusions. Hallucinations are said to occur when an individual experiences a sensory impression that has no basis in reality. This impression may involve any of the sensory modalities (i.e., hearing, sight, smell, taste, touch, or body position in space). Delusions are strongly held beliefs that are maintained despite a lack of supporting evidence. A delusional person may believe that others are reading their thoughts or plotting against them. Attempts to persuade the person that these beliefs are untrue generally fail and may even support the paranoia. In addition to hallucinations and delusions, persons with psychotic illness may have disorganized and confused thinking and may exhibit odd or flagrantly bizarre speech and behavior. These symptoms generally cause considerable disability, particularly in interpersonal relationships and work, and in most Western cultures, are associated with high unemployment.

Persons with psychotic illness may also develop what are known as negative symptoms that impair motivated and spontaneous behavior. Negative symptoms can make it difficult to conduct basic activities of daily living such as maintaining personal hygiene or attend to tasks such as grocery shopping and banking.

Psychotic symptoms may occur in a wide variety of mental disorders. Although most characteristically associated with schizophrenia, psychotic symptoms can also occur in severe mood disorders (e.g., major depression and bipolar disorder), as well as in response to underlying general medical conditions, in certain substance-induced disorders, and with some of the more severe personality disorders.

Psychosis caused by an underlying medical condition remits once the condition has been identified and treated. However, the 1.1 percent of the population suffering from schizophrenia may have psychotic symptoms throughout their lives. Following a first episode of schizophrenia, residual psychotic symptoms, negative symptoms, and a variety of cognitive deficits often persist and can cause significant psychosocial impairments. One of the best outcome predictors for first-episode patients with schizophrenia is treatment adherence, and there are compelling data to suggest that earlier, more intense interventions produce better long-term outcomes.

Psychotic symptoms resulting from a variety of disease states seem to share an underlying common mechanism, as they tend to respond as a group to specific pharmacological interventions. Despite the remarkable improvements that are developing in the treatment of psychotic illness, much remains to be learned about the brain mechanisms underlying psychosis so that more complete and predictable symptom abatement may occur.

PUBLIC STRIPPING

Term used by people with disabilities and disability studies scholars to describe a medical teaching and consultation practice in which disabled people, to receive medical care, were required to display themselves naked (or nearly so) in front of a well-dressed group of physicians, students, and allied health professionals. The practice, often referred to as *grand rounds* by medical practitioners, involves the presentation of a medical case with the actual person present not as a participant but as an object lesson for the assembly. The practice varied from institution to institution and from case to case, but the subjects of these demonstrations describe having hospital gowns and even undergarments taken off so that the professionals and students could examine them more freely. Many report having to walk naked in front of the physicians and others, having their bodies bent, probed, inspected, and exposed in mortifying ways.

The practice has not been limited to the grand-rounds setting. For example, psychologist Carol Gill reports that in 1993, on the popular NBC prime-time news magazine *NBC Now,* a physician pulled up the T-shirt of a 12-year-old girl with cerebral palsy and, without even speaking to her, displayed her scoliotic back to a national television audience.

Disabled people report feeling objectified by this experience, in which their perspectives on their impairment are completely ignored. But worse, they suggest, is the humiliation: These people, whose physical characteristics were the occasion for shame and oppression, were forced to denude themselves and parade those very characteristics for which they were singled out in front of a judgmental group of powerful people who treated them not like a person but like a set of symptoms, like an malfunctioning object.

By the twenty-first century, the practice has become less common, due perhaps to gradual changes in the culture of medicine as well as to changes in medical education, including the advent of advanced information technology. The practice and its impact on its disabled subjects has been explored extensively by crip artists, writers, and performance artists, including Cheryl Marie Wade, Greg Walloch, Mary Duffy, Carrie Sandahl, and Eli Clare.

PUBLIC TRANSPORTATION

As societal divides between domestic and labor environments developed in the Industrial Revolution, public transportation systems were built to address the mobility needs of the labor force. Historically, these systems have been inaccessible to people with disabilities, making removal of transportation barriers a universal disability rights demand. A quick search of the Internet reveals more than 30,000 sites containing information about disability and public transit. Canadian and Australian authorities publish information about how disabled citizens and visitors may access their transit systems. In Great Britain, DAN (Disabled Action Network) has taken to the streets, winning a great victory in Nottingham in 1996. In South Korea, activists have documented their ongoing struggle in a documentary film. In all of these cases, the need for transportation has helped to create and fuel movements for disability rights, making public transportation the fight that is building the disability rights movement around the world.

In the United States, modern public transportation systems began to take shape at the dawn of the twentieth century. In 1895, New York City replaced its steam-powered lines with electric trains, and across the country, horse-drawn omnibuses and carriages were phased out in favor of electric-powered trolleys and streetcars. The first modern city bus, which seated 43 passengers and featured driver-operated doors, was manufactured in 1927. In 1933, Boeing unveiled the first commercial aircraft, which seated 10 passengers, featured upholstered seats and a water heater, and traveled at 155 mph. The development of these early public transportation systems unfortunately coincided with a period of disability history known as the “eugenics” era, in which disabled people were institutionalized, seldom seen in public, and sometimes even prohibited by law from using public streets and facilities. Invisibility led to exclusion so that early public transportation systems evolved for almost three-quarters of a century without considering access for people with disabilities. Transportation equipment and facilities were built without vertical access for people with mobility impairments and without communication access for people with visual or hearing impairments.

With the development of the independent living movement in the 1960s, a new way of thinking about people with disabilities and society emerged. Disability rights activists used the "social model of disability" to move the locus of "the problem" from individual or personal inadequacy (e.g., the inability to climb bus stairs) to society's systematic exclusion of people with disabilities through architectural and attitudinal barriers. In 1973, MAD (Metropolitan Area Disabled), a group of disabled people in Denver, Colorado, began to protest separate and unreliable service for disabled riders. In 1977, the same year that the first wheelchair lift–equipped fixed-route bus was run in San Diego, the Atlantis Community, a client-based organization that provided attendant services to people moving out of nursing homes, filed a lawsuit under Section 504 of the Rehabilitation Act of 1973, demanding access to Denver's public bus system. When a judge ruled against the Atlantis Community in 1978, a group of disabled activists and their allies closed down Denver's bus system for two days until they won agreement to equip all new buses with lifts. By 1982, disabled riders in Denver enjoyed accessible mainline bus service. This group formed the nucleus of what would become one of the most contentious of disability rights groups, ADAPT (American Disabled for Accessible Public Transit).

Throughout the 1980s, the nascent disability rights movement rallied around the demand for access to public transportation. Activists forced public officials to rethink policies that excluded people with disabilities from mainline public transportation systems by debunking inflated cost propaganda and showing that access to public transportation was essential for full participation in educational, social, and vocational activities—integral to connecting with others in the community and moving about freely.

Public transportation authorities through their national association, APTA (American Public Transit Association), vigorously opposed the concept of providing accessible mainline transportation to people with disabilities. Portraying the cost of equipping buses and trains with lifts and other accessibility features as an economic threat, transit authorities appealed to the courts for relief from federal regulations in favor of a "local option" that allowed localities to determine what service to provide to disabled riders. The courts concurred, and in the decade preceding passage of the ADA, most disabled riders continued to be relegated to separate and notoriously unreliable paratransit services, where ride denials were commonplace and spontaneous travel was prevented by laborious administrative and scheduling requirements.

The demand for accessible public transportation was sustained through community activism, protests, and court battles for more than 15 years. In Chicago, disabled riders, many of who were members of Chicago ADAPT, sued for access to the city's buses and rapid rail system under the state human rights law (*Jones v. CTA*). Their victory in 1988 was followed by a sister lawsuit against Chicago's commuter rail system (*Jones v. Metra*), which was also settled in favor of disabled plaintiffs. By the time the Americans with Disabilities Act (ADA) of 1990 was passed, almost half of the nation's bus companies were ordering at least some lift-equipped buses.

With the passage of the ADA in 1990, which established minimum accessibility requirements, many disabled people gained improved access to public transportation systems. Yet compliance has not been easy, and transit entities had to be taken to court, in some cases repeatedly, to enforce compliance. Others have used the "minimum" requirements of the ADA to circumvent accessibility for disabled riders. For example, many public bus companies purchased new inaccessible buses just before effective dates of transportation regulations, with useful lives of 10 to 12 years; this effectively postponed mainline access for a decade. For some, who depended on door-to-door transportation, the ADA resulted in less transportation when not traveling within the required radius of mainline.

"Full compliance" under the ADA does not always translate to equal or full access in practice. For example, as of 2003, the Chicago Transit Authority proclaimed that 35 percent of its stations were ADA accessible, yet the accessibility is unequally distributed, and some key access compliance continues to be deferred into the future. Over time, a key flaw in early disability rights thinking became apparent. Activists in the 1970s and 1980s envisioned a "common" disability population and deprioritized the needs of people with disabilities who could not be accommodated by mainline transportation systems. This includes, for example, people with respiratory impairments who cannot wait for buses in temperature extremes, people with chronic fatigue syndrome, and ambulatory disabled people who cannot stand for long periods of time. While complementary paratransit requirements were included in ADA regulations, service areas are based on travel patterns of mainline bus users, and the regulations allow transit agencies to charge double the standard bus fare for disabled people who cannot access mainline systems, thus effectively pricing public transportation out of reach for many people with disabilities, who remain the poorest minority group in America.

Even where technical compliance on fixed-route services has been achieved, disabled riders are often singled out, separated, and expected to participate in separate additional interactions. "Handicap" turnstiles, separate paths of travel, special call buttons, additional paperwork, separate boarding and debarking processes, and delayed exits from the system all add up to a multiplicity of separate policies and procedures that stigmatize disabled riders.

For many, the promise of the ADA remains out of reach. Just as disabled people were staking a claim to public transportation, funding for public transit declined and private vehicles became a staple of American life. The cost of modifying private vehicles for accessibility is often prohibitive; it is not unusual for modifications to double the cost. Most taxi services also remain inaccessible. Disability rights groups argued that making buses and trains accessible would provide reliable transportation to disabled people and reduce the human and social costs of failing to accommodate—the cost of maintaining millions in unemployed poverty who could work if they could obtain reliable transportation. Yet more than a decade after the passage of the ADA, 65 percent remain unemployed, a significant number cannot or do not drive, and in many parts of the country, people with disabilities, unlike their nondisabled counterparts, remain isolated and excluded from the mainstream of American life.

Despite disappointing progress at times, disabled people continue to press for access to all modes of public transportation. When the Supreme Court found that the Rehabilitation Act did not apply to air travel, disability advocates organized, and in 1986, Congress passed the Air Carrier Access Act (ACAA), which requires the implementation of practices and procedures to ensure access to air travel by people with disabilities, but stopped short of mandating the development of accessible aircraft. At the dawn of the twenty-first century, disabled people would win accessibility on American cruise lines and then go on to press for accessibility on foreign-flagged cruise ships in U.S. waters.

Q

QUALITY OF LIFE

The measurement of quality of life has become central to the evaluation of health care. This has not always been the case; until recently, quality of life was addressed only through indirect inference from more traditional medical variables. The difficulty of defining quality of life in a meaningful and operational manner was in part to blame for the apparent unwillingness of the medical profession, and those allied with it, to engage in systematic evaluation of quality of life in the past. Indeed, the term *quality of life* is inherently ambiguous, as it can refer both to the experience an individual has of his or her own life and to the living conditions in which people find themselves. Consequently, definitions of the concept have varied widely, with some writers viewing quality of life as in some way akin to the Aristotelian notion of the "good life" and others defining it in terms of capabilities (i.e., having the ability to live a good life in terms of emotional and physical well-being). Within the arena of health care, the latter view has tended to dominate, and the term *quality of life* is typically used to refer to individuals' experiences of their own health.

Academic interest in quality of life grew after World War II, when there was increasing awareness, and recognition, of social inequalities. This provided the impetus to social indicators research, and subsequently to research on subjective well-being and quality of life. The term *quality of life* first appeared in the medical literature in the 1960s, and references to it have grown exponentially ever since. In 2003, the term appeared in more than 6,000 articles referenced on Medline alone. For the most part, health care scholars and researchers use the term to refer to outcomes based on patient self-reports. Historically, this had simply not been an integral part of how health was reported in the scientific literature. Undeniably, the patient's view of his or her own health had played some role in the medical consultation, but in terms of the health care literature, researchers did not begin collecting and reporting such data systematically until the late 1960s.

Within the arena of disability research and health care it has become increasingly commonplace to discuss *health-related* quality of life. Interest in health-related quality of life is in keeping with the World Health Organization's definition of health, which incorporates autonomy and physical, mental, and social well-being; health is not merely the absence of disease. The literature in this field covers a wide variety of areas, including role functioning (e.g., ability to perform domestic and work tasks), degree of social and community interaction, psychological well-being, pain, tiredness, and satisfaction with life. To some extent there is a tendency to equate quality of life with those factors of the health state that are not encompassed by traditional medical assessments. Such a view can lead to conceptual confusion and perhaps highlights more than anything else the difficulty in providing a simple definition of quality of life. Suffice it to say that health status and health-related quality of life have come to mean a combination of subjectively assessed measures of health, including physical function, social function, emotional or mental state, burden of symptoms, and sense of well-being.

Most early attempts to develop measures for assessing health-related quality of life included attempts to measure the specific impacts of disability. For example, the Katz and Barthel measures were designed to assess activities of daily living in patients undergoing rehabilitation programs. Measures of emotional health, such as the Beck Depression Inventory, were designed to assess mental health and to give an indication of the severity of depressive symptoms. However, questionnaires are now often specifically designed to cover a wide range of areas that may affect an individual's quality of life. Two broad categories of measures have emerged: those designed to evaluate health-related quality of life in any group of patients (indeed, in any population sample) and those designed to evaluate health-related quality of life in specific illness groups. The former group include measures such as the Sickness Impact Profile and the 36-item Short Form Health Survey (SF-36). These instruments cover a wide range of aspects of life that can be adversely affected by ill health, such as physical functioning, emotional well-being, and ability to undertake work and social activities. Disease-specific measures, such as the Arthritis Impact Scales Version II (AIMS II), the 39-item Parkinson's Disease Questionnaire, the Endometriosis Health Profile, and the 40-item Amyotrophic Lateral Sclerosis Assessment Questionnaire (ALSAQ-40), are designed for use with specific patient groups. They are intended to cover dimensions salient to particular patient groups; thus, like generic measures, they address areas such as physical and emotional functioning, but they also cover issues that may be predominant among patients with particular illnesses (e.g., feelings of loss of control, stigma).

A wide variety of uses have been suggested for quality-of-life data, but the most common applications are the assessment of treatment regimes in clinical trials and health surveys. Other applications include population and patient monitoring, screening, and improvement of doctor-patient communication. One of the most emotive uses of such data, however, is in the economic evaluation of health care, with some measures designed specifically to be used in cost-utility analyses—that is, analyses that attempt to determine the benefits of an intervention in terms of both length of life gained and quality of life. Perhaps the most widely used of these measures is the EuroQol 5D (EQ-5D), which addresses five dimensions of health: mobility, self-care, usual activity, pain, and anxiety/depression. Each of these dimensions is subdivided into three levels according to whether the dimension represents no problem, a moderate problem, or a severe problem. The five dimensions and the three-level classification system generate 243 health states, which the instrument's developers have extended to 245 through the addition of death and unconsciousness. The values attached to these health states, which are based on responses from surveys of the general population, are intended to reflect societal views of the severity of each state. The EQ-5D can produce the quality-of-life component for the calculation of quality-of-life-adjusted years (QALYs), in which quality of life is combined with years of life gained as a consequence of an intervention. Costs of treatment can be linked with the number of QALYs gained to give a cost per QALY.

Clearly, quality of life represents an aspect of health that is different from that generally measured using traditional methods of assessment, such as X-rays, blood tests, and clinical judgment. The latter have tended to dominate within health care and medicine in part because they are seen to be relatively objective. The measurement of quality of life incorporates the subjective views of the patient directly and can provide health care professionals with information that can supplement or, on occasion, contradict traditional assessments. For example, there is evidence that outsiders, such as doctors and relatives, view the quality of life of patients with serious disabilities more negatively than do the patients themselves. Also, in some instances, clinical assessments remain stable over time and yet patients report a worsening of their health. Such divergences between the perceptions of those in a given health state and the perceptions of outside observers highlight the limitations of basing assessments purely on observers' assessments. The main purpose of the health care system is to increase the well-being of those it treats. This can be achieved only if patient views are incorporated into treatment evaluations, thereby ensuring that health and medical care are fully evidence based.

QUEBEC MODEL OF DISABILITY CREATION PROCESS

The disability creation process (DCP) is a conceptual model that enables one to identify and explain the causes and consequences of disease, trauma, and disruptions to the development of a person. It demonstrates that social participation is not only the result of our identity, our choices, impairments to our organs, and our abilities and inabilities, but also of characteristics of our living environment. For example, an individual's preparing meals or going to regular school may be influenced by the reinforcement of that person's capabilities and alteration of his or her functional limitations through rehabilitation, as well as through the reduction of obstacles caused by prejudice, lack of assistance or resources, and absence of accessibility within the home or school.

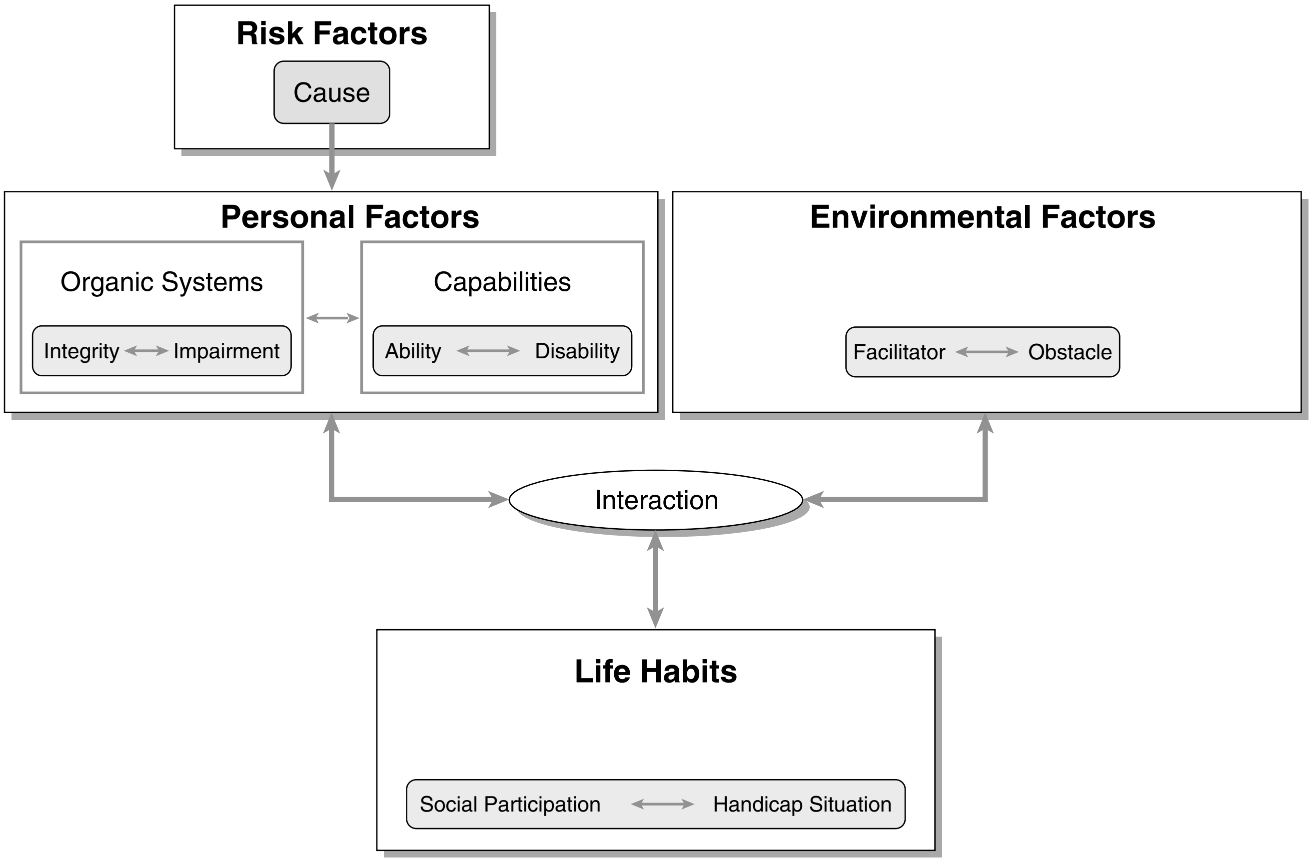

Figure 1 The Disability Creation Process: The Reference Model

The DCP model was developed based on the Quebec government's disability policy, "On Equal Terms," and on the recommendations of international experts, including the World Health Organization, the United Nations, Disabled Peoples' International, and the Council of Europe, at the Quebec Meeting on International Classification of Impairments, Disabilities, and Handicaps (ICIDH) in June 1987. By 1989, Patrick Fougeyrollas, a Canadian anthropologist, and the Quebec Committee on ICIDH published a conceptual framework illustrating the person-environment interactive process of the creation of social participation or exclusion. Throughoout the 1990s, they improved the DCP framework and classification, known also as the Quebec model, and urged the WHO and international partners to revise the ICIDH. From 1993 to 2001, this innovative conceptualization and its scientific applications influenced the revision process that culminated in the WHO's adoption of the International Classification of Functioning, Disability, and Health (ICF).

The DCP model differs from the ICF in its conceptualization of human development and adaptation as well as in its view of the disability process as an interactive person-environment relationship that creates the outcome of quality of social participation. Although the ICF has also adopted a universal, systemic conceptual framework, the DCP illustrates in a heuristic and pedagogical way the dynamics of the interactive process between personal factors (intrinsic) and environmental factors (extrinsic) that determines the situational result of accomplishment of life habits (daily life activities and social roles) corresponding to the person's age, gender, and sociocultural identity. The DCP concepts and taxonomies are mutually exclusive.

The DCP model distinguishes two intrinsic dimensions applicable to every human being: organic systems and capabilities (see Figure 1). The "personal factors" category is larger and more inclusive than the "organic systems" and "capabilities" themselves because other personal identity variables (age, gender, sociocultural identity) must also be considered in the explanation of the performance of life habits. The "environmental factors" category is clearly delimited and includes all dimensions of the context (social, cultural, political, physical, and so on) in which the person lives. The dynamic nature of the interactive process is symbolized by the bold double arrows in Figure 1. The point of central convergence, symbolized in the figure by the word *interaction,* aims at naming the continual relationship and influence of the three conceptual dimensions.

The International Network on the Disability Creation Process is a Canadian nongovernmental organization that promotes the use of the DCP model and the development of applications supporting the exercise of human rights and full citizenship for people with functional and organic differences.

QUEER/DISABILITY STUDIES

As disability studies flourished in the late 1990s, the insights that emerged from points where the field intersected or converged with queer studies proved to be particularly productive. By the turn of the century, this convergence had generated a number of significant texts, events, communities, and institutions. Eli Clare's *Exile and Pride: Disability, Queerness, and Liberation* (1999) was a landmark text in this process, as were a number of edited volumes, including Raymond Luczak's *Eyes of Desire: A Deaf Gay and Lesbian Reader* (1993), Shelley Tremain's *Pushing the Limits: Disabled Dykes Produce Culture* (1996), Victoria A. Brownworth and Susan Raffo's *Restricted Access: Lesbians on Disability* (1999), Robert McRuer and Abby L. Wilkerson's "Desiring Disability: Queer Theory Meets Disability Studies" (2003) (a special issue of the prominent academic journal *GLQ: A Journal of Lesbian and Gay Studies*), and Bob Guter and John R. Killacky's *Queer Crips: Disabled Gay Men and Their Stories* (2003). An efflorescence of cultural work in many other locations both preceded and accompanied these important volumes, including individual memoirs such as Kenny Fries's *Body, Remember* (1997) and Daphne Scholinski's *The Last Time I Wore a Dress* (1998); performance art by Terry Galloway, Greg Walloch, Julia Trahan, and others; the online publication *Bent: A Journal of Cripgay Voices;* and the "Queer Bodies" study and education group, which focuses on queerness and disability, based in New York City at the Center for Lesbian and Gay Studies (CLAGS). A group of activists and academics in the United States initiated a queer disability Listserv on the West Coast in 2000 and, partially through this network, the first international queer/disability conference was organized. That event, which was held at San Francisco State University in June 2002, was attended by artists, academics, and activists, thereby bringing together (in sometimes contentious conversation) the three overlapping communities responsible for generating increased interest in the convergence of queerness and disability.

This wave of interest in queer/disability studies was facilitated both by the perceived connections between some lesbian/gay/bisexual/transgendered (lgbt) subjectivities and some disabled subjectivities and by the affinity certain strands of disability studies seemed to have with what had been known since the early 1990s as "queer theory." Among the perceived connections between lgbt and disabled subjectivities was the recognition that socialization for both people with disabilities and lgbt people often occurred in heterosexual and able-bodied families, isolated from queer and disability communities. Similarly, the rhetoric of coming out that developed in part to resist such isolation and that permeated the disability movement by the end of the century had clear, and sometimes acknowledged, antecedents in the gay liberation movement, and at its best did not signify discovery of some deep essential truth but rather coming out to a vibrant movement intent on collectively and often quite literally rebuilding the world. Both communities have faced ongoing medicalization or pathologization and arguably faced similar new dangers at the turn of the century, normalization perhaps at the forefront. Throughout the 1990s, lgbt communities debated the benefits and liabilities of the normalization process, weighing such factors as increased media visibility and tolerance against the potential loss of a flamboyant and critical militancy, the dangers of tokenism, and the ongoing marginalization of members of the community furthest from what Audre Lorde identified in 1984 as "the mythical norm." For both lgbt and disability communities, the danger of mutual recoil was perhaps the most problematic aspect of normalization: the possibility that acceptance for queers would come first to those perceived as least disabled and that acceptance for people with disabilities would come first to those perceived as least queer.

The origins of queer theory are multiple. Michel Foucault is often located as a founding figure of sorts, with special emphasis placed on *The History of Sexuality,* Volume 1 (1978). In that work, Foucault challenged the notion that sexuality has simply moved from a state of repression or secrecy to liberation and openness. He showed instead the ways in which sexuality in the modern era has emerged as a unique apparatus, composed of and by an array of discourses and institutional practices; he argued that it has not been repressed but *managed.* Foucault made it possible to understand how sexualities (and, indeed, forms of subjectivity and embodiment generally) emerge through the construction, categorization, and dissemination of the "normal" and the "deviant." Foucault's work had affinities with the work of several other gay and lesbian historians and sociologists, who were mostly working outside the academy in the 1960s and 1970s. From Mary McIntosh's groundbreaking "The Homosexual Role" (1968) through Jonathan Ned Katz's *The Invention of Heterosexuality* (1995), these scholars examined the ways in which understandings and experiences of sexual identity (including heterosexuality) are socially constructed, emerging from specific historical and cultural contexts. Since this body of work as a whole focused on embodiment, normality, and deviance as historical entities, other scholars more directly concerned with late-twentieth-century queerness and disability were able to access it to critique the ways in which the institutions and discourses of compulsory able-bodiedness and compulsory heterosexuality worked in tandem to produce and contain both able-bodied heterosexuality and queer disabled subjects who might confirm (by embodying a "deviance" that vouchsafed able-bodied heterosexuality's dominance) or trouble (by resistance to this function and refusal to be kept in place) the larger apparatus.

Queer theory also developed in relation to a late-1980s resurgence of radical lgbt activism, in particular activism that addressed the lack of attention that the medical establishment, the U.S. government, and the media were giving to the AIDS crisis. Although some disability activists resisted the incorporation of HIV/AIDS into the Americans with Disabilities Act (ADA), there were nonetheless many points of identification between AIDS and disability activism. Some AIDS activist groups, in fact, explicitly acknowledged their debt to the disability rights movement, and some disability rights groups, such as ADAPT, in turn developed strategies and styles that explicitly recalled or cited those of AIDS activists, especially activists in the AIDS Coalition to Unleash Power (ACT UP). AIDS activism in the late 1980s and early 1990s was flamboyant and confrontational, stopping traffic on Wall Street, storming the National Institutes of Health, staging a "kiss-in" in front of St. Patrick's Cathedral in New York City (Cardinal John O'Connor had opposed safe-sex education in both private and public schools). The demands of activists included increased funding for education and research; expanded access to treatment, especially for women, people of color, and the poor; and an end to the stigmatization of "AIDS victims," who themselves preferred to be called "people living with HIV/AIDS." AIDS activists, like other disability activists, were also media savvy, recognizing the importance of both challenging dominant media representations and documenting their own movement. A significant body of AIDS cultural theory—including Douglas Crimp's edited volume *AIDS: Cultural Analysis/Cultural Activism* (1987), Cindy Patton's *Inventing AIDS* (1990), Paula Treichler's *How to Have Theory in an Epidemic: Cultural Chronicles of AIDS* (1999), and Cathy J. Cohen's *The Boundaries of Blackness: AIDS and the Breakdown of Black Politics* (1999)—emerged from this period and provided an additional context in which queer/disability studies flourished.

Finally, queer theory also developed as an extension of feminism and, in some cases, as a partial break from feminism. Gayle S. Rubin's "Thinking Sex: Notes for a Radical Theory of the Politics of Sexuality" (1984), specifically responding to what Rubin understood as the "sex panics" of the 1980s, called for new and autonomous theoretical tools that could account for, and counteract, the sexual stratification and oppression of our culture; feminism alone, in Rubin's estimation, was not adequate to this task. Similarly, writers such as bell hooks, Audre Lorde, Gloria Anzaldúa, and Cherríe Moraga critiqued white feminists for their universalizing of all women's experiences and for their explicit exclusion of women of color. In calling for a more fluid, oppositional, and coalitional feminism, these women of color either explicitly articulated their demands as "queer" ("We are the queer groups," Anzaldúa [1981:209] wrote, "the people that don't belong anywhere. . . . and because we do not fit we are a threat") or anticipated similar fluid and oppositional theories that would later emerge under the rubric of both queer and disability activism and theory. The call for autonomous or semiautonomous spaces and the simultaneous emphasis on specificity and coalition suggests that queer/disabled thought and activism, in particular, inherit these complex feminist histories. Queer/disabled individuals and communities have worked to secure recognition and respect for the full range of bodies and desires, and have resisted the ways in which they have at times been made invisible by larger lgbt and disability movements.

QUOTA HIRING POLICY

In many countries of the world, programs have been established to seek to create equitable employment opportunities for persons with disabilities. Known as *affirmative action, positive discrimination, employment equity,* or *quota systems,* these programs all have in common the goal of raising the workplace participation rates of disabled people to match those found in the nondisabled general population. In some countries, these programs encompass not just disabled people but other groups as well, such as women, visible minorities, and aboriginal peoples. This entry provides an overview of such programs found in the United States, Canada, France, and Germany.

UNITED STATES

In the United States, affirmative action programs flow from that country’s antidiscrimination legislation and are not based on the imposition of strict numerical quotas. The term *affirmative action* was first used in the United States in the context of civil rights legislation in the early 1960s. In March 1961, President Kennedy issued Executive Order 10925, which established the President’s Committee on Equal Employment Opportunity. The goal of the committee was to end discrimination in employment by the government and government contractors. The order required that every government contract contain the following pledge: “The Contractor will not discriminate against any employee or applicant for employment because of race, creed, color, or national origin. The Contractor will take *affirmative action,* to ensure that applicants are employed, and that employees are treated during employment, without regard to their race, creed, color, or national origin.” However, the term *affirmative action,* in this context, meant only that the organization should not discriminate.

In 1964, the U.S. Congress passed the Civil Rights Act, Title VII of which outlawed discrimination on the basis of race, color, or national origin in programs and activities receiving federal assistance. The act was amended in 1972 to include in this list religion, sex/gender, and national origin. However, in 1965, President Johnson noted that “fairness” means more than a commitment to impartial treatment. In his commencement speech at Howard University in Washington, D.C., that year, he said:

> You do not take a person who, for years, has been hobbled by chains and liberate him, bring him up to the starting line of a race and then say, “you are free to compete with all the others,” and still justly believe that you have been completely fair.
>
> Thus it is not enough just to open the gates of opportunity. All our citizens must have the ability to walk through those gates.
>
> . . . We seek not . . . just equality as a right and a theory but equality as a fact and equality as a result.

These concepts were embodied in Executive Order 11246, which President Johnson issued in 1965 and amended in Executive Order 11375 in 1967. These orders required that all federal government contractors develop “affirmative action programs” to “promote the attainment of equal employment objectives.” The orders authorized the use of goals but prohibited quotas in regard to race, religion, national origin, color, and sex. In 1971, President Nixon extended affirmative action by issuing Revised Order 4, which required that each contractor develop “an acceptable affirmative action program,” including “an analysis of areas within which the contractor is deficient in the utilization of minority groups and women, and further, goals and timetables to which the contractor’s good faith efforts must be directed to correct the deficiencies." Goals were not to be quotas; rather, they were to be seen as targets that were reasonably attainable.

In 1973, the U.S. Congress passed the Rehabilitation Act, in which Section 503 required government contractors to take affirmative action to employ and promote qualified handicapped individuals. The act also prohibited employment discrimination against qualified persons with disabilities. In 1990, the Americans with Disabilities Act (ADA) was signed into law. This legislation outlawed discrimination against persons with disabilities in employment and in the provision of goods and services. Provisions of the ADA cover both public and private employers. The law does not specifically mandate the creation of affirmative action programs, but the remedies available for violations of the ADA are the same as those available under Title VII of the 1964 Civil Rights Act. In cases of systematic discrimination, the courts may require that an affirmative action order be established, requiring the employer to establish outreach programs to increase the hiring and promotion of disabled people.

Affirmative action programs in the United States, then, are not based on one law but instead have evolved over the years through the adoption of a number of statutes, coupled with the issuance of various executive orders. In recent years, however, these programs have become the subject of much controversy in the United States. Critics of affirmative action contend that it is nothing less than discrimination in reverse, and that affirmative action policies amount to de facto quotas. Supporters of affirmative action programs argue that such efforts are necessary to balance the history of barriers faced by racial minorities, women, and persons with disabilities. A key element in the U.S. debate is the absence of an equality rights provision in the U.S. Constitution that would furnish a constitutional basis for the implementation of affirmative action programs.

CANADA

Canada's affirmative action program for persons with disabilities, known as *employment equity,* also flows from antidiscrimination laws. And, as in the United States, Canada does not impose on employers any requirement to hire specific numbers of disabled employees.

In 1978, Canada's federal Parliament passed the Canadian Human Rights Act. As originally enacted, the law outlawed discrimination in employment and in the provision of goods and services on 10 grounds: race, national or ethnic origin, color, religion, age, sex, marital status, family status, disability, and pardoned conviction. Some years later, sexual orientation was added to this list. This law provided that it is not a "discriminatory practice" for a person to "carry out a special program, plan or arrangement designed to prevent disadvantages that are likely to be suffered by, or eliminate or reduce disadvantages that are suffered by groups of individuals . . . when those disadvantages . . . would be based on or related to the prohibited grounds of discrimination." Thus, this antidiscrimination legislation first allowed employers to implement affirmative action *passively,* with no actual requirement to do so.

In 1982, Canada's Constitution was amended to include the Charter of Rights and Freedoms. Section 15 of the Charter, the equality rights provision, provided the constitutional underpinnings for the mandatory employment equity (i.e., affirmative action) programs that were soon to be enacted.

Despite the antidiscrimination legislation in place, it became evident that existing laws could not deal with structural or "systemic" discrimination that certain groups, including persons with disabilities, found in the Canadian workplace. In 1984, a Royal Commission on Equality in Employment, chaired by Madame Justice Rosalie Abella, issued a report that provided the philosophical rationale for affirmative action:

> Sometimes equality means treating people the same despite their differences, and sometimes it means treating them as equals by accommodating their differences.
>
> Formerly, we thought that equality only meant sameness and that treating persons as equals meant treating everyone the same. We now know that to treat everyone the same may be to offend the notion of equality.

In 1986, Canada passed the Employment Equity Act, which mandated the institution of *positive* policies and practices to ensure that persons in designated groups (women, aboriginal peoples, visible minorities, and persons with disabilities) "achieve a degree of representation in the various positions of employment with the employer that is at least proportionate to their representation (i) in the workforce or (ii) in those segments of the workforce that are identifiable by qualification, eligibility or geography and from which the employer may reasonably be expected to draw or promote employees." The law requires employers to eliminate structural or systemic discrimination and to institute measures that will ensure that persons who belong to one of the four designated groups subject to the law achieve a degree of representation in the various positions of employment with their employers that is proportionate to their representation in the workforce. The law also requires employers to prepare yearly plans that outline the employment equity goals that they propose to reach as well as timetables for achievement of those goals. The requirements of the Employment Equity Act apply to employers that have more than 100 employees and are under federal jurisdiction.

It is important to note that the Employment Equity Act does not contain any provision that actually forces employers to hire anyone. Rather, the law requires that employers prepare annual reports and send copies of those reports to the Canadian Human Rights Commission, the agency responsible for enforcement of the act. Although employers are not required to hire anyone, these reports are public documents, and employers' progress is subject to public scrutiny. Moreover, the Canadian Human Rights Commission may conduct audits of employers and may issue directions to them.

The affirmative action program in Canada has been subject to the same criticisms as such efforts in the United States. However, because of the existence of the equality provisions of the Canadian Charter of Rights and Freedoms, the Canadian program has not been subject to the same intensity of legal challenges that have taken place in the United States.

QUOTA SYSTEMS

In contrast to the programs in place in the United States and Canada, affirmative action efforts in many countries of Europe (France, Germany, Italy, Austria, Poland) do not flow from antidiscrimination legislation, but rather are based on strict numerical quotas. Thus, they are fundamentally different from U.S. or Canadian affirmative action programs, which rely on targets or objectives rather than on requirements concerning fixed percentages of the workforce. Moreover, the quota programs in Europe cover only disabled people, not a broader range of "designated groups" such as racial minorities or women. For the purposes of this entry, the systems in place in France and Germany are described briefly below.

France

In France, a law enacted in 1987 established a quota-levy program. The law stipulates that enterprises with 20 or more workers must have 6 percent of their workforces composed of disabled workers. The legislation also allows for the application of branch or enterprise agreements by which the company agrees to the recruitment and retention of persons with disabilities. These agreements may cover a single enterprise or an entire sector of economic activity. Most of these agreements include job retention objectives for injured workers.

A company that fails to observe its quota obligation is charged a levy commensurate to the number of workers by which it falls short of the quota. The levy averages 2,000 euros (approximately $2,300 U.S.) annually for each employee by which the company falls below the quota. The funds collected by the quota program are administered by the Association Nationale de Gestion du Fonds pour l'Insertion Professionelle des Personnes Handicapées, or AGEFIPH, which is made up of representatives from government, trade unions and employers, and organizations of persons with disabilities.

Germany

Germany has had a statutory obligation for companies to hire disabled workers in place since the end of World War I. In 1917, the German Parliament passed a law requiring companies to hire 1 disabled war veteran for every 50 employees. This was later broadened to require companies to fill 1 percent of all jobs with severely disabled persons, defined as war victims,

victims of industrial accidents, and other persons entitled to public pensions and compensation.

In 1974, the Severely Disabled Persons Act was enacted. This legislation provides, with some exceptions, that all companies with more than 16 employees must fill at least 6 percent of positions with severely disabled persons. This figure represents the proportion of severely disabled persons of working age in the German population as a whole. Under the legislation, severely disabled persons are defined as individuals who have been assessed with as a disability of 50 percent or more from any cause. Companies that do not comply with their quota requirements must pay a monthly levy of approximately 102 euros, or $120 U.S. Certain positions, such as part-time jobs of less than 18 hours weekly and jobs of less than eight weeks' duration, are exempt. It is noteworthy that the compensatory levy is payable solely on the basis that disabled persons are not employed in the firm; it is not predicated on whether disabled persons have actually applied for positions.

CONCLUSION

Despite the existence of quota and affirmative action programs, persons with disabilities continue to experience levels of unemployment far above those experienced by their nondisabled fellow citizens. Unfortunately, this is a statement that is valid for all countries.

Very little evaluative research has been conducted on this topic, so there is insufficient evidence to allow us to state with any certainty whether the affirmative action or quota system models are effective vehicles for the integration of persons with disabilities. However, what these programs have done is place the equity issue in the forefront of public awareness and encourage employers to embark on equity activities they might not otherwise undertake. Certainly in the North American context, it is rare to see a job advertisement that does not proclaim that the company is an "equal opportunity employer" or that it is dedicated to employment equity. Finally, it should be noted that the goal of both quota and affirmative action programs is the establishment of a workforce that accurately reflects the participation rates and percentages of disabled people in the general population. As such, these programs must be seen as works in progress.

R

▣ RACE AND ETHNICITY

Historically, the two social categories of race and disability have had a contentious relationship. Race theorists have sought to distance themselves from any association with disability because such associations have supported, justified, and enacted centuries of oppression, exploitation, and even genocide against bodies marked as racial Others. Even today, the racialized body continues to remain central to the maintenance of a hierarchical social-political world order. For disabled people of color, the double jeopardy of both race and disability continues to locate them at the margins of society.

Despite their contentious relationship, the academic areas of critical race theory and disability studies draw on similar foundational concepts. Both begin with the assumption that race and disability are, in fact, social constructs. For examples, critical race theorists depict race as a product of "human rather than abstract forces," produced through a process often called "racial fabrication." Similarly, some disability studies scholars have described disability as "the attribution of corporeal deviance—not so much a property of bodies [but rather] . . . a product of cultural rules about what bodies should be or do." Both perspectives argue that race and disability are relational concepts. Some theorists, consequently, have argued that races are constructed relationally against one another rather than in isolation, such that the privileges that "whites" (i.e., Nordic Europeans) enjoy are linked to the subordination of people of color. Similarly, in the context of disability studies, scholars point out that "our construction of the normal world is based on a radical repression of disability."

Notwithstanding these commonalities, because disability has historically been associated with "deviance" and "the lack of intelligence," race theorists have attempted to distance race from these attributes. By doing so, however, race theorists have invoked the biological definition of disability as an abnormality rooted in the medical language of symptoms and diagnostic categories. It is this definition that disability studies scholars have critiqued, describing it as a "deficit" model, and have instead opted for an alternative definition of disability as a socially constructed category that has historical, cultural, political, and economic implications for social life. Drawing on this reconceptualization of disability, some disability studies' scholars have foregrounded the theoretical linkages between disability and race by arguing that disability is an ideological construction used to justify not only the oppressive binary cultural constructions of normal/pathological, autonomous/dependent, and competent citizen/ward of the state but also the racial division of labor and other forms of racialized oppression.

EUGENICS AND THE BIRTH OF A RACIST SCIENCE

Theoretical linkages between disability and race have historical roots in Enlightenment thought, where philosophers such as David Hume and Immanuel Kant sought to distinguish between what they thought of as "different breeds of men." Hume's naturalism drew him to identify what he termed nature's "original distinction" between "inferior" breeds of men that were nonwhite (e.g., the Negro) and an "eminent" breed that was white—distinctions that extended to their intellectual and moral aptitudes. Similarly, Kant, in pursuit of an objective scientific theory of human differences, established a meticulous conceptual distinction between "race" and "species" and gave credence to the argument of intergenerational permanence of racial traits. Such theorizations of human difference in the late eighteenth century occurred at the same time as slavery and colonialism were flourishing and served as justification for the brutal violence meted out against nonwhite people who were assumed to be subhuman.

Paralleling the social construct of race as a category of human difference, disability studies scholarship reports that during the latter half of the eighteenth century, "disability" became tied to discourses aimed at remediating, curing, and cataloging variation in human bodies. This argument does not imply that disabled people did not exist in earlier times. Rather, such arguments suggest that while disability in earlier times was seen more as an individual event, in the late eighteenth century, the disabled person was "seen, drawn, dissected, legally placed, morally and ethically determined" (Davis 1995) and, as a result, became associated with a genetic entity or group defect, which was, in turn, also linked to race, class, and gender differences.

Leading scientists of the late eighteenth and nineteenth centuries, such as Carl Linnaeus, Georges Cuvier, Charles Lyell, Charles Darwin, and J. F. Bluemenbach, made linkages between human character and human anatomy and drew on the racial politics of the time to link Africans and other nonwhite races and disability in demeaning ways. By the beginning of the twentieth century, the intimate relationship between nonwhite races and disability was institutionalized by the racist science of eugenics. The term *eugenics* was coined in 1883 in Britain by Francis Galton to describe a program of selective breeding. By the late 1890s, eugenics as a scientific idea crossed the Atlantic and found support in U.S.-educated society frightened by the radical changes in society brought about by economic transformations caused by industrialization and the cultural disruptions caused by new waves of immigration from southern and eastern Europe and the migration to the North of newly freed slaves from the South.

Amid these social upheavals, the fear of racialized Others was fueled by associations of race with genetic degeneration and disease. Medical historians and anthropologists define degeneration as losing properties of the genus. The fear of the loss of this generative force encouraged typological as well as physical and biological speculation and, in doing so, supported unscientific stereotyping of many human differences. As a result, degeneration became a compelling racial metaphor such that certain races were assumed to be intrinsically degenerate and, as a result, could never be improved in any way. Because racial biology was a science of boundaries between groups, the threat of degeneration was seen to occur when boundaries were crossed and certain races found themselves "out of place." This definition was extended to describe the urban poor, prostitutes, criminals, and even the insane, who were now also seen as a "race apart."

By hinting at the imminent possibility of social decay if these degenerate "bodies" were not brought under control, the segregation of race was regarded as a necessity because maintaining biological distance was critical to preventing degeneracy. This fear of degeneracy was attributed not only to nonwhite populations (e.g., African Americans, Mexican Americans, Chinese Americans, and Native Americans) but also to lower-class white populations. Fearing that lower-class whites may overpopulate the nation and weaken the superior stock of the dominant race, eugenicists deemed it necessary to "purg[e] the blood of the American people of the handicapping and deteriorating influences of defective anti-social classes" (Jackson 2000). Scholars have described this eugenic practice as "a white-on-white racial discourse" that required that whiteness be purged and sterilized until anyone who disrupted the social order was eliminated. Like degeneracy, disease was also something to be feared, especially when it was seen as the very embodiment of racial difference. Thus, for example, the travel memoirs of Mark Twain's *The Innocents Abroad or the New Pilgrim's Progress* have been interpreted as equating the Jew with disease and death. In Mark Twain's travel writing, the Jew was represented as illness incarnate. Since Jews were seen as intransigent to the assimilation process because they clung to their language, customs, dress, and habits, the

Jewish body was read in generalized terms as immutable, and by extension, what was translatable was his or her immutable relationship to disease, pathology, and death. Physically, Jewish bodies were described as repellant with "big heads, big mouths, everted lips, protruding eyes and bristle eyelashes, large ears, crooked feet, hands that hang below their knees and big shapeless warts or are otherwise asymmetrical and malproportioned in their limbs" (Twain, quoted in Gilman 1995, p. 107). In other words, the Jew's disease was written on his or her skin.

The association of degeneracy and disease with racial difference also translated into an attribution of diminished cognitive and rational capacities of nonwhite populations. Disability-related labels such as "feeblemindedness" and "mental illness" were often times seen as synonymous with bodies marked oppressively by race. As a result, the presumption of an inbuilt biological inferiority was seen to be both the cause and result of degeneracy. The most terrifying aspect of such biological deterministic ascriptions was that they attributed to nonwhite populations of African Americans, Native Americans, Mexican Americans, Chinese Americans, and Jewish Americans a shared incapacity to assimilate into dominant society—characteristics that eugenicists described as biological rather than cultural. Fearing that such characteristics could be passed down from generation to generation and further pose a threat to the dominant white race, "protective" practices such as forced sterilizations, rigid miscegenation laws, residential segregation in ghettoes, barrios, reservations and other state institutions, and sometimes even genocide (e.g., Holocaust) were brought to bear on nonwhite populations. Thus, disability studies scholars have pointed out that in an attempt to regulate and control differences seen as disruptive to the "natural" order in society, violent schemes were developed to expunge undesirable biological variations that were identified as uniquely racial.

Although the above discussion clearly designates the intricate interconnections between the social constructs of disability and race, it is this discussion that also foregrounds the real tensions between racialized and disabled bodies. Race theorists have critiqued eugenics as a racist science that falsely attributes racial differences as examples of biological defect. By doing so, disability studies scholars point out that race theorists run the risk of achieving "'liberation' from dehumanizing constructs by distancing people of color from their association with the bearers of 'more real' (or material) biological incapacities [i.e., disabled people]" (Mitchell and Snyder 2005). Such a project, contends disability studies scholarship, fails to recognize eugenics as a transnational ideology that used the social category of disability to produce constructs such as IQ (intelligent quotients) and practices such as institutionalization, sterilization, segregated education, and restrictive immigration policies that had detrimental effects not only on persons of color but also on disabled people—all of them grouped under the limited but all-encompassing heading of "defect." By regarding the category of "defect" not as a biological given but instead as a social construct invoked so as to regulate, control, and eradicate difference, scholars in both areas of race theory and disability studies can more effectively expose the oppressive violence enacted against humanity that was inspired by the eugenicists' worldview.

In addition, disability studies scholarship has described the trans-Atlantic cultural exchange in discourses of race in the early twentieth century as the "Eugenic Atlantic" in an attempt to demonstrate the parallels between race and disability as dehumanizing ideological practices that have had devastating material effects on both populations. Some disability studies scholars are critical of how most academic discussions of eugenics dedicated to the engineering of a "healthy" body politic have failed to describe disability as a social category that was "the hub that gave the entire [eugenic] edifice its cross-cultural utility." Thus, the use of term *Eugenic Atlantic* is instrumental in describing how "*the discourse of disability functioned in a diasporic manner*" in the transnational phenomenon that was eugenics and, as a result, permitted scientists and other professionals both in Europe and North America to justify oppressive social, political, cultural, and economic policies based on the argument that racial difference represented pathological defect.

THE ENFREAKMENT OF POPULAR CULTURE: DISABILITY AS RACIST DISCOURSE

Disability's central role as the ideological discourse deployed so as to legitimate racist oppression in the early twentieth century via the practices of colonialism and slavery was played out on hundreds of stages across the country in the form of freak shows. It was at these freak shows that race and disability were brought together via the creative, dishonest, and exotic maneuverings of opportunistic show managers. Scholarship on the U.S. freak show meticulously records the chicanery rampant in these shows where disabled people of color, especially those with mental retardation from other parts of the world, were exhibited in the exotic mode as "savages" and "cannibals." These studies cite several examples of occurrences such as the "Wild Australian Children," who were the African Americans Tom and Hettie, severely retarded microcephalic siblings from Circleville, Ohio; the "Wild Men of Borneo," who were Hiram and Barney Davis, listed in court records as "dwarfs" and "imbeciles" who came from a working-class farming family in Ohio; the "Last Ancient Aztecs of Mexico," who were El Salvadoran peasant children, Maximo and Bartola, bought by a Spanish trader on account of their "dwarfish and idiotic appearance"; and, perhaps the most famous of all, the "What is it? or The Man Monkey!" exhibit, who was William Henry Johnson, an African American from New Jersey with microcephaly.

Other freak show scholarship defines the public's encounter with the "freak" as one where the audience crosses both corporeal and psychic boundaries to experience the terror and the excitement of coming face-to-face with examples of "monstrous" humanity while being reminded of the "unbearable excess that has to be shed to confer entry into the realm of normalcy" (Adams 2001). If this is the case, it is possible to see the significant role that freak shows played in the ideological construct of racial discourses when the exhibits just described as both disabled and racially marked were exhibited as subhumans, cannibals, and savages. To give credence to these racist mythologies, disability studies scholars describe how show managers designed publicity materials, stage settings and props, and a colorful commentary to advertise and exhibit the exotic aspects of their exhibits while contributing to racist knowledge by linking race, disability, and subhumanness all together.

For example, publicity materials for the American Museum, responsible for exhibiting Johnson as the "What is it? or the Man Monkey!" took advantage of the public's interest in the relation of humans to primates to describe Johnson as the connecting link between human and ape. Foregounding his physical features that were a result of his microcephaly, Johnson's "keeper" is quoted as saying, "The formation of the head and face combine that of the native African and of the Orang Outang . . . he has been examined by some of the most scientific men we have, and pronounced by them to be a CONNECTING LINK BETWEEN THE WILD NATIVE AFRICAN AND BRUTE CREATION." Thus, one can see how freak shows drew on scientific discourses of disability, the racial politics of the era, and fears of a public steeped in eugenic thought to produce a discourse that justified and thereby propagated race and disability inequality.

Because persons of color were often seen to dominate freak shows, it is often assumed that a predominantly white audience was attracted to these shows to encounter the deviance of the racial freak. This was not always so. On the other hand, these shows were mostly frequented by populations who were otherwise disenfranchised in U.S. society and who derived some comfort from the sight of Other bodies radically different from their own. Other scholars point out, however, that encountering the freak show produced not just the repudiation of difference but sometimes a painful identification with the object of difference—the Freak. Thus, disability studies reports that when African American audiences came face-to-face with "Ota Benga: The Pygmy in the Zoo," they were faced with "the monstrosity of U.S. racism embodied in the spectacle of a black man in a cage." It is narratives such as these that demonstrate the very painful relationship between race and disability for African Americans, in particular, and people of color, in general.

RACIALIZED SUBJECT AS DISABLED CITIZEN: THE DISCIPLINARY PRACTICES OF THE NATION-STATE

Likewise, some critical race theorists have argued that for a nation to be itself, it has to be perceived as racially and culturally pure. Thus, to come into being, the nation-state embarks on an obsessive imperative of setting up a "stigmata of exteriority and impurity" and, in doing so, produces a double-edged racism—a racism of extermination to purify the social body from the dangers of inferior races (an exclusive racism) and a racism of oppression and exploitation to hierarchize and partition society (an internal racism). What these studies do not explicitly say is that, once again, the category of disability is deployed by the nation-state to police its borders to keep "unfit" immigrants from entering and to control "unfit" citizens who are seen as a threat to the nation-state.

For example, the nation-state supported immigration laws and regulations that drew on discourses of disability by requiring checks on the mental competencies of newer immigrants. Thus, scholars describe how immigrants were faced with batteries of tests at Ellis Island, in an effort to screen for "mental defectives." Similar practices have been reported in Canada, where immigration policies drew on the profession of psychiatry and invoked concepts such as lunacy and idiocy to exclude certain categories of citizens to maintain a more "sanitized" Canadian society. That these practices are not just historical but have contemporary relevance is apparent in Richard Herrnstein and Charles Murray's (1994) book, *The Bell Curve*, which recommended that immigrants be allowed into the country based on an IQ test. Critical of the 1965 Immigration Act that allowed previously excluded immigrants into the country to be unified with their families, Herrnstein and Murray argue that immigration should not be based on what they call nepotism but on competency. Herrnstein and Murray's arguments could be dismissed as the surviving relics of eugenic practices of the past that are now no longer in vogue, but recent policies related to immigration belie that claim. Thus, for example, Proposition 187, which denies vital and legally guaranteed services to anyone suspected of being an illegal immigrant, was passed with overwhelming support in California and funded by a foundation that backed race-based intelligence research. In the most recent election of November 2004, Arizona passed a similar bill that was on the ballot. Thus, once again, it is possible to see that social categories of race and disability are deployed together to police the boundaries of the nation-state.

Birth control is another example of how the ideological category of disability is deployed by the nation-state in its attempts to police the bodies of its racialized citizen-subjects in very intimate ways. At the height of the eugenics era, the state, drawing on eugenicist fears of the deterioration of the Caucasian race, sought to control the reproductive capacities of those it deemed "deviant" and therefore dangerous. Thus, in the early twentieth century, a large number of poor white people, along with Native Americans, Puerto Ricans, Chicanas, and African Americans, were forcibly sterilized in an era that was obsessed with issues such as "racial hygiene" and the spread of "feeblemindedness." While overt sterilization of these populations is no longer in vogue today, several scholars have argued that new discourses, such as "gene therapy" and "health care rationing," and new birth control technologies, such as Norplant and Depo-Provera, are imposed mostly on poor women of color on welfare who, because of their "dependency," are deemed to be unfit for reproduction. Thus, even though birth control drugs such as Depo-Provera were banned in 1978 because of the side effects, which included cancer, long-term sterility, and osteoporosis, to name a few, Depo-Provera reappeared in the late 1980s and was still being prescribed by doctors to poor women of color in cities and to Native American women living on reservations. In addition, current scholarship cites an early 1990s report on HIV-positive Haitian women held at the naval base at Guantanamo Bay being forced to choose between Depo-Provera or permanent sterilization while in captivity.

But the nation-state not only justifies its control of its citizens of color by deploying the category of disability; it also contributes to the construction of disabled citizens of color. In both urban and rural United States, for example, poverty conditions, lack of access to affordable health care, rampant unemployment, and violent neighborhoods contribute to the onset of disability in communities of color living below the poverty line. In addition, working-class communities of color, especially migrant workers—many of whom are considered undocumented immigrants—labor in factories, sweatshops, and nursing homes where wages are low and where working conditions can create disabilities. Moreover, in the armed forces, where many poor and working-class people of color enlist, deployment in a war also produces disability. In each of these contexts, then, there exists a population of disabled people of color who were either born with a disability or acquire a disability during their lifetime and who are therefore forced to negotiate double oppression on account of both their race and their disability. This experience of double oppression has been especially well documented in the United Kingdom by disabled scholars of color. In each of these accounts, what is often foregrounded is that their oppression, on the basis of disability, is often compounded by their racial affiliation in areas such as employment, access to culturally responsive services, and resources. Sometimes, they have even experienced social and cultural marginalization in both their racial/ethnic as well as disability communities. It is in such contexts that the need to examine race and disability in dialectic relationship to each other becomes a necessity for survival.

SPECIAL EDUCATION AS RACIAL GHETTO: THE DIALECTICS OF RACE AND DISABILITY

The dialectical relationship between race and disability is clearly foregrounded in the specific context of education. Advocates for the inclusion of persons marked by race and/or disability in educational contexts have drawn on similar philosophical and constitutional arguments to frame educational policies that support this inclusion (e.g., *Brown v. Board of Education* [1954] and the Education of All Handicapped Children's Act of 1975, now renamed the Individuals with Disability Educational Act [IDEA] of 1990). More recently, race and disability have once again reappeared together on the educational stage in recent court cases (e.g., *Lee v. Macon Board of Education,* Alabama), in which critiques have been made regarding the overrepresentation of minority students in segregated special education classes. This, however, is not a recent phenomenon. As early as 1968, educational research pointed out that nearly 60 to 80 percent of students labeled mildly mentally retarded were from "low-status backgrounds" and included African American, Latino, and Native American children. Nearly 20 years later, in the Woodstock Report of 1993, F. D. McKenzie, a former superintendent of schools in the District of Columbia, observed that although African American students made up approximately 16 percent of the school population, they made up 35 percent of the students assigned to special education classes.

This overrepresentation of students of color in special education classes can be accounted for in different ways. Recent scholarship has described how the predominance of asthma and lead poisoning among poor children contributes to neurological damage that manifests itself as mild disabilities and behavioral disorders in schools. In terms of race, 36.7 percent of African American children compared to 17 percent of Latino children and 6.1 percent white children have been identified as experiencing lead poisoning. Such statistics point to environmentally induced damage that is a direct result of inadequate housing, health care, clean air, and other basic necessities. Students of color also get banished to alternative schools (special education programs for students identified as "behaviorally disordered" or "emotionally conflicted") as a result of the new zero-tolerance policies that were put into place after the slew of school shootings by white students in middle-class suburbs in the United States. Ironically, once again, students of color, especially African American and Latino males, were the ones most often disciplined as a result of this law. According to a study undertaken in 2000, when all socioeconomic indicators are held constant, African American children were noted as being suspended and expelled at much higher rates than white students within the same schools. In both examples, what becomes apparent is that students of color are increasingly "pathologized" in schools—a practice that has become a lucrative business where professionals interact with these children armed with a battery of tests, boot camps, and other behavior management programs that are more profitable to the professionals than to their clients.

George W. Bush's plan for education, which claims to "leave no child behind," furthers supports the oppressive relationship between race and disability. One important aspect of the Bush Education Plan is Project Sentry, whose main goals are to identify, prosecute, punish, and supervise juveniles and to empower teachers to remove violent and disruptive students from the classroom. Such policies draw on philosopher Louis Althusser's concept of "interpellation"—where *interpellation* is the process by which individuals (subjects) are inserted into practices governed by the rituals of ideological state apparatuses (ISAs) such as schools. Thus, it could be argued that schools use the logic of disability to "interpellate" students of color into "disabled" subject positions that marginalize them in both educational and social life. In other words, understood in a racialized context, special education programs become the most effective way of disciplining, regulating, and controlling students of color and teaching them their places within a racial and class hierarchy. By bringing into line through special education those who comply with ideological mandates, as well as by excluding and containing those who insist on staking their claim for recognition as human beings, these policies become the most effective way of supporting the *racialization of disability* and the *disabilization of race* in the ghettoes of special education. Thus, it is in the interests of theorists working on race and disability to continue to pursue collective deconstruction of social categories of difference to ensure their collective empowerment.

RACE, DISABILITY, AND SPECIAL EDUCATION

The long-standing and problematic relationship between race, disability, and special education continues to be evident in the disproportionate placement of students from racial and ethnic minorities in special education programs. Landmark legal cases such as *Diana v. State Board of Education* (1970) and *Larry P. v. Riles* (1971–1979) challenged biases inherent in standardized testing procedures used to identify students as eligible for special education. In *Diana,* a class action suit was filed on behalf of nine Latino/Latina children who were forced to take an individually administered IQ test in English and, as a result, were classified as EMR (educable mentally retarded). Interestingly, when retested by a Latino examiner, only one of the nine children was classified as EMR. In a similar suit, *Larry P.,* the overrepresentation of minority children in EMR classes throughout San Francisco, was determined to be due to educational practices, including teacher bias. Both cases illuminated the role of school personnel, tests, and testing practices in erroneously labeling students of racial and linguistic minorities as disabled and placing them in segregated special education classes. These legal cases demonstrated how special education, like ability tracking, served as a mechanism to resegregate classrooms after the historic *Brown v. Board of Education* (1954) ruled that racially segregated schools were unconstitutional.

These cases drew attention to the ways that special education labeling and placement decisions reflected stereotypic beliefs about white intellectual superiority. Both *Diana* and *Larry P.* called into question the widespread use of "scientifically" objective measures to gauge intellectual ability. The intelligence quotient (IQ) score that had once been viewed as measuring innate, fixed, unidimensional, and naturally distributed "ability" along racial and class lines would now be cast in a different light. As a result of these cases, it became increasingly clear that evaluation instruments and their use falsely reinforced presumed intellectual hierarchies among racial and ethnic groups. Although tests continued to be seen by many as relatively neutral and valid, others came to view standardized tests as forms of institutionalized racism, based on cultural and linguistic biases and norms and predicated on the supposedly universal values and experiences of American, white, middle-class citizens. Because the special education eligibility process typically begins with teacher referral, the widening racial imbalance between the teaching corps and an ever-more diverse population of public school students remains a concern. Recent reports show that 90 percent of public school teachers in the United States are white, while 40 percent of public school students in the United States belong to racial/ethnic minorities. Because cultural, social, class, and linguistic biases often influence teacher perceptions of students' ability, students from racial/linguistic minorities continue to risk having their differences pathologized when measured against exclusionary and ethnocentric norms and standards.

Despite reforms, a disproportionate number of students from racial, ethnic, and linguistic minorities continue to be placed in special education classes. Since the early 1970s, the U.S. Office of Civil Rights (OCR) has reported a persistent problem of minority children being overrepresented in *certain* disability categories. Specifically, racial disparities are highly pronounced in categories requiring specialized clinical judgment. These categories include Mental Retardation (MR), Emotional Disturbance (ED), and Learning Disability (LD). Thus, "invisible" and more subjective disabilities of a cognitive and/or social nature are overly ascribed to racial and linguistic minority students, while less subjective categories such as blindness or deafness are ascribed proportionately to all student groups. In other words, overrepresentation is much more pronounced for more subjective special education labels than in diagnoses that are more obvious or objectively determined.

The most recent government reports reveal that although blacks constitute 14.8 percent of the population, they represent 20.2 percent of all students in special education. Black students remain three times as likely to be labeled MR as white students, two times as likely to be labeled ED, and almost one and a half times as likely to be LD. In fact, black students remain the most overrepresented of all groups in 10 out of 13 disability categories nationwide. Among these categories, MR remains most likely to be assigned to black male students. Furthermore, black students who attend school in wealthier communities are more likely to be labeled MR and assigned to segregated classes than those attending predominantly black, low-income schools. Thus, depending on context, both social class and racial biases can increase the risk of minority children being labeled and placed in segregated classrooms.

The category of LD has also been deeply implicated in the problem of overrepresentation. The label, which emerged during the 1960s, characterized a student with LD as having average or above-average intelligence, specific rather than generalized deficits, and a cultural/familial background unrelated to the academic difficulties experienced in school. This category became associated with white students to such a degree that students of similar levels of achievement were given different labels along racial, ethnic, and class lines. In fact, in the first 10 years following the emergence of the category (1963–1973), the vast majority of students labeled LD were white middle-class boys. Because students were placed in separate classrooms according to their label/disability category, special education became as racially segregated as general education had become with the practice of "ability" tracking.

In states with high Latino/Latina or Native American populations, these students are more likely to be overrepresented in special education.

Data on Latino/Latina students are complicated by the fact that they tend to be underidentified for special education in elementary school but overidentified in high school. Furthermore, students who are English language learners (ELL) or labeled limited in English proficiency (LEP) are overrepresented in special education, especially in the upper grades. Once labeled, minority students are educated in more restrictive/segregated placements in comparison to their white peers. An exception to this trend is the underrepresentation of Asian American students with disabilities. Stereotyped as the "model minority," Asian students are far less likely to be labeled in subjective categories of MR, ED, or LD than any other minority group. Further research is needed to determine if there are within-group differences, especially among newly arriving Asian immigrants, or if there are differences in schools with and without English as a second language (ESL) classes.

Inappropriate classification of racial/ethnic/linguistic minorities for special education leads to lowered achievement and poor postschool outcomes. Students in segregated special education classrooms are denied access to the general education curriculum and their typically developing peers. Often, the instruction provided in segregated classrooms results in poor transition outcomes after the child leaves school. Finally, the child is more likely to experience lowered teacher expectations as a result of being labeled. These factors combine to negatively affect the academic performance of students of color who are labeled disabled, who have higher rates of suspension, face more severe disciplinary actions, and experience a higher dropout rate compared to their white and/or nondisabled peers. It has been documented that failure to obtain a high school diploma further restricts occupational opportunities and leads to the increased likelihood of poverty. These problems are not diminishing but rather are starting earlier with children from economically poor, black, or Latino/Latina families being labeled with the ill-defined "at-risk" category even before they enter school.

Although many have suggested that socioeconomic status accounts for some or even all of the racial disparities in special education identification, the problem cannot be explained by any one factor. There remain large variations within district-to-district and state-to-state levels of overrepresentation in special education, suggesting that the degree of overrepresentation is affected by many variables and contexts. Southern states, for example, continue to have some of the highest incidents of disproportionality, regardless of social class, suggesting that overrepresentation is connected to a longer legacy of racial segregation. Moreover, there are substantial within-group differences, in terms of gender and age of diagnosis. Black females, for example, are less likely to be overidentified than black males but more likely to be labeled than white females and males. In addition, when language is taken into consideration, Latino/Latina students who are learning English are much more likely to experience overrepresentation. Such within-group differences point to an urgent need for more sophisticated research methodologies to fully understand the relationship of race, disability, and special education. Finally, in this era of high-stakes testing, we must also consider how many of our current educational practices are serving as tools of social control and exclusion rather than as tools of social transformation and democracy.

RACIAL HYGIENE (*RASSENHYGIENE*)

The German concept of "racial hygiene" was the predominant term for *eugenics* until the end of the

Third Reich (1933–1945). It comes from physician Alfred Ploetz (1860–1940), who founded the Deutsche Gesellschaft für Rassenhygiene (German Society for Racial Hygiene) in 1910, the main organization of the racial hygiene movement. It committed itself to the introduction of eugenic measures such as marriage bans, forced institutionalization, and sterilization of the supposedly hereditarily ill, alcoholics, and criminals. German racial hygiene, which presents a specifically radical variant of eugenics in comparison to international development, is rooted in racial anthropology. This approach influenced German eugenics/racial hygiene considerably. The French aristocrat Joseph Arthur de Gobineau (1816–1882) formulated the basic ideas of racial anthropology. He started from the assumption that only white, Aryan, Germanic, or "Nordic" races are culturally constructive; all other races are culturally destructive. Racial anthropologists were convinced that racial differences are objective facts. Skull measurements and the diagnosis of other bodily characteristics established so-called racial types, such as the white, black, red, or yellow race. Specific cognitive and spiritual qualities were attributed to individual races. Racial anthropologists believed that miscegenation would lead to the inevitable downfall of the Volk. A strongly hierarchically organized social model was therefore designed in which the upper strata of society dominated as the noblest race. Selection, the battle for existence, and measures against degeneration promoted the "Nordification" (*Aufnordung*) of the race. Racial anthropological approaches pushed forward nationalist thinking and were connected with an extreme anti-Semitism. Main representatives of this extreme line of thinking were engineer Otto Ammon (1842–1915) and doctor and philosopher, Ludwig Woltmann (1871–1907).

Racial anthropology gained influence in Germany before and during World War I in nationalist circles and also determined the eugenic/racial hygiene movement of the Weimar Republic. With their seizure of power in 1933, the National Socialists fell back on a multitude of already existing eugenic, racial hygienic, and racial anthropological proposals for the improvement of the *Volkskörper* ("body of the Volk"). In 1931, the Nationalsozialistische Deutsche Arbeiterpartei (NSDAP) (National Socialist German Labor Party) became the first party in Germany that incorporated racial hygienic thinking into its political program. It strove for a rapidly growing population that consisted of "racially pure," "hereditarily healthy," "Aryan," and productive individuals. To achieve this, the carriers of "foreign" blood should be eradicated. "Foreign" for the National Socialists included those who carried either "hereditarily" or "racially" so-called inferior blood. Many laws were enacted to fulfill these objectives. Already in July 1933, the *Gesetz zur Verhütung erbkranken Nachwuchses* ("Law for the Prevention of Hereditarily Diseased Offspring") was passed, which, in contrast to the drafted sterilization law of the Preußische Ministerialverwaltung (Prussian Ministry of Administration) from 1932, provided for compulsory sterilization. In November 1933 came the *Gesetz gegen gefährliche Gewohnheitsverbrecher* ("Law Against Dangerous Habitual Criminals"), which allowed not only the sterilization of repeat offenders but also the castration of sex offenders. In total, about 400,000 people were forcefully sterilized by 1945, more than in any other country in which a sterilization law existed. In addition, from the beginning, National Socialist politics were focused especially against Jews and gypsies. The first measures taken were the systematic destruction of the economic existence of the Jewish population and the racially biological registration of the Sinti and Roma (gypsies), who were confined in work camps as so-called asocial people and often also sterilized. In 1935, various laws followed that forbade marriage between *Deutschblütigen* (those of "pure" German blood) and Jews, as well as between the "hereditarily diseased" and "hereditarily healthy." In *Beratungsstellen für Erb- und Rassenfragen* (advice centers for heredity and race questions), hereditary and racial "inferiors" were identified. In this way, essential preconditions were put into play, leading to the Holocaust of the Jews and the "euthanasia" action on disabled people.

RACISM

Racism remains, in many minds, a term whose ultimate definition is but vaguely understood. Identification of absolute instances of racism is still contested in scholarship and public discourse much in the way that charges of ableism (or disableism, in some vocabularies) now often prove hotly contested. However, an examination of the development of racism can also demonstrate that a history of systemic discrimination against people with disabilities develops in a somewhat parallel manner. In both cases, the discrimination faced by these populations (not to mention those who find themselves marked as racialized *and* disabled) functions in a much more pernicious manner than mere active group snobbery. Before we can parallel these types of oppression, however, a working definition of racism should be outlined.

Scholars have suggested that formalized racism can be recognized whenever the following conditions exist: (1) publicly sanctioned restrictions on a group's ability to participate in wider social rituals and institutions, (2) formalized segregation policies, (3) demotion to lower caste/class status of a majority of group members, (4) active circulation of propaganda that bolster perceptions of inferiority, and (5) the deepening of legal prejudice over time and, perhaps most important, fears of reproductive contamination. The latter point is key because formal racism—at least our own modern variety—operates as a social guarantee that race purity will be actively policed and maintained. Prohibition from reproductive participation (i.e., miscegenation or sterilization laws) erupts from a belief that one group of individuals represents a biological threat to the integrity of the species. In other words, rather than subordinating an entire group on the basis of faulty beliefs, such as in cases of religious bigotry, modern racism may be said to operate on the principle of in-built inferiorities that cannot be overcome. Such differences (particularly of a visible, physical nature) become a racist formation when characteristics that might be considered "cultural" become associated with innate (i.e., biological) features. This is the key linkage between racist and ablest beliefs—group-based inferiority appears indelible and biologically encoded.

Scholars of the history of racism have placed the origins of such practices somewhere in the fourteenth or fifteenth centuries—specifically, in early modern Spain, when religious intolerance gradually transformed into forms of body-based intolerance. While religious antipathy for another group expressed itself in persecution based on adoption of the wrong faith, there was little sense that such differences were intrinsic to a population's bodily constitution. The key qualifier here depends on the capacity of a despised population to assimilate (even theoretically) to the persecuting culture's status—either through rituals of conversion, renunciation, shifts in habits, ways of communicating, and so on. If members find a way to become integrated into the dominant community, then a racist system may not be operative. Of course, this also suggests that modes of assimilation are primarily cultivated through efforts by members of stigmatized groups to actively participate in the devaluation of their former culture's values, aesthetics, attitudes, practices, and so forth. In other words, the demands of assimilation require a stigmatized member to recognize his or her prior self as inferior. There is a hierarchy of communities that individuals learn to solidify and substantiate in the process of assimilation.

Yet, in the case of racism, such an avenue of escape is closed. Members of the stigmatized group find themselves positioned in an impossible coexistence with the dominant group—specifically, an existence that requires their simultaneous sequestration and subordination. In such a situation, segregated locations—such as reservations or custodial institutions—become a metaphor for the group's individual as well as collective predicament. Identity itself becomes fixed, and ethnic or racial differences cannot be mobilized beyond the boundaries of deviancy established by the enforcers of the norms. No transcendence of one's racial circumstances avails itself, and thus cultural differences transform into markers for inferiority itself. Thus, the superiority of one group is based on a subjective valuing of arbitrary qualities it associates with itself in contradistinction to another (i.e., pigmentation). The presumed characteristics of the marginalized group become synonymous with subjective values of undesirability.

Just as Carolinus Linnaeus sorted vegetation into particular species groups in 1735, he also classified human populations into distinct racial types. While this racial taxonomy was not delineated as hierarchical, the characteristics attributed to each population supported perceptions of northern European superiority. The practice of drawing distinctions based on biological characteristics began as early as the fifteenth century in campaigns such as the Spanish policy of requiring blood certificates (or *limpieza de sangre*), where ethnic belonging became increasingly biologized. Such efforts, not coincidentally, paralleled the rise of modern nation-states, where connections began to be drawn between the attributes of individual physiology and the nation's body as a whole. In each of these cases, we witness the formation of investments in biological determinism where one's birthright preordains some members to increased social status; others inordinately comprise the lowest spheres of social hierarchy—including economic immobility and lack of access to influential social institutions. Thus, the Enlightenment arrived replete with ideological investments in "proving" that social hierarchies exist due to the in-built incapacities of some as opposed to the natural abilities of the fully enfranchised.

While formalized racism has been reported to exist on the basis of group-based limitations that cannot be overcome, physical, sensory, and intellectual differences—often designated today as disabilities—also began to serve scientific systems of differentiation. No longer did those labeled "deviant" exist within relatively amorphous groupings such as the "monstrous," the "crippled," or as "fools," but rather the eighteenth century oversaw the rise of individuated human taxonomies. Debates over the relationship of racial characteristics as environmentally produced effects of climate and geography ultimately lost support in the wake of more biologically determinist models. Thus, human divisions, as expressed in Linnaeus's racial classifications or in the arguments against polygenesis (the development of separate, distinct bloodlines across racial groups) offered by Blumenbach in 1771 and others later in the century, laid the groundwork for discriminatory beliefs about bodies/minds designated as inferior. Consequently, one can witness the parallel cultivation of empirically based hierarchies based on racial, ethnic, and functional identifications in this period. In all cases, a group's failure to thrive socially came to be increasingly associated with in-built insufficiencies rather than cultural inequalities.

Even within the most liberal schemes of their day, those identified as possessing inferior anatomies were used to justify "progressive" science. For instance, single bloodline arguments that situated all peoples as participating in a shared human origin (usually placed in Africa) positioned racial (i.e., "savage") and disabled (i.e., "feebleminded") populations as "proofs" of common human ancestry with animals. In *Descent of Man* (1871), Darwin, the great champion of shared species origins, employed racialized and microcephalic populations as key evidence of primordial "arrested development" in his influential, mid-nineteenth-century theory of evolution. Likewise, his cousin, Sir Francis Galton, coined the term *eugenics* (Latin for "good seed") by arguing that breeding practices in horticulture and animal husbandry could be applied to the artificial cultivation of superior races of human beings. In making such arguments, nineteenth-century science, particularly after the rediscovery of Mendel's recessive/dominant theory of inheritance, rejected a previous era's metaphorical investments in blood as a "carrier" of magical properties in favor of a more literal hereditary vehicle (i.e., germplasm and later genes).

Thus, the late nineteenth and early twentieth centuries increasingly paved the way for science to influence public policy with respect to restrictive legislation toward "flawed" biologies: Jim Crow–era miscegenation laws, marriage laws, coerced institutionalization, segregation, sterilization, and, ultimately, under German National Socialism, state-sponsored murder of disabled, sexually "deviant," ethnic, and racial populations. As historians of racism have argued, the great irony of such developments occurred with respect to "radical" social discourses of human equality and formal emancipation efforts to free marginalized populations from various forms of enslavement. Thus, racism, homophobia, sexism, and ableism all come to fruition as a "back-door" form of discrimination that undermines more egalitarian principles of "all *men* being created equal." The perpetuation of social inequalities, consequently, functions in tandem with scientific justifications of biologically based insufficiencies. The more we classify, the farther we seem to get from a realization of just societies. The history of racism helps to demonstrate—at least to this point—that empirically sanctioned differentiations between individuals and populations inevitably lead to more "modern" forms of inequality (i.e., ideologies and practices that sanction socially derived inequalities on the basis of biologically deterministic criteria).

Late twentieth-century arguments about the fiction of race have been recently championed as a reversal of such trends. If genetic variation between human beings is no greater than 0.01 percent, then investments in genes as the basis for population differentiation based on innate capacities may finally fail from lack of a true biological basis. However, given our modern predisposition for investments in differentiation inherited from the Enlightenment, new efforts to define a distinctive racial genome seem to renew, rather than undermine, biologically encoded distinctions across human communities. For instance, witness recent efforts to establish racial genome banks in order to sponsor a racially specific health care research industry. While science may have lost some ability to sponsor and steer state policy-making agendas since the heyday of eugenics, investments in empirical taxonomies of inferiority based on characteristics marked as racial and/or disabled still garner a great deal of sway over aesthetic and cultural value systems.

RAMABAI, PANDITA

(1858–1922)

Sanskritist and social reformer

Pandita Ramabai was a Sanskritist who earned the honorific "Pandita" from the male scholarly community of her time, an almost unique achievement. She travelled to Oxford to study medicine, but her health deteriorated, and impaired hearing prevented her from enrolling at medical college. Instead, Ramabai became an aggressive campaigner for the social uplift of women in India and established a home for child widows at Kedgaon. Ramabai embraced some Christian beliefs that she integrated with her personal selection from the ocean of Hindu faith and practice, thereby infuriating the orthodox of both religions. She started a mission organization with both Indians and Westerners working under her leadership, another scandalous arrangement in her time. A deaf widow who wanted to join the Kedgaon community had difficulty convincing Ramabai but eventually overcame her resistance and proved willing and competent at work and worship. Apart from her own substantial writings, there is a large hagiographic literature about Pandita Ramabai, in which her significant hearing impairment is almost entirely ignored.

RAPE

Rape is a sensitive and complex topic. A comprehensive discussion of rape must take into account the legal, medical, psychological, and emotional issues that result from this act. When exploring the experience of rape from the perspective of individuals with disabilities, the complexities increase, and several key issues emerge. One major problem is that numerous definitions permeate the literature for sexual violence, sexual abuse, sexual assault, and rape. While there is a sizable body of literature on rape and sexual abuse in the general population, there is very little literature on rape in the disability community.

The following discussion provides the reader with a better understanding of the issues surrounding terminology. In addition, it provides an overview of what is known about risk factors for rape in the disability community, as well as prevalence estimates of rape. The last section highlights gaps in our current understanding of rape and disability. Furthermore, it suggests directions for future research efforts. These include the benefits of using the social model of disability to understand how social and cultural forces negatively affect the abilities of disabled survivors of rape to move beyond this experience.

THE LANGUAGE OF RAPE IN DIFFERENT CONTEXTS

When attempting to understand rape, in any context, it is important to first identify the words used to represent this act, why they are used, and what they mean. This task is important because language has power, and the ways in which we use language give insights into the social and cultural meanings of behavior. Thus, the way terms such as *sexual abuse, sexual violence,* and *rape* are used gives us insights into how society views appropriate and inappropriate sexual behaviors within and across communities.

No formal definitions were identified in the literature for the term *rape* in a disability context. This is not to say that the term *rape* is never seen; rather, it is used as part of a larger discussion of sexual abuse. Within the disability context, rape is subsumed under the labels of *sexual violence* and *sexual abuse.* These definitions are critical for understanding how the intersection of rape and disability is interpreted across contexts (e.g., the legal system, the medical system, the social service system, and within a social network or societal context). One must also note that not only are definitions different, but the nature of the content is different as well. For example, a general definition of sexual abuse "includes molestation, incest, rape, prostitution, or use of a child for pornographic purposes" (*Columbia Encyclopedia* 2001). This definition provides a laundry list of inappropriate sexual behaviors but does not necessarily leave us with a better understanding of what sexual abuse means. A more useful definition for sexual abuse among individuals with physical disabilities comes from the Center for Research on Women with Disabilities. In this definition, sexual abuse is "being forced, threatened, or deceived into sexual activities ranging from looking or touching to intercourse or rape" (Cole 1984; Soeken et al. 1998; Nosek et al. 2001). When referring to individuals with developmental disabilities, sexual abuse has been defined as "occurring where sexual acts are performed on or with someone who is unwilling or unable to consent to those acts" (Brown and Turk 1992) or "being forced, threatened, or deceived into sexual activities ranging from looking or touching to intercourse or rape" (Young et al. 1997). "Sexual abuse of a person with learning disabilities can take place where that person's willingness is unacceptably exploited" is another definition that warrants inclusion in this discussion. This definition is useful in that it moves away from the complexities of consent. It acknowledges that while a developmentally disabled person may willingly engage in a sexual encounter, the act may still be abusive because of the motivation and position of the other person (McCarthy and Thompson 1996). However, from a disability studies perspective, it is troubling in that it seemingly negates a disabled individual's ability to consent in instances where he or she willingly participates in a sexual encounter that is not abusive.

Studies of sexual violence among nondisabled individuals distinguish between sexual abuse in childhood and sexual assaults and/or rape in adulthood. In studies of sexual violence among the disabled, this differentiation of terms does not occur. Specifically, in a disability context, *sexual abuse* is commonly used to describe sexual violence rather than *rape.* One possible explanation for this is the pervasive view of disabled individuals as childlike and powerless. Since sexual transgressions against children are defined as abuse, the able-bodied population perpetuates this usage for adults with disabilities. Another possible explanation for this misuse of terminology is that, like children, individuals with disabilities are viewed as asexual and undesirable.

The legal system offers definitions of two different types of rapes. The first type is simple rape, whereby the victim and attacker(s) have a prior relationship, there is a lack of force and resistance, and there is an absence of evidence corroborating the victim's account. The second type is aggravated rape, in which there is extrinsic violence, multiple assailants, and no prior relationship between victim and offender(s) (Estrich 1987). These distinctions become important in discussions of what happens within the legal system after a rape occurs.

Research conducted on rape within the general population shows that district attorneys are more likely to move forward in the prosecution of an aggravated rape than a simple rape. In cases of simple rape, societal attitudes about sexuality and promiscuity make successful prosecution difficult. In a disability context, the prosecution of simple rape is complicated further because of the societal misconceptions surrounding the sexuality and desirability of individuals with disabilities. In addition, able-bodied persons generally question the ability of a disabled person to consent to sexual activity and to act as a competent witness against the attacker.

THE STATISTICS OF RAPE WITHIN THE DISABILITY COMMUNITY

The overall prevalence of sexual abuse across the spectrum of disabilities is unknown. Research in this area suggests that women with disabilities are assaulted, raped, and abused at a rate two times greater than nondisabled women (Waxman and Wolfe 1999). According to the Centers for Disease Control and Prevention (CDC), the reported rates of sexual violence range from 51 to 79 percent against women with disabilities. When the discussion is limited to cognitively impaired individuals, there are wide variations in the reported prevalence rates of sexual abuse. For example, it has been suggested that women with developmental disabilities face a 68 to 83 percent chance of being sexually assaulted in their lifetime, a rate that is 50 percent greater than that for nondisabled women (Sobsey 1994; Waxman and Wolfe 1999). The CDC estimates that the reported rates for cognitively disabled individuals' lifetime experience of sexual violence range from 25 to 67 percent, which is significantly different than the aforementioned percentages. These variations result from differences in definitions of abuse, differences in populations sampled, and differences in research methodology (McCarthy and Thompson 1996). The discrepancies highlight the need for more research on this problem.

FACTORS PUTTING THE DISABLED COMMUNITY AT RISK

It is a common misperception that the disabled are not at risk of being raped. However, research has shown that disability is not a protective factor against sexual abuse. Rather, disability has been hypothesized to reduce an individual's emotional and physical defenses, making him or her more vulnerable to abuse (Nosek et al. 2001). Researchers have identified several factors that increase disabled individuals' vulnerability to sexual abuse, including dependency on others for long-term care, life in an institution, denial of human rights that results in perceptions of powerlessness, the perpetuator's perception of limited risk of discovery, the difficulty some survivors have in being believed, lack of education regarding appropriate and inappropriate sexuality, social isolation and increased risk of manipulation, physical helplessness and vulnerability in public places, and the emphasis on mainstreaming and integrating disabled individuals without evaluating their capacity to protect themselves (Andrews and Veronen 1993; Groce 2003). It has also been suggested that economic dependency greatly increases the risk of abuse among the disabled. Specifically, individuals with disabilities have fewer opportunities in the labor market than able-bodied individuals.

The overall lack of attention to the issue of abuse against the disabled by both violence and disability researchers has contributed to the invisibility and continuation of misconceptions regarding disability and victimization (Curry, Hassouneh-Phillips, and Johnston-Silverberg 2001). Moreover, while it is increasingly recognized among professionals that individuals with cognitive disabilities or mental illnesses are more vulnerable to sexual abuse and exploitation than the general population (Mansell, Sobsey, and Moskal 1998; Tharinger, Horton, and Millea 1990; Furey 1994), there continues to be limited recognition that the physically disabled are also at significant risk for being raped. For example, it has been suggested that the tendency for women with physical disabilities to be devalued by society is one reason that this group is not included in research on sexual abuse (Coleman 1997, in Curry et al. 2001). This assertion is indirectly supported by the fact that as recently as 2001, fewer than five studies examined the sexual abuse of individuals with physical disabilities (Curry et al. 2001).

Discussion regarding sexual abuse and the cognitively disabled focuses heavily on cognitively impaired individuals' ability to give consent and their competence to give evidence against their attackers. However, several dialogues are equally important and yet virtually absent from the literature. The first emerges from the recognition that discussions of disability and rape are specific to individuals within a disability category (e.g., physical or cognitive). There is little, if any, research that explores sexual abuse across disability types. This points to the need to explore what, if any, differences in service needs exist between physically disabled and cognitively disabled rape survivors. The second area that must be addressed is the identification of the emotional and psychological service needs of cognitively impaired individuals in the aftermath of rape.

GIVING VOICE TO RAPE SURVIVORS

The literature proves that we do not currently have a full understanding of disability and rape. Although sexual abuse and rape are increasingly recognized as significant problems for those with disabilities, research that gives a voice to the survivors of rape has not been conducted. The unique challenges that individuals with disabilities face in bringing charges against their attackers and accessing supportive services to assist them in moving forward with their lives are important topics that have been neglected. An integral piece to gaining understanding is a social model analysis of the intersection of disability and rape. A social model analysis lends itself to the identification and acknowledgment of social barriers surrounding rape: the barriers that isolate and impoverish disabled individuals and put them at risk for rape; the barriers to reporting rape; the barriers to prosecuting perpetrators of rape; the barriers to overcoming the physical, emotional, and psychological effects of rape; and the barriers to overcoming the shame and stigma that having been raped brings.

Proponents of the social model of disability view disablement as the consequence of society's failure to recognize and account for the differing needs of disabled people and to eliminate the barriers they encounter (Oliver 1996). One could also argue that society has failed to recognize that disabled individuals have significantly different risk factors for being raped. In addition, legal and social service systems are nearly impossible to negotiate for individuals with disabilities because they have different needs and abilities that these systems do not recognize. Therefore, a social model analysis challenges societal misconceptions about the disabled and calls for a better understanding of the rape experience within the disability community. The current lack of knowledge on this experience within the disability community denies rape survivors an opportunity to heal on multiple levels. First, it denies them the opportunity to find meaning through talking about their experiences. Second, it prevents them from accessing much-needed legal, medical, and social services following rape. Third, it prevents service providers from fully recognizing and understanding the barriers faced by this community in dealing with the experience of rape. Finally, this lack of understanding perpetuates the isolation of this already marginalized group of individuals.

Another crucial component of this analysis is the lived body experience of rape and disability. Throughout their lives, disabled people are routinely dehumanized by the medical system under the guise of correcting medical conditions and minimizing impairments. As part of this process, disabled individuals are forced to believe that they are not the experts on their bodies. Rather, it is the doctors and therapists who are the experts. This psychological framework, which leads many to try to escape their "deficient" bodies for normal ones, has significant consequences for the healing processes of disabled rape survivors. The reality of this statement is reinforced in the narrative of a disabled rape survivor. In the process of diagnosing her disability, she describes how she was accused of fabricating and exaggerating symptoms as a means of getting attention. The lack of support from family and the "experts" led her to question her authority over her body. Subsequently, while in college, she was raped. This experience, coupled with her lived body experience of disability, led to increased feelings of lack of authority over her body, which drove her to "escape" through drug use and other self-destructive behavior.

To truly understand the intersection of rape and disability, researchers must move beyond traditional research strategies that rely on surveys of service providers and family members of rape survivors. Specifically, researchers must engage in qualitative participatory research strategies that incorporate the experiences of disabled rape survivors in all aspects of the research design. It is only through the inclusion of those who have experienced both disability and rape that we can truly understand the experience.

RAU, FEDOR ANDREEVICH

(1868–1957)

Director of the Arnoldo-Tretiakov School for the Deaf in Moscow

Fedor A. Rau was director of the Arnoldo-Tretiakov School for the Deaf in Moscow. He was also the founder of special education training at the university level and organized the first Russian congress on deaf education in 1910. From 1922 to 1948, he was the head of the faculty of deaf education in the Moscow

State Pedagogical University and the author of many textbooks and manuals for deaf schools, including the *ABC Book for Deaf Children* (1903).

—Anna Komarova and Victor Palenny

See also Natalja Aleksandrovna Rau.

RAU, FEDOR FEDOROVICH (1908–1977)

Speech therapy specialist

Fedor F. Rau was a professor at the Institute of Defectology (now the Institute of Special Education) and a speech therapy specialist. Together with N. F. Slezina, he developed the "concentric" method of speech therapy.

—Anna Komarova and Victor Palenny

RAU, NATALIA ALEKSANDROVNA (1870–1947)

Founder of a kindergarten for deaf children

Natalia Rau, Fedor Andreevich Rau's wife, founded the first kindergarten for deaf children in Europe in 1900. After 1917, she worked as an inspector for a deaf children's kindergarten. In 1922, she organized lip-reading classes for deafened and hard-of-hearing people. She wrote *Pre-School Education of Deaf-Mute Children* (1947).

—Anna Komarova and Victor Palenny

RAY, ISAAC (1807–1881)

Father of American forensic psychiatry

Isaac Ray was one of a handful of men in mid-nineteenth-century America who were largely responsible for establishing the first generation of public institutions specifically aimed at serving the mentally ill population. Along with his fellow asylum superintendents (e.g., Pliny Earle, Thomas Kirkbride, Amariah Brigham), Ray supported the early optimism about the curability of insanity if individuals were housed in specialized hospitals carefully constructed along specific architectural plans, supported with generous funding by the state, supervised by a new class of medical professionals with expertise in mental illness, and handled according to the latest principles of "moral treatment." For 20 years, Ray served as the superintendent of the Butler Asylum in Providence, Rhode Island. In 1844, he was one of 13 asylum superintendents to gather in Philadelphia and found the Association of Medical Superintendents of American Institutions for the Insane (now the American Psychiatric Association). Ray published numerous articles throughout his career that were intended for both an audience of asylum administrators as well as a more general readership of policy makers and influential philanthropists. Ray, who had a special interest and wrote extensively on the need for the reform of criminal insanity laws, is sometimes referred to as the "father of forensic psychiatry."

RECREATION

Recreation is any pleasurable activity that is freely chosen. It is an activity that diverts, amuses, or stimulates. It is an activity that refreshes and recreates, that renews health and spirits by enjoyment and relaxation. Recreation can be done alone or with others, it can be active or passive, and it can be artistic or athletic. Recreation has both intrinsic and extrinsic benefits.

Recreation is an important part of life for all people. It is a powerful force in people's lives. Recreation makes people feel good about themselves and helps people to stay socially connected to other people. Recreation is revitalizing and rejuvenating. Research shows that higher levels of involvement in recreation activities are associated with increased ratings of well-being and life satisfaction. Yet, people with disabilities are often less involved in recreation. Some people with disabilities do not have access because of a lack of exposure to and training in recreation settings. There are myriad reasons, but the fact remains that people with disabilities are involved in recreation less than their typical peers.

Recreation enhances self-esteem and the quality of a person's life as well as the ability to occupy one's free time in a socially valued and acceptable manner, which has a significant impact on where a person is able to live, whether he or she functions successfully in the community, and the quality of relationships that a person develops. Social and recreation experiences have the power to generate skills that can be transferred to work, housing, family relationships, and so on. Thus, recreation experiences can facilitate an individual's successful integration into other spheres of life.

In practice, there are three distinct types of recreation services. They include *inclusive recreation* (often simply called recreation), *special recreation* (sometimes referred to as specialized or segregated recreation), and *therapeutic recreation* (also called recreation therapy). Each will be described below.

INCLUSIVE RECREATION

Inclusive recreation includes pleasurable activities or experiences in naturally occurring environments alongside people with and without disabilities rather than in settings that only include people with disabilities. In inclusive settings, necessary accommodations and supports are provided to ensure that people with disabilities can be involved on as equal a basis as possible. Even when the disability is too severe to "level the playing field," some people with disabilities or their advocates may choose an inclusive recreation setting in which "partial participation" is allowed.

Including people with disabilities in the fabric of life strengthens the community and its individual members. Recreation in naturally occurring environments rather than in special, segregated settings can offer flexibility, choice, self-determination, individuality, and decision making. Inclusive recreation experiences encourage and enhance opportunities for people of varying abilities to participate and interact in life with dignity. The availability of inclusive recreation provides the right to choose from the full array of recreation opportunities offered in diverse settings and environments.

For inclusive recreation to be effective, necessary support, assistance, and accommodations must be provided. This support, assistance, and accommodation must be responsive to each person's needs and preferences. Types of support, assistance, and accommodations include but are not limited to qualified staff, adaptive equipment, alternative formats for printed or audio materials, trained volunteers, and/or flexibility in policies and program rules.

In addition, to facilitate inclusive recreation, environments should be designed to encourage social interaction, risk taking, fun, choice, and acceptance that allow for personal accomplishment in a cooperative context. All physical and programmatic barriers should be eliminated to facilitate full participation by individuals with disabilities.

Inclusive recreation means that all recreation programs are available to all people, regardless of ability level. Ensuring that all people have equal opportunity to participate in recreation activities of their choice can be difficult. A detailed, systematic procedure to facilitate inclusive recreation is outlined in the LIFE (Leisure Is for Everyone) materials and can be found in Bullock and Mahon (1997).

Not everyone believes that inclusive settings and experiences are the best for people with disabilities. Some believe that it is better for people with disabilities to participate in recreation activities alongside peers with similar abilities. In that case, there are many opportunities for recreation involvement in special or segregated settings.

SPECIAL RECREATION

Special recreation is the provision of recreation services and programs in settings only with other people with disabilities. Necessary accommodations and modifications are made to assist the person with a disability to enjoy the activity. Many of these programs occur in municipal parks and recreation departments. Examples of other special recreation programs/activities include the Special Olympics and Wheelchair Sports.

For those who believe that it is best for people with disabilities to be with other people of similar ability levels, there are special or segregated recreation opportunities. Many people believe that it is necessary to first learn skills and have experiences in separate settings and then move to inclusive settings. Others believe that requisite skills can and should be learned in inclusive settings. Whatever the belief, in the United States, it is required by law (Americans with Disabilities Act) that when separate recreation programs exist, there must be options for participation in regular, typical (inclusive) recreation as well. For example, a local parks and recreation agency can offer beginning guitar lessons open only to persons with severe mental retardation; however, any person with severe mental retardation must be allowed to participate in the regular guitar lessons alongside people without retardation, and appropriate accommodations must be made to facilitate participation in the regular (inclusive) setting. Most special recreation programs exist in municipal parks and recreation departments, YM/YWCAs, Boy and Girl Scouts, and similar programs. The Special Olympics is one of the best-known examples of a separate program.

There is another category of specialized recreation programs. These are competitive sport programs for people with disabilities, such as wheelchair sports, that are not available to people who do not have disabilities. Competitive sport for people with disabilities can be traced back to the 1870s in the United States with the beginning of sport programs for students at a state school for the deaf in Ohio. However, sport programs flourished following World War II as a part of the rehabilitation of disabled veterans in the United States and Europe. The disabled sport movement grew steadily and is now characterized by national and international competitive events, the best known and respected of which is the Paralympics, which is held in conjunction with the Olympics.

THERAPEUTIC RECREATION

Therapeutic recreation is the purposive use of recreation/recreative experiences by qualified professionals (therapeutic recreation specialists) to promote independent functioning and to enhance optimal health and well-being of people with illnesses and/or disabling conditions. Therapeutic recreation often occurs in hospitals and other treatment facilities.

Therapeutic recreation is founded on the basic premise that recreation has therapeutic value. Various researchers have found that recreation experiences can assist people to manage and reduce the impact of stressors in their lives, to cope with the transitions of aging, and to maintain overall physical and psychological health. The National Consensus Conference on the Benefits of Therapeutic Recreation in Rehabilitation (1991), funded by National Institute on Disability and Rehabilitation Research (NIDRR), found that recreation had therapeutic benefits in (1) physical health and health maintenance, (2) cognitive functioning, (3) psychosocial health, (4) growth and personal development, (5) personal and life satisfaction, and (6) societal and health care system outcomes (Coyle et al. 1991:353).

As therapeutic recreation has evolved over the years, several different models, or sets of assumptions and beliefs, have emerged. For example, the “medical model” is based on the assumption that growth and development are biological processes that occur in a predictable fashion, that there is a “normal” and an “abnormal” way to grow and develop, that health represents an absence of illness or symptoms, that illness represents a breakdown of biological processes, that the goal of treatment is the removal of symptoms of illness, and that the health care provider possesses the knowledge, expertise, and ability to restore the individual to a state of health.

Working within the medical model, the recreation therapist would take the role of the expert who determines the problems to be addressed, the desired outcomes of treatment, and the specifics of how the intervention will occur. The goal of the recreation therapist’s interventions would be to remove or reduce the symptoms of the illness. The client’s role would simply be to comply as closely as possible with the therapist’s instructions and recommendations.

In contrast, a more “wellness-oriented” model is based on the assumption that growth and development are unique to each individual and occur in response to both internal biology and a supportive and nourishing environment; that “health” represents a full and optimal expression of the individual’s capacities and uniqueness, that illness occurs in response to an interaction between internal and environmental conditions and represents a restricted or limited expression of the self, that the goal of treatment is to enable the individual to fully experience his or her own uniqueness and health, and that the health care provider cannot control the process of healing but rather can only support it.

The recreation therapist working within a wellness model would tend to take the role of a facilitator and supporter. The recreation therapist would collaborate with the client in defining the problem, the desired outcome, and the means of achieving that outcome. The client, rather than being asked to comply, would be asked to be essentially an expert on his or her own health and asked to join actively with the therapist in their common pursuit.

Historically, most recreation therapists have worked either in hospitals or long-term care settings. More specifically, most recreation therapists have worked in psychiatric services, physical medicine services, or nursing homes. Today, recreation therapists work in a broader range of environments, including inpatient health care (hospital) settings in many service areas, outpatient health care settings, schools, and community- or home-based contexts. These contexts are described in detail by Kraus and Shank (1992).

THE PROCESS OF THERAPEUTIC RECREATION INTERVENTION

The practice of therapeutic recreation encompasses a wide and varied spectrum of individuals, interventions, activities, and contexts. “Clinical process” in therapeutic recreation provides consistency—that is, regardless of the context or content of the intervention, recreation therapists follow a systematic sequence of assessment, planning the intervention, implementing the intervention, planning for transition, and evaluation to systematically document the outcomes of their interventions. These processes and activities maximize the likelihood that the services provided by the recreation therapist are individualized, purposeful, outcome focused, and, ultimately, effective.

Assessment is the first step undertaken by the recreation therapist because it sets the direction for the “purposeful intervention” by enabling the therapist to focus specifically on the strengths, needs, and health concerns of the individual being served. Assessment may be defined as a systematic process of gathering and synthesizing information about an individual and his or her world to determine the most effective course of intervention. Some assessments are standardized, while some are more flexible, allowing the therapist more latitude in how and when to administer them. Generally, it is recommended that more than one method or instrument be used to gain the most accurate and complete “sense” of the individual. An effective assessment will provide information about the individual’s functioning at the beginning of the intervention, his or her desires and goals for intervention, and some possible ways to structure the intervention. It provides a “baseline” against which to measure progress and outcomes.

The planning phase (sometimes called “treatment planning,” “individualized program planning,” or “care planning,” depending on the setting) is one in which the strengths, needs, and goals of the individual, as well as the expertise and contributions of the therapist, are organized into a coherent plan that maximizes the chance that the individual will reach her or his desired outcomes. This phase of the therapeutic recreation process is often as much an “art” as a “science,” as it involves creatively and sensitively combining many elements of skill, timing, and relationship to achieve a positive and meaningful goal.

Many settings have particular guidelines or requirements for the development and formatting of intervention plans. In some settings, the recreation therapist will develop specific “recreation goals.” For example, “the patient will be able to fish independently” is a possible recreation-based goal for an individual who has experienced a stroke and needs to master the use of adaptive equipment to continue his or her most valued recreation pursuit, fishing. In others, the recreation therapist will develop goals pertaining to aspects of functioning that are more generalized and are attainable through participation in recreation pursuits. For example, “the client will reduce perceived levels of stress through increased physical activity" is a possible goal for an individual who is experiencing symptoms of anxiety disorder.

The next phase of the therapeutic recreation process is implementation, or the actual delivery of services. Recreation therapists have a wide spectrum of options for their interventions, allowing them to tailor to the needs of the individuals being served. A significant portion of the recreation therapist's training is devoted to studying and mastering these intervention options. Interventions may be conducted one-on-one or in groups. Ideally, the needs and preferences of the client and the professional judgment of the therapist should drive the decision about how services are offered, and many times, a recreation therapist will have the opportunity to work with a client in both one-on-one and group contexts, as needed. Each modality has advantages and appropriate uses. One-on-one services allow for maximum flexibility in individualizing and contextualizing interventions and in truly moving at the client's own pace. They allow the therapist to devote all attention to the individual client, which may be important when a great deal of hands-on assistance is needed. Group interventions, on the other hand, allow for the development of interpersonal relationships and for the reinforcement and encouragement that arise from working together with a group of peers on a common goal or concern.

Services may be provided in a relatively segregated setting, as in a classroom or treatment center, or in an inclusive setting, as in a restaurant or movie theater. It is common practice in therapeutic recreation interventions to deliver interventions in both settings, in a sequenced manner, so that the client may receive instruction and rehearsal opportunities in the safety of the classroom but then will have the opportunity to master those skills in his or her natural environment, at first with support and then with increasing independence.

The next phase of the therapeutic recreation process is sometimes called *discharge planning* (in inpatient, residential, or medical model outpatient facilities) or *transition planning* (in educational contexts). It is a crucial part of the process that provides continuity, as it is the phase in which the individual and the therapist have the chance to look at what has been accomplished, what challenges will emerge in the future, and what supports are needed as the individual moves on to a more independent setting.

Ideally, transition planning should begin during, rather than at the end of, treatment, so that the client will have the opportunity to plan for and preferably visit or experience some of the settings that will be encountered in the next phase of his or her life. Comprehensive transition planning involves exploration of the places, persons, opportunities, and resources that will be part of the individual's life; exploration of the supports available; and identification of "next steps" for that person's development.

The final phase of the therapeutic recreation process is the evaluation of the effectiveness of the intervention. As discussed in the "planning" phase, the therapist does not wait until the end of the intervention to evaluate its effectiveness; rather, built-in mechanisms are already in place for evaluation or monitoring along the way. Various aspects of the intervention may be evaluated, depending on the requirements and needs of the setting, including attainment of identified goals, effectiveness of the intervention over time, satisfaction with services for clients and families, and cost-effectiveness of services.

CONCLUSION

There are increasing efforts to involve people with disabilities in recreation activities and programs. Whether it be inclusive recreation, special recreation, or therapeutic recreation, attention is being paid to the importance of choice to ensure individuality and dignity in the pursuit of pleasurable activity by people with disabilities. Within the recreation field, there is a recognition by professionals that extra efforts are required to ensure that people with disabilities have opportunities to be involved in activities and experiences that refresh, recreate, and renew health and spirits by enjoyment and relaxation of a full array of recreation offered in diverse settings and environments.

REFUSAL OF LIFE-SUSTAINING TREATMENT

A competent person has the right to refuse medical treatment, even when that treatment may be necessary to preserve the person's life or prevent serious illness or disability.

The right to refuse treatment stems from the right to control what is done to your body. This is sometimes referred to as the principle of self-determination or bodily inviolability. In the British common-law tradition, this is best illustrated by the law of battery, where it is said that the merest touching of a person's body without that person's consent is an actionable wrong. Similarly, in the American common-law tradition, it has been held most famously by Justice Cardozo in *Schloendorf v. Society of New York Hospital* (1914) that

> every human being of adult years and sound mind has a right to determine what shall be done with his own body; and a surgeon who performs an operation without his patient's consent commits an assault, for which he is liable in damages.

This common-law right to refuse treatment is also accepted in South Africa, Australia, New Zealand, and Canada.

A RIGHT TO MAKE AN UNREASONABLE DECISION

The right is so fundamental that a person's reasons for deciding to refuse treatment are not subject to review, no matter how objectively unreasonable the decision is. For example in the New Zealand case of *Smith v. Auckland Hospital* (1965), Justice Greeson stated that "an individual patient must, in my view, always retain the right to decline investigation or treatment however unreasonable or foolish this may appear in the eyes of his medical advisers." In Britain, Lord Donaldson, in the case of *Re T* (1922), stated that "this right of choice is not limited to decisions which others might regard as sensible. It exists notwithstanding that the reasons for making the choice are rational, irrational, unknown or even non-existent."

In the American case of *Lane v. Candura* (1978), it was said that "the law protects [the patient's] right to make [his or] her decision to accept or reject treatment, whether that decision is wise or unwise."

The right to refuse treatment has other sources apart from the common-law principle of self-determination. In some cases, the right to refuse has been sourced in the common-law doctrine of informed consent or in rights to privacy. Constitutional guarantees of privacy and freedom of religion have also been found to support the right.

TYPES OF TREATMENT THAT MAY BE REFUSED

A person has the right to refuse all treatments, even minor or minimally invasive treatments that will preserve life. A commonly occurring example is the refusal of blood products, due to religious beliefs, such as those held by Jehovah's Witnesses and Christian Scientists.

People can also refuse artificial ventilation, resuscitation, and artificial feeding in circumstances where they will die without them. This position was accepted in Canada in *Nancy B v. Hotel-Dieu de Quebec* (1992), where the patient's right to refuse ventilation was held to be almost absolute. In *Bouvia v. Superior Court* (*Glenchur*) (1986), the Californian courts upheld the right of a cerebral palsy sufferer to remove a nasogastric tube that was keeping her alive. In *Blackman v. New York City Health and Hospitals Corporation* (1997), a competent 88-year-old woman who was on a ventilator and feeding tube was successful in seeking an order that all medical treatment being provided to her cease, barring treatment to alleviate pain.

Other examples of treatment that have been refused include operations to remove gangrenous limbs (see, e.g., *Lane v. Candura* [1978] and *In Matter of Quakenbush* [1978]) and the administration of psychotropic medication (*Fleming v. Reid* [1991]).

ADVANCE DIRECTIVES OR LIVING WILLS

It is possible to make a decision to refuse treatments that might be offered to you sometime in the future, when you may be unable to communicate a competent decision. Such decisions are most commonly referred to as *advance directives* or *living wills.*

In most common-law jurisdictions, advance directives can be made orally or in writing. To be valid, an advance directive must have been made by a competent person and must be specific enough to be able to be applied in the circumstances that have arisen. Ordinarily, clear and convincing evidence is needed show that the decision was based on an informed opinion and was intended to apply to the circumstances that arose. In addition, weight is also accorded to the question of whether the directive was made thoughtfully, seriously, and in circumstances free of the undue influence of others.

Many jurisdictions have also legislated for advance directives. Every state in the United States has advance directive legislation. Legislative schemes also exist in parts of Australia, and there are also moves toward introducing legislation in England and Wales.

LIMITATIONS ON THE RIGHT TO REFUSE TREATMENT

The right to refuse treatment is not absolute. The first limitation is that a patient be competent before his or her decision to refuse treatment is considered as binding.

The second limitation consists of public or state interests that may override a competent person's refusal. There are several situations in which the courts have upheld the state's interest in preserving life over the individual's right to refuse treatment. Among these are the interests of the state in compulsory vaccination (*Jacobson v. Massachusetts* [1905]), preventing children from becoming orphans when their parents are refusing treatment (*Holmes v. Silver Cross Hospital of Joliet* [1972]), and safeguarding the ethical integrity of the medical profession (*R v. Ashworth Hospital; ex parte Brady* [2000]). Over time, these state interests have become less likely to justify the overriding of a competent refusal of treatment.

Most troubling are those cases where the rights of pregnant women to refuse treatment are balanced against the state interest in protecting the unborn child. Earlier cases indicated that women could be forced to undergo procedures such as caesarian sections, if they were necessary to save the life of the unborn child (*Jefferson v. Griffin Spalding County Hospital Authority* [1981]). Later cases have shown a judicial reluctance to override the rights of competent women on grounds that it would be discriminatory to do so as it would severely limit pregnant women's rights of autonomy. This is the accepted position in many U.S. states and in the United Kingdom (*Re Fetus Brown* 689 [1997] and *St. George's Healthcare NHS Trust v. S; R v. Collins; ex parte S* [1998]).

The state's interest in maintaining order and discipline in prisons has also been used to override a prisoner's right to refuse treatment (including force feeding; see *Laurie v. Senecal* [1995]), but there is a wide variation in the types of rights enjoyed by prisoners across jurisdictions, and in some jurisdictions, it has been said that prisoners even have a right to die (*Reeves v. Commissioner of Police* [1999]).

The state also has an interest in preventing suicide. While committing suicide is no longer criminalized in most jurisdictions, assisted suicide remains a crime. The courts have limited the right to refuse treatment so that it does not extend to cover assistance from a third party to commit suicide. The right to refuse treatment only extends to the withdrawal of life-sustaining treatment, not active voluntary euthanasia. The courts have therefore been very careful to distinguish decisions to refuse treatment from requests for assisted suicide.

This is illustrated by *Rodriguez v. British Columbia* (*Attorney-General*), where a patient with amyotrophic lateral sclerosis (ALS), also known as Lou Gehrig's disease, wished to have a physician supply her with a "suicide machine" that she could activate when she could no longer tolerate her condition. She sought a declaration that would invalidate the criminal provisions that made the aiding and abetting of suicide an offense.

The majority of the Canadian Supreme Court found that the provisions of the criminal law did not infringe on the guarantees of the Canadian Charter of Rights and Freedoms. According to the court, the criminal prohibition may have deprived the patient of her autonomy and caused her physical pain and distress, but such a deprivation was not found to have been contrary to the principles of fundamental justice, as secured by the charter. The court could not make fundamental changes to the long-standing and almost universal policy against euthanasia.

There are several difficulties with the prohibition against assisted suicide and its relationship with refusals of treatment—namely, the logical and legal distinction between the two. The courts have attempted to distinguish active euthanasia from treatment refusal on two grounds. The first ground is that the person is not suicidal because this individual does not desire death: he or she only wishes for treatment to cease. The second ground relied on by courts is to say that death is not caused by the person refusing treatment but by the underlying disease or disability.

Many commentators see these arguments as spurious. First, while it may be true that some patients do not desire death in refusing life-sustaining treatment, there are several cases where patients expressly stated that death was their aim (see, e.g., *State v. McAfee* [1989]). Second, to say that death is caused by disease or disability ignores the fact that the disease or disability would not have caused death without the treatment being ceased. Moreover, it ignores the active role played by physicians in actively helping the patient by administering sedatives or painkillers that accelerate the dying process.

Regardless of these logical problems, the law in several jurisdictions has upheld the distinction between refusing treatment and assisted suicide, accepting the former and criminalizing the latter.

REHABILITATION ACT OF 1973 (UNITED STATES)

The roots of today's rehabilitation system for civilians with disabilities in the United States, particularly those with work injuries, lie in the Smith-Fess Act of 1920. The act was based on the belief that, with professional training and intervention, people with disabilities could return to productive employment. Support for vocational rehabilitation (VR) programs grew during the years that followed until finally, in 1935, the law made the provision of VR services by each state mandatory.

During the next several decades, the act was expanded to broaden the definition of eligibility for rehabilitation services to include people with more severe, congenital disabilities, such as blindness, mental illness, and mental retardation. Services were expanded to include physical restoration and living expenses, as well as vocational evaluation and work adjustment. The act provided funds for graduate programs in rehabilitation and funded construction of rehabilitation centers and sheltered workshop facilities, although these activities are no longer funded. In 1973, the act was again amended to mandate that agencies establish an "order of selection" to ensure that people with severe disabilities receive services before individuals with less severe disabilities and to require that a written rehabilitation plan be developed to ensure that clients themselves have a strong voice in the services they receive.

The 1973 amendments also included Title V, the first civil rights legislation for individuals with disabilities. Passing with little congressional debate, Title V bans discrimination against people with disabilities in programs receiving federal financial assistance. Section 503 requires that federal contractors adopt affirmative action programs to hire individuals with disabilities. Section 504 requires that programs receiving federal financial assistance make "reasonable accommodation" for individuals with disabilities to participate fully in their programs and activities, in addition to the nondiscrimination requirements. For the first time, accessibility was required of federally funded transit systems, colleges and universities, health care institutions, and state and local programs that receive federal financial assistance. But for Section 504 to be implemented, federal agencies must adopt regulations implementing this legislation. When President Jimmy Carter refused to sign the regulations without significantly weakening the language, hundreds of individuals with disabilities protested. They occupied regional offices of the Department of Health Education and Welfare, the agency responsible for promulgating the regulations, until the regulations were finally signed into law.

In 1990, the Americans with Disabilities Act (ADA) was passed, which broadened these nondiscrimination and access requirements to include public services and other entities that did not receive federal dollars. The ADA's drafters incorporated many of the provisions of the Section 504 regulations into the act.

In 1998, the Rehabilitation Act and other employment programs were incorporated into the Workforce Investment Act (WIA). The goal of the WIA is to increase the employment, job retention, and earnings of people who participate in employment-related activities, including people with disabilities. The intent of the WIA is to create a user-friendly, one-stop system of service delivery through the coordination of multiple workforce development programs. This one-stop system must be designed to address the needs of all individuals and must be accessible to people with disabilities as required under the ADA and Section 504 of the Rehabilitation Act of 1973. The state rehabilitation program must be an integral part of this one-stop system.

Today, the Rehabilitation Act is guided by strong principles, including respect for the dignity of all individuals, personal responsibility, self-determination, and pursuit of meaningful careers; the act promotes inclusion, integration, and full participation of people with disabilities. The Rehabilitation Act contains seven titles that regulate and fund disability employment and independent living programs. Some of the key titles are the following.

Title I provides grants to each designated state agency, which employs rehabilitation counselors to provide job training, advanced education, job placement, postemployment support, assistive technology, and other services to assist individuals with disabilities to find and keep work.

Title III establishes the National Institute on Disability and Rehabilitation Research, to promote and coordinate research, demonstration projects, and training related to people with disabilities.

Title V requires affirmative action by federal contractors in hiring individuals with disabilities (Sec. 503) and nondiscrimination against people with disabilities in programs and activities receiving federal financial assistance (Sec. 504). In 1998, Section 508 was added to require that electronic and information technology purchased by or used in federal programs be accessible to people with disabilities.

Title VII regulates and funds independent living services and centers for independent living, which provide services and advocacy for individuals with significant disabilities. Chapter Two of this title provides services to older blind individuals.

REHABILITATION COUNSELING

Rehabilitation counseling is a pragmatic, strength-based approach to counseling persons with disabilities. It shares similarities with certain aspects of a number of related disciplines, including physical rehabilitation and occupational therapy, psychiatry, psychology, nursing, and social work. Rehabilitation counseling is most commonly provided to individuals newly disabled by a physical event or injury or to those with a serious mental health or substance abuse problem. What makes rehabilitation counseling distinct from other disciplines is that it is activity focused, involving learning by doing within real-world contexts. Other disciplines tend to be therapy focused, usually occurring in institutional settings. The evaluation component of rehabilitation counseling typically involves the assessment of a client's problems or goals and the formulation of a treatment plan. The counseling component may seek to assist clients across a wide range of life domains, including activities of daily living, vocational functioning, social functioning, advocacy and resource acquisition, coping, and lifestyle change. The central aim of rehabilitation counseling is to empower clients to live more independently and satisfactorily while also advocating for clients' rights, needs, and hopes. Rehabilitation counselors help to reduce the cultural stigma that persons with disabilities experience. Generally, society views persons with disabilities as flawed and needy. This cultural milieu promotes feelings of dependence and inadequacy in persons with disabilities. Rehabilitation counselors counter these attitudes by helping persons with disabilities to function and excel in real-world educational, vocational, domestic, and familial contexts.

One of the hallmarks of rehabilitation counseling is that it is a pragmatic approach that facilitates rehabilitation through the use of techniques found across multiple fields. Frances Reynolds (1999) distinguishes it from other approaches to physical rehabilitation in that it may borrow techniques from a variety of orientations to facilitate adaptation and adjustment to a disability. For example, rehabilitation counselors such as Richard Hardy, Warren Rule, and John Cull have described using various psychodynamic approaches in rehabilitation counseling contexts. Hardy (1999) has also described the use of Gestalt therapy and hypnosis, while Joseph Ososkie (1998) has described existential perspectives, and Gerald Gandy (Gandy, Martin, and Hardy 1999) and a number of others have used cognitive-behavioral therapy and integrative techniques to facilitate a person's acceptance and adjustment to a disability. Nancy

Crewe (1997) has contributed a number of articles on functional assessment and outcomes rehabilitation counseling for individuals with spinal cord injury and traumatic brain injury that have provided valuable insight into the lives of persons with disabilities. Brian McMahon has written a number of articles about rehabilitation counseling and supported employment for individuals with a wide range of disabilities, including traumatic brain injuries that have moved the field toward a more empowerment-focused ideology (e.g., McMahon and Shaw 1996). In sum, the field of rehabilitation counseling can be characterized by a wide variety of approaches that are drawn from the distinctive psychological issues facing people with disabilities and from the theory, research, and practice of general counseling and psychotherapy. To an important extent, these approaches are framed by the goal of a person retaking his or her full potential and ability after the onset of a disability.

With respect to training and certification, two initiatives in the United States have worked to ensure that rehabilitation counselors are adequately educated and sufficiently competent to enter the profession: program accreditation and certification for practice. These two movements have helped set national standards for skill-level proficiency and knowledge adequacy of rehabilitation counselors. National standards include knowledge about vocational counseling and consultation, effective counseling, case management, service availability, medical and psychosocial aspects of disability, and history and systems of rehabilitation. A similar movement has taken place in Canada. Michael Leahy has written about perceptions of knowledge requirements among certified rehabilitation counselors in Canada (see, e.g., Leahy, Chan, and Magrega 1997). Domains of required knowledge identified by Canadian counselors were very similar to the domains of knowledge that U.S. rehabilitation counselors endorse, including knowledge of psychosocial aspects of disabilities and systems of rehabilitation.

Scholars such as Jared Schultz, Joseph Ososkie, and Elias Mpofu have commented on the state of the field of rehabilitation counseling. The field of rehabilitation counseling tends to serve a diverse population of individuals with disabilities using a wide range of approaches. In addition, rehabilitation counselors work in varied settings. These settings range from private settings, such as private rehabilitation centers and hospitals, health insurance companies, and employment counseling firms, to public settings that include the state agencies of rehabilitation services, the federal Social Security Administration, and other governmental organizations. For these reasons, these scholars argue that many may not understand the unique and cohesive mission and vision of the field. In addition to this challenge of understanding breadth, the field has been forced to confront changes in practice settings, evolving federal legislative regulations, and the certification movement. The field has attempted to respond to these challenges by explicitly defining major areas of required knowledge and skills. Recently, Leahy, Chan, and Saunders (2002), as well as others, have sought to describe the job functions and training requirements of certified rehabilitation counselors for the twenty-first century. One set of core job functions concerns employment and includes vocational assessment, counseling, and consultation to identify interests and competencies, provide job retraining and practice, identify potential job placements for clients, and, ultimately, increase client readiness for and likelihood of stable employment. Another central role of the rehabilitation counselor concerns promoting effective coping with daily and community life. It involves counseling activities that range from assessment of clients in terms of resource needs to case management. It also includes specific counseling interventions that are designed specifically for the consumer's abilities and environment. Rehabilitation counselors also conduct community-based rehabilitation service activities, where their knowledge of health care and disability systems empowers them to engage in professional advocacy. In sum, rehabilitation counselors work with the psychological, medical, functional, and environmental implications of disability to support and ready their clients for independent functioning and community integration.

Over the past 30 years, the profession has expanded outside of state vocational rehabilitation agencies and into schools, medical settings, mental health settings, substance abuse settings, geriatric settings, employee assistance programs, private practice settings, and community-based organizations. Relatedly, a growing number of integrative, community-based approaches to rehabilitation counseling have developed. These approaches seek to combine counseling and advocacy efforts. David Hershenson (1998) has described one approach that involves four elements of rehabilitation. These include restoring or replacing assets and skills, reintegrating identity and self-image, reformulating goals, and restructuring the environment. Lloyd Goodwin (1986) described another approach that involves eight dimensions of rehabilitation: supporting wholeness of the client, wellness, responsibility taking, prevention, uniqueness, disability as an opportunity for growth, healing and rehabilitation approaches, and environmental sensitivity. Other fundamental principles of rehabilitation counseling include normalizing roles and relationships within society, building informal and egalitarian relationships, emphasizing empowerment, focusing on present-moment concerns, and promoting community integration. Principles that have emerged more recently within rehabilitation counseling include multicultural sensitivity, evaluating outcomes, incorporating family members into treatment, and interdisciplinary collaboration. All these new approaches signify the strength of the rehabilitation counseling field as it evolves and adapts to new political, cultural, and fiscal contexts.

REHABILITATION ENGINEERING

Rehabilitation engineering is a field that brings the art and science of engineering to the assistance of persons with disabilities. It encompasses engineering research and development activities but also includes direct engineering services to persons with disabilities.

Rehabilitation engineering is frequently viewed as a component of the more general field of biomedical engineering, which brings together engineering with medicine and biology. As a direct service to people, it is related to occupational therapy and, to some extent, physical therapy. Although examples of rehabilitation engineering are almost as old as civilization itself, the field was not identified widely as "rehabilitation engineering" until the 1960s, when health agencies in a number of countries began to recognize the benefits of engineering insights and methods in the provision of assistance for persons with disabilities.

DEVELOPMENT AND SCOPE

Limb prosthetics is a subspecialty of rehabilitation engineering. It is concerned with the replacement of arms, hands, and legs with artificial components. Since antiquity, specialists have provided artificial replacements for lost limbs, particularly limbs lost in the conflicts of wars. After World War II, persons with limb loss often reentered society successfully, and high-quality artificial limbs coming out of federally sponsored research and development programs in prosthetics at that time contributed to this success. Consequently, in the late 1960s, the generalizing concept of rehabilitation engineering evolved, based on the thought that if engineers could work creatively with rehabilitation physicians and clinicians to improve limb prosthesis outcomes, they probably would also be able, through engineering techniques and scientific principles, to assist with the rehabilitation process for many other disabling conditions. Thus, the generalized field of rehabilitation engineering was launched.

In the late 1960s, one of the original objectives for the new field of rehabilitation engineering, as proposed by James B. Reswick, was "to improve the quality of life of the physically handicapped through a total approach to rehabilitation, combining medicine, engineering, and related science." Today, this field is viewed much more broadly, placing many chronically disabling conditions under the possible purview of engineering approaches. Physical disabilities such as limb loss are only one aspect of this field that now also includes communication disabilities, sensory disabilities, cognitive disabilities, and the many disabling conditions resulting from spinal cord injuries, head injuries, strokes, blindness and visual impairments, hearing impairments and deafness, neuromuscular diseases, musculoskeletal conditions, arthritis, orthopedic disabilities (bone and joint), cerebral palsy, pulmonary insufficiencies, cardiac deficits, disabling conditions from birth, disabilities of aging, disfigurement, and numerous other traumas, conditions, and diseases.

TECHNOLOGY SERVES THE PROCESS

Rehabilitation engineering is connected with treatments and therapies (e.g., robotic-aided therapy). It is associated with the avoidance of secondary disabling conditions and with comfort and alleviation of pain (e.g., witness the significant role engineering played in the orthopedic success of total joint replacements). This field also has to do with access to medical and rehabilitation services, tele-rehabilitation, and a wide scope of health care and possible cures that may result from genetics and stem cell medicine.

PERSONAL AIDS

The possibilities and prospects of rehabilitation engineering are as broad as life itself, which makes them innumerable. There are walking aids, functional electrical stimulation of muscles, manipulation aids, and wheeled mobility (e.g., powered chairs such as the unique iBOT Mobility System). Issues to be addressed include proper seating and positioning in wheelchairs and elsewhere, and management of pressure on body tissues. There are memory aids, and self-care aids (e.g., for handling one's medical prescriptions), speaking aids, reading aids, writing aids, hearing aids, visual aids, eating aids, teeth hygiene, toiletry aids, bladder and bowel management, recreational aids, temperature and lighting controls, telephone controls, control of entertainment equipment, assistance for caregivers, and attention in general to as many aspects of independent living as are feasible and reasonable. Modern computer-based technologies and wireless communication systems are making many of the aids listed available and easily customized to individual needs.

ASSISTANCE ON A LARGER SCALE

Rehabilitation engineering deals with aspects of the built and natural environments that may be inhibitory to persons with disabilities. The elimination of architectural barriers, development of universal designs for home and public environments, and the arrangement for home and work site modifications are all within the domain of rehabilitation engineering. There is need for access to secure living quarters, access to transportation and travel, and access to education and employment opportunities. Access to information (e.g., the Internet) and to the origination of information is highly desirable. With the right technical tools, meaningful work can be made accessible. This kind of technology may also permit pursuit of hobbies and avocational activities that can be invigorating and life enriching.

MULTIDISCIPLINARY INVOLVEMENT

As a general rule, engineers in rehabilitation cannot be successful alone with their efforts. They need to work together with physicians, surgeons, nurses, therapists, prosthetists, orthotists, and people with disabilities, their family members, and friends. This need for multidisciplinary experience exists both for engineers who conduct research on new methods and technologies to better serve persons with disabilities and for engineers who directly delivery rehabilitation engineering services to people. Nevertheless, the two kinds of rehabilitation engineers—the service-providing engineer and the research and development engineer—work in fundamentally different ways.

RESEARCH AND DEVELOPMENT

The rehabilitation engineer who conducts research and development (R&D) work usually is employed by a company that designs and/or manufactures rehabilitation engineering equipment or is involved in R&D work through a university-based laboratory that is funded by research grants. The R&D employee usually is a research engineer or scientist, often with a Ph.D. in biomedical engineering or some related area of science or engineering. The researchers usually work closely with rehabilitation professionals and ideally may have disabilities themselves. The aim is to develop new knowledge (science and engineering) concerning rehabilitation processes and new superior ways to solve problems that persons with disabilities experience. Much of the R&D work in rehabilitation is what might be described as applied research and development. However, new approaches at the cellular and molecular levels, new concepts in tissue engineering, new nanotechnologies, and new biomaterials are basic research arenas that may open up completely new concepts in rehabilitation.

SERVICE PROVIDERS

Engineers who deliver service directly to individuals with disabilities work basically as clinicians. Through training and experience, through working with other rehabilitation professionals, and through close interaction with the persons being served, they can begin to help their clients with rational decisions about which rehabilitation engineering approaches and assistive devices may help them. Many providers of rehabilitation engineering services in the United States are credentialed by RESNA (Rehabilitation Engineering and Assistive Technology Society of North America). The positions examined are assistive technology practitioner (ATP), assistive technology supplier (ATS), and rehabilitation engineering technologist (RET). The credentialing process attempts to provide safeguards for clients and to increase client satisfaction.

Clients usually should have their medical conditions stabilized before being seen for rehabilitation engineering consultation. Modes of communication also need to be established beforehand, if possible, so that the client can interact in the discussions and in decision-making processes. After communication has been achieved, it is important to determine if the person is comfortable. If not, the possible causes of discomfort need to be investigated and eliminated. For example, good seating and positioning frequently need to be established to help clients relax and be more comfortable. After the client can communicate and is comfortable, an early step is to try to provide that person with independent mobility. From this point on, it is usually possible to begin to address the many individual and unique needs of each client. Inevitably, this process usually involves many compromises as well as medical, engineering, and financial constraints.

A HUMAN ENDEAVOR

In the end, rehabilitation engineering methods and techniques cannot rehabilitate a person with disability. True rehabilitation must somehow come from within the person with disability, aided primarily by human love and compassionate care. Nevertheless, if one is truly rehabilitated, the methods and techniques provided by rehabilitation engineering can indeed greatly enlarge the scope of his or her life.

REHABILITATION ENGINEERING AND ASSISTIVE TECHNOLOGY SOCIETY OF NORTH AMERICA (RESNA)

The Rehabilitation Engineering and Assistive Technology Society of North America (RESNA) is an interdisciplinary association composed of individuals interested in technology and disability. Professionals in RESNA include occupational therapists, physical therapists, rehabilitation engineers, speech-language pathologists, special educators, manufacturers, and durable medical equipment suppliers. Consumers of assistive technology also belong to RESNA.

RESNA started in 1980 as early research and development work in the field began at federally funded rehabilitation engineering research centers (RERCs). Each RERC focuses on one specific area of assistive technology, developing new technology, training new professionals, and providing information to the public.

RESNA provides a forum for individuals with a common interest in a particular area of assistive technology, through special interest groups (SIGs). In addition, RESNA's professional specialty groups (PSGs) provide a way for specific disciplines to communicate with one another.

Through the Technical Assistance Project and Alternate Financing Project, RESNA provides assistance to the 56 state and territory assistive technology programs. These programs are funded under Public Law 105–394 to increase awareness of and access to assistive technology in each area.

Through its credentialing program, RESNA provides a mechanism for professionals to demonstrate a knowledge and skill base critical to the delivery of assistive technology services. Three credentials exist: assistive technology practitioner (ATP), assistive technology supplier (ATS), and rehabilitation engineering technologist (RET).

RESNA's international sister organizations—the Association for the Advancement of Assistive Technology in Europe (AAATE), the Rehabilitation Engineering Society of Japan (RESJA), and the Australian Rehabilitation and Assistive Technology Association (ARATA)—provide forums for similar work around the world. On August 26, 2000, the leaders of the four organizations signed the Tokushima Agreement to promote exchange of information and collaboration.

REHABILITATION ENGINEERING SOCIETY OF JAPAN (RESJA)

The Rehabilitation Engineering Society of Japan (RESJA) was established in 1986 and is composed of approximately 1,000 members. RESJA's membership is interdisciplinary, including engineers, occupational therapists, physical therapists, speech therapists, educators, physicians, and consumers.

RESJA organizes an annual conference, the Japanese Conference of Advancement on Assistive and Rehabilitation Technology (JCAART). The conference provides a forum for the presentation of approximately 700 papers. An additional dissemination avenue is the *Journal of RESJA,* which is issued four times each year.

RESJA is organized around 10 special interest groups (SIGs). Current SIG topics include the following: automobile, communication, functional electrical stimulation, house design, seating, self-help devices, wheelchairs, special education, transfer aids, and devices to prevent pressure sores.

RESJA interacts with its sister organizations—the Rehabilitation Engineering and Assistive Technology Society of North America (RESNA), the Association for the Advancement of Assistive Technology in Europe (AAATE), and the Australian Rehabilitation and Assistive Technology Association (ARATA)—to advance assistive technology use worldwide. On August 26, 2000, the leaders of the four organizations signed the Tokushima Agreement to promote exchange of information and collaboration.

REHABILITATION MEDICINE, INTERNATIONAL

Rehabilitation is used as a term for different medical, psychological, social, and vocational measures that aim to support a person with disability to regain as normal a life as possible. The ultimate goal for rehabilitation is that the person will participate actively in life roles of importance for that person. This entry concentrates on rehabilitation within medicine, with special emphasis on the situation in Europe.

GENERAL ASPECTS AND DEFINITION

For the development of rehabilitation, the concepts first given by the World Health Organization (WHO 1980) in the International Classification of Impairments, Disabilities, and Handicaps (ICIDH) and recently (approved 2001) in the International Classification of Functioning, Disability, and Health (ICF) have played a great role. Rehabilitation works on all levels in ICF (body function and structure, activity, and participation), also taking environmental factors into account. Impairments (the level of body function and structure) can be treated to reduce or eliminate the reduction in function by pharmacological means, training through physiotherapy, occupational therapy, speech therapy, neuropsychological means, and so on, or they can be compensated for by assisted devices. Rehabilitation aims at reducing the activity limitations (the level of the individual) by training, changing an activity pattern (e.g., more appropriate way to handle objects for a person with joint disease), and using assistive devices and modifications of the environment (e.g., housing adaptation). Finally, the aim is to increase participation, where social and psychological factors play a great role and should include attention to the attitudes of relevant other persons. Emphasis may be placed differently on those three levels, depending on the phase and actual goal of rehabilitation, but all should always be kept in mind. In the early acute stage, measures to reduce impairment and limitation in basic daily activities may dominate, whereas in the more subacute stage of rehabilitation, reduction of activity limitation in a broader sense may be the dominant goal. The need for treatment of specific body functions (impairments) should therefore be analyzed in such a perspective. In a later stage, after an individual leaves the hospital, social aspects related to family life, occupation, hobbies, and leisure activities will be given an increasing importance for the rehabilitation efforts.

Rehabilitation measures and programs can be divided into different categories:

- separate rehabilitation measures, which may or may not be coordinated, such as physiotherapy, occupational therapy, and speech and language therapy;
- coordinated rehabilitation within different clinical specialities, but without participation of a clinical specialist in rehabilitation medicine;
- team-based rehabilitation in specialized rehabilitation units (clinics) and led by a specialist in rehabilitation medicine (in the United States, a physiatrist).

The activity of the rehabilitation team should essentially be goal oriented and should take account of the preferences and goals of the patient, who is an active participant in the rehabilitation process.

Many medical disciplines have a rehabilitation component within their work, but of special note are psychiatry, rheumatology, cardiology, neurology, orthopedics, and respiratory medicine. Specialized clinics are established by specialists in physical and rehabilitation medicine to address the needs of special groups of patients, where a broad and more timely approach is required. Thus, the medical speciality that is most greatly concerned with the medical rehabilitation of physically disabled people is physical and rehabilitation medicine. It goes under a variety of names in different countries, reflecting different priorities:

> Rehabilitation medicine: Hungary, Ireland, Luxembourg, the Netherlands, Poland, Portugal, Sweden, United Kingdom
>
> Physical and rehabilitation medicine: Official Title in the Union of European Medical Specialists (UEMS) and also in France, Germany, Denmark, Greece, Switzerland
>
> Physical medicine and rehabilitation: Austria, Belgium, Croatia, Czech Republic, Denmark, Estonia, Finland, Greece, Italy, Latvia, Liechtenstein, Lithuania, Norway, Slovakia, Slovenia, Spain, Turkey, United States

The term *physical medicine* is still used in some countries but represents a slightly different activity from rehabilitation medicine. In some countries, such as in the United States, a specialist in physical and rehabilitation medicine is named a physiatrist.

Definition

The speciality will hereinafter be referred to as physical and rehabilitation medicine (PRM). So what is PRM? The European Union of Medical Specialists (UEMS) section of PRM has defined it as follows:

> PRM is an independent medical specialty concerned with the promotion of physical and cognitive functioning, behaviour, quality of life (activities and participation) and with the prevention, diagnosis, treatment and rehabilitation management of people with disabling medical conditions and co-morbidity across all ages.
>
> Specialists in PRM have a holistic approach to people with acute and chronic conditions, examples of which are musculo-skeletal and neurological disorders, amputations, pelvic organ dysfunction, cardiorespiratory insufficiency and the disability due to chronic pain and cancer.
>
> PRM specialists work in various facilities from acute care units to community settings. They use specific diagnostic assessment tools and carry out treatments, which include pharmacological, physical, technical and educational and vocational interventions. Because of their comprehensive training, they are best placed to assume responsibility for the activities of multi-professional teams in order to achieve optimal outcomes.

There are variations from country to country, but the common aspect is the relationship of the rehabilitation physician to other members of the multiprofessional team. This is quite different from that found in acute medicine.

Aims of Physical and Rehabilitation Medicine

The concepts in the ICIDH, published in 1980 by WHO, have made a great impact on rehabilitation. However, the terms have changed in the recently published ICF. The overall aim of rehabilitation is to reduce or eliminate disability, as its definition in ICF still applies. Rehabilitation is a precise activity and is quite different from care and describes a goal-oriented activity. Similarly, it is quite different from "therapy," which contributes to the rehabilitation process in individual recipients but may not always be required for everyone. *Therapy* and *rehabilitation* are not synonymous.

Rehabilitation—WHO Definition. This is an active process by which those disabled by injury/disease achieve a full recovery or, if full recovery is not possible, realize their optimal physical, mental, and social potential and are integrated into their most appropriate environment.

Health-Based Rehabilitation: Working Definition. This dedicated, designated, multiprofessional activity, which takes an active and holistic approach to care and is centered on the individual needs of patients and carers, starts in earnest when the patient is medically stable and continues through community reintegration and beyond, is goal oriented, and is easily and appropriately accessible.

Rehabilitation Medicine. This is a consultant subacute speciality concerned with the secondary and tertiary management of the medical aspects of physical disability (especially in the fields of neurological and musculoskeletal disease, trauma, and amputation), which require specialist rehabilitation expertise.

Rehabilitation Therapy. This includes treatment provided by, or under the direction of, nurses, physiotherapists, occupational therapists, speech and language therapists, clinical psychologists, dieticians, chiropodists, and so on. They each have their professional philosophies, but space prevents from describing each.

Medical practice is based on the concept of arriving at a diagnosis and providing a treatment that aims to cure the patient. In the context of medical and social progress and the increasing importance of degenerative diseases in medical practice, the relatively new concepts of improving quality of life and preventing deterioration and complications have assumed greater priority.

General Structure in Europe

The general structure of PRM services across Europe is fairly similar despite the differences between health care systems. PRM is recognized as a core service in each of the 19 member states of Europe and the new associate members also adopt the same principles. The names may be different from place to place, but the essential services appear in the following form.

> *General Rehabilitation:* Characterized by health professionals working within their professional roles in relative isolation from others.
>
> *Special Services:* Dedicated areas of working, where individual professionals have varying degrees of contact with others involved in the rehabilitation process—for example, continence and tissue viability services, dysphagia services, and so on. For specific conditions, such as multiple sclerosis, Parkinson's disease, and back pain, individuals may have a general clinical role working within a team and an extra responsibility to these respective patients.
>
> *Specialized Rehabilitation:* Dedicated multidisciplinary or interdisciplinary rehabilitation, where the team meets to define the rehabilitation objectives and activity and professionals work together to achieve the aims of the process. It is often inpatient based, but there are now a number of community teams working in this way.

The numbers of specialists in PRM across Europe varies considerably, and this depends to a large extent on geography.

Training in PRM

Specialist training covers a four- to five-year course in UEMS member states. The route to start training is slightly different in each country, but, despite different entry points to a four- to five-year training program, the curriculum has much similarity across the continent. The European Board of PRM has the task of harmonizing specialist training across Europe and has taken on the following roles.

- European examination for recognition of specialist training
- Continuing professional development and medical education with five yearly revalidations
- Recognition of the European trainer and training unit through site visits

The eventual aim of this harmonization is to produce specialists who can work across European health care systems and allow national medical authorities/employers the knowledge of the training content and experience of the specialists working for them.

DELIVERY OF REHABILITATION SERVICES

With such a burden of physical disability in the population, adequate and equitable delivery of health care to the disabled population is clearly a major logistical problem. Services provided in most countries are patchy, fragmented, and overall inadequate. Facilities are needed for both inpatients and outpatients, and the criteria for inpatient rehabilitation are as follows:

a. patients requiring 24-hour nursing and medical supervision for their rehabilitative needs;
b. patients with neurological and locomotor disorders who have the capacity for, require, and will benefit from rehabilitation (i.e., patients in whom the evidence shows that active intervention improves function and life satisfaction or prevents deterioration);
c. severely disabled patients, whose needs can only be met by a multiprofessional team practicing interdisciplinary rehabilitation;
d. patients with complex needs (i.e., requiring more than two professionals working in a team);
e. some very severely disabled patients with little hope of improvement in personal functioning but who require assessment and appropriate equipment and whose families require education for caring purposes.

A number of basic core services are required in each area. Logistics demand that rare and complex conditions require designated specialist services, and because they will not be available in each locality, an access network is necessary.

Acute Services

As the pressure on acute facilities increases, rehabilitation in acute hospital beds should be available to achieve optimal outcomes, reduce complications and disability, and allow a clear pathway for efficient ongoing rehabilitation after discharge. The barriers to achieving this are as follows:

- lack of recognition by the acute care team of what the specialist center can offer in addition to that provided by the acute physician/surgeon,
- lack of access (availability of services, waiting time to enter rehabilitation),
- financial restrictions (hospital/clinician/insurance).

Specialist Centers

Certain individual groups of both old and younger adults and children require dedicated centers/services for specialized rehabilitation, and the standards proposed by the British Society of Rehabilitation Medicine on the number of required beds per district for rehabilitation medicine only account for younger adults. These centers need both inpatient and outpatient rehabilitation facilities, which are separated from acute beds and long-term care facilities for the elderly.

Disease-Specific Clinics

Specific clinics and activities have been developed for managing certain long-term conditions, such as multiple sclerosis, epilepsy, Parkinson's disease, or inflammatory joint disease. In addition, back pain services have been set up, and these clinics certainly have the advantage of providing an expert multidisciplinary approach, which is familiar with the specific problems of that disorder. The team can supply information and counseling support and can act as a focus for self-help groups.

Community Rehabilitation Teams

Follow-up from the acute hospital-based rehabilitation team is essential for many people with significant disabilities to provide continuity of support and access to appropriate health resources after discharge. A community team can still work in a multi- or an interdisciplinary manner in the same way as the acute rehabilitation team but tends to concentrate on changing abilities in activities and participation rather than on the relationship between impairments and abilities. A team is effective for a population of about 120,000. Teams may be peripatetic, based in health/community centers or in community hospitals. Their essential aims are to ensure the well-being of disabled people in the community by organizing therapeutic interventions to ensure optimal outcomes following hospital stays and prevent hospital admissions.

Case Management

Disabled people, particularly those with severe and wide-ranging disabilities, will need a complex array of health and social services. The concept of case management has been developed as a way of assisting disabled people with the coordination of the necessary professional staff. Case management can include the following:

simple coordination within a single agency;

coordination across agency boundaries;

service brokerage, in which the case manager negotiates with the key agencies on the client's behalf;

budget-holding responsibility, where services can be purchased on behalf of the client from statutory bodies or other voluntary or private agencies.

There have been very few controlled studies of the efficacy of case management, which is widely practiced within the United States, Canada, and Scandinavia. It may provide a better and more coherent service, particularly for those who have a degree of cognitive impairment who are unable to find their own way through the maze of services.

Links with Other Agencies

Health-based rehabilitation goes hand in hand with social and vocational rehabilitation, and services need both formal and informal means to break down the artificial barriers between the participating agencies. Cross-representation is necessary at both the strategic and operational levels, and disabled people not only need to be involved but also should lead when and where it is appropriate. There is no single preferred model to suit every location, and each will depend on the local facilities and assets of the participating individuals. However, all new services should take into account the views and advice of users and disabled people's groups on disabled living (Living Options principles and European Year for Disabled People 2003).

REHABILITATION RESEARCH–ACADEMIC BASE

Rehabilitation research is growing in activity and sophistication. However, randomized controlled trials are, to some extent, difficult to perform in this field, but a recent increase in the publication of such studies can be seen. There are now a lot of data about the effectiveness of rehabilitation, and what is now required are data on the value of rehabilitation through cost-effectiveness studies, some of which are under way. Rehabilitation will also have a more solid theoretical basis as the perspectives of fields such as neurobiology, applied physiology, and biomechanics increasingly provide a background for rehabilitation. There is also an increasing use of modern and relevant methods to treat ordinal scale data from various instruments to assess activity limitation, participation restriction, quality of life, and perception of health—all very useful in rehabilitation research.

REHABILITATION PSYCHOLOGY

Rehabilitation psychology is a specialty area of practice that applies psychological knowledge and understanding on behalf of individuals with disabilities and society through research, clinical practice, teaching, public education, development of social policy, and advocacy. Rehabilitation psychologists participate in a wide range of activities, including clinical care and direct service, program development, research, education, administration, and public policy.

They work in acute care hospitals and medical centers, inpatient and outpatient physical rehabilitation units, nursing homes and assisted living centers, and community agencies serving people with specific types of disability or chronic illness (e.g., vision loss and low vision, cerebral palsy, multiple sclerosis, deafness). Their employers include private facilities and government facilities such as Veterans Administration hospitals and centers, industry, and universities, colleges, and private practice. The focus of rehabilitation psychology covers the lifespan from early childhood through late adulthood. Advocacy is an important activity for rehabilitation psychologists as they seek to improve the life conditions for people with disabilities and chronic illnesses; many have sought to develop and promote legislation such as the Americans with Disabilities Act of 1990.

Clinical and counseling services provided by rehabilitation psychologists assist individuals to cope with and adjust following the onset of chronic, traumatic, or congenital injuries or illnesses. These conditions include spinal cord injury; brain injury; stroke; amputations; neuromuscular disorders; medical conditions with the potential to limit functioning and participation in life activities such as cancer, AIDS, multiple sclerosis, or limb weakness; chronic pain; congenital or chronic developmental disorder such as mental retardation; chronic mental illness; alcohol and other drug abuse; impairments in sensory functioning; burn injury; deafness and hearing loss; and blindness and vision loss. Many of these impairments are compounded by cultural, educational, and/or other disadvantages and social stigma.

Psychological services often have the goal of reducing the consequences of impairment, activity limitations, and societal participation restrictions. Persons served are engaged as active partners in the rehabilitation process by taking into account the person's preferences, needs, and resources. Following the World Health Organization's International Classification of Functioning, Disability, and Health (ICF), rehabilitation psychologists have helped address personal factors affecting the ICF domains of impairments, activities, and participation. They do this by addressing neurocognitive status, mood and emotions, desired level of independence or interdependence, freedom of movement, self-esteem and self-determination, subjective view of capabilities and quality of life, and satisfaction with achievements in specific areas such as work, social relationships, and community access. Rehabilitation psychologists consider the influence of culture, ethnicity, gender, residence and geographic location, visibility and assumption of disability on attitudes, and available services when planning services. Also explored are environmental barriers to participation and activity performance, including accommodations and adaptations in existing structures or materials and the use of assistive technology and personal assistance services.

Families, primary caregivers, and other significant people in the individual's social life and community are valued and engaged in rehabilitation activities so as to assist the individual with disability or chronic illness achieve optimal physical, psychological, and interpersonal functioning.

Rehabilitation psychologists work within a wide variety of health care settings and with a broad range of persons with varying disabilities and illnesses. Some specialize in a particular area of clinical practice, while others' practice is broader. Interdisciplinary teamwork is a hallmark of rehabilitation psychology practice across settings and the area of specialization. Rehabilitation psychologists are respected and provide services within existing networks of biological, psychological, social, environmental, and political environments to assist the persons served in achieving their rehabilitation goals. Consultation regarding disability and health issues is another important professional role of rehabilitation psychologists. Attorneys, courts, government agencies, educational institutions, corporate facilities, and insurance companies are the recipients of these services.

Rehabilitation psychologists complete doctoral degrees in psychology and have had extensive predoctoral and postdoctoral training in health care settings. Rehabilitation psychologists who provide clinical services are usually required to be licensed to provide services in their state of practice and to receive reimbursement for services from health insurance payers. The American Board of Professional Psychology (ABPP) recognizes rehabilitation psychology as a specialty area of practice within psychology; the board's definition of rehabilitation psychology was an important source in the development of this description. Rehabilitation psychologists belong to many professional organizations relevant to their area of practice and specialization. The major organization representing rehabilitation psychology is the American Psychological Association (APA), Division of Rehabilitation Psychology. Division 22 publishes a scholarly journal and newsletter; it also sponsors sessions relevant to rehabilitation psychology research and practice at the annual APA conference held annually in August, a midwinter meeting, and other education venues for psychologists and other health professionals. Several excellent textbooks are available on the general topic of rehabilitation psychology, as well as books on areas of specialization within this field.

REHABILITATION ROBOTS

There are two main types of rehabilitation robots. The first type is an assistive robot that substitutes for lost limb movements. For example, the MANUS robot arm attaches to a wheelchair. The user controls MANUS using a chin switch or other input device. This process is called "telemanipulation" and is similar to an astronaut controlling the space shuttle's cargo bay robot arm from inside the shuttle's cockpit. Powered wheelchairs are another example of teleoperated, assistive robots.

The second type of rehabilitation robot is a therapy robot, which is sometimes called a "rehabilitator." Neuroscience research over the past 20 years has shown that the brain and spinal cord retain a remarkable ability to adapt, even after injury, through the use of practiced movements. Therapy robots are machines or tools for rehabilitation therapists that allow patients to perform practice movements aided by the robot. The first robot used in this way, MIT-Manus, assisted patients with stroke in reaching across a tabletop if they were unable to perform the task by themselves. Patients who received extra therapy from the robot improved the rate of their arm movement recovery. Another recent therapy robot, the Lokomat, supports the weight of a person and moves the legs in a walking pattern over a moving treadmill, with the goal of retraining walking after a spinal cord injury or stroke.

Assistive robots are not yet widely available because of limited functionality and cost. Teleoperating a robot arm to pick up a bottle of water and bring it to the mouth is time-consuming and requires an expensive robot. Robot arms on wheelchairs will become more common as engineers build more intelligence into them. Making robots understand voice commands, recognize objects, and agilely manipulate them in the "real world" is a cutting-edge research area in robotics. Another promising area of research is at the cutting edge of neuroscience: implanting computer chips directly into the brain so that all a user has to do is "think" a command and the robot will do it. This sounds like science fiction, but researchers have recently shown that monkeys can be trained to move a robotic arm in just this fashion—through thought alone.

The main issue limiting therapy robots is that researchers do not understand what exactly the nervous system needs to adapt. Hard work by the patient is important, but what should the robot do? Researchers are developing therapy robots that assist in movement, resist movement when it is uncoordinated, or even make movements more uncoordinated in an attempt to trick the nervous system into adapting. Therapy robots will become more prevalent as researchers figure out the best training techniques. Therapy robots will also likely play a role in assisting the nervous system to regenerate appropriate neural connections following stem cell and other medical treatments.

Finally, the distinction between assistive and therapy robots may fade in the future. Imagine wearing a robotic exoskeleton that helps you to get tasks done but also teaches you to get better at doing those tasks. Such a rehabilitation robot will help people with disabilities by gradually making itself obsolete.

RELIGION

A religion is a system(s) of belief(s) and ritual through which people relate to and express their experience of

God(s), the sacred or divine dimensions of life, and their understandings of the meaning of life. Religion includes the practices whereby people live out their faith, and both historically and today, it is a major force in the lives of cultures and civilizations. Hence, people with disabilities and their families are influenced by those religious traditions and systems. In turn, the experience of impairment, as well as its social expression, disability, affects religious understanding and practice as people with and without disabilities seek to understand the meaning of disability, God's relationship to disability, and the subsequent understandings of practice and relationship to which a belief and tradition calls them.

The intersection of disability and religion has complex historical, practical, scientific, and theological dimensions. Disability is paradoxically often central to religion (such as the brokenness of God in Christianity) yet has, in large part, been overlooked in systemic research and the study of religious systems. A critical understanding assists in understanding the historical treatment of disability and its intersection with culture and faith traditions. Religion can be a force for both good and ill regarding disability.

EXPLORING THE COMPLEX RELATIONSHIP

There is no one generalized definition or explanation of the relationship between religion and religion. While religion is a major force in societies, many other factors influence people. Adherence to, or interpretation of, a faith tradition is also shaped by numerous other forces that influence personal and social understandings of disability.

Religion and faith can endorse and enshrine social attitudes and practice or challenge them. There are many examples of ways that faith and religion have been a support to people with disabilities and their families. Likewise, there are many examples of its use to exclude, dehumanize, or harm people with disabilities.

Certainly, there is no central understanding of how religious tradition or faith relates to disability. Reflecting dominant power relations, in faith traditions, disability is not a major focus. Most religious leaders do not live with disability, and few cite sermons or teachings on disability and religion. There are also many different understandings, doctrines, beliefs, and approaches about many issues within a specific religious tradition, including disability.

Hence, even if there were a central understanding or practice within a given tradition about disability, it does not mean that practice would be uniform. Many different forces and experiences shape attitudes and practice.

EXPLORING RELATIONSHIPS AND EMERGING RESEARCH

Despite this, the relationship between religious beliefs and practice and disability (or disabilities) is an area for rich and powerful exploration and research. Having a disability or close relationships with people with disabilities raises many questions about the meaning of life, the nature of suffering, the role of God and divine purpose, difference and community, and understandings of individual rights and justice. Religion and faith shape personal and communal identity, help people to find meaning and purpose regarding core life questions, express understanding of the sacred/divine, and guide ethical practice. Religious traditions and faiths can sustain people in times of crisis, through belief systems, practice, and a wide variety of supports and services within one's religious community (church, synagogue, mosque, etc.). As already stated, these can effect change, both for good and ill.

Religions can support a wide range of beliefs and practices in societies and cultures. This is an area of emerging research in both religious and secular disciplines—for example, strategies shaping inclusive/accessible faith communities or understandings of how faith and religion affect attitudes and coping skills within families and people with disabilities. There is a growing impact of the disability rights movements on religious understandings and practice. This relationship illustrates how disability may not have played an obvious role in its early development of central beliefs, practices, or sacred texts of most religious communities, yet core beliefs and practices (or first principles) can be used to address these issues. Two further areas of research/study arise. First, scholars and practitioners can reexamine religious texts and traditions via social, cultural, and rights understandings of disability, helping shape new appreciation of disability in tradition. Second, disability stories/experience can shape belief and revised practice within a given religious community, often in the name of inclusion or acceptance.

CORE RELIGIOUS QUESTIONS

A common thread in religions about disability is the human search for meaning in the world. There are also common questions about life in different faith traditions and similar forms of exploration. Comparative religion scholars approach those in numerous ways. Two basic dimensions have already been noted: belief and practice.

Four questions/dimensions identify the ways religions and faith traditions understand and relate to disability:

1. What is the belief about the source of disability (i.e., why it happened) and the role of God or the divine?
2. How does that understanding of source affect the understanding and identity of a person with disability?
3. What, then, is the role and purpose of the person with disability in society? In other words, “what am I called to do?”
4. What is the role of the community of faith—that is, what are others called to do, out of their faith, toward persons with disabilities?

EXPLORING WHY: DIVINE ROLE AND PURPOSE

All religious traditions struggle with asking and answering the question “Why?” regarding suffering, death, and difference/deviation. The answer is usually in terms of divine origin (God caused it or sent it) and/or personal responsibility (my fault or someone else’s). Given that most faith traditions envision the divine in charge of events in life and mostly have understood disability as misfortune, a central thread in many faith traditions is that disability is a sign of punishment, moral deviance, or some kind of fallen state.

Thus, in Christian traditions, a disability such as epilepsy might be seen as demonic, or the control of an evil spirit, as in the story of the Gerasene demoniac in the Gospel of Mark. In Judaism, the exclusion of some forms of disability from religious practice or community has often been quickly interpreted as a sign of divine disfavor or as the result of punishment or sin (“The sins of the parents are visited upon the children. . . .”). In Islam, disability has been interpreted as a misfortune sent by Allah or as a challenge to the individual and his or her faith. In Hinduism and Buddhism, disability has been interpreted as something fearful, a punishment for a misdeed in a former life, or one’s karma. People with disabilities and families across many faith traditions can recount stories of the ways that blame, fault, or sin has been ascribed to them by others, with the added weight of God’s will and punishment.

Disability has also been portrayed as a sign of evil or fallen state, with its absence portrayed as a sign of healing or of paradise. Thus, people with disabilities struggle with common understandings of the healings by Jesus in which their disability is cured, or their capacity for healing is equated with the depth of their faith. In Zoroasterism, there was a core vision of a perfect world in which there was no disability or death, a vision with similarities in heaven in other religions. The contrast of a perfect, disability/disease/suffering-free society is central to the founding story of Buddhism, where the young Buddha, raised in a world free of suffering, encounters it for the first time as he moves out of the castle into the world. His life, and the world’s, is forever changed.

But there are also interpretations within major faith traditions that see disability as more neutral, as a challenge to the individual and his or her soul. Going further, in Judaism, Christianity, and Islam, there is a strong belief in the sacredness of every life, and in Eastern religions, there is more focus on the importance of the connection of the individual to the community and the whole of creation. A famous text in the New Testament (John 9) disconnects the equation of disability with sin when the disciples ask Jesus why a man was born blind. The disciples asked whether it was the fault of the blind man or his parents. Jesus' response was, "Neither . . . he was born blind so that God's works might be revealed in him." That captures an understanding of the role of people with disabilities in wider society, in which religious traditions see the disability as an opportunity to teach lessons to others. In Buddhism, the question is not whether God caused the disability but how one's mindfulness and spiritual discipline might shape one's response.

The importance of historical, exegetical, and theological research in this area is shown by the ways that popular religious understandings equating disability with sin or punishment by God are in fact challenged by a more disciplined exploration of religious texts. Religious credence has often blessed or enshrined social attitudes, even perpetuating rather than challenging them. Yet careful research begins to note, for example, that Jewish understandings of disability did not equate it with deviance. Disabled people continued to be part of the community. The blind Levite could not be a priest because one of the functions of a priest was to examine sacrifices for the lack of blemish. A disability did not keep a person from being a major religious leader (e.g., Moses and his speech defect, Jacob and his limp, and Paul and his "thorn in the flesh"). Religious leaders in many traditions have been blind or had other disabilities that were thought to imbue them with special vision and insight. A careful exploration of the understandings of disability as karma can reframe that understanding of disability as punishment for a sin in a former life to a belief that, in a former life, one might have mistreated a person with a disability or been guilty of pride or arrogance, and thus this current disability is a time for rehabilitation, a necessary corrective stage in the journey of one's soul.

Largely nondisabled accounts of divine purpose regarding suffering led to understandings of disability as punishment or evil when the divine is understood as all powerful or in battle with other gods (demonic) or when disability is interpreted only as misfortune and suffering. In more recent times, as science and other disciplines have shaped new religious understanding, religious leaders such as Rabbi Harold Kushner (also a parent of a child with a disability) have questioned whether God is all-powerful. Disability begins to be understood in terms of physical origins, just like other conditions and differences. Other religious traditions and understandings have claimed the "specialness" of people with disabilities in divine creation. Whether that comes out as "angels unaware" or "inspiring example," it is the opposite end of the spectrum of religious interpretation of misfortune as either evidence of bad/evil or good/blessing. Some theologians have also begun to explore the question of how disability relates to our understanding of the divine (e.g., Eiesland 1994).

DISABILITY AND IDENTITY: RELIGIOUS DIMENSIONS

The spectrum from "evil/demonic" to "good/special" also reflects disability as a major characteristic shaping and defining personal identity. Disability is defect, and thus the person is defective. The individual or family becomes the bearer of whatever religious interpretation is placed on the disability, ranging from demonic, curse, and punishment to special and holy. Disability is the fault of the individual/family, the fault of a former incarnation, or God's will/design. Disability thus controls and is a person's identity, rather than being just one of many characteristics. Thus, people with disabilities were seen within religious traditions as they were within society, as "the blind," "the lame," "the possessed," the "idiot," "the deaf," and so on.

Social and religious identities and roles are thus intertwined. Evil and thus shunned or avoided, people with disabilities were often scapegoats for religious questions and social worries. Social and economic factors combine with negative attitudes to create structural disadvantage. In some societies, that led to the religiously sanctioned practices of killing infants with severe disabilities. In others, identity meant a life as "beggar," with the expected religious custom and behavior of supporting those who were weak, a feature in Judaism, Christianity, Islam, and Eastern religions.

The opposite is also true when identity was seen as "special" or "holy." Those traditions ranged from practices of having people with disabilities as jesters in courts, or collected by royalty for entertainment, to beliefs that a person with a disability may have a special ability and capacity to reveal the divine. As will be noted later, in some Eastern religious and cultural traditions, people with various disabilities were expected to develop particular gifts, such as becoming musicians or storytellers. In the Christian tradition, the "deaf" shall in fact "hear," the "blind" see, and "last" be "first."

In contrast to an either/or spectrum of identity, many religions also affirm the value of each person. In Judaism, all humans are a disclosure of the divine, each created "in the image of God." All life has value. All life is a gift. All life has strengths and weaknesses. Christianity is full of stories of Jesus recognizing and affirming the humanity of each person and using the gift of healing not only to remove a disability but also to overcome projections of sin and punishment and restore a person to the community. In Islam, all creation is to be honored. Allah's measure of worth for a person does not depend on physical attributes or achievement but on spiritual maturity and development. Thus, for example, Islam was one of the first faiths to see deaf sign language as valid social and religious communication.

Hence, in all major faiths, there are affirmations of the worth and value of each person. However, evidence of disablism, as well as an illustration of the way that religious attitudes both shape and are shaped by social attitudes and understanding, is found when the language and terms of disability are used as metaphorical descriptions of defective faith and character. For example, in the Qur'an, people could be deaf to the law of Allah or blind to the true path. Lack of faith could be described in terms of disability, and disability was then seen and interpreted as a lack of faith or evidence of wrongdoing. There are many forms of diminishment found in disability labels, with their negative meanings to describe "nondisabled" people whose faith or practice was considered inadequate, wrong, or defective. Yet the ways that people with disabilities have been treated by religious people, communities, or societies can also be used as examples and metaphors of faith that is righteous and just.

As disability is increasingly seen as one part of a person, with difference an expression of human diversity rather than disease, there are new frameworks from which to explore the religious understandings of the giftedness, value, limitations, vulnerabilities, and call of every person and community.

A CALL? THE ROLE AND PURPOSE OF DISABILITY

The purpose of life is a central theme in all faith traditions, with wide variation. For some, it is to follow an individual call, to be a disciple in the Christian tradition, to continue learning in Jewish circles, to keep seeking truth in Islam, to move toward mindfulness and understanding in Buddhism, and so on. The sense of vocation, or following the purpose of one's life, has been much proscribed for people with disabilities by others. Thus, one might ask, was the role for people with disabilities often that of beggar because of their disabilities—that is, was that the only thing they were allowed to do? Or, conversely, we might wonder how social conditions and poverty contribute to disability over time, as they do today, and thus prescribe roles from another direction. This is one area where the social and contextual understandings of disability need profound study and reflection in faith traditions.

Many faith traditions also have affirmed that people with disabilities face the same obligation to obey the divine and practice their beliefs as anyone else, with considerations taken for their disabilities. In Judaism, the person with a disability was obliged to observe the Sabbath and, if a man, could be counted in the minyan for a worshipping community. People with disabilities could not be priests, but in Leviticus, only Levites could be priests, and Levites with disabilities could still eat the food in the temple. In many faiths, rites of passage could be adapted for people with various forms of disability. A fascinating debate in early Islam was about whether people with intellectual disabilities could inherit family resources. That gave rise to some of the first guardianship provisions, as well as a debate that said to take away a right to inherit and the right to make a mistake like anyone else was worse than losing a family fortune.

In Islam, if one could not make a living because of a disability, then one could appeal to Allah and the community for justice, not necessarily charity, because if Allah deprived one of the ability to earn, then it was the duty of everyone to give that person his or her due. People with disabilities were exempt from military service but could serve if they wanted. There was no blame for the lame or blind if they could not participate in other duties, but everyone should still respond to the call of God as much as they can. A Christian understanding of people with intellectual disabilities as "holy innocents" often exempted them from any responsibility and thus denied them a capacity to learn.

In Far Eastern traditions, such as Daoism, there are parallel understandings of the potential "special" role of people with disabilities but also philosophical and religious understandings that "uselessness" could have its own merits. The useless could outsmart the "useful," who tend to get used up (e.g., by being killed in wars). There are parallels here in Christian theology that reflect on the power of the "powerless." There are also Japanese traditions of guilds of professional musicians and storytellers who are all blind.

In every major faith tradition, there are stories of religious leaders with disabilities. We can legitimately ask whether that "holiness" is ascribed to them because of their "difference," such as how they learned how to deal with their situation and/or whether it was a function of living on the boundary between ordinary, divine, and/or demonic worlds. There are also stories, with many different interpretations, about key religious leaders being challenged by a person with a disability, including the famous story of Muhammad being rebuffed for turning away a blind man, Jesus being called to task by people with disabilities, the young Buddha being profoundly changed by death and disease, and more. Yet in most traditions, disability is an impediment to pursuing religious vocation (e.g., admission to a monastic order, seminary, or Holy Orders). This, again, is an area of great change, as people with disabilities seek to break out of confining expectations and disabling environments. As religions seek more valued social roles and callings for everyone, perhaps we also will recover traditions from the past in which every person was expected or had to work simply because families and communities could not afford for anyone to be idle. Religions may now help individuals and societies to reevaluate the vocation or calling of a person with disability.

DISABILITY AND COMMUNITY RESPONSIBILITY

All of the major faith traditions call for people to practice faith in relationship with others, calling for people to be compassionate to others in pain, suffering, or want. In Christianity and Judaism, it is called the Golden Rule. In Islam, charitable acts were not to be done out of pity but as a gesture of seeking good will from Allah and, as noted, establishing justice by giving people their due. Like Judaism, most faith traditions have equivalent injunctions to the commands that others should not put stumbling blocks in the way of the blind, make gestures at them that they cannot see, or curse the deaf. One was not to mock or obstruct people with disabilities. Even if they did not know, God saw. These acts of charity, many of which formed the basis for social support agencies of all kinds throughout the centuries and certainly in modern times, are just as much a part of religious traditions as are the stories and examples of religious shunning of people with various forms of disability because of assumptions about sinfulness and punishment.

At another level, religious faiths have often used the treatment of people with disabilities, along with the treatment of the "weak," "poor," and "widows and orphans," as a measure of the righteousness and character of the society. Jewish prophets, Islamic scholars and leaders, and Christian ministers and leaders have all suggested that society is to be judged by, or will succeed only through, the ways it treats the "least of these." This has led in the past century to new forms of religious advocacy, service, and explorations of the ways that faith and religious communities have a responsibility not just to care for but to include people with disabilities and their families.

In many places in the world, the religious call to charity or service is the major foundation for social services and supports for people with disabilities. In others (sometimes the same places), modern understandings of the abilities and rights of people with disabilities are at odds with confining religious/social attitudes. And in others, people with disabilities and their families are challenging a system of services and supports based on a charity model, whether it comes from a "religious" or "secular" source. A major challenge exists in many Western countries, where governments may use charities auspiced by religious traditions to deliver welfare, sometimes requiring service practices that can marginalize clients.

A BRIEF HISTORICAL OVERVIEW

The examples cited in this discussion of four dimensions of religions and disability emerge from recent research into the historical intersections between religion and disability. Yet the narration and findings of that history depend in measure on what one looks for, in terms of both positive and negative outcomes for people with disabilities and their families. Researchers are beginning to uncover and reexamine old stories and long-held assumptions, and they are finding ways to overcome the fact that disability is not often a major theme in any religious creed, system, or scripture.

Recent scholarship points to ancient rulers in Eastern traditions whose religion and faith led them to develop disability supports and service. Early Islam was one of the first traditions to recognize the rights of people with disabilities, such as the deaf, and develop services for people with mental illness. Christian hostels formed early community services for people with disabilities and were often connected in medieval Europe to the village or town cathedral. Jewish scholars and traditions explored “functional” definitions of disability long before it became a modern practice.

In the past century and a half, in North America and Europe and elsewhere, religious communities have often been the impetus for new services and supports, even if they were gradually taken over by public or secular professions and services. Since the 1950s, there has been growing attention to the intersection of religion and disability, as religions developed special religious education programs for children with disabilities, formed “deaf ministries” networks, and began to work on making religious buildings more accessible and religious communities more inclusive. Leaders such as Helen Keller in the area of blindness, Dorothea Dix in mental illness, and Harold Wilke in physical disabilities, along with Jean Vanier and L’Arche communities in mental retardation and intellectual disabilities, have changed both religious understandings of disability and spawned countless new practices and services. Since the International Year of Disabled People in 1981, most major faith traditions have developed and disseminated position papers and statements on faith and disability, such as the Roman Catholics Bishop’s Pastoral of 1979 or the World Council of Churches statement of 2003.

In more recent developments, there have been partnerships such as the Accessible Congregations Campaign in the United States, coordinated between secular and religious support organizations. Christian and Jewish groups have developed strategies for accommodating religious education, worship practices, and rites of passage to include children and adults with any form of disability. There has been an explosion of written resources for Christian and Jewish networks, as well as the beginnings of scientific research into the power and impact of spirituality and spiritual supports for people with disabilities and their families. One example is the national *Space to Listen* research project by the Foundation for Learning Disabilities in the United Kingdom, which explores the role of spirituality in the lives of people with intellectual disabilities. The *Journal of Religion in Disability and Rehabilitation* has developed into the *Journal of Religion, Disability, and Health.* Theologians and practitioners are exploring ways to include disability in theological education and to affirm the right of people with disabilities to be in training for religious roles.

While admittedly Western in focus, this brief overview points to the huge need for further cross-cultural understanding and research. Some positive developments highlighted are not meant to hide the ways in which faith traditions and practice still often oppress people with disabilities and their families. There are huge questions, such as why religious traditions and communities have often been at the forefront of leadership in civil and human rights in North America but not so connected to the disability rights movement.

It is clear that the intersection of religion and disability:

occurs at many different levels and dimensions, from scholar through the intense believer to the public stereotypes of both religion and disability;

includes many voices, backgrounds, and perspectives—disabled and nondisabled—and a huge diversity of religious understandings; and

affects many areas of "religious" life, such as worship, theology, ritual, ethics, understandings of tradition and history, and reexamination of sacred text, all with implications for individual and community responsibility and practice.

This complexity and diversity has vast room for research and dialogue, the potential for all kinds of misunderstanding and oversimplification, and the possibility of building new bridges of understanding between people with and without disabilities, theoreticians and practitioners from many disciplines, and followers of many different faiths.

—Bill Gaventa and
Christopher Newell

REPETITIVE STRAIN INJURIES

Repetitive strain injuries (*RSIs*), *cumulative trauma disorders, repetitive motion injuries,* and *work-related musculoskeletal disorders* are synonymous terms describing a broad range of injuries resulting from excessive use of the spine, arm, hand, leg, or foot. In 1999, these injuries constituted 9 percent of the injuries in U.S. private industry that resulted in lost workdays. Wrist and hand problems accounted for the majority of the injuries and were the most costly and the most disabling. Some health care systems no longer accept a categorical diagnosis of RSI and insist on more specific diagnoses (e.g., tendonitis, neuritis, fascitis, myositis, carpal tunnel syndrome, thoracic outlet syndrome, cubital tunnel syndrome, degenerative arthritis, tendinosis, fibromyalgia, herniated disk, focal hand dystonia, neuropathic pain).

Healthy tissues constantly turn over, repair, and remodel, a maintenance function that requires good hydration, nutrition, and balanced loading and rest. Normally, structural tissue damage postinjury activates a cellular cascade to mediate the inflammation and initiate repair. However, in patients with chronic repetitive strain injuries, cumulative loading can lead to reduced perfusion (blood supply), poor axonal transport of peripheral nerves and excessive tissue inflammation, scarring, cell compression, matrix degeneration, muscle fiber loss, and cell death. This can lead to tissue discontinuity, biomechanical irritation, pain, and change in the type and organization of the collagen in tendons and ligaments that alters strength, compliance, and flexibility. Thus, some individuals with RSIs can develop severe pain (with or without inflammation), others lose strength and endurance, and still others experience excessive fatigue, poor sensorimotor feedback, and painless loss of fine motor control, specifically at the work task (focal hand dystonia).

Repetitive microtrauma is usually classified by stage:

Stage 1 = injury, probably inflammatory without pathological alterations

Stage 2 = injury associated with pathological alterations

Stage 3 = injury associated with structural failure (rupture)

Stage 4 = injury meets criteria for stages 2 and 3 plus other changes, such as osseous calcification

This classification system focuses on the soft tissue response to injury without consideration of secondary, aberrant central nervous system degradation. Risk factors for RSI include occupation (e.g., heavy, stressful schedules of repetitive hand use that demand high levels of accuracy and progressive task difficulty), biomechanics (e.g., end range, forceful movements), patterns of use (e.g., rapid, stereotypical, near simultaneous, alternating movements), personal health (e.g., prior injury, disease status, hydration, fitness), psychosocial issues (e.g., emotional state, personality, perfectionism, anxiety, family support), and administrative factors (health care coverage, disability benefits, legal issues). These factors can affect the incidence of injury, the extent of the impairment, the potential for recovery, and the magnitude of disability.

Treatment initially includes rest from work, rest of the part, and anti-inflammatory medications. Ideally, intervention should also address prevention, including ergonomic modifications, decreased forceful repetition, aerobic and postural exercises, good hydration, and nutrition. If disabling signs and symptoms persist, intervention must factor in the stage of tissue pathology, the extent of tissue damage, the status of change in cortical function, and whether surgery, medications, therapeutic modalities, assistive devices, and/or therapeutic exercises, including learning-based sensorimotor training, are essential to recovery.

REPRESENTATIONS OF DISABILITY, HISTORY OF

Patterns of the historical representation of disability in literary, artistic, and visual media cannot be generalized. This is due to the fact that while all cultures have wrestled with the meaning and nature of disability, social responses themselves vary greatly across time, region, cultures, and situations. Nevertheless, a survey of disability representations demonstrates the degree to which human differences pose substantial conflicts for all communities. Thus, representational art has always grappled with such conflicts, and these documented efforts create a significant historical discourse about disabled people.

Here, we define representation as the efforts of cultural workers to speak on behalf of an individual or group in artistic arenas. While one may argue that images of disability in any textual or visual arena are equally imaginative, we are primarily interested in the specific productions of disability in genres identified as "creative." Representation suggests an effort to imagine perspectives difficult to come by in our everyday lives. In part, this places an ethical demand on art to conjure the lives of those significantly distant from a reader's own experience. The historical sequestration of disabled persons makes them a common representational objective in that artists employ the uniqueness of such perspectives as an impetus for generating audience interest. For instance, in the Greek play *Philoctetes,* the abandonment of the disabled title character on an island because he is inconvenient and "un-useful" ultimately makes it necessary for his fellow warriers to return to retrieve him. Besides recognizing that Philoctetes holds Heracles's bow as a weapon, which could ensure victory in war, his literal absence also causes significant interest as to how he has lived and what wreckage on his psyche the impairment (a painful, festering wound) has caused. His abandonment results in the necessity of a return to the society that originally rejected his body, as if his removal ultimately comes full circle back to our interest in what has become of him. Since representation produces one thing that stands for another, the drama of Philoctetes's rejection ultimately becomes an opportunity to contemplate social tolerance toward difference. Therefore, disability's common ouster from social contexts ironically results in ritualistic returns in imaginative texts. One is tempted to draw a mathematical formula of inverse relations: the degree to which an experience appears absent from social life determines the degree of interest lavished on that object in artistic discourses.

Consequently, while many minority groups have argued that social marginalization occurs, in part, as a result of the absence of their images in artistic discourses, images of disabled people suggest a different representational fate. Their social marginality has occurred despite widespread circulation. In fact, the presence of disability, as allegory, motif, and social cause, can be said to serve as a critical component of a further silencing by representation that disabled persons may experience. In contemporary life, this circulation may be due to the mysteries that attend to bodies that have been hidden away for their lack of propriety. Whether for the sake of charitable act, freak show shock, indication of mysteries, evidence of suffering, or body difficulty that requires social attention to research and prevent it, representations of disability have remained central to acts of cultural production. Until recently, with the generation of a collective discourse concerning disability representation, this circulation of disability imagery has been little discussed by critics, historians, and cultural commentators. Recently, open interpretation of the disability implications of artistic discourses has occurred as an educational and research priority that accompanies deinstitutionalization and human rights initiatives on behalf of disabled persons. Still, representational critique refers us back to a lack of social consensus as to whether access and inclusion, as opposed to cure or sequestration, are the best goals to be held out for disabled persons.

Disability persists as a perpetual topic of commentary (particularly in representational mediums) due to a variety of historical developments:

1. Disability has largely been consigned to the domain of medicine as a matter of individual dysfunction or insufficiency.
2. Stories about disability often conclude with solutions that result in the erasure of impairments either through death or cure.
3. The alleviation of disability in our cultural narratives ultimately asks nothing of the wider society in terms of accommodation, political action, or social recognition.
4. Stories about disability have often featured a single individual existing without reference to a larger population of like-minded/embodied individuals.

While exceptions to these four general patterns of plot certainly exist, as narrative winds its way toward surprise, suspense, and satisfactions for the recipient, the list helps to explain the reasons why disability may be overlooked as a significant mode of characterization or metaphor in literary critical history.

Throughout the scant written records of ancient civilizations such as those from the regions of ancient Mesopotamia and Greece, one encounters the mark of disability as commonly relating to a metaphysical predicament. This fact alone suggests that the appearance of characteristics deemed highly distinctive, while presumed largely detrimental by other social residents, occurs with some frequency. Within the texts of these ancient societies, disability is often treated either as a punishment visited upon individuals and communities for the sins of the past or, at least, in a purely symbolic way as a message from the gods that must be interpreted. In either situation, disability references the mysterious ways of divinities and their unpredictable plans for human communities. At the epistemological level, ancient civilizations often treated disability as if it represented an encoded missive from a vaguely discernible extraterrestrial order—one that demands recognition of its symbolic significance and an appropriate response from the community at large.

Thus, we witness the existence of early prophetic texts, such as cuneiform tablets or oracles that predict future outcomes as encoded by the bodies of aborted fetuses and babies with birth disabilities. For instance, ancient Mesopotamian texts interpret human and animal "deviancies," disabled fetuses and demarcations in sacrificial herd animals, as a sign that something serious is in store for the recipient culture. These references by anatomical difference do not necessarily predict negative events—in some cases, predications about organic differences remark on lengthy regimes for a ruler or a favorable harvest. Yet, more often than not, metaphysical readings prompt visions of cultural catastrophe. Characteristics considered deviations from societal norms rarely refer to individual fates in these early texts. Instead, an entire community or society will be implicated by the meaning derived from a single anatomy. Thus, the arrival of visibly disabled offspring must have precipitated significant anxieties among leaders and citizens alike. Reported practices of the infanticide of "deformed" or "unhearty" children help to solidify this interpretation.

In classical Greek literature, perhaps the first extensive repertoire of disability texts available for scrutiny, we meet up with well-known characters such as the blind and hermaphroditic prophet Tiresias, the ensnared and cane-walking hero Oedipus, the untimely wounded Philoctetes, and the one-eyed gigantic Cyclops representing wholly other physical castes of tribes—among many others—whose bodily differences signify the need for their location on the periphery of various communities. Yet, whereas prophetic texts contended a direct correspondence between disability and social fate, these texts offer up reflexive contemplations of the question. While many narratives eventually justify exclusion based on human differences or presume a naturalized segregation of communities, there are numerous instances where social exile is shown up as an insufficient solution.

In much Greek literature, disabilities function as a sign of a character's "tragic flaw" or "compensatory insight." Tiresias's blindness provides him with an uncanny ability to predict the future and provide sagely commentary on a range of social conflicts; Oedipus's limp (a result of his father, Laius's, efforts to pin his ankles and leave him to die of exposure on a hillside) allows him to draw from his experiences of disability to solve the riddle of the sphinx (an anomalous hybrid figure in her own right); as discussed earlier, Philoctetes's agony from an untreatable wound prompts his fellow soldiers to abandon him on an island; and Cyclops's monstrosity is emphasized by physical characteristics that mark him both as racially foreign and less intellectually agile than his wily captives. Each of these stories turns on revelations drawn directly from the specific disability of each character. Thus, it can be said that Greek literature helps to initiate the long-standing historical reliance of literary characterizations upon disability as a means to differentiate heroes or villains from their less distinguishable (and thus often less storied) literary peers. For instance, the cycle of plays about Oedipus (translated from the Greek as "swollen foot") seems to hurdle toward the revelation that his limp marks him as an ill-fated agent. In other words, the meaning-laden significance of disability must be recognized for its social layering, its predictive consequences, and its psychological, albeit angst-ridden, complexity.

Whereas one finds key literary characters accompanied by disabilities in ancient literature, early Christian and Islamic sources adopt disability as either a strict marker of exclusion or as a generic characteristic of denigrated populations. The Hebrew Bible, for instance, tells the story of Jacob's struggle with his faith (represented as a "stranger" at the river) that results in a permanent disability from severe hip dislocation; Leviticus defines priestly purity primarily through the absence of disability as a source of potential contamination; Tobit's blindness allows him to be duped and then is "cured" by God as a reward for his daughter's loyalty; and Mephiboseth's childhood accident leaves him with a mobility impairment that both disqualifies him from his rightful claim to the kingship and provides him with an all-purpose excuse for his various shortcomings. There is little questioning or interrogation in the Old Testament regarding the way disabled persons should be addressed. Commentators struggle over translations that only continue to certify a naturalized derogatory meaning such as that King David is said to hate the blind and lame and therefore desired their eradication en route to conquering Jerusalem.

In contrast to this narrative tradition, the New Testament seems to offer a more rewarding series of scenarios. Cripples, deaf-mutes, the blind, and epileptic individuals show up with some regularity in these stories—particularly at key moments when the prophetic powers of Christ or his disciples prove in need of exhibition. Still a largely mass phenomenon, disabilities arrive as the characteristics of hordes of unfortunates, as if human vulnerability equates with the imperfection of an earth-bound existence. One finds some of the first lineups of disabled people as supplicants in these stories as an opportunity to demonstrate divine capacities exercised upon human imperfections. This foregrounding of misery through suffering embodiment situates early religious texts at the origins of a lengthy tradition of disability representation. Many biblical scholars have championed the cure of cripples in the New Testament as a historical transition of acceptance toward destitute populations. Furthermore, some scholars have argued that the flayed and broken body of Christ indicates an early form of social integration toward imperfection and suffering on Earth.

However, a paradox of the cure scenario, so often repeated in New Testament writings, turns upon the erasure of disabilities. An alternative tradition of argumentation has begun to take shape around interpretations of miracle cures as the obliteration of human differences rather than as justification for integration or social acceptance. At the very least, the parallel of divinity with the remedy of dysfunction, incapacity, or aesthetic deviation makes little demand on action at the level of wider social networks. Short of existing in a moment populated by a magical healer (the figure of Jesus Christ as one of the first rehabilitation specialists), disabled people (one might suppose) whose differences cannot be erased would find their integration hardpressed at best. Later Christian works, such as those contained in St. Augustine's *City of God* or the stories of St. Francis of Assisi kissing a leper, provide examples of piety demonstrated by the efforts of religious figures to eschew their worldly possessions and live among the downtrodden. A conspicuously promulgated morality exists in decisions to take up an intimacy with those excluded on the basis of fears of contagion, aberrancy, and social transgression.

Meaningful alternatives to these Western traditions of disability representation can be identified among traditions in the Middle East, Asia, and Africa, where disabled people can be found performing important social functions. Such productive representations of disabled people's contributions can be found in works such as "The Meadows of Gold" by Al-Ma'sudi (c. 896–956 CE), which tells a tale of a deaf person thought most worthy to represent the inhabitants of Kufa to the Caliph and also includes discussions about Abu al-Ayna, a blind person of great wit. In addition, the biographies of several prominent deaf, blind, and physically disabled people are detailed by the thirteenth-century Muslim writer Ibn Khallikhan in his biographical dictionary. Such biographies of exceptional persons include a learned blind man in Basra named Katada Ibn Di`ama As-Sadusi (679–735/6); Abu'l-Aswad ad-Duwali, who limped in public and experienced seizures from "palsy" (d. 688/9); renowned deaf teacher Abu'l-Abbas Muhammad Ibn Yakub al-Asamm (d. 957); Muhammed Ibn Sirin (653/4–729), the deaf law lecturer who also wrote one of the early translations of the life of the prophet Muhammed; poet Dibil Ibn Ali-l-Khuzai, who was reportedly deaf and hunchbacked from a "scrofulous swelling on the back"; and Abu 'l-Abbas Ahmad Ibn Yahya Ibn Zaid Ibn Saiyar (also known as Thalab the Grammarian), who became deaf but continued as an influential scholar in Baghdad. In addition, we might also look to the *Semimaru* (Plays of the No Theater) in Japan, written by Zeami during the twelfth century. These plays feature the exploits of a blind *biwa* player who lived on Mt. Osaka and was sentenced to death because of his visual impairment by his father, Emperor Daigo. Zeami's renown as a musician caused the son of prince Minamoto Hakuga to make a long, difficult trip just to hear him play.

In various Asian locales, there exists a long tradition of cultivating the talents of people with sensory disabilities in one particular skill such as music or massage. Far fewer examples of similar investments in those with cognitive or physical disabilities exist. However, a few examples of recuperated meanings around historical individuals with physical disabilities may be found. If we research back to ancient Egypt, King Amenemope, the fourth ruler of the twenty-first dynasty who ruled a substantial kingdom from 993 to 984 BCE, is reported to have had a series of visible physical differences identified in the many statues of him left behind such as an elongated head, large ears, distended stomach, and wide hips. Similarly, we might also reference the later example of the African Oba of Benin (1500–1597), who, upon experiencing lower limb paralysis, claimed that his legs had been transformed into the sacred mudfish. Since mudfish can navigate land on their legs and swim in water, they served as a symbol of the king's capacity to move between earthly and spiritual realms. Such an inversion of the meaning of disability saved this oba from the fate of his predecessors, who were often executed after falling ill. While such examples suggest individuals with disabilities of exceptional talents, they may also gesture toward the possibility of a more inclusive cultural moment in which disability did not automatically disqualify one from participation.

Of course, as in any tradition, one can also find evidence of more dehumanizing treatments toward people with disabilities. For instance, in eleventh-century Persia, instructional manuals for princes published by Kai Kaus ibn Iskander ibn Quabus (1082/3) inaccurately argued the following: "all dumb (i.e., mute) people are deaf" because they lack access to oral speech. In the wake of such beliefs, reports exist that Emperor Akbar undertook some early experimentation on disability by raising groups of children with deaf-mute nurses in a locked house. In addition, there exist many reports from European travel writers that the Ottoman court employed dozens of deaf-mute individuals as reliable servants to various rulers. Their valued capacities included beliefs that the impairments of these individuals rendered them incapable of hearing or bearing witness to the behind-the-scenes escapades of those in power. In these instances, incapacity becomes an ironic "value" while also overlooking the fact that sign languages served as an equally powerful means of communication among presumably incommunicative subjects.

Other than these brief references to the role of disabled people in various rulers' dominions, disability in the Middle Ages becomes increasingly sidelined as an expression of human difference. One finds some early treatment texts on devastating plagues such as those on leprosy and compound fractures of the skull. The sudden diminishment of disability as a common representational device (if this can be said to be the case) may be interpreted in a number of ways. This noticeable dearth of representations signals a new and perhaps even more pronounced disregard of disabled people. One gets the feeling that late Christian texts in this period, such as St. Francis's devotion to communities of people with leprosy as well as the practice of other religious figures renouncing material goods while taking up residence with the poor and incapacitated, play out efforts to combat this widespread neglect. Likewise, we could look to *The Book of Margery Kempe* (1430) for an example of a medieval woman's guild of the Holy Trinity that devotes itself to the care of convalescing disabled women. Such examples, as some scholars have argued, may represent shifting values about human embodiment and a new devotion to those most vulnerable to the violence of social rejection. Disabled and poor people become enshrined during this period as a population that some refuse to reject as deviant or unworthy of human care.

Yet, we might also consider the degree to which devotions paid to socially marginalized peoples provide a moral opportunity in this period to ensure one's own right to salvation in an afterlife. In other words, devotion to the "less fortunate" becomes a powerful system of exchange in this period, wherein one commits oneself to support of these communities as a way of guaranteeing outward signs of divine "election." We could celebrate these examples of religiously derived support to those who are often violently excluded during this period, without having to relinquish analyses of the social benefits that accrue to those who practice benevolent devotions.

Another possibility is that we might comprehend the fading significance of representations of disability during this period as a product of rampant social crises in the transmission of diseases. If much of Europe, for instance, found itself exposed to the ravages of various plagues, then a deepening sense of human vulnerability might have developed. Disabled people have often held down the terms of a radical frailty that others find threatening. Efforts to distance ourselves from disability often expose the degree to which we fail to acknowledge our own potential exposure to various human-made and natural forces. Perhaps one could locate this period as an example of a time when many people felt as if their mortality and/or functionality could be easily compromised, and thus the ability to distance oneself from the vagaries of human embodiment undermined a more explicit division across bodies. Perhaps the degree to which one could afford to recognize disability as a chasm between ourselves and others collapsed during the period, resulting in a failure of common othering strategies determined by investments in bodies and minds as a reliable partition between the vulnerable and invulnerable. We might also look to later texts such as St. Augustine's *City of God* (1467) for its efforts to challenge common beliefs in "monstrosity" as somehow outside of a divine plan of the universe of human embodiment.

However, somewhere between the fourteenth and sixteenth centuries, one starts to witness a desacralization of disability. While various religious systems continued to recognize disabled bodies as an object of charitable investments (massive charity networks developed just prior to this period), a corresponding secularization of disability begins to develop. Although earlier examples of state- and community-sponsored supports exist—such as the monetary provisions to disabled persons identified in the Athenian Constitution of ancient Greece—European legislation of various kinds becomes increasingly numerous. Most of these policies served as early "diagnostic" efforts to divide the "deserving" from the "undeserving" poor. This division would prove key in most Western locations, in that productive capacity to labor became increasingly critical to the definitions of citizenship in the modern nation. Accompanying the rise of urban trading centers and the decline of feudalism as a dominant economic system, cities and towns passed numerous ordinances to punish idleness and the practice of alms seeking. In the English Statute of Laborers, approved in 1349, imprisonment was used as an incentive to compel most citizens into "labor[ing] for their necessary living." While this early legislation identifies a vague group of social misfits based on unwillingness to labor, later legislation deepens this division based on the status of "cripples" as a material inability to work. In addition, such legislation suggests at least the suspicion of an outbreak of crippled pretenders—those who would feign disability to pursue begging as a viable career option to other socially recognized forms of labor. Later, around the year 1697, these English laws were further amended to require that those who were legitimately "on relief" had to wear a badge or mark (such as a large "Roman P") visible to all on their clothing. Such badging efforts were portrayed in the pinning of fox tails on disabled beggars, as seen in Pieter Brueghel the Elder's famous painting of "The Cripples" (1568), now hanging in the Louvre in Paris. Similar badging practices were resuscitated in National Socialist Germany during the 1940s toward those targeted on the basis of disability, sexuality, ethnicity, and race. These two systems—charity and labor capacity—continue to compete for interpretive authority for several hundred years; in fact, we could say that they continue to struggle for cultural capital as two primary modes of modern disability response.

From 1500 to 1800, we witness an explosion of works about "fools" and "court jesters" that represent social struggles over the presumably decreased capacities of individuals with cognitive disabilities and deafmutes, as well as the power often bequeathed to these individuals by rulers and other prominent members of ruling regimes. The court fool was ridiculed and scoffed at for these idiosyncrasies and served as a source of entertainment for gatherings at various royal assemblies. Yet, in addition to these prurient practices of human exhibition, celebrated fools also managed to garner a significant degree of power for their roles. Some individuals with cognitive and physical disabilities were thought to communicate in more metaphysical realms such that their "babblings" proved alarmingly insightful. While most participants in a leader's entourage were expected to comply with and support the dictums of their ruler, fools often found some room for maneuver in these circles. They could openly critique and satirize the doings of those in power as if fools provided a mirror to the rulers under whom they served. Such characters proved relatively singular in these instances, but their mockery provided an effective antidote to the arrogance that often developed in ruling circles. The Spanish painter Velasquez captured the function of fools as agents of critique among hierarchies of power when he positioned his jester figure as the lone individual whose stare breaks the plane of the painting and meets the gaze of viewers directly. The figure poses as both amused and knowing—as if he holds secrets that might easily undermine the "pretense" of the aristocratic family in which he serves.

Texts by European travelers to modern-day territories such as Turkey, the Middle East, and northern Africa during the period between 1500 and 1800 all describe the multitudes of disabled populations in attendance at various ruling class ceremonies. Hordes of deaf-mutes, dwarves, dumb men, eunuchs and women of seraglios, and others provide evidence of the degree to which human differences did not exclude one from participation at the highest levels of culture (no matter how hierarchical and diminished such inclusion might prove). One inventory from 1594 of the royal court in Constantinople by the English traveler, John Sanderson, lists the employ of 300 "falconers, dwarfs, and dome [dumb] men" in a workforce of more than 1 million for Sultan Murad III. As in the earlier discussion of deaf-mutes employed as guards who would not expose secrets or private affairs at court, such figures also played a key role in the seraglios. If rulers and other top officials were allowed to practice their sexuality across populations of women, disabled individuals—particularly those rendered sexually impotent as eunuchs—were thought to be ideal sentries who could not fall prey to the enticements of the harem. At the same time, narratives from the 1550s about the reign of Suleiman in Istanbul suggest that a disabled son in line for the throne could be contested on the basis of his physical differences. In addition, the British historian Richard Knolles reported that a group of seven mutes participated in the brutal assassination of the heir-apparent Mustapha during 1553. All of these stories help to establish the expansive roles of disabled people in various court intrigues. Their differences are invested with various meanings in which their distinct capacities—and, most important, incapacities—situate them within unique proximity to antics of power. Yet, it is not until the sixteenth century that we witness the publication of texts that foreground disabled individuals' own designs on power within such settings.

Perhaps, ironically, the first truly "modern" protagonist, William Shakespeare's rendition of Richard III (1591–1592), develops out of the revelation that disabled people inevitably participate in the seductions of power. In what is widely recognized as the beginning of modern literature, Shakespeare's disabled usurper of the throne delves theatergoers into his conscious musings on his status as a disabled person. For instance, his much-performed opening monologue points out the fact that while his "deformities" allow him full participation in wartime scenarios—where, presumably, the ugliness of military clashes eclipse Richard's own physical "distastefulness"—the peacetime that follows provides no viable role for such a figure. Throughout the drama, Richard mobilizes his disability status to his advantage by simultaneously playing on perceptions of his incapacity while also pursuing a violent scheme of retribution toward those he believes have wronged him on the basis of his disabilities. Thus, Richard III inaugurates a cultivated depth of characterization by hosting a character that appears one way but unveils his interior musings as existing in contradiction to his cultivated public demeanor. Disability could be said to have inaugurated a split between public and personal presentation that would continue to characterize representational strategies from this point onward as an inaugural moment in modern literatures.

One also witnesses the rise of the empirical method during this period as the European Enlightenment gets under way. Sir Francis Bacon and others craft a relationship to natural and social worlds that promises to expose the logical underpinning of the universe without reference to an omnipotent consciousness. The system of analysis depends heavily on what Barbara Maria Stafford (1993) refers to as "technologies of the visible." New instruments and "reading" strategies allow investigators to get below the surface and arrive at the essence of an object made newly available for scrutiny. Various taxonomic systems get under way in this period, such as Carl Linnaeus's *Systema Naturae* (1735) cataloguing of plants and animal life into various classifications of belonging—genus and species, flora and fauna. Likewise, human forms came under similar efforts to sort kinds of humanity into their appropriate columns. For instance, Linnaeus also put his efforts to sorting racial types—Americanus, Europeus, Asiaticus, and Afer—into a hierarchy of values based on his own privileging of northern European civilizations as superior to the denizens of more tropical locales. Disabled people's differences prove particularly critical to this venture in that an increasing premium was placed on the meaning of visible differences as a referencing system for otherwise intangible traits of character. In his essay "Of Deformity" (1601), Bacon—perhaps using Shakespeare's Richard III as his universal model—wrote about the unacknowledged "advantage" of deformity among participants in royal courts. Whereas previous literature had largely emptied out the subjectivity of disabled people from designs of power, Bacon invests "deformed persons" with aspirations of their own. As in the Shakespearian drama, Bacon cultivates an early psychological model of disabled subjectivity by arguing that deformity is a spur to individuals who seek to remove themselves from social ridicule. Rather than divest deformed persons of awareness, Bacon turns the tables and argues that their conditions give them an even greater degree of motivation for climbing the royal hierarchy.

By deploying deformity as an external sign of internal (albeit largely malignant) motivation, Bacon help to set off an entire tradition of sciences of the surface—those fields of investigation that rely on surface phenomena (such as facial countenance or bumps on the skull or visible deformities) to interpret otherwise difficult to detect moral qualities. While this practice was not new—some researchers trace the practice of interpreting questions of moral character in facial expressions back to ancient Greece—physiognomic systems came to be increasingly legitimated as "scientific." For instance, in 1778–1779, Johann Kasper Lavater published a highly influential system for reading the truth of one's character in the slope of the forehead, shape of the ears, line of the nose, and lips. Disabled people faired rather poorly in these interpretive systems, in that their "insufficient" bodies were immediately suspect—as if there existed an automatic shorthand available to locating deficiencies of personal integrity in the "obvious" deficiencies of the body, mind, or senses. Such efforts provide us the opportunity to trace out a history of the rise of normalcy, where the identification of the "deviant" body becomes the grounding for an imaginary normative body—one that is symmetrical, fully functional, independent, racialized, gendered, and economically mobile. Significantly, this idealized normal body came to be increasingly identified as a representative of the "healthy" nation.

Ironically, the rise of literary Romanticism positioned itself in contrast to this burgeoning bodily ideal. Rather than tout the efforts of empiricists and states to analyze, govern, and control the unwieldy nature of the body, Romantic writers took scientific efforts at dominion over nature as their antagonists. Wordsworth's "idiot boy" (1798), Coleridge's chronically depressed mariner (1798), Shelley's Frankenstein monster (1818), Hawthorne's blemished femininity (1843), Poe's obsessive narrators and claustrophobic interiors such as "The Fall of the House of Usher" (1839), Byron's hunchbacked protagonist, and Arnold, in his unfinished drama "The Deformed Transformed" (1824), all point to an era of literary production where disability came to be more synonymous with—rather than divergent from—conditions indicative of human vulnerability. Within these works—perhaps one of the richest in Euro-American representational traditions of disability—the nonidealized body becomes a vehicle of resistance and social critique. Thus, we follow Wordsworth's and Coleridge's entrance into sublime experiences of Nature with disabled characters as our guides; the Frankenstein monster's interrogation of his creator's rejection on the basis of his nonnormative appearance and functionality; the exposure of the alchemist, Aylmer, whose efforts to achieve perfection in his spouse through pursuit of a cure erases a birthmark on her face while also killing her; Poe's shifting mental states as undermining investments in static rationality; and Byron's social critique of disability as engendering violent responses from family and neighbors on the basis of solidifying normative expectation to which he cannot conform. All of these texts establish Romanticism as a key critic of normalcy's violent social scheme—that which the African American writer, Toni Morrison (1970:97), calls the most destructive concept in Western traditions—against which literature must resist. It also inaugurates a period where literature imagines science as a primary opposition in its promotion of schemes that often prove socially inflexible.

In fact, in many ways, we might read the alarm registered in Romantic literature toward empirically backed efforts of dominion over Nature as quite prescient. As the eighteenth century gives way to the nineteenth, one finds disability increasingly targeted by various efforts at "training" and institutionalization. In European locales such as France, Britain, the Netherlands, and Germany, as well as in Canada and the United States, the science of eugenics takes shape. Coined by the British statistician, Sir Francis Galton, in 1889 from the Greek word for "good seed," eugenics recognized certain cognitive, physical, and sensory disabilities as a threat to the progress of the nation. Eugenicists argued that, as in the sciences of horticulture and animal husbandry, human communities had the responsibility to oversee and protect their "hereditary stock" through active breeding practices. Such arguments began to establish a lethal cultural atmosphere toward "inferior" peoples of maligned ethnicities, races, sexualities, and particularly people with disabilities who cross all these identity groups. British social commentator Anna Laeticia Barbauld (1825), for instance, would apply rising sentiments of intolerance when she excoriated writers of her day to avoid defacing their work by populating plots with unsavory characters "suffering" from various bodily ailments. Others, such as entrepreneur Phineas Taylor Barnum (1810–1891), sought to capitalize on the prurience of public sentiments of the time through the exhibition of human "oddities" as a form of specular entertainment. His exhibits explicitly sought to exploit people with disabilities in their marketing as extraordinary anomalies, such as individuals of short stature (e.g., Tom Thumb and Lavinia Warren), those of exceptional height or congenitally truncated limbs, and people of color showcased as evidence of Darwin's evolutionary "missing links." In all cases, individuals with and without bodily anomalies performed for viewers through enhancements that emphasized their differences so as to achieve the desired effect—exceptions so extraordinary that they could command large audiences in the context of the freak show.

Freak shows played upon a fascination with human anomalies as their state-sponsored suppression increased. With the advent and later adoption of theories developed by researchers such as the Dutch botanist, Gregor Mendel, regarding the workings of regressive and dominant genes, eugenics sought to apply forms of reproductive control on human communities as well. Edouard Séguin in France, Samuel Howe in the United States, and Arthur Tredgold in Britain all worked to segregate those diagnosed as "idiots" in the mid-nineteenth century. In many respects, these figures participated as social reformers who identified familial and community neglect of people with disabilities as their primary nemesis. Yet, their arguments increasingly culminated in the proliferation of rabid fears in North American and European nations (as well as among various colonial outposts) that the wealth of the country was directly tied to its ability to promote the reproductive participation of those with good heredity while restricting such liberties for individuals recognized as "defective." Thus, as the nineteenth century draws to a close and the twentieth century begins, we find the proliferation of laws intended to actively police bodies. Marriage restriction laws for those who have experience bouts of "insanity," coerced institutional policies that could imprison "feebleminded" individuals against their will, sterilization laws that required those seeking to avoid institutionalization to exchange reproductive rights for their liberty, and, ultimately, Nazi extermination practices developed on the bodies of disabled people in psychiatric institutions all serve to expose the degree to which Romanticism proved accurate in its association of scientifically backed intolerance toward human variation with an upsurge in violent social practices.

Often in contradistinction to eugenic ideologies, leftist literature of the period sometimes held a close identification with disabled people in that their bodies could provide the material proof of inhumane work conditions as industrialization sped on and capitalist-based economic orders proliferated. In *Uncle Tom's Cabin* (1857), Harriet Beecher Stowe would use disability to metaphorize the wreckage of slave labor on the bodies of her African American characters; Karl Marx (1867) would argue that capitalism sought to make bodies expendable through the creation of surplus labor pools, thus exhausting the capacities of those who labored and then discarding "used up" bodies in favor of fresh, able ones; and in the novella, *Life in the Iron Mills* (1872), Rebecca Harding Davis would present her female hunchbacked narrator as evidence of an industry that mangles its employees with regular frequency. In a parallel spirit, many women writers such as Elisabeth Stuart Phelps (1877), Mary Wilkins Freeman (1890), Charlotte Perkins Gilman (1899), and others provided a "mute" or "hysterical" female body as evidence that patriarchal institutions sought to stifle women's ability to participate meaningfully in public domains gendered as exclusively masculine. Furthermore, one might turn to influential African American sociologist W. E. B. Du Bois (1903), who theorized racial feeblemindedness as a product of inadequate access to education and insufficient diet due to impoverished conditions that prevailed after the Civil War.

Disability allows one the opportunity to reconstruct a rich cultural fabric that weaves all identities into a shared project largely imposed from without. The rise in pathologizing designations during this period oversaw a proliferation of ways in which one could become "inferior." During the European and American nineteenth and early twentieth centuries, one can find racial, sexual, economic, ethnic, and gendered classifications of human deviance all dovetailing beneath the banner of defect—one that depended on a biologically encoded idea of embedded inferiority that could not be transcended to any significant degree by acculturation, training, or rehabilitation. Developments such as Native American reservations, segregated systems of racial apartheid, and widespread institutionalization efforts all shared an interest in sequestration practices as a response to reproductive fears of contamination. Each marginalized group was believed to share a similar capacity in the midst of multiple incapacities: an unnaturally high fertility rate. For instance, eugenicists claimed that those diagnosed as feebleminded of all races reproduced at 6 to 10 times the rate of "normals." As the famed Supreme Court justice Oliver Wendell Holmes stated in *Buck v. Bell* (1927), "Three generations of imbeciles are enough."

This period also witnessed a further tightening of immigration requirements, such as the passage of the Chinese Immigration Act (1885) and an increasingly expanding definition of which disability categories could be barred from entry. Eugenicists who had been instrumental in obtaining restrictive legislation against an array of conditions believed abnormal—feeblemindedness, epilepsy, homosexuality, a variety of psychiatric conditions, and various congenital physical disabilities—played a key role in associating various ethnicities with a greater prevalence of such variations. In fact, in 1913, noted U.S. eugenicist Henry Goddard was invited by the U.S. government to bring his staff from the institution at Vineland, New Jersey, to immigration headquarters at Ellis Island; the purpose was to demonstrate their greater proficiency at "spotting" feebleminded and other defective individuals as immigrant hordes passed by the surveillance station. Eugenics ideology deepened an already growing suspicion of difference across Europe and the United States based on biological rather than cultural principles of inferiority. Entire populations could be placed under suspicion as a result.

The impact of such a sanctioned national ideology would inevitably surface in representational works of the era. Many modernist writers, for instance, would use disabled characters to signify varieties of cultural collapse. If the "rough beast" of Yeats's celebrated poem came "slouching towards Bethlehem" (1919), then that monster often proved disabled in some manner. William Carlos Williams would represent the pure products of America in the figure of a "broken-brained" maid named Elsie (1923); T. S. Eliot would resuscitate the blind prophet, Tiresias, from ancient Greek mythology as a hermaphroditic figure who exposes the cultural wasteland that rolled out before dulled modern sensibilities (1922); Virginia Woolf would explore the promise of incapacitating illness for a woman writer while also espousing eugenic-like scorn for her own mentally disabled sister (1930); Sherwood Anderson would use physically and mentally "grotesque" figures to symbolize the stultifying lives of rural, midwestern existence (1919); the lethal German medical and legal team, Binding and Hoche, would forward an idea of "useless eaters" and "lives unworthy of life" as the central thesis of their tracts on euthanasia (1920); D. H. Lawrence would metaphorize a war-torn, beleaguered masculinity as the impotent, wheelchair-using Clifford Chatterley (1928); and William Faulkner would emblematize the era's chaos as a tale told by a 33-year-old "idiot" named Benjy in his experimental novel *The Sound and the Fury* (1929). All of these literary portraits deploy disability as an indicator of the extent to which nineteenth-century ideals had come crashing down around the moderns.

One can find a similar sensibility extant in graphic arts of the period. German expressionist painter Otto Dix's (1891–1969) paintings teem with disabled figures, as if the imperiled body saturated social landscapes indifferent to their losses. His experience with multiple wounds as a German soldier in World War I fueled his allegorical visions of an amputated civilization going about its business as if nothing had changed. Picasso and other cubist experiments with multiple perspectives sought to destabilize investments in singular, integrated vantage points on well-worn artistic subjects such the female nude, still lifes, and socially marginal individuals, such as his portrait titled *Blind Man's Meal* (1903). Paul Strand's photograph of a blind woman wearing a sign announcing her diagnosis (1916) and Giorgio de Chirico's abstract painting of disabled female muses (1918) also signal artistic efforts to use disability as a device to upstage long-naturalized sites of male investment in feminine "beauty." Whereas Francisco de Goya (Spanish, 1746–1828), Vincent Van Gogh (Dutch, 1853–1890), and Frida Kahlo (Mexican, 1907–1957) explored the rich territory of their own experiences with disability, most artists sought out disability as a metaphorical path to more paranoid visions. Whereas Romanticism would premise a desirable, yet vulnerable and even tragic, humanity through various human incarnations of imperfection, most modernist artists refused this stance as overtly sentimental—thus, disability came to be transformed in this period as evidence of one's willingness to peer, unwaveringly, into the cultural wreckage. In fact, one might be tempted to analyze much of modernist art as a reactionary movement to the artistic efforts about disability that preceded it by approximately one hundred years.

One can worry over the dehumanizing tendencies that so often crop up in the art of this period or marvel at the centrality of disability (even as it references other social conditions beyond itself) to this cultural moment's concerns. With the flood of disabled veterans in the aftermath of two world wars, disability must have been on the minds of many—particularly after effective treatments for bladder infections decreased the mortality of wheelchair users significantly. The rise of key institutions such as vocational rehabilitation, special education, and the various therapies (physical, occupational, speech) that all began—to one degree or another—in eugenics-based training programs of socially segregated populations began to compete with many of the institutions in which they originally appeared. At least in the United States, eugenics began to fracture amid a sea of institutions all vying for the management of disabled populations; rather than full-time segregation in institutions, for instance, special educators argued that a significant cost-saving measure could be achieved by educating handicapped and subnormal students in ungraded classrooms while sending them home each night to receive care in their homes. In Canada, vocational rehabilitation facilities and disabled veterans organizations would press for the provision of technologies—such as hand controls in automobiles or white cane travel training—to reintegrate institutionally static populations into their local communities. This call for disability-specific technologies proved necessary not only on behalf of the restoration of dysfunctional bodies but also largely on the basis of the inaccessibility of mass public transit systems in urbanizing economies. This "reintroduction" of a narrow array of technologized, cyborgian disabled citizens—particularly paraplegic, visually impaired, and postpolio populations—required a historical realignment on the part of societies that had avoided the necessity of more meaningful contact. Thus, just as the female protagonist Scout in Harper Lee's novel, *To Kill a Mockingbird* (1962), has to recognize the humanity of her cognitively disabled neighbor, Boo Radley, so did many Western countries start the difficult process of reintroducing disability perspectives—along with other minority constituencies—to their representational repertoires.

To the extent that early twentieth-century representational arts recognized disability as an encounter with cultural disintegration, many late twentieth-century artists recognized opportunities for unheard stories in the experiences of disabled persons. Andrew Wyeth's celebrated painting, *Christina's World* (1948), appears as a typical pastoral landscape on a farm until one realizes that her vantage point on the ground is that of a woman with a neuromuscular disorder. In photography, American documentary artist Dorothea Lange used her perspective as a woman with post–polio syndrome to identify with and create stirring images of people in the grips of rampant poverty during the U.S. Depression era. In the late 1950s, she also took a series of photos of her atrophied right foot as an object of contemplation and personal difference. In literature of the African diaspora, one witnesses a counterrepresentational effort to distance portrayals of racialized disability from earlier efforts, such as W. E. B. Du Bois's eugenics-era formulation of the "talented tenth" (1903). Rather than adopt this hierarchical model of exceptional racial genius created to combat associations of race with biological models of inferiority, contemporary writers of color began to explore disability as a meaningful part of the mosaic within their own communities. Mrs. Hedges's corpulent and scarred figure in Ann Petry's *The Street* (1946), Ralph Ellison's analyses of social invisibility in *The Invisible Man* (1952), Toni Morrison's multiple examples of disabled characters (Polly and Pecola Breedlove in *The Bluest Eye* [1970], Shadrack and Eva Peace in *Sula* [1973], Sethe in *Beloved* [1987], etc.), Alice Walker's Meridian and Wild Child (1976), Maxine Hong Kingston's "wild man of the Green Swamp" in *China Men* (1980) and Whitman Ah Sing in *Tripmaster Monkey: His Fake Book* (1989), and Louise Erdrich's (1984) and Leslie Marmon Silko's (1977) disabled Native American veterans provide a glimpse into new artistic efforts to revivify disability as part of—rather than a slander upon—racialized communities of color. In the United States alone, such influential minority authors precipitated a representational renaissance of minority viewpoints that often included disability as integral to the burgeoning of nonmainstream narratives.

As literary and cultural critic Leslie Fiedler ([1962] 1996:386) would announce, disability functioned as a "final frontier" of representational exploration. Whether this proclamation would prove true, developed disability perspectives helped to fuel social commitments to the portrayal of devalued lives during the final half of the twentieth century. As civil rights and women's movements gathered steam as vectors of political revision and social renewal, the disability rights movement galvanized its own successes for meaningful integration of bodies deemed formerly unproductive. Rather than late-nineteenth-century emphases on human difference as pathology, disability played a key role in representational efforts to reclaim rejected bodies and lives. Along with the passage of key disability legislation in a variety of global outposts, the stories of disabled people—particularly those produced by contemporary disabled visual, textual, and performance artists and their close allies—became one critical site for reimagining representational domains as critical sites of struggle over meaning. Given the debilitating depictions often associated with disability—those that largely overwhelmed various efforts to appropriate disability as a meaningful aspect of human diversity—media have become increasingly recognized as key to political interventions. Such efforts have not eclipsed the role of art in presenting less nuanced representations, but they have, at the least, charged the field of representation as one that is crucial to contemporary disability politics. Efforts to reimagine disabled people's critical relationship to a variety of social contexts often take place in representational domains—those imaginative landscapes that can provide meaningful blueprints for worlds where disability is treated as integral to human endeavor that have not yet been realized.

REPRESENTATIONS OF DISABILITY, SOCIAL

A phrase such as "representing disability" or "representing disabled people" bears many meanings. The most common refers to the act of (re)presenting disabled people in literature, the arts, and the media. An analysis of the evolution of these forms of representation through history, in particular in literature and the pictorial arts (including cartoons, cinema, and other media), informs us about the place that societies make for impairment in a given era. A second, more conceptual, meaning of representation, which encompasses the first, refers to a theory derived from social psychology. The concept of social representation takes into account the formation of bodies of knowledge originating from common sense and has been widely used in various disciplines of the social sciences.

A third meaning for the term *representation,* more distant and not discussed in this entry, refers to action in the name of another person or a group, that is, becoming a spokesperson or advocate on the political level. Disabled people thus have "representatives" and "representers" in a variety of instances.

REPRESENTATIONS OF DISABILITY IN ARTS AND MEDIA

Since the close of the 1970s and with the emergence of disability studies as an academic discipline, there has been a sharp increase in critical and historical works that address the ways in which disabled people are portrayed in culture, in particular in literature, cinema, and the media. Recurring stereotypes are associated with impairments: "There was the passively suffering angel of the house, the overcompensating supercrip, the tragically innocent disabled child, the malignant disabled avenger and the angry war veteran" (Mitchell and Snyder 2001:202). Some impairments are frequently depicted—epilepsy, restricted growth, the blind, the cripple, the leper—while others are ignored (Shakespeare 1994).

A Dominant Feature: The "Psychologization" of Disability

A first characteristic of works that bring disabled people onto the scene is a general tendency to pass over social conditions in the experience of disability, such as the inadaptation of the physical environment, in favor of individual factors. Thus, social isolation will not be attributed to the staircase that makes the outdoors inaccessible but to the paralysis that prevents walking. The process of "psychologization" that follows associates certain personality features with disabilities. Isolation is made into a tendency toward introversion, the presumed consequence of a necessarily tragic life experience.

Images Creating Ambivalence

A second characteristic of these representations is their bipolarity, which inspires such paradoxical feelings as fear, pity, and guilt but also admiration. The vulnerability and passivity of the innocent afflicted child are contrasted, now with the demonical and vengeful personality of the frustrated cripple, now with the heroism that permits another to "overcome" his or her disability. "In Victorian children's books, crippled young people teach messages of courage, forgiveness and generosity; witches are always ugly, and villains generally have had an impairment—Captain Hook, Long John Silver and all" (Shakespeare 1994:284).

The recurrence of such images and the plots into which they are introduced contribute to reinforcing cultural prejudice toward disabled people. As Barnes (1992:39) emphasized, "They form the bedrock on which the attitudes toward, assumptions about, and expectations of disabled people are based."

Disability as Metaphor

However, the simple distinction between negative and positive images of disability, acceptable or not, does not suffice to explain the metaphorical role that disability plays in culture. In addition, the criteria for what constitutes a negative or positive representation are not easy to define and vary according to the time and the culture.

A historical approach to this artistic reproduction points up the great complexity and richness of representations of disability and illuminates their symbolic and social functions in different periods. By representing the human body in all its diversity, its deficiencies, and its malformations, the artist goes beyond the visible that is apparent to everyone else "to reveal the hitherto concealed visible, to free our gaze from conventions and stereotypes, to imagine, fantasize, to open onto new scenes of human reality that are still unknown or ill known" (Blanc and Stiker 2003:10).

First, an observation: In all of this, the motif of disability is central in all eras, which leads to its recognition as a fundamental category of human experience, the rule rather than the exception (Mitchell and Snyder 2001). Another noteworthy fact is the use of disability as metaphor. By making reference to disability, the author most often seeks to represent, in figurative fashion, misery and depravity as one facet of the human condition. Thus, Clifford Chatterley, the impotent industrialist created by D. H. Lawrence, symbolizes "the decline of privilege and power in the British aristocracy" (Mitchell and Snyder 2001).

Stainton (2003) showed how the Renaissance marked a historical turning point in the ways in which madness and other forms of disability were represented. Until the close of the Middle Ages, representations of madness were purely allegorical. The famous painting *The Ship of Fools,* in which Hieronymus Bosch points up the folly of humans, is one illustration. Bosch stages a group of characters representing the whole of mankind, voyaging through the seas of time on a small ship gone adrift, eating, flirting, playing witless games, and pursuing unattainable objectives. With the exception of one "madman," recognizable by his cloak and hood, who is situated in the background and thus serves as a kind of cipher, none of the characters represented is stigmatized in one way or another. The *Ship of Fools* is not about other people; it is about "common individuals and common institutions, serving as the features of everyman"

(Stainton 2003:235). It is the group as a whole and its context, and not any one person in particular, that represents madness and folly.

Some years later, Brueghel, in *The Cripples,* portrays people voluntarily stigmatized with the help of prostheses. As in Bosch, their representation is metaphorical. The ridiculous headdresses worn by the characters symbolize organized social groups (the Church, peasantry, middle class, aristocracy). Given to our gaze is an inverted social space, "the disorder to be found in order, the mirror of a society that is always ill-formed" (Stiker 2003:128). However, where the rupture occurs, according to Stainton, is that starting with this period, representations of disability begin to be primarily representations of individual people. They are "increasingly associated with moral defects, and the study of physiognomic features as indicators of character was a pseudo-science popular in the sixteenth century" (Stainton 2003:237).

This observation may be juxtaposed with a more general evolution that characterizes the Renaissance: awareness of the existence of an internal self that determines conduct. Philosophers and poets became more and more interested in the workings of the mind. The idea that appearances are deceptive occurs frequently in the works of the period, in particular in the theater of Shakespeare. This cultural context favors the emergence of a belief in an association between physical appearance and character. Shakespeare's *Richard III* is doubtless one of the first illustrations of a natural correspondence between physical imperfection and villainy (Mitchell and Snyder 1997).

In their capacity as metaphors, representations of disability have a symbolic function. They are often hardly realistic and are remote from the experience of the people in question because they have another goal than to inform the public objectively. In a general way, they suggest significations, decoded with the help of the cultural tools available in every age (e.g., mythology, religion, psychology, biology, . . .), of what appears strange, unfamiliar, or even exceptional. These cultural interpretations make it possible to familiarize and domesticate what causes fear. Thus, medieval stories of fantastical children, such as changelings, attribute supernatural powers to children with congenital defects, which were inexplicable at the time. But at the same time as they supply meaning, representations of disability propose new categories of human variations and define, in ways that vary with the culture and the era, the characteristics that will make up the norm and those that will be excluded from it. "Disabilities exemplify that the ideal of the norm cannot exist without its 'deviant' contrast" (Mitchell and Snyder 2001). Here we have all the ambiguity of these representations, which, in a single interpretive act, seek both to domesticate the alien and keep it at a distance.

SOCIAL REPRESENTATIONS OF DISABILITY

The concept of social representations proposed by Mocovici (1984) provides a theoretical framework that allows the linking of representations of disability to the overall culture from which they emerge, and a better understanding of their dynamics, their functions and evolution.

Constructed at the juncture between the individual and the collective, between the subjective and the objective, agency and reproduction, social representations constitute a body of knowledge of common sense particular to a culture. They bring a sense of commonality and they organize social life. "Social representations live and die through the media, conversations, narratives, rituals, myths, patterns of work and art, among many other forms of social mediation" (Jovchelovitch 1996:127). Emerging into the public sphere, the space where intersubjective reality is constructed, they are at one and the same time descriptive, evaluative, and prescriptive. By determining both causes and consequences, they give sense to events, situations, and actions at the same time as they are the vehicle of a judgment, of an evaluation concerning them. These interpretations, socially connoted and shared by the members of a same group, orient future actions, at times serving as their justification. It should also be noted that this common knowledge, to which the dynamics of social representations contribute, is above all practical. It is elaborated at the very heart of daily actions and interactions, in a close relationship with current praxis.

Disability and Representations of the Person

Representations of disability in our cultures can be understood only in the context of the most general representation of the person. The increasingly central place that the rational individual is assuming in the modern age requires the formation of a common understanding—or "common knowledge"—of how the functioning of this individual, along with the reasons and meaning of his or her actions, is to be comprehended. The emergence, in the mid-eighteenth century, of physiognomy and phrenology, which sought to identify character on the basis of facial features or the shape of the skull, was a first manifestation of this need to understand.

Today it is "popular" as distinct from academic psychology that most often fills this same function. The modern individual is free and responsible for personal actions. Even if the individual is subject to the influences of the immediate environment, she or he has the power to control emotions in order to act rationally. The origin of behavior is, then, to be sought in the individual as defined by character or personality, which, once formed, displays a certain stability over time and through situations.

In this new cultural context, the metaphor of disability is transformed. It no longer evokes the human condition in general but an individual situation that nonetheless has a universal character. It becomes the symbol of personal tragedy, of brutal experience with unforeseen and irreversible consequences, experience that any person may encounter but that has victimized the disabled person. It is then the lived dimension of this experience, perceived as terrifying, and its consequences for the individual that social representations seek to articulate through artistic and media-related expressions. Reflective of the ambivalence generated by strangeness, the psychology of the disabled person oscillates between two poles: one marked by dependence, passivity, and frustration (general characteristics of social maladjustment) and the other by its heroic antithesis, driven by will power, coping, and perseverance. In both cases, to be carefree, spontaneous, and "comfortable in one's skin" are characteristics foreign to the dominant representations of disabled people.

Representations Inscribed in Social Practice

The psychological types associated with disability have their roots in a specific historical context. They correspond to the ideology of normalization through rehabilitation that dominated the introduction of medical and social care in the 1950s. The objective was to return people who had been wounded in war or injured in accidents to the multiple interactions of ordinary life, in particular, to the labor market, by acting as if there were no disability and one could become "normal" by trying harder. This pressure toward normalization has been costly in terms of energy and commitment on the part of those involved. The individualism that ignores social causes in favor of individual responsibility produces an effective reversal: Will power and self-control, consequences of great efforts to live up to social expectations, are considered causes of successful rehabilitation (Ville et al. 1994). Viewing as natural what is in fact a social response results in a reinforcement of representations and a legitimization of rehabilitation practices. In fact, such representation makes it possible to impute the failure of normalization to a weakness of character.

Social representations, in their capacity as cultural products rooted in praxis, also participate in the structuring of identities, which are in one sense self-representations. Thus, persons who contracted poliomyelitis (polio) in the 1950s and who responded to the demands of rehabilitation, in particular by assuming "normal" professional activities, exemplify a uniform representation of self, marked by the qualities of self-control, sense of duty, and meticulousness. "This post-polio identity overshadows all other social categories such as age and sex," unlike persons with paraplegia who acquired their impairments on average 25 years later (Ville et al. 1994:314).

New Representations and the Experience of Living with Disability

There has, in fact, been some evolution over the past three decades that offers alternative representations of the experience of disability. Through their collective mobilization and the emergence of disability studies as a discipline, disabled people refute these representations of themselves that are remote from their own experience. Instead, by means of their own production (artistic, scientific, media related), they propose realistic representations in which, neither victims nor heroes and heroines, they are seen above all as people confronting certain difficulties, difficulties most often related to the attitudes of others.

Beyond the variety of these representations, two great trends have today come to the fore, each playing on a different register. The first states its opposition to the individualist conception outlined above by shifting responsibility for the disability from the individual to the social environment. It is the social treatment of people who function differently from the norm that produces disability, that is, all the barriers to social participation (inaccessibility, exclusion, prejudice, and discrimination). The second would reverse the stigma by valorizing the experience of disability, the recognition of a specific culture, and the sense of achievement in contributing to it—disability pride.

While the first approach proposes new causes, located in the environment, the second assigns value to the positive consequences of experience of life with impairments. Although not mutually exclusive, each, by the specific sense that it conveys, seeks to initiate a certain kind of behavior. In the first case, the agenda is clearly political. It is a matter of engagement in actions whose aim is the overthrow of the physical and social barriers present in the environment. The second, on the other hand, stimulates cultural exchanges and cultural production. But they have the common feature of offering the opportunity for positive identifications for disabled people as political or cultural agents, and this can only contribute to anchoring these new representations in both the larger public and in themselves.

REPRODUCTIVE RIGHTS

Reproductive rights and disability issues intersect in two broad areas: whether people with disabilities can become parents and whether all prospective parents should be expected to use prenatal testing and abortion or embryo diagnosis to reduce the births of children who would have impairments.

PEOPLE WITH DISABILITIES AS PARENTS

Most disability does not prevent women and men from participating in creating or raising children, but many developed nations have placed informal and formal barriers to parenthood for people with a range of disabling conditions. A few impairments include female infertility and male sterility (Turner's syndrome and cystic fibrosis for women and men, respectively). Sometimes, women with certain impairments will be advised that a pregnancy will endanger their physical health and significantly increase the physical difficulties occasioned by such conditions as diabetes or multiple sclerosis. This entry concerns the nonmedical factors that influence the reproductive freedom of people with disabilities.

Opposition to parenthood for people with disabilities is especially surprising when it is remembered that most people whose disabling conditions occur after the births of their children simply carry on their parenting responsibilities. Yet for those who acquire impairments before the ages of typical family formation, parenthood is often discouraged. Regardless of impairment, people with disabilities have been assumed incompetent to keep their children safe or to give them the emotional and social guidance necessary for functioning successfully in society. It is believed that children of disabled parents would consequently need financial and social resources from the larger society to ensure their survival and growth. Yet another source of opposition links to social goals of reducing the numbers of people with disabilities in the population because it is feared that people with disabilities would transmit genetic conditions to future children. As a result of these views, many developed nations have encouraged the sterilization of people with a wide range of impairments late into the twentieth century, and prospective disabled parents report hostility from medical professionals, adoption agencies, and social welfare agencies, which have been known to remove children from their rearing parents simply because of a parent's disability. Notwithstanding these professional practices, people with disabilities are becoming parents through ordinary sexual relations, adoption, and assisted reproduction; at least one major national organization exists to provide services and assistance to parents with disabilities (Through the Looking Glass). Adult children of disabled parents have started to publish their reflections of being raised by people with disabilities, and a small body of research has started documenting the strategies that people use to raise their children successfully.

PRENATAL TESTING AND SELECTIVE ABORTION

Worldwide, disability organizations, disability rights activists, and theorists have taken up the question of how the increasing use of prenatal testing and selective abortion affects the place of people with disabilities in the world. Bioethicists, civil libertarians, health professionals, and the public generally argue that prenatal testing, followed by pregnancy termination if an impairment is detected, promotes family well-being and the public health. Testing and termination is simply one more legitimate method of averting disability in the world.

Although sometimes prenatal testing occurs outside of a plan to abort based on results of the test, most people who seek testing plan to abort the fetus if they learn of a disability. Standard justifications include the following.

Attitudes toward congenital disability per se have not changed markedly. Both premodern as well as contemporary societies have regarded disability as undesirable and to be avoided. Not only have parents recognized the birth of a disabled child as a potentially divisive, destructive force in the family unit, but also the larger society has seen disability as unfortunate.

In the absence of adequate justification, a child is morally wronged when he or she is knowingly, deliberately, or negligently brought into being with a health status likely to result in significantly greater disability or suffering or significantly reduced life options relative to the other children with whom he or she will grow up.

The parent's/parents' harms include emotional pain and suffering, loss of opportunities, loss of freedom, isolation, loneliness, fear, guilt, stigmatization, and financial expenses.

Parents of a child with unwanted disability have their interests impinged on by the efforts, time, emotional burdens, and expenses added by the disability that they would not have otherwise experienced with the birth of a healthy child.

Parens and Asch (1999) describe the disability rights critique of prenatal testing as follows.

Rather than improving the medical or social situation of today's or tomorrow's disabled citizens, prenatal diagnosis reinforces the medical model that disability itself, not societal discrimination against people with disabilities, is the problem to be solved. In rejecting an otherwise desired child because they believe that the child's disability will diminish their parental experience, parents suggest that they are unwilling to accept any significant departure from the parental dreams that a child's characteristics might occasion.

When prospective parents select against a fetus because of predicted disability, they are making an unfortunate, often misinformed decision that a disabled child will not fulfill what most people seek in child rearing.

The disability critique argues that the practice and the rationales for it are misinformed about the nature of disability and morally problematic in the attitudes they connote about both disability and parenthood. The rationales for the practice are of three types. First, people with disabilities are more costly to society than others, and society should use its resources for children and adults who will not have impairments. Second, either the lives of disabled children are so miserable that they are not worth living at all, or they are more miserable than the lives of nondisabled children are expected to be. Third, the lives of parents and family members will be harmed by the psychological, social, and economic burdens of caring for the child, and these burdens will not be offset by the expected psychic and social rewards of raising a child without a disability.

Disability rights criticism of prenatal testing stems neither from general opposition to abortion nor from misgivings about technology. It is aimed at professional support for testing and abortion for some particular group of characteristics but not other characteristics, suggesting that health professionals, bioethicists, insurers, and policy makers believe that the births of people with some set of characteristics should be prevented. Pro-choice opposition to prenatal testing for disability shares much with those who oppose using the technology to avert the births of children of a particular sex. Suggesting that prospective parents select against an otherwise-wanted child because of its gender or disability implies that people who exist with these characteristics might be less desirable to others and less happy themselves than people with different characteristics. The critique is aimed at changing the way that testing technology is described to prospective parents, as well as at persuading professionals and parents that they have inaccurate ideas about disability and are using testing out of myth and stereotype rather than current information about how disability affects a child's or family's life.

Critics contend that this practice differs from other actions that prevent disability and should not be compared with prenatal care for women, vaccinations for children, or health promotion for everyone. Selective abortion and preimplantation embryo diagnosis both prevent disability not in an existing human being, or in a fetus likely to come to term, but rather prevent disability by preventing the embryo or fetus from becoming a person with a disability. The practices connote that if people do not meet a certain health standard, they should not be welcomed into the family or the world. Critics do not seek to ban the practice, but they believe that aborting a particular fetus differs from aborting any fetus because a woman does not want a child. They respond to each of the claims offered for prenatal testing by arguing the following.

Even if every disability diagnosed prenatally were followed by abortion, it would not materially reduce the prevalence of disability in the world or the need for society to change to better include those with impairments. As contrasted with the claims of Green (1997), who perceives a disability as an unacceptable infringement on a child's future, people with disabilities frequently enjoy their lives and do not generally perceive them as blighted by tragedy, even if their impairments impose some constraints on them. Furthermore, such constraints may be diminished or eliminated by societal changes to better include all citizens.

Most families raising children with disabilities are not ruined by the experience, and, on average, families including disabled children fare as well as other families on measures of well-being and family functioning.

Marsha Saxton (1998) expresses well the sense of offense experienced by many disability rights critics when she says,

> The message at the heart of widespread selective abortion on the basis of prenatal diagnosis is the greatest insult: some of us are "too flawed" in our very DNA to exist; we are unworthy of being born . . . fighting for this issue, our right and worthiness to be born, is the fundamental challenge to disability oppression; it underpins our most basic claim to justice and

> equality—we are indeed worthy of being born, worth the help and expense, and we know it! (p. 391)

Most disability rights opponents of prenatal testing and selective abortion would not claim that the practice is "eugenic" because few governments compel it. However, the very offer of testing for some characteristics, but not all potentially diagnosable ones, connotes that only some characteristics are worth the expense and trouble to avoid. Thus, using embryo diagnosis and prenatal testing is a social decision, expressing societal views, and a direct challenge to the societal claims to include people with disabilities as full citizens and participants in the moral and human community.

The disability critique includes the idea that the sentiments behind offering and using embryo diagnosis and prenatal testing and abortion to avoid bringing children with impairments into the family and the world will ultimately undermine parental appreciation of any children they raise. Pro-choice disability critics agree that if a prospective parent makes a considered decision that the family or the child will have an unacceptable life based on parental hopes and values, embryo rejection or abortion should be available. They caution that such assessments may be misguided about both the nature of disability and the nature of parent-child relationships. Every life, every family, and every parent-child relationship contain disappointment as well as delight. Prospective parents may be misguided and misinformed about parenthood and may thus shortchange themselves and any children they raise by adopting a selective approach to parenthood.

RESEARCH

In industrial societies, demographic trends and advances in health care are swelling the ranks of individuals with disabilities. Plunging birthrates are increasing the numbers of elderly populations. Many individuals with catastrophic injuries and illness who previously might have died now survive and become candidates for rehabilitation. As a result, the incidence of chronic disease has accelerated. From both a personal and societal perspective, the incentive to find better solutions for the problems of disability is very high.

Scientific inquiry is a systematic way to solve problems and to have some assurance that the solutions are trustworthy. Disability research is a broad subject, encompassing a wide range of populations and research topics. This entry examines the way in which disability research is conducted, some of the major problems involved and their solutions, and what the future holds for the field.

How disability is defined determines the direction of inquiry. The book *Disability in America,* edited by Andrew M. Pope and Alvin R. Tarlov (1991), provides a traditional view. “A disability refers to limitations in physical or mental function, caused by one or more health conditions, in carrying out socially defined tasks and roles that individuals generally are expected to be able to do” (p. 35). Deficits are a characteristic of the individual in relation to societal expectations, and remediation comes from treatment by health professionals. Although there is recognition that there is an interaction between the individual and the social environment, there is no mention of changing that environment.

A second view of disability is that it is not an attribute of the individual but a social construction that is the product of society and attitudes about disability. Both the built environment and customs and attitudes limit opportunities. It is society’s responsibility to make the necessary modifications so that individuals with disabilities can be integrated into society. Under the second perspective, disability becomes a political issue. These two views are not mutually exclusive; indeed, the World Health Organization’s (WHO’s) International Classification of Functioning, Disability, and Health incorporates both.

The headings that follow organize studies roughly on the basis of the numbers involved and the level of inquiry, which determine the goals of research and the methods by which to attain them. There are overlaps between sections. The classification is a rough scheme by which to organize a very large body of work.

THE SPECTRUM OF RESEARCH STUDIES

Population Studies

For governments to make informed decisions about allocating money, initiating new programs, or determining the effects of existing ones, it is necessary to have an estimate of the numbers of individuals with various disabilities and their status. The aim of epidemiology is to determine the incidence (the number of new cases per year), the prevalence (the number of existing cases at a particular time), or the health status of individuals with a particular condition. Population surveys devoted exclusively to disability are rare; most information comes from those that have other purposes. Census data, which attempt to reach the entire population, provide an estimate of the number of individuals with a disabling condition but have little detailed information. In the United States, the National Center for Health Statistics conducts an annual National Health Interview Survey on 48,000 households that includes questions on impairment or health problems that limit activity. The estimate is that more than 33 million individuals have some degree of activity limitation.

Mental illness is one of the most prevalent disabilities. It has also been one of the most difficult to identify because of changing definitions and methods of diagnosis. In the most recent research, individuals are identified as mentally ill if they have a cluster of signs and symptoms that result in impaired functioning. Most population surveys rely on telephone interviews in which strict sampling methods are used to ensure that the group contacted is representative of the population at large. Also, elaborate systems of questioning have been devised that maximize the potential for receiving truthful answers regarding various symptoms.

The 1999 report of the U.S. Surgeon General estimates that about 20 percent of the U.S. population is affected by mental disorders during a given year, the societal costs of which are enormous. The report found that direct costs of mental health services in 1996 were $69 billion. Indirect costs, estimated for 1990 at $78.6 billion, come from lost productivity at the workplace, school, and home. Additional estimates from surveys are also needed to determine the proportion of those identified with mental illness who need treatment. Most studies find large gaps between the numbers needing treatment and the facilities available.

Community Studies

Community-based studies focus on a sample of people living in one identified area, such as a city or region, with the assumption that the community is reasonably representative of other larger populations. A sample is drawn from the community, so it is possible to study individuals in considerable detail. The research can be a one-time study or repeated surveys that may extend over many years. Longitudinal studies are fairly rare because of the expense involved, but the information derived may be invaluable.

The Framingham Study is a well-known example of work that began in one city in Massachusetts in 1948 and has followed the fate of the study population ever since. The project, aimed at the effects of cardiovascular disease, selected 5,184 men and women between the ages of 28 and 62 at entry and followed them biannually with physical examinations, laboratory testing, and health history evaluation. It has been the source of some of the most important information available on risk factors for coronary heart disease. Because of the long time over which data have been collected, the Framingham Study has also been able to document the natural history of aging and what chronic diseases resulted in illness and functional limitations. Better information is needed on the major determinants of disability among those with chronic diseases to find ways to reduce and prevent physical disability in an aging population. During the 1983–1985 set of examinations, when the population had an average age of 72 years, more than 92 percent reported having no disabilities or functional limitations.

Another example of a community-based study, one that used a single time frame, is the Copenhagen Stroke Study. The question under investigation was whether a dedicated stroke unit resulted in better outcomes than other forms of traditional care. There has been considerable research devoted to this topic, but small numbers and selection bias made it difficult to draw definitive conclusions regarding the effectiveness of special stroke care. When one community in Greater Copenhagen set up a stroke unit that handled all the individuals in that area with strokes, it was possible to compare the results with a neighboring community without a special unit. The key to the research design was that a high proportion of all strokes in the two communities (88 percent) went either to the stroke unit or to medical or neurological units. Treatment on the stroke unit reduced the relative risk of death by 50 percent, reduced the relative risk of discharge to a nursing home by 40 percent, and almost doubled the chance of discharge home. The length of hospital stay was reduced by 30 percent. This was the first study to report on the effect of stroke unit treatment in unselected patients and demonstrated the effectiveness of stroke special units.

Community studies, either short term or longitudinal, are costly and require the mobilization of a team of investigators that may include clinicians, survey research specialists, biostatisticians, and interviewers. If done carefully, however, the yield can provide information that may not come from any other source.

Clinical and Educational Interventions

The largest proportion of disability research comes from a broad spectrum of work involving clinical or educational populations. Studies can range from large, multisite projects to much more modest research aimed at providing insights for the particular facility involved. Unfortunately, a high proportion of published work is not executed with enough attention to research design and methodology to provide useful answers. For several years, large-scale searches of the medical literature to determine the best treatments have found many studies wanting. The implication is that standards for both the execution and publication of research must be improved to ensure that the time and resources will be well spent.

Clinical Research

There are success stories in disability research, however. The example below illustrates several important principles of research. First, it investigates an important problem. Second, it has theoretical foundations that have evolved from several fields of investigation. And last, it took several years of work to develop the insights that were eventually established.

Edward Taub, a neuropsychologist at the University of Alabama at Birmingham, spent several years studying the behavior of monkeys with limb paralysis. He pursued this line of investigation because clinical work with humans with paralysis as a result of strokes or traumatic brain injury had shown limited success in improving functional recovery of upper extremities. Because patients valued the ability to use both limbs, they were frustrated at the lack of improvement.

When affected monkeys had their intact limb strapped down and went through graduated shaping procedures using the paretic limb, Taub found that there was considerable improvement in performance. When the animals had been free to use whatever limb they wanted, they naturally chose the intact one, resulting in a condition he called "learned disuse." Turning to individuals with hemiplegia as the result of stroke, Taub and his associates applied the techniques they had developed with monkeys. They found that immobilization of the good arm and an intense course of physical therapy resulted in impressive gains in ability (see Taub, Crago, and Uswatte 1998). Other research groups have begun to apply these techniques, termed *constraint-induced movement therapy,* and a body of evidence is accumulating regarding their effectiveness.

Educational Research

An essential tool of the research investigator is the ability to review past work. It not only provides a means for determining what has been done in a field of study but also identifies gaps in knowledge and the direction of future research. Easy access to electronic databases also makes the search much easier than in past times. There are large-scale collaborations among nations in the medical and educational literature to establish research evidence. The study below provides an example of a review in an area of study in which there are literately hundreds of pieces of work.

One of the most vexing issues in special education is the appropriate placement for children with disabilities. There is widespread agreement that, whenever possible, such children should be "mainstreamed," that is, included in classes of nondisabled children. The argument has been made on philosophical and legal grounds that children with special problems benefit educationally, socially, and in other ways from such exposure. The issue is a highly complex one, requiring different perspectives depending on age level, classroom objectives, and broader policy considerations.

Virginia Buysse and Donald B. Bailey Jr. of the Frank Porter Graham Child Development Center at the University of North Carolina at Chapel Hill were interested in comparing the outcomes of preschool children with disabilities in integrated and segregated settings. There are many benefits advanced for the integration of such young children, but there have been no reviews that compared these two settings. The authors set up a series of criteria by which to judge studies, particularly those related to the quality of research designs and methodology (Buysse and Bailey 1993). It is obviously important to identify those with strong designs and eliminate those for which conclusions cannot be drawn. Out of the dozens of studies examined, the authors found only 22 that matched the strict criteria they had set up.

The mean level of developmental outcomes, as assessed by standardized measures, did not vary in integrated as opposed to segregated placement. Integrated environments did provide a context that facilitated peer-related behavior; that is, children with disabilities had more social interactions in such settings. But there were questions about whether this led to more sophisticated levels of play and thus would have permanent effects. Integrated settings did show that children had more complex levels of play, with the opportunity to develop play-related skills. All in all, the review showed that there did seem to be some benefits for social-behavioral skills, although there were no advantages developmentally. Their work shows the complexities of trying to answer what seems on the surface a fairly simple question.

A second example of an educational intervention concerns the management of chronic disease. Medical care is limited in the ability to reverse disease processes or relieve symptoms. Individuals with chronic diseases then must learn to live with the disease and to manage their condition. There is a widespread need for health education methods that can assist with chronic disease management. A particularly promising effort is the Chronic Disease Self-Management Program, devised by Kate Lorig and colleagues (1996) at the Stanford University School of Medicine. This group had 12 years of experience with community-based educational programs for people with arthritis. In addition, the group conducted a series of focus groups of both well elderly and those with various chronic diseases. In these groups, they tape-recorded sessions in which the participants described their conditions, expressed their feelings about dealing with illness and disability, described the impact of the disease on the lives of the individuals and their families, and explained how they coped with such events. The records were then systematically analyzed. Finally, they incorporated a social psychology theory called self-efficacy into the program after finding that individuals with arthritis experienced pain reduction and enhanced capabilities when they felt they were in control of their symptoms. In the program that resulted from all this work, trained lay leaders conducted classes in community settings such as senior centers, libraries, hospitals, and recreation centers, teaching individuals how to develop exercise programs, problem solve, use communication skills, use medications, deal with emotion, and improve cognitive strategies for dealing with pain and disability. After training, individuals were better able to cope with chronic disease, experienced less pain, reported a better quality of life, and reduced their use of health care.

OUTCOMES RESEARCH AND QUALITY OF LIFE

The body of work reviewed above illustrates that disability research has many aims. A particularly prominent aim in an era of cost containment has to do with establishing the worth of program interventions. The usual objective of research is to test a hypothesis or establish some relationship, but outcomes research is management oriented. The applied research techniques that are employed still follow the tenets of scientific investigation, but there is relatively little control over what is studied. The goal is to monitor the effectiveness of interventions and to improve their quality.

Clinicians, counselors, and social service workers—all those who provide services—have always had an enduring interest in the success of their efforts. And, of course, clients have had similar concerns. It has only been in the era of accountability, rising costs, and the search for cost-effective care that the results of service have come to be called *outcomes.* The implication of the term is that results will meet some standard of acceptability and that the level of costs will also be acceptable. Programs of all types, from medical to educational, are charged with demonstrating that their outcomes meet expectations. Managers are to "manage" outcomes by improving services and by "risk adjustment," which simply means trying to select those who will benefit most. Unfortunately, this also has the effect of marginalizing many disabled people who are in greatest need.

Outcomes research must identify the principal results of programs and how to measure them. The usual list of outcomes includes improvement of physical and cognitive capabilities, greater independence, decreased need for assistance, decreased use of medical and personal care services, greater life satisfaction, and greater feelings of well-being. When programs are concerned with influencing physical and social environments and increasing opportunities for participation by those with disabilities, measurement of outcomes becomes more complicated. Indexes here include employment, financial support, access to transportation, access to health care, and other such evidence.

A view of service outcomes that is gaining greater acceptance is that the ultimate aim is to improve the day-to-day life of clients and patients. In health care, treatment populations increasingly are those with chronic disease for which there is no cure, but pain and discomfort can be relieved, the patient's functional ability may be improved, and outlook on life can be enhanced. *Quality of life* has been used as an umbrella term to include all the various aspects of health status, daily activities, economic circumstance, and perspective on life. A number of generic health status measures have been advanced as measures of quality of life related to health, but their applicability to disability is in doubt.

A major problem with health-related quality-of-life measures is in what constitutes health. In response to the question, "Does your health result in any limitations to activities?" a person with spinal cord injury might answer no. Likewise, someone with a severe disability that limited the ability to travel outside the house might still regard his or her quality of life as good, a perspective that might be puzzling to an outside observer. Quality-of-life conceptions, even though still not clearly defined or measured, will continue to be used. Whether funding agencies will pay for treatment aimed at improving quality of life could be a problem, although many such organizations recognize that individuals whose health, functional capacity, and life satisfaction improve may use health care services less.

DISABILITY RESEARCH AND EMPOWERMENT

Several forces have converged to force an examination of the role of those with disabilities in the research that affects them. In the 1960s, the civil rights movement resulted in social legislation aimed at improving the way society treated minorities. Although the movement initially concerned individuals of color, it soon spread to include anyone who was disadvantaged, including women and the disabled. A parallel phenomenon, although hardly distinctive enough to be called a movement, was the increasing attention given to the views of consumers. Initially concerned with commercial transactions, the consumer's perspective began to play an increasing role in various services, particularly health care and education. As health care became more competitive, the views of patients on the services they received and the results of services were solicited by means of satisfaction questionnaires. Other types of services have also begun to look at satisfaction. Because a high proportion of respondents indicate they are happy with what happened, satisfaction measurement is a blunt instrument that needs research on the underlying factors that determine satisfaction.

In the 1970s, a coalition of individuals with permanent disabilities began the independent living movement. It was a rebellion against what they saw as a paternalistic system that attempted to dictate how they should live and what services they should receive. This group has vigorously pursued the concept that those with disabilities should, wherever feasible, direct their own care and have a role in whatever studies are done about them. Funding agencies are increasingly requiring that whatever advisory groups grants create, there should be representation from those with disabilities.

To some extent, research investigators are caught between the two models of disability already mentioned. There has been far more research under the medical model, with the search for more effective treatment methods and other ways to improve performance deficiencies. For the most part, this body of work has been planned and executed by professionals with only occasional consultations with those whom it affects. The second model, which has been termed the *socioecological model,* involving the social and physical environments in which individuals with disabilities live, has been given increased standing by inclusion in the WHO International Classification of Functioning, Disability, and Health. In addition, the National Institute on Disability and Rehabilitation Research, the principal source of government-sponsored research funding in the United States, has made its "new paradigm" the centerpiece of planning. In this point of view, the aim is to reduce barriers, create access, and promote wellness and health. The individual with disability is regarded as a research participant and collaborator; decisions regarding research directions are to be made jointly with professionals.

This avenue of investigation produces considerable challenges, however. Ways to characterize and measure either social or physical environments are in early stages. It is not easy to do research in this area, particularly when a high proportion of such work is carried on by those trained in medical aspects of disability rather than in the social sciences. Greater interdisciplinary collaboration is obviously in order. Still another problem in research under the socioecological framework is that the ultimate aim of this work is to make social reforms of some kind. Researchers are not always comfortable in the role of social activist, however.

THE FUTURE

Although there have been impressive gains in the past 25 years in the status of individuals with disabilities and in the services they receive, there is still much to accomplish. Research is hardly the sole instrument in bringing improvements, but it contributes heavily to the development of new methods of treatment and education and in evaluating the effectiveness of those in use. Unfortunately, the priorities for research have come more from legislation and funding sources than from serious attempts at an integrated body of work founded on theory. With research spanning such a variety of problems, it is not surprising that findings are scattered without much organization. Several issues need to be addressed if disability research is to have an impact.

A Common Language. The lack of uniform concepts and a common language has plagued the field from its beginning. There is no consensus for even basic terms such as *disability* and *functional limitations,* which makes it difficult to compare measures and results. The addition of concepts such as *health status* and *quality of life,* even though they have important implications for outcomes, has brought additional confusion. Most studies do not define terms very well, so investigators often simply use an instrument and label it as measuring whatever they want. As a consequence, it is difficult to compare studies, and new knowledge accumulates slowly. In the end, however, it is up to researchers to better define terms and explain the procedures they use.

The Consumer Point of View. Although the views of the consumers of services for disability are sometimes sought, there has been little systematic effort to solicit priorities and preferences. Quite often, what an individual with a disability values as a contribution to his or her lifestyle is very different from the preoccupations of research professionals. The usual program outcomes that are measured are often the result of what can be measured rather than what is of special interest to the subjects studied. There needs to be a systematic method for determining client and patient goals at the beginning of a program and integrating such views into treatment plans and outcomes.

Outcome Measures for Disability. Many of the measures in use in social and medical programs are either of a utilitarian nature, reflecting a decreased burden to society or to caregivers, or enhancement of personal skills. Newer measures such as health status, quality of life, and health-related quality of life were developed without regard for applications with populations with disabilities. Although they are often used anyway or some modifications are made, their utility is less than if they were tailored to the needs and priorities of individuals with disabilities. Development of such measures may be costly, but the number of individuals with chronic diseases and injuries is easily sufficient to justify the effort. The shift in program goals to a socioecological perspective, in which better integration into society is important, will also require as yet undeveloped methods of determining outcomes.

The Subjective Experience of Disability. In the 1940s and 1950s, there were a number of observational studies of the mental hospital, some of which involved researchers being admitted as patients. They were then able to experience the often needless restrictions, the bureaucratic rules invoked primarily for the convenience of the staff, the lack of dignity with which patients were treated, the occasional physical abuse, and the pervasive boredom of routines with nothing to do. Such studies contributed to widespread questioning of the benefits of institutionalization and, ultimately, to the discharge of hundreds of patients from what was viewed as a noxious environment. Unfortunately, such patients were often turned out without adequate provisions of aftercare, and many drifted as homeless people.

Over the years, there have been occasional accounts of what life is like after a stroke, spinal cord injury, or other catastrophic condition. A few individuals have sufficiently recovered from autism to chronicle their experience. Unfortunately, most of these descriptions have been treated as idiosyncratic accounts that do not provide insights of general interest. All of this is in spite of the professed interest in the client/patient point of view. An array of qualitative research methods could provide a rich source of information about the disability experience.

The Challenge of Technology. There are accelerating advances in the miniaturization of circuits, new materials, and computerization of devices useful to those with disabilities. It is necessary, however, to determine the utility of such equipment for everyday life. The history of the use of lower leg braces, for example, has many accounts in which individuals have discarded braces, even though they provided physiological benefit, because they required great effort to use or were cosmetically unacceptable. The integration of special technology into routine life requires more than ever the collaboration of those for whom it is intended if use is to be successful.

Assessment procedures in which patients or clients must respond by computers are destined to become a much more frequent occurrence, even if these individuals have had no experience with this equipment. Touch screens or light pens can be used for multiple-choice answers and do not require keyboard use. Some aspects of personal and health history can be obtained this way, as can responses to a variety of health status questionnaires. Less staff time is required, and the responses can be instantly entered into a database, but respondents may need to be trained in the use of such devices.

Disability research holds great promise for improving the lives of those with disability, but such research is a product of the social and political context in which it occurs. The extent to which it is valued and understandable dictates whether it will be used. There are no shortcuts for creditable work. It must follow scientific principles, the individuals involved must be partners, and society must provide the resources.

RETT SYNDROME

Rett syndrome is a progressive developmental disorder associated with intellectual disability, growth retardation, loss of speech and motor skills, and emergence of stereotyped hand mannerisms. The condition is named after Andreas Rett, an Austrian pediatrician, who first described the disorder in 1966. His initial description of 22 patients remained largely unknown until 1983, when Bengt Hagberg of Sweden and his colleagues published an English-language account of an additional 35 cases. In 1999, mutations in the $MCEP_2$ gene were identified in almost one-third of a sample of 21 individuals with Rett syndrome. Further analyses suggest that mutations within this region may account for 50 to 75 percent of all cases of Rett syndrome.

The severity of Rett syndrome varies from mild to profound. Children with Rett syndrome appear to develop normally during the first 6 to 18 months of life, although subtle problems in muscle tone, posture, and movement may be evident from birth. The major clinical signs of Rett syndrome are usually pronounced by 2 years of age, and by 5 to 7 years of age, most children will have progressed to the fourth and final stage of the disorder. Clinical features that emerge over this period include loss of muscle tone, deceleration of head growth, seizure disorder, loss of acquired speech, and deterioration of motor skills, with mobility and functional hand use being significantly impaired. One of the more distinctive features of Rett syndrome is the nearly constant stereotyped hand mannerisms, which typically involve rubbing, wringing, and washing-like movements.

The condition primarily affects females, but similar symptoms have been described in males. Overall prevalence is estimated at 1 in 10,000 to 1 in 15,000 female births, making it the single most common cause of severe developmental and physical disability in females. As the identification of Rett syndrome improves through refined laboratory tests, estimates of prevalence are likely to change and become more accurate.

There is no cure for Rett syndrome, and the prognosis for significant improvement in the cognitive, social, and motor domains is poor. Still, quality of life can be improved by providing opportunities for participation in meaningful and preferred activities. A multidisciplinary treatment approach is recommended, with treatment focused on maintaining health and including provision of physical, occupational, music, and speech therapy. Communication is a major area of need. Even when some speech is preserved, individuals with Rett syndrome generally rely on informal body movements and facial expressions to communicate. Some can be taught to use augmentative communication devices to indicate basic wants and needs. There has been some success in reducing stereotyped hand movements through behavior modification. Individuals with Rett syndrome are often aware of and responsive to others and will therefore benefit from integration experiences in typical classroom and community settings. With regular and sound multidisciplinary management, many individuals with Rett syndrome can be expected to survive into adulthood, although death from malnourishment is not uncommon, and some otherwise healthy individuals may die suddenly from cardiorespiratory problems.

RIGHT TO WORK

At the beginning of the twenty-first century, for the first time in history, international social, economic, and political forces are acting in concert to promote widespread labor force participation of people with disabilities. The United Nations (UN) has acknowledged the right of individuals with disabilities to work, in order to promote equal opportunity and protection from poverty. The economic contributions of workers with disabilities can no longer be ignored in a constantly changing global economy, interlinking notions of work and citizenship. At the same time, an international movement of political activism among people with disabilities promotes a social theory of disability in which employment is seen as one route to community inclusion and protection of civil rights, albeit not the only route.

INTERNATIONAL AFFIRMATION OF THE RIGHT TO WORK

The UN Convention on the Protection and Promotion of the Rights and Dignity of Persons with Disabilities has proposed a series of fundamental principles for member nations. Article 22 of the convention is titled "Right to Work" and affirms that the opportunity to make a living doing work that is "freely chosen" in the "open labour market" is a basic human right. The need to protect workers with disabilities against discrimination in hiring, working conditions, pay, and advancement is affirmed in the article. Perhaps most important, recognizing that people with disabilities are "the poorest of the poor," an explicit connection is made between employment and "protection from poverty."

THE INTERNATIONAL EMPLOYMENT STATUS OF PEOPLE WITH DISABILITIES

Around the globe, people with disabilities live on lower incomes, receive less education, and have fewer job opportunities than their nondisabled counterparts, as revealed by international research statistics, as well as discussions among participants at the UN convention. In Latin America, for example, 75 percent of people with disabilities are not employed. More than two-thirds of British citizens with disabilities are out of the labor force or underemployed. Legislation in many countries forbids citizens with disabilities from entering certain professions. In countries with high unemployment, the labor market exploitation of disabled workers is often greater, so that when they do have access to jobs, these positions are often poorly paid and concentrated in a limited number of stereotypical occupations. Women with disabilities face particularly severe consequences of unemployment and associated poverty. In countries with publicly funded disability income support programs, large numbers of individuals with disabilities are trapped in poverty by income support policies that act as disincentives to employment.

POLITICAL ACTIVISM IN THE DISABILITY COMMUNITY

At the same time, a new conceptualization of disability has emerged that emphasizes community inclusion, accommodation, and protection of civil rights over the traditional focus on assessing impairment and remediation of functional deficits through professional services. Called the new paradigm, the social model, or the sociopolitical model, this new way of thinking about disability has its roots in the many political movements that grew out of the social protest and civil rights era of the 1960s. For example, the international disabled people's movement in the 1960s and the independent living movement of the 1970s sought a better quality of life for people with physical disabilities through equal opportunity and dignified treatment.

By the 1980s, disability rights advocates endorsed shifting the definition of disability from a focus on functional impairments and limitations to a sociopolitical perspective by means of a civil rights–based, "minority group model" of disability. This new paradigm views disability as an interaction between characteristics of an individual and features of his or her cultural, social, natural, and built environments. In this framework, disability does not lie within individuals but in the interface between their characteristics (such as their functional status or personal or social qualities) and the nature of the environments in which they operate. Put simply, the old paradigm views a person with a disability as someone who cannot function because of an impairment, whereas the new paradigm views this person as someone who needs an accommodation to function.

Use of this new model shifts the focus away from being solely on the individual to one that equally encompasses the environment. It highlights how the environments of people with disabilities often are socially isolating, economically constraining, legally exclusionary, and emotionally unsupportive. It also directs the search for solutions and remedies away from the sole concentration on "fixing" individuals by correcting their deficits to removing barriers and creating access through accommodation and reorganization of "disabling environments." It acknowledges that the "employment problem" for people with disabilities is due to faults in national and global economies and not deficiencies of individual workers. Concomitantly, the source of potential interventions expands beyond health professionals and clinical/rehabilitation service providers to include peers, mainstream providers, and consumer advocacy and information services. Most important in the new paradigm, the role of the person with a disability shifts away from being an object of intervention or a patient toward one of a customer, empowered peer, decision maker, and agent of social and political change.

Because these new paradigms have not been universally embraced, both national and international disability policy continues to lack coherence and direction. Much disability policy around the world has remained rooted in economic paradigms that pit benefits for individuals with disabilities against costs to the rest of society, thus reinforcing the medical rehabilitation model. In other countries, no formal disability policies exist, or a laissez-faire, de facto policy of benign neglect characterizes the approach that is taken.

LABOR FORCE DYNAMICS VIEWED THROUGH THE NEW PARADIGM OF DISABILITY

Use of the new paradigm allows for a more comprehensive understanding of the place of people with disabilities in the labor market and, especially, labor force dynamics for people with disabilities. This involves acknowledging that people with disabilities are both similar to and different from those without disabilities in their labor force attachment, experiences, and decision making. In the United States, for example, studies have shown that, while people with disabilities experience proportionally larger gains in employment during periods of market expansion, they also evidence greater losses during times of market contraction than people without disabilities.

The vulnerability of those who return to work while on the public disability insurance rolls in the United States is evident from studies showing that most reenter the labor force because of financial need rather than medical improvement. Those who do return to work tend to be younger and better educated than those who do not. Their initial jobs after reentry are lower paying and for fewer hours than the job held prior to disability onset, and they tend not to return to their previous employers. Finally, while workplace accommodations may extend the average duration of employment, there is evidence that injured workers who receive job accommodations "pay" for these accommodations in the form of lower wages.

These findings support the notion that return to work following onset of disability is a complex phenomenon encompassing more than the individual's level of impairment and functional limitations. Other factors, such as employers' attitudes, labor market conditions, availability of workplace accommodations, and prior employment, all are part of the environmental context that is critical to understand.

Most recently, disability scholars have questioned the notion that workforce participation can be the sole or even the most important route to social inclusion and emancipation. They argue that oppression of people with disabilities reflects a devaluing of impaired modes of being, which can never be fully corrected by inclusion in productive activity. Since the very nature of disability is defined by the ways in which a society organizes its productive activity, significant advances in employment for people with disabilities can only occur through a "radical reformulation" of the meaning and organization of work. This requires changes in the fact that productive activity in much of the Western world reflects values such as profit maximization, competition among organizations and their workers, and waged labor. It is these values, as well as the practices that stem from them, that limit or "disable" people with perceived impairments, rather than the functional limitations themselves. As long as work is organized around these principles, the inclusion of people with disabilities in productive activity is unlikely to bring about large-scale improvement in their economic circumstances. Such skepticism regarding the role of employment in the emancipation of individuals with disabilities is tied to the call for governments to adopt more interventionist labor market policies to encourage full integration. Disability advocates remind us of the long tradition in Western government of labor market restructuring through tax breaks and funding for business and industry to stimulate economies and enhance national security. In line with this thinking, members of the UN committee discussed encouraging member nations to pursue active labor market policies as part of promoting employment opportunities.

TRENDS IN GLOBAL WORKFORCE GROWTH AND LABOR DEMAND

Current trends in the worldwide labor market indicate the occupational context within which job training and employment placement will be occurring over the coming decades. Increasing economic globalization and technological advances have shifted the economy from a focus on "primary production" to one of "postprimary production," in which human services are the primary source of employment and information technology has replaced material production. For example, U.S. labor market projections indicate that the occupations with the largest job growth are expected to be retail trade, business services (including computer-related jobs), health services, and public and private education (including health care providers, teacher aides, teachers, and professors). Also, self-employment is expected to increase by almost 15 percent.

Some have argued that these new forms of production and technological advances offer unprecedented employment opportunities for people with disabilities. Environmental changes in workplace technology, telecommunications, and transportation systems have made the workplace more accessible to people with all kinds of disabilities through expanded transportation options and Internet technology. For example, mobility-impaired individuals can have enhanced access to job opportunities through the World Wide Web, a setting that already has been the focus of rehabilitation efforts.

On the other hand, new technologies must be accessible to people with disabilities if these alterations in the organization of work are to be advantageous. Increased funding to enhance innovation and affordability of assistive technology and universal design are essential. Accessibility to advanced telecommunications and transportation systems remains a major advocacy issue, with primary influence on an individual's likelihood of employment. In developing countries, access to advanced technology is limited among both nondisabled and disabled populations, pointing to the need to bridge the international digital divide.

THE NEED FOR REHABILITATION

In its statement of Right to Work, the UN committee called for increased access to technical and vocational guidance programs, placement services, and employment training, along with vocational and professional rehabilitation and return-to-work programs. The latter point highlights the importance of carefully integrating people with disabilities into mainstream government-sponsored employment programs to eliminate poverty. Special mention was made of "self-employment and starting one's own business," acknowledging the importance of building entrepreneurial skills as part of the rehabilitation process. In public discussions, some UN participants felt that this model applied especially for women with disabilities. Others noted that entrepreneurship provides people with greater freedom to participate in the economic sector of their own countries since they can act as their own employers and provide their own accommodations. A trend toward services and supports delivered by peers with disabilities is growing in many countries. However, in many others, access to vocational rehabilitation is severely limited or nonexistent.

NEW ROLES FOR EMPLOYERS

With expansion of the global economy, businesses have changed through downsizing and outsourcing, resulting in such phenomena as the flattening of workplace hierarchies and the erosion of job security. These trends suggest the need to incorporate employers and their organizations into the vocational rehabilitation process. Employers have been characterized as the "forgotten partners" in vocational rehabilitation efforts. Especially relevant to the new paradigm of disability are models of collaboration with business communities, which view the employment of people with disabilities as a socioenvironmental issue that can be addressed by a "trilateral" approach involving employers, consumers, and service providers. The UN committee recognized the need to encourage employers to hire workers with disabilities through affirmative action programs, incentives, and quotas. Also acknowledged was the need to educate employers about disability-related job discrimination and reasonable accommodations in the workplace.

THE INTERACTION OF DISABILITY AND POVERTY

Poverty co-occurs with disability around the world. In Western countries, this persists despite a series of public disability benefits and entitlements, including cash payments, vouchers, and other income support mechanisms. In countries without nationalized health care, such as the United States, disability beneficiary status provides the only access to medical and mental health treatment, and the need to protect this benefit leads many citizens with disabilities to forgo or limit their labor force participation. Yet even in countries with universal health care access, individuals risk their economic safety net when they work.

Providers of vocational rehabilitation services must be cognizant of service consumers' individual situations regarding eligibility for disability income and how they are affected by employment. Financial planning involving the sharing of accurate information is required so that consumers can consider the relative advantages and disadvantages of different work options. This means that the alleviation of poverty is explicitly addressed as part of the vocational rehabilitation process.

SUMMARY AND CONCLUSIONS

In conclusion, guaranteeing the right to work of people with disabilities might best be characterized as necessary but not sufficient to promote social integration and full participation. Without a reorganization of the values underlying the concept and organization of social production, labor force participation alone will not combat oppression. In the meantime, however, as stated in the UN article on "Social Security and an Adequate Standard of Living," in today's economy, "the best guarantee for independence and social security is employment."

It is hoped that tomorrow's global economy can be restructured through international policies so that employment is only one of the tools of emancipation from oppression available to people with disabilities.

RISK AND RISK SELECTION RELATED TO INSURANCE

In this entry, the concepts of risk and risk selection in the insurance industry are discussed in the context of the disabled community in the United States. Risk in the insurance industry is a condition in which there is a possibility of an adverse deviation from a desired outcome that is expected or hoped for. The undesirable event is the adverse deviation, and insurance coverage is an attempt to provide protection from the undesirable event. Illness and injury would be undesirable health insurance events.

Adverse selection is the tendency of persons with a higher than average probability of loss to seek or continue insurance to a greater extent than do persons with an average or below-average probability of loss.

While an insurer will provide health insurance coverage to policyholders, the company must protect itself from excessive financial losses and examine its spread of risk by line of business, thereby avoiding a concentration of risk. Health insurance coverage to the disabled community presents the insurer with a business challenge in providing coverage, and the insurer will consequently do so in a manner that limits its risk.

INSURANCE ACCESS

The initiatives to guarantee health care access have been incremental since the introduction of Medicare and Medicaid in 1965. While new delivery models were introduced to promote patient access to providers, the ability to pay for services ultimately guarantees access to providers. The number of people without health insurance increased by 2.4 million, the largest increase in a decade, raising the total to 43.6 million. The increase brought the proportion of people who were uninsured to 15.2 percent, from 14.6 percent in 2001 and 13.6 percent in 2000.

Estimating health insurance demand is difficult to do because of the way health insurance is purchased in the United States. Almost 90 percent of insured individuals younger than 65 years of age obtain coverage from their employer or as dependents of a family member with group-sponsored health insurance. Insurance for medical expenses and for loss of income due to disability is provided by three basic sources: individual insurance policies, employee benefit plans (including fully insured, partially insured, and self-insured programs), and social insurance, including the Old Age, Survivors, and Disability Insurance (OASDI); Medicaid; and Workers Compensation programs.

THE INSURANCE PERSPECTIVE ON RISK

Competing with the public's demand for insurance is the business interest of the insurance company itself. An insurance company is an enterprise in the business to make a profit through the sale of policies to prospective policyholders. Business profiles are developed on an insurance company by various rating services that drive current and future operating performance and can affect long-term financial strength and the company's ability to meet its obligations to policyholders. In analyzing a private insurance company's financial strength, a company's book of business is assessed by line in terms of its geographic, product, and distribution diversification.

Large companies usually write conservative lines of business and avoid a concentration of risk. It would follow that insurance companies will avoid writing insurance policies, be it life or health, to policyholders who presented an untoward risk of injury or death. A companion issue with that of insurance risk in writing a policy is the issue of adverse selection. Adverse selection occurs if those who elect to participate in the program are sicker than average, and program costs may exceed expectations and/or premiums to participants may have to increase.

Adverse selection may cause the insurer to include waiting periods for preexisting conditions and limited benefits (such as exclusion of mental health coverage) in an effort to control selection. In addition, insurance deductibles are used in property, liability, and health insurance. The purpose of the deductible mechanism is generally to reduce problems with moral hazard by requiring that the insured take some responsibility for loss payments. Coinsurance and maximum limits also arise as a result of adverse selection in a competitive insurance market. This is the rationale for the insurance questionnaire prior to a policy being written that requests information of a policyholder's education and drinking and driving habits, as well as access to medical records to verify various medical conditions that may or may not be covered in the policy. The company is prospectively attempting to determine the potential risk of writing a policy to the insured.

From the perspective of an insurance company, the key consideration is whether it can charge a premium rate that reflects the expected cost of a potential enrollment group. The primary purpose of insurance is a controlled spreading of risk across the entire insured population. For example, with experience rating, the insurer estimates the premium based on the past cost experience of the group and then offers a self-supporting premium rate to that group that covers expected medical costs, administrative expenses, other loadings, and a profit. Therefore, obtaining insurance coverage is not precluded just because a group is higher than average cost, but there must be an insurance market for persons/groups of that type, and insurance companies must be willing to offer coverage to those groups. If an insurer can make a reasonable profit (and accurately estimate the cost of the group), then it is likely that insurance is feasible. Risk adjustment methods are another way of estimating costs for groups that have varying levels of risk (in addition to experience rating).

Managed care is another relevant concept in the insurance market. For example, for mental health and substance abuse services, a managed care organization can provide care at a cost that is under a fee-for-service and unmanaged arrangement. In addition to cost containment, managed care organizations (MCOs) usually provide greater access to care (a higher percentage of users), although more care is outpatient, and inpatient care is substantially reduced (in the MCO). The same group of disabled persons may receive a number of different premium rates from different insurers (assuming there is a market), and at least part of the cost difference is a result of the level of cost containment that the insurer can achieve.

DISABILITY

There is no consensus definition of disability that suits all purposes. While the U.S. Social Security Administration defines disability in terms of functional limitations as they affect employability, the Americans with Disabilities Act (ADA) defines disability as a physical or mental impairment that limits one or more major life activities. The point to be made here is that disability includes a number of physical, psychological, and medical conditions from arthritis, congenital anomalies, depression, HIV, hearing and vision impairment, multiple sclerosis, and impairment following an accident or medical episode, among others.

The context of the disability condition and its corresponding disability time period, be it short or of a lengthy duration, will determine the type of insurance that is warranted. Ultimately, disabled people will have to be their own advocates to gain access to insurance and to monitor claims payment to the provider by their insurance.

DISABILITY INSURANCE SOURCES

Risk and adverse risk selection are managed differently based on insurance source. The Social Security Act established Medicare and Medicaid in 1965. Medicare extended health coverage to Americans age 65 or older, disabled persons receiving cash benefits for 24 months under the Social Security program, and persons suffering from end-stage renal disease. Medicare provides health benefits to 41 million elderly and disabled Americans. Medicaid is a program that pays for medical assistance for certain individuals and families with low incomes and resources. The program is jointly funded by federal and state governments. Medicaid covers 47 million low-income people, including 24 million children, 11 million adults, and more than 13 million elderly and disabled people.

Workers' Compensation is insurance coverage, purchased by the employer, that covers occupational accidents and illnesses. Musculoskeletal disorders (MSDs) are the most prevalent and expensive work-related injuries in the United States. These MSDs are injuries and disorders of the muscles, tendons, ligaments, nerves, joints, cartilage, and supporting structures, such as spinal disks, which account for at least one-third of all work-related injuries. Around 1.8 million workers report work-related MSDs, and about 600,000 miss work due to MSDs each year. The final source for insurance is the individual nongovernmental market, developed to fill the gaps left by the employer market, including self-employed persons, graduate students, short-term and part-time workers, unemployed or soon-to-be displaced workers (pending layoff), the smallest of small business that cannot obtain group coverage, and persons before they are eligible for Medicare. The individual nongovernmental market served an estimated 16 million Americans in 2001.

THE DISABLED AND THEIR HEALTH NEEDS

Twenty-eight percent of insured people with disabilities reported that they needed particular therapies, equipment, or medications that were not covered by their health plans, compared to 7 percent of those without disabilities. Nineteen percent of disabled persons reported that they needed medical care within the previous year but did not get it, compared to 6 percent of nondisabled persons. Persons with disabilities attributed these failures to a variety of factors, including lack of insurance coverage (35 percent), high costs (31 percent), difficulties or disagreements with doctors (8 percent), problems getting to doctor offices or clinics (7 percent), and inadequate transportation (4 percent) (Reis et al. 2004). Reis et al. (2004) report that people with disabilities typically have a "thinner margin of health" due to their impairments and functional limitations, fewer opportunities for health maintenance and preventive health care, earlier onset of chronic health conditions, susceptibility to secondary functional losses, and, not uncommonly, a need for complicated and prolonged treatments.

The insurance needs of the disabled community are varied and diverse. Clearly, one insurance source will not satisfy all needs. A person who becomes disabled for a temporary or protracted time period will have to investigate his or her insurance needs and act as an advocate to make sure his or her needs are met.

CONCLUSION

Insurance risk examines the probability of illness, disease, and injury along with the duration of each. Adverse selection is the prospect that an insurer will enroll those who are sicker than average, thereby increasing their medical and administrative costs. Market forces in the private health insurance market dictate that an insurer enroll those who are healthy and who will make limited demand of the insurer. A prospective insured with an excessive need for health care services would not be a financially viable group for a private insurer. Workers' Compensation, Medicare, and Medicaid have provisions for those who become incapacitated for short and permanent time periods.

ROARTY, JOHN JOSEPH (1921–1996)

Author and disability rights activist

John Roarty was born on February 10, 1921, in Merewether, New South Wales, the youngest of three boys, to Cyril and Margaret Roarty. He was born with cerebral palsy and, as a result, was severely disabled. As well as severe spasticity in all limbs, he had a speech impediment. Roarty never had the advantage of a formal education. His father abandoned the family when John was very young, and his mother got a job as a housekeeper on a property so she could keep the children with her. He eventually became too heavy for his mother to lift and carry around.

On July 11, 1937, at the age of 16, he moved to Weemala Nursing Home, where he resided until his death. In 1971, he was instrumental in forming the Residents' Committee. The lack of access to electric wheelchairs and the curfew on residents were the driving issues of the day. This was one of the first pieces of direct action by residents in an institution for disabled people in Australia.

Roarty's dream of writing his life story was realized when he published *Captives of Care* in 1981, during the International Year of Disabled People (IYDP). He wrote, "That is what this story is about: domination and the power of authority, and our struggles to curb that power and assert our independence and our rights as human beings" (p. 12).

A video of the same title was produced and aired on the ABC in 1982 and went on to win 11 International Awards. This led to a stage production produced by John L. Simpson, a long-time friend of Roarty.

Roarty, who was baptized Roman Catholic, had great commitment and dedication to his Christian spiritual beliefs.

The ultimate accolade to Roarty's commitment to the disability sector came in the form of the Order of Australia in 1988.

ROBERTS, ED (1939–1995)

Founder of the independent living movement

Ed Roberts, a John D. and Catherine T. MacArthur Fellow in 1984, was one of the most recognized and admired leaders of the independent living movement of persons with disabilities, which began in the late 1960s. He was a founder of the independent living center concept, served as executive director of the Center for Independent Living (CIL) in 1972–1975 and director of the California Department of Rehabilitation from 1975–1983, and was cofounder and president of the World Institute on Disability (WID) from 1983 until his death in 1995. Roberts contracted polio at age 14. It left him paralyzed from the neck down. Relying on an iron lung or a respirator, Ed became the first severely disabled student at the University of California, Berkeley. While there, he worked with the university to develop a program run by and for disabled students to provide wheelchair repair, attendant referral, peer counseling, and other services that would enable them to live in the community. Due to coverage by *60 Minutes* (CBS News) and other media, Roberts's work to promote the concept of independent living became known throughout the world. In 1996, disability and community leaders created the Ed Roberts Campus, an international center and a service facility in Berkeley, California, in his memory.

ROOSEVELT, FRANKLIN DELANO (1882–1945)

32nd president of the United States

The central human characteristic that marked Franklin D. Roosevelt (FDR) the person—his severe physical disability—was concealed during his lifetime. From August 21, 1921, to April 12, 1945, every day had to be planned and structured to adapt to his disability. At first, he was confined to his bed at Campobello Island in New Brunswick, Canada, while his wife ministered to his physical and emotional needs. After he was transported back to his home in New York City, he learned to adapt to his disability by working with a nurse therapist who came to his home. After two years, he could stand and ambulate with minimal assistance by means of braces and crutches. After seven years, he was ready to plunge back into the rough-and-tumble world of politics. In his day, many men and women who held high responsibility would have broken under such intense strain. Not one in a thousand returned to combative political life. None except Roosevelt became a world figure.

THE POLIO ATTACK

In July 1921, FDR testified before a congressional committee investigating homosexual acts at a Newport, Rhode Island, naval training station. He had been the assistant secretary of the Navy in the administration of President Woodrow Wilson. On the way back to his summer home in Campobello, he stopped briefly at a Boy Scout camp in New York. Whether he contracted poliomyelitis in Washington or in New York is not known. The incubation period ranges from 3 to 35 days, with the average period lasting between 4 and 10 days. On August 10, he spent a strenuous day with his family swimming and fighting a forest fire. The next morning, he awoke with weakness in his left leg and pain in his back and both legs; by nightfall, he registered a temperature of 102° Fahrenheit. His illness was misdiagnosed by a local physician and by a Philadelphia surgeon, Dr. W. Keen, who was vacationing nearby. Keen's diagnosis was a spinal cord infarct resulting from bladder congestion. FDR's uncle, Fred Delano, contacted the Harvard Infantile Paralysis Commission, whose specialist, Dr. Robert Lovett, was called to Campobello, and he confirmed the diagnosis of infantile paralysis, the term for poliomyelitis used in the early decades of the twentieth century.

Legend has clothed FDR's recovery from the acute phase and his rehabilitation in myth and half-truth. In reality, he was by all accounts deeply depressed during the initial period of the fall of 1921 and the winter of 1922. After a brief stay at Presbyterian Hospital in New York under the care of Dr. George Draper, he was sent home to work with his nurse therapists, Kathleen Lake and Edna Rockey, who observed him daily in his struggle to sit and regain muscle strength. In an effort to spare him the knowledge that his back muscles were impaired, Draper devised a back support. Gradually, the paralysis in his upper extremities receded and was left in his legs. By October 15, he had worked through a severe reactive depression, carefully masked by a facade of cheerfulness. His nurse therapists and his physician observed an extraordinary sensitivity to the psychological aspects of his illness and maintained constant emotional support. His knees were contracted and very painful; although he regained power in his hip muscles, he could not walk. Despite considerable stress, his therapists observed that he was a compliant patient.

FDR's illness placed an enormous burden on his family. His wife, Eleanor, and their five children adapted to a husband and father who had previously been active in state and national politics and who now was confined to home and a limited existence. His mother, Sara Delano Roosevelt, wanted him to return to their country estate at Hyde Park, New York, and assume the role of a country gentleman. His political adviser, Louis Howe, kept up a constant stream of political correspondence to feign an active political life. FDR became the center of a titanic struggle for his soul and his future career, as was observed in the correspondence from Draper to Lovett: “I was able to see with a better perspective the intense and devastating influence of the interplay of these high voltage personalities one upon another.” In June 1922, he went to Phillips House at the Massachusetts General Hospital in Boston to be fitted for a new set of braces. His departure for Boston broke the tension in the Roosevelt household. As long as he remained in New York, he assumed the sick role. When he returned, he had made his adjustment, and in the words of Albert Brewster, a young doctor who knew him in Boston, he was always smiling and seemed to have a charming personality undisturbed by all of the attention around him.

Two years after the poliomyelitis attack, Roosevelt had learned to manage with braces and crutches, but there was no restoration of permanently atrophied muscles. His last visit to Lovett showed only a trace of motion in the quadriceps on the right side and none on the left side, hip flexion was poor bilaterally, and bowel, bladder, and sexual functions were left undiminished. Although he vowed to walk independently, he never walked again without the assistance of a strong person holding his weak left side.

POLITICAL IMPACT OF HIS DISABILITY

Prior to 1921, FDR was perceived as a highly ambitious, rather supercilious young man whose social contacts were composed entirely of people in the higher political and diplomatic circles in Washington. Although he had successfully run for the New York state senate in 1910 and was familiar with the conditions of city slums at the turn of the twentieth century, he had little contact with the working classes and no contact with the problems of rural poverty in the Deep South. Those who knew him at Groton, a private preparatory school, and Harvard College remembered him as extremely ambitious to be popular but also as a snob who seemed ill at ease with people outside of his social group. One Harvard classmate who worked with him on the college newspaper said he did not have the common touch at all and that all of his humanitarianism came much later after he had had the polio attack. Frances Perkins, FDR’s secretary of labor, who knew him before and after the polio, said he changed enormously, that he broadened his sympathies for the underdog and the underprivileged. During his long rehabilitation, he came into contact with ordinary citizens who had suffered polio, and he maintained correspondence with people disabled from polio throughout the United States and Canada.

Polio taught him to be patient and to bide his time for an appropriate reentry into politics. He was moving toward progressive positions in state and national politics before the polio, but he was no flaming liberal. The 1920s was a period of conservatism and isolation from foreign affairs. Although he nominated Al Smith for the presidency in 1924, he did not take an active role in politics until 1928, when he ran for governor of New York. When the stock market crashed in 1929, leading to the Great Depression, he was ready to assume the leadership of the Democratic Party. Polio gave him the chance to gain greater knowledge of the problems of poverty, to enlarge and broaden his circle of friends, and to concentrate on his political goals. In 1932, the nation and the world needed a leader who was as strong and clever as the European dictators. The nation was paralyzed by fear and economic depression. Roosevelt’s triumph over his personal disability became a metaphor for national regeneration. During his 12-year presidency, there was increased attention paid to people with disabilities, through congressional legislation and through periodic charitable drives for people with polio, most significantly the March of Dimes. Perhaps the greatest contribution to the awareness of disability was Roosevelt himself, transferring from a chair to a standing position with the help of an aide, ambulating awkwardly to the podium, and gripping the lectern while deflecting the crowd’s attention with his magnificent smile.

POST-POLIO SYNDROME

Since FDR’s death, new information has been discovered about the late effects of poliomyelitis. Whereas polio was considered in his era to be a viral illness that had marked effects on breathing, movement, and sensation up to 2 years following the initial attack, it was not expected to progress or cause weakening of muscles that had not been initially affected. Patients often regained strength in some muscles and learned to sit, stand, and ambulate by a regimen of exercises and physiotherapy, such as FDR had undertaken. Studies in rehabilitation over the past 20 years, reviewed by Halstead (2004), have demonstrated a wide variety of symptoms experienced by former polio patients, ranging from 20 to 70 years after the polio infection. These symptoms are summarized as fatigue, decreased muscle endurance, muscle pain, joint pain, weakness in previously affected muscles and in unaffected muscles due to disuse, and atrophy. The problem of differential diagnosis is especially difficult with patients who are aging and have complex medical disorders that may simulate symptoms caused by polio. For example, many neurological and orthopedic disorders have similar symptoms of joint pain, muscle weakness, and fatigue. Therefore, a comprehensive medical examination, including an electromyogram, is necessary to confirm the existence of changes in muscle strength and sensation.

Did Roosevelt have post–polio syndrome? The medical evidence is limited by the absence of any continuous medical history from 1928 to 1944. These 16 years witnessed FDR in the governorship and the presidency. Apart from intermittent examinations to document his health for the electorate and to treat chronic sinusitis by his White House physician, Ross McIntyre, there is no record of his various illnesses. The laboratory reports during his presidency were stored under a pseudonym at the U.S. Naval Hospital in Bethesda, Maryland, and could not be found after his death. The most comprehensive and authoritative report was made by Howard Bruenn, a young cardiologist who treated him from March 27, 1944, to April 12, 1945. Bruenn diagnosed him with hypertension, hypertensive heart disease, left ventricular cardiac failure, and acute bronchitis. He recommended bed rest, limited work up to four hours per day, digitalis, a light and easily digestible diet, restricted salt, codeine for cough, sedation at night for sleep, and gradual weight reduction. The gaunt, haggard facial appearance of his last days was due to the loss of weight. Bruenn treated him for 12 months with no significant reduction in blood pressures, which fluctuated widely, from 170/88 to 240/130. Despite occasional chest pain, with one notable episode of substernal pain, FDR avoided an acute myocardial infarct or stroke until April 12, when he died from a massive cerebral hemorrhage. He was 63.

The confirmation of post–polio syndrome (PPS) cannot be made from Bruenn's clinical notes. The only evidence we have is completely anecdotal. Members of his family and of his inner circle of White House aides reported that he had lost muscle strength and endurance as early as 1941. The evidence is consistent with current criteria for diagnosing PPS after 15 years of neurological and functional stability. Moreover, he had less time for aerobic exercise such as swimming and for periodic rest such as frequent vacations due to the unprecedented stress of the world war. He was intolerant to cold, requiring extra warm blankets at home and while traveling to distant lands. After April 1944, Bruenn stopped his swimming in the White House pool because of hypertension. Although some of these symptoms may be caused by vascular disease, they are also indicative of PPS.

Did the late effects of polio contribute to his hypertension and hypertensive heart disease? In my conversations with Bruenn, he said that FDR's blood pressures were essentially normal during his first two terms. He was very active, swimming almost daily in the White House pool, traveling to Warm Springs, and going on frequent fishing trips for relaxation. The muscles in his legs were atrophied, so he used only his arms for moving his wheelchair and for swimming. During the war years, polio prevented him from managing muscle weakness and getting proper rest. Other causes of hypertension, such as renal disease, were absent. Hypertension and arteriosclerosis developed in an aging man, and polio did not have a specific effect on the elevation of blood pressure.

IMPACT ON THE DISABLED COMMUNITY

FDR's impact on people with disabilities came from many contributions: first, he established in 1926 a center for the treatment of polio patients at Warm Springs, Georgia. He spent four years there in an attempt to restore his atrophied muscles. Although he did not learn to walk unassisted, he did learn to use canes and benefited from the psychological support of other patients. He invested two-thirds of his inherited wealth, $201,667, to acquire the property of an old resort, including cottages, springs, and 1,200 acres of land, and established a modern hospital for the treatment of the aftereffects of polio. Some of the methods used to exercise weakened muscles, including physiotherapy, were adopted in a therapeutic environment shared by patients, nursing assistants, and "push boys" who maintained a spirit of equality and teamwork. Second, he established the Warm Springs Foundation, which hired medical specialists from Atlanta to direct orthopedics, build new pools, and expand the facilities. Third, in 1937, he became the prime mover behind the National Foundation for Infantile Paralysis Research, which raised funds for basic research to isolate the polio virus and develop a vaccine. The National Foundation's efforts led to the cultivation of the polio virus in a laboratory by John Enders, Thomas Weller, and Frederick Robbins, as well as the development of the Salk and Sabin vaccines. The announcement of the Salk vaccine was made on the 10th anniversary of FDR's death.

The voluntary campaign for the treatment of polio was the first widespread attempt to raise funds for a major disability. In an era when people with disabilities were either hidden or kept at home, pretty poster children with polio became models for acceptance. Roosevelt was used as a model who overcame his handicaps. It was thought that FDR had learned to stand, walk, and grasp the lectern as he made his political speeches. When a visitor entered his White House office or the State dining room, he was already seated. On the campaign trail, he held the railing of the rear train car while he flashed his magnificent smile and waved to the crowd. "If Roosevelt can do it, I can do it." In his era, he concealed the full extent of his disability in public, where his paralysis was shielded from the eyes of onlookers. Photographers had an unwritten agreement to avoid showing his atrophied legs. He was never seen in public in a wheelchair until March 1945, when he addressed Congress after making a strenuous trip overseas to Yalta in the Crimea.

Fifty-two years later, when the Roosevelt Memorial was opening in Washington, D.C., some disabled citizens criticized FDR for being a poor model since he concealed his disability during his lifetime. After public debate and controversy, a sculpture of him in a wheelchair now graces the memorial. The symbolism of Roosevelt triumphant over disability does not depend on the visible signs of braces and wheelchair but on the inspiration he provided for millions of disabled and able-bodied individuals throughout the world.

ROUSSEAU, JEAN-JACQUES

(1712–1778)

Philosopher and writer

Jean-Jacques Rousseau was one of the most influential thinkers of the eighteenth century, and his work continues to inform debates on education, the state, social welfare and morals. Rousseau spent most of his life residing in his native Switzerland and in Paris. In the novel, *Emile* (1762), he addressed critical issues in education, proposing a pragmatic approach to learning that focused on developing the natural proclivities of the individual and on learning through experience. He thought that teachers should not invest much energy in trying to educate "weak and sick" children because they would essentially end up being caretakers and guardians. He advocated that teachers ought to devote most of their efforts to the more "promising" students. In *The Social Contract* (1762), he argued that individuals could be more successful in facing threats in their lives by belonging to a society, a state, rather than by acting as individuals. The resulting "compact" between individuals about rules of behavior and sanctions for unwanted behavior sets the conditions for membership in society, including both rights and responsibilities. This work laid the foundations for discussions of the state, welfare, and care systems for the aged and disabled. Rousseau made a further contribution to disability discourse in his work on politics and morality. He stated that politics and morality cannot be separated and that the state is obligated to act in moral fashion or it will cease to exercise authority over its citizens. He also argued that the state is created to provide freedom for individuals. Thus, on individual and societal levels, Rousseau provoked discussion and took positions on issues critical to the place of disabled people in society.

RUSH, BENJAMIN (1745–1813)

Physician and father of American psychiatry

Rush is known equally for his political and medical activities during the early years of the United States. He was a signer of the Declaration of Independence and served during the subsequent war as the physician general of the Medical Department of the Army. After the Revolutionary War, he actively pursued the still-new medical specialty of mental health and, in 1787, became supervisor of the section of the Pennsylvania Hospital devoted to those with psychiatric or intellectual disabilities (or "madness" and "fatuity," as Rush referred to these conditions in the writings). His textbook, *Medical Inquiries and Observations upon the Diseases of the Mind,* published near the end of Rush's life in 1812, served for many years as an influential summary of the knowledge base in the emerging field of psychology. In 1965, the American Psychiatric Association officially designated Rush as the "father of American psychiatry."

Rush wrote on occasion of the importance of humane treatment in terms that seem to foreshadow the "moral treatment" promoted by psychiatrists in the decades following Rush's death, describing how patients should "taste the blessings of air, and light, and motion, in pleasant and shaded walks in summer." However, many of his ideas and most of his practices were very traditional, punitive, and outdated even for their time, often relying on bloodletting, restraints, rapid spinning, and confinement to straw-covered cells in the basement of the hospital.

—Philip M. Ferguson

RUSK, HOWARD (1901–1989)

Physiatrist

Conventionally considered the "father" of organized rehabilitation medicine in the United States, Rusk took his MD at the University of Pennsylvania, trained as an internist in St. Louis, and entered the Army Air Force's Medical Corps as a major during

World War II. Stationed near St. Louis, Rusk was exposed to the military's bimodal system of "rehabilitation." A patient was either "convalescent" and given few functional activities or deemed ready for duty and subjected to 10-mile hikes in full gear.

He designed a convalescent training program, incorporating psychological, physical, and vocational training to increase the functional state of the soldiers. The U.S. Army embraced this model and expanded it to military care facilities throughout its network. At the end of the war, Rusk took this model into civilian life. The military took the model into founding the Veteran's Administration hospital system.

Rusk's methodology invoked holism when reductionism in the medical model was particularly popular. An experimental demonstration while he was in the army, in which one barrack of disabled soldiers received intensive, holistic rehabilitation and another the standard "convalescent" care, dramatically showed the functional value of Rusk's methods to the military bureaucracy and to civilian observers. His genial style garnered him the nickname "Dr. Live-Again," also representing the prominence of the medical model in his early work.

In Manhattan, he founded the Institute of Rehabilitation Medicine at New York University, later named for him. He began a residency training program linking physical medicine with rehabilitation (a reason for his "father" status of the field). His public fund-raising efforts included privately lobbying the powerful, publicly persuading congressional budgeteers, and editing a column in the *New York Times.* Central to his unifying role was membership on the 1943–1952 Baruch Committee on Physical Medicine. He was preceded by figures such as John Coulter, George Albee, Henry Kessler, and Frank Krusen, who also played significant roles in establishing the twain fields of rehabilitation and physical medicine.

RUSSELL, HAROLD (1914–2002)

Veteran and actor

A disabled veteran from World War II who, after 1945, briefly became a movie star and then a longtime advocate, in a variety of roles, for war veterans and people with disabilities, Harold Russell symbolized American disabled war veterans of the World War II era. Born in Nova Scotia, Canada, Russell immigrated to Boston with his family in 1933 and then worked as a butcher. He enlisted in the U.S. Army the day after the attack on Pearl Harbor. He trained as a paratrooper and then became a demolitions instructor, but he never saw action outside the United States. While working in the latter capacity, a defective fuse exploded a charge of TNT while he was holding it and led to the amputation of both his hands. Boyish charm and a positive attitude toward rehabilitation recommended him to the Army documentary makers, who sought a typical American soldier-amputee for a short training film intended to encourage amputees to achieve normalized lives. Though Russell had no speaking part in *Diary of a Sergeant* (1945), his natural grace before the camera recommended him to director William Wyler, who cast him as Homer Parrish in the Hollywood classic, *The Best Years of Our Lives* (1946). Russell won two Academy Awards: a Best Supporting Actor award for his performance and a humanitarian award for inspiring disabled veterans. Though he made brief appearances in other films and on television thereafter, his principal activities were as an advocate for both veterans and people with disabilities. He helped organize the World Veterans Foundation and served as vice president of the World Veterans Fund. He served three terms as national commander of the American Veterans of World War II (AMVETS). He maintained a consulting firm, which specialized in expanding job opportunities for the disabled. Following an appointment by President Lyndon Johnson in 1964, he served as chairman of the President's Committee on Employment of People with Disabilities, in which capacity he served until 1989. For many years, he also spoke widely on advances in the field of prosthetics. The Harold Russell Foundation continues his work through its

International Veterans Amputee Project, which assists disabled veterans to find and learn to use prosthetic limbs.

—David A. Gerber

CHRONOLOGY

1500 BCE Egypt: The Ebers Papyrus, a medical textbook, devotes an entire chapter to eye diseases. It also shows that deafness is well understood and that clinical knowledge has developed.

400 BCE Graeco-Anatolian Hippocratic writings coin the word e*pilepsy* for a convulsive condition they view as a disease rather than a possession or punishment. Today, it is estimated that more than 80 percent of the 40 million people who currently have epilepsy throughout the world have little access or no access to contemporary treatments.

300 BCE China: *The Yellow Emperor's Internal Classic* is the first text to outline acupuncture. Ordinances on emergency relief for the disabled date to the Han Dynasty, 206 BCE–AD 220. Fiscal and administrative disability classification date at least to the Tang Dynasty, 618–907.

1250–1350 High point of medieval medicalization during which theoretical explanations for conditions gain currency in Western Europe. Prior to this time, in the most general of terms, lay explanations held more sway, ranging from the superstitious to the spiritual to the vindictive. With the founding of the universities, medical theory, typified by the four humors, became more influential in governmental, legal, and elite social circles. Disabling conditions like epilepsy, strokes, and paralyses, as well as psychiatric conditions, increasingly fell under the social control of doctors.

1400 Turkey: Deaf people work in the Ottoman Court from the 15th to the 20th centuries. Sign language becomes a recognized means of communication among both hearing and deaf courtiers.

1593 England: The origins of disability as a social and political category emerge with the first state disability benefits being enacted by Parliament for those disabled in war.

1593 Europe and the United States: English Parliament initiates Europe's first national system of benefits for rank-and-file disabled veterans. The first veterans' homes—France's Hôtel des Invalides, Britain's Chelsea Hospital, and Frederick the Great's Invalidenhaus in Berlin—are established in 1633, 1685, and 1748, respectively. Following the American Civil War, the U.S. government responds with a system of homes, preferences in government hiring, land grants, free prosthetics, and pensions for disabled veterans (however, southern veterans were limited to usually scanty state pensions).

1601 England: The Poor Law is passed to provide family and community support for those unable to make a living for themselves.

1604 Laws on witchcraft in the colonies all evolve from a 1604 English Statute that makes "being a witch" punishable by death. During outbreaks of witch-hunting, the "different" body itself is targeted as a sign and symptom of one's confederation with demonic forces.

1697 England: The first English workhouse for people with mental and physical disabilities is established in Bristol in 1697.

1704 Bethlem Hospital in the United States has 130 residents housing the "furiously mad."

1714 Canada: The Bishop of Quebec opens the first building in Canada exclusively for the confinement of mentally disturbed individuals. It is adjacent to Quebec General Hospital.

1749 France and England: Denis Diderot pens one of the most influential treatises on the blind and education in his *Letter on the Blind* in which he argues that the blind can be educated. In 1784, Valentin Haüy opens the first school for the blind in Paris. He perfects a system of raised *letters* to enable the blind to read. In 1828, Louis Braille modifies a raised *dot* system invented by Charles Barbier, which is used today by blind persons to read and communicate. In 1847, William Moon, an Englishman, develops an embossed script based on Roman capitals that blind adults can learn to read in a few days. It is the first reading system for the blind to be widely adopted across the world, but because it is costly to print, the Braille system, which can be produced by blind individuals for themselves, overtakes Moon's system.

1755 France, the United States, and Germany: The Abbé Charles-Michel de l'Épée establishes the first state-supported school for the training of young deaf children, where he teaches sign language. The school serves as an inspiration for the establishment of other European schools and has a dramatic impact on social attitudes toward the deaf. In 1817, Thomas Gallaudet and Laurent Clerc establish the Asylum for the Deaf (now American School for the Deaf) in Hartford, Connecticut. Clerc imports the French sign system, which influences the makeup of contemporary American Sign Language (ASL). In 1778, Samuel Heinicke establishes a school in Leipzig, Germany, where the "oral method" is used.

1800 France: Victor of Aveyron, a "feral child" found in southern France, is brought to Paris. Jean Marc Gaspard Itard, a French physician, develops a systematic training program for the boy and works intensively with him for five years. Itard considered his attempt at educating Victor to be a failure because the boy did not learn to use a language. Nevertheless, Itard's disciples, including Edouard Séguin, Maria Montessori, and Alfred Binet, continue his work by establishing classes for children considered to be "mentally retarded."

1802 France: The world's first pediatric hospital, L'Hôpital des Enfants Malades, is founded.

1817 The American School for the Deaf is founded in Hartford, Connecticut. It is the first school for disabled children in the Western Hemisphere.

1817 James Parkinson, a London physician, describes what is to become known as Parkinson's disease.

1817 Thomas Gallaudet and Laurent Clerc open the American Asylum for the Education of the Deaf and Dumb in Hartford, Connecticut.

1828 Frenchman Louis Braille, blind from childhood, modifies a raised-dot system of code, one of the most important advances in blind education. It not only allows the blind to read at a much faster rate but also makes it possible for the blind to be teachers of the blind. UNESCO creates the World Braille Council in 1952.

1829 France: Louis Braille publishes an explanation of his embossed dot code.

1832 Samuel Gridley Howe is chosen to direct what is later to be called the Perkins School for the Blind in Boston. It becomes the model for schools around the nation. Laura Bridgman and Helen Keller attend Perkins. In 1837, Ohio establishes the first state-sponsored school for the blind.

1834 England: The English Poor Law Amendment stipulates five categories of those unable to work: children, the sick, the insane, defectives, and the aged and infirm. This sets the stage for the development of specialty institutions that isolate the disabled from the community.

1841 P. T. Barnum purchases Scudder's American Museum in New York City. This moment is considered to be the beginning of the "Golden Age" of freaks, which persists until the 1940s. The tension

between freaks and disability rights comes to a head in 1984, when disability rights activist Barbara Baskin successfully lobbies the New York State Fair to remove Sutton's Incredible Wonders of the World Sideshow, featuring a limbless man who performs as the "Frog Boy," from the midway.

1843 Due to the influence of Dorothea Dix, an American social reformer, the Massachusetts legislature allocates funds to greatly expand the State Mental Hospital at Worcester. Dix also plays an instrumental role in the creation of 32 mental hospitals and becomes nationally known for her reform efforts. By the late 1840s, Dix focuses on developing a national plan that addresses the treatment of people with mental illness.

1846 William Thomas Green Morton discovers anesthesia and in 1867 Joseph Lister provides a model for antisepsis. These new technologies play a central role in the future of aesthetic surgery as well as surgical intervention for every type of disability that calls for it. Penicillin is discovered in 1929, cutting mortality rates in hospitals dramatically.

1848 The North Carolina School for the Deaf begins the first publication for Deaf persons with its school newspaper, *The Deaf Mute.* First published in 1907, the *Matilda Ziegler Magazine for the Blind* is an ongoing Braille publication.

1848 Samuel Gridley Howe founds the first residential institution for people with mental retardation at the Perkins Institution in Boston.

1851 In the United States there are 77 residential institutions for children, 1,151 by 1910, and 1,613 by 1933. By the 1950s and 1960s, family members and politicians throughout Western Europe, Canada, and the United States push for the deinstitutionalization of people with disabilities.

1851 The first International Sanitary Conference is held in Paris, France, with 12 countries participating. It leads to the World Health Organization, the WHO, which formally comes into existence in 1948.

1857 Edward Miner Gallaudet, youngest son of Thomas Hopkins Gallaudet, establishes the Columbian Institution for the Instruction of the Deaf, Dumb, and Blind, located in Washington D.C. Its college division, eventually known as the National Deaf-Mute College, is the world's first institution of higher education for deaf people. Abraham Lincoln signs its charter on April 8, 1864; today it is known as Gallaudet University.

1857 English philosopher Herbert Spencer is first to use the expression "survival of the fittest." The application of his idea in combination with Charles Darwin's theories in his 1859 book, *The Origin of the Species,* is called Social Darwinism. It is widely accepted and promoted in Germany in the 1920s and leads Adolf Hitler to express prejudice against the weak, sick, and disabled.

1863 Louis Agassiz, a significant American naturalist, advocates the permanence of different races and worries about the "tenacious influences of physical disability" if races were mixed.

1864 Germany: Karl Ferdinand Klein, teacher for deaf-mutes, and Heinrich Ernst Stotzner are considered the founding fathers of the *training school,* which calls for schools to be created for less-capable children with the goal of improving their lot. Training schools remain in effect today, but critics maintain that there is an over-representation of socially and economically underprivileged students in this type of setting experiencing little academic success.

1868 Sweden: The Stockholm Deaf Club is the first recorded organization of people with disabilities.

1870 England and Wales: Education for children with disabilities begins when universal elementary education is first introduced around this time. From 1895 onward, schools for "defective" children spring up. In 1899, Alfred Eichholz, an inspector of special education, draws up key recommendations, which leave their mark on the historic 1994 Education Act legislation. In 1978, the Warnock report

introduces the term *special needs education,* which soon gains acceptance worldwide. With the 1994 UNESCO Salamanca Statement and Framework for Action on Special Needs Education, a major shift in organizing educational services for children with disabilities is confirmed internationally.

1876 ◆ Isaac Newton Kerlin, Edouard Séguin, and others establish the Association of Medical Officers of American Institutions for the Idiotic and Feeble-Minded Persons. Today, it is known as the American Association on Mental Retardation. Séguin, who staunchly believes in the educability of those with significant cognitive disabilities, is styled as "apostle to the idiots," by Pope Pius X, reflecting the attitude of the time.

1880 ◆ The United States National Association of the Deaf (NAD), the first organization of deaf or disabled people in the Western Hemisphere, is established. In 1964, the Registry of Interpreters for the Deaf (RID) is formed to establish a national body of professionals who are trained and certified to enable communication between deaf, signing persons and nondeaf, speaking persons.

1880 ◆ Helen Keller is born in Tuscumbia, Alabama. An illness at the age of 19 months leaves her totally deaf and blind. In 1887, Anne Sullivan, recently graduated from Perkins Institution for the Blind, joins the Keller household as Helen's teacher and remains Keller's companion for nearly 50 years. For many, Keller's story is the quintessential overcoming narrative.

1881 ◆ The Chicago City Council enacts the first American "ugly law" forbidding "any person, who is diseased, maimed, mutilated or deformed in any way, so as to be an unsightly or disgusting object, to expose himself to public view."

1882 ◆ The first major federal immigration law in the United States, the Immigration Act of 1882, prohibits entry to "lunatics," "idiots," and persons likely to become unable to take care of themselves. Most of the restrictions that apply specifically to disability are removed from U.S. law in 1990. Today, disabled immigrants are still denied an entry visa if they are deemed "likely to become a public charge."

1887 ◆ Walter Fernald serves as superintendent of the Massachusetts School for the Feeble-Minded (now known as the Fernald Center) from 1887 to 1924. Unlike most of his colleagues, Fernald moderates some of his earlier extreme views and eventually develops one of the country's largest "parole" systems for moving institutional residents back into smaller, community-based residences.

1887 ◆ The American Orthopaedic Association is founded. German and British counterparts are founded in 1901 and 1918, respectively.

1895 ◆ The chiropractic profession is founded. This type of care is used to relieve musculoskeletal pain, one of the most common causes of disability.

1899 ◆ Maria Montessori and a colleague open the Scuola Magistrale Ortofrenica in Rome, an educational institute for disabled children and a training institute for instructors. Her method relies on the concept of sensory-based instruction as a means for developing intellectual competence. Her methods allow the child the greatest possible independence in order to foster his or her own development (the child's own inner "building plan").

1904 ◆ Sir Francis Galton, half first cousin of Charles Darwin, defines the term e*ugenics* (which he coined in 1883) in a paper he presents to the Sociological Society on May 16. He argues for planned breeding among the "best stock" of the human population, along with various methods to discourage or prevent breeding among the "worst stock." Galton also develops the idea for intelligence tests. The term *feeblemindedness* is defined as broadly as possible and is widely used by eugenic social reformers to conflate myriad social problems. Further naming, classification, and labeling provides eugenicists with a troubling rationale for treating people with coercion, disrespect, and profound inhumanity. Persons within the various categories of sub-normality become particularly vulnerable

to state-sanctioned segregation, institutional confinement, and enforced sterilization. Eugenics is widely practiced in Europe, the United States, and Canada, culminating in the systemic murder of more than 260,000 disabled people by the Nazis between 1939 and 1945. Today, the so-called new eugenics, known as "human genetics," appeals to the needs of the individual. Critics (some of the first in Germany), however, criticize individualistic eugenic approaches and disclose the connections between human genetics, national socialist racial hygiene, and eugenics.

1905 Alfred Binet and Theodore Simon publish the first intelligence scale, known as the Binet-Simon Test.

1908 The publication of Clifford Beers's *A Mind That Found Itself* initiates the mental health hygiene movement in the United States. Speaking out against mistreatment and neglect within the system, Beers establishes the Connecticut Committee of Mental Hygiene, which expands in 1909, becoming the National Committee for Mental Hygiene and is now known as the National Mental Health Association. In 1940 there are 419,000 patients in 181 state hospitals. In 1943, the patient-doctor ratio is 277:1, and by the mid-1950s in New York state alone, there are 93,000 inpatients. The Bazelon Center for Mental Health Law, founded in 1972 by a group of committed lawyers and professionals in mental health and mental retardation, attempt to improve mental health service provision through individual and class action suits. In 1980, a group of these lawyers form the National Association of Rights Protection and Advocacy (NARPA). One-third of its board of directors must identify themselves as current or former recipients of mental health care. The association is committed to the abolishment of all forced treatment.

1908 Pastor Ernst Jakob Christoffel establishes a home in Turkey for blind and otherwise disabled and orphaned children. This grows into Christoffel-Blindenmission (CBM), an independent aid organization of Christians of various denominations united to help disabled people in third world countries. Today, it supports more than 1,000 development projects in 108 countries. In 1999, CBM, other agencies, and the World Health Organization initiate VISION 2020: The Right to Sight, a global initiative for the elimination of avoidable blindness by the year 2020.

1909 Germany: The German Organization for the Care of Cripples is created as an umbrella organization for the care of the physically disabled. The Prussian Cripples' Care Law of 1920 for the first time provides a right to medical care and scholarly and occupational education for this group.

1912 Henry H. Goddard publishes *The Kadikak Family,* supports the beliefs of the eugenics movements, and helps create a climate of hysteria in which human rights abuse of the disabled, including institutionalization and forced sterilization, increases. In 1927, the U.S. Supreme Court, in *Buck v. Bell,* rules in favor of forced sterilization of people with disabilities, further fueling eugenics movements—the number of sterilizations increases.

1914 By this date, Sigmund Freud develops his most enduring influence on the study of disability, namely, the theory of psychosomatic illness in which a psychopathological flaw is given corporeal form as a symptom, thereby establishing the notion that people succumb to disease or disability because they feel guilty about past or present repressed desires.

1918 The Smith-Sears Veterans Rehabilitation Act passes, authorizing VR services for World War I veterans. In 1916, the National Defense Act marks the beginning of the U.S. government's supportive attitude toward rehabilitation. In 1920, the Smith-Fess Act marks the beginnings of the civilian VR program. The Social Security Act of 1935 establishes state-federal VR as a permanent program that can be discontinued only by an act of Congress.

1919 Edgar "Daddy" Allen establishes what becomes known as the National Society for Crippled Children. In the spring of 1934, the organizational launches its first Easter "seals" money-making campaign. Donors place seals on envelopes containing their contributions. The seal is so well-known that it

becomes part of the organization's official name. Today, Easter Seals assists more than one million children and adults with disabilities and their families annually through a nationwide network of more than 500 service sites. During the 1920s, Franklin D. Roosevelt inspires the March of Dimes.

1920 ◆ At about this time, the Shriners open hospitals for the care of crippled children. President Herbert Hoover establishes a "Children's Charter" in 1928 highlighting the need to attend to the needs of crippled children.

1921 ◆ Franklin D. Roosevelt contracts poliomyelitis. Despite damage to his legs (which makes him a wheelchair user) and deep depression, through enormous rehabilitative effort, he eventually re-enters politics and becomes president of the United States. His triumph over personal disability becomes legendary. Critics, however, fault him for choosing to minimize his disability in what is called his "splendid deception." He establishes a center for the treatment of polio patients in Warm Springs, Georgia, called the Georgia Warm Springs Foundation (1927), which hires medical specialists from Atlanta to direct orthopedics. In 1937, President Roosevelt becomes the prime mover behind the National Foundation for Infantile Paralysis Research.

1921 ◆ Mary L. McMillan (Molly) establishes the American Women's Physical Therapeutic Association, which is known today as the American Physical Therapy Association (APTA).

1921 ◆ The American Foundation for the Blind is established.

1921 ◆ Canada: Researchers isolate the hormone insulin. In 1922, Frederick Banting, Charles Best, J. B. Collip, and J.R.R. Macleod produce and test the pancreatic extract on people with diabetes, for which they are awarded a Nobel Prize. Insulin becomes a wonderful treatment for diabetes, but not a cure.

1921 ◆ France: Three historical waves of advocacy movements can be identified beginning with the National Federation of Injured Workers (FNAT) in 1921 and other organizations that focus essentially on the protection of rights. Another factor that stimulates advocacy groups in the first wave is the wounded veterans of World Wars I and II. A second wave dates from the period after World War II. Many advocacy groups form between 1950 and 1970, such as the Union of Associations of Parents of Maladjusted Children (UNAPEI) in 1960. A third wave finds a gradual emergence of three types of associations: those that run specialized facilities (for example, Living Upright, which, in 1970, leads to the creation of the first group living facility); those interested in trade unions; and those represented by user-advocate associations. Financing comes in large part from public funds, thereby creating a government-association partnership.

1922 ◆ The founding of Rehabilitation International sets the stage for the establishment of other international organizations of and for people with disabilities that link together throughout the world. Later international organizations include, among numerous others, the World Federation of the Deaf (1951), Inclusion International (1962), the International Association for the Scientific Study of Intellectual Disability (1964), Disabled Peoples' International (1981), and the International Disability Alliance (1999).

1925 ◆ The American Speech-Language-Hearing Association, today the American Academy of Speech Correction, is established to provide high-quality services for professionals in speech-language pathology, audiology, and speech and hearing science, and to advocate for people with communication disabilities.

1928 ◆ Charles Nicolle is the first deaf person to be awarded a Nobel Prize.

1929 ◆ Seeing Eye establishes the first dog guide school in the United States.

1930 ◆ The Veterans Administration is created to administer benefits, promote vocational rehabilitation, and return disabled veterans to civil employment. There is a record of provision for disabled veterans in the United States since the Revolutionary War and the Civil War. After World War I, three agencies administer veteran's benefits.

1932 Herbert A. Everest, a mining engineer with a disability, and Harry C. Jennings collaborate to design and patent the cross-frame wheelchair, which becomes the standard for the wheelchair industry that exists today. Developed during World War I, the first powered wheelchair appears, but doesn't gain popularity for another 30 years.

1935 President Franklin D. Roosevelt signs the Social Security Act of 1935 on August 14. Beginning in 1956, SSA amendments provide disability benefits.

1935 By 1935, in the United States more than 30 states pass laws allowing for the compulsory sterilization of those deemed genetically unfit in state and federal institutions. By 1970, more than 60,000 people are sterilized under these laws.

1935 As a result of being denied participation in the Works Progress Administration (WPA), six young people with disabilities hold a sit-in at the offices of New York City's Emergency Relief Bureau, demanding jobs in non-segregated environments and explicitly rejecting charity. The League of the Physically Handicapped is born out of this activism and operates in New York from 1935 to 1938. The League identifies social problems that remain issues today.

1935 Peer support in the United States is traced to the establishment of Alcoholics Anonymous in this year. Interest in peer support increases in the 1960s and is adopted by the disabled community. Movements, such as the Center for Independent Living, and groups, such as the National Spinal Cord Injury Association, make peer support one of their major activities.

1936 The American Academy of Physical Medicine & Rehabilitation is founded, leading to the approval of the American Board of Physical Medicine & Rehabilitation by the American Medical Association in 1947.

1937 The Fair Housing Act of 1937 passes with a mandate to assist the poor, a group that includes people with disabilities, by creating public housing. However, it is not until the Rehabilitation Act of 1973 that housing law specifically deals with discrimination faced by individuals with disabilities in housing programs that receive federal funding. The 1988 amendment to the Fair Housing Act of 1968 extends protection for people with disabilities beyond those of Section 504 of the Rehabilitation Act to include private housing.

1939 The Nazi regime institutes the Aktion T4 program in Germany. Children and, later, adults with disabilities are selectively killed both in hospitals and in special centers. The program was officially terminated by Adolf Hitler in August 1941, but practitioners "informally" continued it through a phase historians have called "wild euthanasia."

1940 State activists for the blind, including Jacobus Broek, come together in Wilkes-Barre, Pennsylvania, to charter the National Federation of the Blind (NFB). In 1957, the NFB publishes the first edition of the *Braille Monitor,* which is still in print today. In 1960, dissatisfied NFB members form the American Council of the Blind (ACB).

1940 Paul Strachan establishes the American Federation of the Physically Handicapped, the nation's first cross-disability, national political organization.

1942 The American Psychiatric Association develops a position statement in favor of the euthanasia of children classified as *idiots* and *imbeciles.*

1943 The LaFollette-Barden Act, also known as the Vocational Rehabilitation Amendments, adds physical rehabilitation to federally funded vocational rehabilitation programs.

1943 The United Nations is established on October 24 by 51 countries. The global Programme on the Disability is the lead program concerning disability. Many other types of programs, activities, and instruments include the 1975 Declaration on the Rights of Disabled Persons, the 1981 International Year of

Disabled Persons, the 1982 World Programme of Action Concerning Disabled Persons, the 1983–1992 UN Decade of Disabled Persons, and the 1993 Standard Rules on the Equalization of Opportunities for Persons with Disabilities. In 1988, the first UN Disability Database (DISTAT) publishes statistics from 63 national studies covering 55 countries and the 2001 publication presents 111 national studies from 78 countries, indicating a growing interest worldwide for the collection of usable data. In 2005, a UN Ad Hoc Committee continues to consider a Convention on the Rights of Disabled Persons that is a legally binding human rights instrument. Today the UN membership totals 191 countries.

1943 Sweden: In possibly the first reference to the concept of normalization, the most significant driving force in the ongoing closure of state-run or state-funded institutions for people with a disability is made by the Committee for the Partially Able-Bodied, established by the Swedish Government. Through the advocacy of people such as Niels Erik Bank-Mikkelsen, normalization, with its profound positive effect on the lives of people who were once removed and segregated from society, remains relevant today.

1944 Richard Hoover invents long white canes known as Hoover canes that are used by many blind people.

1944 The word *genocide* first appears in a book by a Polish lawyer Raphael Lemkin titled *Axis Rule in Occupied Europe* in which he describes Nazi Germany's practices but also seeks the adoption of legal restrictions so that genocide will not occur. In 1948, the United Nations adopts a declaration and then a convention on genocide that describe both against whom genocide might be directed and acts constituting genocide. Article 6 of the Rome Statute of the International Criminal Court (ICC), established in 2002, uses language identical to that in the UN convention to define genocide. More than 90 countries are parties to the ICC, but not the United States.

1945 President Harry Truman signs into law an annual National Employ the Handicapped Week. In 1952, it becomes the Presidents' Committee on Employment of the Physically Handicapped, a permanent organization, which reports to the President and Congress.

1945 Canada: Lyndhurst Lodge, the first specialized rehabilitation center for spinal cord injury (SCI) in the world, and the Canadian Paraplegic Association, the first association in the world administered by individuals with SCI, are established.

1946 The first chapter of what will become the United Cerebral Palsy Association, Inc. is established in New York City. It is chartered in 1949, and along with the Association for Retarded Children, it becomes a major force in the parents' movement of the 1950s.

1946 The National Mental Health Foundation is founded by attendants at state mental institutions who aim to expose abusive conditions. Their work is an early step toward deinstitutionalization.

1946 The National Institutes of Mental Health (NIMH) are founded in the United States.

1946 Europe: The European Union is founded on September 17 in Paris. It consistently shows its commitment to eliminating discrimination on many fronts through joint declarations, resolutions, directives, and action programs. With regard to disability, the European Union supports actions in favor of people with disabilities, principally in the form of European Social Fund interventions. Action programs aim at facilitating the exchange of information between member states and nongovernmental organizations with a view to identifying good practices, integrating people with disabilities into society, and raising awareness of related issues. The EU Council of Ministers Recommendation on the Employment of Disabled People (1986) calls on member states to "eliminate negative discrimination by reviewing laws, regulations and administrative provisions to ensure that they are not contrary to the principle of fair opportunity for disabled people." Further

steps are taken in 1996 when a communication on equality of opportunities for disabled people sets out a new European disability strategy that promotes a rights-based approach, rather than a welfare-type approach. This is strengthened in 1997 when the heads of state act to strengthen Article 13 of the European Community Charter of Fundamental Social Rights of Workers (1989), giving the European Community specific powers to take action to combat a broad spectrum of discrimination that includes disability.

1948 ◆ The National Paraplegia Foundation is established as the civilian branch of the Paralyzed Veterans of America.

1948 ◆ The World Health Organization is established. The WHO actively promotes human rights and the principle of equity in health among all people of the world, including persons with disabilities. Today it consists of 191 member states, but strives for universal membership. In 1980, the WHO publishes the International Classification of Impairments, Disabilities, and Handicaps (ICIDH) and issues a revised version in 2001, the International Classification of Functioning, Disability, and Health (ICF).

1948 ◆ The United Nations General Assembly adopts the "Universal Declaration of Human Rights," which promotes and affirms the fundamental rights to life, liberty, and security; to medical care and social services; and to the benefit from scientific progress and its uses.

1948 ◆ Sir Ludwig Guttmann organizes the first Stoke Mandeville (England) Games for the Paralysed, thus launching the Paralympic movement. The Games become international in 1952. In 1960, the first Paralympic Summer games are held in Rome and the first Paralympic Winter Games follow in 1976. The Paralympic Games are multi-disability, multi-sport competitions and have become the second-largest sporting event in the world, only after the Olympic Games.

1948 ◆ World War II bomber pilot and war hero Leonard Cheshire establishes what is to become the largest charitable supplier of services for disabled people in the United Kingdom. In the 1960s, the resistance of disabled people who live in one Leonard Cheshire home, Le Court, plays a major role in establishing the British disabled people's movement. In the late 1990s, the Leonard Cheshire organization establishes the Disabled People's Forum, which is run by disabled people and supports disabled people's involvement and empowerment.

1949 ◆ Timothy Nugent founds the National Wheelchair Basketball Association, and the first Annual Wheelchair Basketball Tournament takes place.

1949 ◆ Europe: The Council of Europe, an intergovernmental organization, is founded. Its activities cover all major issues facing European society other than defense. Human dignity, equal opportunities, independent living, and active participation in the life of the community form the heart of the Council of Europe's activities in relation to people with disabilities. The European Social Charter of 1961 and its revision in 1996 include specific wording and expand the rights of individuals with disabilities.

1950 ◆ The Social Security Amendments of 1950 provide federal-state aid to the permanently and totally disabled (APTD), which serves as a limited prototype for future Social Security assistance programs for disabled people.

1950 ◆ The National Mental Health Association is formed with the mission to continue 1908-advocate Clifford W. Beers's goals of "spreading tolerance and awareness, improving mental health services, preventing mental illness, and promoting mental health."

1950 ◆ The National Association for Retarded Children (NARC) is established by families in Minneapolis. It is the first and most powerful parent-driven human-services lobby in the nation to emerge in the 1950s.

1950 Amniocentesis is developed by a Uruguayan obstetrician. Later, advanced prenatal testing provides a battery of powerful medical tools to predict risk of disability and provide information to parents about their pregnancies.

1951 With the founding of the World Federation of the Deaf, the deaf community becomes international.

1953 Francis Crick and James Watson propose a three-dimensional structure for the DNA molecule. The paper they publish also gives clues to genetic mechanisms. Today, more than 6,000 monogenic disorders have been identified, and these affect approximately 1 in 200 live births.

1955 The polio vaccine, developed by Dr. Jonas Salk, becomes available, thus ending polio epidemics in the Western world. A new oral vaccine, developed by Dr. Albert B. Sabin, is approved for use in 1961.

1956 Social Security Disability Insurance (SSDI) becomes available through amendments to the Social Security Act of 1935 (SSA) for those aged 50–64. Other important amendments to SSA include the following: 1958: provides for dependents of disabled workers; 1960: removes age limit; 1965: Medicare and Medicaid provide benefits within the framework of the SSA (until 1977); 1967: provides benefits to widows and widowers over the age of 50; 1972: Supplemental Security Income (SSI) establishes a needs-based program for the aged, blind, and disabled; 1984: the Social Security Disability Reform Act responds to the complaints of hundreds of thousands of people whose disability benefits have been terminated; 1996: President Clinton signs the Personal Responsibility and Work Opportunity Reconciliation Act, making it more difficult for children to qualify as disabled for SSI purposes.

1959 The UN Declaration of the Rights of the Child is adopted; the UN Convention on the Rights of the Child is adopted in 1989. A central principle of both documents is access to education for all children including those with disabilities. In 1993, a related UN document, the Standard Rules for the Equalization of Opportunity, extends this to preschool children, and in 1994, UNESCO's Salamanca Statement and Framework for Action specifies the provision of special education for children with disabilities or learning difficulties. These documents constitute a universal bill of rights that can serve as a framework in the development of national policies worldwide.

1961 The American Council of the Blind is established.

1961 Europe: The European Social Charter (ESC) protects "the right of physically and mentally disabled persons to vocational training, rehabilitation and social resettlement." In 1996, it is revised, updated, and expanded to take account of social changes.

1961 Michel Foucault's work *The History of Madness in the Classical Age* becomes obligatory reading for those concerned with the archaeology of madness and its treatments. It continues to be an academic *rite de passage.*

1962 Battered child syndrome is defined. Researchers estimate that the incidence of maltreatment of children with disabilities is between 1.7 and 3.4 times greater than of children without disabilities.

1962 Russia: The Moscow Theater of Mime and Gesture is the first professional deaf theater in the world. It has been in continuous operation for more than 40 years and has staged more than 100 classic and modern plays.

1963 Congress enacts new legislation to ensure funding for a comprehensive program of research on mental retardation through the National Institute on Child Health & Human Development. In 1965, the Office of Economic Opportunity launches the Elementary and Secondary Education Act (ESEA), commonly known as Project Head Start. The goal is to prevent developmental disability by providing increased opportunities for disadvantaged children in the preschool years.

1963 The Developmentally Disabled Assistance and Bill of Rights Act (DD ACT) is authorized, with its last reauthorization in 1996. It focuses on individuals with developmental disabilities such as intellectual disability, autism, cerebral palsy, epilepsy, and hearing and visual impairments, among others.

1964 The Civil Rights Act is passed. It becomes the model for future disability rights legislation.

1964 France: L'Arche is established. By the beginning of the twentieth-first century, it includes more than 113 communities in 30 countries. "The Ark" is a distinctive style of community living, based on "core members" and "assistants," who view their commitment as sharing life *with* people with disabilities, rather than as caregivers.

1965 Newly enacted Medicare and Medicaid provide national health insurance for both elderly (over 65) and disabled persons.

1965 The Vocational Rehabilitation Amendments of 1965 are passed. They provide federal funds for the construction of rehabilitation centers and create the National Commission on Architectural Barriers to Rehabilitation of the Handicapped.

1965 The Autism Society of America is founded.

1967 Deaf actors establish the National Theatre of the Deaf (NTD). It is the world's first professional deaf theater company and the oldest continually producing touring theater company in the United States. Today, after almost 40 years, the NTD chronicles over 6,000 performances. The National Theatre Workshop for the Handicapped begins in 1977 and the Other Voices Project in 1982. These groups are among the earliest groups formally to place the disability experience at the heart of their creative endeavors.

1967 Heart transplantation is introduced. This technology is preceded by open-heart surgery developed in the 1950s and coronary bypass and internal pacemakers in the1960s. The Framingham Heart Study begins in 1948. It collects data over the next decades that help identify major risk factors contributors to heart disease.

1967 Paul Lemoine in France in 1967 and Kenneth Jones and David Smith in the United States in 1973 independently describe the condition fetal alcohol syndrome (FAS), which comprises a recognizable pattern of birth defects attributable to the adverse effects of maternal alcohol abuse during pregnancy.

1967 England: St. Christopher's Hospice in South London opens. It is the first attempt to develop a modern approach to hospice and palliative care.

1968 Congress enacts the Architectural Barriers Act. The ABA requires access to facilities designed, built, altered, or leased with federal funds.

1968 The Fair Housing Amendments to the Civil Rights Act of 1968 guarantees civil rights of people with disabilities in the residential setting. The amendments extend coverage of the fair housing laws to people with disabilities and establish accessible design and construction standards for all new multifamily housing built for first occupancy on or after March 13, 1991.

1968 Sweden: The origins of People First® go back to a meeting of parents of children with intellectual disabilities whose motto is "we speak for them." However, the people with disabilities in attendance wish to speak for themselves and start their own self-advocacy group. Similar groups quickly spread to England and Canada. The name People First is chosen at a conference held in Salem, Oregon, in 1974. People First is an international self-advocacy organization run by and for people with intellectual disabilities to work on civil and human rights issues.

1970 Landmark legal cases such as *Diana v. State Board of Education* (1970; Latino students) and *Larry P. v. Riles* (1971–1979; minority students) challenge biases inherent in standardized testing procedures used to identify students as eligible for special education. Both cases call into question the widespread use of "scientifically" objective measures to gauge intellectual ability. Today, despite reforms, a disproportionate number of students from racial, ethnic, and linguistic minorities continue to be placed in special education classes.

1970 Japan: The Disabled Persons' Fundamental Law (DPFL) becomes one of the 27 fundamental laws that stipulate basic principles in each policy area. Major revision takes place in 1993 reflecting a progress of guiding principles in disability policy that are deeply influenced by international movements such as the International Year of Disabled Persons (1981) and the UN Decade of Disabled Persons (1983–1992). Disability Studies as well as modern disability movements are born this same year, when members of Aoi Shiba, a group of people with cerebral palsy, protest publicly for the first time against sympathetic views toward the killing of disabled children by their parents. Aoi Shiba and other disability movements join in the establishment of Disabled Peoples' International in 1981. In 1986, the Rehabilitation Engineering Society of Japan (RESJA) is established. In 1992, disability movements in Japan initiate the Asian and Pacific Decade of Disabled Persons 1993 to 2002. The Japan Society for Disability Studies is established in 2003 and a unified national organization, Japan Disability Forum (JDF), is established in 2004.

1970 United Kingdom: The Chronically Sick and Disabled Persons Act (CSDPA) strengthens the provisions in the 1948 National Assistance Act (NAA). Later, the Disability Discrimination Acts of 1995 and 2005, together with the Disability Rights Commission Act of 1999, constitute the primary source of antidiscrimination legislation for disabled people.

1971 A U.S. District Court decision in *Wyatt v. Stickney* is the first important victory in the fight for deinstitutionalization.

1971 WGBH Public Television establishes the Caption Center, which provides captioned programming for deaf viewers.

1971 Gerontologist M. Powell Lawton defines *functional assessment* as any systematic attempt to objectively measure the level at which a person is functioning in a variety of domains. Over 30 years later, functional assessment, in combination with *outcomes analysis,* is considered one of the "basic sciences" of rehabilitation. In 1980, the World Health Organization proposes a series of definitions, which have a profound impact on the assessment of functional status and outcomes in rehabilitation. It is modified and revised in 1993 and 2001.

1971 The Declaration on the Rights of Mentally Retarded Persons (UN 1971), the Declaration on the Rights of Disabled Persons (UN 1975), and the World Programme of Action Concerning Disabled Persons (UN 1982) indicate the emergence of a global discourse of rights for disability.

1972 A group of people with disabilities (including Ed Roberts, John Hessler, and Hale Zukas), known as the Rolling Quads, living together in Berkeley, California, formally incorporate as the Center for Independent Living (CIL). This first CIL in the country becomes the model for Title VII of the Rehabilitation Act of 1973. In the late 1980s and early 1990s the group's advocacy efforts help pass the Americans with Disabilities Act (ADA). CILs are always controlled by disabled people. Accepted by most people as the birth of the modern independent living movement, the Berkeley concept migrates to other countries. In 1999, a global summit on independent living is held in Washington D.C. The summit brings together more than 70 countries. The Washington Declaration that comes out of the conference establishes a set of basic principles. In 1996, the Ed Roberts Campus, an international center and a service facility, is created in Berkeley, California, in memory of Edward V. Roberts, founder of the independent living concept.

1972 ◆ A young television reporter for the ABC network, Geraldo Rivera, is given a key to one of the wards at Willowbrook State School on Staten Island, New York. Established in the late 1930s as a state-of-the-art facility for the "mentally deficient," by 1972, Willowbrook becomes a warehouse for the "socially undesirable" of New York City, with a substantial minority having no disability at all. The inhumane conditions deteriorate to the extent that a visitor remarks, "In Denmark we don't let our cattle live this way." Rivera's exposé leads to a lawsuit that results in the Willowbrook Consent Decree of 1975, which creates a detailed system of monitoring and oversight of all residents living there at that time, to be met until the last of the "class clients," as they are sometimes referred to, pass on. The property has since been sold to a college.

1972 ◆ Paul Hunt's call for a consumer group to promote the views of actual and potential residents of institutional homes for the disabled in the United Kingdom results in the establishment of the Union of the Physically Impaired against Segregation (UPIAS). The group's aim is to formulate and publicize plans for alternative forms of support in the community. Hunt is regarded by many disability activists as the founder of the modern disabled people's movement.

1972 ◆ New Zealand: Three key pieces of legislation pass have long-term effects on the disabled community: the 1972 no-fault Accident Compensation Act that provides monetary compensation to victims based on level of impairment suffered; the 1975 Disabled Persons Community Welfare Act, giving assistance to disabled people, parents, and guardians, as well as voluntary associations; and the Human Rights Act of 1977, which does not include disability as a recognized grounds for discrimination. Today, disabled populations in New Zealand continue to fight to establish an identity as disabled people rather than a group needing "welfare." One task is to promote legislation that includes disability as a group against whom discrimination is outlawed.

1973 ◆ The Rehabilitation Act of 1973 lays the foundation for the disability rights movement. Its Section 504 asserts that people with disabilities have equal rights that prevent discrimination based on their disability in programs or activities that receive federal funding. This is the first major nationwide antidiscriminatory legislation designed to protect disabled Americans. These rights are further protected with the landmark Americans with Disabilities Act (ADA) of 1990.

Section 501 of the Act requires affirmative action and nondiscrimination in employment by federal agencies of the executive branch. Section 502 creates the Access Board, which grows out of the 1965 National Commission on Architectural Barriers to Rehabilitation of the Handicapped. As a result of the commission's June 1968 report, Congress enacts the Architectural Barriers Act (ABA). Section 503 requires that to receive certain government contracts, entities must demonstrate that they are taking affirmative action to employ people with disabilities. The enduring hallmark of the act, Section 504, provides that no otherwise qualified individual with a disability shall, solely by reason of his or her disability, be excluded from the participation in, denied the benefits of, or subjected to discrimination under any program or activity receiving federal funds. However, it would take five years of lobbying and protesting before the American Coalition of Citizens with Disabilities (ACCD) wins the release of regulations that allow Section 504 to be implemented.

The Act is in many ways the direct predecessor to the ADA. However, the primary focus is vocational training and rehabilitation, and over the next half-century, disability law and advocacy move from the medical (medical issues) and vocational (often a justification for welfare and benefits) models to a civil rights model, which seeks to remove the barriers that impede the full integration of people with disabilities into society.

1973 ◆ The term *mainstreaming* emerges within the educational jargon associated with the Education for All Handicapped Children Act (EHA), the early U.S. legislation subsequently reauthorized as the Individuals with Disabilities Act (IDEA) in 1990.

1973 ◆ Ronald Mace is the driving force behind the creation of the first accessible state building code in the United States (North Carolina, 1974) and in the drafting of national accessibility codes and

standards. He coins the term *universal design* to capture and promote his expanded philosophy of "design for all ages and abilities"—curb cuts being his favorite example.

1973 Washington D.C. introduces the first handicap parking stickers. The Federal-Aid Highway Act funds curb cuts.

1974 First Lady Betty Ford and investigative reporter Rose Kushner are diagnosed with breast cancer. They help break the public silence on this topic. In 1954, Terese Lasser begins Reach to Recovery, a program of volunteers who have previously undergone radical mastectomies who provide emotional support to hospitalized women who have just had the operation. Today, one in eight women is diagnosed with breast cancer during her lifetime.

1975 The Education for All Handicapped Children Act, the first separate federal legislation authorizing special education for children and youth, passes, due, in part, to the advocacy efforts of a group of parents. In 1990, it becomes known as the Individuals with Disabilities Education Act, or IDEA.

1975 The Developmentally Disabled Assistance and Bill of Rights Act, providing federal funds for programs that provide services for people with developmental disabilities, passes.

1975 The Association of Persons with Severe Handicaps (TASH) is founded. It calls for the end of aversive behavior modification and deinstitutionalization of people with disabilities.

1975 The UN General Assembly adopts the Declaration on the Rights of Disabled Persons, which states that all persons with disabilities have the same rights as other people. This document is not legally binding and can be attributed in part to a UN Ad Hoc Committee set up in 2001 to consider a Convention on the Rights of Disabled Persons that is legally binding.

1975 United Kindom: The Union of the Physically Impaired against Segregation (UPIAS) publishes a paper that redefines the term *disability,* which becomes known as the social model of disability as it radically transforms the way disabled people see themselves and their place in society.

1976 The Higher Education Act of 1965, which establishes grants for student support services aimed at fostering an institutional climate supportive of low-income and first-generation college students, is amended to include individuals with disabilities. In March 1978, the Association on Handicapped Student Service Programs in Post-Secondary Education is founded. It later becomes the Association on Higher Education and Disability (AHEAD).

1976 Sponsored by Ralph Nader's Center for the Study of Responsive Law, the Disability Rights Center is founded in Washington D.C.

1977 Protesting the federal government's delayed enactment of the rules and regulations for the implementation of the Rehabilitation Act of 1973, disabled activists on April 1 organize protests at the federal offices of the Department of Health and Human Services in various cities across the United States. In San Francisco, protesters hold the regional offices hostage for 28 days, gaining national attention and resulting in an agreement with federal officials for the rapid establishment of the rules and regulations to implement Section 504 of the Act.

1977 Max Cleland is appointed to head the U.S. Veterans Administration. He is the first severely disabled person to hold this post.

1977 S. Z. Nagi defines *disability* as an individual's performance of tasks and activities related to achievement of social roles—a distinct concept, different from *impairment*. It is further formalized with the introduction of the World Health Organization's International Classification of Impairments, Disabilities, and Handicaps in 1980 and further refined in 2001 in its International

Classification of Functioning, Disability, and Health. Nagi's model is used as the basis for the Americans with Disabilities Act, for almost all disability social policy in the United States, and for statistics at the United Nations and in Europe.

1978 ◆ The Child Abuse Prevention and Treatment and Adoption Reform Act of 1978 and the Adoption Assistance and Child Welfare Act of 1980 promote the adoption of children with special needs, including disabilities.

1978 ◆ The Atlantis Community, the second independent living center in the country after Berkeley, is established in Denver, Colorado, in 1975. On July 5–6, 1978, twenty disabled activists from the Atlantis Community block buses with their wheelchairs and bodies and bring traffic to a standstill at a busy downtown intersection. This act of civil disobedience results in the American Disabled for Accessible Public Transit, the original name for the American Disabled for Attendant Programs Today, or ADAPT.

1978 ◆ Legislation creates the National Institute on Handicapped Research. In 1986, it is renamed the U.S. National Institute on Disability and Rehabilitation Research (NIDRR). Its mission is to contribute to the independence of persons of all ages who have disabilities. It is located in the Department of Education under the Office of Special Education and Rehabilitation Services.

1978 ◆ The World Health Organization starts to promote the concept of community-based rehabilitation (CBR) as a means of helping people with disabilities in the developing world. It emerges, in part, from the WHO primary health care campaign Health for All by the Year 2000. Around the same time, in Western countries, home-visiting programs in which a trained worker regularly visits the family to advise on ways of promoting child development become one of the success stories of modern disability services. Among the best-known programs are those based on a model originating in Portage, Wisconsin, and now used in many countries.

1978 ◆ England: The Warnock report introduces the term *special needs education.* It marks a major shift in organizing educational services for children with disabilities and results in the new conceptualization of special needs education. This change is confirmed internationally by the Salamanca Statement and Framework for Action on Special Needs Education at the UNESCO's Conference held in Salamanca in 1994. This theoretical shift is marked with the change of the term *integration* to *inclusion* or *inclusive education.*

1978 ◆ USSR: The Action Group to Defend the Rights of the Disabled is established to advocate for legal rights for Soviets with disabilities.

1979 ◆ The Disability Rights Education and Defense Fund (DREDF) establishes itself as a leading cross-disability civil rights law and policy center. It is founded by people with disabilities and parents of children with disabilities. Because its philosophy is closely aligned with other civil rights struggles, in 1981, DREDF is invited to join the executive committee of the national's largest coalition of civil rights groups, the Leadership Conference on Civil Rights. In 1987, DREDF establishes the Disability Rights Clinical Legal Education Program and begins teaching disability rights law at the University of California's Boalt Hall School of Law.

1979 ◆ The National Alliance for the Mentally Ill (NAMI) is founded. NAMI is an advocacy and education organization.

1979 ◆ Germany: The first Cripples' Group is founded as a cross-disability group with emancipatory aims. In an attempt to reinterpret disability in positive terms, the cofounders choose the term *Krüppel* over handicapped or disabled.

1979 ◆ Nicaragua: The Organization of the Revolutionary Disabled is set up in the wake of the Sandinista victory.

1980 ◆ The California Governor's Committee on Employment of People with Disabilities and entertainment and media industry professionals establish the Media Access Office (MAO).

1980 ◆ About the time Congress is considering passage of the ADA (1990), marketers begin to acknowledge the economic potential of the disabled community; consequently, the appearance of disabled characters in consumer goods advertising mushroom and ability-integrated advertising becomes much more commonplace. Organizations such as MAO and NOD (National Organization on Disability) provide advertising strategies and guidance.

1980 ◆ The Rehabilitation Engineering and Assistive Technology Society of North America (RESNA), an interdisciplinary association composed of individuals interested in technology and disability, is founded.

1980 ◆ The World Health Organization's International Classification of Impairments, Disabilities, and Handicaps (ICIDH), a groundbreaking, but controversial, classification system is tentatively released for trial purposes with the goal of uniform information collection worldwide. It has a negligible impact on disability statistics or data collection; however, researchers argue that it is a vast improvement over available tools. It is renamed and vastly revised in 2001.

1980 ◆ England: Graeae Theatre Group, composed of disabled actors, directors, and other theater professionals, is founded in London by Nabil Shaban and Richard Tomlinson. It takes its name from the the Graeae of Greek mythology, three gray-haired sisters who shared one eye and one tooth. Graeae's first production is *Sideshow*.

1980 ◆ Netherlands: The Liliane Foundation starts by assisting 14 children. In 2002, it helps 31,982 children spread over 80 countries. The Foundation's efforts are directed primarily toward children with disabilities living at home. Its aim is to have direct contact with the child within the home situation and to assist the personal growth and happiness of the child, thus providing "tailor-made" assistance.

1980 ◆ Taiwan: The Physically and Mentally Disabled Citizens Protection Law is promulgated. It guarantees legal rights for the disabled and creates a significant improvement in their welfare. Although most of the disabled people in Taiwan still struggle to earn their due respect, today, public awareness of this group is emerging gradually and significantly.

1980 ◆ United Kingdom and Europe: The Black Report (*Report of the Working Group on Inequalities in Health)* is published. Among other groups it targets disabled people for better conditions that lead to better health. The report does not find favor with the Conservative government, but begins to be implemented under the Labour government in 1997. With its central theme of equity, the report plays a central role in the shaping of the World Health Organization's Common Health Strategy of the European Region.

1981 ◆ The Reagan Administration begins to amend and revoke disability benefits, a policy that continues throughout his administration and leads several disabled people who are in despair over the loss of their benefits to commit suicide.

1981 ◆ Justin Dart, recognized as the founder of the Americans with Disabilities Act (ADA, 1990), is appointed to be vice-chair of the National Council on Disability. The council drafts a national policy on equal rights for disabled people; the document becomes the foundation of the ADA.

1981 The Committee on Personal Computers and the Handicapped is established in Illinois, an indicator of the disabled community's interest in information technology (IT) accessibility, but in order to stimulate the development of suitable products, activists lobby for legislative protections, which are included in the Americans with Disabilities Act of 1990. In 2000, a suit brought by the National Federation of the Blind against AOL is suspended when AOL agrees to make its software accessible by April 2001. The World Wide Web Accessibility Initiative (WAI) launches in 1997. It raises the level of awareness of disability accessibility issues within the Internet community, especially among those who design and implement web pages.

1981 The first reported cases of AIDS in the United States appear in June. Today, the World Health Organization estimates that worldwide, approximately 40 million people are living with HIV/AIDS; 22 million men, women, and children have died; and 14,000 new infections are contracted every day. Around the world, in the year 2003, the AIDS epidemic claims an estimated 3 million lives, and almost 5 million people acquire HIV, 700,000 of them children. Currently, 6 million people infected with HIV in the developing world are estimated to need access to antiretroviral therapy to survive, but only 400,000 have this access.

1981 Disabled Peoples' International (DPI) is officially founded at a meeting in Singapore. The establishment of such international organizations around this time represents the disability movement becoming a global social movement instead of a national one. DPI is directed by persons with disabilities working in human rights advocacy. It sponsors World Assemblies, which are held every four years to develop a multiyear action plan. The most recent one is held in 2002 in Sapporo, Japan, where delegates from more than 100 countries come together. A leading slogan for DPI and other disability groups, coined in the early 1990s, is "nothing about us without us."

1981 The International Year of Disabled Persons encourages governments to sponsor programs that assimilate people with disabilities into mainstream society. Despite the positive worldwide effects it has, the UN program also creates some angry activists with disabilities who protest against the charity approach officially adopted for the event. Consequently, the activists build their own infrastructure consisting of counseling and advocacy facilities as well as job creation programs.

1981 Australia: Australia's modern disability policy takes shape after the 1981 International Year of Disabled Persons. Examples: The 1980s see a shift away from institutional care; the Commonwealth Disability Service Act provides a framework for the provision of disability services; and in 1991, the federal Disability Reform Package maximizes the employment of disabled. In 1995, a legal decision represents a watershed in telecommunications policy for people with disabilities when a commission's inquiry finds the national carrier, Telstra, guilty of discrimination against people with severe hearing or speech impairments. The success of the action results in the Telecommunications Act of 1997, which includes new provisions for the deaf community.

1981 Mexico: The Program of Rehabilitation Organized by Disabled Youth of Western Mexico begins as a rural community-based rehabilitation program.

1981 Soweto: The Self Help Association of Paraplegics begins as an economic development project.

1981 United Kingdom: Disabled people set up the British Council of Disabled Persons (BCOPD), the United Kingdom's national organization of disabled people, to promote their full equality and participation in UK society.

1981 Zimbabwe: The National Council of Disabled Persons, initially registered as a welfare organization, becomes a national disability rights group.

1982 Disability Studies originates with the formation of the Society for the Study of Chronic Illness, Impairment, and Disability. In 1986, it officially changes its name to the Society for Disability Studies (SDS). Disability Studies is a critical field of study based in human and social science.

1982 *In re Infant Doe* (commonly known as the Baby Doe case) launches the debate as to whether parents or medical authorities should choose to let a disabled infant die rather than provide the necessary medical treatment and nourishment essential to sustain life. In response to this and other cases, the U.S. Department of Health and Human Services creates a rule maintaining it unlawful for any federally funded hospital to withhold medical treatment from disabled infants. In 1984, the U.S. Congress enacts the Child Abuse Amendments, which calls for the medical treatment of newborns with disabilities unless the child would die even with medical intervention. The issue makes it to the U.S. Supreme Court in 1986 with the *Bowen v. American Hospital Association* case. The Court holds that denying treatment to disabled infants does not constitute legally protected discrimination under Section 504 of the Rehabilitation Act and that hospitals and physicians are to implement the decision of the parents. The decision results in the passage of the Child Abuse Prevention and Treatment Act Amendments of 1984. In the year 2000, a scholar argues that the Amendments, presidential commission writings, and disability advocates "have all combined to ensure that most babies who can benefit from medical interventions do receive them."

1982 Disability Awareness in Action (DAA) and other groups such as the Disabled Peoples' International (DPI) and International Disability Alliance (IDA) are the driving force behind the globalization of disability issues through the World Program of Action (1982), the United Nations Standard Rules of Equalization of Opportunities for People with Disabilities (1993), the World Summit for Social Development (1995), and the Education for All Framework for Action (2000), as well as the current campaign to secure a UN convention on the rights of disabled people.

1982 The National Council on Independent Living (NCIL) is formed in the United States. It provides an excellent example of leadership for people with disabilities by people with disabilities.

1982 Canada: The Charter of Rights and Freedoms section of the Constitution provides protection to persons with disabilities.

1982 France: Handicap International is founded in Lyon. It is active in various areas associated with all the causes of handicaps, both traumatological (land mines, road accidents) and infectious (polio, leprosy). In the 1990s it begins working on mental disability issues as a result of experience with Romanian orphanages and the war in the Balkans. In 1992, Handicap International creates its first two mine clearance programs and in 1997 it is the joint winner of the Nobel Peace Prize for its leading role in the fight against landmines.

1983 Rights-based approaches to disability rapidly gain currency in many developing countries since the UN Decade of Disabled Persons, 1983–1992. UNESCAP's Biwako Millennium Framework for Action towards an Inclusive, Barrier-Free and Rights-Based Society for People with Disabilities in Asia and the Pacific sets the priorities for the extended Decade of Disabled Persons, 2003–2012.

1983 Access and accessibility are concepts discussed throughout the World Programme of Action Concerning Disabled Persons passed by the UN General Assembly. The General Assembly in 1993 passes the Standard Rules on the Equalization of Opportunities for Persons with Disabilities.

1983 England: The first Covent Garden Day of Disabled Artists is held in London.

1983 Thailand: DPI-Thailand is established.

1984 The Access Board issues the "Minimum Guidelines and Requirements for Accessible Design," which today serves as the basis for enforceable design standards. The 1990 Americans with

Disabilities Act (ADA) expands the board's mandate to include developing the accessibility guidelines for facilities and transit vehicles. The Rehabilitation Act Amendments of 1998 give the Access Board additional responsibility for developing accessibility standards for electronic and information technology. In 2001, Section 508 of federal law establishes design standards for federal websites, making them accessible to individuals with disabilities.

1985 The U.S. Department of Health and Human Services issues the first comprehensive national minority health study, which shows racial disparity in health and concludes that the difference in mortality is not acceptable. In 1998, studies indicate that racial disparity has not improved as much as hoped; consequently, President Bill Clinton launches an initiative that sets a national goal of eliminating disparities in six key areas by the year 2010. Some of these areas include diseases and conditions considered to be disabling as well as life threatening.

1986 The Air Carrier Access Act (ACAA) passes. It requires the U.S. Department of Transportation to develop new regulations that ensure that disabled people are treated without discrimination in a way consistent with the safe carriage of all passengers. The relevant regulations, Air Carrier Access rules, are published in March 1990.

1986 The National Council on the Handicapped publishes its report *Toward Independence.* It recommends that "Congress should enact a comprehensive law requiring equal opportunity for individuals with disabilities" and suggests that the law be called "the Americans with Disabilities Act." In its 1988 follow-up report, *On the Threshold of Independence,* the council takes the somewhat unusual step of publishing its own draft of the ADA bill.

1986 The Equal Opportunities for Disabled Americans Act allows recipients of federal disability benefits to retain them even after they obtain work, thus removing a disincentive that keeps disabled people unemployed.

1986 Australia: The Disability Services Act provides that a person with disability has the right to achieve his or her individual capacity for physical, social, emotional, and intellectual development. In 1992, the Disability Discrimination Act supports nondiscrimination in education and training. It also makes it unlawful to discriminate in relation to access to premises, including public transportation.

1986 Canada: The Employment Equity Act mandates the institution of positive policies and practices to ensure that persons in designated groups, including persons with disabilities, achieve at least proportionate employment opportunities.

1986 England: The first issue of the magazine *Disability Arts in London* (DAIL) is produced in London.

1986 Southern Africa: The Southern Africa Federation of the Disabled is formed as a federation of nongovernmental organizations of disabled persons.

1988 The Technology Act (Technology-Related Assistance for Individuals with Disabilities Act of 1988 and its 1994 amendments), and, in 1998, the Assistive Technology Act (AT) provide financial assistance to states to support programs of technology-related assistance for individuals with disabilities of all ages. The1988 act defines *assistive technology* (AT). The Americans with Disabilities Act of 1990 prohibits discrimination against people with disabilities in employment, public institutions, commercial facilities, transportation, and telecommunications, which includes accessibility to all entrances, bathrooms, program areas, and parking spaces as well as interpreters for the deaf and Braille and large-print materials for the blind. The Telecommunications Act of 1996 requires the telecommunication industry to make equipment that will support transmission of information in forms accessible to people with disabilities including broadband and television program captioning. By 2000, approximately 10 percent of the U.S. population uses AT devices and/or modifications to their home, work, or school that allow them to participate in major life activities.

1988 ◆ Congress introduces a series of amendments to the Civil Rights Act of 1968, including a prohibition of housing discrimination against people with disabilities. These amendments are known as the Fair Housing Act Amendments of 1988.

1988 ◆ China: Deng Pufang, a wheelchair user and son of the late Chinese leader Deng Xiaoping, is the driving force behind a series of laws and programs initiated to improve life for the disabled. In 1984, he sets up the China Welfare Fund for Disabled Persons and, in 1988, the China Disabled Persons' Federation, which endeavors to improve public images of disabled people. Today, there are 60 million disabled people in China.

1989 ◆ The European Network on Independent Living (ENIL) is set up. It focuses on personal assistance as a key component of independent living.

1990 ◆ ADAPT, the American Disabled for Attendant Programs Today, originally called the American Disabled for Accessible Public Transit, continues to gain public awareness through tactics of civil disobedience until regulations are finally issued with the passage of the Americans with Disabilities Act (ADA).

The ADA passes, after ADAPT uses tactics of civil disobedience, in the tradition of other civil rights movements, in one of the largest disability rights protests to date (600 demonstrators), the "Wheels of Justice March," during which dozens of protesters throw themselves out of their wheelchairs and begin crawling up the 83 marble steps to the Capitol to deliver a scroll of the Declaration of Independence. The following day 150 ADAPT protesters lock wheelchairs together in the Capitol rotunda and engage in a sit-in until police carry them away one by one.

George H.W. Bush signs the ADA on July 26. It provides employment protections for qualifying persons with disability. It is the most prominent and comprehensive law prohibiting discrimination on the basis of disability in the United States, expanding the mandate of Section 504 of the Rehabilitation Act of 1973 to eliminate discrimination by prohibiting discrimination in employment, housing, public accommodations, education, and public services.

In June 2000, the National Council on Disability issues a report, *Promises to Keep: A decade of Federal Enforcement of the Americans with Disabilities Act,* which includes 104 specific recommendations for improvements to the ADA enforcement effort. On December 1, 2004, the council issues a final summary report, *Righting the ADA,* in order to address "a series of negative court decisions [that] is returning [Americans with disabilities] to 'second-class citizen' status that the Americans with Disabilities Act was supposed to remedy forever."

1990 ◆ The ADA requires public entities and businesses to provide effective communication to individuals with disabilities. Title IV of the ADA mandates that nationwide telecommunication systems be accessible to persons with speech or hearing disabilities. The Federal Communications Commission (FCC) requires relay services to be in place by July 26, 1993. The Telecommunications Act of 1996 adds provisions to the Communications Act of 1934 that requires manufactures and providers of telecommunications equipment and services to ensure accessibility to persons with disabilities. In 2000, President Bill Clinton establishes regulations governing the accessibility to people with disabilities of the electronic and information technology used within the federal government.

1990 ◆ The Individuals with Disabilities Education Act (IDEA) is enacted. It guarantees the right to free and appropriate education for children and youth with disabilities and focuses on higher expectations, mainstreaming students where possible, and an increased federal rule in ensuring equal educational opportunity for all students. IDEA requires schools to provide a free and appropriate public education to eligible children with disabilities. It also requires schools to develop an individualized education plan (IEP) for each child and placement in the least restrictive environment (LRE) for their education. IDEA is amended in 1997 and reauthorized again in 2004 as the Individuals with Disabilities Education Improvement Act.

1990 Legislation establishes the National Center for Medical Rehabilitation Research (NCMRR), whose mission is to foster development of scientific knowledge needed to enhance the health, productivity, independence, and quality of life of persons with disabilities. It has primary responsibility for the U.S. Government's medical rehabilitation research that is supported by the National Institutes of Health (NIH).

1990 The World Declaration on Education for All (EFA) is adopted in Jomtien, Thailand, by more than 1,500 persons representing the international community. Article 23 of the UN Convention on the Rights of the Child states that disabled children have the right to a "full and decent life" and that member nations provide free education and training to disabled children whenever possible in order to provide the "fullest possible social integration and individual development." UNESCO is the lead UN organization for special needs education.

1990 Korea: The disability movement celebrates the passage of the Employment Promotion Act for People with Disabilities. The government imposes control over the disabled population in the 1960s and 1970s by forwarding institutionalization under the banner of "protection," promoting sterilization, and violating the rights of disabled people in general. The 1981 International Year of Disabled Persons influences the government, and new laws, such as the Welfare Law for Mentally and Physically Handicapped, are enacted, and the human rights of disabled people becomes the dominant rhetoric of the disability movement.

1990 United Kingdom: The National Disability Arts Forum is launched at the UK-OK Conference at Beaumont College in Lancashire, UK.

1991 The Resolution on Personal Assistance Services is passed at the International Personal Assistance Symposium. Personal assistance services are the most critical services for individuals. Critical aspects of these services are that they must be available up to 24 hours a day, 7 days a week, to people of all ages, and with access to governmental payments. In the United States alone, personal assistance services affect the lives of more than 9.6 million citizens with disabilities.

1991 Australia: The federal Disability Reform Package is introduced; the Disability Discrimination Act, which covers issues of discrimination in education, is enacted in 1992; and the Commonwealth Disability Strategy, designed to provide equal access to government services for people with disabilities, is first introduced in 1994 and then revised in 2000. During the 1990s similar discrimination legislation emerges in other countries, such as New Zealand's Human Rights Act, the U.K.'s Disability Discrimination Act, Israel's Disabled Persons Act, Canada's Human Rights Act, and India's Disabled Person's Act.

1991 China: The most important laws and initiatives reside in the 1991 Law on Protection of Disabled Persons and a series of National Work Programs for Disabled Persons (1988, 1991, 1996, 2001), which integrate disability into the government's Five-Year Plans. China participates heavily in the United Nations Decade of Disabled Persons, 1983–1992, and initiates the Asia Pacific Decade of the Disabled Persons, 1993–2002. China continues to collaborate with UN projects involving the disabled and will host the 2007 International Special Olympics in Shanghai.

1991 Serbia and Montenegro: From the 1960s to the 1980s, post–World War II Yugoslavia is lauded for being a socially advanced nonaligned nation, but the contemporary wars that decimate Yugoslavia begin in 1991, and today there are more than one million disabled citizens, refugees, and casualties due to the wars. Disabled people in Serbia and Montenegro (formally named the Federal Republic of Yugoslavia—FRY) are left with shattered pieces of the spent past with little hope for the near future. Although the FRY constitution prescribes special protection of disabled persons in accordance with legal provisions and Serbia is party to numerous UN documents and acts, a disabled expert in 2004 admits that discrimination against persons with disability in Serbia and Montenegro is a

long-term problem that people without disability tend to ignore. Two of the most effective advocacy groups making in-roads today are the Association of Students with Disabilities and the Center for Independent Living in Belgrade.

1992 ◆ The UN Economic and Social Commission of Asia and the Pacific (ESCAP) proclaims a 10-year program known as the Asian and Pacific Decade of Disabled Persons 1993–2002 with goals of full participation and equality for persons with disabilities.

1993 ◆ The United Nations publishes the Standard Rules on the Equalization of Opportunities for Persons with Disabilities, which becomes the international legal standards for disability programs, laws, and policies. Although not legally enforceable this instrument sets an inclusive and antidiscriminatory standard that is used when national policies are developed. It marks a clear shift from the rehabilitation and prevention paradigm to the human rights perspective on disability.

1993 ◆ Slovak Republic: The Czech and Slovak Republics separate into two independent countries. They both join the European Union in 2004. In Slovakia, a large number of highly innovative and resourceful grassroots nongovernmental organizations emerge to address the human rights, quality-of-life, and independent living priorities of citizens with disabilities. They pursue this mission, however, with extremely limited resources and with varying degrees of support from a multiparty parliament.

1993 ◆ Sweden: The Independent Living Institute (ILI) is founded.

1994 ◆ Two networks, one for elderly persons and the other for persons with disabilities, join together to form the U.S. National Coalition on Aging and Disability. In following years, policy makers and advocates begin to see the benefits of merging some services.

1994 ◆ Germany: The disability rights movement is successful in using for its own aims the reform of the German constitution, which is made necessary by the reunification process. An amendment to the constitution forbids discrimination on the grounds of disability. Other such laws as the Rehabilitation of Participation Law (2001) and the Federal Equal Rights Law (2002) are formulated with the active contribution of disability rights activists, and in 2003, the official German program of the European Year of People with Disabilities is organized by a prominent activist.

1994 ◆ Sweden: The Swedish Disability Act (LSS) comes into force. It expands the 1985 Special Services Act. The LSS is also more ambitious than its predecessor, calling for “good living conditions” rather than just an “acceptable standard of living.”

1995 ◆ The National Council on Disability, a federal agency, makes recommendations to the president and Congress on disability issues. Among other issues, it calls for the end to the use of aversives (techniques of behavior control such as restraints, isolation, and electric shocks) because they are abusive, dehumanizing, and psychologically and physically dangerous. Other organizations follow, such as the Autism National Committee in 1999, TASH in 2004, and the International Association for the Right to Effective Treatment in 2003.

1995 ◆ The Commission for Case Management Certification (CCMC) incorporates. Case management is a process of care planning and coordination of the services and resources used by people with disabilities and their families.

1995 ◆ Europe: The Association for the Advancement of Assistive Technology in Europe (AAATE) is founded as an interdisciplinary association devoted to increasing awareness, promoting research and development, and facilitating the exchange of information. AAATE is composed of more than 250 members from 19 countries. It interacts with sister organizations in North America, Japan, and Australia to advance assistive technology worldwide. The Tokushima Agreement, signed in 2000 by AAATE, the Rehabilitation Engineering and Assistive Technology Society of North America

(RESNA), the Rehabilitation Engineering Society of Japan (RESJA), and the Australian Rehabilitation and Assistive Technology Association (ARATA), promotes exchange of information and collaboration.

1995 United Kingdom: The campaign for antidiscrimination legislation begins in earnest with the emergence of the disability movement in the late 1970s. The Disability Discrimination Act of 1995 (DDA) together with the Disability Rights Commission Act of 1999 constitute the primary source of antidiscrimination legislation for disabled people in the United Kingdom. The Disability Discrimination Act 2005 extends the protection.

1996 There are 1.4 million fewer disabled older persons in the United States than would have been expected if the health status of older people had not improved since the early 1980s.

1996 Advocates for mental health parity such as the National Alliance for the Mentally Ill (NAMI; 1979) believe that mental illnesses are real illnesses and that health insurance and health plan coverage for treatment should be equal with coverage of treatment for all other illnesses. Due in part to advocacy, the Mental Health Parity Act becomes law in 1996. In 1999, mental illness ranks first in causing disabilities among many industrialized nations, including the United States, which experiences a loss of productivity in this year of $63 billion. In the United States, 5 to 7 percent of adults suffer from serious mental disorders and 5 to 9 percent of children suffer from serious emotional disturbances that severely disrupt their social, academic, and emotional functioning.

1996 Costa Rica: Approval of a law called Equal Opportunities for People with Disabilities is a turning point for the population with disabilities, which is among the most excluded sectors of society. The law is inspired in part by the United Nations Standard Rules on the Equalization of Opportunities for Disabled People (1993). Disability experience in Costa Rica is definitely transformed as a result of the mandates of this generic law, as people with disabilities and their families start to use this legal instrument as a strategy to empower themselves.

1996 Europe: Created in 1996, the European Disability Forum (EDF) is today the largest independent, trans-European organization that exists to represent disabled people in dialogue with the European Union (EU) and other European authorities. Its mission is to promote equal opportunities for disabled people and to ensure disabled citizens full access to fundamental and human rights through its active involvement in policy development and implementation in the EU. The EDF has national councils in 17 European countries and has 127 member organizations. The European Year of People with Disabilities 2003 is one of the EDF's most important campaigns.

1996 India: The Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act, 1995, becomes law. It is the first legislation for equal opportunities for disabled people. Prior to this, disabled persons receive services but not legal protection. Improvements in conditions begin in 1981 with the International Year of Disabled Persons. India is a signatory to the UN resolution of 1976 establishing it and is thereby committed to improving the lot of the disabled. The Lunacy Act of 1912 is repealed and the National Mental Health Act is passed in 1987. Nonetheless, with approximately 70 million disabled people residing in India (in a population of over a billion), the government does not include the domain of disability in the 2001 census, which reflects the attitudinal barriers in acknowledging the disabled identity.

1997 Government expenditures on behalf of persons with disabilities may total as much as $217.3 billion (taking into account the costs that would be expected among persons with disabilities in the absence of the disability), the equivalent of 2.6 percent of the gross domestic product in the United States for 1997.

1997 The landmark 1997 UNESCO Universal Declaration on the Human Genome and Human Rights frames the actual application of the new scientific developments raised by genetics. As a policy

statement, it provides the first signs that genetics will be applied in ways that maintain human rights. In 2003, the Council of Europe and the council's Steering Committee in Bioethics issue policy statements in a working document titled Application of Genetics for Health Purposes. In the case of gene therapy, in 1994, the Group of Advisors on the Ethical Implications of Biotechnology of the European Commission voices concern regarding equity, maintaining that all genetic services that are available for the entire population should be equally available for persons of disability. Today, UNESCO's Human Genome Organization's Ethics Committee, the World Health Organization, the Council of Europe, and consumer organizations such as Inclusion International, Rehabilitation International, and Disabled Peoples' International play major roles in translating genetic innovations into health service and public health fields, helping develop policies that focus on the general recognition, respect, and protection of the rights to which all people, whether disabled or nondisabled, are entitled. Concerns related to the possible undermining of human rights are expressed in 2003 when Disabled People's International demands a prohibition on compulsory genetic testing.

1997 ◆ Colombia: The General Act for People with Disabilities, also known as the Disability Act: Law for Opportunity, passes. The 2003–2006 National Plan of Attention to Persons with Disabilities estimates that 18 percent of the general population has some type of disability. Despite the existence of at least 37 disability-related legal policies (2001), the government provides limited spending on programs that protect the rights of people with disabilities, and the lack of enforcement of rights remains a major concern. Today's awareness efforts include marathons with the participation of the general population to raise money for educational programs for children with special needs, Special Olympics, new organizations such as the Colombian Association for the Development of People with Disabilities, and media awareness campaigns.

1998 ◆ President Bill Clinton issues an executive order ensuring that the federal government assumes the role of a model employer of adults with disabilities.

1998 ◆ President Clinton signs into law the Rehabilitation Act of 1973 Amendments. Section 508 requires that electronic and information technology (EIT), such as federal websites, telecommunications, software, and information kiosks, must be usable by persons with disabilities.

1998 ◆ Ireland: The Irish Employment Equality Act entitles all individuals, including disabled persons, equal treatment in training and employment opportunities. The Education Act of 1998 requires schools to provide education to students that is appropriate to their abilities and needs. The Education for Persons with Disabilities Bill passes in 2003. A Disability Bill published in 2001 fails to underpin a rights-based approach and is withdrawn amid a storm of protest in 2002; a redrafting of a new Disability Bill is suffering from continuing delays. Traditionally, Irish voluntary organizations play a reactionary role in the development of services for people with disabilities and a key role as pressure groups trying to keep disability issues on the political agenda.

1999 ◆ The National Center on Physical Activity and Disability (NCPAD) is established as an information and resource center that offers people with disabilities, caregivers, and professionals the latest information on fitness, recreation, and sports programs for people with disabilities.

1999 ◆ Established by a panel of experts brought together to evaluate the UN Standard Rules on the Equalization of Opportunities for Persons with Disability, the International Disability Alliance (IDA) encourages cross-disability collaboration and supports the participation of international disability organizations in the elaboration of a proposed UN convention on disability.

1999 ◆ England: The first disability film festival, Lifting the Lid, is held at the Lux Cinema in London.

2000 The National Telability Media Center collects documentation of 3,000+ newsletters, 200 magazines, 50 newspapers, 40 radio programs, and 40 television programs dedicated to disability in the United States alone. *The Ragged Edge, Mainstream* (Internet-based), and *Mouth* are examples of disability rights-focused publications.

2000 *Healthy People 2000,* the second edition of the Surgeon General's report on health promotion and disease prevention (the first edition published in 1979), includes some reference to the health and well-being of people with disabilities, but few data are available. In the mid-1990s, the U.S. Department of Health and Human Services begins a dialogue with the Centers for Disease Control and Prevention to include people with disabilities in the third edition, *Healthy People 2010.* The resulting report includes more than 100 objectives that include "people with disabilities" as a subpopulation for data gathering.

2000 The World Bank, increasingly concerned with how to include disabled persons in the economies and societies of developing nations, establishes an online clearinghouse to make documents concerning the disabled readily available to member nations and the general public and holds its first course on disability issues in 2004 in Guatemala.

2000 Africa: The African Decade of Persons with Disabilities, 2000–2009, is adopted by the Declaration of the Organization of African Unity. The African Network of Women with Disabilities (2001) and the community-based rehabilitation organization CBR Africa Network (CAN) are examples of the many activities that result from the African Decade.

2000 Brazil is one of the few countries to include an entire section on disability in its 2000 census. Results show that 14.5 percent of the population, roughly 24 million people, report having some form of disability, the poorest region, the northeast, reporting the highest percentage and the richest, in the south, the lowest. People with disabilities in the first half of the twentieth century have no voice or representation. In 1932, the first Pestalozzi Society, a community-based school for children with intellectual disabilities, is founded. By the end of the twentieth century, there are 146 Pestalozzi Societies and more than 1,700 chapters of the Association of Parents and Friends of the Exceptional. The first center for independent living is established in 1988 (CVI-RIO). In 1992 and 1995, CVI-RIO organizes two international conferences on disability issues called DefRio, out of which comes "Goals of the ILM," a document that delineates the basis for the independent living movement in Brazil; however, financial support is not provided by the government, creating a struggle for sustainability. Brazil has progressive policies toward disability. The constitution includes sections on the rights of people with disabilities, and laws have been passed with regard to accessibility, education, and employment.

2000 Europe: A European Community directive requires all member states to have introduced antidiscrimination laws in the fields of employment and training by the end of 2006. It seeks to establish a general framework for equal treatment in employment and occupation and to render unlawful discrimination based on, among other categories, disability. The European Union Charter of Fundamental Rights sets out in a single text, for the first time in the EU's history, the whole range of civil, political, economic, and social rights of European citizens. Disability is included in the general nondiscrimination clause (Article 21), but Article 26 specifically states that the Union recognizes and respects the rights of persons with disabilities to benefit from measures designed to ensure their independence, social and occupational integration, and participation in the life of the community.

2000 The Human Genome Project (HGP), an international effort to specify the 3 billion pairs of genes that make up the DNA sequence of the entire human genome, produces its first draft in June 2000. Formally begun in October 1990, it is completed in 2003.

2001 President Clinton declares in Executive Order No. 13217 the commitment of the United States to community-based alternatives for individuals with disabilities. This ensures that the *Olmstead v. L.C.* decision (1999), which mandates the right for persons with disability to live in the least-restrictive setting with reasonable accommodations, is implemented in a timely manner. The executive order directs federal agencies to work together to tear down the barriers to community living.

2001 In the United States, census data indicate that only 48 percent of citizens 25 to 64 years old with severe disabilities have health insurance compared with 80 percent of individuals with nonservere disabilities and 82 percent of nondisabled Americans. Women with disabilities in general are more likely to live in poverty than men. Minorities with disabilities are more likely to live in poverty than nonminorities with disabilities. In 2003, in the United States, about 28 percent of children with disabilities live in poor families compared with 16 percent of all children.

2001 A UN Ad Hoc Committee begins discussions for a legally binding convention under the draft title Comprehensive and Integral Convention on the Protection and Promotion of the Rights and Dignity of Persons with Disabilities. Its fifth session is held in early 2005.

2001 A new World Health Organization classification of people with disabilities, the International Classification of Functioning, Disability, and Health (ICF), replaces the old International Classification of Impairments, Disabilities, and Handicaps (ICIDH). The ICF definition shifts the focus from disability as an innate deficit ("medical model") to disability as constructed through the interaction between the individual and the environment ("social model"). This shift encourages a focus on the kinds and levels of interventions appropriate to the needs of individuals.

2001 UNESCO launches pilot education projects for disabled children in Cameroon, the Dominican Republic, Egypt, Ghana, India, Madagascar, Mauritius, Nicaragua, Paraguay, South Africa, Vietnam, and Yemen. The global initiative Education for All 2000 has as its primary millennium development goal universal education by the year 2015.

2002 The U.S. Supreme Court rules that executing persons with mental retardation is unconstitutional.

2002 Disabled Peoples' International's 2002 Sapporo Platform, developed by 3,000 delegates from more than 90 countries, urges members to take every opportunity to seek publicity and awareness in order to change negative images of disabled people.

2002 Canada: The Canadian International Development Bank announces the approval of the Canada-Russia Disability Program, a four-year $4 million project, focusing on education, disability studies, social work practice, social policy, and information dissemination.

2003 A national survey that updates the Disability Supplement to the 10-year-old National Health Interview Survey highlights barriers to care among the uninsured. The uninsured are four times as likely to postpone care and three times as likely to go without needed supplies.

2003 The National Association of Social Workers (NASW) issues a policy statement that discusses their core values with respect to working with people with disabilities, including self-determination, social justice, and dignity and worth of the person. The statement emphasizes that social workers are responsible to take action with people who have disabilities in advocating for their rights to fully participate in society.

2003 The Disability Awareness in Action (DAA) database contains a total of 1,910 reports of known abuse affecting nearly 2.5 million disabled people. In the area of education alone, it documents

118 cases affecting 768,205 people in 67 countries. Responding to this documentation and other reports, the United Nations Commission on Human Rights creates the Global Rights campaign to address human rights abuses. Disability rights organizations use this information to insist on a UN convention on the rights of disabled people that would be legally binding on nation-states.

2003 ◆ The International Association for the Study of Pain has more than 6,700 members, representing more than 100 countries and 60 disciplinary fields. Chronic pain is one of the leading causes of recurrent and permanent disability in the developed world today, yet less than 1 percent of the U.S. National Institutes of Health's budget supports research into mechanisms and management of pain. The U.S. Congress declares 2000–2010 the Decade of Pain Control and Research.

2004 ◆ The *Journal of Gene Medicine* (January) reports that 636 gene therapy clinical trials are completed or ongoing, involving 3,496 patients. The first gene therapy clinical trials begin in the early 1990s.

Today ◆ Seventy to eighty percent—approximately 400 million—of the world's disabled people (600 million, or 10 percent of the world's population) live in the developing world, and of the world's poorest of the poor, 20 to 25 percent are disabled. In most countries, 1 out of 10 persons has a disability. Many international efforts are under way to address poverty and disability, such as those of the Action on Disability Development and the Chronic Poverty Research Centre.

Today ◆ E-health is the use of emerging interactive telecommunications technologies such as the Internet, interactive TV, kiosks, personal digital assistants, CD-ROMs, and DVD-ROMs to facilitate health improvement and health care services, including those with disabilities. E-health relies on environments that use a variety of technologies that can compensate for the lack of sensory ability. Telerehabilitation is an example of services delivered information technology and telecommunication networks.

Today ◆ Celebrating difference is the mantra and visible manifestation of disability culture in all regions of the world.

SEARCHING FOR AND EVALUATING WEBSITES

Anne Armstrong

The Internet, or Web, provides a vast number of channels through which researchers can find information on virtually any subject. The expansiveness of the Web can be daunting to new researchers. On the other hand, researchers often assume that they have mastered the Web in its entirety when indeed they have merely scratched the surface in terms of the numbers of resources they have consulted and searches they have performed.

Because the field of disability studies is continually evolving and inherently multidisciplinary, Web searchers can draw on previously conducted research from disciplines within the humanities, social sciences, and health sciences. This guide aims to expose beginning researchers to a mixture of general and subject-specialized Web-based search tools, as well as strategies for performing sophisticated Web searches and criteria for evaluating websites. In addition to its broad subject coverage, the field of disability studies differs from most fields in that many researchers may themselves have disabilities affecting their ability to perform research on the Web. For this reason, this description concludes with an overview of accessibility issues on the Web and suggestions for further reading.

OVERVIEW OF WEB-BASED RESEARCH TOOLS

When approaching Web searching, researchers should be aware of the multitude of search tools available to them, in addition to the varying purposes of these tools. Many users approach Web searching with the assumption that "everything is in Google," but this is a limiting misconception. No single search engine contains everything on the Web. Furthermore, all search engines function differently and rank results differently. Therefore, sampling various search tools increases the comprehensiveness of results on any topic. This discussion outlines multiple types of search tools available on the Web and offers potential starting points for Internet research on issues related to disability studies, whether from a health sciences, social sciences, or humanities perspective.

The Web-based search tools outlined in this chapter include general search engines, subject-specialized search engines, directories, indexes, catalogs, and Listservs. It is important to note that different types of search tools cover different parts of the Web. The Web is composed of layers. The top layer is detectible by general search engines, while a deeper layer termed "the invisible Web" can be penetrated only by specialized search engines, indexes, and catalogs. Readers should be aware that because the Web is in a constant state of flux, currently available resources may become obsolete over time, and newer, more sophisticated search tools will undoubtedly evolve.

General Search Engines

Most people who have searched the Web are familiar with sites such as Google, HotBot, or Lycos, which allow them to enter a string of keywords into a search box to retrieve a list of relevant websites (see Table 1). These sites, referred to as search engines, search the Web by means of a program called a *spider* (also

Table 1 Selected General Search Engines

Name	*URL*
AltaVista	www.altavista.com
Excite	www.excite.com
GO	www.go.com
Google	www.google.com
HotBot	www.hotbot.com
Lycos	www.lycos.com
Yahoo!	www.yahoo.com

called a *robot* or *crawler*). Since search engines tend to index millions of websites, they are most useful for entering specific search terms rather than broad concepts such as disability studies.

While Web searchers tend to pick a favorite search engine and return to it repeatedly, it is important to note that different search engines produce varying results, and that a truly comprehensive Web searcher should compare the results of multiple search engines. The variation between search engines can be attributed to differences between the spiders fueling the search engines as well as differences in the level of indexing and the order in which results are ranked. While some search engines index the full text of documents, others may index only the first page, or merely the *meta-tags*, which are lines of code containing keywords. Web searchers should be aware that developers of websites may intentionally increase their usage of certain words or meta-tags to increase the prominence of their website among search results. This practice has been referred to as *spamdexing* and is most prevalent among the developers of commercial websites advertising products and services. Due to the constant fluctuation of the Web, no search engine is entirely up-to-date; results produced by identical searches can vary greatly from one day to the next, even when one is using the same search engine.

Subject-Specialized Search Engines

Subject-specialized search engines (also referred to as subject portals) developed by educational institutions, associations, government agencies, and corporate entities narrow the broad scope of the Web, providing a focused channel by which researchers can search for information when they have determined the discipline from which their topic stems. Examples of such search engines are listed in Table 2. While subject-specialized search engines index considerably fewer websites and documents than general search engines, the information contained within them has been preselected, ideally by experts within a given field. Many subject-specialized search engines expose searchers to parts of the "invisible Web" not indexed by general search engines. Subject-specialized search engines can ease the research process by whittling down the Web to a more manageable size. However, researchers who use them should take the time to view the criteria for selection of

Directories

Directories are hierarchically arranged subject guides composed of websites chosen by or recommended to editors of the directory (Table 4). Usually, directories follow a template in which major subject categories such as health, sciences, social sciences, or humanities are posted on the top-level page. Each of these links leads to lists of narrower subcategories. The links on the second level lead to narrower subcategories, and so on. A sample hierarchy from the directory created by Google (available at http://directory.google.com) lists the following subject breakdown: Society → Disabled → Disability studies.

Directories provide Web searchers with the ability to browse recommended resources in various subject areas without having to enter specific search terms. Other useful attributes of directories are that they often contain summaries and evaluations of websites.

a. These sites contain both directories and general search engines.

Article Indexes

Article indexes allow researchers to search by topic for published articles in magazines and scholarly journals. Researchers could certainly locate journal and magazine articles using a freely available search engine such as Google, but they would merely be skimming the surface of what has been published. While the Web provides access to *more* content, it does not provide comprehensive access to research published in journal articles. Article indexes are for the expressed purpose of finding journal articles. With a few exceptions (such as PubMed, an article index of health sciences journals developed and maintained by the National Library of Medicine), article indexes are not freely available on the Web. Libraries purchase subscriptions to multiple article indexes covering a wide spectrum of disciplines. The indexes available through a given library are often dictated by the curriculum of the college or university that the library serves. Thus, large research institutions offer a greater number of specialized article indexes than smaller institutions and public libraries. Due to licensing agreements between article index providers and libraries, off-site access to indexes is usually limited to faculty and students of a college or university. However, there are many libraries that allow members of the public to use their article indexes from within the library. A local public library would be a good starting place for those not connected with academic or commercial organizations.

Since article indexes are proprietary products developed by companies for sale to libraries, they tend to offer specialized search features that are not always available on freely available search engines. These features include subject headings, thesauri, abstracts (summaries of articles), and frequently the full text of articles. Researchers should familiarize themselves with online tutorials, "help" screens, and "about" pages to increase the effectiveness of their searching.

Freely available article indexes relevant to disability studies include the following:

- PubMed: A product of the National Library of Medicine, which includes more than 14 million citations for biomedical articles dating back to the 1950s. URL: http://www.ncbi.nlm.nih.gov/entrez

- CIRRIE: Center for International Rehabilitation Research Information and Exchange, a database containing more than 24,000 citations of international research published from 1990 to the present. URL: http://cirrie.buffalo.edu

Catalogs

While researchers can search indexes to find articles on specific topics, they can search online catalogs to find books. Some catalogs list the books available at individual libraries, while others contain the holdings of multiple libraries and institutions. The individual catalogs of public libraries and universities are usually freely available on the Web. The most comprehensive catalog is called WorldCat, developed by an organization called OCLC (Online Computer Library Center). WorldCat lists books available at public and academic libraries throughout the world. Like most article indexes, WorldCat is not freely available on the Web and must be accessed through a library.

Listservs

Listservs are mailing lists on the Internet that facilitate online discussions on various subjects. They allow researchers within a given field to communicate about scholarly issues via email. People customarily sign up for Listservs by sending an e-mail to the Listserv address stating that they wish to subscribe. Several Listservs related to disability studies are listed in Table 5. In addition, Web searchers can perform a search on a database called tile.net to search for Listservs by topic.

SEARCH STRATEGIES

Since search capabilities vary from site to site, Web searchers should use online "help" screens and tutorials to learn search tips and strategies for improving their search results. Some search techniques common to several Web-based search tools are summarized below.

Quotation Marks

When entering a search, users should enter phrases in quotation marks to stipulate that they would like the results to contain a specific word combination and order. For instance, multiword concepts such as "disability studies," "adaptive technology," and "section 508" should be entered within quotation marks. Proper names can also be entered within quotation marks.

Table 5 Disability Studies Listservs

Women's International Linkage on Disability (D-WILD)	http://groups.yahoo.com/group/d-wild

Truncation

Truncation symbols allow Web searchers to simultaneously search for multiple endings of a given word. For instance, assuming that the asterisk is the designated truncation symbol in a search engine, entering the word "impair*" would produce results including all forms of the word after the root, including "impair," "impaired," "impairment" and "impairments." In addition to adding truncation symbols to the end of words, users may also insert internal truncation symbols if there are potential variations for the spelling of the middle of a word. For instance, entering the word "colo*r" would simultaneously search for the words "color" and "colour." "Help" screens or "search tips" usually list the designated truncation symbol for a given database.

Boolean Logic

Developed by the English mathematician George Boole, Boolean logic is a mathematical framework that Web searchers can apply to broaden or refine their searches. There are three words, or *operators*, that Web searchers can use to combine their keywords to perform more complex searches: AND, OR, and NOT. The three Boolean operators are summarized below, along with potential applications. It is important to read the online "help" section of a database before performing a Boolean search, as Boolean searching does not work in all databases.

Using the Boolean Operator "AND"

Combining words with "AND" narrows a search, as the database retrieves only items that contain *all* the words entered. The second search example below will produce fewer results than the first, since there are three keywords that must appear within the content of each result.

"disability studies" AND theory
"disability studies" AND theory AND history

Using the Boolean Operator "OR"

Entering the term "OR" between keywords stipulates that any, but not all, of the words entered must appear within the search results. Using "OR" is a way of searching for synonyms or related terms when there are multiple words for the same concept. The example below shows how you could broaden your search if you wanted to search for multiple adaptive technology applications in a search engine. The second search example will potentially produce more results than the first, since there is an additional keyword that the results could include.

JAWS OR "Ruby OpenBook"
JAWS OR "Ruby OpenBook" or "window eyes"

Using the Boolean Operator "NOT"

Entering the Boolean operator "NOT" after a word stipulates that the word should not appear within the results. Using "NOT" in a search can be particularly useful if a word is frequently used in multiple contexts and you wish to eliminate results dealing with a particular topic. In the example below, the second search will ideally eliminate items relating to the state of New Mexico, given that the researcher is looking for information on legislation related to disabilities in the country of Mexico. The use of NOT can be too limiting. The second search would eliminate results that discussed both Mexico and New Mexico.

Disabilities AND legislation AND Mexico
Disabilities AND legislation AND Mexico NOT "new mexico"

Nesting

Nesting allows Web searchers to simultaneously search for multiple search terms relating to the same topic. The grouping of synonymous terms within parenthesis is referred to as nesting, as multiple terms relating to the same idea are clustered together as a single concept. When using nesting, the words within the parenthesis are connected by the Boolean operator "OR."

To find information about software for people who are visually impaired, search results are increased by using nesting to group multiple words for each facet of the topic:

(software or "adaptive technology") AND ("visually impaired" or blind)

Plus and Minus Signs

Most general search engines allow users to enter plus or minus signs before a particular word. Entering a plus sign before a word (e.g., +ADA) stipulates that the word must appear within the search results. A minus sign before a word (e.g.,–mobility) stipulates that the word should not appear within the results. Since some search engines also use plus and minus signs as substitutes for Boolean operators, it is important to view online "help" or "search tips."

Search Limits

Most search engines allow users to limit their results by date, language, or document type. Limiting capabilities vary from site to site and are customarily outlined in online "help" screens. In general, article indexes have more sophisticated limiting capabilities than search engines that are freely available on the Web.

EVALUATING WEBSITES

A researcher weighing the quality of a journal article faces a lesser challenge than a researcher considering a website as a potential resource. The publishing industry applies labels to periodicals of varying type: Scholarly journals, popular magazines, trade publications, and newspapers comprise the major categories. Articles submitted to scholarly journals undergo a peer review process by experts in a given field. If in doubt as to the suitability of journal for scholarly purposes, a researcher can consult a directory of periodicals such as *Ulrich's Periodicals Directory,* which indicates whether or not a journal is peer reviewed.

The fact that the Web has no comparable methods of control complicates the task of determining whether a website is appropriate for research purposes. While websites produced by certain types of agencies and organizations certainly undergo a form of *internal*

review, the Web is a free forum; people can post anything they want, and no one has the right to force to take it down if it fails to meet certain standards of quality or accuracy. To complicate the matter, inaccurate or inexpert information can hide like a wolf in the sheep's clothing of sophisticated graphics, layout, and design. The Web has no peer review process to ensure quality. While none of the evaluation criteria outlined below can provide the final word as to the suitability of a website for scholarly use, a researcher who searches the Web with multiple evaluation criteria in mind expedites the process of finding quality information.

Authorship

When determining the credibility of a website, researchers should use multiple techniques to determine the credentials of the author as well as the character of the organization hosting, or sponsoring, the site. If individuals are listed as authors, researchers should take steps to determine their credentials and reputation in the field by performing a search in a general search engine to find biographical information or other documents written about the author. This will also produce references to the author on the sites of other authors within a field. Researchers can also consult a number of biographical sources available at libraries, such as *Who's Who in the America* or sources tailored to particular fields of study, such as *Who's Who in Science and Engineering.*

Website addresses, or URLs (Uniform Resource Locators) can also provide hints as to author affiliations and potential bias. Personal websites are often hosted on commercial ISP (Internet Service Provider) Web servers such as aol.com, or geocites.com. URLs of personal websites often contain first or last names, as well as percent (%) or tilde (~) signs. While personal websites may contain authoritative information, researchers should question why the same content does not appear on a site sponsored by an educational or research organization.. Was the site created as a pastime or to serve as a forum for airing personal views? Or does the site reflect serious scholarship backed up by other credentials and research published in scholarly publications?

Every website URL ends with a *domain name*, usually a series of three letters preceded by a period. The domain name denotes the type of institution that hosts the website and can often provide clues as to the purpose or potential bias of a site. Common domain names include the following:

Educational sites: .edu
Government sites: .gov, .mil, or country codes (e.g., .uk = United Kingdom, .au = Australia, .do = Dominican Republic)
Nonprofit organization sites: .org
Commercial sites: .com

Most URLs contain multiple levels separated by slashes (e.g., http://www.nod.org/stats/). To learn more about the sponsor or publisher of a particular site, you can remove levels of the URL one by one to see where the site is hosted and determine the character of the sponsoring entity. For instance, if a site is hosted on the site of an association, viewing the mission statement on the home page of the association can provide clues as to the bias or purpose of the content. When judging the credentials of the publishing entity, researchers should look for contact information and institutional logos. In general, sites devoid of identifying information or contact numbers and addresses should raise suspicion.

Audience

When evaluating a site, researchers should determine whether the content succeeds in addressing the stated audience through tone and presentation. Sites for adults should not have a childlike appearance or tone. Likewise, sites may be deliberately overrun by technical language or jargon to confuse or mislead a particular audience. High-quality sites clearly define their intended purpose.

Currency

Medical research findings or population statistics may become obsolete at a faster rate than research in the humanities. Web researchers should check sites for copyright dates and the date of the last update. Broken links are a sign of neglect, as they may indicate that URLs have changed or become obsolete since the last update of the site. To verify the currency of information on a site, researchers should check for several sites covering the same subject matter.

Accuracy

Determining accuracy involves further research to ensure that the claims or findings on a site are substantiated by other sources. If a site presents original research, the methods of the research and instruments used should be clearly explained, as well as potential limitations of the research. If authors make claims or conclusions, they should cite their

sources, and these sources should be tracked down to ensure their existence and authenticity. Websites should contain a list of works cited or footnotes on par with any print book or article. Since websites sometimes include fabricated resources, and erroneous or incomplete citations, sources should be verified using library tools such as indexes and catalogs. Lists of works cited with multiple errors reflect irresponsible research. If a website contains links, the links should be checked. Researchers should be wary of websites populated by broken links or links to defunct websites.

Quality

In general, sites that are poorly organized or sloppy should be approached with caution. Shoddy design may point to further weaknesses. Poor grammar and spelling errors are also red flags.

Bias

While bias is not always a negative attribute, Web searchers should be cognizant of bias as the search for information. The bias of a website can be partially discerned by the domain name (as discussed above under "Authorship"). Commercial websites may be motivated by the goal to market a product or service. Nonprofit organizations may promote a political agenda. While bias may be clearly stated in mission statements and "about" pages, many websites deliberately shroud their bias. Thorough research involves consulting additional sources to determine the history and activities of a particular organization. If a site contains links to other sites, those links should be checked to discern the character and activities of the other organizations listed. If a site is sponsored by other organizations, researchers should consider the relationship between the sponsors and the creators of the site.

Special Considerations for Evaluating Health Information on the Web

The American Medical Association (AMA) has published "Guidelines for Medical and Health Information Sites on the Internet" outlining evaluation criteria for websites publishing health information, whether for consumers or health professionals. While these guidelines are technically enforced only on sites sponsored by the AMA or affiliated organizations, they could be applied to all sites containing health information. Many of these guidelines mirror the previously outlined criteria for evaluating all websites, but there are certain factors that are heavily emphasized in the AMA guidelines, including the importance of peer review by experts in the field, the importance of clearly identifying sources of funding, an explanation of the relationship between individual researchers and the institutions sponsoring the research, the importance of clearly stating the purpose and intended audience of a site, and the need to address the stated audience in a consistent and effective tone. Seven criteria for assessing the quality of health information on the Internet have been developed by the Health Summit Working Group (Health Information Technology Institute 1999).

Information on health-related websites should be verified by checking sources such as journal articles, books, and other websites. These measures are needed as health information on the Web frequently includes unsubstantiated claims.

OVERVIEW OF ACCESSIBILITY ISSUES ON THE WEB

Disability studies research is unique in that many scholars in the field have disabilities that may impact their ability to effectively search the Web. While in many ways the Web "evens the playing field" by making a vast number of resources available electronically, inaccessible design frequently places barriers on Web searchers with disabilities.

Principles of Web accessibility have been developed by the World Wide Web Consortium's (W3C) Web Accessibility Initiative (WAI). The WAI establishes guidelines for creating accessible websites, browsers, and authoring tools to increase the ease of use of the Web for users with disabilities. Multiple scenarios outlining potential challenges to Web searchers with disabilities are summarized in a W3C working draft titled "How People with Disabilities Use the Web" (2001). Among other scenarios, the document emphasizes that many Web searchers with cognitive or visual disabilities use OCR (optical character recognition) software, which reads Web page text and transmits the information to a speech synthesizer and/or refreshable Braille display. Many users with visual disabilities use text-based Internet browsers instead of standard graphical browsers. The successful use of these tools requires that images on websites be accompanied by descriptive text and *ALT tags*. ALT tags are textual labels that appear on the computer screen when a mouse moves over an image. Since visually impaired

Web searchers often enlarge Web-based text using screen magnification programs, Web designers must create pages with nonfixed font sizes that can be altered as necessary. These are only a few of the issues facing Web searchers with disabilities. Other population groups with disabilities discussed in the guidelines include individuals with cognitive disabilities, hearing impairment, and mobility-related disabilities. Readers should consult the WAI website for the complete guidelines (http://www.w3.org/WAI/).

To support the goals of WAI, an online tool called Bobby™ helps website developers test the accessibility of their sites and adhere to accessibility guidelines. By entering a URL into the Bobby website, a Web developer can generate a report outlining which features of the site need to be adjusted to make it "Bobby compliant" and adhere to both W3C accessibility guidelines and guidelines established by the U.S. government's Section 508, a 1998 amendment to the Rehabilitation Act requiring that all federal agencies make their electronic and information technology accessible to people with disabilities. Complete information about these guidelines can be found on the Section 508 website (www.section508.gov).

CONCLUSION

While "one-stop shopping" in Google may be tempting, there is no single search engine leading to everything on the Web. Comprehensive and effective research in disability studies involves consulting multiple search tools, including but not limited to general search engines, subject-specialized search engines, directories, and indexes. In addition to using multiple search tools, Web searchers should experiment with multiple search strategies to maximize the effectiveness of their searching. As there are no standards of quality on the Web, researchers should apply multiple evaluation criteria to every website, verifying that research findings posted on sites are supported by other sources. Web accessibility is a crucial component to disability studies, as the Web has the potential to deliver equal content to all users but frequently presents barriers to people with disabilities by failing to adhere to standards of accessible design. Researchers can develop an awareness of accessibility issues on the Web by familiarizing themselves with the standards outlined by W3C's Web Accessibility Initiative and Section 508.

READER’S GUIDE

The Reader’s Guide is provided to help readers locate entries and primary sources by topical category. It classifies the A–Z entries (Volumes I–IV) and primary source documents (Volume V) into twenty-five categories: Accessibility, Arts, Biographies, Children and Infants, Deafness and Deaf Culture, Disability Studies, Economics and Employment, Education, Ethical Issues, Experience of Disability, Health and Medicine, Health Care, History of Disability, Information Technology, Language of Disability, Law and Social Policy, Models, Organizations, Politics, Rehabilitation, Rehabilitative Engineering and Assistive Technology, Religion, Science, Sports, and Therapies. Some entries and documents may appear in more than one category.

Page numbers for primary source documents and illustrations can be found in the Table of Contents and List of Illustrations for Volume V, which appear in the front matter of each volume, and in the index.

SAINT VITUS' DANCE

St. Vitus, the patron saint of dancers and performers, grew up in Sicily and became a matyr during the reign of Emperor Diocletian (ca. 243–316). Sometime during the sixteenth century in Germany, his name began to be invoked to ward off diseases and conditions such as epilepsy, nervous disorders, and, most notably, Sydenham chorea minor and major. Sydenham chorea, referred to as St. Vitus' dance throughout the seventeenth century, caused involuntary movements of the muscles associated with the onset of rheumatic fever. These movements were thought to be stress-induced responses of "wild dancing." Multitudes of people were recorded as experiencing this condition across the continent of Europe, particularly during the fourteenth century. The condition could last from days to weeks and has been traditionally associated with women. The spasticity of movement was often believed to be a sign of insanity. As Burton's *Medical Encyclopedia* explained in 1621, "They that are taken with it can do nothing but dance till they be dead, or cured." The U.S. television show, *Buffy the Vampire Slayer,* spoofed this condition as a demon-induced plague in the musical episode "Once More with Feeling."

SANGER, MARGARET (1879–1966)

Birth control activist

"Margaret Higgins" was the sixth of 11 children born live to her Irish American working-class parents, Anne and Michael Higgins. When her mother, who suffered from tuberculosis and became progressively weaker with each pregnancy, died at age 49, Margaret attributed her death to her numerous pregnancies. Margaret herself acquired tuberculosis, and during her nursing training at White Plains Hospital in New York state, she was afforded an early example of a disability accommodation when her work/study day was shortened by several hours so that she could take walks and get fresh air, the treatment then for tuberculosis. Her only daughter, Peggy, contracted polio at age three and died of pneumonia two years later. When her second husband, millionaire Noah Slee, suffered a stroke in 1943 and began using a wheelchair, Sanger installed a bell on the wheelchair by which he could summon her. She devoted herself to his care until he died a few months later.

Like early feminists before her, Sanger linked birth control with freedom of sexual expression and reproductive rights. Over time, Sanger's arguments evolved to portray birth control as a women's health issue as well as a method of social control. Sanger explicitly linked birth control to eugenics, and one of the goals of International Planned Parenthood, which Sanger founded, included establishing scientific research into the "elimination of harmful dysgenic births in the nation." She also supported research for hormonal anovulants, and by the time of her death, an oral contraceptive had been developed and was being used by women worldwide.

In addition to tuberculosis, Sanger experienced a number of disabling conditions during her adult years, including a nervous disorder, depression, heart condition, alcohol and drug dependency, and leukemia. She spent her last five years in a nursing home, where she died at age 86.

SARASWATI, VIRJANANDA

(1779–1868)

Vedic scholar

Swami Virjananda Saraswati was blinded by smallpox when he was about five years old and orphaned six years later. At 15, he left his brother's unwelcoming home, found refuge among the scholars and saints at Hardwar on the Ganges, and became an assiduous student of Vedic literature, orally taught. Virjananda eventually became a teacher of Sanskrit grammar among religious students at several of northern India's holy cities. He denounced the vast range and shallowness of superstitions bound up in popular Hindu belief and campaigned for a return to the austere fundamentals of Vedic teaching. In later life, Virjananda had a profound influence on Dayananda Saraswati (1824–1883) and thus on the founding and direction of the powerful Hindu reform movement, the Arya Samaj, with effects continuing into the twenty-first century. Dayananda sat at Virjananda's feet in Mathura from 1861 to 1863, showing more perseverance than most, for the blind guru was famously volcanic. Centuries of the downmarket end of Hindu belief and practice received condign punishment from the elderly scholar, whose cane fell on the nearest proxies, the hapless students sitting before him.

SAUNDERSON, NICHOLAS

(1682–1739)

English mathematician, linguist, and teacher

Nicholas Saunderson, blinded by smallpox in infancy, became a proficient mathematician, linguist, and teacher. In childhood, his education was mostly informal, but the teenage boy's intelligence attracted teachers, and his mathematical ability was assisted by two tactile learning boards that he devised for arithmetic and geometry. The first enabled him to calculate rapidly, using his own code of larger and smaller pins in a grid of holes. On the second board, he made and altered shapes with thread attached to pins. Saunderson continued his education from various tutors, and in 1707, he went to Cambridge, where his talents as a teacher were exercised. In 1711, he received an M.A. and was elected Lucasian Professor, against stiff competition. He was highly regarded as a teacher of mathematics and science, both by his students and colleagues, although some of the former found his standards too exacting and tried his patience, while some of the latter suffered from his frankly aired opinions. A modern mathematician notes that Saunderson hardly contributed to mathematical research but produced useful textbooks and guides to his subjects. He married in 1723 and had children. With some adjustments, Saunderson apparently lived the typical life of an able and gregarious professor of his times.

SAVELJEV, PAVEL ALEKSEEVICH (1890–1975)

First chairman of the All-Russian Federation of the Deaf

Pavel Alekseevich Saveljev lost his hearing at the age of nine. In 1924, he started publishing the newspaper *Life of Deaf-Mutes.* In 1926, he set up the All-Russian Federation of the Deaf and was its chairman from 1926 to 1949. He also organized evening schools, workshops, factories, and vocational training for the deaf. In 1957, he organized a drama school that attracted many amateur deaf actors. In 1960, the school became a part of the Schukin Professional Drama College in Moscow. Seventeen deaf students were trained there and, in four years, received certificates as professional drama actors. Three more groups of deaf actors graduated from the drama school.

SCHIZOAFFECTIVE DISORDERS

The term *schizoaffective disorder* was originally coined by Kasanin (1933) to define a subgroup of psychoses in which affective and schizophrenic symptoms are prominent simultaneously, or within a few days of each other, within the same episode of illness. Historically, other concepts, such as *intermediate psychoses* or *mixed psychoses,* have been also used to describe the psychoses between affective and schizophrenic disorders. The current definition in the diagnostic manuals of mental disorders states that this co-occurrence of affective and schizophrenic syndromes is required for diagnosis. Two types of schizoaffective disorders have been established according to the affective symptoms: *manic or bipolar type* if the mood disturbance includes a manic or a mixed episode and *depressive type* if the mood disturbance includes only major depressive episodes. About 1 in every 200 people (0.5 percent of population) develops a schizoaffective disorder at some time during her or his life. Although it is well established that this is a biological disorder, the specific cause or causes are unknown. The studies of sociodemographic, clinical, biological, and outcome characteristics have demonstrated that schizoaffective disorders lie midway between the two major psychoses, schizophrenia and pure affective disorders. Although patients with schizoaffective disorders suffer from recurrent episodes and thus need preventive treatment, they usually make a full recovery, and only a small percentage of cases end in chronicity or a defect state.

SCHIZOPHRENIA

Schizophrenia is a serious mental illness that begins early in life and leads to substantial morbidity, increased mortality, and significant disability. Recent World Health Organization (WHO) estimates suggest that schizophrenia is among the top 10 causes of disability worldwide. Characteristic symptoms include hallucinations, delusions, unusual behavior, and disorganized thinking (positive symptoms); decreased motivation, decreased energy, and social withdrawal (negative symptoms); and cognitive impairments leading to functional disability. Basic social skills, including the capacity to read and respond to facial expressions, are often lacking, making social communication difficult. The illness runs a protracted course in many patients and frequently leads to chronic institutionalization or multiple hospitalizations, homelessness, unemployment, and social isolation. There is evidence that in less industrialized countries, individuals with schizophrenia have a more favorable outcome and less disability as they are better able to manage the social skills needed for survival in less complex societies.

While conventional antipsychotic medications effectively control positive symptoms, they have little impact on cognitive impairment and functional disability. Recent research suggests that atypical or "second-generation" antipsychotics compared with conventional antipsychotics may have superiority in rectifying functional impairments in schizophrenia. However, atypical antipsychotics produce only limited improvements in overall disability; a comprehensive approach to overall management, including individual-, group-, and community-based psychosocial treatments, is therefore critical. There have been recent major advances in such treatments.

MODELS OF COMMUNITY CARE

A good deal of research has been conducted on two approaches to community care: the assertive community treatment (ACT) and intensive case management (ICM) models. ACT provides a continuum of medical, psychiatric, and social services to patients in the community via mobile outreach teams of clinicians providing services needed to keep patients out of the hospitals. Such services include case management, social service entitlements, housing, vocational rehabilitation, crisis intervention, financial support, and advocacy. Specifically, case managers help in discharge planning, establishing linkages with community programs, and networking to confirm that quality community care is provided. These models reduce time in the hospital and improve housing stability, especially among patients who are high service users. ACT and ICM also have moderate effects on improving symptomatology and quality of life. However, most studies suggest relatively less effect of ACT and ICM on disabilities in social functioning, arrests, time spent in jail, or vocational functioning. Some British studies have failed to replicate American observations of improved outcomes in ACT. However, these differences might reflect variable implementation of differences in available resources for ACT in the United Kingdom versus the United States.

SUPPORTED EMPLOYMENT

Most patients with severe mental illness live in the community, but many are socially isolated and few have jobs. In recent years, supported employment, an approach that uses the "place and train" as opposed to the "train and place" method, has been increasingly gaining acceptance as the preferred method for vocational rehabilitation. Such supportive employment, coordinated with clinical care, increases the rate of competitive employment, lower hospital admission, and better treatment compliance. The addition of social skills training, combined with supported employment, may enhance the individual's ability to meet the interpersonal demands of the workplace.

SUPPORTED HOUSING

The gradual deinstitutionalization in the past several decades has necessitated the need for developing a variety of housing alternatives, ranging from transitional housing, 24-hour highly staffed residential care or board, and home care through staffed group homes to less supervised and more normalized community settings. Too frequently, states have allowed the "warehousing" of chronic schizophrenic patients in nursing homes, which have little or no treatment or rehabilitation interest. Recent years have witnessed a move from facilities in which to "place" patients toward partnership between the mental health service provider and providers of ordinary housing. A range of mobile case management, crisis intervention, and continuous treatment services allows patients to be managed in the housing of their choice. Patients and treatment providers often prefer this approach; quality of life is usually increased, and length of hospitalizations may also be reduced.

SOCIAL SKILLS TRAINING

Social skills training is a widely used psychosocial intervention in the management of schizophrenia. Complex social skills are broken down into simpler and smaller steps and then taught using a variety of techniques, including didactic and Socratic instruction, modeling, corrective feedback, and homework exercises. Several randomized controlled trials have shown that social skills training produces improvement on specific behavioral measures, although changes in symptoms and community functioning are less pronounced.

The Schizophrenia Patient Outcomes Research Team (PORT) pointed to the underutilization of these approaches and recommended their inclusion in the treatment package. Social skills training was also included in the practice guidelines for treating patients with schizophrenia published by the American Psychiatric Association.

FAMILY INTERVENTIONS

It has been known for some decades that patients who return to families with high expressed emotion (EE) (e.g., criticism) have a higher likelihood of relapse than those whose families are low in EE. Family interventions (i.e., family psychoeducation and behavioral family therapy) are highly effective for reducing families' EE and improving patients' relapse rates and outcomes. Furthermore, family interventions are also associated with reduced family burden. Several studies have demonstrated the efficacy of family psychoeducation leading to reduced relapse rates, improved recovery of patients, and improved family well-being among participants. Effective approaches in family psychoeducation programs include empathic engagement, education, ongoing support, and clinical resources during periods of crisis; social network enhancement; and problem-solving and communication skills. Coordination among patient and family advocacy organizations, clinician training, and ongoing technical consultation and supervision can help in implementing psychoeducational approaches in routine clinical settings. Family psychoeducation for a particular patient and family should be tailored to the extent and quality of family and patient interest and involvement.

COGNITIVE REMEDIATION

In the past few decades, cognitive dysfunction has been recognized as a fundamental disability feature of schizophrenia. Domains of cognition that are impaired in schizophrenia include attention, working memory (e.g., capacity to keep things in mind long enough for immediate use, such as directions or a phone number), and learning and general memory. Other deficits include impairments in forward planning, concept formation, initiation, and self-monitoring. These impairments are noticeable against a background of generalized cognitive deficits and may affect between 40 and 95 percent of individuals with schizophrenia. Specific executive deficits appear to be related to specific symptom clusters and are linked to structural and functional brain abnormalities. Recent research has convincingly demonstrated a relationship between cognitive deficits and functional outcome in schizophrenia.

Cognitive remediation involves repeated practice and acquisition of compensatory strategies on cognitive exercises designed to engage underfunctioning brain systems. Researchers in Pittsburgh have recently developed a novel approach to the cognitive remediation in schizophrenia, called cognitive enhancement therapy (CET). This approach capitalizes on observations that deficits related to social cognition—the ability to act wisely in social interactions—may be of particular importance in impeding social and vocational recovery. Social cognition is acquired during adolescence and early adulthood and may be at least partly independent of formal IQ and neuropsychological problems. CET draws on a contemporary neurodevelopmental model of schizophrenia whereby social cognition deficits are thought to serve as intermediary links between impairments in executive cognitive functions and the emergence of characteristic symptoms of schizophrenia. CET is designed to facilitate the individual's transition from prepubertal to young adult style of social cognition and emphasizes developmental learning experiences during the remediation of social cognitive deficits. The treatment involves helping the individual to develop a "gistful" appraisal of interpersonal behavior and novel social contexts. Cognitive remediation strategies vary widely along dimensions of duration, intensity, method, target of behavioral intervention, and clinical status of participants. Using these approaches, improvements have been observed on measures of working memory, emotion perception, and executive function. Functional magnetic resonance imaging studies have begun to suggest changes in task-evoked brain activation in several functionally relevant neural systems.

COGNITIVE ADAPTATION

U.S. researchers in Texas have developed cognitive adaptation training. This involves modification of the patients' environment to allow patients to bypass their deficits. Following a detailed behavioral assessment and analysis of the home environment, behaviors are modified by increased structure, signs and labels, and electronic devices—such as tape recorders—for providing cues and instructions. Cognitive adaptation interventions have also been found, in a controlled trial, to produce improvements in symptoms, psychosocial status, and relapse rates.

CONCLUSIONS

More research is needed to establish cost-effective approaches to psychosocial rehabilitation in schizophrenia. The best evidence suggests that if rehabilitation interventions can begin in early adolescence or young adulthood, schizophrenia can be far less disabling than it has been historically. Characteristics of successful psychiatric rehabilitation programs include interventions that (1) are direct and behavioral; (2) have specific effects on related outcomes, with generalization to other domains; (3) are long-term; (4) are delivered close to patients' natural environments; and (5) combine skills training and environmental support. However, despite improved knowledge about approaches to psychosocial rehabilitation, a wide discrepancy persists between efficacy in trials and effectiveness (what is actually implemented in naturalistic settings). Administrative, financial, and organizational barriers need to be broken down by obtaining evidence-based new information and disseminating such knowledge to the relevant professional groups, advocacy groups, and policy makers.

SCOLIOSIS

A condition of the lateral deviation of the spine, scoliosis has been documented in skeletons dating from at least 26,000 years ago. One of the first medical descriptions of scoliosis occurs in the *Hippocratic Corpus* from the fourth century BCE. Historically, there are many examples of figures, both prominent and less so, who reputedly had scoliosis, ranging from Tutankhamun to Richard III.

As a clinical condition affecting between 3 and 30 percent of the U.S. population, scoliosis can exist at birth or be acquired from trauma, infection (e.g., tuberculosis), or disease of the nerves and muscles; the most common cause is from unknown causes (idiopathic). Scoliosis is categorized as congenital, infantile, juvenile, adolescent, or adult (degenerative) in onset. Either static or progressive, scoliosis can lead to pain, weakness, impaired breathing, or death from a compromise of lung function. "Discosmetic" effects are suggested by the term *hunchback.* Kyphosis, a condition in which there is forward deviation of the spine, is frequently associated with osteoporosis (e.g., "dowager's hump"). Contemporary Western medicine characterizes scoliosis by the anatomical location of the curvature, the severity of the curvature, and progression. Intervention varies from observation (the most common therapy) to bracing and casting (usually until growth of the bones has stopped) to surgical correction, including fusing vertebrae together or the introduction of stainless steel rods to maintain the straight position of the spine.

Scoliosis as an object of focused medical intervention started in the late eighteenth century and had an early peak in the 1830s in France with the rise of a bourgeoisie concerned about their posture and its implications for employment and marriage. Putative correction through exercise, bracing, regimental programs, and proprietary devices was the means through which a variety of kinds of medical practitioners competed for clientele. Orthopedists, early therapists, nonsurgical physicians, and nonprofessional healers all offered therapies. With the advent of anesthesia and antiseptic/aseptic surgery in the mid- to late nineteenth century, orthopedists increasingly "won" this competition. The invention of the X-ray examination of the spine gave investigators a tool to make numerical studies of scolioses and gradually allowed them to gather enough epidemiologic knowledge to create decision rules about when to intervene. By the early twentieth century, pediatricians began to include examination for scoliosis in their emerging "routine" physical examination of schoolchildren. The other significant interventional tool has been pulmonary and cardiovascular evaluation. The first artificial disk was cleared by the Food and Drug Administration in June 2004. While the physical effects of scoliosis can be significant, inspiring the above medical developments, the physically and psychologically damaging effects of medical interventions over the centuries have been equally profound. That history has yet to be written.

In literature and art, scoliosis has often been a trope for indicating the outcast or menacing character, such as Shakespeare's Richard III. This theme has led some to argue that people with severe scolioses were burdened with unfortunate fates in premodern cultures. Nevertheless, figures such as the hunchback, Quasimodo (meaning "partially formed"), in Victor Hugo's *Notre-Dame de Paris* show that individuals with scoliosis were also employable and could evoke respect as well as pity.

SCOTT AND DISABLED PEOPLES INTERNATIONAL (AUSTRALIA) v. TELSTRA (1995)

The decision in *Scott and Disabled Peoples International (Australia) v. Telstra,* handed down following a four-day Human Rights and Equal Opportunity Commission (HREOC) inquiry in 1995, represents a watershed in telecommunications policy for people with disabilities. The commission found Australia's national carrier, Telstra, guilty of discrimination against the class of people with severe hearing or speech impairments. In particular, a joint complaint from Geoff Scott and Disabled Peoples International (Australia) (DPI(A)) claimed the carrier exercised indirect discrimination for not providing them with access to teletypewriters (TTYs) on the same basis as others obtained standard telephone handsets (T200s) to access the telecommunications network. The findings of the committee were as follows:

> In my opinion, the services provided by the respondent are the provision of access to a telecommunications service. It is unreal for the respondent to say that the services are the provision of products (that is the network, telephone line and T200 [standard handset]) it supplies, rather than the purpose for which the products are supplied, that is, communication over the network. The emphasis in the objects of the Telecommunications Act (s.3(a)(ii)) on the telephone service being "reasonably accessible to all people in Australia" must be taken to include people with a profound hearing disability. (Human Rights and Equal Opportunity Commission 1995:12)

At the time, Australians requiring TTYs paid approximately $600 for the equipment.

The case tested the application of the Disability Discrimination Act of 1992 and the inclusiveness of the definition of universal service obligation (USO) in the Telecommunications Act of 1991.

The Telstra lawyers claimed that the carrier was not discriminating against anyone because people had a right to use its services or not. Primarily, the counsel acting for the carrier claimed that it was not in the business of supplying specialized equipment but a standard service that gave access to the telecommunications network. Furthermore, Telstra revealed that it had supplied millions of dollars of free and heavily subsidized services to Australians with disabilities.

The complainants argued that the carrier exercised discrimination against hearing- or speech-impaired consumers by placing unreasonable conditions for network access, which are not required of most in the wider community. Furthermore, Scott and DPI(A) argued that Telstra's corporate generosity was irrelevant to the issue before the commission.

The commissioner, Sir Ron Wilson, accepted Telstra's claim that it had no obligation to provide a new service as stated in section 24 of the Disability Discrimination Act. However, Wilson also accepted the complainants' argument that they were not seeking a new service but access to the existing service that formed Telstra's social obligation under the USO.

Wilson's statement at the beginning of this entry identifies the telephone service primarily as a social phenomenon and not a technological system or even a market commodity. Once a social context is used as the defining environment in which the standard telephone service operates, it is difficult to dispute the claim that *all* does not include people with disabilities. Part of the service includes the point of access in the same way that a retail shop front door is a point of access for a customer to a shop. Consequently, the disputed provision is not a new or changed service but another mode of access to the existing service. Furthermore, the commissioner ruled that Telstra exercised illegal discrimination by refusing to accommodate those affected with modified access to the network in the form of affordable access to TTYs, which would not place unjustifiable financial hardship on the national carrier.

The HREOC inquiry represents a tension among discourses of disability. Arguably, the respondent framed disability within charity and market models of policy, which emphasize corporate philanthropy, dependency, and profit maximization. In contrast, the complainants framed disability within a rights model that emphasized the legislated entitlement of citizen-consumers as active political subjects. The success of the action resulted in new provisions for the Deaf community and people with severe speech impairments in the Telecommunications Act of 1997, which provided affordable equitable access to TTYs and associated services.

SEATING AND POSITIONING

The term *seating* refers to all components (seat cushion, back support, external body supports) that assist a person in achieving and maintaining a sitting position. This includes items that individuals use daily such as dining room chairs, desk chairs, couches and seats in automobiles as well as specialized supports designed for individuals with disabilities.

The term *positioning* means placing and maintaining a person in a specific postural alignment such as sitting, side lying, standing, supine, or prone. Some examples of positioning devices include seats, back supports, and standing devices. For all individuals, the primary goals of positioning are to maximize an individual's comfort, support, and function to allow participation in a given task. For individuals with disabilities, additional positioning goals include improving postural alignment and stability, improving motor control, preventing or minimizing contractures and deformities, and improving sensory and bodily functions.

Typically, an individual's seating and positioning needs are assessed with relation to wheelchair mobility (either manual or electric powered). The purpose of the assessment process is to determine the postural needs of an individual and relate those needs to appropriate positioning components and methods of mobility. An individual or a team of individuals with specialized experience and training in the field of seating, positioning, and wheeled mobility devices performs the evaluation. These individuals can be (but are not limited to) physical therapists, occupational therapists, and rehabilitation engineers.

An individual's seated posture is assessed in parts and as a whole. The alignment of the pelvis is typically assessed first because this is the base of support in a seated posture. Once a functional pelvic position is established, the alignment of the lower extremities, the spine, and ultimately the head and neck position is assessed and established. Emphasis is placed on the individual's ability to perform functional tasks from this position.

Typical cushion materials used in manufacturing specialized seating include foams, air, and viscous fluids. The materials can be used alone or in combination with each other to create a support surface that matches an individual's postural and pressure management needs. Material properties such as density, stiffness, and envelopment are critical to the decision-making process when selecting a material for a specific application.

There are three main categories of specialized seating systems for use by individuals with disabilities. They are linear/planar, generically contoured, and custom contoured/custom molded.

Linear/planar cushions. These cushions (seat or back) are typically made of foam and covered with fabric upholstery (e.g., Lycra, Cordura, vinyl). They are typically flat and provide a firm base of support.

Generically contoured. Nearly all seat cushions and back supports available commercially today fall into the generically contoured category because they have a generic, preestablished shape. The shapes, typically, cannot be easily altered but offer general curves and contours to provide a functional base of support for some individuals. They can be made of foam, air, viscous fluids, or combinations of them.

Custom contoured/custom molded. These seat cushions and back supports represent the highest end of options. These supports are custom made for an individual to conform to body parts to provide increased pressure distribution and increased postural control. They are typically made of specialized foams.

SÉGUIN, EDOUARD ONESIMUS (1812–1880)

French physician

Styled the "apostle to the idiots" by Pope Pius X, Edouard Séguin studied at the *lycées* of Auxerre and St. Louis in Paris prior to learning medicine with Jean Itard and Jean-Etienne Esquirol. Following Itard's halting methods to help the "Wild Boy of Aveyron," Séguin convinced Esquirol of the possibility of teaching "idiots"; Esquirol obtained a post for him at the Bicêtre. Upon the death of his mentors, Séguin also took a post at the Salpêtrière and continued a long string of publications. His meteoric rise in Parisian medical circles was halted after a shadowy falling out with the Bicêtre medical staff and his dismissal in

1843. Despite relative disgrace, Séguin continued a private practice and his writing, including his most influential book, *Moral Treatment, Hygiene and Education of Idiots* (1846). In 1850, he emigrated to the United States, where he helped found a large number of institutions for children with disabilities, finally obtained a medical degree (University Medical College of New York), and died in New York City.

Séguin's influence came from his staunch belief in the heretofore unthinkable educability of those with significant cognitive disabilities, regarded by contemporaries as "idiots" or "backward." His "physiological method" employed exercise and the senses as a lever to stimulate the will, ideas, and thence education; these techniques were influenced by Philippe Pinel's (1745–1826) "moral treatment" of the insane, Rousseauvian ideas of the senses, and Christian socialism, then popular among Parisian mental health reformers. Séguin also absorbed the contemporary Parisian emphasis on comparison with "the normal," and after his MD, his writings increasingly evoked the medical model. Séguin's influence was particularly strong in the United States, especially among those working in institutions for "idiots" and reforming them, helping to remove "the mark of the beast," as a eulogist noted.

SELF-SUFFICIENCY

Self-sufficiency is a goal that the disability rights movement has promoted, challenged, and redefined in its quest to increase options available to people with disabilities. Some advocates view self-sufficiency as an impossible standard that should be rejected in favor of recognition of universal interdependency. Others claim self-sufficiency as a right to which all are entitled, including those who may need support to exercise it.

Historically, Western culture has put a high value on self-sufficiency, defined as the ability to provide for one's own needs with minimal assistance or support from other people. In this light, the goal of self-sufficiency assumes and requires that all individuals are equally capable of functioning within the existing environment. By this definition, which many disabled people were unable to fulfill, disability was seen as inadequacy and as a reason to exclude people with disabilities from social roles and benefits. Without the capacity to be completely self-sufficient—for instance, because of a need for physical assistance, extra learning support, or other help—people with disabilities were judged unfit to compete and thus undeserving of equal resources, rights, and responsibilities. Dependency, neediness, and failure were therefore deemed to be the inevitable consequences of disability.

Because of this bias, disabled people who could not be entirely self-sufficient (i.e., those who need assistance or support) have often had to forfeit some of the basic choices and opportunities that other citizens take for granted. For example, people needing help with dressing, eating, and other activities of daily living are often forced by public policy to enter a facility, the only setting in which an adequate level of support is available. People who need publicly subsidized health care coverage and/or in-home support services may have to forego employment because poverty is a precondition for eligibility. These forfeited choices and opportunities, mandated by social conditions and political decisions, tend to undermine disabled people's self-sufficiency much more than the disabilities themselves.

Beginning in the 1970s, the U.S. independent living movement has put forward a new view of disabled people as being capable of independent choice and responsibility, even if not capable of fully independent functioning. Independence, these advocates insisted, is not a matter of doing everything unassisted but of making one's own decisions without penalty or coercion. Some explicitly rejected the concept of self-sufficiency, arguing instead for self-determination. Others have used the terms *self-sufficiency, self-determination,* and *independence* more or less interchangeably.

Currently, the term *self-sufficiency* is most often used in the context of employment and the ability to support oneself financially. For example, in the preamble to the 1990 Americans with Disabilities Act (ADA), Congress found that "the Nation's proper goals regarding individuals with disabilities are to assure equality of opportunity, full participation, independent living, and economic self-sufficiency" (ADA 1990, sec. 2(a)8).

SEQUOYAH (1770?–1843)

Cherokee warrior who devised the Cherokee alphabet

Disabled due to a swelling on his knee, Sequoyah (1770?–1843) was made lame by the shortening of his diseased leg. While his lameness prevented him from becoming a foot warrior, he participated as a horse-mounted combatant, serving in the Cherokee regiment under Colonel Gideon Morgan against the 1813 Alabama Red Stick Creeks in the Battle of Horseshoe in General Andrew Jackson's campaign. Though lame, Sequoyah led his people, the Cherokees, to heights untenable to other Native American Indians: the path to literacy. He analyzed and reduced a complex inflected multidialect language to 85 (originally 86) minimal sound units, to each of which he attached a particular symbol. A daughter assisted him during the arduous process. Completed by 1819 and spread by 1821, this writing system allowed Cherokees to become literate almost overnight and culturally revitalized. Sequoyah's discovery of the concept of the phonemic structure predated academic linguists one hundred years. Fascinated with European American writing styles that he named "talking leaves," he worked tirelessly to bring all Cherokees together through his unique writing convention. Correspondence between east and west Cherokees could easily be facilitated because the efficiency of the syllabary permitted Cherokees to become proficient writers with a few days' study.

Born in the prehistoric capital, Echota, on the Little Tennessee River in what is now Monroe County (Tennessee) between 1760 and 1770, Sequoyah left his ancient village among the Overhill Cherokees and migrated south as far as his territory would take him, then to Willstown, in what is now DeKalb County (Alabama). He followed other Cherokees who had been moving south for decades to escape border ruffianism.

After introducing his writing style to Cherokees in the East in 1821, he migrated to the Arkansas Territory in 1822 to join fellow Cherokees, who had left the East for the West. There he continued to teach his syllabary. After the infamous Trail of Tears (1838–1839), whereby eastern and western Cherokees reunified their nation in Indian Territory, Sequoyah's syllabary was the nucleus of unification for both traditional and acculturated Cherokees. Cherokee shamans recorded sacred formulas for ceremonial purposes in the syllabary. The power of his writing convention facilitated his teaching of the syllabary to Cherokees in the Indian Territory and those living beyond its borders.

Seeking to usher in literacy among as many Cherokees as possible, in 1842, Sequoyah left the Cherokee capital Tahlequah (Oklahoma) in an oxcart for Mexico, where he hoped to create literacy among Mexican Cherokees. In 1843, Sequoyah died in northern Mexico before his companions, once alerted to his grave condition, were able to get him assistance.

SEX INDUSTRY, INTERNATIONAL

The term *international sex industry* includes prostitution and prostitution-related activities; the pornography industry; the sex-related entertainment industry, including phone sex and Internet sex services; syndicates involved in the trafficking business in persons and drugs; travel agencies that promote sex tourism; and other related activities. Commercial sexual services also include paramedical areas such as sexual surrogate therapy. The relationship between disability and the sex industry has become increasingly visible globally as the sexuality of people with disabilities has emerged as an important issue.

Due to the heavily gendered aspect of sex commerce—typically involving men as buyers and women as sellers—any discussion of the sex industry requires attention to the issue of gender as well as disability and other categories of inequality. The gender dynamic involved in the operation of the sex industry complicates the position of disabled women and men but also highlights the limitations of considering “disabled people” as a unified category. Another important factor is the global dynamic associated with commercialized sex, which exploits disabled and nondisabled women from the non-Western world for the benefit of men from wealthier countries.

DEFINITIONS AND SCOPE OF THE INTERNATIONAL SEX INDUSTRY

The international sex industry is a multi-billion-dollar concern operating all around the world. Income from the sex industry supports a massive underground economy of pimps, procurers, and organized criminals, as well as multinational conglomerates operating hotels, airlines, and tourist industries. Definitions of the sex industry from feminist perspectives have emphasized its financial aspects and its power differentials. Brock and Thistlethwaite (1996) define sex industries as the institutionalized sexual use by more powerful members of male-dominant societies of the less powerful. One of the most important elements of the international sex industry is trafficking in human beings, which usually targets vulnerable sections of the population, including disabled people. Human trafficking has been defined in the “UN Protocol to Prevent, Suppress and Punish Trafficking in Persons, Especially Women and Children” in the following manner:

> Trafficking in persons’ shall mean the recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation. Exploitation shall include, at a minimum, the exploitation of the prostitution of others or other forms of sexual exploitation, forced labour or services, slavery or practices similar to slavery, servitude or the removal of organs. (see http://www.state.gov/g/tip/rls/fs/2005/43630.htm)

The United Nations reports estimate that 4 million women have been trafficked, both within countries and from one country to another. U.S. reports estimate that between 700,000 and 2 million women and children are internationally trafficked each year for the sex industry and for labor (Richard 1999). Most of the victims of human trafficking are women and children, and they are often moved to other countries where they are isolated and essentially enslaved. The sale of mail-order brides and sex tours are important dimensions of human trafficking. Mail-order brides are typically from Asia and Eastern Europe and are often promoted as conforming to more traditional, “feminine” notions of womanhood than their Euro-American counterparts. In 1998, the International

Labour Organization (ILO) estimates of the number of prostitutes in Indonesia ranged from 140,000 to 230,000; in Malaysia, from 43,000 to more than 142,000; in the Philippines, from 100,000 to 600,000 (and the ILO suggests that 500,000 is a more reliable figure); and in Thailand, the estimated number of prostitutes in 1997 was between 200,000 and 300,000. Such figures are not unique to Asian countries—an article in the *New York Times* by Michael Specter in 1998 estimated that approximately half a million women are also trafficked into Western Europe every year. The European Conference on Trafficking in Women in June 1996 claimed that women from Africa (Ghana, Nigeria, Morocco), Latin America (Brazil, Colombia, the Dominican Republic), South East Asia (the Philippines, Thailand), and Central and Eastern Europe (Czech Republic, Hungary, Poland, Romania, Russia, Ukraine) were being trafficked into the European Union in large numbers.

The key issues regarding disability and the sex industry can be identified as follows: (1) disabled people's entrance to the sex industry in various forms as workers, (2) disabled men's access rights to prostitution or pornographic material as consumers, (3) seeking destigmatized or legalized prostitution by relying on a rationale that it is necessary for disabled men, and (4) advocating for medically prescribed sexual services (not involving prostitution) such as sexual surrogacy for disabled people, with an emphasis on the psychological benefits of sex for self-esteem.

DISABLED PEOPLE'S ENTRANCE TO THE SEX INDUSTRY

Disabled people are employed as sex workers in a number of fields. Some customers specifically look for certain attributes in prostitutes—such as disability—as a form of sexual fetish. It is becoming increasingly common for a "disability fetish" to be advertised on commercial Internet sex sites. There are niche markets for videos of disabled women having sex, pictures of naked amputees, and pictures of naked little people. For instance, recent videos include *Gimp Lovin, Roped Gimp, Gimp Pain,* and *The Gimp Sees a Doctor.* Websites such as "criptease.com" or "disabilitypayperview.com" sell photos and videos of fantasies involving disabled people who use wheelchairs and braces, who are amputees, who use strong glasses and other ocular devices, or who have leg casts. Often, these sites involve disabled women from Asia or Eastern Europe—such as Romania and the former Soviet Union. Similarly, there are devotees whose fetish involves other impairments, such as blood clotting. Calendars showing naked disabled people are also available and are advertised under such titles as "Gimps Gone Wild." A related fetish is the "medical fetish," which is also served by the commercial sex industry, through the production of videos of people receiving medical examinations, enemas, and so on. This industry also sells medical equipment such as neck braces, straitjackets, electrostimulators, catheters, mouth spreaders, and speculum (http:// www.medicaltoys.com/enemas.htm).

It has also been noted that the technological involvement in the sex industry, including Internet and phone connections, has resulted in an increase in both the number and the nature of sexual workers. In particular, there has been an increase in sex work outside of the sphere of genital contact. Many disabled women have been recruited into the industry in this way. For instance, increasing numbers of women with physical disabilities have been employed in the phone sex industry. In South Korea, it is reported that women with cognitive or physical disabilities have been procured and forced to prostitution. Disabled women often enter into traditional prostitution as the lowest and cheapest commodity due to their extremely marginalized status (commonly lacking resources and education and having a history of sexual abuse). *The Women's News* reported in 2003 that the Coalition for Eradicating Sex Trade of Women with Disabilities and the Rescue Hotline have been recently installed to deal with this problem in South Korea. In Zimbabwe, forced marriages and prostitution put women and girls, including the disabled, in danger of contracting sexually transmitted diseases or HIV/AIDS. This seems to be more serious for women and girls with disabilities as they are being sexually abused and raped by people who believe that HIV/AIDS can be cured by having sex with someone with a disability.

While Indian women and girls are trafficked into Kuwait and other Middle Eastern countries for purposes of prostitution, disabled Muslim children, primarily girls, are trafficked to Saudi Arabia for the purposes of begging or being sold into brothels. Hwang and Bedford (2003) reported that mentally disabled girls and other aboriginal girls were forced into indentured prostitution and kept in control with violence, deception, indebtedness, and affection in Taiwan. In China, the most common traditional image of the blind woman is a prostitute. Traditionally, blindness became an advantage in a prostitute, presumably because the client's own identity and defects were thereby spared any scrutiny.

DISABLED MEN'S RIGHT TO COMMERCIAL SEX AS AN ACCESS ISSUE

Some Western disability rights movements have made a connection between disabled people's sexual rights and the need to use commercialized sex. Sexual liberalism arose among disability activists to challenge discriminatory attitudes prohibiting and controlling disabled people's sexuality. Sexual liberalism suggests that disabled people should have equal access to prostitution and to other kinds of paid sexual services that are available to able-bodied citizens. This argument sometimes asserts that the cost of such commercial sexual services should be covered by a state welfare fund. It is proposed that prostitution is often the only way disabled people can have sex or even close physical contact with another person. This approach emphasizes the private and personal nature of purchasing a sex service. It is based on an individual's personal choice, and the fact that disabled customers can enjoy themselves away from their families and personal assistants is a sign of independence, which is thought to be a key element in their pleasure as sex industry consumers.

In addition to being positioned as an access issue, within sexual liberalism, disabled people's right to hire prostitutes often falls within a discourse of consumerism. There was a disabled Dutch man who fought a seven-year battle to win a 1997 court ruling giving him a monthly allowance for using the sex industry, paid by his council (Ananova 2005). Following the lead of a Dutch town that implemented a similar program, Ivo Konings, a city councilor with a disability in Hasselt, Belgium, proposed to give disabled men money to visit prostitutes. Konings, a former adviser to the Belgian government, consulted an organization of prostitutes in Hasselt about providing discounted rates for disabled customers and education for prostitutes. However, conservative arguments promote the abstinence of disabled people by emphasizing the potential danger of sexual activities to physical and mental health. Religious ethics forbid disabled men from seeking an "alternative" way of having sexual lives as well. Responding to such conservatism, the liberal approach is often paralleled by moves for the legalization of prostitution, with the prostitutes' rights movement asserting the necessity of their work in terms of disabled people's needs. In this way, disabled people's campaigns for practical solutions that will enable them to have access to sexual relationships converge with the efforts of the sex industry to promote access for "special" customers. For example, the Netherlands Prostitution Information Center provides tips for disabled customers on its website.

The Pink Palace in Melbourne also gained favorable media attention by carrying out building modifications that made their premises more accessible. Its new features included enlarged doors to accommodate wheelchairs and the installation of a sit-down shower. George Taleporos (2001), a researcher in the area of sexuality and disability, said in a BBC interview that many disabled people used prostitutes and brothels because it is difficult to date in the "usual" way. In Australia, the Accsex Network aims to provide disabled people with "therapeutic help" and access to sex services. The name *Accsex* stems from a combination of the words *access* and *sexuality.* Two of the major achievements of Accsex were establishing a fund by the Eros Foundation (Australia's sex industry trade union) to financially assist people with physical disabilities on low incomes to access the sex industry and raising awareness with attendant care providers about the need for "sex attendants" or attendant carers who are prepared and trained to assist their clients in sexually related activities. These activities, according to Taleporos, may include, among other things, "visiting a brothel, having sex with a partner, being assisted to purchase or use erotica or sex toys or providing assistance with masturbation."

The issue of access to pornography in alternative formats and assistance to purchase pornography has been controversial. A Braille copy of *Playboy* was provided by the National Library Service for the Blind and Handicapped in the United States, but Congress banned later funds for its production. Many people in the disability rights movement saw this as the violation of the First Amendment of the U.S. Constitution. Of course, disabled people are not only consumers of pornography but also may be its objects. For instance, the June 1987 *Playboy* employed disabled female Ellen Stohl. Ellen Stohl sought to express her sexuality by being included in the sex industry. The position of nondisabled caregiving women complicates the arguments regarding the right of disabled people to access the sex industry. A number of specialty brothels are provided for disabled men, and state-employed caretakers, who are mostly women, must take these men to the brothels if they wish to go. The competing rights of these women to be free from an environment that they may find objectionable and objectifying complicates the argument that disabled men, as their employers, have an unfettered right to access the sex industry.

USING DISABILITY TO DESTIGMATIZE PROSTITUTION

In contrast to the movement to end prostitution entirely, sex workers and some feminist movements have advocated decriminalization of all prostitution between consenting adults and have promoted the destigmatization of prostitutes. The need to sexually serve disabled people is often employed as a rationale for justifying prostitution in this context. Some sex workers find pride and identity in their roles, particularly when they define themselves as sex experts helping people with disabilities. In this paradigm, sexual exchange between a disabled man and a prostitute is perceived as friendly, mutual, supportive, and therapeutic. The asexual or emasculated image of disabled men can position disabled men as naive and in need of care, and prostitutes become seemingly authoritative in terms of sexual experience and knowledge. The power domination and violence prevalent in some feminist criticisms of prostitution are often assumed to be absent in prostitution relationships involving someone with a disability. In 2003, when New Zealand passed the Prostitution Reform Bill that decriminalized prostitution, it was argued that access to prostitution improves the lives of disabled people. The Green Party argued that prostitution was often the only way people with disabilities could have sex or even close physical contact with another person.

The call for respect for prostitutes, improvements in their conditions of work, and acknowledgment of prostitution as a profession has been addressed in a number of concrete schemes. For instance, as Shrage (1994) points out, as a result of the growing AIDS risk in the international sex industry, there have been some attempts to promote the medicalization of sex services and the licensing of prostitutes as "sex providers" with college-level education to assign social authority. The 1997 International Conference on Prostitution included the workshop on "Sex Work, Sex, and the Disabled." Sex surrogates working with a variety of disabled people called on fellow sex workers to deal with disabled clients with particular care and sensitivity. In this context, the label *sex surrogates* refers to prostitutes who specialize in dealing with disabled clients.

Tuppy Owen, organizer of Britain's annual Sex Maniac's Balls, which raise funds to "help handicapped people find love," has gone so far as to describe neighbors, friends, and hospital staff who masturbate people who are unable to masturbate themselves as "sex angels" (Steinberg 1997). Another argument that is used to justify prostitution is that it provides sex for persons who would otherwise be deprived of sex, for example, male migrant workers without their wives, disabled or old men, or men in the military. However, in responding to these arguments, feminists who are against prostitution argue that this argument is underpinned by an assumption that men, in any and every circumstance, must be able to have sex. Feminist organizations have made a strong stance against the exploitation of women, including disabled women, by the commercial sex industry.

In the words of Australian activists Mary Sullivan and Sheila Jeffreys (2001), from the Coalition Against Trafficking in Women,

> So normalized has brothel become that the sex industry markets itself as promoting the "rights" of people with disabilities by specifically catering to men and disability charities. Disabled men are seen as a good

> market opportunity by the legalized sex industry, and carers are expected to help these men engage in the abuse of women in brothels, or at least deliver them and wait in the lounge. It is the "rights" of men that are being catered to here. Disabled women are not mentioned.

MEDICALLY PRESCRIBED SEX SERVICES FOR DISABLED PEOPLE

Medicalized practices around disabled sexuality are another axis in the discussion of disabled men's participation in the sex industry. The sexological invention of sex therapy (more specifically, sexual surrogate partner therapy) has been employed for disabled men from the early 1980s in the United States. In this approach, sexuality is considered as a psychological and biological necessity for life and has to be promoted in a certain way. Disabled people's access to such sexual experiences and commercial sexual service first emerged in clinical settings. Promoters of sexual surrogacy for disabled people tend to distinguish sexual surrogacy from prostitution by arguing that sexual surrogates provide more than sexual service to the clients with whom they work. They attempt to meet the special psychological needs of clients and emphasize the therapeutic effects of their work. The term *partner surrogate,* suggested by Masters and Johnson (1970), refers to the partner provided for an unmarried man referred for treatment, who has no one to provide psychological and physiological support during the acute phase of his therapy. In the 2002 volume of *Disability Studies Quarterly,* it was suggested that disabled people should have the cost of hiring sexual surrogates incorporated into Ontario's government-sponsored personalized funding program presumably because sexual surrogacy functions as a real and meaningful form of erotic communication and self-realization and is practiced widely in the United States.

However, as Noonan (2000) points out, sexual surrogate therapy tends not to address heterosexual disabled women since heterosexual male surrogates remain the most rare of sex surrogates. Despite the fact that the concept of sexual surrogacy came from medical sex therapy discourse and was associated with professional discourse through the involvement of the team therapist, a licensed and/or certified professional with an advanced degree, sex surrogacy is actually more likely to exist within a continuum of sex industry practices. European advocates of sexual surrogacy are closely related to prostitute/sex worker organizations. The employment of sex therapy for disabled people's sexual experience or "fulfillment" in the rehabilitation paradigm is a relatively recent combination. Sex therapy has been mostly dedicated to the problems of able-bodied males who experience general anxiety over fulfilling cultural standards of masculine sexuality. Many sex therapists are not members of the medical profession. However, as researchers such as E. J. Haeberle (1983) suggest, there are tendencies on the part of many therapists and promoters to borrow respectability and authority from the medical establishment.

Even though sexual surrogates are supposed to be paid to aid people to express and develop their sexuality and not to give sexual gratification, there have been criticisms that sexual surrogates are simply providing medicalized and institutionalized sex. There have also been suggestions that surrogacy places disabled people's sexuality in the medical area alongside many other therapies; Shakespeare, Gillespie-Sells, and Davis (1996) and O'Brien (1990) both argue that suggesting sex workers require "special" training to engage in sexual activity with a disabled person can be seen as reinforcing the medical model of disability and ignoring institutional oppression and societal barriers, which are some of the causes of imposed celibacy.

A Swiss organization, Pro Infirmis, launched the "touchers project" in Zurich in June 2003 and publicized this project internationally. The pilot scheme involved training 12 professional "touchers" under the guidance of Dutch disabled sex pioneer Nina de Vries. Service would range from massage, body contact, stroking, holding, and bringing people to organism. "The successful applicants were then expected to offer sexual and emotional relief to the Zurich disabled community." However, after this project was announced, the organization suffered a significant reduction in donations. Pro Infirmis decided to end its direct involvement in the project and announced that it was looking for an independent association to take over. Similar programs were known to be running for years in Germany, Denmark, and the Netherlands, where it was called *Stichting Alternatieve Relatiebemiddeling*. The expansion of "therapeutic sexual services" for disabled people has therefore opened up new occupations for sex workers, sexual counselors, and surrogates.

The concept of sexual surrogacy came from a medical sex therapy discourse and seems to evoke a sense of professionalism because it involves a team therapist who is a licensed and/or certified professional with an advanced degree. However, sex surrogacy should still be understood in the context of a massive worldwide effort to make profits out of the sex industry. Often, sexual surrogates simply refer disabled people to sex workers who are prepared to have sex with them. In effect, *sex surrogacy* is interchangeable with *prostitution* in its implementation.

CONCLUSION

The international sex industry is a large-scale industry that includes prostitution, pornography, sex-related entertainment such as phone sex and Internet sex services, sex tourism, and other related activities. Representatives of the international sex industry often use disability to justify their existence by suggesting that commercial sex is the only way of helping disabled people meet their sexual needs. Commercial sex activities are also commonly discussed in a medicalized discourse, such as when they are euphemistically referred to as "therapy." At the same time, sex therapy in medical settings provides programs for disabled people who presumably have problems in sexual relationships. Sexual surrogate therapy emphasizes its psychological benefit to disabled people. However, the fact that the sex industry largely involves women from the non-Western world and many disabled women performing sexual activities for the benefit of men from wealthier countries makes it difficult to sustain the arguments that access to the commercial sex industry is an issue of "equal rights for all." Instead, this argument seems to involve an extension of male privilege to include disabled men, with little regard for the women who work in the industry, including the disabled women who work in prostitution, phone sex, pornography, and other related fields. It has been noted that the expansion of sexual services, facilitated by technological developments, has increased the number and nature of sexual workers, especially outside the sphere of genital contact. Expansion of the therapeutic sexual service area has also opened up new occupations for sexual counselors and surrogates. Such specialized sexual services are often used to justify the existence of sexual labor in general.

SEX THERAPY

Sex therapy offers treatment for problems of sexual function and expression. A professional therapist will use specialized clinical skills to help individuals and couples to overcome sexual problems. The types of issues that clients present with include loss of desire, erectile dysfunction, premature ejaculation, pain on intercourse, and communication or other relationship problems. Many individuals are uninformed or unconfident about sexual issues. Many people experience sexual problems at some point in their lives.

Sex therapy is of particular relevance to disabled people. Some impairments may lead to loss of feeling or to difficulty in achieving sexual positions or performing sexual acts. Others may affect body image and lead to the individual feeling abnormal or unattractive. Those who are born with impairment may have been treated as asexual. They may not have received sex education or support in developing their sexuality. Some individuals may also not have been able to express feelings of same-sex attraction due to dependence on family and carers. Those who become impaired may believe that their sexual lives are over. They may experience this reaction from family, friends, and medical professionals. These attitudes may undermine self-esteem, self-confidence, and sexual expression. Disabled people's sexual problems are social and cultural as well as medical and physical: experience of social exclusion and disempowerment may be as important as particular functional issues.

Sex therapists should be trained in sexual anatomy and physiology, have counseling or therapeutic training, have the experience of relationship counseling, and adhere to a professional code of ethics. A series of sex therapy sessions will start by identifying problems and then finding solutions. A program of exercises and activities may be devised for the client(s) to do at home.

Sexual surrogacy is a separate and more controversial form of sex therapy in which an individual with sexual problems is referred by a sex therapist to a sexual surrogate, who will engage in sexual activity with that individual. Whereas sex therapy may work on emotional problems and may offer advice and exercises, sexual surrogacy works with bodies and offers practical sexual activity to resolve difficulties. The dividing line between sexual surrogacy, facilitated sex, and sex work or prostitution may be blurred and may not be recognized by law in some jurisdictions. Disabled people, who may have had difficulties forming relationships and may have issues with sexual activities or with body image and confidence, are commonly cited as potential beneficiaries of sexual surrogacy services.

Sexuality is an important part of self-identity; therefore, sexual problems may be experienced as undermining and distressing in general. Sexual rights have been neglected within both traditional rehabilitation services and the disability movement's campaigning and advocacy work. Disabled people have the same needs as nondisabled people, and sex therapy and sex education should be regarded as priorities alongside more obvious goals such as independent living, employment, and education.

SEXUAL ACCESS

Despite an increase in critical approaches to disability, gender, and sexuality (Shuttleworth 2000b, 2003; Shuttleworth and Mona 2002), researchers need to develop conceptual frames that can be applied to a wide range of relevant issues and also assist in politicizing these issues. The concept of sexual access has recently been proposed to fit the bill for elucidating both the impediments and avenues to sexual well-being for disabled people (Shuttleworth and Mona 2002; Shuttleworth 2003, forthcoming; Grossman, Shuttleworth, and Prinz 2004). Application of the cornerstone disability studies concept of access has traditionally been limited to easily demarcated contexts such as schools, workplaces, and the built environment. A legalistic and technical understanding of the term has held sway that does not appreciably alter even when programmatic access becomes the analytical target (see, e.g., Burgstahler 1994). Embodied feelings, communicative processes, and the symbolic aspects of disability are usually not taken into account. Yet in terms of disabled people's sexual issues, these aspects are often the most crucial to interrogate.

Conceptualization of sexual access as it is developing in disability studies must be clearly differentiated from a similar term used by bioevolutionary scholars to refer to the degree to which males of a species have access to sex with females (e.g., Buss 1994). Instead, sexual access as theorized by the above disability studies researchers encompasses several related meanings. First and foremost, interpersonal sexual negotiations are viewed as situated within a cultural and sociostructural framework of inclusion-exclusion. It is important to interrogate not only sexual negotiations themselves but also multiple aspects of this framework to discern the degree to which these aspects work toward access to sexual expression and sexual relationships for disabled people. Depending on a disabled person's particular situation, relevant aspects of this framework may include physical access to environments and social contexts in which sexually relevant interpersonal encounters may occur, monetary access, programmatic access to personal assistance services, access to transportation, communication access, and many others. Perhaps the most powerful impingement on disabled people's interpersonal sexual negotiations, which presents formidable difficulties for systematic investigation, is the adverse context of cultural images and meanings of disability and sexual desirability.

Sexual well-being is reliant on psychological, social, and cultural supports that sustain a positive sense of one's sexual self. The availability of these supports for disabled people is another sense by which sexual access or exclusion may be gauged. Disabled people, whether it is in their families of origin, institutional contexts, or in the society at large, often experience a lack of support for their sexuality. For instance, people with early onset impairments often report that family members do not expect them to experience a sex life and marriage (Shuttleworth 2000a, 2000b; Mona and Gardos 2000; Shakespeare, Gillespie-Sells, and Davies 1996; Rousso 1993). One example of the way psychological, social, and cultural supports might reinforce each other to promote disabled people's sexual access and sexual well-being is if disabled people were represented in more sexually positive ways in the media. For some disabled people, this more positive sexual representation might result in a more positive sexual self-identification and heightened sexual self-esteem, which might also result in many nondisabled people perceiving them in a more sexual light.

A final sense in which the concept of sexual access might be fruitfully used is in interrogating the formation of gender and sexual identities for disabled people. For significantly disabled people, especially those who live in more structured living environments such as nursing homes and group homes, access to opportunities for sexual and gender expression may be limited given the multiple social restrictions operating and minimal sociocultural support within these institutions (Shuttleworth and Mona 2002; Hamilton 2002; Wade 2002). The question that needs to be asked is to what degree can one form a sexual or gender identity (normative or not) and a sense of one's self as a sexual agent in these kind of living environments.

The concept of sexual access can thus be used to critically frame many of disabled people's sexual issues. Use of an access frame importantly situates disabled people's sexuality squarely within a political context on par with other issues on the disability rights agenda (Shuttleworth 2003, forthcoming).

SEXUALITY

Historically, people with disabilities have either been regarded as asexual or sometimes as sexually deviant and threatening. The sexuality of people with disabilities has often been ignored by health and social services. If the sexuality of people with disabilities were considered, it was mostly in relation to physiological functioning. The psychosocial influences on the sexual lives of people with disabilities were generally overlooked in favor of purely medically focused models. After the Vietnam War, there was a significant increase in U.S. attention toward physical impairment and sexual functioning in men but sparse recognition of the wider issues.

Today, there is widespread awareness that sexuality is equally important to men and women with disabilities and that sexuality is an integral part of the development and experience of all people. Disability activists have played a strong role in this, campaigning for the sexual rights of people with disabilities to be recognized, including the right to have sexual relationships, the right to be parents, and the right to access sexual services.

Recognizing the physiological, psychological, and social aspects of sexuality is essential to obtaining an understanding of the issues related to the sexuality of people with disabilities. While hormones, the nervous system, and the human body in general play a significant role in regulating sexuality, sexuality is also influenced by psychological characteristics, culture, and society.

PHYSIOLOGICAL ISSUES AND SEXUAL FUNCTION

Different impairments affect sexual response in different ways, and most disabilities do not affect sexual functioning. However, impairments that affect the sensory pathways, such as spinal cord injuries and multiple sclerosis, are often associated with challenges for people in sexual function. Men can find it difficult to achieve and maintain an erection and ejaculation, and vaginal sensation and lubrication and orgasm can be problematic for women. Some developmental disabilities are also associated with impaired sexual functioning.

PHYSICAL DISABILITY AND SEXUAL FUNCTIONING

For men with spinal cord injury (SCI), sexual response is likely to be permanently affected in some way. This will vary according to the level and completeness of the lesion and whether a sphincterectomy, which commonly abolishes erectile function, has been performed. Many men with SCI are capable of erections. Erections have been reported to occur in most men within one year following their injury. Those with incomplete upper motor neuron lesions are more likely to have erectile capabilities. The type of erection experienced may be either psychogenic, caused by a psychological stimulus, or reflexogenic, caused by a physical stimulus. Psychogenic erections are more likely in men with incomplete lower motor neuron lesions, and reflexogenic erections are more likely in men with complete upper motor neuron lesions. Ejaculation is less likely than erection because of the common experience of retrograde ejaculation, where the semen is ejected into the bladder rather than the urethral meatus. The frequency of self-reported orgasm is approximately 45 percent.

Vaginal lubrication may remain in women with incomplete injuries at all spinal levels. For women with complete injuries between the T10 and T12 level, there is typically an absence of either psychogenic or reflexogenic lubrication. The act of sexual intercourse may be made difficult as a result of spasticity of the adductor muscles and pelvic floor. It has been reported that 53 percent of women experience orgasm after SCI.

Difficulties with erections may eventually be experienced by nearly half of men with multiple sclerosis (MS), and this is likely to be caused by lesions of the thoracic spine and autonomic nerves. Sexual difficulties, ranging from premature ejaculation to lack of sexual interest and reduced frequency of masturbation, are also common. Women also experience sexual difficulties as a result of MS, including loss of libido and lack of vaginal lubrication. Women with MS also report difficulty achieving orgasm and a decrease in their frequency of having intercourse since diagnosis. Women with MS also commonly report numbness, spasms, fatigue, and painful intercourse.

An inability for people with disabilities to perform sexual acts may be associated with depression and low sexual esteem for the person with the impaired sexual response, particularly when social and cultural values are considered. For example, some may feel like they are not suitable as sexual partners because of their impaired sexual functioning, particularly in Western society, where there is a strong emphasis on sexual performance.

INTELLECTUAL DISABILITY AND SEXUAL FUNCTIONING

People with intellectual disabilities generally do not experience difficulties in sexual function as a direct result of their impairment. There are a few exceptions of note where the genetic etiology affects sexual development and function of the individual's reproductive capacity. Men with Down syndrome have been observed to have a very low fertility rate and may require reproductive assistance to become a parent. Men with Down syndrome can also experience cryptorchidism (undescended testes). Almost all men with fragile X syndrome experience macrorchidism (enlarged testes), and this is frequently not observed until puberty. Men who have Prader-Willi syndrome can experience cryptorchidism and hypogonadism (smaller testes and penis) and may not develop secondary sexual characteristics (voice breaking, body hair, etc.) due to lower testosterone production.

People who have psychiatric disabilities and are prescribed psychotropic medications sometimes report the medications having an impact on sexual function and libido. This impact may be caused by the impairment itself, a result of side effects from their prescribed medication, or a combined effect.

Women with intellectual disabilities have commonly experienced sterilization, often without their knowledge and consent. Women who have had a hysterectomy at a young age have reported difficulties sexually. Some of these women have experienced menopause at a young age and have difficulties with vaginal lubrication and report sex to be painful.

Many women with intellectual disabilities have described sex as painful. When discussing sex, very few talk about it as a source of pleasure or mention that they have orgasms when they have intercourse. Sex is something that they describe being done to them rather than them having an active role. Much of their experience of sex is from sexual assault. When women with intellectual disabilities describe the consenting sex they have, it is frequently void of foreplay and can often be very hurried, resulting in a painful experience due to poor vaginal lubrication.

Men with intellectual disabilities can also be subject to medical control of their sexuality. The negative perceptions of others toward these men's sexual expression (including masturbation) can result in chemical intervention through the prescription of antiandrogenic drugs that reduce testosterone levels or various forms of confinement or control.

SOCIAL AND PRACTICAL BARRIERS TO SEXUAL EXPRESSION

While sexual dysfunction relates to specific impairments, other barriers to sexual expression are likely to exist across the range of impairments. These barriers are associated with societal attitudes as well as the physical impediments that are associated with decreased mobility, speech impairment, and a dependence on others for care.

Societal Attitudes

It is widely accepted that the problems people with disabilities face in sexuality more often reflect attitudinal barriers set up by our culture and accepted by both disabled and nondisabled persons rather than actual physical limitations. Furthermore, it is claimed that sexual problems experienced by people with disabilities are more often related to culturally established attitudinal barriers rather than physical limitations.

A common social attitude is that people with physical disabilities are dependent and helpless. This attitude may lead to other assumptions that prevent an able-bodied person from accepting a person with a disability as a sexual partner. For example, the person with the disability may be perceived as very "needy," and a relationship with this person could be viewed as extremely demanding and never equal. This attitude may be internalized by people with disabilities as they come to believe that they will always rely on their families and that their dependency makes them undesirable life partners.

Dominant beliefs held about the sexualities of people with disabilities come from mythologies. People with intellectual disabilities, in particular, are either believed to be oversexed and dangerous because of an innate inability to know what they want and control themselves in a socially acceptable way or they are perceived to be asexual, eternally childlike, and not in possession of adult sexual desires. Other pervasive myths about people with disabilities are that they are unable to parent, conceive, or adequately raise children.

The myth that people with disabilities are asexual or that sex is not relevant to them is also commonly blamed for the exclusion of people with disabilities from sexual activities. This has been highlighted by an increasingly vocal constituency of people with disabilities who have expressed frustration at the social barriers to full participation in life, particularly in the taboo area of sexuality.

According to Tom Shakespeare (2000), a prolific author in this field, where disabled people are seen as sexual, it is in terms of deviant sexuality, for example, inappropriate sexual display or masturbation. Therefore, the sexuality of people with disabilities is more likely to be considered when it is a problem. Shakespeare also argues that there is an unspoken taboo about sexuality and disability, pointing out that disabled people's sexual and emotional needs are rarely included in any discussion or representation in popular culture such as movies, music, and magazines. This reinforces the public's attitudes and expectations toward disabled people as seeing them as "sick and sexless" rather than participating in full sexual and family relationships.

Much of what we know about the social barriers that people with disabilities face in relation to their sexuality comes from the reports of people with disabilities themselves. Robert Murphy (1995) drew on his personal experience living with quadriplegia to reflect on the position of physical disability in American society. He argued that the disabled, individually and as a group, contravene all the values of youth, virility, activity, and physical beauty that Americans cherish. He believed that disabled people are resented by the able-bodied and are seen by them as ugly and repulsive—they are perceived as subverters of social values and ideals. According to Murphy, these values and ideals include strength, independence, virility, and health, and they are promoted and affirmed constantly in the media, while the disabled body is hidden or presented as something to be avoided, corrected, and pitied.

The sexualities of people with disabilities have been and continue to be affected by the ideology of eugenics. Historically, there has been a fear that people with disabilities will produce offspring with disabilities, as well as a belief that this is something that should be avoided. This stems from a fear of disability and a belief that people with disabilities are of less value and a threat to the genetic good or survival of the human species. Sometimes the message is implicit and at other times explicit. Explicitly, the continuing practice of sterilization as a reproductive control of people with disabilities (particularly women with intellectual disabilities) and the institutionalization of people with disabilities (particularly people with intellectual, cognitive, or psychiatric disabilities) show the continuing influence of the eugenic ideology and have a serious impact on sexuality.

There is also evidence that people with disabilities (particularly women) experience sexual abuse at a higher rate than in the general population. This may be because people with disabilities are more likely to live in institutions or to have contact with a wide range of caregivers; it may be because communication barriers mean that people with disabilities are less likely to be heard or believed if they report abuse; it may also be because of physical vulnerability or availability. Awareness of the dangers of abuse may be lacking and protection absent. Conversely, focus on abuse may lead to overprotectiveness of people with disabilities and an unwillingness to provide information about their bodies and sexual behavior. It may be thought that raising awareness of sexuality increases vulnerability, whereas appropriate education may instead reduce the likelihood of an assault and increase the possibility of individuals reporting inappropriate attention or actions.

People with disabilities are vulnerable to sexually transmitted infections like any other member of society. People are placed at increased risk of exposure if they do not receive education on the risks and protective measures that people can take. Particular groups of people may be more vulnerable due to their sexual practice and where they live (e.g., men who have sex with other men where there is a high prevalence of HIV among homosexual men). Sex education and HIV/AIDS education need to take into account information barriers: for example, making health information available in simple text, via sign language and in different formats for people with visual impairments.

General societal attitudes toward sexuality are also likely to affect people with disabilities. Society places a great deal of emphasis on sexual intercourse, and other kinds of sexual behavior, such as kissing, cuddling, and mutual masturbation, are viewed as less significant and labeled "foreplay." The achievement of orgasm is also emphasized, and sensation and movement are equated with sexual eligibility. For some people with physical disabilities, these attitudes could hinder their sexual esteem, as they may be physically unable to engage in the sex acts that are socially valued. Likewise, they are discouraged from participating in the acts that they are capable of because they are socially devalued. A more open approach to sexuality may value nonheterosexual forms of sexuality, may foster a more imaginative and experimental approach to sexual expression and activity, and may enable people with disabilities to achieve pleasure and intimacy in diverse and individual ways.

Practical Barriers

Reduced mobility may interfere with sexual expression in all physical impairments, but the exact nature of the practical difficulty is likely to be disability specific. For example, people with an impaired urinary system, such as those with MS and SCI, may need to contend with removing an indwelling or external catheter or bending and taping the catheter when preparing for sexual intercourse. They also risk spontaneous bladder and bowel emptying. People with impairments that cause physical weakness, such as neuromuscular conditions, may not have sufficient motor strength to masturbate to orgasm or to sufficiently pleasure a sexual partner. Mobility problems involving inaccessible public transport, clubs, and housing are also likely to affect opportunities to socialize and meet potential sexual partners.

Speech impairment can also be a significant barrier to establishing sexual relationships. The use of augmentative communication devices requires skill and patience, and consequently, the speech-impaired person's opportunities to express his or her personality and attract a partner through two-way communication are affected.

Dependence on others for care can also seriously restrict an individual's opportunities to freely express his or her sexuality because of a lack of privacy and overprotective parents or caregivers. For people who live with their parents, the establishment of sexual relationships is likely to relate to the degree of independence from parental figures. However, the person with a disability often remains dependent on parents much longer than the able-bodied individual. The parents of a person with a disability may have difficulty acknowledging the sexuality of their child and struggle accepting that their son or daughter could have a life independent of them. These overprotective parents may be especially concerned about their child being "hurt" or "exploited," and they may communicate, either directly or indirectly to their child, that a sexual relationship and marriage are not a realistic possibility. Overprotective parents and a dependence on others for care can be a contributing factor to social isolation, which limits the social and sexual opportunities of a person with a disability.

For people with disabilities who reside in supported accommodation, social isolation and barriers to sexual relationships can be even more serious as a result of cramped conditions, a lack of privacy, and the intrusion of support staff. These people are often more segregated from able-bodied people, and in some institutions, sexual contact between residents is prohibited. In cases where sexual contact is allowed, it is still unlikely to be possible if both residents have mobility problems, and often the only able-bodied people they associate with are professionals who are forbidden to engage in sexual relationships with a resident or to provide the assistance needed for two residents to have sex.

People with disabilities may experience enormous external pressures that impinge on their sexualities. This control can come from family members, carers, service providers, and support agencies that provide accommodation, recreation, or medical services. To self-advocate and assert their choices and express sexual desires in such a negative climate takes huge courage and determination. The places where people with disabilities live (institutions, nursing homes, boarding houses, hospitals, prisons, group homes, and, particularly for people with cognitive and psychiatric disabilities, on the street) all have an impact of the sexuality of people with disabilities and affects the way they see themselves and their opportunities for forming a positive sexual identity. People with intellectual disabilities who have experienced living in institutions and group homes in the community have sadly reported fewer opportunities in group homes to have sexual relationships due to the increased level of supervision (those staff see it as their job to prevent sexual contact rather than enable people's relationships) than when people resided in institutions. Many aspects of people's lives have seen conscious planning and support for people to gain independent skills or have their needs met by services in the areas of managing finances, learning housekeeping skills, and having educational and vocational opportunities, but the area of sexuality has largely been ignored, reinforcing the belief that people with disabilities are not whole and that emotional and sexual connections with others should not be encouraged.

Wider discrimination against people with disabilities also affects the capacity to achieve intimacy and express sexuality. For example, people with disabilities may be isolated and lonely. Many people make friends or meet partners at college or in the workplace: if people with disabilities are excluded from both those domains, their social life may suffer. To participate in leisure activities, they need money to buy clothes, pay for admission to venues, and buy drinks and meals, but because many people with disabilities are poor, this may be impossible for them. Above all, meeting people and making friends and becoming lovers all depends on individual self-esteem and confidence: if people with disabilities are socialized into dependency, feel bad about their bodies, or lack self-worth, then they may find it difficult to overcome barriers to interaction and may be seen as unattractive or undesirable.

SEXUAL MINORITIES WITH DISABILITIES

While most are probably heterosexual, some people with disabilities are gay, lesbian, bisexual, intersex, and transgender. These sexual minorities face unique challenges when they are coupled with disability. For example, a dependence on others for care makes the exploration of a person's sexuality and the gay, lesbian, bisexual, and transgender community more difficult. This early exploration is usually achieved privately and independently, at a time when the person feels a sense of apprehension and cautiousness. The nondisabled person can do this with minimal risk and with little fear of his or her family and friends knowing. However, a person with a disability may need support to attend a gay or lesbian venue, such as assistance with transport, communication, or personal care. This often requires negotiation and disclosure and the need to "come out" at a time when the person may not feel prepared or confident. Furthermore, physical access to the venue also needs to be considered. For transgendered people who require assistance to dress, there may be a fear of asking to wear clothing of their choice. If they do ask, their requests may be refused, and they may be subjected to abuse and ridicule.

The sexualities of people with disabilities are also affected by common assumptions that people should only have monogamous relationships and that the sex they have cannot involve experimentation, sexual role-play, cross-dressing, or an expression of fetishism. Engaging in any of these activities is often perceived as being sexually deviant if one or more partners have a disability, whereas it is seen to be within the spectrum of sexual behavior for those without disability.

SEXUAL RIGHTS OF PEOPLE WITH DISABILITIES

In the face of the many barriers, it is important to consider the sexual rights of people with disabilities. Ann Craft (1994) identified the following rights. First, they have the right to be treated as adults and not perceived by others as eternally childlike and sexless and to be treated with the dignity and respect accorded to adults. Second, they have the right to be provided with accurate knowledge about sex and sexuality in ways that they can understand. Third, they have the right to be sexual and to make and break relationships. People with disabilities need to be able to exercise risk taking in order to learn and should not be overprotected for fear they may suffer some emotional or physical harm. A lack of experience will place the person at greater risk. Fourth, they have the right not to be at the mercy of the individual sexual attitudes of different caregivers. Those supporting people with disabilities need to promote self-realization in the individuals, not compliance, enabling them to make their own choices and be able to express their own sexual identity without a prescribed notion of what constitutes a norm. Finally, they have the right to live in humane and dignified environments, free from sexual abuse. To foster a positive and healthy sexuality, people require a safe space that affords privacy, personal control, and choice.

While traditional service providers have neglected the sexual rights of people with disabilities, for reasons discussed above, it is perhaps more surprising that the disability movements have been slow to take up the campaign for sexual rights. American disabled feminist Ann Finger (1992) argues that the disability rights movement has not put sexual rights at the forefront of its agenda:

> Sexuality is often the source of our deepest oppression; it is also often the source of our deepest pain. It's easier for us to talk about—and formulate strategies for changing—discrimination in employment, education, and housing than to talk about our exclusion from sexuality and reproduction. (p. 9)

Perhaps because other disability rights have been prioritized, perhaps because acknowledging the exclusion from intimacy is painful, or perhaps because of wider taboos about sexuality, effective work to achieve the sexual rights of disabled people has been neglected in many countries. However, promising developments include better campaigns around HIV/AIDS and sexual health, often based on peer education; better training for professionals, carers, and personal assistants; provision of nightclubs and other social activities for people with learning difficulties; respect for privacy and the right to have control over your own body; and new positive images of disabled people's bodies, sexuality, and relationships, such as the Australian Intimate Encounters project.

Despite the history of exclusion and the reality of isolation and abuse for many people with disabilities, it is important to note that for other people with disabilities, their sexual rights are being achieved, and they are leading satisfying sexual lives. People with disabilities are having relationships of all kinds, heterosexual, homosexual, monogamous, and polyamorous. People with disabilities are having children. Many are marrying other disabled people and people who do not have disabilities. People with disabilities are dating, loving, touching, kissing, hugging, sucking, fingering, and fucking. Some are accessing the sex industry, visiting sex workers, working as sex workers, consuming pornography, and, in some instances, making pornography. People with disabilities are learning and teaching about sex, as sex educators, counselors, and researchers. They are finding and sharing useful ways to enjoy sexuality and increase sexual pleasure and sexual esteem. Prioritizing the sexual rights of people with disabilities, as well as breaking down taboos and silences, will ensure that these successful stories become the norm for most people with disabilities in years to come.

SHELTERED EMPLOYMENT

Sheltered employment provides paid work opportunities for people with disabilities for whom a job in the community-based labor force is believed to be unlikely. These work activities are typically offered in protected environments or sheltered workshops, where the demands of competitive employment are minimized. For example, the sheltered working environment can be constructed to reduce levels of responsibility, hours of employment, pace of work, and the number of work demands placed on an employee. It is organized to provide assistance from human services support personnel so that individuals engaged in sheltered employment can reach their maximum level of performance and productivity.

In recent years, sheltered employment has been the focus of much critical debate because the underlying beliefs about work and disability, as well as the structure and practices of this employment model, have serious implications for the community inclusion and citizenship of people with disabilities.

THE STRUCTURE AND FUNCTIONS OF SHELTERED EMPLOYMENT

Sheltered employment is offered in small- to medium-sized organizations, typically employing fewer then 100 persons. It is administered by private, nonprofit, or voluntary organizations. The jobs offered by sheltered employment are varied, but they may include commercial ventures (e.g., a car wash, catering, or woodworking business serving the public), subcontracts negotiated through other industries (such as packaging or assembly), activities to serve the administrative organization (such as mailing and filing), or simulated work activities. In most cases, sheltered employment receives government funding or subsidy for costs such as human resources, equipment, space, and employee payment. Control of the income realized through the sales of goods and services depends on the relationship to the funding source. The extent to which organizations offering sheltered employment retain control of their income will have significant implications on their ability to purchase equipment, offer compensation to workers, upgrade facilities, and other activities that are common in workplaces in the regular community labor market.

Sheltered employment has been developed to fulfill several functions. The first is to provide people with disabilities the opportunity to participate in work for pay. From this perspective, the person is considered an employee, and sheltered work can be conceptualized as the person's job or occupational status.

A second function of sheltered employment is to create a context for improvements in health and well-being. Through participation in work activities, individuals with disabilities have the opportunity to experience psychosocial benefits, including the development of self-esteem and worker identity, promoting a sense of personal competence, which contributes to the community and establishes social relationships. Work is thought to have therapeutic functions, and sheltered work improves physical, mental, and emotional impairments. From this perspective, individuals working in sheltered employment are clients of a health service that is an integral part of their treatment.

Finally, sheltered employment provides training to develop skills essential in the regular, community-based labor force. These include skills needed to successfully perform work activities (such as concentrating on the task, consistently producing high-quality products, working at speeds that are considered standard in regular employment settings), work-related skills (such as good grooming and personal hygiene, traveling to work, punctuality and attendance), and social skills at work (including getting along with coworkers, following instructions, and respecting authority). Sometimes, sheltered employment is organized to include work enclaves, direct job placement, and follow-up support to assist in the move to regular employment settings. From this perspective, the individual involved in sheltered employment is a trainee, learning skills that can lead to employment in the regular community labor market.

HISTORICAL PERSPECTIVES

Contemporary applications of sheltered employment for persons with disabilities can trace their origins back to the sixteenth and seventeenth centuries. The development of workhouses for the poor, as well as asylums for the indigent and people with disabilities, established work settings segregated from the public, which provided relief from poverty and the spiritual deterioration associated with idleness and loss of employment. In the nineteenth century, sheltered employment was developed on the grounds of institutions that provided long-term care with a view to promoting the therapeutic benefits of work participation and a daily routine, including a balance of work and rest. The rehabilitation functions of sheltered employment likely originated from efforts by schools for the blind in the late nineteenth century to facilitate the vocational training of students. Sheltered employment was actively promoted as a viable option in vocational rehabilitation until the late 1970s, when the model was criticized by activists promoting the civil rights of persons with disabilities. The model also came in conflict with legislation designed to combat worker exploitation. It was also shown that sheltered employment did not lead to full and integrated employment. New models of employment in the 1970s and 1980s demonstrated how individuals with disabilities could be supported directly in regular employment settings, encouraging a trend toward vocational rehabilitation efforts that supported, rather than sheltered, people in their employment.

PROBLEMS WITH SHELTERED EMPLOYMENT

Sheltered employment has been criticized because its tenets and assumptions are inconsistent with contemporary perspectives on disability that highlight the basic rights of all persons to participation in the life of the community, including full integration in regular occupational settings, and on the social and economic costs incurred when the potential of all citizens is underused. Sheltered employment designs the work situation with the aim of promoting workers' health and well-being, as well as their potential for regular employment. Traditionally, though, sheltered employment has not incorporated practices consistent with the social perspective of disability, such as working directly with employers to secure an integrated employment situation, one that incorporates accommodations and other supports that help workers function in integrated work settings.

The sheltered employment model has been criticized precisely because it "shelters" workers from the demands of regular work and segregates them from larger society. While workers in sheltered employment may contribute to society through the goods and services they produce, the model is structured to regulate the extent to which workers have direct contact with people in their communities, with nondisabled workers, or even with other community businesses to acquire needed supplies or services.

Sheltered employment has generally been unable to prepare people for employment in the open labor market. The nature of the work that can be done in segregated settings is limited, and generally it has not been able to provide jobs that are consistent with the knowledge, innovation, and technological demands of the current economy. It has been argued that the model cannot adequately prepare people if they are not exposed to the actual production and social context of mainstream employment. Similarly, individuals with disabilities are deprived of experiencing all of the personal benefits of work, including elements of work that might contribute to their own motivation to seek and maintain employment. For example, holding a job in the regular labor force may provide an individual with a social status that is personally valued and encourages staying at the job.

Critics also point out that the many functions of sheltered employment are incompatible, which hinders efforts to achieve mainstream employment. For example, the therapeutic functions of the model mean that it is likely to depend heavily on government funding, while the employment functions of the model support a more heavily production-oriented organization that is oriented to decreasing government assistance. This has significant implications for people with disabilities who may be held back in the sheltered setting because of their capacity to contribute to production demands. It can also affect those who are denied access to sheltered employment because they are perceived as less able to meet production standards.

The working conditions of sheltered employment have also been the object of some concern. The physical plant, work tasks, and the social segregation of sheltered work environments give the impression of an asylum and contribute to negative social attitudes. In addition, the nature of the work offered tends to be repetitive, requiring a low skill level, and without opportunities for advancement. This undermines efforts to present sheltered work as a credible place to acquire work skills and possibly contributes to discrimination toward persons with disabilities in the regular workforce. Furthermore, workers in sheltered employment may not have access to basic rights of employment enjoyed in the open labor market, such as compensation for unemployment and vacations, the protection of minimum wage standards, or the ability to organize themselves as a collective to negotiate their conditions of employment.

INTERNATIONAL PERSPECTIVES

Sheltered employment is an international phenomenon, and it is on the increase, despite efforts to develop alternate models that favor mainstream employment through the provision of supports and accommodations directly in regular community work settings.

There is considerable variation in the way sheltered employment is organized and structured around the world, so it is difficult to generalize about sheltered work. For example, sheltered employment will be affected by the employment rates of a country. Where the unemployment rate is rising, the numbers of individuals in sheltered employment can be expected to rise. There is also considerable variation between countries with respect to the nature of the disabilities experienced by workers in sheltered employment. Countries take different approaches to sheltered employment. European countries, for example, tend to focus on production functions and so are more likely to have people without disabilities working alongside disabled people, which is less common in North America.

Legislation will influence the prevalence of sheltered work. In countries with strong legislation to promote inclusion in the workforce, sheltered employment is likely to be a less prominent employment model. Where standard labor laws are applied to sheltered employment, employees can benefit from the standards and rights enjoyed by all workers. National policies may categorize some workers in sheltered employment as trainees or as employees, each with distinct policies governing their employment. Some countries recognize workers in sheltered employment only as clients of a service, and no formal employee relationship is established. While most countries provide some form of income support for persons with disabilities who are not economically self-sufficient, national policies will differ on the status granted sheltered employment with respect to minimum wage provisions and the remuneration for labor.

THE FUTURE OF SHELTERED EMPLOYMENT

The future of sheltered employment is uncertain. There are powerful arguments for the termination of sheltered employment as a vocational support program. Yet, the model persists internationally, probably because it is so difficult to change established social structures. The pressure to close sheltered work will be resisted by the support staff. Workers with disabilities may also resist, especially if they are long-time employees in sheltered settings. There are also concerns that, although more consistent with the ideals of mainstream employment, new employment models will not secure work opportunities for all people with disabilities, both because of constraints within the open labor markets (e.g., variable employment rates) and because it will be hard to support those with the most severe disabilities. Some worry that supported models may lead to bad working conditions and segregation within the workplace, without the benefits of the camaraderie available in the sheltered employment setting.

In response to criticisms directed at the model, modification can be expected. For example, sheltered employment may be modified to incorporate supported employment services or to develop a broader variety of work options and opportunities for advancement. Attempts may be made to enhance worker ownership and control, as well as develop training measures that are more likely to lead to the development of skills associated with success in mainstream employment. Whether true "sheltered" employment remains after these changes is not entirely clear.

—Terry Krupa

SIBLINGS OF PEOPLE WITH DISABILITIES

Unlike their parents, who remember a time "before," the nondisabled siblings of people with disabilities often possess an intimate familiarity with disability from their first memories. Psychological literature identifies many common themes in the lives of such siblings: gradual awareness of the disabled sibling's difference, competition for the parents' resources, fear that the sibling's disability will reflect on their own competence or health, increased sensitivity and acceptance of diverse abilities, and rebellion against, or acquiescence to, the expectation that they will take on advocate or guardian roles for their disabled sibling into adulthood. These assumptions are generalized mainly from recent, Western, family studies; whether they apply across cultures and eras remains to be seen. While past decades saw an emphasis on warning about the problems siblings would experience, current thinking holds that most siblings in otherwise "functional" families gain useful adaptive skills through their relationships to disabled brothers or sisters.

Many historical figures have been the siblings of people with disabilities. In the American context, at least two U.S. presidents (Thomas Jefferson and John F. Kennedy) had sisters with mental retardation. Ralph Waldo Emerson was responsible for the supervision of more than one institutionalized brother; his friend Margaret Fuller held a similar role in her family.

As siblings are seen as potential lifelong supports to individuals with disabilities, public programs have begun to concentrate some effort on addressing their concerns and educating them for this role. For example, "Sibshops" are offered by many community agencies serving people with disabilities; usually, but not always, developmental disabilities are the focus. Directed at school-age brothers and sisters of children with disabilities, they enable peer interaction through discussion, recreation, and activities designed to increase disability awareness in age-appropriate ways.

Beyond juvenile literature, support group curricula, and advice books for parents, reflective memoirs (and other literary nonfiction) by adult siblings have been published in increasing numbers in recent years. Rachel Simon's (2002) *Riding the Bus with My Sister* is perhaps the most lauded of these. This genre is still far less developed than the parental narrative but shows promise as a useful alternative glimpse at family life and disability.

SICK ROLE

Sick roles are the culturally established expectations for how a person should act when he or she is ill or is perceived as ill/abnormal in a particular group. Each person learns these sick roles through a process known as socialization, in which people are subtly educated in the norms of a particular group.

While the term *socialization* can be used to refer to modest processes such as introducing a new employee to the norms of a business or institution, here we are interested in the broader and more fundamental socialization that teaches a person how to become a member of society. This process starts neonatally and occurs at each moment of interaction with others. Over time, by living and interacting with others within a given society, each person internalizes the norms and expectations of others, sometimes to such an extent that they seem essential and natural—the only way the world could possibly be and the only way people could possibly behave within it. When this occurs, those "essential" norms and expectations become tinged with morality so that people refer to them with "shoulds" and "ought tos" and look disapprovingly at any ideas, behaviors, or realities that flaunt them. This process embeds within each person more or less a similar sense of appropriate behavior, for example, that murder and theft are bad and following traffic rules is good. Socialization makes society possible in a very fundamental way. And yet, the socialization of the sick role, the assumption that people with any illness or disability are morally obligated to behave in a particular way, has become deeply problematic in American society. But before exploring this, let us review the scholarly history of the notion of the sick role so that we might understand the recent backlash against it.

The first scholarly work on the subject of sick roles was published in 1929 in German by the medical historian Henry E. Sigerist. Sigerist, examining Western civilization but also drawing on cross-cultural information, defined illness as whatever disturbed the rhythm of a person's life so that the physiological symptoms isolated him or her, making that person suffer in helplessness, pain, and fear. For Sigerist, this sick role of isolation, dependency, and fear was the universal outcome of physiological suffering.

Talcott Parsons, the mid-twentieth-century American sociologist who made the notion of sick roles famous, did not take such a universalistic approach and instead grounded sick roles in the cultural and social dynamics of American medicine in the 1940s and 1950s.

Parsons recognized that for Americans of that era, illness and disability were both a deviation from an idealized norm of health and a deviation from the normal expectations of society. Parsons outlined basic features of the American sick role. First, the person who showed signs of deviating from health is exempted from his or her normal social activities and obligations and is exonerated from normal expectations of self-responsibility; in essence, the person takes on a dependent, childlike social status. Second, and largely because of the first feature, the person is socially isolated. Third, the person must accept that he or she is in this undesirable state, in need of help, and morally obligated to cooperate with others' therapeutic efforts at restoring the person to society's ideal of normal health so that the person can resume or take on normal social activities and obligations. The most appropriate source of therapy was seen as Western biomedicine.

This American model of the sick role developed out of an idealized notion of the body as normatively healthy and in conjunction with a model of biomedicine as a hierarchically structured, active, authoritative, parental institution that was responsible for making grateful, passive, childlike, and cooperative patients into healthy persons who could fulfill society's normal expectations and responsibilities.

There have been numerous scholarly criticisms of Parsons's sketch of the sick role, particularly the problems of applying it to specific physical conditions. Parsons based his sick role on the patterns of behavior that arise in response to those maladies that are temporarily incapacitating. Many conditions do not fit comfortably within his typology, including pregnancy, alcoholism, mental illness, chronic illness, congenital abnormalities, and many physical and mental disabilities. In such cases, the classification of sickness and its corresponding expectations for sick role behavior simply do not fit.

Indeed, the central problem of Parsons's sick role is the idea that perfect health and a perfect body are normal, and any deviation from these idealized norms constitutes sickness and the need for a sick role.

Norms of health vary tremendously cross-culturally, as do the expectations of what a person does when identified as sick. Sick roles, as the expectation for behavior when identified as ill or disabled, also vary significantly cross-culturally based on two variables: (1) who has access to medical information and technology and (2) how health is defined.

In societies where all people consider themselves more or less well, however far from perfect health, as long as they can fulfill some modest responsibilities in a society, illness itself becomes narrowly circumscribed to those instances of acute suffering. In such societies, long-term or chronic conditions are unlikely to be socially labeled as ill, but simply as a personal characteristic of the particular person. Among the Sasak of Indonesia, a place where the people describe themselves as "less than healthy," disabilities stemming from conditions such as skeletal deformities, chronic heart failure, and severe arthritis may physically limit tasks and are evaluated on a case-by-case basis, but they do not carry automatic expectations of changed behavior or responsibilities. The anthropological record, in fact, is full of examples in which people with chronic or debilitating conditions are not isolated or even viewed as sick until contact with the Western biomedical gaze medicalizes conditions, isolating their victims in the process.

The theoretical idea of a sick role has come under fire in the social sciences since the 1980s for various reasons. First, sick roles are an ideal type that may describe patterns of behavior across patients in a given culturally constituted social group but cannot predict or thoroughly describe the behavior of any particular patient. Second, the sick *role* has theatrical implications, suggesting that a person can perform or take on a role without being intricately bound to it; the notion of a sick role does not reflect the ontological reality and suffering of people who are ill or disabled. As a result of these criticisms, social science research has been more person centered, focused on patient narrative, patient experience, and sociolinguistic detailing of physician-patient interactions. The results of this work show a tremendous amount of diversity in the behaviors, attitudes, experiences, and interpretations of people who are ill or disabled.

In addition to this scholarly reaction, significant portions of Western society itself have reacted against the social expectations of patient passivity and isolation that Sigerist and Parsons described. Beginning in the 1970s but taking off in the 1980s, particularly with the AIDS movement, for some members of the population, ideals of passivity have changed gradually into expectations for activity and engagement. For people in America today, there are at least two widely distributed cultural ideas of what someone should do when he or she is sick. First, the passive, isolated behavioral expectation as described by Parsons and Sigerist remains a salient model for behavior. Second, there is an active and engaged model in which patients remain engaged in their lives, keep their social responsibilities, are considered responsible for their own recovery, and are educated and empowered consumers of health care. Recent scholarship suggests that people may choose either role or blend the two as best suits their particular needs and circumstances at the time.

Sick roles, as the cultural expectations of how someone who is ill or otherwise disabled should behave, can and do shift over time within a single society and vary significantly across societies.

SIGN LANGUAGE

Sign language is a means of communication through the use of body movements, gestures, and facial expressions. It could be described as plainly as pointing, shrugging, and grimacing or could be as complex as a combination of coded manual signals or signs.

Beyond simply a means of communication, American Sign Language (ASL) is the primary language used by Deaf and hard-of-hearing people in the United States and in parts of Canada. It is the native language of many Deaf men and women, as well as some hearing children born into Deaf families.

ASL is a visual-spatial language based on concepts rather than words. It is a linguistically complete language, gaining recognition and acceptance as a genuine, formal language due in large part to the research done by an English professor named William Stokoe. Stokoe worked to legitimize ASL, proving scientifically and unequivocally that ASL meets the full criteria of linguistics phonology, morphology, syntax, and semantics to be classified as a fully developed language. ASL shares no grammatical similarities to English and should not be considered in any way to be a broken, mimed, or gestural form of English. For example, ASL has a topic-comment syntax, while English uses subject-object-verb.

The history of ASL begins in the mid-eighteenth century in France. In 1755, Abbé Charles Michel de L'Épée (1712–1789) of Paris founded the first free school for deaf people, where the first sign language was developed. In 1815, Thomas Hopkins Gallaudet (1787–1851), an American Episcopal priest, traveled to Europe to study methods of communicating with the Deaf. After several months, Gallaudet returned to the United States with Laurent Clerc, a Deaf instructor from the Paris school for the Deaf. In 1817, Gallaudet established the first American school for the Deaf in Hartford, Connecticut, and Clerc played a primary role instructing Deaf children using sign language. The opening of subsequent residential schools for the Deaf throughout the United States promoted the standardization of ASL. Today, America has one of the most complete and expressive sign language systems of any country in the world, owing much to the French sign system, from which many present-day ASL signs, though modified, have been derived.

ASL is the primary language of Deaf people in the United States. This number of people represents those who view themselves as members of a cultural-linguistic minority group (Deaf), as opposed to those who audiologically are unable to hear (deaf). Estimates for the number of ASL users in the United States range from 300,000 to as high as 900,000. The most recent estimate given by the Gallaudet Research Institute puts that number at 360,000. Precise numbers are hard to come by due to the difficulty of discerning in the population those who are audiologically deaf and those who are culturally Deaf. In addition, it is also difficult to discern and measure the actual sign language used. A spectrum exists between ASL and other manually coded English (MCE) signs. Beginning signers, mainstreamed Deaf children, and late-deafened adults generally comprise the MCE side of the spectrum, while expert signers and Deaf families fall on the ASL side of the spectrum. In between there exist signers with a wide variety of skill.

The Deaf share a common history, language, value system, beliefs, characteristics, and behaviors, with American Sign Language as the common thread that binds them together. ASL is the fourth most commonly used language in the United States.

Deaf communities around the world use native sign languages that are indigenous to Deaf communities within specific countries and geographic locations. Within each signed language, there are regional dialects and variations that represent geographical differences; sign language is not universal. Signers in Great Britain use British Sign Language (BSL), while those in France use French Sign Language (LSF), and those in Switzerland have five distinct sign language dialects. There are international communication systems such as Gestuno and International Signs, which are similar to spoken Esperanto and commonly used in international conferences. These systems are more or less agreements on a vocabulary of signs among the international Deaf community.

SIGN LANGUAGE INTERPRETATION

Sign language interpreting has been a practice since signers came into contact with speakers. Facilitating communication between these two groups of people constitutes what Stewart, Schein, and Cartwright (1998) call "the art and science" of sign language interpreting, a profession now centered on enabling communication between deaf, signing persons and nondeaf, speaking persons. The interpreting process involves more than just these two (groups of) people, however. Indeed, interpreting is always a triangular act, calling on three—and sometimes even four—groups of people: those who know and use sign or sign languages, those who do not, those who interpret between those two, and sometimes also those who administer and finance interpreting programs.

While the practice of sign language interpreting is nothing new, the development of a profession around it is. The unlicensed predecessors of this profession were (more often than not) anonymous individuals—most likely friends or family—who have interpreted for deaf people in oral/aural-centered communication situations throughout undocumented periods of history. In this preprofessional period, interpreting was usually performed as a favor. The interpreting profession in the United States marks its inception in June 1964, when Ball State Teachers College in Muncie, Indiana, hosted the Workshop on Interpreting for the Deaf, sponsored by the Vocational Rehabilitation Agency, and members of this workshop voted to establish a national body of professional interpreters. This body was originally known as the National Registry of Professional Interpreters and Translators for the Deaf and is now known, more simply, as the Registry of Interpreters for the Deaf (RID). Fifteen years later, in 1979, Canadian interpreters formed the Association of Visual Language Interpreters of Canada (AVLIC); similar associations have also been formed in Great Britain, Australia, and a few other countries. Interpreting, as a recognized and organized profession, still rarely exists throughout the rest of the world.

Immediately after the RID was formed, two institutions developed interpreter training programs (ITPs): California State at Northridge in 1965 and the National Technical Institute for the Deaf (NTID) at Rochester Institute of Technology (RIT) in 1966. In 2003, the RID listed 159 interpreter training programs offering the following degrees: Certificate in Interpreting (43), associate's degree (75), bachelor's degree (30), graduate degree (3), and distance learning programs (8).

KEY LEGISLATION IN THE UNITED STATES

Several important pieces of legislation have helped instigate, effect, and even reinforce the professionalization of sign language in the United States. The Vocational Rehabilitation Act amendments in 1965 (P.L. 89–333) gave state rehabilitation agencies the authorization to employ interpreters for deaf clients, and in 1973, interpreting for deaf people in additional settings was mandated with the Rehabilitation Act amendments. This 1973 act contained Section 504, guaranteeing rights for "the handicapped." Included in those rights, the provision of interpreters—especially trained and qualified ones—in schools and "under any program or activity receiving Federal financial assistance" was no longer seen as a favor or a fairly rare occurrence. The power of this 1973 law was carried forward and even expanded with the passage of the Americans with Disabilities Act (ADA) in 1990. Between those two key pieces of legislation, the Bilingual, Hearing and Speech Impaired Court Interpreter Act was also passed by the U.S. Congress in 1977, stating that a federal court must appoint and pay for interpreting for a deaf person who is the subject of any criminal or civic action initiated by the federal government.

THE REGISTRY OF INTERPRETERS OF THE DEAF (RID)

In July 2002, full RID membership stood at 10,007, with 3,779 of those (about 37 percent) currently fully certified and practicing. These numbers are also supplemented by interpreters who are certified by the National Association of the Deaf (NAD). The RID now follows the definition of the ADA (see above) as its standard for recognizing a "qualified interpreter" as "an interpreter who is able to interpret effectively, accurately and impartially both receptively and expressively, using any necessary specialized vocabulary." As an indicator of the increasing demand for qualified interpreters and the specialization of this evolving profession, the RID currently offers 20 different certificates, including, for example, the following: Certified Deaf Interpreter (CDI), interpreters who are themselves deaf or hard of hearing; the Reverse Skills Certificate (RSC), for interpreting between American Sign Language and other English-based sign language forms; four different certificates for oral transliteration or interpreting; and specialist certificates for legal interpreting or performance arts interpretation (see www.rid.org).

THE INTERPRETING PROCESS

There are three key steps in the interpreting process: the interpreter must first understand the meaning of the message being received, the message must then be encoded into the target language, and the message must then be effectively expressed in that target language. In these steps, the ability to use both short- and long-term memory simultaneously is necessary as the interpreter moves between reception, encoding, and expression across not only two languages but also two modalities (spoken to visual/manual or vice versa). Interpreters must be able to walk (in one language) and chew gum (in another) at the same time.

Several sets of factors can greatly influence the interpreting process: physical, psychological, forms of interpreting, and the settings/scenes for the interpretation. Physical factors are often related to the auditory field, the visual field, personal factors, and the environment itself. In the auditory field, for example, the positioning of the three members of the triangulated situation, the acoustics of the setting, and the ambient noise all matter. The visual field also influences the interpreting process in such dimensions as the positioning of three members (again), the available lighting, the background "visual noise," and even the appearance of the participants. Interpreters tend to dress in dark, single colors and to avoid patterns in their professional clothing to present an uncomplicated and visually effective background for their hands. Personal factors also come into play in the interpreting process: interpreters should have good eyesight and hearing, the ability to focus in potentially distractive settings, and mechanisms for managing the cumulative stress that recent research shows often—carpal tunnel syndrome and repetitive stress tendonitis in their arms and shoulders, for example. Finally, management and manipulation of the communication environment itself must often take place to facilitate the process. For example, while a seating/standing rearrangement of not only the speaker, interpreter, and receiver (or vice versa) often occurs in interpretation, even nonparticipants in the interpreting process must also often resituate themselves—moving out of the line of sight, giving up the front-row seats, and so on.

Psychological factors play as great a role, if not sometimes even greater, as do physical ones. The interpreter's success at becoming either anonymous and seemingly absent in the process—and yet also, if needed, the center of attention—is one dimension of the psychological arena that interpreting often occurs in. Interpreters often find that they must also walk multiple fine lines: moving between their needs and their client's needs, practicing advocacy without oppression or paternalism, negotiating the stress of communication speed and time, dealing with overlapping speech and/or signs, balancing their own ethics (over the discourse they receive) with the accuracy of what they express back, and simultaneously maintaining distance—yet some camaraderie—with their clients. Gender variations in receiving, encoding, and processing language are also likely to influence the interpreting process, although little research has been conducted in this area (the profession is dominated by approximately 75 percent women).

In addition to these psychological factors, as the availability and even quality of interpreters seem to increase, so do the standards of the people who use them. Thus, the interpreting process can be affected by these standards when interpreters are almost always caught in the center of blame for failed communication between the other two stakeholders and when interpreters are sometimes viewed as merely communication conduits (not humans with inherently fallible communication capabilities) or as prostheses (akin, for example, to a hearing aid). Psychological causes and effects have also come to surround the tension created by legislating deaf citizens' "rights" for interpreters and the institution of their existence as a paid professional act. A vacillation between (too much or too little) trust of them and a concern over too much dependency on them commonly defines their contemporary relationship with deaf clients, who have also come to understand that interpreters make a living (and a good one, at that) off of their socially constructed "disability." Interpreters in the post-ADA era are often cursed if they do and cursed if they don't do their jobs.

Beyond physical and psychological factors are variations in discourse/language forms and in the settings that interpretation takes place in. Examples of forms might include interpreting for deaf-blind clients, oral interpretation, transliterations of cued speech, relay interpreting (often used with clients who have minimal language competency) when two or more kinds of interpreters are involved, and the now common use of tag-team interpreting—when paired interpreters alternate turns in timed periods over the course of a longer period. Each of these interpreting formats can change the interpreting process substantially. In addition, the form of the signed language itself matters: whether, for example, American Sign Language (ASL) or a pidgin/contact version that moves toward English is used, such as Signed Exact English (SEE) or Pidgin Signed English (PSE). Code switching and lexical borrowing between these three, as well as across regional "dialects" of signs and levels of formality, are also likely to enter into the interpreting process.

Interpreting now takes place in an endless variety of settings. Even the most common of these settings illustrates the breadth of skills any one interpreter might need to successfully insert specialized discourses into the interpreting process: legal, health/medical, mental health, rehabilitation and workplace, performance or "platform," religious, educational (across all levels and subjects), and emergency situations.

EDUCATIONAL INTERPRETING

Since the Education for All Handicapped Law (P.L. 94–142) and the Individuals with Disabilities Education Act (IDEA) in 1973, educational interpreting has comprised the largest arena of certified interpreting. The "mainstreaming" or "inclusion" of deaf and hard-of-hearing students into "regular" classrooms and public school settings has probably created more questions and issues (and demands) for the interpreting profession than any other dimension. The stakes are so high and the ethical, legislative, and policy implications for placing (typically adult) interpreters alongside (typically children) clients throughout the course of a school day are so varied and immense that research around and general attention to educational interpreting have come to the forefront of the interpreting profession. As one study published in the *American Annals for the Deaf* has shown (Antia and Kreimeyer 2001), interpreters often come to occupy an interesting variety of additional roles in the course of those school days—clarifying teacher directions, facilitating peer interactions, tutoring deaf children, and even informing teachers of the deaf child's progress or difficulties.

ETHICS

As might be expected, the ethical issues around interpreting are thick and thorny. When one group of people (sign language interpreters) represents the communication of another group of people (deaf, signing) and literally even "voices" their expressions and ideas, difficulties are likely to arise. The development of an official code of ethics was one of the first acts the RID undertook at its inception. The first code set forth in 1964, however, was heavily flavored with religious undertones since interpreting in the United States and Canada was grounded in volunteers who interpreted for church services. But by 1965, only a year later, the first official RID Code of Ethics had been substantially revised to include eight major points that interpreters were expected to strive for and maintain: (1) confidentiality about client, assignment, and so forth; (2) accuracy and completeness of message; (3) impartiality; (4) discretion, especially in not working beyond their own competence; (5) compensation commensurate with professional standards and situation; (6) professional standards; (7) professional obligations such as continuing their education and updating skills; and (8) application of sound judgment in all interpreting situations.

SIGN POETRY

Sign poetry, like its written and spoken counterparts, is a literary art form recognized for its heightened use of language. Yet, rather than featuring the acoustic patterns of spoken language, sign poetry manipulates the visual, spatial, and kinetic properties of its embodied medium.

As manual languages have had no written form, the Deaf community has been practicing what could ironically be referred to as an "oral" literary tradition. They have handed down their traditions from generation to generation in Deaf schools, clubs, and social gatherings. As a part of this "oral tradition," the American Deaf community has generated several unique genres that derive from technical and literary play on the "manual constraints" of the language. The most prominent of these are known as "ABC poems," "number poems," and "handshape poems," where the poetic narratives are told with predetermined pattern of handshapes, either those of the manual alphabet or the number system, or other specific handshapes. These predetermined structural forms may be similar to other literary traditions that feature formal constraints such as sonnets, haiku, and acrostic poems. The literary merit of a poem is often determined by the poet's ability to work within the constraints to produce a poem that ultimately transcends them.

While this oral tradition has been a lively part of the Deaf community since the nineteenth century, two events in the last half of the twentieth century have had an impact on sign poetry. First, the validation that American Sign Language (ASL) is a full human language, which began in the 1960s, instigated a desire to exploit this language for its poetic potential in ways analogous to spoken and written poetic language. Several Deaf poets originally composed poems in written English until it became apparent that ASL could just as easily be the primary language of a new body of Deaf literature. Many of these poets emerged as their work was supported through the National Theatre for the Deaf, including Bernard Bragg, Dorothy Miles, Gil Eastman, Ella Mae Lentz, Joseph Castronovo, and Pat Graybill. The National Theatre of the Deaf's landmark performance of *My Third Eye* in 1971 represented a break with previous traditions of sign performance, which still placed the written text as the "script." Instead, *My Third Eye* began to feature sign language for its strong ability to create visual imagery, thereby placing the written text in a secondary role.

This newfound awareness of sign language and a growing sense of a Deaf culture were accompanied by the advent of video technology, which allowed poets to "write" their poems on video. Deaf poets began to create and revise their works according to rough video drafts of a poem. This technology transformed an "oral" tradition into a body of poetry that became published and distributed much like written poetry, only in video format. The first ASL poetry videotapes appeared in 1988, in the *Poetry in Motion* series produced by Sign Media Inc. These featured the works of Patrick Graybill, Debbie Rennie, and Clayton Valli. These tapes still sell widely within the Deaf community, yet as they are not voice interpreted, they are not accessible to nonsigners. In 1995, Ella Mae Lentz produced *The Treasure,* which broke new ground it its use of cinematic effects, including stage sets, costumes, and camera movements. Clayton Valli's *ASL Poetry: Selected Works of Clayton Valli,* which appeared in 1995, features a collection of Valli's poems. The author, however, does not recite the poems; instead, they are performed by a host of different signers, ranging from children younger than age 10 to older members of the Deaf community. After all of the poems have been performed, the text replays each in slow motion, explaining the various poetic techniques employed in the poems. Valli's *Selected Poetry* demonstrates the ways in which the linguistic validation of signed languages, accompanied by the use of video technology, has influenced the ways that critics discuss sign poetry and poetics.

Clayton Valli has identified a wide range of poetic techniques as they appear in signed languages. Rhymes, for example, are based not on sound patterns but on visual patterns of linguistic units. These units, which are equivalent to phonemic elements, consist of

- particular handshapes,
- movement paths of the hands,
- signing location,
- palm orientation, and
- nonmanual signals on the face and body.

A single poem may be threaded together with one or more of these rhyme types. A single handshape may run throughout a poem, a movement path (i.e., circular, diagonal, etc.) may lend a particular symbolic and aesthetic structure to a poem, or a repeated pattern signing location may accentuate contrasts between stanzas and topics.

In Clayton Valli's "Hands," for example, the principle handshape is the open "five" handshape, which Valli then uses to weave images that correspond to the seasons, each of which is placed along a larger circle, representing the full-year cycle. Valli ends the poem with breaking the plane of the circle, foregrounding his hands. In this poem, which takes less than a minute to perform, there is a complex structure of handshape, signing location, and nonmanual signals (facial expressions) that work simultaneously to create a distinct visual and spatial poetic effect.

Clayton Valli's work is highly structured and often lyrical. In fact, he often likens his work to the poetry of Robert Frost, who represents a lyrical, highly symbolic poetic tradition in American poetry. Yet, just as with broader traditions in American poetry, sign poetry also features emerging traditions. On one hand, poets such as Ella Mae Lentz, Clayton Valli, and Patrick Graybill create poems that are densely structured, highly lyrical, and often related to Deaf themes; other poets have created a more experimental, avant-garde tradition that might be likened to the imagist poetry of Ezra Pound and the beat poetry of Allen Ginsberg. These poets emerged from Rochester, New York, the hotbed of ASL poetry in the 1980s, including Debbie Rennie and Flying Words Project—Deaf poet Peter Cook and hearing collaborator, Kenny Lerner. This poetic community, inspired in part by hearing poet Jim Cohn, promoted sign poetry to both Deaf and hearing communities by sponsoring the first national ASL poetry conference and meetings with hearing poets such as Allen Ginsberg. Flying Words Project has now produced two videotapes, titled *The Year of Walking Dog: The Early Poems* and *The Can't Touch Tour: Current Works.*

This poetic tradition emphasizes the cinematic nature of the signed languages, often making deliberate use of the poetic technique named by Bernard Bragg as "visual vernacular." This technique enables the poet to embody characters and images within the poem, giving a distinctly cinematic impression, replete with such signed versions of cinematic techniques as closeup, medium and distant, and cut-away shots. In Debbie Rennie's "Missing Children," for example, Rennie deftly assumes the character of a small Nicaraguan boy and then a member of a government death squad, back and forth, until we witness the murder of the boy, which is told using another cinematic technique, slow motion. In addition, Flying Words Project often features cinematic techniques as a means of producing hard, clear images.

The work of Flying Words Project is unique in its use of spoken English as a part of the text. Most sign poetry has not been translated for hearing audiences. Poets are often very aware of the difficulties in translating a text from the visual, spatial, and kinetic domain of sign to the static written page, or the invisible voice. This is not to suggest, however, that sign poetry is not relevant to the wider practice of poetry. Indeed, poets have been experimenting with the visual and performative aspects of poetry. Sign poetry seems to realize some of the creative experimentations in poetic form, while also contributing to the aesthetic and literary aspects of Deaf culture.

Sign poetry, therefore, is an emerging domain of creative practice that promises to produce works that give a voice to Deaf resistance and affirmation, in addition to furthering the boundaries of conventional poetic practices that have been mostly confined to speech and writing.

▣ SOCIAL CAPITAL

Social capital is becoming an increasingly important and more generally accepted concept within the broad area of inquiry commonly referred to as social determinants of health. Social determinants of health include factors that influence health at multiple levels, including the individual, group, organization, community, system, and global levels. Factors such as risky behavior, social support, organizational culture, environmental stress, and the political system work simultaneously to determine the health of individuals and populations. More recently, the concept of social capital has been demonstrated to be an additional determinant of health and health outcomes (e.g., physical and mental morbidity) at both the person and group levels.

There are numerous definitions of *social capital,* but in general, the term is understood to refer to "resources" available to a population that bind it together as a system of social relations. The World Bank defines social capital as the norms and social relations embedded in the social structures of societies that enable people to coordinate action to achieve desired goals (www.worldbank.org/poverty/scapital/). Some research suggests that the resources that comprise social capital can be broken down into two parts: structural (i.e., how people interact with each other) and cognitive (i.e., how people perceive their interactions with others). Structural aspects of social capital could include the number and strength of social relationships, and cognitive aspects of social capital could include issues such as trust, sharing, and support. A second way to understand social capital is to view the "resources" according to their function. In this view, social capital is understood to have both a "bonding" and a "bridging" function. The bonding perspective suggests that social capital functions to bond similar and like groups to one another (social cohesion) at a horizontal or "within the same context" level. The bridging perspective suggests that social capital functions across contextual levels or vertically and aims to bridge relationships between different societal levels (social integration). An important distinction to keep in mind when defining social capital is that it is essentially an ecologic characteristic that is related to social structure. It is not a characteristic that is related to individual attributes as are the concepts of social support and social network.

The empirical relationship between social capital and health has just recently been demonstrated. In the United States, social capital has been shown to be associated with self-ratings of health, violent crime, heart disease, infant mortality, and life expectancy. In developing countries, social capital has been related to general household status. Several instruments to measure social capital have been developed, and most of them include variables that measure the structural and cognitive aspects of the construct. For example, factors related to connectedness and participation with family, friends, local communities, work, and neighborhoods are used to measure structure while, factors such as feelings of safety, trust, and tolerance of diversity can be used to measure the cognitive aspects of social capital.

The inclusion of social capital concepts, particularly as might be related to disability, provides numerous opportunities for new empirical research. For example, the notions of bonding and bridging functions suggest that the disability community might gain both local and national political power as it builds local community and national-level constituencies. Likewise, increased access to organizations that promote the working status of disabled individuals may increase feelings of self-esteem, thus demonstrating the positive impacts of both the structural and cognitive social capital.

More research is needed on how to incorporate the bonding and bridging concepts into social capital measurement, and there is also a need for combining these quantitative measures with more qualitative measures that might better capture the social capital of communities with diverse cultures, history, and health status.

SOCIAL MODELS

See Models

SOCIAL MODEL: SWEDEN

Before "social model" became an established way of thinking in disability research, a similar but not identical way of conceptualizing disability was developed in Swedish politics and research.

Since the 1970s, Swedish disability policy and disability research have been guided by what has become known in Sweden as "the relative concept of handicap." The basic meaning of such a concept is that handicap is something that arises in the meeting between an individual and his or her environment.

Handicap/disability was defined as a specific area of politics in the mid-1960s. A parliamentary investigation made clear that some groups were lagging behind in the development standard of living. Many of them suffered from chronic illness or different kinds of impairments. To capture their vulnerable situation, these different groups were collectively labeled "handicapped." Of course, several measures had been taken for groups with different impairments before that, but they were usually dealt with and thought of as separate groups—one type of measures for the intellectually disabled, another type for the visually disabled, and so on. What was new was the explicit formulation of a broader group as "handicapped."

Introducing such a general concept created a need to know what groups with different impairments had in common. In official documents, they were described in terms of the substantial difficulties they experienced in their daily living. From that definition, it was but a small step to realize that those difficulties were not in themselves a necessary outcome of having impairment. They were also dependent on the kind of environment in which individuals lived their daily lives. The relative way of defining handicap/disability grew out of that insight. It was especially promoted by the organizations of the disabled. In response to the general definition of handicap, organizations for groups with different impairments/disabilities came together during the 1970s and formed an "umbrella organization" that most energetically argued for a relative definition. If the environment is adjusted to the capabilities of disabled people, there will be no handicap. So, this organization argued, general reforms to change the environment are the most effective way of reducing the problems for people with impairments. The creation of "a society for all" should help eliminate or at least diminish problems of handicap in society. A clear expression of those ambitions was the internationally well-known formulation of the principle of normalization by Bengt Nirje, who was the ombudsman at the organization for persons with intellectual disabilities, which argued for the right of such persons to life patterns and living conditions that were as close to the normal patterns as possible.

In response to those demands, several reforms (such as a law demanding that new buildings be made accessible, the implementation of transport services in the municipalities supported by state grants, and laws that obliged the employer to adapt work environments and only to fire people on "objective grounds") were introduced.

During "the golden age of the welfare state," the social democratic hegemony in politics was well established. The beginning of the postwar period was driven by an ambition to create a material safety net for all citizens, but in the 1960s, those ambitions were raised. This was a decade of fast economic growth and bright forecasts for the future. But the structural changes that created the economic growth also created new social problems. This was pointed out by different interest groups (e.g., organizations of the disabled), and claims for further social reforms were often supported by public opinion.

The shift in ambitions was articulated in the vision of "the strong society": a society that had the means and resources to help "weak" persons and disadvantaged groups should not have social reforms that just aim at caring for or curing manifest problems. The ambition of prevention, of getting to the cause of the problems to solve them, became apparent in many areas. Education is a case in point. Earlier reforms strove to abandon a parallel school system in favor of a comprehensive school that gave equal opportunity to everyone. The school reforms of the 1970s had much broader ambitions. In a comprehensive school, children with such problems should not be segregated, but resources should be allocated to support managing problems within the ordinary school context.

The relative definition of handicap and the ideological arguments as formulated by the organizations of the disabled were thus in accordance with the general welfare ideology of the time.

The relative concept of handicap also influenced research. When the first initiatives to promote social research in the field (which had up until then been dominated by medical/clinical research) were taken in 1980s, it was explicitly stated that disability research should occupy itself with the process by which impairments were transformed into handicap—that is, the interplay between individual and environment that created disadvantages for persons with impairments. The initiative contributed to a wave of research that focused on evaluating reforms, often with the emphasis on how they affected the everyday lives of persons with disabilities, their social relations, and the possibilities to influence that situation.

The extent to which there is a "Swedish social model" grew out of these ambitions to create a "strong society," which were directed toward general environmental reforms, and the perspective on disabilities was a relative one.

But since the "golden era of the welfare state" and the introduction of the relative notion of handicap, Swedish society has changed. The centralized social engineering that characterized the "golden age" has been succeeded by a more decentralized and individualistic system. In the field of disability, this manifests itself in several ways. One is the introduction of "right laws," where a person with a severe disability can apply for specific services to which she or he is entitled to by law. The social engineers and the state are no longer responsible for centrally intervening and producing the services but are, through legislation, trying to strengthen the position of the individual in his or her dealing with local authorities. The general trend of individualization is also mirrored in the way different actors in the field conceptualize influence for persons with disabilities. In the earlier period, influence meant influence for the disability organizations, something that mirrors the collective and cooperative ideas of the time. The "strong society" needed a strong collective counterpart to legitimate the reforms. Nowadays, *influence* always refers to the possibilities that the individual has to influence her or his everyday life. Also, a concept such as "empowerment" is nowadays usually interpreted as empowering individuals, not collectives, with common interests.

This means a substantial change in what might be called "the Swedish social model." Redistribution of resources by collective labels is substituted by legally strengthening the individual's possibilities to steer her or his own life. Material welfare is substituted by identity politics. Formal rights of individuals are emphasized rather than obligations of the state to correct unjust distribution of resources.

This change can also be noticed in social research, although it is not as obvious. Most researchers still try to apply a relative perspective on disability. But the emphasis in research mirrors the political changes by focusing on the political catchwords of today: participation, influence, and empowerment for individuals rather than collectives and organizations, as well as individual identities more than political ideologies.

The basis of the "Swedish model," the relative definition of handicap, is still adhered to in politics as well as research. But the application of that framework is now more individualistic than before.

In international literature, "the social model" referred to is usually the one developed by English disability researchers. That model has a strong materialistic base and emphasizes the oppression that different groups of the disabled share. In that sense, it can be said to be a collective model that also underlines the liberation from oppression to be a collective task.

In that perspective, the "Swedish model" developed in the 1970s and 1980s shares some characteristics of the British model, at least more so than the present individualistic one. But there are also differences, the major one perhaps being that the "Swedish model" was developed in a close interplay between central politicians ("social engineers") and organizations of the disabled and consequently was more reformist than the comparatively militant British one. One way of expressing the difference is to say that both the Swedish model (in both its earlier and its present manifestations) and the British model share a relative notion of disability, emphasizing the role of environment. But the Swedish model is more focused on the interplay between individual and environment at different levels, while the British model focuses on the environmental side of that interplay. Or, to put it another way, the Swedish model is a "weak" example of a social model, while the British model, at least in its earliest formulation, is a "strong" social model.

SOCIAL NETWORKS

Social networks are basic building blocks of human experience. They map the connections that individuals have to one another. They also map relationships among organizations, for example, examining "cracks" in social service systems. Networks hold the potential to be rich sources of support, care, and information as well as monitoring, control, and hassle.

The idea that "others" are important has become a major focus in epidemiological and health services literatures. Much existing research has focused on the role of social ties, particularly social isolation, on mortality and morbidity. Networks have been demonstrated to be vectors of the incidence and prevalence of infectious disease, from common colds to HIV infection, as well as chronic problems such as heart disease. Networks have also been implicated in the consequence of health and disability, including the recognition of problems as physical or mental health issues, help seeking (e.g., knowledge, advice, access, system barriers), involuntary treatment (e.g., coercion), caregiving, adherence, and outcomes.

THE NATURE OF NETWORKS

The central focus is on relationships between a social actor ("ego" or the "focal" person, organization) and the social actors ("alters") with whom they have a certain kind of relationship. Three overall characteristics are central to mapping social networks: structure, content, and function. Structure targets the overall size of the network, the different types of relationships that people can have (e.g., kin, coworker), the basis of connection (i.e., multiplexity), how tightly knit the social network is (i.e., density), and strength (strong/weak, frequent/infrequent, close/distant). Content taps the kinds of things that flow from or to each individual or organizational actor (e.g., social support, contact-based resources, positive/negative valence, belief structure). Network ties can be helpful or harmful; they can integrate individuals into a community or isolate them from others. Finally, networks serve a variety of functions—emotional support (e.g., care and concern), instrumental aid (e.g., lending money, providing transportation), appraisal (e.g., evaluating a problem or a source of aid), and monitoring (e.g., making sure a person takes his or her medications).

For health- and disability-related concerns, another simple distinction is important—external and internal social networks. *External social networks* are composed of family and friends, which Freidson (1970) referred to as the "lay referral system" and Wellman (1982) called "personal communities of meaning." They map individuals' community-based relationships and represent the more usual notion of "community ties." *Internal social networks* are ties within treatment and rehabilitation organizations and systems. They open up the "black box" of treatment by seeing it, at least in part, as the human provision of care. Internal networks are not "treatment," but any diagnostic, treatment or rehabilitation instrument, or medication or manipulation delivered by human providers in human service organizations. Interventions determine "what" is offered; internal networks shape "how" it is implemented.

Three types of external tie relationships are important: between individuals and providers (client-provider), among providers within organizations (provider-provider), and among providers across organizations (agency-agency). The nature of these provider- and organization-level networks influences client participation and outcomes. Finally, inside and outside networks meet at the interface of community and treatment networks. They can work together or in opposition.

NETWORK THEORY

Social network perspectives aim to understand behavior through social relationships that shape everyday lives and experiences through exposure, consultation, resource sharing, suggestion, support, and nagging. While many epidemiological studies incorporate networks into their analysis of risk and protective factors, the most detailed theoretical frameworks address issues related to service use. For example, the health belief model, which focuses on whether individuals seek out preventive or curative medical services, incorporates social networks into its concept of normative influence. "Others" shape individuals' views of the efficacy and applicability of services.

The only existing network-based theory synthesizes work from a number of relevant traditions. The network episode model (NEM) starts with the idea that dealing with any health problem or disability is a social process managed through the contacts that individuals have in the community, the treatment system, and social service agencies. Interaction in social networks is the underlying mechanism at work, thereby contextualizing the response to disabilities in everyday life. Individuals are seen as pragmatic, having commonsense knowledge and cultural routines that they draw from past experience. People face disabilities by interacting with other people who may recognize (or deny) a problem, send them to (or provide) treatment, and support, cajole, or nag them about appointments, medications, or lifestyle. These day-to-day encounters provide meaning to issues surrounding health or physical impairment.

The "illness or disability career" marks all of an individual's attempts to cope with the onset of an episode of a health or physical impairment or associated acute illness episode, charting what individuals do and when they do it. Careers are embedded in personal lives and changing communities. At any time, network advisers may or may not be consulted, they may or may not be a stable set, or they may or may not be consistent in their advice. Strong ties may provide the greatest support, but weak ties act as a bridge to other resources. Too much oversight, whether positive or negative, can be stifling and repressive.

MEASUREMENT ISSUES

Deciding which kinds of social networks are of interest and how to elicit the ties are critical issues. There is no standard way to chart network relationships—they may be derived from a list on a survey form where individuals are asked to name persons they trust, consult, or dislike. The information may come from observing the behavior of individuals (e.g., who they talk to in their work group) or the behavior of organizations, checking which organizations in the health care system have referral agreements. They may also be different from the perspective of the interacting parties.

In surveys, the selection of the "stem question" or "network generator" can determine, for example, whether a researcher taps into a personal support network, a trail of contacts in a search for information, or a set of formal treatment arrangements. The network generator can elicit ties sent (e.g., On whom do you depend for advice?) or ties received (e.g., Who depends on you for advice?).

Sociodemographic characteristics, such as age, sex, race/ethnicity, and social class, cannot be used as indicators of existing social networks because their role in placing limits around interaction partners is decreasing historically. Sociodemographic characteristics may interact with social networks, for example, making the influence of social networks different for men and women.

FUTURE DIRECTIONS

Network theory contrasts with approaches focusing on individuals' cognitive maps. However, symptoms, identity, cognition, and even biology may shape and be shaped by social bonds. This view requires bringing together the expertise of different, traditional disciplines. Furthermore, networks are dynamic, not static, structures and processes. A consideration of the degree of change inherent in social networks requires that we consider the ebb and flow across time and over the illness career. This also raises the issue of the causal relationship between social networks and health status. The ability to form and maintain social ties may be the result of changes in health status (social consequence), not simply factors implicated in their cause (social causation).

Finally, a social network approach presents challenges in capturing social networks. Can they be measured with reasonable scientific precision and ethical sensitivity? Can we improve the measurement of networks while reducing their current cumbersome approaches? In 1986, Berkman suggested that adequate social network measures had not been developed and that this issue remains. We have only recently begun to discuss the inevitable ethical questions that surround asking people about intimate connections or using them clinically.

In sum, at this point in time, empirical findings mostly document that social networks matter rather than how or why they operate; how and why they change; how they are meshed with psychological, biological, or clinical factors; or how to efficiently and ethically map them.

SOCIAL SUPPORT

Social support has been diversely defined in the human services fields, often as perceived social support in the context of relief of stress (Sarason, Sarason, and Pierce 1990). In its purer sense, social support is a positive aspect of exchange between or among parties, offering benefits for the persons involved, families, neighbors and coworkers, organizations, associations, and even the broader community and society (human ecological roots; Brofenbrenner 1979).

The research contributions in this field concentrate on negative support (Riley and Eckenrode 1986) and the costs of social support (Schumaker and Brownell 1984), in addition to an understanding of its benefits to the well-being of the person. Social support is viewed as buffering critical life events (e.g., Lin, Woelfel, and Light 1985) and provides protection against the difficulties encountered in life (e.g., unemployment, death of spouse, divorce).

Social support has been defined in family support as mediating outcomes for the child, person, and family. In the research sense, it is a "multi-dimensional construct that includes physical and instrumental assistance, attitude transmission, resource and information sharing, and emotional and psychological support" (Dunst and Trivette 1986:403). Social support is also a personality characteristic (attachment theory), a sense of acceptance, and highly related to concepts such as intimacy (Sarason et al. 1990).

Social support is viewed as enhancing child rearing in families and as "encompassing a multitude of activities, relationships and subjective appraisals" (Vaux 1988). One of the goals of social support theory and practice is to improve the skills of community resources. Social support has more than 20 years of research and is one of the largest literatures in community and social intervention (Barrera 1999) contributing to the growth in community support.

Social networks is a related concept and research area that introduces the complexity of social ties and their contradictory nature (Cochran 1990). Social network research involves the acquisition of friends, the neighborhoods, the family status, social class and structures, and cultures of the world (e.g., Sweden). Social support intervention is also one of the purposes of social support research and has been the subject of studies on children and families, in work and welfare, in the community and neighborhoods, and in caregiving and service systems.

Today, social support has been described as consisting of formal and informal supports (Bulmer 1987), improving the understanding of the service systems that have proliferated in nations such as the United States and in countries in Europe, Asia, and Africa. In this context, social support has been studied by contrasting the perspectives of service users and workers on support (Racino and O'Connor 1994). Social support theory remains as leaders in many fields worldwide both conceptually and practically merge it with the newer consumer empowerment theories, including in service systems (see Racino 2000).

SOCIAL WORK

Social work is a profession that includes practice with individuals, families, groups, organizations, and communities toward the goal of enhancing human functioning. A key concept in social work practice is simultaneous emphasis on change for both individuals and the environment. According to the Code of Ethics of the National Association of Social Workers (NASW) in the United States, the mission of the social work profession includes helping to meet the basic human needs of all people, with a primary focus on the needs and empowerment of people who are poor, vulnerable, and/or oppressed. People with disabilities have historically been an important group to social workers as part of their professional mission. Core social work values relevant to working with people with disabilities include self-determination, social justice, and dignity and worth of the person.

The NASW issued a policy statement in 2003 that discusses these core values with respect to working with people with disabilities. Self-determination is a key value that emphasizes the importance of working *with* consumers rather than providing services *for* them. The NASW policy statement mandates the promotion of full participation of people with disabilities in decisions regarding housing, community accessibility, education, employment, income, and health care. Consistent with another key value, that of social justice, the NASW statement emphasizes that social workers are responsible to take action with people who have disabilities toward advocating for their rights to fully participate in society. The value of dignity and worth of the person implies that social workers should recognize people with disabilities from a strengths perspective, which requires a focus on abilities rather than limitations. Although these ideals are consistent with the current emphasis in the field of disabilities on choice and empowerment, actual social work practice with people who have disabilities has room for improvement in meeting these ideals.

Throughout the history of services for people with disabilities, social workers have fulfilled many roles. These roles have included a micro focus on working with individuals and families, a midlevel focus on developing and managing programs for people with disabilities, and a macro focus on advocating for changes in policies and attitudes on behalf of and with people with disabilities and their families.

Over the past several decades, the specific roles of social workers working with people with disabilities and their families (micro-level practice) have varied and evolved depending on shifting paradigms and service delivery models. During the 1960s and before, a medical model of service delivery was prevalent, and persons with disabilities were typically characterized as patients who had disorders, illnesses, and impediments. Service delivery settings included large institutions and custodial care. Within this context, social workers were often part of an interdisciplinary team of health professionals. They frequently served as counselors who helped individuals and primarily their families adjust to the diagnosis and disability. During the 1970s and 1980s, a developmental approach was used in service delivery. Deinstutionalization was taking place, and community placement was the focus of intervention. Persons with disabilities were typically considered to be clients. Social workers served as case managers who coordinated individual program plans. These plans were focused along a developmental continuum that assessed skills needed by persons with disabilities to move them into less restrictive vocational and living environments. More recently, a support model of care is being implemented that considers persons with disabilities to be consumers and works to provide a number of individualized supports. The goal in this model is for consumers and their circles of support to direct their own service planning. In this context, social workers are collaborators with persons with disabilities and serve in roles as consultants and brokers.

Some examples of the support model are family support programs and cash and counseling programs. Family support programs are a way of providing flexible services to families who have children with disabilities through the provision of vouchers or cash allotments. Self-determination and empowering families are key components of these programs. Within family support programs, social workers serve as service coordinators, advocates, and brokers. Cash and counseling programs are a relatively new joint initiative of the Robert Wood Johnson Foundation and the Office of the Assistant Secretary for Planning and Evaluation at the U.S. Department of Health and Human Services. These programs allocate a monthly allowance to people with disabilities to use for long-term supports. A personal broker, who is often a social worker, is made available to help consumers make decisions about services, locate resources, and monitor the quality of supports and services. Consumers also have the option of managing an individualized budget instead of choosing a broker.

Although the support model of care is most consistent with the ideals and values of the social work profession, its implementation is in varying stages across the United States. Barriers to the expansion of home and community-based services include budgetary constraints and waiting lists. Furthermore, remnants of the medical and developmental models persist in many settings, and social workers continue to fulfill roles within these models.

In addition to support models of care, other domains that social workers are involved in include supportive living, vocational and employment services, health and mental health, transportation and accessibility, leisure and recreation, and social and sexuality issues. Social workers also fulfill roles in programs across the lifespan related to disabilities (e.g., birth to age three programs, school age, transition planning for older teens, adult services, and programs for the growing aging population). In their varying roles on the micro level of practice, social workers are trained to work across systems and on interdisciplinary teams as well. While health professionals address specific medical and treatment needs for people with disabilities, social workers complement these areas by working with people who have disabilities on social and environmental issues in their lives and on helping with the overall coordination of services. This may include advocating with and on behalf of consumers to eliminate barriers to receiving services or other necessities. Social workers are also involved in building bridges and supporting persons with disabilities to use the "generic" human service systems.

Within the field of disabilities, social workers are also involved in midlevel practice such as designing agency programs that serve people with disabilities and serving as managers and administrators of those programs. Social work education provides social workers with skills for community and administrative work, including the ability to see the larger picture of individuals and their interactions in the environment.

At the macro level, social workers are involved in advocating for and developing state and national disability policies. An important part of social work education is the development of skills relating to policy analysis and development as well as specialized skills in advocacy. Social work researchers are frequently involved in analyzing disability policy and programs and investigating the effectiveness of new programs and models of care. An example of social work professionals' involvement in advocacy is the active participation in the self-advocacy movement by the late Gunner Dybwad. Professor Dybwad was a social worker and lawyer by training as well as a professor at the Heller School of Social Welfare Policy at Brandeis University in Waltham, Massachusetts. Professor Dybwad, other social workers, and professionals in other fields have worked side by side with people with disabilities to build national organizations and a national movement to push for empowerment of people with disabilities on a political level.

In summary, the movement in the disability field toward self-determination and empowerment is consistent with the mission and ideals of the social work profession. While social workers are involved in the provision and coordination of services to people with disabilities, their role as collaborators and advocates is essential to their own professional values and to the disability movement. Social workers play valuable roles in service provision and ensuring quality of life for people who have disabilities, and these roles encompass micro, midlevel, and macro levels of practice.

SOCIOECONOMIC CLASS

Disability and *social class* are both contested terms, so this entry begins by noting the different ways in which both of these terms have been used by different actors and for diverse purposes. Subsequently, the interaction of disability and social class is examined in a range of key policy arenas (health, employment, income, and benefits and education). Because of difficulties in accessing international statistics in this area, selected Scottish and U.K. statistics are used. A different picture might emerge in different international contexts (e.g., the United States, Nordic countries, developing countries). Overall, it is argued that the relationship between disability and social class has not been widely explored in part because both these terms are conceptually complex. However, in his classic study of poverty in the United Kingdom, undertaken in the 1970s, Peter Townsend (1979) noted, "More of the working, than the middle class, particularly unskilled manual workers and their families, are disabled. Increasing incapacity is correlated with falling cash incomes. . . . At successive ages, greater incapacity was associated with greater risk of being poor." Today, the evidence continues to indicate that poorer people are more likely to be disabled, and disabled people become poorer as a direct result of their impairment and of the discriminatory attitudes and barriers that surround them. There is very little research and writing, however, on the subjective experience of social class and disability and the way these two elements interrelate in the formation of individual identities. Before discussing the available evidence, it is necessary to review briefly current thinking in relation to the conceptualization of both disability and social class.

DISABILITY AND SOCIOECONOMIC CLASS: DEFINING THE CONCEPTS

In the welfare states of industrialized countries, disability has often been defined in terms of administrative categories devised by social security or social services to determine access to benefits and services. For example, Deborah Stone (1984) noted that disability originated as an "administrative category out of a collection of separate conditions understood to be legitimate reasons for not working." Major surveys conducted within the United Kingdom and Scotland have sought to determine how many people are disabled by asking whether individuals have a long-term illness or disability that has an impact on their normal daily activities or ability to work. Surveys conducted in Scotland for a range of purposes have produced similar findings with regard to the proportion of disabled people. For example:

- The Scottish Executive Health Department, based on its own data, estimated that there were 800,000 disabled adults in Scotland in 1999. This is about 20 percent of the adult population.
- The Scottish Household Survey of 2001 found that 20 percent of respondents reported a disability or long-standing illness.
- Labour Force Survey data estimate that there are 636,000 disabled people of working age in Scotland (20 percent of the working-age population).
- The Scottish Household Survey of 2001 found increasing incidence of disability with age. Forty percent of people age 65 or older reported a disability or long-term illness, in contrast to 5 percent of people ages 16 to 24.

The surveys referred to above adopt a categorical approach, assuming a dichotomy between disabled and nondisabled people. The Disability Discrimination Act of 1995 also operates on the assumption that a distinction may be drawn between disabled and nondisabled people. Under the terms of the act, a person is disabled if he or she has a physical or mental impairment that has a significant and long-term adverse effect on that person's ability to perform normal day-to-day activities.

This categorical view of disability has been challenged by the social model of disability, which drew a distinction between disability and impairment and emphasized the social relational nature of disability (see, e.g., the work of Michael Oliver [1990] and Colin Barnes [1991], key players in the development of social model thinking in the United Kingdom). Within the social model, disability is seen as independent of impairment in that it is a product of the social context in which impairment is experienced. Recently, postmodern and poststructuralist writers have taken these arguments further, critiquing the taken-for-granted distinction between disabled and nondisabled people. Writers such as Mairian Corker and Tom Shakespeare (2002) have argued that such dichotomies perpetuate Enlightenment fallacies that social categories and constructions are "real." Recent writing on disability, culture, and identity has draw attention to the diversity of disabled people's cultural experiences, which may be shaped by their age, gender, or ethnic identity as well as the nature of their impairment. There is, therefore, an unresolved tension between those who work on the assumption that the categories of disabled and nondisabled are meaningful, having their basis in material reality, and those who see these categories as social constructs.

Very similar tensions exist in the field of social class, and commentators have noted the problematic nature of social class categories. Many different definitions of social class exist, but they are generally based on the idea that an individual's social class position is determined by his or her access to economic, social, and cultural resources or capital. Social class is often defined in relation to occupation, and a number of classificatory models and scales are still used extensively. The Registrar General's Classification of Occupation, until recently the most commonly used system in the United Kingdom, grouped the population into six classes on the basis of occupation (1, professional; 2, managerial; 3-NM, skilled nonmanual; 3-M, skilled manual; 4, partly skilled; 5, unskilled). A similar social grade system is used by the Market Research Society (A, B, C1, C2, D, E). Such scales are frequently revised. For example, in November 1998, the Office for National Statistics (ONS) announced the U.K. government's new social classification system, the National Statistics Socio-Economic Classification (NS-SEC), which uses seven occupational categories.

There are a number of problems with occupational classification systems. For example, people who are economically inactive are classified as "other," and in certain parts of the United Kingdom, numbers thus classified may be as high as 50 percent of the population. Members of the category may be very diverse since it includes people on long-term incapacity benefits and those who have been out of work for a short period of time but are likely to find work, possibly at a professional level. The categories were defined with men rather than women in mind and do not accommodate easily families in which the mother and father have different occupations. In addition, as the service sector expands, more jobs are likely to be classified as 3-NM, but in terms of substance, pay, and degree of autonomy, these may differ little from jobs in the old manufacturing sectors. Furthermore, the categories do not readily reflect the position of young people such as university students. It is assumed that young people retain the social class of their families until they have independent jobs. However, with the collapse of the youth labor market in the late 1970s, there has increasingly been a delay in young people having occupational locations independent of their parents. Critics of the occupational classificatory system also point out that the category assigned to individuals may bear little relationship to their internal sense of social class. So, for example, those with professional occupations would be defined as middle class, irrespective of their social origins and identity. Even if individuals have professional occupations, their parents may have had unskilled occupations, and their working-class origins may be more significant in their identity than their more recently acquired occupational status. An assigned social class status may therefore have little subjective validity.

As a result of dissatisfaction with defining social class in relation to an individual's occupation, alternative ways of measuring deprivation have focused on assessing multiple indicators of deprivation. Classificatory systems, such as the Carstairs Deprivation Index, characterize geographical areas on the basis of the characteristics of individuals and households in those areas. The Carstairs Deprivation Index is based on measures of overcrowding, male unemployment, low social class (as measured by occupation), and car ownership. In Scotland, the population is normally distributed from 1 (least deprived) to 7 (most deprived), but some areas have far greater concentrations of people in the most or least deprived categories. For example, in the area covered by the Greater Glasgow Health Board, more than half (51 percent) of the population lives in deprivation categories 6 or 7.

Given the spatial distribution of deprivation, there are arguments over whether regeneration strategies should focus on individuals or on areas where there are clusters of deprivation. There are also debates between those who argue that poverty should be the focus of analysis and those who maintain that there should be a wider focus on social exclusion. The concept of social exclusion, which is highly influential within European and U.K. social policy, emphasizes the multidimensionality of marginalization, which may relate to, for example, people's ethnic as well as their social class location. Social exclusion theorists also stress the complex ramifications of exclusionary processes, which go beyond material deprivation to inadequate social participation, lack of social integration, and lack of power.

To summarize, in relation to both disability and social class, the use of categorical data has been criticized for imposing an oversimplified dichotomous worldview (see, e.g., Paul Abberley's [1987] critique of the OPCS [Office of Population, Censuses and Surveys, United Kingdom] categorization of disability, on the grounds that it is based on a medical reductionist view of the world). Alternative approaches have been suggested by cultural theorists such as Raymond Williams, who argues that social class goes much deeper than occupation and should be understood in terms of the structuring of emotions and consciousness. The sociologist Bourdieu (1984) developed the idea of social class habitus, reflecting the idea of social class as a fundamental framework structuring experiences and shaping the lens through which the individual views the world.

While categorical data on social characteristics have been criticized as tools of an increasingly managerialist society, it is important to remember that such information may also be used in pursuit of social justice goals. Monitoring of institutional performance against equality indicators is promoted by the British Equality Commissions and U.K. Government Social Inclusion Units. Some researchers have explicitly tried to work with both categorical and interpretative approaches. For example, Louise Archer's study of widening access to higher education adopted multiple strategies, using fixed categories to analyze statistical patterns of participation while also exploring the way in which particular groups of students negotiate their identities within specific institutional contexts (Archer, Hutchings, and Ross 2003).

Note: Deprivation categories 1–7 are based on the Carstairs Deprivation Index. See text for an explanation.

In the following sections, official statistics are used to explore some of the emerging relationships between social class and disability before considering the types of research that will be needed in the future to investigate the ways in which subjective identities and experiences are shaped simultaneously by a range of factors, including social class and disability.

DISABILITY, SOCIAL CLASS, AND HEALTH

Sickness and *disability* are not synonymous, and many disabled people are perfectly healthy. However, it is important to recognize that people who are seriously ill are likely to be disabled; indeed, stroke is the biggest cause of long-term impairment in Scotland. Within a number of European countries, including Scotland, there are marked and growing inequalities between the health of richer and poorer communities. Abberley (1987) drew attention to the importance of investigating the social creation, as well as the social construction, of disability, pointing out that, particularly in the developing world, much illness and disability arise as a result of war, pollution, and the lack of access to clean drinking water and basic medication. In the developed world, the growing gap between rich and poor has led to greater diversity in life chances and life expectancy. It is extremely important, therefore, to examine the links between major illnesses and social class.

Figure 1 illustrates the relationship between stroke, deprivation category, and age. The incidence of stroke increases with age (in 1997–1998, more than 80 percent of people admitted to the hospital with stroke were age 60+). For people who are age 65 and older, there is no significant relationship between deprivation category and death from stroke. However, for people younger than 65, there is a very strong relationship. In essence, younger people from the most deprived backgrounds in Scotland are about three times as likely to die from stroke as people from the least deprived backgrounds. Among stroke survivors, about half are left with a permanent impairment. A recent study of young stroke survivors in Scotland, led by Pauline Banks of the Strathclyde Centre for Disability Research at the University of Glasgow, found that two thirds of these people did not return to work after experiencing a stroke.

There are also very strong associations between mental health problems and social deprivation. In contrast with the erroneous perception that high-flying business executives experience the greatest levels of stress, Figure 2 demonstrates that people with the highest levels of deprivation are about three times as likely to visit their general practitioner (GP) as a result of a mental health problem compared with those with the lowest levels of deprivation. Figure 2 also reveals an important story in relation to gender, with women in all social groups significantly more likely than men to visit their GPs as a result of a mental health problem.

Poorer people in Scotland are also more likely to be diagnosed with lung and cervical cancer, and among

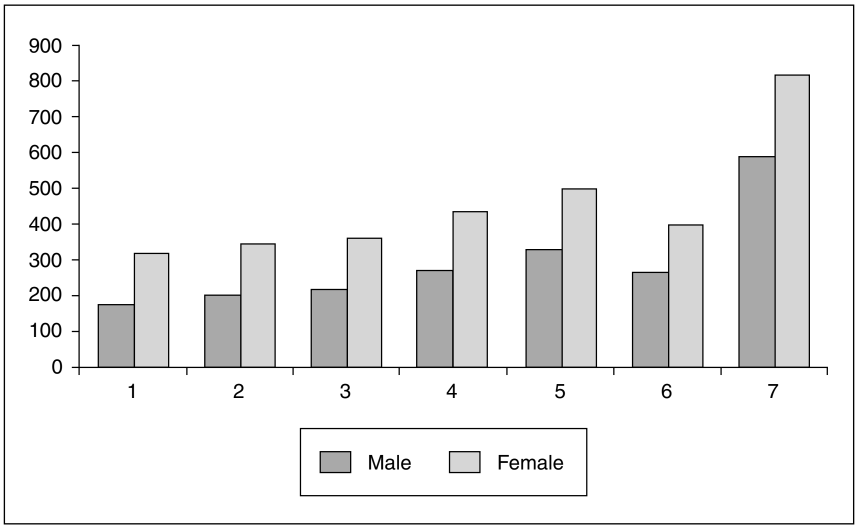

Figure 2 Mental Health: GP Contacts (Rate Per 1,000 Population) by Deprivation Category in Scotland, Year Ending March 2000

Note: Deprivation categories 1–7 are based on the Carstairs Deprivation Index. See text for an explanation.

the four most common forms of cancer (lung, cervical, breast, and bowel), there is decreased survival with increasing deprivation. Scottish Executive data reviewed by Riddell and Banks (2001) demonstrates that children living in deprived areas are also more likely to be killed or injured in road traffic accidents. These findings all reinforce the arguments made by Carol Thomas that there is a need for a greater rapprochement between disability studies and medical sociology, recognizing that the latter may be one of the "engines for the formulation of an ever more sophisticated sociology of disability." The development of a social model of health in tandem with the social model of disability may help to develop a "materialist theorisation of disability, but one that encompasses questions of culture, difference and impairment."

DISABILITY, SOCIAL CLASS, AND EMPLOYMENT

As noted above in relation to young stroke survivors, there are strong associations between disability, health, and employment, with significant consequences for income, quality of life, and life chances. Using Labour Force Survey data, Figure 3 illustrates the marginalization of disabled people in Scotland in relation to employment. In Scotland, in winter 2001, the Labour Force Survey found the following:

- Disabled people in Scotland account for 20 percent of the working-age population and 11 percent of the workforce.
- Of disabled people, 39 percent had work, in contrast to 81 percent of nondisabled people.
- Fifty percent of disabled people were not working and were on state benefits compared with 6 percent of nondisabled people.
- Of the disabled people of working age in Scotland, 22 percent were not working and were on state benefits but would like to work, compared with 5 percent of nondisabled people.
- Of the disabled people on benefits, 41 percent would like to work. This represents about 136,000 people.

The U.K. New Labour government emphasizes employment as the key to social inclusion, and in a green paper published in 1998, it promised "work for those who can; security for those who cannot." The government's strategy to improve the position of disabled people in employment is three-pronged. First, the Disability Discrimination Act (DDA) of 1995 (as amended) made it unlawful for employers to discriminate against disabled people in relation to employment, access to goods and services, and, since 2001, education. Second, a range of government-funded programs is intended to help disabled people enter and retain employment. Finally, as spelled out in a green paper published in 2003, access to long-term incapacity benefits is to be made more difficult, so that fewer people are certified as permanently incapable of working. Evidence of the success of these measures suggests that employers may not be aware of their new duties under the DDA and that government programs may offer insufficient support to disabled people, particularly those with higher support needs. The extent

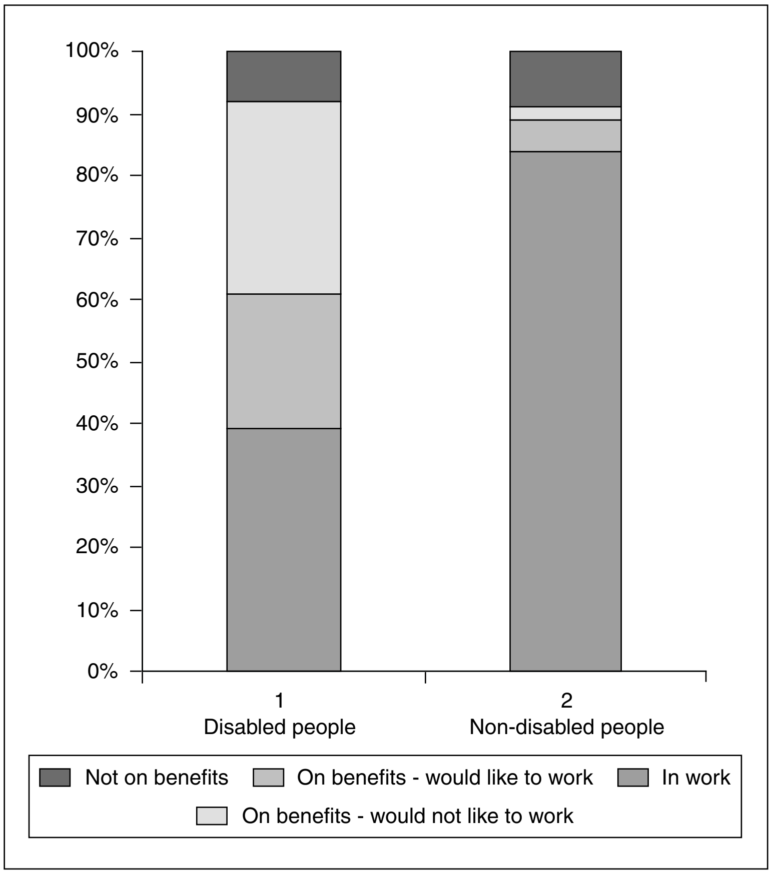

Figure 3 Disabled People in the Labor Market in Scotland

Source: Labour Force Survey, winter 2001.

to which the government will be successful in its goal of reducing the number of people on long-term incapacity benefits remains to be seen.

The complexity of this area is illustrated by analysis of economic inactivity in Glasgow, based on data from the Department for Work and Pensions for 2002. In Glasgow, 111,000 (40 percent of the working-age population) claimed some sort of state unemployment benefit. Claimants fell into the following categories:

18,700 unemployed claiming Job Seekers Allowance

16,800 lone parents

70,800 sick and disabled

4,700 other category

There are thus almost four times as many people on long-term incapacity benefits as there are on unemployment benefits, and the percentage of people who are claiming long-term incapacity benefits accounts for 25 percent of the working-age population (1 in 4). Clearly, these numbers need careful interpretation; during the 1980s, there was a deliberate policy to move people onto incapacity benefits to massage the unemployment figures. For claimants themselves, there are advantages to claiming incapacity benefits because these are slightly higher than unemployment benefits, and at least until recently, there has been no pressure on claimants with incapacity benefits to seek work. However, as we noted in the previous section, Glasgow has very poor health compared with Scotland, the rest of the United Kingdom, and Europe. This results in extremely high levels of impairment, with serious consequences in terms of poverty and social marginalization.

The focus of research in relation to disabled people and employment has tended to be on those who are economically inactive because the level of long-term incapacity benefits claims is construed as a "social problem." Much less is known about the employment experiences of professional or skilled disabled workers, although Alan Roulstone (1998) studied disabled people's experience of new technology in employment and included a wide range of people, including those attempting to break into the labor market, who had little control over the technology, and those working in higher-level occupations, who had much more say over the way in which new technology was used to enhance their working lives.

DISABILITY, SOCIAL CLASS, AND HOUSEHOLD INCOME

As noted above, disabled people are much less likely to be employed than are nondisabled people, and this has major implications for quality of life, power, and autonomy. Overall, 11 percent of the working-age population in Scotland receives incapacity benefits (although the proportion in certain areas, such as Glasgow, is much higher). Scottish Household Survey data in Figure 4 show that 33 percent of households with a disabled person have an income of less than £6,000, compared with 26 percent of households of persons without a disabled person. Only 6 percent of households with a disabled person have an income of more than £20,000, in contrast to 24 percent of households without a disabled person. As we noted earlier, disabled people are more likely to be poor than the rest of the population, and occupational-based measures of social class may fail to capture this concentration of poverty, classifying those who are economically inactive as "other," particularly if they have been out of work for many years or have never worked.

DISABILITY AND DECLINING SOCIAL CLASS

For many people, disability is linked to declining access to economic, social, and cultural capital. Research has demonstrated, for example, that the onset of illness or the worsening of a long-term condition is associated with a drop in living standards and the loss of employment. Figure 5, for example, draws on data from a study of people with neuromuscular dystrophies, led by Pauline Banks of the Strathclyde Centre for Disability Research, University of Glasgow. People with neuromuscular dystrophies were asked if they had a job, including self-employment, but were no longer working; how long they worked after first noticing symptoms of their illness; and at what age they had stopped working. Analysis revealed the following:

- More than half of all people with neuromuscular dystrophies (51.4 percent) stopped working prior to age 60. Of these, 33 (26.2 percent) stopped working in their 50s, 31 (24.6 percent) in their 40s, 28 (22.2 percent) in their 30s, 24 (19 percent) in their 20s, and 10 (7.9 percent) during their teens.
- Of people with neuromuscular dystrophies who retired before they were age 60 (n = 126), 54 (42.9 percent) did not work at all following the onset of symptoms, 39 (31 percent) worked for between 1 and 5 years, six (4.8 percent) worked for 6 to 10 years, and 27 (21.4 percent) worked for 11+ years.

Qualitative data from the Strathclyde Centre for Disability Research studies of people with neuromuscular dystrophies and Parkinson's disease indicated that the loss of work was accompanied by a deepening sense of financial anxiety and social marginalization. These findings echo Townsend's (1979) work, which documented the cumulative detrimental effects of lacking the financial resources necessary to participate in normal social events such as having holidays, visiting friends, and giving birthday presents.

It should be noted that there are negative consequences associated with having any member of the household with a disability. For example, living with an older disabled relative or having a disabled child affects the ability of working-age adults, particularly women, to hold down a job and advance in their career. This finding is reinforced by Kirsten Stalker's review of services supporting disabled children and their families in Scotland, funded by the Joseph Rowntree Foundation. A number of studies have also

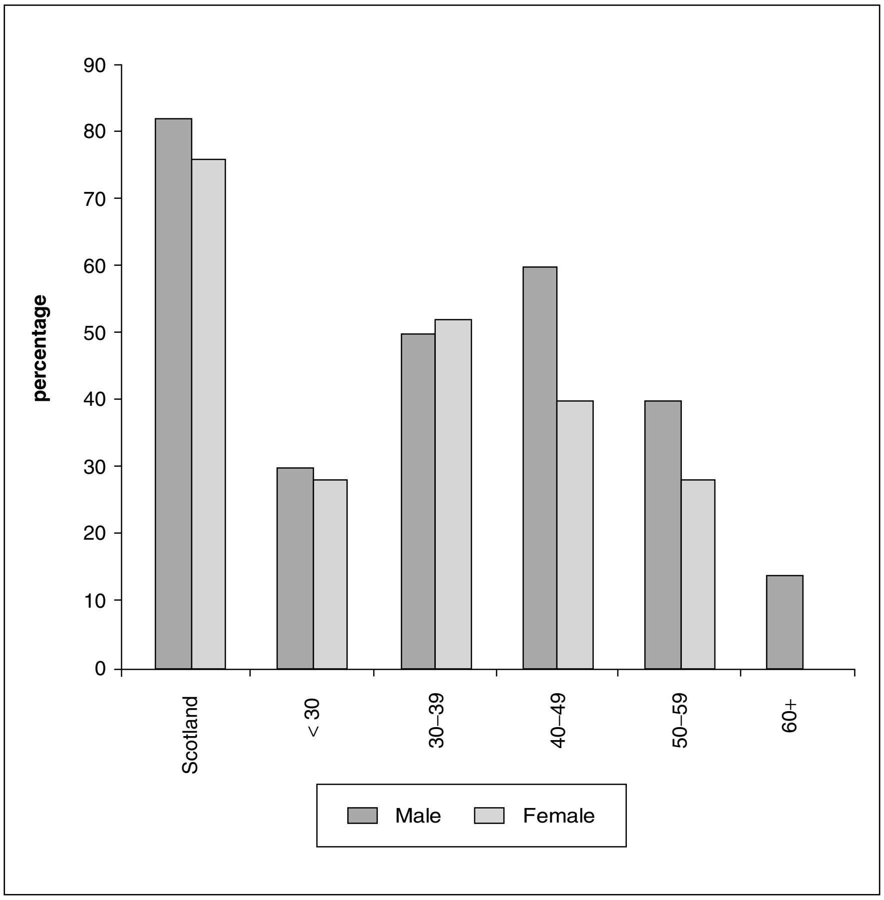

Figure 5 People with Neuromuscular Disorders and Scottish Employment Rate by Gender and Age Group

Source: Edson et al. (2003).

pointed to the inadequacy of benefits that are intended to assist disabled people and parents of disabled children. In the United Kingdom, the Disability Living Allowance (DLA) is intended to help people with the added expense of having a disability. A recent study funded by Disability Agenda Scotland found that 97 percent of respondents had extreme difficulties in claiming the funds available, partly as a result of overcomplicated forms and difficulty communicating with the Benefits Agency.

A number of Scottish studies mentioned above indicate that many of those at risk of experiencing illness or having a disabled child are already leading a marginalized and stressful social existence and often living in poor housing conditions on rundown estates (see the data presented earlier on mental health problems, stroke, and deprivation). Local education, health, and social services may have become residualized, as market-based policies ensure that the more entrepreneurial are able to use services in more advantaged neighborhoods. The onset of illness or the birth of a disabled child may intensify an existing experience of social exclusion. At the same time, it is important to remember that illness or the birth of a disabled child may affect people across the social spectrum, including the relatively comfortable middle class. There is therefore a need for longitudinal research to track the interaction of illness and social class over time.

DISABILITY, SOCIAL CLASS, AND EDUCATION

Within educational sociology, there is a considerable body of research in the "political arithmetic" tradition that has charted working-class pupils' poorer educational attainment on entry to school and their slower rates of progress compared with middle-class pupils during their time in school. More recent work has begun to explore the strategies used by middle-class parents to secure their family's positional advantage within education. While it is known that children of poorer parents, particularly boys, are more likely to be assessed as having moderate learning difficulties and/or social, emotional, and behavioral difficulties, studies of educational outcomes in relation to social class have generally not considered disability as a key variable. There is a body of work, however, that has explored the construction of deficit categories in school over time. It has been noted, for example, that dyslexia is much more likely to be diagnosed among middle-class than working-class pupils.

Within the higher education sector, greater attention has been focused on access to higher education

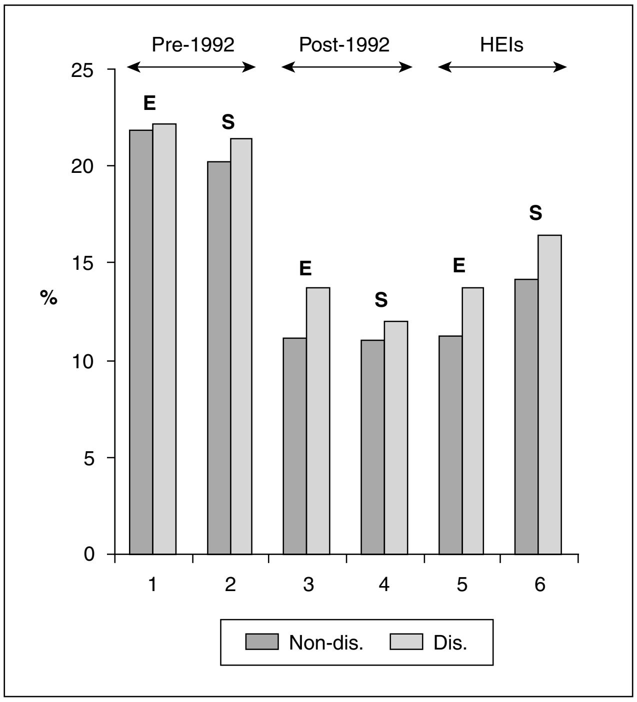

Figure 6 Percentage of Undergraduates from Social Class 1* by Sector, Country, and Disability Status

HELs: Higher education institutions without university status.

over recent years, given the growing importance of higher-level qualifications in accessing professional and managerial employment. Studies have traditionally compared the relative chances of children from working-class and middle-class families of winning a place in higher education. Government reports on widening access to higher education have picked up on these studies and have often interpreted access to higher education in terms of enhancing the access of children whose parents (usually fathers) have working-class occupations or are from low participating neighborhoods and schools.

Until 2002, data on the disability status of higher education students were not published by the U.K. Higher Education Statistics Agency. Disabled students are now included officially as an "underrepresented group," and the disability indicator is based on the number of students receiving the Disabled Students Allowance on the basis of a needs assessment. The Funding Councils make additional premium payments to institutions based on social class and disability indicators. The benchmarks published in relation to each indicator are based on the performance of other comparable institutions in the sector and are intended to signal to institutions whether they are performing better or worse than expected.

Recent work by Riddell, Wilson, and Tinklin (2002) on access to higher education in the United Kingdom has looked at the interrelationships of a range of variables, including social class, gender, disability, and ethnicity. Higher education institutions fall into three categories: traditional pre-1992 universities, new post-1992 universities, and higher education institutions, which have degree-awarding powers but not university status. The findings, shown in Figure 6, indicate that disabled students in the elite universities share the privileged social class background of the majority of other students in those institutions. This again underlies the point that it is quite wrong to regard disabled people as a homogeneous group. The divisions among disabled people in relation to social class, ethnicity, gender, and nature of impairment need to be investigated to develop a more sophisticated sociology of disability.

DISABLED PEOPLE AND REGENERATION

It was noted earlier that there have been ongoing debates about whether deprivation should be measured on the basis of an individual's social class or in relation to the cumulative measures of deprivation within an area. Traditionally, urban regeneration programs have focused their energies on areas rather than individuals. However, recent reviews of regeneration strategies have indicated a tendency to base their interventions on the assumption of a homogeneous population. Little attention has been paid to the particular situation of disabled people, those from minority ethnic groups, travelers, lone parents, and so on. Regeneration programs have frequently sought to involve community groups, but disabled people have rarely formed pan-impairment groups and, as a result, have not been easily identifiable in consultation processes. Where disabled people have been involved in regeneration strategies, it is often as a result of a particularly targeted initiative, and they have rarely been included in consultations as ordinary members of communities. Given the overrepresentation of disabled people in areas of deprivation, it is important that more effective ways are found of consulting and involving them in local economic development.

CONCLUSION

We began by noting the conceptual problems in trying to work with disability and social class as social variables. Nonetheless, the categories do still have some utility as organizing frameworks connected to the material realities of people's lives. Statistical data were used to demonstrate that people experiencing high levels of deprivation, another way of measuring social class, were much more likely to experience serious health problems than people living in more socially advantaged circumstances. Attention was drawn to the concentration of disabled people among those classified as economically inactive, highlighting the problem with traditional measures of social class, which would assign all those not working to the category of "other." Data on household income revealed the financial consequences of exclusion from the labor market, with many households including a disabled person experiencing a significant degree of poverty. Despite the evidence of the links between social deprivation and disability, as well as the tendency of the onset of illness to trigger further social and economic hardship, urban regeneration programs have tended to bypass disabled people because of their invisibility.

Overall, there appear to be strong arguments for the development of more research that systematically investigates the links between different equality and social justice concerns, so that people are not conceived of as unidimensional subjects. Such studies would also need to track changes in social identity and social status over time. This is in line with the U.K. government's attempts to "mainstream" equality issues, possibly establishing a single commission to deal with all six equality strands covered by Article 13 of the European Union's Employment Directive. However, it should be noted that social class does not feature as an equality issue, being dealt with as a social justice concern under a separate policy stream. Much research on disabled people, including work informed by the social model, has tended to assume that all disabled people have similar social class backgrounds and therefore encounter the same barriers. Research such as the higher education study, referred to above, notes that disabled people from socially advantaged backgrounds may share some of the positional goods of their social class, such as access to elite higher education institutions. Recognizing the diverse social class interests of disabled people may be seen as undermining the unity of the disability movement, but in the long run, a more nuanced analysis is likely to lead to a stronger sociology of disability that is able to feed into the future development of the political movement.

SOCIOLOGY

The identification and experience of disability takes place on a daily basis within the social context, whether in the home or workplace, a rehabilitation center or a shopping center, a neighborhood or a foreign country. Because of this, sociology, which is a discipline that examines the social structure as well as social relationships and interactions, provides a key perspective to understanding that identification process and the experience of living with a disability. Disability is most commonly examined within the specialization of medical sociology, which is an area that focuses on the structure of the health care system as well as the delivery and receipt of health care within the health care institutions that have been developed in a particular society. These institutions can be hospitals, rehabilitation facilities, and health maintenance organizations in the broader U.S. society or the system of barefoot doctors within the Chinese culture. However, many of the other specialty areas of sociology can also provide insights into how we come to define disability and the ways that disability affects personal experience and relationships.

As a discipline, sociology provides ideas about how things work, at either a macro level or a micro level. Those ideas help to explain outcomes associated with a particular organizational structure or relationships in a particular social setting. For example, at the macro level, understanding how the factors within an organizational structure that are part of the accepted way to do things can either facilitate or inhibit the access of people with disabilities to employment within that organization. Sociologists try to understand these underlying assumptions that guide organizational behavior and thus create the outcomes that are observed. At a more micro level, sociologists try to understand how people interact with each other and what aspects of the cultural norms influence interaction in a variety of settings, both formal, such as a court of law, and informal, such as the family setting.

More than ever before, populations in most societies are experiencing circumstances that lead to disability, and these can also be addressed by sociological perspectives. It makes no difference whether the population varies ethnically, racially, or by age or gender; the increased presence of chronic illness, effects of pollution from environmental toxins, industrial or automobile accidents, and the increase in armed conflicts throughout the world create disabling problems for people everywhere. How, when, or why a society intervenes will influence the number and types of disabilities developed among the population. Medicine has taken on primary responsibility for those who experience disease or injury, but medical institutions, medical knowledge, and medical technology are inadequate to address all the issues that take place in the social context of the person who is born with or acquires a disability during his or her lifetime. Sociology as a discipline has developed a group of theories about how the social structure works or how people interact in social relationships. Any number of these can be applied to the study of disability.

One of the first and most important contributions of sociology to our knowledge about disability is the understanding that what constitutes "disability" itself is socially defined. Saad Nagi, a sociologist, was among the first to observe and write about the importance of the social context in defining and understanding disability. In 1965, he noted that disability can be understood as a pattern of behavior that evolves in a situation where there is long-term impairment associated with functional limitations. He described how these patterns of behavior are influenced, not only by the characteristics of the impairment and subsequent functional limitation but also by very socially defined aspects of life. These social aspects include the individual's definition of the situation and his and her reaction, *as well as* the reactions and expectations of those around the individual with the limitations. In more recent years, theoretical models of the relationship among impairments and functional limitations and social contextual factors have proliferated, with the Institute of Medicine model and the World Health Organization model being widely regarded as the most important. While there are some disagreements between the two models, both rely heavily on sociological concepts about social structure and social role.

SOCIAL DEFINITION

Paul Higgins (1992) has helped to explain how society defines disability by elaborating on the processes that are involved in that construction. Higgins and others have pointed out that we make disability through our beliefs and behaviors, through our interpersonal interaction, and through our organizational and social activities, and it is an active process that is ongoing daily. The beliefs and actions of a particular culture about disability are built through government policy, the media, programs that serve the disabled population, work or school situations, and the family. An important point to recognize in this process is that we produce the variation we recognize in others, whether it is associated with physical or mental capacity or skin color or age or gender. While this approach helps us understand how disability comes to be defined, it also documents how having a disability or being labeled as having a disability is experienced.

Most conceptualizing of disability individualizes the phenomenon; that is, the problem or condition is seen to reside within the individual. This is particularly reinforced in the medical setting, where the disease or impairment is diagnosed, labeled, and, if possible, treated. This is not necessarily inappropriate in that particular setting. However, when that label is attached to the individual, it not only provides a protocol for treatment but, when taken up by other branches of the social structure, also provides a validation for attributing the problem to the individual, thereby reinforcing the differentiation. Other elements of the "defining" process are associated with the socialization process, which is a common concept in sociology. We are all socialized into a variety of roles as we grow and mature. Our family socializes us to the role of son or daughter, sister or brother, while our schools socialize us to be students and to take on roles of independence such as work roles, citizenship roles, and others. Thus, the expectation that a person with an impairment or functional limitation is somehow less independent or less able to do certain tasks or take on certain roles (such as working) becomes a part of the social interactions surrounding and molding the person.

Other useful approaches to understanding the social construction of disability have also been developed. The minority group perspective that was developed by Hahn (1988), Gliedman and Roth (1980), and others does help to develop the conceptualization beyond the individual and forces the recognition of prejudice and discrimination toward the group of individuals with disabilities. A precursor to this approach was the study of attitudes toward persons with disabilities, which demonstrated that some impairments, such as mental retardation, are viewed more negatively than others. While the focus on attitudes was still based on the individualized approach to disability, it documented the widespread and relative uniform prejudice and discrimination toward specific groups. The minority group perspective was a step toward considering individuals as part of a group, regardless of their individual impairments, and subject to experiences because of their group membership rather than their individual characteristics.

SOCIAL MOVEMENTS

Sociological social movement theory has also contributed to understanding the changes in the opportunity structure for persons with disabilities in more recent years. As an outgrowth of the minority group perspective, Barnartt and Scotch (2001), among others, began tracking how persons with disabilities have sought to regain power and self-determination by participating in protests and other actions to improve (and, at times, reclaim since many acquired disability at later ages and at one time had lived as the "standard" of expectations) their status in society. In many ways, the upsurge of the disability movement, which began to be evident in the early 1970s, was not unlike the civil rights movement and the women's movement, although it took quite a while for the movement to gain the widespread support and recognition those earlier movements received.

Social movements are a form of collective behavior that occurs outside of the usual social structural context. Sociological theory provides discussion of the membership and goals of social movements as well as the types of tactics used in social movement activities. Basically, these movements are a reflection of power and politics and are generally focused on change of some sort. What is interesting about a social movement on disability is that the participants need to develop a collective consciousness to see beyond their individualized impairment. With the development of this consciousness on the part of persons with disabilities, the purpose of moving the social structure beyond the individualized perspective is solidified.

Early social movement activity by parents and caregivers for persons with disabilities, particularly mental retardation and mental illness, was aimed at improving conditions for these individuals who were often living in institutions. But those early movement activities did not reflect a collective consciousness on the part of persons with disabilities themselves, which was essential to develop the emotion needed to engage in the risky actions necessary to demonstrate the issues. The development of this collective consciousness across impairment types and the ability of those with disabilities to see themselves as one group with boundaries and also as one group with common experiences of prejudice and isolation was an important step in changing the social structure not only attitudinally but also physically.

As with blacks in the civil rights movement and women in the women's movement, a very important issue for the disability movement was equal opportunity, as represented by equal access to education and employment. However, the demands of the disability movement go further to address the issues of environmental accessibility of the built environment so that the buildings housing the education or work opportunity, as well as the shopping areas and other commercial areas, are useable for the population. Even governmental entities such as motor vehicle offices, public transportation, and the voting place have been areas for the focus of equal access.

MEASUREMENT AND COUNTING

The success of the disability social movement in changing both the social structure to protect the civil rights of persons with disabilities (as represented by the Americans with Disabilities Act) and the environmental access of people with disabilities to the built structure (through the Architectural Barriers Act) has created an imperative to be able to measure and count persons with disabilities to monitor the success of these laws. Sociology methodological studies have made an important contribution to this activities. However, measurement and counting are very tenuous activities. Measurement of a phenomenon is very much influenced by how it is defined, and the definition is associated with the purpose of the counting activity. The policy issues associated with these laws and other programs focused on the disabled population create a need for a fixed and dichotomous way to identify the population similar to a measure of sex or race. However, in fact, disability is more accurately conceived of as fluid and continuous. Irving Zola (1993), whose work made well-known contributions to the sociological study of disability, wrote about this problem with measuring and counting persons with disabilities and identified many of the problem areas.

A well-known analysis about the political aspects of enumeration concludes that "political judgments are implicit in the choice of what to measure, how to measure it, how often to measure it and how to present and interpret the results"(Alonso and Starr 1987:3). How we define disability, often a political decision, can make a great difference in how many we count and who we count. For example, if we define disability in terms of chronic disease conditions, we will undoubtedly find a different number than if we define disability in terms of specific functional limitations experienced by the individual. Not only will the numbers be different, but the people who are counted can also be different, at least partially, since not all persons with chronic conditions have functional limitations, and not all persons with functional limitations have chronic conditions.

Today, several groups, involving sociological methodologists, are seeking to define disability and measure it for a variety of purposes. Concern with the employment rates of persons with disabilities has prompted the Bureau of Labor Statistics to develop a measure of disability to use in its surveys that track employment rates of the working-age population. At the same time, another group associated with the census also seeks to develop a useful measure to identify the population with disabilities for the purpose of distributing resources and developing programs nationwide. This measure is of concern to the Social Security Administration as well since workers who can no longer work because of disability are eligible for benefits. Budgeting for this group requires accurate estimates of the potential numbers who will seek those benefits.

Once again, measurement of disability in large social surveys or in the census focuses on the individual and identifies a person as disabled based on his or her conditions, impairments, level of physical functioning, or ability to participate in major roles such as work roles and family roles. While the social movement activity and the theoretical models that explain disability have introduced the very important element of the environment to understanding that disability is the result of the interaction of the person with his or her environment, we are not yet able to adequately measure environment. Much of the social science research that contributes to our understanding of disability and the circumstances of the person with a disability is based on large national surveys whose methods for measuring disability vary widely. Great care must be taken in developing the measures, using the measures, and interpreting the measures and the results of analyses, be it levels of employment, living arrangements, or the use of assistive devices. Sociology has taken a lead in this important work.

As this brief discussion of the application of sociological theories, methodologies, and perspectives shows, sociology has been a rich source of intellectual ideas to help in understanding disability. Sociology contributes to a clear understanding of how the human variation that is identified as disability has come to be defined, both interpersonally and structurally. It has also contributed to developing measures of this phenomenon and interpreting the measures and the counts of persons with disabilities that result. Sociology also holds the potential for further contributions to the study of disability by providing a greater understanding of the role of the environment and the larger political context as a counterbalance to the interpretation of the individual responsibility for the problem. The important contributions of sociology to understanding the causes and consequences of poverty, the role of gender in the life of an individual, and the structure and functioning of social organizations are indicators of the largely untapped resource that sociology can provide to this field. In addition, the study of disability provides an important challenge to the field of sociology. Disability is a multifaceted construct, with all the complexity of gender or race but with additional dimensions as well. It can provide a test of the theories and methodologies that have been so carefully crafted over the past 100 or more years and will undoubtedly improve and refine those theories and methodologies in the process.

SOCRATES 469–399 BCE

Greek philosopher

According to his intellectual heirs, Plato and Aristotle, Socrates ceaselessly engaged his fellow citizens in an examination of the right way to live by a method of cross-questioning. Socrates's contemporary, the comic Aristophanes, shows us another side of the Athenian perception of Socrates, in which his interests are esoteric and his methods are annoying. From the perspective of disability studies, Socrates is especially interesting for two reasons. First, he is characterized in literature and in artistic representation as extremely unattractive, a counterpoint to the idea that the Greeks believed that wisdom and beauty were inseparable. Second, Socrates's characteristics, such as his susceptibility to trances and his unkempt appearance, would be categorized today as a medical diagnosis, perhaps schizophrenia or autism. Temple Grandin, in *Thinking in Pictures* (1995), points out that genius is, after all, an abnormality. Grandin describes geniuses such as Albert Einstein, who had little sense of social convention or personal appearance—"he just did not care" (p. 183). At the height of classical Athens, Socrates was tolerated—and venerated by some—for carrying out what he thought was his duty to be a stinging fly biting the horse of Athens so that Athens would not become complacent. After the disastrous Peloponnesian War, when Athens had crumbled and its citizens were nervous, a jury of his peers condemned Socrates to die in 399 BCE.

SOKOLOV, SERGEY I. (1888–1945)

Russian organizer of the Moscow Society of the Deaf

Sergey I. Sokolov was one of the organizers of the Moscow Society of the Deaf (1912) as well as chairman of the All-Russian Union of the Deaf (1917–1920). In the 1930s, he organized and was the director of a training course for sign language interpreters.

SOUTH ASIAN ARCHETYPES

In the Indian epics *Mahabharata* and *Ramayana,* characters such as blind King Dhritarashtra and his blindfolded wife, Gandhari; Ashtavakra, the "eight ways disabled" scholar; and the crafty hunchback Manthara (also known as Kubja) may be hard to link with historical people having dates of birth and places of residence. However, over centuries, they have been popular South Asian archetypes of disabled persons, known to hundreds of millions of people through local dramas drawn from the epics and, more recently, on film, video, the Internet, and schoolbooks.

Dhritarashtra, born blind, was thereby disqualified from kingship. He managed, nevertheless, to acquire the kingdom after his half-brother Pandu died. His disability and legitimacy thus became pivotal to the conflict between his own sons and Pandu's sons, providing the frame story for the *Mahabharata.* Dhritarashtra married Princess Gandhari, who immediately began wearing a blindfold to avoid the shameful situation of knowing more than her lord. Later, Dhritarashtra complained to his driver that because he was blind and could not engage actively in the conflict, his eldest son Duryodhana considered him a fool and paid little heed to his words.

Ashtavakra also appeared in the *Mahabharata.* When the learned Kahoda's wife became pregnant, the fetus, who was already well versed in the Vedas, found fault with Kahoda's reading. Kahoda cursed his yet unborn critic to be eight ways crooked. At King Janaka's court, Kahoda was defeated in academic debate by Vandin and forfeited his life. Later, as a young man, Ashtavakra went to King Janaka, but the guards refused him entry. He then asserted his rights as a Brahmin over "the blind, the deaf, the women, carriers of burdens, and the king respectively." He gained admittance and defeated Vandin in debate. Kahoda reappeared and reflected that weak men may have strong sons, stupid men may have clever sons. Ashtavakra later entered the river Samanga, and his limbs were straightened.

Manthara, hunchbacked maid to Queen Kaikeyi, was the hinge on which the *Ramayana* frame story turned. When King Dasaratha, the (earthly) father of Rama, became decrepit and nominated Rama to succeed him, Manthara persuaded the junior Queen Kaikeyi to campaign for enthronement of her own son instead. Manthara's wiles resulted in Rama's exile to the forest with his wife Sita. In Valmiki's *Ramayana,* Queen Kaikeyi thought that women with deformities were usually sinful and perverse, but Manthara's "hunch" contained her knowledge and wisdom. In some versions, Rama later reflected that in his boyhood, he teased Manthara about her disability, and this was why she took revenge on him or was the instrument by which the consequences of his mistaken conduct were visited upon him. (Such reflections do not appear in later versions that emphasize the divinity of Rama.)

SPECIAL EDUCATION

THE HISTORIES

Depending on the perspective taken, special education can be defined as follows: a legally mandated system of services that ensures access to educational provision for disabled students and their families; a mechanism that ensures some, but not all, children will be afforded access to life opportunities as a consequence of historically inequitable educational provision; or as an institutional safeguard to protect students and teachers in the general education system from the problems posed by disability and difference in public schools. Despite recent efforts that call for "inclusion" in public schools through the return of disabled students to the general education classroom and their neighborhood schools, special education continues to predominate within practice. In teacher education programs, inclusive education now forms part of the curriculum, either replacing "special needs" provision or coexisting uneasily with it. According to Slee (2001), inclusive education has been adopted enthusiastically by special educators because it has enabled them to continue their practices from a publicly acceptable base and to convert the student teacher into a "card carrying designator of disability" (p. 171).

Rather than retell the often-told story about special education and its origins in the Western world, what is offered here is an attempt to trouble that which Brantlinger (2003) casts as the "peaceable kingdom" narrative of continuous progress in the field of special education. We draw from primary sources and the analyses of some historians (Foucault 1977; Richardson 1999; Trent 1994) to question the naive interpretation of linear progress that typically frames special education despite its obviously problematic core assumptions. These include the following: (1) disabilities are pathological conditions that students have, (2) differential diagnosis is objective and useful, (3) special education is a rationally conceived and coordinated system of services that benefits diagnosed students, and (4) progress results from rational technological improvements in diagnostic and instructional practices (Skrtic 1991). We also draw on contemporary scholars (Baker 2002; Slee 2001, 2004) to trace some of the key elements in the trajectory of special education and to analyze the nature of its resilience.

THE GENESIS OF SPECIAL EDUCATION

Depending on the perspective taken, special education histories trace back over centuries, with origin stories that generally begin with a recounting of educational provision in special schools for deaf and blind students early in the 1800s and, later, for students with physical, cognitive, and emotional disabilities. The creation of the special school in contexts across the world isolated the disabled individual from the community as such facilities were typically located in rural settings where educational provision was impairment specific and cast in the rhetoric of individual and specialized instruction. Undeniably, contemporary special education is informed by multiple histories, some more nuanced than others and some that remain, as yet, unexcavated. Our analysis aims to inform awareness of the conditions that emerged to establish the need for special education and its unyielding resilience. Our insights fall outside the narrative of rational technical progress in the field of special education "proper" as this remains a naive and unproblematized history of self-congratulation among professionals for the hard-won rights of children. The trajectory we provide considers issues of practice and the resulting effects of special education on children and their families. Likewise, our analysis troubles the critical links between special education and class issues rooted to economic need and the growth of industrial capitalism in both the United States and the United Kingdom.

COMPULSORY SCHOOLING AND SPECIAL EDUCATION

Richardson (1999) provides insight into the effects of compulsory attendance laws that ultimately served as an "essential precondition" for the development of policy and the systematic provision of special education services. The evolution of European-based practices of book learning and apprenticeships in the trades, accompanied by mandatory "enrollments of indenture" that included a range of student abilities, would, no doubt, inform inclusion as it is cast in the present moment. What is pertinent here, however, is that by the mid-nineteenth century, "standardized" education across society was becoming common. At roughly the same time, the "invention" of idiocy signaled the launch of processes to differentiate dependent people throughout society. In the language of contemporary special education discourse, the early nineteenth century signaled the beginning stages of the development of qualification criteria, needs identification, assessment, and the necessary legal authority to act on behalf of children with special needs. Through these established disciplinary mechanisms for social control, as Foucault (1977) has argued, communities were empowered to exercise compassion and benevolence toward the "poor and the infirm." This nascent form of special education turned on securing the legal authority to supersede the traditional rights of parents in favor of arguments for the promotion of a broader welfare. Over time, these disciplinary mechanisms advanced a form of professional zealotry common among many special education professionals who position themselves as advocates driven to act in the "best interests of the child." Despite mounting evidence that long-term placement in special education yields poor academic and social gains for children (National Council on Disabilities), the profession maintains that theirs is a moral calling to act on behalf of children with disabilities (for an insightful critique of the profession, see Skrtic 1991; Slee 2001, 2004; Tomlinson 2004).

SPECIAL EDUCATION PRACTICE

Public school classes for mentally defective children were common throughout Europe in the late 1800s and as early as 1867 in Germany. Although some institutions in the United States imported the European model, others pressed for a community-based response to the education of feebleminded children. Citing decades of limited success among the American institutions to sort successfully the feebleminded from the "merely" backward youth, Walter E. Fernald, superintendent of the Massachusetts School for the Feeble-Minded, called for improved technologies and the creation of special classrooms in urban public schools (Fernald 1904). He was at once sympathetic to families forced to institutionalize their children in their "tender" years and critical of those families who "lacked" the desirable moral and intellectual influences necessary for encouraging proper developmental gain among their offspring. This early campaign to relocate children from institutions to their local community and schools slowly shaped the view of special education as a place rather than a service—an enduring problem inherent in our dual system of service delivery model in the twenty-first century.

SPECIAL EDUCATION AS PLACE

By 1917, compulsory schooling was well under way in the United States, and for students unable to progress through the system of a graded curriculum, the "special class" emerged. Similar in structure to the special school, provision in the special class was disability specific and cast in the rhetoric of individual and specialized instruction. A close examination of the historical record of compulsory education provides insight into the organizational dilemmas posed by enacting schooling for the "backward child"—the then commonly used terminology for students in need of schooling that was "less for the head and more for the hand," as Ware (forthcoming) has observed. Earlier distinctions of difference included terms such as "troublesome, truant, backward, defective, retarded, slow, mentally deficient, those with excessive 'badness' and those with physical and mental markers of imbecility or idiocy" (Ware forthcoming). Buried within these descriptors was reference to the foreign-born and burgeoning immigrant population. Under the auspices of improved social welfare, kindergarten-age students at the Training School at Vineland, New Jersey, were enrolled in a curriculum that emphasized "punctuality, obedience to authority, patience, teamwork, and respect of the rights of others" (Trent 1994:109). Vineland researchers noted this population included "those whose minds have not developed normally" and "American born children of parents who have not succeeded . . . [and who] . . . are deprived from birth of the possibility of even a moderate degree of success" (Irwin 1913:67). Armed with new protocols to medicalize difference, these early researchers contrasted the "familiar" East Side neighborhood populated by first-, second-, and third-generation Americans with their target community—one in which the "foreign-born population swarms the streets and a strange language meets the ear from every hand" (Irwin 1913:67).

It was initially projected that roughly 1 percent of children younger than 14 years of age enrolled in the public schools were "defective mentally," but data collected in 1920 indicated that in New York City, 31 percent of the population labeled "mental defectives" were immigrants. Exploring the intersections between immigration and special education would obviously enrich contemporary analyses of the overrepresentation of minorities in special education; however, in the United States, such excavations are rare compared to the rich analyses undertaken by British sociologists, who have persistently probed these critical connections. Their insights trouble the previously blurred lines between ensuring educational provision for those children who were formerly institutionalized and the creation of the urban special class that served as the mechanism to absorb increasing student diversity in the public schools. Although the threads may appear less evident when attempting to link the parallel development of curriculum for both populations, the section that follows indicates how disenfranchised youth on both sides of the Atlantic, whether disabled or ethnic, were tracked into a skills-based education that targeted vocational ends and minimized exposure to enriched educational experiences. Thus, their life options were circumscribed by institutionally sanctioned limits on learning.

SPECIAL EDUCATION PEDAGOGY

In the example of special education pedagogy and practice, Edouard Séguin, celebrated by Pope Pius X as the "apostle to the idiots," remains a central figure (Trent 1994). Séguin, who was a student of Itard, developed pedagogy that assumed that all idiots shared the twin characteristics of dormant senses and an undeveloped will. His curriculum aimed to awaken the senses through "physiological education" that emphasized the interplay between physical motor activity, sense stimulation to arouse the intellect, and moral intervention to shape the will. Trent (1994) notes that Séguin's approach has been modified very little in the past 150 years and remains "amazingly contemporary." However, the context and aims of his method and the subsequent curriculum shifted as a consequence of divided class interests and increasing pressures for social control. The dramatic decline of state-based provision and the increased availability of private care prompted a reappropriation of his curriculum for common usage as "habit training." In a culture enthralled by eugenic tendencies and the demand for regulating difference, correcting for atypical characteristics emerged as a worthy goal.

Researchers forged agreement on the problem of the feebleminded child as primarily a school problem, and thus the first step was to separate all children into classes best suited to their needs so as to "rid the normal children of this unnecessary burden" (Irwin 1913:68). The Binet test (later, Stanford-Binet) emerged to sort students into categories labeled as follows: the normal (those testing within two years of their chronological age), the backward (those testing between two and three years younger than their chronological age), and the feebleminded (those whose differences exceeded three years). This early research inspired the scientific approach to the diagnosis and treatment of difference, where the lines easily blurred between those with inherited or congenital difference and those whose ethnic difference marked their "strangeness" as troublesome within the same boundaries of feeblemindedness. Subsequently, the curriculum for both populations became one that aimed toward vocational training: the exact opposite direction originally conceived by Séguin. Although a seemingly subtle shift, the effect intensified over time as new emphasis was placed on human worth and one's ability to produce in a capitalist society.

These early influences ensured the development of special education as a technical field, located within a positivist framework, concerned with issues of diagnosis, assessment and causes of disability, and appropriate forms of treatment. New York City took the lead and organized special classes for "pedagogic reasons" into three levels: (1) bright truants, (2) normal children with sensory deficits, and (3) children truly mentally defective. Once the categories existed, school administrators could weed out those children from the normal classes, justified by the rhetoric of "relief." Fernald (1904) espoused the logic of bureaucratic convenience, arguing that relief was overdue for educational systems inundated by the influx of immigrant children who taxed the ordinary capacities of educators. These early arguments influenced the development of special education as an institutional safeguard to protect general education students and teachers from the problems posed by disability and difference in public schools. Although Fernald also claimed that "relief" was due to families who suffered "ceaseless anxiety and sorrow caused by the presence of the blighted child" (p. 34), his claims were issued in the same era as the nascent formation of a factory/machine bureaucracy for school organization—one that privileged bureaucratic convenience over student needs. This vestige of the past, as noted by Skrtic (1991), guarantees the inability of schools to meet the needs of individual learners.

THE SPECIAL EDUCATION LEGACY

The stigmata associated with disability have historically centered on perceptions of deviance; as a consequence, individual conditions have been considered alternately mysterious and deserved, dangerous but exploitable, and alien yet innocent. While interactions with the nondisabled community were infrequent, the public perception of disability was readily shaped by fear, pathos, and scorn so as to fix our gaze on the person labeled mentally retarded. As a consequence, research aimed no further than individual pathology and social problem. That the original interventions of Séguin's system of physiological education have witnessed little fundamental innovation in more than 150 years is both evidence and indictment of special education's enduring legacy—an inability to move beyond pathologizing discourses that unproblematically demand perfecting technologies, as Baker (2002) has noted. Not only does this lesson endure, but we are temperamentally unable to unlearn it and unable to resist the "hunt for disability." Slee (2001, 2004) concurs, arguing that the continuing dominance of special education has had a domesticating and taming effect on inclusive education. Special education continues to be preserved, while inclusive education discourses are silenced, not least of all by professionals in the United States who hold a vested stake in protecting their own interests in segregated education by issuing dire warnings about the "illusion" of full inclusion. In the United Kingdom, the defense of special education is less emphatic but no less effective. Both Baker and Slee contend that the legacy of special education can only be challenged by reframing it as cultural politics and by encouraging professionals to turn the gaze back on themselves and, thus, to better understand their own complicity in preserving special education.

SPEECH AND LANGUAGE PATHOLOGY

The field of speech-language pathology encompasses both human communication behaviors and disorders, as well as swallowing functions and disorders. Speech-language pathologists are professionals who work with individuals of all ages to provide prevention, screening, assessment and diagnosis, intervention, counseling, and follow-up services for a variety of disorders that affect communication and swallowing. The practice of speech-language pathology also includes elective modification of communication behaviors that may result from cultural and linguistic factors, as well as enhancement of personal or professional communication performance. By affecting measurable and functional changes in the individual's communication or swallowing status, speech-language pathologists help the individual to participate as fully as possible in all aspects of life—social, educational, and vocational—thereby enhancing quality of life for the individuals they serve.

COMMUNICATION DISORDERS

Speech-language pathologists work with individuals who have communication disorders. A communication disorder may be developmental or acquired and may range in severity from mild to profound. A communication disorder may result in a primary disability, or it may be secondary to other disabilities. An estimated 46 million people in the United States, of all ages, races, and gender, have experienced some type of communication disorder. Communication disorders include disorders of speech, language, cognition, and hearing. Individuals may demonstrate one or any combination of these disorders.

A speech disorder refers to difficulty with the articulation of speech sounds, fluency, and/or voice. An articulation disorder, the atypical production of speech sounds, is characterized by substitutions, omissions, additions, or distortions that may interfere with intelligibility. Articulation disorders are among the most prevalent communication disabilities among preschool and school-age children. Children with articulation disorders may be at risk for reading and writing disabilities. The goal of speech therapy is to improve the accuracy and use of speech sounds and to achieve maximum intelligibility in single words and connected speech in all settings in which communication occurs.

When the speech impairment is caused by neurological damage, it is called a dysarthria and is characterized by slow, weak, uncoordinated movements of the speech musculature. Dysarthria can be congenital (e.g., cerebral palsy) or acquired (e.g., Parkinson's disease, stroke). In developing and implementing a treatment plan for speech disorders associated with degenerative diseases such as amyotrophic lateral sclerosis, speech-language pathologists match the intervention to the stage of the disease because such diseases frequently progress through a series of stages from mild speech impairment to loss of speech.

Fluency disorders, or stuttering, are another category of speech disorders. Fluency disorders are characterized by a disruption in the flow of speech and include repetitions of speech sounds, hesitations before and during speaking, and the prolonged emphasis of speech sounds. This may be accompanied by excessive tension, struggle behavior, and secondary mannerisms. Clinical evidence shows that individuals who stutter can benefit from treatment provided by speech-language pathologists at any time in their lifespan. Treatment typically focuses on changing the timing of speech (e.g., slowing down, stretching out sounds) or reducing the physical tension during speaking (e.g., gentle onsets of speech movements). Treatment also focuses on improving the speaker's attitudes toward communication and minimizing the negative impact of stuttering on the speaker's life.

A voice disorder is characterized by abnormal pitch, loudness, or vocal quality resulting from disordered laryngeal function and may cause pain or vocal fatigue. Voice disorders range from mild hoarseness to complete voice loss and limit the effectiveness of oral communication. Voice disorders can be caused by an injury resulting in paralysis of a vocal fold, an improper breathing pattern, or misuse of the voice. Voice disorders can also be due to medical or physical conditions, or they may be neurological in nature. Studies find that voice treatment, including vocal hygiene, can improve voice function and reduce the occurrence of laryngeal pathology.

A language disorder refers to impaired comprehension and/or use of spoken, written, and/or other symbol systems. The disorder may involve the form of the language (phonology, morphology, syntax), the content of the language (semantics), or the use of the language in context (pragmatics). Language disorders may affect individuals across the lifespan. For children who do not use language normally from birth or who acquire an impairment during childhood, language may not be fully developed or acquired. Many adults acquire disorders of language because of stroke, head injury, dementia, or brain tumors. One role of the speech-language pathologist is the establishment of augmentative and alternative communication techniques and strategies, when needed. Augmentative/alternative communication systems attempt to compensate and facilitate, temporarily or permanently, for the impairment and disability patterns of individuals with severe expressive and/or language comprehension disorders. Speech-language pathologists may also coordinate the selection and use of other kinds of assistive technology.

Cognition and language are intrinsically linked and reciprocally related in both development and function. Cognitive-based impairments of communication are referred to as cognitive-communication impairments. Speech-language pathologists work on improving cognitive aspects of communication, including attention, memory, perception, organization, reasoning, problem solving, and executive functions. Speech-language pathologists also may address other areas of function affected by cognitive-communication impairments, including behavioral self-regulation, social interaction, activities of daily living, learning and academic performance, and vocational performance.

Speech-language pathologists may provide services to individuals with hearing loss and their families/caregivers. Services may include auditory training, speech reading, speech and language intervention, and visual inspection and listening checks of amplification devices for the purpose of troubleshooting.

SWALLOWING DISORDERS

Speech-language pathologists identify, assess, and treat individuals of all ages—infants, children, and adults—with dysphagia. Treatment approaches include compensatory strategies designed to have an immediate effect on the swallow (postural changes or diet manipulation), as well as direct muscle-strengthening exercises for improving the swallowing physiology. Treatment approaches improve nutritional status and hydration and reduce morbidity from pneumonia.

SPEECH-LANGUAGE PATHOLOGY SERVICES

Speech-language pathologists deliver services that are consistent with the framework and components of the World Health Organization's International Classification of Functioning, Disability, and Health (2001). Assessment is conducted to identify the strengths and deficits related to underlying structures and functions that affect communication and swallowing performance, as well as the effects of these impairments on the individual's activities (capacity and performance in everyday contexts) and participation. Assessment also identifies the contextual factors that serve as barriers to or facilitators of successful communication/swallowing activities and participation.

Intervention is designed to capitalize on the strengths and address the weaknesses related to underlying structures and functions that affect communication/swallowing. The goal of intervention is to facilitate the individual's activities and participation by facilitating the acquisition of new communication/swallowing skills and strategies. Intervention also includes modifying contextual factors to reduce barriers and enhance facilitators of successful communication/swallowing activities and participation, as well as providing appropriate accommodations and other supports. Since speech-language pathology services are provided to individuals of all ages, intervention strategies reflect changing developmental stages and language needs and proficiencies throughout the lifespan.

At the present time, there are a number of acceptable treatment approaches for each type of communication and swallowing disorder. However, the field of speech-language pathology is dynamic and evolving. Speech-language pathologists keep current with best practices in prevention, assessment, and intervention. Research and outcome data alter assessment and intervention techniques, influence models and theories of practice, and expand the scope of practice of speech-language pathologists.

Speech-language pathologists provide services in a wide variety of settings, which may include the following: public and private schools; health care settings (e.g., hospitals, medical rehabilitation facilities, long-term care facilities, home health agencies, community clinics, behavioral/mental health facilities, neonatal intensive care units); early intervention settings, preschools, and day care centers; group homes and sheltered workshops; community and state agencies and institutions; correctional institutions; private practice settings; universities and university clinics; individuals' homes; corporate and industrial settings; and research facilities. Although speech-language pathologists are autonomous professionals, successful delivery of speech-language pathology services often requires the collaborative involvement of other professionals, as well as the patient, family, and significant others.

The American Speech-Language-Hearing Association (ASHA) is the professional, scientific, and credentialing association for speech-language pathologists, audiologists, and speech, language, and hearing scientists in the United States and internationally. The mission of the American Speech-Language-Hearing Association is to promote the interests of and provide the highest quality services for professionals in speech-language pathology, audiology, and speech and hearing science and to advocate for people with communication disabilities. The association was originally founded in 1925 as the American Academy of Speech Correction. The current name, the American Speech-Language-Hearing Association, was adopted in 1978.

SPINAL CORD INJURY

Injury to the spinal cord can be caused by acute or chronic trauma as well as by medical conditions. Frequent causes of chronic compression injury are herniated intervertebral disks and primary or secondary tumors. Acute deterioration of blood perfusion, as seen in anterior spinal cord syndrome, can also severely compromise spinal cord function. However, probably the most dramatic setting for spinal cord injury (SCI) is acute trauma.

EPIDEMIOLOGY OF ACUTE SPINAL CORD TRAUMA

Estimates of incidence vary, depending on country and mode of reporting, ranging from 15 to 71 per million. According to estimates by the Canadian Paraplegic Association, about 35 new cases per million population are seen each year in Canada. Of the 12,000 new cases of paraplegia and quadriplegia that occur in the United States each year, 4,000 patients die before reaching the hospital. Causes for acute SCI include motor vehicle accidents, work-related accidents, recreational accidents, and violence (shot and stab wounds). Men are afflicted four times as often as women. About 60 percent of the injury victims are 30 years or younger. A long-term outcome study of patients ages 25 to 34 who had suffered acute traumatic SCI while still in the pediatric age group showed that the employment rate was only 54 percent, while the employment rate in the general population for the same age group was 84 percent. Limitation or complete loss of the capability to achieve economic independence following SCI can cause severe economic hardship for the afflicted person and his or her immediate family. Further limitations to participation in social life are caused by architectural barriers (i.e., buildings accessible by stairs only, lack of ramps on boardwalk intersections) and barriers created by negative or overprotective attitudes of healthy, noninjured people toward persons with spinal cord injury. Where reintegration of young SCI victims cannot be achieved, society might suffer a double loss: not only are contributions to society lost, but heavy expenses are incurred to pay for special lifelong care. In 1990, the costs for acute and long-term care of surviving spinal cord injury victims were estimated at $4 billion annually in the United States alone.

THERAPEUTIC APPROACHES AND CHANGING ATTITUDES

The first known description of acute spinal cord trauma and resulting neurological deficits was found in the so-called Edwin Smith papyrus, which is believed to be more than 3,500 years old. In this ancient Egyptian document, typical conditions encountered in medical practice were presented as case descriptions, and advice regarding treatment was offered. According to the papyrus, spinal cord injury was “an ailment not to be treated.” This was possibly an expression of helplessness on the side of the medical profession at the time. A doctor’s value would be measured by the extent of cure achieved. Since no strategies that ensured long-term survival for patients with spinal cord injury existed, the doctor would waste time and efforts and endanger his reputation. This basic attitude toward victims of spinal cord injury lasted well into the twentieth century.

Medical statistics from World War I show up to 95 percent mortality for patients with spinal cord injury, attributed mainly to urinary sepsis and pressure sores. During World War II, the number of both military and civilian casualties, including those with spinal cord injuries, increased dramatically in Europe. The success of specialized hospital units (so-called peripheral nerve centers), developed between the wars in Germany and the United States, had demonstrated the advantages of concentrating special-needs patients under specialized care. Great importance had been attributed to the unique opportunities offered by such specialized units—namely, to gain new insight in the natural course of the disease and to further the development of new therapeutic strategies. Building on those experiences, several specialized spinal cord units were opened throughout England in the 1940s. Pioneered by the team of Dr. Ludwig Guttmann at the Spinal Cord Unit of the Stoke Mandeville Hospital, new treatment approaches included frequent repositioning of paralyzed patients to avoid development of bedsores as potential source of sepsis and intermittent sterile catheterization to prevent urinary sepsis. The success, measured in patient survival, was dramatic enough to require the development of completely new strategies for social reintegration of patients with spinal cord injury. The creation of adapted workplaces and wheelchair-accessible housing, as championed in the 1940s and 1950s by the English Red Cross, has today become an integral component in the framework of social politics in most industrialized countries. While respiratory complications are now perceived as the leading cause of death in patients admitted with SCI, the runners-up are heart disease, septicemia, pulmonary emboli, suicide, and unintentional injuries.

THE PARALYMPIC GAMES

Guttmann and his colleagues viewed physical rehabilitation as the basis of social reintegration, both physically and psychologically. Consequently, they supported the idea of athletic competition in disciplines adequate and adapted to the physical capacity of their patients. Starting with a two-team competition in 1948, paralleling the Olympic Games in England, the idea of competitive sports for the paralyzed developed rapidly. In 1960, the first Paralympic Games were held in Rome. Not only were competitions held in the same year as the Olympic Games for the able-bodied, but both the Olympic and Paralympic games were using the same facilities, a tradition that has been followed ever since. The idea of competitive sports has long since been extended to include people with a multitude of physical handicaps other than spinal cord injury.

INITIATIVES AND PUBLIC AWARENESS

Noticeable is the number of initiatives that have sprung up at communal and national levels in many countries, with the intent to decrease the incidence of spinal cord trauma, to lend support and advice to patients with spinal cord injuries and their families. Some also offer financial support for basic science and clinical research. The prevention-oriented “Think First” initiative, Canadian-based CORD and Wheels in Motion, the Christopher Reeve Paralysis Foundation, the U.K. Spinal Cord Trust, and the Paralyzed Veterans of America, to name but a few, maintain informative sites on the Internet, where further valuable information on the subject of spinal cord injury can be found.

Although the overall incidence of SCI has not yet decreased noticeably, there is an appreciable decrease with regard to the severity of injuries (i.e., fewer complete injuries and an increased survival rate have been reported). This has been attributed to improvements in prehospital care, including widespread instruction in the principles of first aid as well as introduction of the principle of spinal cord immobilization during rescue and transport. Increased public awareness of risk factors leading to head trauma and spinal cord injury, the introduction of the mandatory use of safety belts, and the installation of air bags in cars furthermore are suited to decrease trauma severity.

RESEARCH

Until fairly recently, a dogma underlying the approach to spinal cord injury research postulated that, once spinal cord trauma had occurred, nothing could be done to alter the natural course of developing pathology, that damage to the central nervous system (CNS) was permanent and repair impossible. At the beginning of the twenty-first century, this dogma ceases to exist in the minds of scientists, clinicians, and patients and their families. In laboratories around the world, research is focused on two general approaches: prevention of *secondary injury* and repair of manifest damage. The term secondary injury is used to describe the observation that CNS structures, which have survived the primary, mechanical trauma, die at a later time point due to deterioration of the milieu at the site of injury. The volume of secondary tissue injury can be significantly larger than that caused by the primary injury. Research is focused on the identification of substances and therapeutic methods that help to minimize secondary injury. New methods in the field of cell biology allow the study, isolation, and manipulation of specific cell types. Efforts are being made to induce certain cell types, including stem cells and olfactory ensheathing cells, to help repair damaged CNS structures.

The focus of clinical research is on ameliorating the consequences of spinal cord injury (i.e., stimulators for bladder control, orthopedic correctional procedures) and on physical mobilization. Integration of biomedical research (i.e., pattern generators, mechanics and kinetics of movement) with the latest developments in computer science and engineering has led to the creation of neuronal networks. On this basis, neuroprostheses are being developed, which allow completely paraplegic persons to ambulate.

SPORTS AND DISABILITY

Sport plays an important role in the lives of many people, and sports programs have high visibility in many communities around the world. Participation in sports activities is an important goal for many persons with disabilities, and it has been shown to have significant and positive effects on physical function, psychological and emotional status, and general health. People with disabilities who participate in sports have higher self-esteem and quality of life, and their participation in sports activities, limited for many years for the able-bodied, contributes to the elimination of myths and misconceptions surrounding disability and the removal of barriers to integration into society. Among other things, sports participation can be used to (1) maximize the benefits of the rehabilitation process early after injury or disease, (2) facilitate community reintegration efforts after rehabilitation, (3) provide leisure-time recreational opportunities, (4) enhance skill- and health-related fitness and general health, and (5) provide the high-performance competitive experience that many athletes enjoy.

REHABILITATION

The restoration of form and function (i.e., rehabilitation) after injury or illness can be achieved using a wide variety of therapeutic strategies and interventions.

These include occupational and physical therapy, speech therapy, recreation therapy, nutritional counseling, psychological interventions, and pharmacological management. Most people with disabilities have mobility limitations, and it is not surprising that sports programs can be used to provide some of the occupational, physical, and psychological therapy that is needed early in the rehabilitation process. Furthermore, sports participation can also be included in the process of "habilitation" of children with congenital disabilities or impairments acquired very early in life. Recovery or development of muscle strength, cardiorespiratory endurance, balance, and coordination, all fitness-related attributes lost as a result of injury or disease, can be facilitated through the participation in sports activities. Traditionally, gym-based activities have been used for this purpose, but the addition of sports activities (outdoors and indoors) such as windsurfing, horseback riding, and kayaking has brought much-needed diversity to the traditional programs. Patients in a rehabilitation hospital may be more motivated to do their exercises if the activity providing the stimulus is similar or more relevant to their favorite sport. The use of sport during the rehabilitation process was pioneered by Sir Ludwig Guttmann in the United Kingdom.

RECREATION

Leisure-time physical activity is an important component of a healthy lifestyle. People who participate in recreational activities develop confidence in their ability to participate in and contribute to society. Through recreational sports participation, people with disabilities can learn to enjoy life, reduce stress, develop special skills, improve functional capacity, and take control over their lives. Furthermore, many recreational activities can include the family. In fact, participation of husband or wife and their children can enhance compliance with activity programs. Also, leisure time can provide that much-needed opportunity to socialize with friends who share the same recreational interests. By eliminating barriers such as poor self-image and low self-esteem, recreational activities increase the chances of a successful return to community life, including family and occupational obligations.

HEALTH AND FITNESS

With advances in health care, many people with disabilities have a longer life expectancy. The causes of death in some groups of people with disabilities, such as those with spinal cord injuries, are more similar to those in the general population now than 20 years ago. For example, the incidence of chronic diseases, including coronary heart disease and atherosclerosis, is increasing in this population. Therefore, interventions that can reduce risk factors for chronic disease such as high blood pressure, sedentary lifestyle, and high cholesterol levels and enhance cardiovascular and metabolic functions can be of great benefit for persons with disabilities. The benefits of physical activity and exercise in men and women of all ages have been extensively studied and documented in the past 50 years. People with disabilities should receive the same benefits, and participation in several sports is one way of providing the exercise stimulus needed to enhance fitness and health. Sports such as wheelchair racing, swimming, and cycling provide that stimulus necessary to develop cardiovascular fitness and reduce the incidence of risk factors. Furthermore, fitness programs in sports clubs designed to enhance flexibility, strength, and aerobic capacity have become more popular among people with disabilities.

Sports participation can be used to enhance fitness in persons with disabilities due to chronic illnesses. Examples of chronic diseases that could benefit from sports programs include asthma, high blood pressure, obesity, stroke, osteoarthritis, osteoporosis, diabetes, and others. The use of sports programs in this context can be considered a form of secondary prevention. The benefits are many and could include better medical control of the disease, a reduction in the amount of medication needed to treat the disease, a reduction in the rate of complications, and an improvement in the functional capacity and tolerance to regular activities.

COMPETITIVE SPORTS

Competitive sports represent a real option for persons with disabilities who like the challenge of high-level athletic performance. Sir Ludwig Guttmann organized the first international sports competition for people with disabilities at Stoke-Mandeville in the United Kingdom. The Paralympic Games became part of the Olympic program, starting in 1960 with the summer games and in 1976 for the winter sports.

Many people with disabilities can participate in sports using standard equipment, depending on the requirements of the sport and the level of disability. However, an important consideration for persons with disabilities interested in many competitive sports programs is the need for special equipment that could make their participation possible and/or safer. Dramatic improvements in technology and biomaterials have allowed persons with a wide range of disabilities to participate in sports such as wheelchair racing, archery, golf, cycling, quad rugby, goal ball for the blind, horseback riding, boating, weightlifting, basketball, tennis, snow skiing, swimming, ice hockey, and many others. New prosthetic devices for amputees and ice hockey players, lightweight wheelchairs for racers and basketball players, and field event chairs for the javelin throw are some examples of devices that enhance the individual's activity and participation level.

Participation and competition in different sports are facilitated by the use of classification systems to make sure that athletes with disabilities competing against each other have equivalent levels of impairments and disabilities. This is consistent with the Olympic principle of "fair play" and may be consider equivalent to the classification systems based on, for example, body weight used in sports for people without disabilities. Sophisticated classification systems have been designed for use in local, regional, national, and international competitions such as the Paralympic Games. One example is the classification used by the U.S. Cerebral Palsy Association, which divides the competitors into eight groups based on the level of involvement of the limbs and torso, the need for a wheelchair, coordination, and related characteristics. Other examples are the classification system used for people with spinal cord injuries based on eight levels of injury and impairment and the classification of sports for three classes of visual impairment. More recently, the participant's functional capacity and performance in real sports activities has been proposed as the most effective way of classifying athletes. Although sometimes controversial, classification systems must be developed for all sports and understood by those who organize competitions for people with disabilities. These systems, however, may not be useful or necessary in recreational activities or when sports participation is used to enhance fitness and health.

Participation in sports per se can be positive, but persons with disabilities involved in serious sports competitions must follow a training program designed to enhance fitness and sports performance. Many training principles followed by athletes without disabilities also apply to the preparation for events such as the Paralympics. A sound training program must (1) include appropriate training loads that vary according to the dates of the competition, (2) be specific for the sport, (3) include the technical and tactical aspects of the sport, (4) monitor closely the health of the athlete, (5) include adequate nutritional support, and (6) never use doping agents or boosting techniques to artificially enhance performance during competition. Because many sports are practiced using a wheelchair, particular attention must be given to the training of the upper limbs and torso. It is important to keep in mind that athletes with disabilities have the same risk of injury per athletic exposure for an athlete without a disability. Physicians practicing sports medicine must understand the risk factors for overuse and traumatic injuries in this population. In addition, the specific medical needs that may result from the interaction between the medical condition that resulted in a disability (high-level spinal cord injury, diabetes) and the demands of training and competition must be taken into consideration. For example, some athletes with spinal cord injuries may be intolerant to the heat and high humidity typical of many cities during the summer. Also, exercise may alter the metabolism and effects of drugs such as insulin, requiring adjustments in the dose before training sessions or competitions.

STEIFF, MARGARETE (1847–1909)

German toy manufacturer

When the German toy manufacturer, Margarete Steiff, died at the age of 61, she left behind a world-famous enterprise. She was born on July 24, 1847, in Giengen, south Germany. At the age of 1, she contracted polio, which left both legs and her right arm paralyzed. Steiff, along with her three siblings, had a carefree childhood. She took part in the games of the neighborhood children—while sitting in a wooden wagon—and attended the local elementary school. Two long stays in a children's hospital were combined with the hope that she would walk again. This hope proved futile. Also, an operation brought no success. Steiff stated in her memoirs, "The useless search for a cure does not let an individual come to peace."

Economic independence was very important to Steiff for she was dependent on her mother and, later, on her sister-in-law with respect to her caretaking needs. She bought herself a sewing machine and maintained a sewing room at first. Later, she got some assistants and soon produced felt slips and coats, which were very successful. In 1877, she opened a "Filzkonfektionsgeschäft," a ready-made felt business. A little later, she began to produce stuffed animals as children's toys. Her business—which she built with the help of her nephews—flourished. She placed a great amount of worth on the quality of her products. Her success made it possible for Steiff to build a new, ramped residential and business house in 1903.

In the same year, the Steiff firm introduced a new stuffed animal at the toy fair in Leipzig: a bear with a hump. Shortly before the fair closed, an American dealer purchased the entire bear collection, and soon thereafter, the new toy had a catchy name. The bear was named "Teddy" after American President Theodore Roosevelt. Provided with the well-known brand name "Knopf im Ohr" ("button in ear"), it soon became a huge international success. At the 1904 World's Fair in St. Louis, Steiff was awarded the "Grand Prize" for her life's work. She died unexpectedly on May 9, 1909, from pneumonia.

STEREOTYPING

See Stigma

STERILIZATION

The earliest use of sterilization in North America likely occurred in institutions for "feebleminded" people around 1890. The procedure used was *castration,* a term that institutional authorities applied to both sexes. (Besides hysterectomy, female castration included salpingectomy, the removal of the fallopian tubes, and ooephorectomy, the removal of the ovaries.) In 1892, Isaac Kerlin, superintendent of the Pennsylvania Training School for Feeble-Minded Youth, argued for “asexualization” before his colleagues at the annual meeting of the Association of American Institutions for Idiotic and Feeble-Minded Persons. Kerlin told his fellow superintendents that castration controlled “epileptic tendency” and aided in the “removal of inordinate desires which [are] . . . an offense to the community.” He noted that he had allowed the sterilization of one inmate at the Pennsylvania Training School. That case involved the removal of the “procreative organs” of a young woman. When Kerlin referred to “inordinate desires,” he alluded to a problem that he and other superintendents faced in their institutions—inmates who publicly masturbated. Especially troublesome during Sunday visits from church groups or during the visits of relatives, inmates who masturbated were an ongoing embarrassment for the superintendents.

Two years later in March 1894, F. Hoyt Pilcher, the superintendent of the Kansas State Asylum for Idiotic and Imbecile Youth, began castrating older boys and men who masturbated. By 1895, he had castrated 11 inmates. Around 1895, he expanded the castrations to women. His practice drew the attention of several regional medical journals and local papers. Eventually, the publicity became a state scandal, with officials expressing both support and opposition for Pilcher’s surgeries. Nevertheless, he continued his practice, and by 1897, he had castrated 47 additional inmates, 14 women and 33 men.

What began as a curiosity in the 1890s would become, after 1900, an increasingly discussed practice among superintendents of institutions for the so-called feebleminded. By the end of the first decade of the new century, superintendents of insane asylums, penitentiary officials, and social welfare authorities joined their colleagues in feeblemindedness to show their interest in sterilization. Two factors influenced this growing attention. First, eugenics, along with the newly discovered work of Gregor Mendel, opened institutional officials to new ways of linking heredity and mental disability, heredity and crime, and heredity and pauperism. Second, two new surgical procedures, the vasectomy and the tubal ligation, made sterilization a more socially acceptable practice.

In 1899, Harry C. Sharp, a physician at the Indiana State Reformatory, developed the vasectomy. The surgery achieved male sexual sterility without castration. In 1902, he published a paper on the new procedure. In it, he made an explicit connection between sterilization and heredity. Although the first tubal ligation was performed around 1880, the procedure became an involuntary means of sterilization after 1900 in institutions that housed “feebleminded” women. By the first decade of the new century, then, new views about heredity, as well as new and less invasive procedures, would allow institutional officials to expand sterilization from behavioral control to the control of heredity. These same officials would appropriate the term *eugenics,* first coined by Francis Galton, to identify and justify their new interest in hereditary control.

With the support of the State Board of Charities, in 1907, Indiana became the first state to pass a sterilization statute. Focusing on habitual criminals and rapists, the legislation also allowed for the involuntary sterilization of the state’s institutionalized insane, epileptic, and “feebleminded” populations. By 1917, in the name of eugenics, 11 more states had authorized the use of sterilization. After World War I, 15 additional states passed sterilization legislation. In most states, institutional superintendents (at least behind the scenes) led support for the legislation, and usually they did so in the name of eugenics. Joining these institutional officials were academics such as sociologist E. A. Ross and biologist Michael F. Guyer, who advocated for sterilization before the Wisconsin legislature; businessmen such as New Jersey real estate executive Bleeker Van Wagenen and Michigan’s John H. Kellogg of the cereal fortune; and religious leaders such as Ohio’s Washington Gladden, Harry Emerson Fosdick in New York, and Louis Poteat in North Carolina.

Not all of the institutional superintendents supported involuntary sterilization, and some would change their support over the years. Opposition also came from state and national figures. By 1921, of the 15 state statutes, only 10 were still law. The New York Supreme Court declared its sterilization laws unconstitutional in 1918. After that, statutes in New Jersey, Nevada, Michigan, and Indiana were thrown out by their respective state courts. In 1911, the governor of Indiana, where the first law had been signed, declined to release state funds to any institution that performed involuntary sterilizations. In Oregon, Vermont, Nebraska, and Idaho, governors vetoed sterilization legislation.

Although it lost much of its steam by the 1940s, involuntary sterilization continued to find pockets of state-sanctioned support. In New Jersey, North Carolina, and California, state-sanctioned sterilization mechanisms continued even into the 1960s and 1970s. Since the 1970s, various federal and state court rulings along with regulations from the executive branches of the federal and various state governments have reduced, if not eliminated, involuntary sterilization.

STEVENSON, ROBERT LOUIS (1850–1894)

Scottish writer

The Scottish-born writer Robert Louis Stevenson suffered from severe lung problems, possibly including tuberculosis, in addition to other chronic ailments. His major works include *Treasure Island* (1883), *Kidnapped* (1886), "The Strange Case of Dr. Jekyll and Mr. Hyde" (1886), and *A Child's Garden of Verses* (1885). Advised to go abroad for relief from his lung problems, Stevenson wrote about his travels in *An Inland Voyage* (1878) and T*ravels with a Donkey in the Cevennes* (1879), both about France; *The Silverado Squatters* (1883), about California; and *In the South Seas* (1896). He found better health during the last five years of his life in Samoa—the backdrop for his late fiction and political writings. Much of his work is concerned with physiological trauma and with spiritual, emotional, or physical compensations. Dr. Jekyll's quest to transcend human limitations through an elixir that produces instead the deformed, malignant Mr. Hyde is the best-known instance, but debilitated, neurasthenic, and melancholic characters proliferate in his work, as do fantasies of unrestrained adventure and magical power. He died of a cerebral hemorrhage.

STIGMA

The ancient Greek term *stigma* referred to tattoos or other bodily marks, but in modern times, stigma has come to refer to any signs that expose something unusual or bad about a person. According to Erving Goffman (1963), there are three main types of stigma. These include abominations of the body (physical deformities), blemishes of individual character, and tribal stigma of race, nation, and religion. The bodily signs differentiate a person from what society considers normal. This deviation from societal norms is classified as deviant, and those who fall into this category often face discrimination from other members of society. Attitudes toward individuals with tribal stigmata depend on the ways the tribe or group is viewed.

Although the term *stigma* is still used today, it now refers more to the disgrace itself than to the mark, bodily or otherwise, that reveals it. Today, stigma refers to any persistent quality of an individual or group that evokes negative or punitive responses from others. Individuals are said to be stigmatized when they are singled out from the population for ridicule or maltreatment due to differences in physical, mental, behavioral, or other attributes. When they encounter prejudice or discrimination due to their perceived limitations, persons with disabilities fit this definition of stigma. They are the recipients of unwanted and unfavorable identities. At one time, the problems faced by persons with disabilities were attributed to their impairments and/or medical conditions alone. Recently, however, attitudinal and environmental factors are coming to be seen as important in the definition of disability. Many today believe that it is societal restrictions and social responses rather than functional limitations or personal impairments that constitute the greatest problems faced by individuals with disabilities. This perspective is a core belief of the social model of disability and places the process of stigmatization front and center in the lives of persons with disabilities.

THE ORIGINS OF STIGMA

The process of stigmatization excludes certain individuals from particular types of social interactions due to characteristics they possess or due to their membership in a certain group. Stigmatization occurs when members of a society reject members of a group due to a particular characteristic shared by group members, such as the color of their skin, their inability to see, their age, or some other quality. Persons with disabilities may be stigmatized in social interactions if they do not meet the normative expectations of others. This has often been the case when individuals with disabilities are stigmatized by society. Goffman's (1963) theory of stigma is that it occurs when a mark becomes linked to an attitude that negatively views the bearer of the mark. The negative attitude associated with the mark may at first be associated with one activity or type of social interaction and later be generalized to other areas of life and society. Similarly, once members of a group are marked for exclusion from one activity or type of interaction, they may be excluded or ignored in others as well. Not only may stigma generalize outwardly to apply to multiple social contexts, but it may also generalize inwardly to the individual's own self-concept. For this reason, stigmatized individuals may come to possess negative perceptions of themselves as well as the quality or characteristic that signifies a social identity that is devalued in one or more social contexts. For people with disabilities, the quality or characteristic that leads to stigma may be a physical disability (e.g., paralysis, quadriplegia, etc.), a sensory disability (e.g., blindness, deafness), an emotional disability (e.g., schizophrenia, bulimia), or an intellectual disability.

Why do people participate in stigmatizing others? Three functions have been suggested. People may stigmatize others to (1) enhance their self-esteem, (2) enhance their social identity, or (3) justify a social, political, or economic structure. From an evolutionary perspective, stigma may serve any of several functions for those who are not stigmatized:

Dyadic Cooperation. Stigma may be an adaptation designed to lead an individual to avoid interactions with others who are viewed as poor partners for social exchange, who pose greater costs than potential benefits in social exchange, or who fail to meet any other criteria for being potentially valuable social partners. Individuals with disabilities may be seen as being unable to fully contribute to social roles (e.g., job, family duties, and social relationships) and to require high levels of care. Their strengths and abilities go unrecognized.

Coalitional Exploitation. This refers to adaptations designed to cause the exclusion of individuals from enjoying benefits widely available to members of society and to exploit these excluded individuals. Nondisabled individuals may dissociate themselves from persons with disabilities to prevent them from using scarce resources and exclude them from certain groups (e.g., the educated, the employed, and homeowners) and take advantage of them. For example, the public transit system may require a person who uses a wheelchair to get up at 5:30 a.m. to schedule a ride with the public paratransit service for that day. A sheltered workshop may pay people with intellectual disabilities a dollar an hour to assemble lamps at a time when the customary wage in society is $8 an hour for the same work.

Parasitic Avoidance. This may arise from the belief that persons with disabilities are likely to carry communicable pathogens. These adaptations are designed to prevent contact with individuals who may transmit their condition to others. The belief that persons with disabilities have defective genes and are undesirable sexual partners may also result in parasitic avoidance. Since only some disabilities involve a genetic predisposition and/or can be socially transmitted, the factual basis for this kind of adaptation is quite limited. In sum, this evolutionary approach offers these adaptations as perhaps a partial explanation for why members of groups can agree on who should be stigmatized and why the stigmatization of persons with disabilities is present in most, if not all, cultures.

DIMENSIONS OF STIGMA

The Experience of Stigma

Having a disability not only means limitations to one's physical or mental capabilities but also involves experiencing discrimination, vulnerability, and assaults on one's identity and self-esteem. Stigma is, thus, a form of oppression through social restrictions and disapproval. Many believe that these experiences are a result of the undesired differences that separate people with disabilities from the general population and give way to stigmatization.

Stigma and Expectations

Stigma causes discomfort and stress to persons with and without disabilities. It has been suggested that such tension may be a result of persons with and without disabilities not understanding each group's expectations of the other. Neither knows what the other expects. The tension created by misunderstood and unexpressed expectations may increase the tendency for persons without disabilities to ostracize those with disabilities and for those with disabilities to avoid contact with persons who do not have disabilities.

Cultural Values and Stigma

The expectations of Western culture concerning certain desirable characteristics of persons also may perpetuate the stigmatization of individuals with disabilities. Western culture places a great deal of value on independence, self-reliance, beauty, and health. Because they may differ from traditional expectations concerning these qualities, persons with disabilities may both be stigmatized and feel stigmatized.

Media and Stigma

Media in Western society tend to portray persons with ideal forms of the cultural values noted above, especially beauty, thereby heightening their relevance. Media also frequently present persons with disabilities in stereotypical ways. This is particularly true for persons with mental illness, who are often characterized as more dangerous or threatening to persons without disabilities than they are in fact. Such negative portrayals foster stigma and may justify poor treatment of persons with disabilities in the popular mind.

Stigma and Self-Perception

Stigma affects the self-perceptions of persons with disabilities. Not only does the stigmatization of individuals with disabilities affect the perceptions of others, but the stigma can also have a tremendous effect on the person with the disability as well. A stigmatized person may have some sense of normalcy and of being like other people and may be treated by most others in a manner consistent with such a perception. However, this individual may perceive quite correctly that whatever others profess, they do not really accept him or her and do not meet him or her on equal grounds. Therefore, despite some sense of normalcy, the person with a disability also may accept the premises and values that underlie a discredited social identity. Such a spoiled identity may increase the likelihood of internalized shame, withdrawal from others, and even social rejection and financial insecurity as the individual shies away from opportunities that might provide personal and substantive rewards. Spoiled identity may lead to loss of social status and a sense that one is discounted and discredited. Such internalized shame can focus a person on the label "disabled" as a central and primarily negative focus of the person's identity, engendering greater anxiety, shame, and withdrawal.

CONCEALABLE AND VISIBLE DISABILITIES

Even though there are many types and effects of disability, all disabilities are either concealable (e.g., bulimia) or visible (e.g., physical disability). People with concealable disabilities are often able to hide their disabilities at least temporarily in the attempt to avoid stigmatization. In fact, societal stigma is so substantial that even people with what are commonly considered visible disabilities, such as blindness, report passing as nondisabled, so as not to call attention to their limitations. However, people who conceal their disabilities are often in some important way not accepting themselves. Consequently, they appear to be more likely to demonstrate effects associated with negative self-perceptions such as depression, anxiety, or suicidality than individuals with visible disabilities who do not conceal them. Because their disabilities are concealable, and others with these disabilities are also concealing them, a state called pluralistic ignorance may exist. That is, individuals with concealable disabilities are less likely to be aware that others share their situation. They may even believe that there are few, if any, other people like them. They lack the benefits of similar others, such as meaningful group membership, successful social interactions, and moral support. Contact with similar others can buffer the negative effects of stigmatization on the mental well-being of culturally stigmatized persons.

Persons with concealable disabilities may find it difficult to find people who share their group membership. To do so, they are faced with a dilemma: either risk social rejection in hopes of finding social contact or shun social contact to avoid social rejection. Individuals will be most vulnerable to negative self-perceptions when they are unable to find similar others for support. Research has shown that, compared to participants with conspicuous stigma, individuals with concealable stigma felt worse about themselves and were more anxious and depressed. Only in the presence of similar others did these individuals improve in mood and self-esteem. Similar others may provide positive self-perceptions because they decrease individuals' sense of isolation and feelings of being different. Being with similar others may also result in more positive attitudes about the group. Despite these potential benefits, the fear of negative social evaluation may be more potent than the anticipated benefits of interaction with similar others.

According to a preoccupation view of secrecy, attempts at keeping a concealable disability secret activate a set of cognitive processes, which may lead to an obsessive preoccupation with the disability. The preoccupation results in renewed attempts to keep such thoughts suppressed. Eventually, intrusive thoughts and thought suppression occur cyclically. This cycle yields a continuous preoccupation with the individual's disability that can extend beyond the circumstances that prompted the initial secrecy. This obsessive preoccupation, combined with lack of support from similar others, can be of great harm to individuals with concealable disabilities. They may be overly distracted by the task of impression management and suffer in performance of cognitive tasks.

Individuals with disabilities that cannot be concealed are also subject to internalized negative evaluations and anticipated negative behavior of others. There have been numerous examples in which individuals who believed others were aware of their disabilities also believed that such awareness caused them to be less appreciated or to be judged in a negative manner. Persons with visible and concealable disabilities may have difficulties in social interaction. These may be partially due to how they believe others will react to their disability. Stigma consciousness (i.e., the extent to which individuals focus on their stereotyped/stigmatized status) may have important implications for how the individual experiences being stereotyped. People who are high in stigma consciousness are more negatively affected by the stigmatization of their disability. However, individuals with conspicuous or visible disabilities have an easier time identifying groups of similar others. Constructive connections with similar others often create positive self-perceptions among group members, which may decrease the extent to which stigma consciousness affects their reactions to stigma.

OTHER FACTORS AFFECTING THE DEGREE OF STIGMA

The degree of stigmatization also depends on other factors. These factors include the type of disability, the perceived responsibility of the individual for the disability, the perceived consequences of the disability for others, the outward manifestations of the disability, and the perceived impact of the disability on an individual's level of socially valued competence. Research also shows that the permanence of the disability affects others' perceptions and responses. Those with observable physical impairments have been found to suffer relatively fewer effects of stigmatization, whereas those with mental illness seem to be stigmatized to the greatest degree. Greater stigmatization of persons with mental illness may be due to perceived danger posed by the person to others and perceptions that a person with mental illness is responsible for his or her disability.

WAYS TO REDUCE/DISCREDIT STIGMA

Research offers three strategies to diminish the stigmatization of disabled individuals and groups: protest, education, and positive contact with stigmatized individuals. Protest may increase awareness of and decrease negative attitudes and beliefs about people with disabilities. However, to date, research suggests that it does not promote positive attitudes or increase knowledge about disabilities. Protest may also lead to short-term reactive effects; that is, it may make negative information about the disabled group more salient for a time. However, little research has been done on the effects of repeated protests on attitudes or beliefs. It is possible that reactive effects may be less likely to occur with repeated protests. To date, research has only examined the effects of protest on attitude change. It will be important to examine the effects of protest on behavior toward persons with disabilities.

Education facilitates greater understanding of persons with disabilities by providing accurate information. People who have a better understanding of a stigmatizing condition are less likely to endorse the stigma and discrimination. The type of information received may affect responses toward persons with disabilities. Participants in one study were either told about an individual's symptoms or his or her after-care plan. Those who received information regarding psychological symptoms increased their negative attitudes about the mental illness, while the after-care information reduced negative judgments. Greater knowledge of a disability prior to participating in an education program reduces stigmatizing attitudes after completing the program.

Personal contact with persons who have disabilities also decreases stigma. This decrease may be due to the positive effects of attitudes and beliefs about the common humanity and empowerment of persons with disabilities. Ultimately, greater social inclusion and changed societal attitudes may be the key to addressing the negative effects of all aspects of stigmatization.

The recent developments in the disability rights movement are creating stronger awareness of a positive disability culture. The development of disability culture identifies and affirms the strengths of people with disabilities, their high degree of life satisfaction, and their contributions to others with disabilities and to society at large. For people with disabilities, disability culture can be an effective antidote to stigma and its deleterious effects. For people without disabilities, it can provide important information about the impact of mainstream society, positive and negative, on people with disabilities. It can provide mainstream society with a more complete and ultimately positive perspective concerning people with disabilities. Thereby, disability culture may promote the development of mainstream cultural values that are inclusive of all people, as well as media reports that accurately reflect the challenges and celebrations of living with a disability.

STIGMA, INTERNATIONAL

The stigma associated with disabilities can be seen in every culture regardless of religion or ethnicity. In some cultures, people with disabilities are viewed as unclean or dangerous. Individuals with disabilities may be seen as the cause of societal "pollution." People with disabilities may also be viewed as being in a transitional state between sickness and health. Some aspects of the stigma associated with disabilities are quite consistent cross-culturally. For example, mental illness is strongly stigmatized in most cultures, with exceptions including some Native American and Russian societies. Across many cultures, disabilities that manifest themselves in unpredictable or odd behavior are associated with greater stigma (e.g., schizophrenia, addictions) than are other disabilities that do not (e.g., polio).

Despite these similarities, the stigma associated with disability does differ across cultures. Because societal views of disabilities are socially constructed, stigma associated with disabilities varies among cultures in many respects. The lives of persons with disabilities around the world are usually far more limited by prevailing social, cultural, and economic constraints than by specific physical, sensory, psychological, or intellectual impairments. Cultures differ in their popular explanations for why some individuals and not others have disabilities and how persons with disabilities should be treated. Societies differ in what roles are appropriate and inappropriate for persons with disabilities and what rights and responsibilities individuals with disabilities are either entitled to or denied.

Besides differences in the content and rationale for stigma, there is also a difference in the degree to which stigmatization occurs in different countries and cultures. There are differences in which and how many disabilities are viewed negatively and therefore are stigmatized to a greater extent. Popular wisdom and mythology regarding the causes of disabilities vary across cultures and lead to different levels of stigmatization.

The treatment that persons with disabilities receive is based in part on cultural beliefs about how and why they became disabled. Explanations for disabilities may include factors as diverse as divine displeasure, witchcraft, evil spirits, reincarnation, negative parenting, tainted blood, and genetics. More positive mythologies also exist. For example, in northern Mexico and Botswana, the birth of a disabled child may be welcomed as evidence of God's trust in the ability of specific parents to care for a delicate child.

Variations in cultural values may also be, in part, responsible for differences in stigma across cultures. The valued and devalued attributes or qualities admired in a society play a role in influencing which disabilities are more heavily stigmatized. Typically, those with disabilities are socially and culturally devalued and therefore are discriminated against in many forms. For example, in a society where survival is based on the success of hunters and gatherers, physical stamina and strength are of particular importance. Individuals with physical disabilities who cannot contribute to these tasks are likely to be more stigmatized than they would be in a society that relies on a virtual economy in which one can earn a good living working in physically accessible offices and meeting rooms. Moreover, because views of disabilities are socially constructed, the degree to which a particular disability is stigmatized may depend on factors unrelated to the disability itself, such as gender or income. For example, in North American society, bladder control problems are associated with stigma more for men than for women. In some Pacific Island societies, a man's status is determined in part by his ability to speak well in public. Therefore, hearing loss or a speech impediment will be stigmatized more heavily than other disabilities.

Another source of cross-cultural differences in the perceptions of disability is the extent to which collectivism, rather than individualism, is a cultural value in a society. Disabilities are often more heavily stigmatized in collectivist societies than in individualistic societies. Collectivist societies view the individual as an extension of the family or community collective. In a collectivist society, an individual may choose an occupation because it is needed in the community. The individual's achievements and failures may be viewed as sources of pride or disgrace to his or her family more than is the case in more individualistic cultures. Persons with disabilities will be stigmatized based on the extent to which the disability limits their contribution to the collective and the extent to which a disability is a source of shame for the collective.

Collectivist societies emphasize conformity to a greater extent than do individualistic societies, where nonconformity may be valued. The strong emphasis on conformity in collectivist cultures results in stigmatization of those who deviate from the norm in any respect. Persons with disabilities may be unable, because of their disabilities, to conform and thus may be stigmatized more heavily in collectivist societies. Another reason those with disabilities are more apt to be stigmatized in collectivist societies is that those with disabilities are associated with the inability to fulfill contributory roles in society. If they are not able to fulfill their part and contribute meaningfully to society, they are stigmatized.

In 2000, it was estimated that approximately 80 percent of the world's persons with disabilities lived in Third World nations in Asia or Africa. In these countries, malnutrition and unsanitary conditions contribute to low birth weight and birth defects and thus children with disabilities. Disabilities in the adult population are often the result of wars, natural disasters, and traffic accidents as the development of safety regulations lags behind rapid modernization. Stigma can limit the claim of people with disabilities on the scarce resources available. Given the concentration of people with disabilities in Asia and Africa, we will focus our attention on these parts of the planet as we consider stigma of persons with disabilities internationally.

STIGMA AND DISABILITIES IN ASIA

Across the many cultures of Asia, nations tend to emphasize the well-being of the community over that of the individual. In countries as diverse as India and Japan, this collectivist emphasis is closely intertwined with concepts of harmony and duty, and these values strongly influence the lives of individuals and communities. In Asian societies, people with disabilities tend to feel less shame at being dependent on others than would be the case in individualist countries such as the United States. It is common practice for family members to take care of other family members with disabilities. China has more people with disabilities than any other country in the world. A cultural norm among the Han Chinese, the major ethnic group, is to experience significant instinctive embarrassment at having a disability or having persons with disabilities in their midst. This embarrassment may be associated with an array of behaviors related to stigmatization, including discrimination and abandoning or euthanizing newborns with disabilities. In Thailand, families sometimes feel so ashamed of relatives with disabilities that they do not submit the birth certificates of babies born with disabilities to the government. Thai parents may see the disability of a child as a direct consequence of some previous transgression of the parent. In India, persons with leprosy go to great efforts to hide signs of it from view. They seek to avoid the judgment that they have engaged in sexual transgressions for which they are being punished and to avoid the further sanction of being excluded from their community. The Hindu/Buddhist idea of karma as the inevitable consequence of individual actions, even across generations in a family, is deeply entwined with perceptions of disability.

Social embarrassment at disability may also result in excessive protection of persons with disabilities, instead of considering them as having equal rights. It is not unusual for parents of children with disabilities to be unwilling to allow their children to go out by themselves. This same strong tendency to shelter or protect those with disabilities can be seen in the Philippines. Such protection, often done with the best of intent, can have serious long-term consequences. It is likely to limit opportunities for full development, reducing opportunities for people with disabilities in education, employment, marriage, and participation in community life. As is the case with the treatment of persons with disabilities in China and the Philippines, this belief system of shame and embarrassment results in people adopting stigmatizing extremes: overprotectiveness or discrimination, sometimes simultaneously.

In Japanese society, the pattern of stigma has been similar and now is showing some signs of change. The term used to refer to people with disabilities is *shougaisha.* This term conveys perceptions of people with disabilities as people of "obstacles," "illness," and/or "loss." Similar to views in other parts of Asia, the Japanese believe that being sick or having a disability is the result of sin in the past or in a previous life. This belief results in feelings of shame for having someone with disability in one's family. Japanese individuals without disabilities tend to perceive those with disabilities as being like children. In Japan, the distinction between persons with and without disabilities is clearly drawn. An example is the existence of disabled-only bathrooms, which, unlike their counterparts in some other societies, have stigma associated with them. The Japanese tend to have clearer categories and expect others to adhere tightly to the categorization.

Insights into stigma in Japan may come from the concepts of uncertainty avoidance and *Kegare.* People high in uncertainty avoidance perceive people and ideas that deviate from societal norms to be dangerous. Cross-cultural studies suggest that Japan has one of the highest population levels of uncertainty avoidance of any country in the world. *Kegare* is a Japanese term that implies impurity/contamination and encompasses everything that is outside the blessings of the gods. *Kegare* is thought of as contagious in Japanese culture and is associated with individuals with disabilities. *Kegare* also has a kinship connection. The mother of a child with a disability would be considered to be linked to the child's perceived impurity. Historically, children with disabilities were often kept from public view and given fewer opportunities to develop their abilities.

Presently, there are efforts in Japan and nascent efforts elsewhere in Asia, such as China and Korea, to reduce the stigma associated with disability and its negative effects. Programs to reduce the prevalence of abuse of people with disabilities, to increase educational and employment opportunities, and to promote independent community living all can help reduce stigma and its sequelae. Advocacy groups are working to build greater awareness of the positive contributions of people with disabilities to Japanese society. Students planning to enter the human services have positive rather than stigmatizing attitudes toward people with disabilities. As other Asian economies strengthen over time, it is reasonable to anticipate reduced stigma associated with disability.

PEOPLE WITH DISABILITIES IN AFRICA

In many ways, African conditions for persons with disabilities are similar to those in Asia. In African nations such as Botswana, the family rather than the individual is the primary unit of society. Persons with disabilities are involved in families and communities. For this reason, Western concepts such as inclusion, integration, least restrictive environment, and normalization may have little meaning. However, recent studies have shown that the introduction of Western education systems, which encourage greater focus on the individual, has led to segregated classes for pupils with disabilities.

The languages of many African nations and cultures have no term for disability. For example, the language of the Songye culture in Zaire has three categories of "abnormal children": (1) ceremonial, (2) bad, and (3) faulty. The Songye tend to attribute the acquisition of disability to ancestral acts, insufficient payment by the wife's family of dowry upon marriage, sorcery, or God's punishments rather than to any sort of genetic/chromosomal cause. In a similar vein, the Maasai culture in Kenya views illness and disability as signs of cosmic disorder projected on the human body. The Maasai, however, do not make the direct link between physical limitation, on one hand, and stigma and resulting inferior treatment, on the other. Both the Songye and the Maasai include persons with disabilities into their subsistence-oriented community life.

In Uganda, the issue of insider-outsider status is crucial for an individual with a disability. Specifically, an individual with a disability who is part of the community will be integrated, whereas an outsider with a disability may be isolated and avoided by the rest of the community. Part of this outsider avoidance may be due to the perceived contagiousness of disability. Ugandans' initial concern is that the loss of function related to the disability will spread rather than how the persons with disabilities compensate for their impairment. The idea of spread posits that the loss of one function leads to a decrease of capacity in other physical functions. In contrast, the idea of compensation posits that the loss of one function is likely to lead to increased capacity of other functions. As is the case in other countries, the degree of stigmatization may differ by gender. Finally, similar to Asian societies and many others, the power differential between the genders has, in general, been found to lead to more stigmatization for disabled females than males.

In addition, as is true in Asia, African societies see the individual according to his or her ability to contribute to the well-being of the community. Although persons with disabilities may be viewed negatively because of religious or philosophical interpretations in both Asian and African cultures, they usually are included in family and community life, receiving care from family members. Recent years have challenged these traditional structures, however. The HIV/AIDS epidemic has taxed the resources of families and communities, created many more people with chronic illness and disability, and decimated the ranks of potential caregivers.

In sum, cultural, psychological, religious, and economic factors all affect the degree and form of stigma associated with disabilities across cultures. While progress is being made internationally to improve the status and reduce the stigma of people with disabilities, such improvements are subject to changing conditions and attitudes in every human society. If the past is prologue, then the future is likely to see progress that continues to be uncertain, uneven, and reversible.

STRESS

Stress is defined as a reaction to external situational pressures, resulting in both physical and psychological changes in the individual. It is most often viewed as negative in the form of anxiety-producing and compromising physical and mental well-being. In some cases, however, stress is seen as positive (eustress)—perhaps pushing an individual toward extra effort or associated with positive changes in the life course, such as marriage. Stress related to disabilities can be examined in terms of physical characteristics (e.g., sight/hearing impairment) as well as mental or cognitive characteristics and impairment (e.g., learning disability/dementia). A concept closely tied to disabilities and stress is stigma, or the real or perceived ostracism, labeling, and “devaluation” of individuals and groups, often resulting in compromised social status, associated with having a disability. Stress associated with disabilities must be examined from social and interactional perspectives. A significant factor in reducing distress and important to the acquisition of legitimacy for people with disabilities is self-esteem—both at the individual and group levels—which allows people to believe they are included as members of society and, therefore, strive for the achievement of integration.

The impact of disabilities on the family has been a particular focus related to stress. Parents of children with developmental disabilities have been shown to have greater stress, depression, and health problems than parents of children without disabilities. Of interest, while children with disabilities can have a negative impact on parents' marriage, it has been reported that children with disabilities can also bring parents closer together and that a strong marital relationship is one of the most important factors mediating parental stress. Coping resources that have been shown to minimize familial stress related to disabilities include social support from friends and individual personality and beliefs (e.g., religious faith). Literature on the coping responses of adolescent siblings of children with disabilities indicates the need for professional support and the establishment of strong support networks to facilitate coping.

Research on disability and job stress indicates that people with work disabilities often experience increased risk for physical and psychological complications of job stress. Disability management programs implementing stress management interventions—targeting such disorders as back pain, multiple sclerosis, HIV, chronic fatigue syndrome, arthritis, high blood pressure, headache, and general psychological distress—have been shown to improve physical and mental health, reduce costs to employers, and facilitate the reintegration of injured individuals into the work environment. Interventions include use of cognitive behavioral stress management and a team approach, including physicians, nurses, psychologists, occupational therapists, social workers, and physical therapists.

Understanding and addressing quality of life, including stress, in people with disabilities requires modifications in social and societal attitudes and behaviors. In medical encounters, people with disabilities, while generally satisfied with their medical care, report lack of satisfaction with doctors' understanding of their conditions, thorough discussions of health problems, and being hurried during medical visits. The concept of the "disability paradox" looks at the inconsistency between general perceptions of the undesirable daily existence of people with disabilities compared to their own views of good or excellent quality of life. In examining and addressing stress in people with disabilities, quality of life needs to be understood in the context of the individual's balance between mind, body, and self and relationships with the social and environmental context.

STROKE

Stroke is one of the most common causes of acquired disability in adults throughout the world. The World Health Organization estimates that 15 million individuals worldwide sustain a stroke each year, with 5 million deaths. Of the survivors, approximately 5 million are left with significant disability.

The existence of stroke as a distinct condition has been known since antiquity. Psalm 137 appears to describe the symptoms of stroke. "If I forget thee, O Jerusalem, let my right hand forget her cunning. If I do not remember thee, let my tongue cleave to the roof of my mouth." Ancient Greek physicians, including Hippocrates and Galen, recognized the essential symptoms of "apoplexy," though they debated the causes and location of the disease. Characterization of the anatomical basis of stroke syndromes, such as Broca's aphasia, occurred during the nineteenth century. A clear understanding of the mechanisms and major risk factors for stroke occurred during the twentieth century.

Because of its prevalence and ability to cause substantial disability, stroke has affected numerous world figures and altered the course of history. A prominent example from the twentieth century is the severely disabling stroke sustained by Woodrow Wilson during his second term as U.S. president. This stroke prevented him from exercising his duties as chief executive. The extent of his disability was hidden from the public and even from most of his cabinet; a small inner circle, including his wife and personal physician, controlled all access to the president during the remainder of his term. Subsequent recognition of the inadequate provisions in the U.S. Constitution for the disability of the president ultimately contributed to the adoption of the 25th Amendment in 1967. Other contemporary examples of the impact of stroke on world history include Franklin Roosevelt's death while in office from a cerebral hemorrhage in 1944 and Joseph Stalin's death from a stroke in 1953.

Strokes are broadly divided into two categories based on the cause of damage to the brain. Approximately 88 percent of strokes are ischemic and result from the loss of the supply of blood to an area of the brain that occurs when a blood vessel becomes blocked. The remaining 12 percent of strokes result from bleeding either within the brain (hemorrhagic stroke) or adjacent to the brain from the blood vessels that supply it (subarachnoid hemorrhage). The destruction of brain tissue that results from these various etiologies results in neurologic deficits that are the hallmark of stroke.

Risk factors for ischemic stroke are well established, and many are amenable to behavioral or medical preventive measures. Age and race are important nonmodifiable risk factors, with men having a higher risk than women (approximately 1.25 times the risk) and African Americans having a higher risk than Caucasian Americans (nearly twice the risk). Hypertension, smoking, inactivity, and obesity are all important modifiable risk factors that may be addressed in part through behavioral changes and in part through medical treatments. Behavioral modifications include smoking cessation, regular exercise, limiting caloric intake, and reducing intake of saturated fats. Preventative medical treatments include the use of platelet-inhibiting medications such as aspirin and clopidogrel; in selected circumstances (such as atrial fibrillation), anticoagulants (primarily warfarin) are indicated. In individuals with a severely narrowed carotid artery (one of the major blood vessels supplying the brain), surgery to remove the blockage within the artery can reduce the risk of stroke significantly.

Stroke can cause disability by affecting one or more of a multitude of neurologic functions. Loss of muscle strength and coordination (hemiplegia) is the most common cause of physical disability after stroke. Aphasia (loss of the ability to comprehend and/or produce speech or other linguistic communication) is another major cause of disability. Cognitive impairments, including reduced attentiveness, memory loss, and loss of insight, are frequent sequelae of stroke and contribute to the burden of disability. Swallowing difficulties (dysphagia) can cause malnutrition, dehydration, and predisposition to pneumonia. The location of a stroke is the major determining factor in the resulting neurological impairments; a small stroke in a critical area can cause more profound symptoms than a larger stroke in a less critical region. Some strokes are "silent" inasmuch as they do not result in any noticeable symptoms. Prior silent strokes are commonly discovered incidentally when brain imaging is performed for a new (symptomatic) stroke.

Improved acute treatment of stroke remains a priority area of medical research. As recently as the early 1990s, acute stroke care largely consisted of supportive measures to prevent medical complications, and no interventions were available to limit damage from an ongoing stroke. Intravenous medications (such as alteplase) are used to dissolve blood clots depriving brain tissue of blood flow and are now an important part of the management of acute stroke. Unfortunately, relatively few individuals with stroke are eligible for thrombolytic (clot-dissolving) treatments due to the narrow time window for their use (typically within three hours of symptom onset). The use of catheters threaded through the blood vessels to instill these medications directly to the vicinity of the blood clot is under study, as are other interventional approaches to opening blocked arteries. A variety of medications have been studied as potential neuroprotectants to reduce the damage induced by a stroke, but none has yet reached routine clinical use.

Due to the limitations in stroke prevention and acute treatment, residual disability is a common result of stroke. Stroke rehabilitation has its roots in antiquity, and references to the use of a crutch after stroke are found in Babylonian texts from the second millennium BCE. Modern rehabilitation has increasingly emphasized the use of active participation by the stroke survivor to achieve maximal recovery, rather than the use of passive treatments provided by medical providers. Stroke rehabilitation in developed countries typically includes physical, occupational, and speech therapy for a period of weeks to months. Efforts to reduce hospital or other institutional stays are ongoing, with increasing emphasis on rehabilitation in the home environment. Rehabilitation hospital stays after stroke now average two or three weeks in the United States; they remain longer in other countries, such as Japan.

Rehabilitation in less developed countries varies widely. Some rely more on family members and informal rehabilitation than on medically directed rehabilitation. Little data are available to compare functional outcomes between the various rehabilitation systems in different countries.

Recent research has found considerable plasticity in the adult human brain. Both changes in brain function, as demonstrated with the use of functional magnetic resonance imaging and other techniques, as well as changes in motor abilities have resulted from therapeutic exercise programs. This plasticity can be harnessed by structured exercise programs to improve motor outcomes after hemiplegic stroke. Intensive exercise programs appear to provide greater benefit than lower dose exercise programs and are being actively studied. Some centers are also exploring the use of technological aids such as robotic exercise devices to facilitate the delivery of exercise after stroke. The use of medications, growth factors, and stem cells to expand the capability of the brain to recover from stroke is being studied and is likely to be combined with rehabilitation programs in the future.

Plasticity clearly affects other impairments resulting from stroke, such as aphasia and cognitive deficits, and therapeutic interventions directed at these impairments appear to facilitate recovery. The optimal program of therapeutic interventions to stimulate brain plasticity and maximize functional recovery remains to be elucidated.

Functional outcome after stroke can be measured using a variety of tools, including the Functional Independence Measure, the Barthel Index, and others. Among ischemic stroke survivors in the United States who are at least 65 years old, 26 percent are institutionalized in a nursing home six months after a stroke. Depression is a common consequence of stroke, and as many as 40 percent of stroke survivors experience significant depression within the months following a stroke.

SUBSTANCE ABUSE

EPIDEMIOLOGY

Substance abuse is one major source of health problems afflicting individuals worldwide. It is estimated that one fourth of Americans experience a lifetime substance use disorder. Substance-related disorders are covered under the Americans with Disabilities Act of 1990. Therefore, problems derived from substance abuse can be viewed as disabilities.

Even excluding substance abuse as the primary disability diagnosis, persons with cognitive and physical disabilities are more likely to have a substance use disorder than the general population, yet they are less likely to obtain and complete treatment for it. Treatment barriers include not only those related to physical accessibility but also poor professional training to deal with the particular needs of individuals with concurrent substance abuse and disabilities.

It is estimated that 20 to 40 percent of persons in treatment for substance use disorders have some sort of mental or physical disability (mostly a comorbid psychiatric condition, followed by mobility, developmental handicaps, and sensory—vision and hearing—impairments). Often undetected, the presence of a disability, even subtle, may affect treatment effectiveness. A high prevalence of comorbid disability and substance use is also observed in other settings such as prison and court populations, where approximately 50 percent of offenders with an intellectual disability also have an alcohol problem.

ETIOLOGY

Substance abuse is often a factor in trauma-related physical injuries. Driving under the influence of alcohol contributes to traffic accidents and related disability. Despite the fact that legal blood alcohol concentrations (BACs) vary widely across countries, evidence shows increased risk of car crashes with BACs above 0.02 percent (that translates to approximately one bottle of beer, but factors such as sex and body weight may interfere with this estimate).

A relationship between unfavorable childhood conditions, early deviant behavior, and later alcohol abuse and related disability has been demonstrated. Drunken driving and criminal behavior in young males were related with more disability pensions and sick leaves on a 20-year follow-up. Thus, monitoring of such behaviors may help identify at-risk populations for disabilities. The relationship between substance abuse and disability seems more complex than just one of cause and consequence, with substance abuse working both as a risk factor and a maladjusted response augmenting disability after injury. For instance, substance abuse that develops after an injury can be a hindrance to rehabilitation.

Aside from physical disability, substance abuse is also implicated in psychological maladjustment, particularly among young people, demonstrated by increased rates of conduct and personality disorders (mainly those characterized by intense impulsiveness, such as antisocial and borderline). A number of psychiatric conditions are also overrepresented in substance-abusing populations, including affective, anxiety, and psychotic disorders. The risk of other addictive disorders is increased (polydrug abuse and eating disorders, particularly bulimia nervosa, for instance). Adding to the physical sequels of addiction, pathological gambling is another concern, with its associated impulsiveness (with greater likelihood of suicide attempts and criminal offenses), risk of bankruptcy, discredit, and deeper social disruption. Rates of attention deficit disorder are increased among substance-abusing individuals. Women are at higher risk for psychiatric comorbidity and to develop iatrogenic substance abuse/dependence as they are more likely to be prescribed medications such as benzodiazepines. Worries about body image also put them at risk of abusing amphetamines and other diet pills. Theories to explain these increased associations include (1) self-medication of a primary mental disorder, (2) substance abuse leading to the development of secondary psychopathology, (3) coexistence of substance abuse and psychiatric morbidity independently, and (4) a common etiologic factor leading to both substance abuse and psychiatric morbidity.

Substance abuse is also etiologically related to development of a disability during pregnancy. For instance, fetal alcohol syndrome (FAS) represents the third most common cause of mental retardation (the leading cause if genetic causes are excluded), with increasing risk in association with binge drinking. It produces long-term consequences, particularly social maladjustment and communication deficits. The full syndrome is present in about 30 percent of the offspring of women who consume 10 standard drinks daily. Fetal alcohol effects (FAE) are often underdetected. Symptoms may include central nervous system abnormalities, with mental retardation in about half the cases of full syndrome, facial dysmorphism (characterized by short palpebral fissures, epicanthic folds, and maxillary hypoplasia), and other birth defects (microencephaly, altered palmar creases, and heart abnormalities). Diagnosis after puberty is even more difficult, as the facial dysmorphism is usually not as pronounced. FAS and FAE are often associated with increased psychiatric comorbidity, substance use disorders, antisocial behavior, and multiple pregnancies in adolescence and adulthood. Early detection and appropriate referral may prevent further morbidity. Because safe levels of alcohol consumption during pregnancy are not defined, it is best to recommend complete abstinence to prevent FAS and FAE.

Tobacco use during pregnancy is also associated with perinatal problems (e.g., fetal growth retardation, obstetric complications, premature delivery, low birth weight and height, neonatal mortality, sudden infant death syndrome, and hypertension), with some long-term physical and behavioral consequences to the offspring (such as reduced lung function, substance abuse, criminality, and antisocial behavior), independent of other factors. Both alcohol and tobacco (by far the substances that cause the most problems if consumed during pregnancy) have addictive effects in combination with other substances. Besides the effects of substances themselves, the lifestyle often associated with substance abuse, including poor nutrition, lack of resources, and appropriate medical care, further contributes to these long-lasting disabilities in offspring.

Environmental circumstances faced by persons with disabilities may contribute to substance use and abuse, such as job problems and unemployment, lack of leisure opportunities, social isolation, poverty, homelessness, and various forms of abuse (emotional, physical, and sexual, both from domestic and external sources).

To improve detection of coexisting disabilities among persons entering treatment for substance use disorders, it is strongly recommended that every person should be specifically screened for disabilities, not only those obviously affected. More important than diagnosing a potential disability—a task that most professionals in addiction treatment centers are not prepared for—the levels of functionality need to be assessed since adjustments in the treatment protocol will be based on these aspects. This is important because even people with similar disabilities may have very different abilities and limitations. Assessment should be tailored to the nature of the disability (e.g., finding alternatives to self-report questionnaires for the mentally handicapped or to visual-analogical scales for the vision impaired).

In addition, the assessment team needs to be sensitive to the fact that some people have more difficulties accepting an eventual disability than others (depending on issues such as severity, age, marital status, income, and sociability). Likewise, a confidential climate needs to be ensured (particularly important when the disability implies that family members and friends will accompany the client) to enable the collection of relevant and accurate information. Clients should be referred for additional assessment by a qualified professional if initial screening indicates that a disability diagnosis might be present. Screening can be part of the usual assessment process for potential clients and can incorporate indirect questioning (such as questions about environmental factors that may be related to disabilities; prior medical history, including medications and hospitalizations; and accidents) and direct questioning (such as questions about history of any disability or health benefits and learning, hearing, reading, communicating, writing, decision-making, or mobility difficulties). Besides work absences, effort to function should be considered. Recently, the 36-item short form health survey of psychosocial functioning has been proposed as a tool for screening and measuring disability due to psychiatric conditions.

Attitudes toward persons with coexisting disabilities in addiction treatment should emphasize accommodation of any special needs and requirements.

In addition to avoiding rigid rules and deadlines that may make treatment participation virtually impossible, professionals must attempt not to enable clients' negative attitudes (such as accepting a client's refusal to attend mutual-help meetings for fear of not being accepted by peers) that could erode treatment efforts. Arranging for alternative groups and schedules is a more desirable option. Many clients with coexisting disabilities may be under a medication regimen. Some addiction treatment programs demand that potential clients discontinue any medications before entering treatment, which is obviously not feasible in many circumstances.

Finally, getting acquainted and networking with disability-related resources in the community, by ensuring referral to properly equipped services, may save time and effort that can be best directed to treatment itself.

SUBSTITUTE DECISION MAKING

Substitute decision making occurs when a person lacks mental competence to make a decision, and the situation requires that a decision be made. Substitute decision making ordinarily becomes controversial when the decisions concern very serious financial or health matters. The controversies tend to center on two main issues. The first issue is the choice of who should be the substitute decision maker. The second issue is concerned with how the decision should be made.

DECISION MAKERS

There are numerous ways that a person can be chosen to be a substitute decision maker, and the legalities of the process vary across jurisdictions. Generally speaking, there are three types of decision makers: a decision maker appointed by the incapacitated person prior to incompetence, a decision maker appointed by the state, and a decision maker in an emergency.

A Decision Maker Appointed by the Incapacitated Person

Many jurisdictions allow individuals to appoint someone to take care of their property and health matters in the event that they become unable to make decisions for themselves. For example, in parts of the United States, Britain, Australia, New Zealand, and Canada, it is possible to create an *enduring* or *durable power of attorney,* which grants a substitute decision maker the power to act on behalf of a person who has become mentally incompetent. These powers of attorney are described as "durable" because, unlike ordinary powers of attorney, they continue to be effective after the grantor of the power has become incompetent.

In addition to choosing a decision maker, powers of attorney will normally define the role of the decision maker and contain instructions on the types of decisions that can be made and the preferences of the person subject to the power. It should be noted that these documents are different from advance directives or living wills because they allow the substitute decision maker to make the ultimate choice. In an advance directive, the patient is the decision maker.

One limitation exists with this method of choosing a substitute decision maker. These documents cannot be created by a person who has always lacked mental competence.

A Decision Maker Appointed by the State

The state has a role in protecting people who are unable to make decisions for themselves. In the common-law tradition, this is evidenced by the *parens patriae* jurisdiction, an eleventh-century English concept, which granted to the sovereign the power and responsibility to care for infants, "lunatics," and "natural fools and idiots." The parens patriae jurisdiction has survived into modern times and is still relied on by courts in Australia, Canada, New Zealand, and the United States as the source of power to make substitute decisions for mentally incompetent adults and children. It is also used to appoint other decision makers. Strangely, England no longer has a parens patriae jurisdiction over adults because of an administrative error in 1969, which removed it from the list of prerogative powers enjoyed by the sovereign.

Most jurisdictions provide for state-based appointment of substitute decision makers, ordinarily when the person has not exercised a choice via a power of attorney, either using the parens patriae power or legislative powers. Most commonly, state-appointed substitute decision makers are referred to as *guardians,* but the terms *conservator, custodian,* and *curator* are also employed in parts of the United States. Courts or specialist guardianship tribunals are ordinarily given the task of appointing guardians. Ordinarily, a relative or close friend is chosen because they are best equipped to look after the person under guardianship.

If no suitable candidate is available to be appointed as a guardian, a public body or official (such as a court, guardianship tribunal, adult guardian, or public guardian) may be appointed in the role.

A Decision Maker in an Emergency

It may be necessary in an emergency for someone to make a substitute decision for another because that other person is mentally incapable and has never appointed a substitute decision maker. The most common example of this occurs in medical emergencies, when a person is unconscious or seriously injured and unable to make a decision about treatment.

In parts of the United States, it has been assumed that relatives automatically have the power to consent in such situations, and in emergencies, doctors will ordinarily seek the consent of a relative unless the situation demands immediate treatment. In countries in the British Commonwealth (such as Australia, Canada, New Zealand, United Kingdom), relatives only have power to consent to treatment when the patient is a child. Relatives cannot consent to emergency treatment for incompetent adults. This gap in consent has led some legislatures to grant powers to relatives so that they can consent to emergency medical treatment, without the need for a power of attorney or an order by the courts. For example, in the Australian states of New South Wales, South Australia, Tasmania, Victoria, Queensland, and in the Australian Capital Territory, legislation allows relatives to consent to treatment when the patient is not competent. If no relative is available, a doctor may continue to treat the patient according to the patient's best interests. There are moves to adopt such laws in England and Wales.

What if a person's relatives cannot be contacted? In such emergencies, the common law empowers health professionals to treat an incompetent person, even in situations when the treatment is quite invasive. Such situations are seen as an exception to the general rule against touching another person without his or her consent. Health professionals can raise the defense of emergency (sometimes called the defense of necessity) to any claims of battery or wrongful interference. To properly mount such a defense, the health professional must be able to show that the patient was incompetent, that there was no substitute decision maker to seek consent from, and that the treatment was a necessary and proportionate response to the illness or injury of the patient.

Some jurisdictions (e.g., parts of Australia, Scotland, and the United States) have enshrined these rights of emergency medical treatment in legislation.

HOW SHOULD DECISIONS BE MADE?

Generally speaking, two approaches can be employed in substitute decision making.

The Best-Interests Approach

The best-interests approach requires the decision maker to choose the course of action that can be considered on objective grounds to best serve the interests of the incompetent person.

For example, in the United Kingdom case of *Airedale NHS Trust v. Bland* (1993), the House of Lords had to decide whether it was in the best interests of a young man in a permanent vegetative state to continue to be treated with artificial feeding and hydration. The House examined the issues of the probability of success of treatment, the likelihood of recovery, and issues concerning the man's lack of quality of life. The House took evidence from doctors and other health professionals to assess these factors and decided that it was no longer in best interests to receive such treatment.

The best-interests test is the standard of substitute decision making most commonly employed in the United Kingdom, Australia, New Zealand, and Canada. It is also employed in some states in the United States.

The problem with the best-interests approach is that it can be vague, and best-interests assessment can often be disputed. It is difficult to pinpoint exactly what objective factors should be considered in different types of decision, and the approach says nothing about how those factors should be weighed against each other. There is also the possibility that the decision maker's own prejudices will be disguised as "objective assessment." The best-interests test also runs the risk of reducing the autonomy of the incompetent person because of its focus on objective factors rather than the subjective desires of the incompetent person.

Substituted Judgment

The substituted judgment approach requires the decision maker to take into account the subjective beliefs, feelings, and desires of the incompetent person. A person exercising substituted judgment must choose the course of action that (according to the decision maker) would be the course of action chosen by the incompetent person.

The substituted judgment approach originated in English equity courts in their supervision of an incompetent person's property. It was primarily used to justify gifts from the estate of the "lunatic" to the lunatic's family or friends on the basis that such gifts would have been what the incompetent person would have wanted. In modern times, it is widely employed in the United States as the method of substitute decision making.

We can compare the best-interests approach used in *Bland* above with the substituted judgment approach used in a similar case, *Matter of Quinlan* (1976). In this case, the father of a severely disabled patient sought to be appointed her guardian, so that he could authorize the cessation of her respiratory support. The court appointed the father as guardian and said that he should exercise his best judgment as to whether the patient would have refused treatment in the circumstances that arose. Later, in *Superintendent of Belchertown State School v. Saikewicz* (1977), a case concerning a never-competent man with cancer, it was said that the substitute decision maker dons the mental mantle of the incompetent and substitutes herself or himself as nearly as possible for the individual in the decision-making process.

Several criticisms have been made of substituted judgment. The first is that it is a fiction to presume that another person knows what would have been decided by the mentally incompetent person. To counter this critique, some jurisdictions require clear and convincing evidence of what the incompetent person would have decided, such as statements made by the incompetent person or evidence of similar decisions made by the person previously. Others have said that this raises the standard so high that the evidence required is the same evidence that would be required to substantiate advance directives.

Problems also occur when the incompetent person never expressed an opinion or desire or never had the ability to express a desire or opinion. In Canada, the substituted judgment test has undergone judicial criticism for this reason. In *Re Eve* (1986), Justice La Forest denied that the test had any bearing on the issue of the sterilization of a mentally handicapped woman who had suffered from the disability since birth. Justice La Forest saw the substituted judgment test as "sophistry" and "speculation."

Combined Approaches

To counter the difficulties with both approaches, some jurisdictions (such as New Jersey) have adopted a combined approach, whereby substituted judgment is attempted first, and if it is not determinative, best-interest factors can be considered. Alternatively, an expanded best-interests test is employed in some jurisdictions, which contains elements of substituted judgment (see, e.g., cases from Minnesota and New Zealand).

SUGIYAMA, WA'ICHI (1610–1694)

Acupuncturist

Sugiyama Wa'ichi lost his sight in childhood. As a young man, he went to Edo (Tokyo) and studied acupuncture under the teacher Kengyō Yamase. However, "because he was too slow to learn he was expelled by his master." Later, Sugiyama overcame his difficulties, developed an innovative technique for guiding the insertion of needles, and eventually became a famous practitioner and official acupuncturist to the Shogun Tsunayoshi. Kengyō Sugiyama Wa'ichi founded his own school, wrote books on the field, and at the end of his life achieved the highest position in the powerful Guild of the Blind. He is credited with "establishing acupuncture as a common occupation for the blind" and organizing them into a cohesive group during the seventeenth century.

SUICIDE

The relationship between disability and suicide hinges simultaneously on scientific, political, and moral questions. The scientific question is whether disability represents a significant risk factor to suicide and why. The political question is whether people with disabilities who threaten suicide should receive the same response from health professionals as nondisabled people. The moral question involves the question of "quality of life" and whether disabilities make "life not worth living." Underlying all three of these questions is our cultural attitude toward self-sufficiency and interdependency.

THE SCIENTIFIC QUESTION

Very little data have been gathered with regard to suicide risk factors for people with disabilities, but there is no reason to assume that they differ from risk factors for nondisabled people. Warning signs for suicide for both groups can be found in (1) disruptive family history factors such as abuse or neglect in childhood, enmeshment, separation, loss, and suicide itself; (2) toxic personal history factors such as depression, schizophrenia, substance abuse, low self-esteem and frustration tolerance, demoralization/hopelessness, and rigid/constricted thinking; and (3) personal stressors such as relationship loss or abuse, loss or control over life, social isolation, and problems in work, housing and finances. People with disabilities may face social discrimination that heightens some of the above triggers for suicide.

For example, people with disabilities may face difficulties with the legal and medical system, difficulties of obtaining personal assistance, social devaluation, and threatened loss of independence. These factors may be especially overwhelming for people with newly acquired disabilities. Physically disabled people are no different in this regard from many people with mental disorders such as schizophrenia. The risk for suicide, for example, is much higher in the first few years after a diagnosis of schizophrenia and diminishes after that as schizophrenia turns into a more chronic condition, suggesting some adjustment to illness. However, individuals with schizophrenia are again at increased risk when psychotic symptoms such as auditory hallucinations return, suggesting that adjustment to illness and symptoms themselves may independently be suicide risk factors. People may adjust to physical disability in the same way.

There is concern and debate around the issue of physician-assisted suicide for patients with terminal illness and/or disabilities. Data suggest that disability is a risk factor in people seeking physician-assisted suicide and/or perhaps in being selected by medical personnel for this "treatment." However, the data also suggest that it may not be disability per se that leads people to seek suicide but psychological factors associated with suicide that would also push nondisabled people to attempt to end their lives.

For example, there is a case on record of a woman with cerebral palsy who expressed the wish for physician-assisted suicide after a series of severe losses, including a miscarriage and a marital separation that left her essentially homeless and impoverished. A videotape of another patient revealed a highly accomplished patient with the beginning of Alzheimer's who found that much of her activities and abilities were now discounted and belittled. For example, although she could still play tennis, she could no longer keep score on her own. Even though she could still play piano, she could no longer sight-read.

THE POLITICAL QUESTION

The political question stems directly from these examples. Are disabled people who threaten suicide treated the same or differently than nondisabled people who threaten suicide?

When a person comes to a health professional with suicidal desires, such desires are typically interpreted as the product of a temporarily self-destructive and tumultuous state of upheaval leading the person to be temporarily tunnel-visioned and to temporarily see suicide as the solution to problems. The person may be hospitalized, friends and family will be notified, and the suicidal wishes will be interpreted as profoundly irrational—indeed, a permanent solution to a temporary problem. The health professional will attempt to keep the person safe until the temporary madness has passed.

For example, a young woman may have just ended a destructive romantic relationship and feels that nothing in her life has any value. The woman's feelings are interpreted by the professional as only temporary. The professional may emphasize that when one is in a depression, he or she always views the future through a negative lens. Likewise, a man whose spouse has died may be devastated and, in his bereavement, may become highly suicidal. Similar examples can be found in many life crises, including loss of a job, infidelity of one's spouse, and death of a loved one. Before a person is able to gather social support networks and can cope sufficiently to envision a future after the loss, he or she may be very drawn to suicide as an alternative to the pain of living. The mental health professional will work to minimize the effects of the loss to prevent collateral damage. The therapist must emphasize to the patient that although he may have failed, he is not a failure. He will get another, perhaps a better, job. The therapist must play for time with the patient, until the person's coping mechanisms activate and he or she is able to reassert a drive for life. Consider these examples if the person is disabled.

Here the temptation is to see the person's suicidal desires as not irrational at all but rational, stemming from the disability, rather than from the actual psychosocial stressors underlying the suicidal wishes. The desire to die may not be interpreted as suicidal but as an attempt to free oneself from suffering. This may be especially true if the person depends on medical intervention to remain alive. A desire for suicide may be euphemized as "refusing treatment."

The person's suicidal desires may be interpreted as rational, rather than irrational, even though the triggering factors are the same as for a nondisabled person. This fixation on disability represents what the disability community labels a "deadly compassion," which may emerge because of one's own fear of becoming disabled. The professional in such a situation may not try very hard to prevent the person's suicide and, if not actively assisting him or her in it, may well give implicit approval that the suicide is quite understandable. Indeed, in the physician-assisted suicide case discussed above, the husband of the patient suffering from the beginning of Alzheimer's opined that he would take his own life if such a calamity befell him. Such a double-tiered approach to suicidal wishes is profoundly troubling to the disability community. Suicidal wishes in a nondisabled person will be labeled as irrational and evoke suicide prevention responses on the part of health professionals. The same wishes on the part of a disabled person might be labeled as rational and evoke silence or even calls to assist the person to carry out his or her suicidal wishes.

THE MORAL QUESTION

The moral question is whether life is of unconditional worth or whether it is only worthwhile if it has a certain "quality." This debate goes back to biblical Israel and Greece of classical antiquity. The Greek and Roman stoics advocated suicide if life no longer conformed to a person's expectations or desires. Disability, as well as simply boredom, could well represent a rational reason for suicide. Suicides were abundant in ancient Greece and Rome, and Greek tragedy is filled with such instances. The Judeo-Christian biblical world, in contrast, does not view suicide as rational and indeed equates it with homicide. Strikingly, no such concept as "quality of life" exists in biblical thought. Life is not seen as divisible but as having an intrinsic and infinite worth. Suicides are rare in the Bible and not associated with disability. There are data also to show that people living in countries where religion imposes strict taboos against suicide have lower rates, but again, these data have not been separated for disabled people only.

One major concern to address when considering the suicide-disability relationship is how society views dependency and independence. There are cultures that highly value or arguably overvalue independence, and in such societies, a disabled person may feel unvalued and even a burden, making suicide a natural action to consider. Other societies highly value connectedness on interdependency within the context of extended family or cultural group. In such societies, being dependent might not have the same pejorative connotation and therefore not as likely to lead to suicidal thoughts.

SULLIVAN, ANNE (1866–1936)

Special educator

Anne Sullivan was born in 1866 near Springfield, Massachusetts. At the age of 4, she became totally blind due to trachoma, an eye disease associated with poor sanitation. Her mother died when she was 10, and she and her younger brother were sent to the almshouse, at Tewksbury. Shortly after their arrival, her brother died from tuberculosis, but Annie lived there for another four years and then was sent as a charity student to the Perkins Institution for the Blind in Boston. Her sight was partially restored through a series of experimental surgeries, though her vision remained impaired, and eventually she became blind again at the end of her life.

In 1887, Sullivan was chosen to travel to Tuscumbia, Alabama, to serve as the teacher of a young deaf-blind girl named Helen Keller. Using methods develop by Perkins founder Samuel Gridley Howe, in his work with the deaf-blind girl, Laura Bridgman (1829–1889), she trained Keller to communicate with the manual alphabet for the Deaf. Sullivan's innovation was to simulate the way a hearing child learns to speak by being constantly surrounded by spoken language. She did not restrict her instruction to scheduled lessons but spelled constantly into Keller's hand. She remained Keller's companion for nearly 50 years, helping her to pursue her education and acting as her interpreter at lectures and as an editor of her numerous publications. In 1905, she married John Macy, Harvard professor and editor of Keller's first book, *The Story of My Life.* The couple separated a decade later, though they were never divorced.

Sullivan and Keller never felt that Sullivan's work as an educator received the recognition it deserved. She was alternately lauded as a miracle worker and critiqued as a self-promoting charlatan who exaggerated the accomplishments of her pupil. Both views reflect a general belief that Keller's accomplishments were exceptional, far in excess of what should be expected from a deaf-blind child.

SUMMARY MEASURES OF POPULATION HEALTH

The generic label *summary measures of population health* (SMPH) refers to a class of statistics that describe and quantify different elements of population health. The relatively large number of SMPHs is attributable to the variety of uses for SMPHs and the fact that each use might, in principle, require a somewhat different SMPH. The resulting set of SMPHs reflects the various and evolving approaches to measurement that have been used over time by different researchers and health-related organizations.

Table 1 Purposes of SMPHs

1. Intrinsic interest: Indicating how long and in what state of health different individuals are likely to live
2. Cross-national comparisons and benchmarking
3. System planning: Indicating the likely future health profile population for social and economic planning
4. Planning time: Time-series data to monitor health and plan health services and health workforce
5. "Micro" planning: Disease-specific population measures
6. Comparison of subpopulations within a country
7. Measuring the *burden* of different diseases in health sector planning
8. Measuring health benefits from medical or other interventions
9. Epidemiological and health services research
10. Prioritizing medical research

Table 1 lists 10 possible uses for SMPHs. Broadly, these include the intrinsic interest, benchmarking, social and health sector planning, and the evaluation of performance at both national and program levels. The resulting SMPHs vary along a number of dimensions, some of which are summarized in Table 2. While some of the differences in SMPHs are attributable to different technical approaches to measurement, most differences in Table 2 arise because of differences in the concept being measured—for example, life versus the value of life and prevalence or incidence of a disease.

Different concepts, in turn, arise because of the different purposes for which they were created. For example, the measurement of the current burden of disease uses a prevalence-based metric, whereas measuring the total impact of new health policies often uses an incidence-based concept. These decisions tend to be pragmatic and arbitrary, depending on ease of access to appropriate data.

Depending on the purpose, the construction of an SMPH can involve up to seven stages:

1. defining the objectives of the measure;
2. defining the populations to be described, such as a whole country or a randomized controlled trial study group;
3. defining the time span of the measure, such as a human lifetime or a five-year period;
4. defining the range of health states and illnesses to be included in the measurement process;
5. measuring the numbers of people in the different health states and illness in the population;
6. estimating the severity of the health states of the people in the population by a process of valuation;
7. defining the health target or goal to be achieved in the population.

HEALTH EXPECTANCIES AND HEALTH GAPS

The most basic distinction in Table 2 is between the measurement of health expectancy and health gaps, and this is used to classify the SMPHs in Table 3, which summarizes the different measures. Health expectancies are based on the actual health experience of a population. Health gaps estimate the difference between actual health and some theoretical norm or goal of population health.

Health Expectancies. Health expectancies (HEs) estimate the expectation of years of life lived in various health states, expressed as average survivorship from fixed ages (e.g., life expectancy from birth). This includes expectations for specific health states (e.g., disability-free life expectancy) and for value equivalents of different health states (e.g., disability-adjusted life expectancy).

Table 2 Characteristics of SMPHs

Quantity Measured
Health expectancy versus gap
Lives versus life years
Incidence versus prevalence
Unadjusted data (mortality/1,000) versus adjusted data (life expectancy)
Life versus value of life
Technical issues
Cohort versus period measures
Mean versus median
Dichotomous versus continuous

Health-Adjusted Life Expectancies. Health-adjusted life expectancies (HALEs) are those HEs that estimate the expectation of equivalent years of good health, calculated for health states defined in terms of valuation of disability severity. HALEs give a weight of 1.00 to years of good health and weights between 0.00 and 1.00 to other states of less than good health. Healthy life expectancy is now used as a synonym for HALE, rather than its previous usage for a health state expectancy for perceived (self-reported) good health. Disability-adjusted life expectancy (DALE) is a synonym for HALE but uses a different valuation methodology. HEs are of two main classes: those that use dichotomous health state weights (including disability-free life, disabled, demented, or dead) and those that use health state valuations for an exhaustive set of health states (based on specific valuations of measured ICD disease prevalence and the measured distribution of different disability states within the diseased populations).

QALYs. Quality-adjusted life years (QALYs) are generally used for measuring the outcomes of health services or programs but could be interchanged with disability-adjusted life years (DALYs) as an SMPH. Years of full health are assigned an index (index) value of 1.00. Morbid years are weighted by an index of utility (strength of preference), as measured by the time trade-off, standard gamble, or rating scale techniques. DALYs are a form of QALY estimated with a particular methodology, which includes age weights and the use of the person trade-off technique of preference elicitation.

Health Gaps. Various health gaps have been defined that vary according to (1) the selected normative target used to measure the difference (health gap) from the current health conditions in a population, (2) the method used to value time spent in health states

Table 3 Table of Terms

Measure	*Date*	*Description*	*Reference*
Health Expectancy (HE)		Generic term for summary measures of population health, which estimate the expectation of years of life lived in various health states.	Chiang, C. L. 1965. *An Index of Health: Mathematical Models*. Vital and Health Statistics Series 2, No 5. Washington, DC: National Center for Health Statistics.
Life expectancy (proposed)	1964	A weighted average time to death from different ages (e.g., birth, 21, 50, 75): usually based on the current mortality rates extrapolated into the future.	Sanders, B. S. 1964. "Measuring Community Health Levels." *American Journal of Public Health* 54(7): 1063–1070.
Life expectancy (developed)	1972		Sullivan, D. F. 1971. "A Single Index of Mortality and Morbidity." *HSMHA Health Reports* 86(4): 347–354.
Quality-adjusted life expectancy (QALE)	1970	A form of health-adjusted life expectancy (HALE) that is based on a question on activity restriction in the Canada Health Survey.	Fanshel, S., and J. W. Bush. 1970. "A Health-Status Index and Its Application to Health Services Outcomes." *Operations Research* 18(6): 1021–1065.
Active life expectancy (ALE)	1983	A form of disability-free life expectancy (DFLE) based on survey questions on limitations in activities of daily living (ADL).	Katz, S., L. G. Branch, and M. H. Branson. 1983. "Active Life Expectancy." *New England Journal of Medicine* 309:1218–1224.
Disability-free life expectancy (DFLE)	1980s	A weighted average time to onset of disability from different ages.	Mathers, C. D. and J. M. Robine. 1993. "Health Expectancy Indicators: A Review of the Work of REVES to Date." In *Calculation of Health Expectancies, Harmonization, Consensus Achieved and Future Perspectives* (Proceedings of the 6th meeting of the International Network on Health Expectancy and the Disability Process REVES, October 1992, Montpellier), edited by J. M. Robine, C. D. Mathers, M. R. Bone, and I. Romieu. Paris: John Libbey Eurotext.
Health-adjusted life expectancy (HALE or DALE)	2000	A weighted average time to death from different ages, with the value of the time between onset of disability and death reduced by standard fractions for different diseases based on some community judgment of the impact of those disabilities.	World Health Organization (WHO). 2000. *The World Health Report 2000. Health Systems: Improving Performance*. Geneva, Switzerland: World Health Organization.

(Continued)

Table 3 (Continued)

Measure	*Date*	*Description*	*Reference*
Quality-adjusted life year (QALY)	1978	QALYs for full health and death are assigned scores of 1.00 and 0.00, respectively. Marked years are weighted generally by the standard gamble, time trade-off, or rating scale techniques by the strength of preference (utility) for the state. Various SMPHs are derived from the use of different techniques for conceptualizing and quantifying the numerical value of years of ill health.	Torrance, G. W. 1986. "Measurement of Health State Utilities for Economic Appraisal." *Journal of Health Economics* 5:1-30.
Health gaps (HG)		A generic term for summary measures of population health; estimates the gap between the current population health and a normative goal for population health.	
Years of life lost (YLL)	1947	The component of the DALY (q.v.) that measures the years lost through premature mortality, with morbid years weighted by the extent of the disability.	Dempsey, M. 1947. "Decline in Tuberculosis: The Death Rate Fails to Tell the Entire Story." *American Review of Tuberculosis* 56:157-164.
Disability-adjusted life years (DALYs)		The health gap attributable to a disease, with marked years weighted by a person trade-off (PTO)-based assessment of the severity. Conceptually similar to the QALY.	Murray, C. J. L. and A. D. Lopez. 1996. World Health *Organization Global Burden of Disease*. Geneva, Switzerland: WHO.
Years of healthy life (YHL)	1995	A form of DFLE (q.v.) based on two questions collected in the U.S. National Health Interview Survey, which are concerned with activity limitations and perceived general health.	Erickson, P., R. Wilson, and I. Shannon. 1995. *Years of Healthy Life*. CDC/NCHS, Healthy People, Statistical Notes No. 7. Hyattsville, MD: U.S. Department of Health and Human Services, National Center for Health Statistics.
Healthy life years (HeaLYs)	1998	A health gap (q.v.) measure calculated on the basis of the incidence of pathological processes and the future nonfatal health outcomes and mortality from those processes.	Hyder, A. A., G. Rotllant, and R. Morrow. 1998. "Measuring the Burden of Disease: Healthy Life-Years." *American Journal of Public Health* 88(2): 196-202.

less than ideal health, and (3) the inclusion of other social values, such as age weights, time preference, and equity weights.

The normative targets may be a fixed age (e.g., years of life lost to age 75), the expectancy of the healthiest known populations within countries, or a mathematical projection of the expected optimum life expectancy based on the mortality and morbidity experience of the whole world (e.g., the HALE of the World Health Organization's [WHO's] World Health Report 2000). Fixed-age health gaps are simple to calculate but place no value on life beyond the age threshold. Normative targets based on national or international comparisons are more complex to calculate but do not contain implicit age biases.

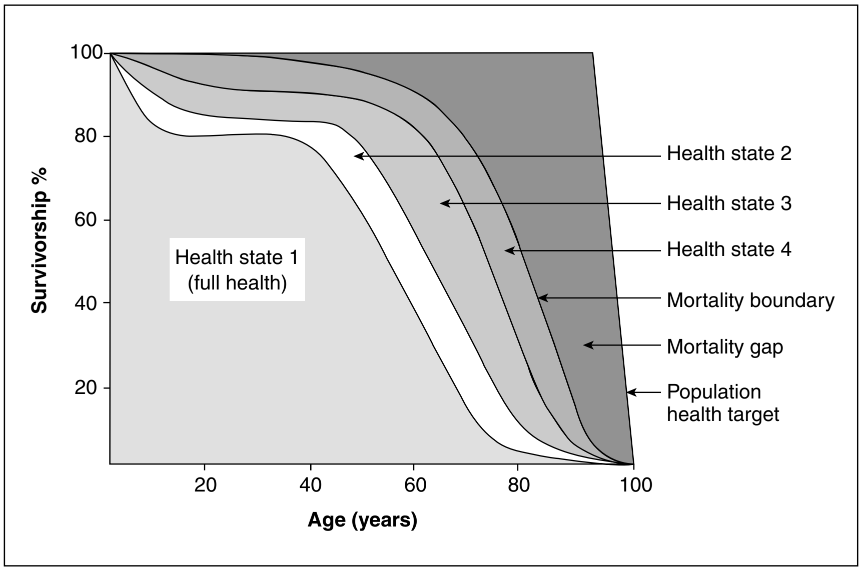

Figure 1 Survivorship Curves Used to Calculate Health Expectancies and Health Gaps

Health gap estimation is most useful when it identifies the constituent populations and causes of the loss of health and allows planning for the elimination of the gaps. The WHO Global Burden of Disease studies estimate the mortality and morbidity incidence and prevalence based on reported national mortality statistics and other estimates of disease prevalence. This approach assumes that all causes of loss of health are understood and can be identified by the disease classification systems. Its measurement is not always independent of the activity of health services.

Measurement of Health Expectancies and Health Gaps. Health expectancies are estimated for populations using routine mortality statistics, supplemented by measurement of morbidity rates using a variety of routine health service activity measures and health surveys. Period HEs are used to predict the future by assuming that the age-specific mortality and disease prevalence rates today will be the same as those that will be achieved by the corresponding age-specific cohorts in the future. These are constructed mathematically by applying the observed mortality and morbidity rates to a theoretical population existing only in a computer. Cohort HEs are the actual measure of the survival and health experience of a real age cohort observed over decades, but these can only be known in retrospect and so are not available for service planning.

Figure 1 schematically represents a limited number of survivorship curves constructed from the measured mortality and morbidity rates in a population. HALEs measure the area under the survivorship curve, taking into account different weighting for years lived in different health states. The position of the population health target is an entirely "political" construct.

SMPHs are calculated using the following formulas:

Life expectancy = $\text{HS1}_{\text{area}} + \text{HS2}_{\text{area}} + \text{HS3}_{\text{area}} + \text{HS4}_{\text{area}} + \text{HS}i_{\text{area}}$

Health-adjusted life expectancy = $\text{HS1}_{\text{area}} + \text{value}_2 \times \text{HS2}_{\text{area}} + \text{value}_3 \times \text{HS3}_{\text{area}} + \text{value}_4 \times \text{HS4}_{\text{area}} + \text{value}_i \times \text{HSi}_{\text{area}}$ population

Mortality gap = $\text{PHT}_{\text{area–}}$Life expectancy

Health gap = $\text{PHT}_{\text{area–}}$Health-adjusted life expectancy

where $\text{HS}i_{\text{area}}$ is the average years in health state i (measured by area under the curve), value_i is the weighting assigned to health state i, and TPH_{area} is the total number of years if the entire population achieves the population health target.

While population sizes and mortality rates may be fairly accurately known, morbidity rates are more problematical. If the purpose of the SMPH is to judge the effectiveness of health services, it may be inappropriate to use health service activity alone as a measure of morbidity. Unmet needs will be unmeasured, and service activity data may not include sufficient information to determine the disease severity levels in a way that can be translated by valuation into life-year equivalents in reliably comparable forms. This issue is important for common, high-impact conditions that are underdiagnosed, such as depression and chronic pain syndromes. Health surveys may measure symptoms of illness, whether or not the illness is being managed, but may not be able to accurately diagnose the cause of the symptoms.

DISCUSSION

SMPHs are often composite measures that combine the quality and quantity of life according to some algorithm. Some have argued that the resulting composite is conceptually confused—that it is not possible to add apples and oranges. The appropriate response to this is that apples and oranges are not combined. Rather, it is the *value* of the different attributes that is combined. It is legitimate to criticize the combination rule (algorithm), but this is a separate issue from the conceptual validity of combining dissimilar attributes, something done routinely in what is probably the most useful construct in the social sciences—namely, the gross domestic product (GDP), which compares the *value* of a vast array of goods and services.

A second methodological issue concerns the way in which SMPHs are selected. One approach is to presuppose that a single broad concept exists that is the correct measure in any health-related context—namely, the concept of "health" per se. This approach has elsewhere in the physical and social sciences resulted in a search for the "essence" of the concept associated with general terms and an attempt to codify the essence in a precise definition that can then be used in deductive argument or for the guidance of measurement. The approach has been historically associated with intellectual stagnation. Karl Popper's (1974) summation of the impact of "essentialism" is as follows:

> The development of thoughts since Aristotle could, I think, be summed up by saying that every discipline which still uses the Aristotelian method of definition has remained arrested in a state of empty verbiage and barren scholasticism, and the degree to which the various sciences have been able to make any progress depends upon the degree to which they have been able to get rid of this essentialist method. (This is why so much of our "social sciences" still belong to the middle ages.) (p. 9)

The alternate preferred approach is to commence with the problem of interest, to determine, conceptually, the likely solution and then to select or create the definitions that help to describe and summarize the relevant concepts and operationalize the solutions ("nominalism"). SMPHs have arisen not as a result of differing attempts to capture the essence of a healthy population but (generally) as a result of the differing "problems" involving population health, the differing solutions, and the concepts, definitions, and metrics implied by these solutions. A life insurance company may be interested in its future financial obligations. For this purpose, life expectancy is the most useful metric. Health authorities may be interested in "that which society wishes to maximize." This might lead to the concept of a QALY or DALY, possibly with importance weights for equity and probably with preference weights for the timing of the benefits (i.e., discounting).

Finally, the field of SMPHs is evolving. This commonly involves disagreement, and in the SMPH literature, there have been and remain contentious issues. These include the choice between period- and cohort-based life expectancy, the theoretical life expectancy used in gap measurement, the measurement of quality or "disability," the use of incidence- and prevalence-based measurement, and the inclusion of age or other social weights.

Ongoing debate over both technical issues of measurement and social objectives makes it highly likely that the field of SMPH will continue to evolve.

SUPPORTED EMPLOYMENT

Supported employment is an approach to helping people with disabilities find and keep jobs in the community. It is defined as competitive work in integrated settings, with ongoing support for individuals who have traditionally been excluded from the workforce. Although it emerged as an approach for people with developmental disabilities in the United States, supported employment is currently being practiced in many countries around the globe for individuals with various disabilities, including psychiatric, physical, intellectual, and cognitive disorders. The emergence of supported employment has dramatically changed the lives of many individuals with significant disabilities who were previously denied access to employment opportunities outside segregated settings.

VALUES AND GOALS OF SUPPORTED EMPLOYMENT

Supported employment is based on the fundamental belief that all citizens should have opportunities to participate in the workforce and earn a competitive wage. The underlying assumptions are as follows: every individual can be gainfully employed if provided with the proper supports, each person has something unique to offer, and people with disabilities can be dedicated, hardworking employees. Supported employment entails principles of choice, empowerment, and equality. Accordingly, no person should be denied access to such services due to limitations caused by their impairment. Supported employment is about finding the right support to enable persons with disabilities to reach their full potential as workers.

The main goal of supported employment is to promote active social inclusion and community participation of people with disabilities through the workplace, by providing opportunities to find permanent competitive employment and to receive the individualized support required for successful job performance. It is through workplace participation that supported employment strives to increase the capacity of local businesses and communities to provide the support their citizens need to realize their full potential as contributing members of society. The success of supported employment is measured in terms of its capacity to build meaningful relationships among community members and to increase the quality of life of citizens with disabilities.

Several factors strengthen the rationale for supported employment from the perspective of people with disabilities, employers, and community members. First, it addresses the inadequacies of the traditional approach to vocational services for people with disabilities by helping people maximize their potential within competitive work opportunities. At the same time, there is a growing recognition of the importance of meaningful work experiences in building relationships with others, formulating a self-identity beyond the disability, and developing increased self-esteem and self-worth. The underlying philosophy and goals of supported employment represent an important progression toward equality and empowerment of people with disabilities in society.

COMPONENTS OF SUPPORTED EMPLOYMENT

Supported employment contains three basic components: competitive work, integrated settings, and the provision of ongoing, individualized support. Competitive work refers to a job that may be available to all citizens, regardless of their ability, in which the worker is paid the labor market wage for the position. Integrated work settings are workplaces where persons with disabilities work alongside those without disabilities. This component reflects an emphasis on social inclusion and involvement of persons with disabilities in the workforce, a critical aspect of community life. Placing individuals with disabilities in the workplace with nondisabled peers is a vital aspect of supported employment and a shift from previous models of vocational services.

The provision of ongoing, individualized support is the most distinctive characteristic of the supported employment approach. While traditional vocational programs provide only time-limited support, supported employment calls for support that is ongoing and individualized. That is, support by an employment specialist (or job coach) is made available to workers with disabilities for as long as each individual wants and needs it. The frequency and intensity of the support are flexible and designed to meet the ongoing and dynamic needs of the worker on the job.

Traditional sheltered workshops and vocational programs typically provide lengthy employment readiness assessments and preemployment training. Once placed, support is often reduced or terminated. Thus, the traditional approach has been referred to as the “train-place” model. Supported employment, by contrast, uses the “place-train” approach, where the preemployment phase is relatively short and the focus is on rapid placement and time-unlimited support on the job in the actual work setting.

HISTORICAL OVERVIEW

The concept of supported employment evolved with shifts in social values and beliefs, especially dissatisfaction with the inability of traditional sheltered workshops and vocational programs to move beyond segregated or “practice” settings. Transition from traditional vocational programs into competitive employment was extremely slow, if not impossible. Most individuals did not progress to competitive employment and experienced few opportunities for advancement. As awareness of these limitations and shortcomings increased, people began to search for alternative ways of providing employment opportunities and choices to people with disabilities. Some revolutionary programs emerged that transformed the perceived employment potential of people with disabilities. For example, the clubhouse model, which was developed in 1948 by former psychiatric patients at Fountain House in the United States, is considered an early precursor to supported employment.

In the early 1970s, the growth of the disability rights movement and the emergence of the principles of social inclusion and “normalization” emphasized the need to provide all persons with opportunities to participate in valued social roles in the community. Implementing these ideas into employment practices meant a move toward real work in the community, rather than “make-work” in segregated facilities. In this way, employment programs using the principles of supported employment were developed.

The success of supported employment spread from the United States to other countries. In Canada, the Metropolitan Toronto Association for Community Living and the Sioux Lookout-Hudson received government funding in the mid-1970s to provide long-term support in the workplace to people with disabilities. Supported employment services also emerged in Asia and Europe. For example, supported employment has existed in Hong Kong since the late 1980s and in Finland since the mid-1990s. Although local modifications to the supported employment approach may alter the target population and the level of success achieved, the basic premise and components remain the same internationally.

MODELS OF SUPPORTED EMPLOYMENT

A number of different models of supported employment are being practiced, including some that focus on individuals in supported work settings, others on groups of individuals with disabilities who are placed in supported work settings. The individual placement model (IPM) offers intensive and individualized training and support for individuals with disabilities. It is the most common approach to supported employment and the most effective, with employment outcomes surpassing those of group models. The IPM is also less stigmatizing, as there are no special groupings at work, and the person with a disability is generally hired as a regular employee, earning the same wages as other workers.

The IPM incorporates job development (finding or creating appropriate jobs), job placement (carefully matching the person to the job), on-the-job training (skill training by a specific staff member who is aligned with the worker), ongoing assessment of work performance, and job maintenance strategies (including problem solving, job modifications, and advocacy for job retention). An employment specialist is usually responsible for these functions and remains involved as a formal support on a long-term basis. The expectation, however, is that the intensity of support will fade over time. The individual approach is more challenging to maintain for clients whose job skills, rate of work, and work behaviors do not match job requirements.

A modified version of the IPM can be found within the psychiatric literature and service delivery system. The individual placement and support (IPS) model incorporates rapid job search, integration of rehabilitation and mental health services, attention to consumer preferences, continuous and comprehensive assessment, time-unlimited support, and competitive employment as the goal.

The enclave model involves groups of individuals with disabilities working with ongoing support within a business or industry. It is the second most common form of supported employment and is frequently found in the developmental disability literature and service delivery system. Full-time support, training, and supervision are provided by an employment specialist or enclave supervisor, who may be employed by an outside supported employment agency or by the business itself. The supervisor locates and develops jobs from the company, trains the workers, and supports them through their integration into the workplace. Most often, the outside agency employs the workers and is subcontracted by the business to provide the labor force. Workers may also be hired directly by the business. Examples of enclave models vary in their documented rate of pay: some are at minimum wage; others are lower and based on production. Enclave models have been criticized for low pay and the potential for isolation from the general workforce. Accordingly, work in an enclave is recommended as a stepping stone to individual placements for those workers who meet job demands and become acclimatized to the workplace.

An adapted form of the enclave model is the cluster model, where workers are dispersed throughout a work area and integrated with nondisabled coworkers. Often, these cluster placements evolve as workers are added to a job site. These placements can look like individual placements, but an enclave supervisor is available on an ongoing basis within the business.

Work crews or mobile work crews are small businesses with small groups of persons with disabilities, which perform work for an employer on a contract basis at the employer's work site. An employment specialist secures the work, supervises and trains the workers, supports them in adjusting to the workplace, and ensures that quality work standards are met. Ideally, the work crew is established as a small business and manages the quantity and type of work according to the changing needs of its employees. Staff responsibilities include not only employment support services but also tasks of managing and marketing a small business. Most commonly, the work performed by work crews consists of housekeeping, janitorial, or groundskeeping services. Workers are usually paid by the supported employment program from contract revenue.

EFFECTIVENESS

Literature comparing the effectiveness of supported employment models as they cross disability groups is very limited. Most outcome research on supported employment deals with the effectiveness of a single model for a defined population. The few studies that do cross models and disabilities reveal that everyone, regardless of disability, benefits from supported employment and that individual placement models generate employment outcomes superior to those from group models. Differences in employment outcomes across groups have been found in the areas of wages, type of employment, and job retention, but the paucity of research on this issue prohibits firm conclusions. The most common populations discussed are psychiatric and developmental disability groups.

In the psychiatric disability literature, randomized controlled trials that compare supported employment with prevocational training reveal that clients in supported employment earn more and work more hours per month than those in prevocational training. Other studies reveal that although placement rates for people in supported employment programs are strikingly higher than those generally cited for this group, employment outcomes such as wages, job satisfaction, and long-term job maintenance are questionable. Characteristics of exemplary supported employment programs for this group include use of multiple funding sources, integration of mental health and vocational services within the same programs, early entry into competitive employment with intensive support, a high degree of involvement of the employment specialist in the interview process, and an interest in evaluating supported employment services.

Outcomes in the developmental disability literature have been very positive: rates of people entering the workforce through supported employment opportunities have grown over the past decade, and integration and wage benefits are strong when compared with sheltered work and segregated settings. Components of service delivery associated with successful outcomes within this group include an emphasis on collateral behavior (social and communicative interaction), client advocacy, a focus on job analysis and job matching, follow-up support, and the use of advisory councils or local businesspeople to assist with marketing. Supported employment with persons with developmental disabilities is often criticized because those most often placed in supported employment settings are only mildly or moderately disabled, thus excluding individuals with more severe disabilities. Others have raised concerns regarding funding disincentives, that is, the way the system reduces or cuts levels of social assistance as people earn wages. Therefore, supported employment is sometimes used as an additional service option rather than the standard course of action.

COST EFFECTIVENESS

Some evidence is available to show that supported employment programs approach or achieve cost efficiency. However, many studies of cost-benefit draw on such small samples that the results need to be interpreted with caution. A few studies suggest that while costs may initially exceed benefits, the reverse is true several years after the establishment of a supported employment program. Savings to public income support vary across funding systems. Studies in the United States suggest that savings are generally low, possibly due to low salaries of employees and the resulting need to draw on social assistance even while working. Canadian research reports substantial reduction in individuals' need for social assistance. Furthermore, every individual in supported employment programs pays and contributes to pension and employment insurance plans. Reports documenting the conversion of existing programs to supported employment programs demonstrate improved vocational outcomes without increasing costs.

Supported employment offers hope and work opportunities to people with disabilities within mainstream employment. Businesses and communities at large are recognizing the multiple benefits possible through supported employment opportunities.

SUPPORTED SERVICES

In the past, people with disabilities had little choice about what kind of services, if any, were open to them. Institutions smothered individual differences, while an absence of any form of help meant that many individuals were simply left adrift in an unforgiving environment. By contrast, *supported services* refers to an array of supports that are available when and where individuals require them. What unifies these personal, social, instrumental, and tangible interventions is the notion that, whether or not they have disabilities, people live their lives connected to their environments and the people with whom they live and work.

A human story unearthed from sites where humankind’s remote ancestors lived shows that they must have cared for their young and also for others who were evidently vulnerable. From the current vantage some thousands of years later, one can only infer their motives—whether affective or whether calculated to ensure that more people in a group would thrive and thus be strong enough to protect each other. All humans need support in infancy and childhood. And most will do so into their old age, an ever more certain horizon in the future for people in both developed and still developing countries. Even in the prime of life, people look for help to prosper, to keep healthy, and to fulfill obligations to families and employers.

In every society and every age, there are individuals who need much more support than others. Those with disabilities, for instance, may have particular needs for support that punctuate the course of their adult lives. The place that people with diverse needs should hold in a modern democratic society is but one issue fuelling today’s debates in political philosophy. The debate is whether to embed social contracts on the premise that some individuals are more vulnerable than others, not merely as infants or older, dependent people. Given that *disability* is a construct whose boundaries are fuzzy across time, cultures, and contexts, it follows that the nature of optimal support made available to individuals in a society will vary as well. In addition, individuals identified as having the same disabling condition may manifest distinctive patterns of living, and thus uniform solutions to meet their support needs are not useful. Typically, individuals draw on support from family members and friends. In societies where formal systems of health and social services have been organized, they may also depend, at least in part, on these sources of support. Private and public domains intersect at the point where an individual with disability encounters support—perhaps personal intimacy, friendship, instrumental assistance in carrying out daily tasks, income, or other benefits in kind.

In the past, people with disabilities were often numbered among the deserving poor, albeit a drain on society’s purse if alms were not forthcoming. Separate but unequal systems of providing support for people with disabilities became widespread. The industrialized countries built structures to classify and sustain people with disabilities within health and social systems shored up by public funds. An administrative solution might take the form of a segregated facility housing people with intellectual and other disabilities and associated conditions—mental illness or epilepsy, for example. Remnants of large-scale institutional care persist today, not only in former Eastern bloc countries of Europe but more widely. In many less prosperous countries, whether through tradition or simply through lack of means, large-scale institutions were never built.

Yet it is striking to reflect that worldwide, most people with disabilities live with their families and rely on them for care and support. Today, adults in societies where independence is valued may chafe at what they perceive as intrusive services and aspire to live in their own homes. As people with disabilities grow older, it is more likely for them to move away from the family home if alternatives are available. While some developed countries have embraced community living for their citizens with disabilities as the standard for adults, others have been slow to give up large residential centers.

As institutions have declined in prominence in many industrialized countries, supported residential services aim to help people with disabilities find a good place to live by themselves or with the people they choose. Since the last decades of the twentieth century, many thousands of people with disabilities began to leave old-style institutions, moving to ordinary homes and workplaces. In their stead, *supported services* have come about to meet the needs of individuals with disabilities in their pursuit of satisfying life outcomes. The ultimate aim of such services is to support individuals so that they can live and work as they wish. The springs of this sea change flowed in part from radical rethinking about the injustice of segregation for any marginal social group and the primacy of self-determination expressed in fresh policies and laws. In the United States, for example, disability advocacy groups, federal legislation, and judicial decisions converged in policies promoting individualized supports to achieve the person's own preferred goals. *Person-centered planning* is a programmatic tool developed to identify and attain these goals with the support of the individual's named allies, including family members, human service staff, and others. A focus on the person as director of his or her life plan turns the tables on previous practices, which tried to shape individuals so that they would fit into preexisting forms of social support devised for groups. Today, many people with disabilities live satisfying lives of their choosing in their own homes, perhaps with coresidents of their choice. Service agencies are charged not with herding people under a single roof for ease of administration but rather with tempering supports to suit particular needs in the individual's own home.

Typically, adults with disabilities experience very high rates of unemployment. Many thousands of these individuals have no jobs at all or work only in sheltered settings where prospects are modest and where there are no employees who do not have disabilities. For those who wish to do so, supported employment services help them to find, get, and keep preferred jobs. Many individuals with disabilities will in time outgrow the support needed at the outset as they enter the ordinary workplace, such as through in-service job training. Others will require coaching throughout their careers from a mix of specialist and natural sources such as coworkers. Supported services have made it possible for thousands of men and women with disabilities to enter the ordinary workplace and earn an income for the first time. However, supported employment—offering an ordinary job, full- or part-time—is not as widely available as may be indicated by policies favoring social and vocational integration in Europe and other regions of the world.

The widespread transfer from block services to individualized supports for people with disabilities yields dilemmas. Individuals and their family members may reasonably be anxious if the balance between autonomy and risk shifts to their disadvantage. They have concerns regarding the adequacy of support for people with complex, significant disabilities and those with physical disabilities of such scope that they need others to help with every aspect of their personal care to aspire to anything like independent living.

The abandonment of large institutions can potentially leave a vacuum in the lives of some people with disabilities if sufficient supports are not in place.

Those who believe that vulnerable people thrust into a complex world may lose out in terms of stability and companionship argue that some individuals will always need the special supports available in professionally run, separate residences or workshops. Others argue that society, in time, will simply care less about people inserted into the mainstream without the trappings of special status. Furthermore, many people with disabilities living in very poor circumstances—sharing conditions of deprivation, with little opportunity for a comfortable, secure life—need additional supports. There is an ongoing debate about whether independence in the community is the only legitimate goal for these people.

Independence was a foremost goal as people with disabilities moved away from the confines of institutions and separate forms of care. Sometimes social isolation resulted, fomenting pleas for a return to old ways of gathering together people with disabilities. More recently, interdependence has emerged as a crosscutting principle in all aspects of society. On the world stage, globalization is founded on the premise that the political and economic fortunes of all countries are linked. At the personal level, interdependence is expressed in transactional models of human development: individuals interact with family members, friends, and the socioeconomic and physical contexts in which they grow and develop. From infancy through old age, individuals are both influenced by their environments but also shape these environments actively. People with disabilities may seek supports to help negotiate these reciprocal relationships.

No injection of funds and no political decision can confidently produce an ideal form of support for each person in every circumstance: some argue forcibly that it is not society's business to try to do so. Rather, questions about how society values people who are dependent or especially vulnerable and responds to their distinctive needs for support reflect dilemmas springing from the human condition. For as the American philosopher Martha Nussbaum (2001:34) reminds us, "The way we think about the needs of children and adults with disabilities is not a special department of life." Supported services are a tangible sign that society recognizes that individuals have needs that are worth meeting and that to do so is for everyone's sake.

SUR DAS (1480s?–1580s?)

Indian musician and poet

For four centuries, Sur Das has been the most famous blind musician and poet of North India, with the result that "Sur Das" as a nickname could get attached to any (male) blind Hindu or Sikh who sang or played music. The "original" Sur Das has become elusive, and no detail can be fixed with certainty. The theory that the celebrated poet and musician was identical with a documented Sur Das, son of Ram Das, who lived at Braj, was blind, and performed at the court of Akbar (regn. 1560–1605), is unquestioned by many Indian scholars and supported by some Westerners (Lehmann 1982; Vaudeville 1971). Most people concede that the legend originated with a real-life artist and poet, who composed most or all of the thousands of poems in the *Sur Sagar* (*Ocean of Song*).

Traditional assertions about Sur Das continue to be questioned—especially by those who dismiss Indian oral history, argue about the mentions of blindness in Sur's literary work, and are surprised that, "if Sūr was blind, he did not make a great point of it before the world" (Hawley 1984).

SURGERY AND DISABILITY

A number of surgical procedures produce postoperative disabilities. Although these procedures may alleviate discomfort, save or prolong life, or provide a cure because the diseased tissue or organ is excised, they nevertheless leave a significant postoperative residue or set of new disabling problems with which the patient and their carers have to cope. In other words, because of the surgical rearrangement of the human body, impairment is created in the form of a loss, reduction, or change in function, which actually or potentially limits the full engagement of the individual in the social world.

The types of surgery that fall into this category include amputations; radical surgery to the head, face, and neck; mastectomies, colostomies, ileostomies, and urostomies; surgery of the prostate and the penis; and some gynecological operations. Not infrequently, these procedures are conducted to deal with life-threatening diseases, especially cancer, or with long-term chronic illnesses such as diabetes, colitis, and Crohn's disease. While the patient's life may be saved, the disease held in check for a further period of time, or a total cure effected, the postoperative period brings with it a new series of problems. These problems may temporarily or permanently make the patient's quality of life worse rather than better. From the patient's point of view, surgery may seem especially undesirable preoperatively. The surgical outcome may seem to be worse than the disease itself.

LOSS OF FUNCTION

This is the most obvious type of postsurgical disability and the one most easily linked to the traditional literature on disability. Loss of the ability to walk or significant reduction in mobility following limb amputation would be good illustrations. Amputations of hands or arms or lower limb extremities have differing degrees of functional loss consequent on them. The extent of the loss of mobility will be determined by a range of factors. These are the extent of the amputation, the effectiveness of and ability to use prostheses, the age of the individual, the presence of other comorbidities, the home environment, and the degree of support provided by carers in the family or though health and social services.

Other types of surgical procedures involving loss of function have different, more attenuated functional consequences but are nonetheless very serious. Surgery of the mouth, tongue, face, and neck has potentially very significant functional implications for eating, drinking, and phonation. Surgery of the throat, voice, and larynx has impacts on the ability to speak and eat. Surgeries of the prostate, vagina, penis, anal sphincter, bladder, and gut all have a significant impact on the functions of urination, defecation, nutrition, and sex. Operations on the uterus may affect fertility, and a range of procedures may affect male fertility and potency. Bodily functions that the normal healthy human routinely takes for granted are undermined. In the postoperative state, patients have to relearn skills they originally acquired in childhood. So when surgery affects the ability to speak, eat, and control feces and the bladder, it is striking at some of the most fundamental aspects of our humanity.

What is at issue here is not that individuals cannot do what they used to do or that, with the aid of prostheses and appliances, they can find a functional alternative. It is rather that the skills and competencies that define what it is to be a competent adult member of society—to walk, manipulate objects in the environment, talk, eat, and control the anal sphincter—are changed.

One need not subscribe to a psychoanalytic view of the world to see that destroying the basic skills acquired in childhood of walking, manipulation, eating, drinking, talking, and emptying the bowel and bladder is to assault the human psyche, as well as the human body, in potentially profound ways.

RESPONSE TO LOSS

It has been observed in many types of surgical procedures—especially but not exclusively coronary artery bypass grafts, mastectomies, and ileostomies—that the consequent emotional response is very powerful indeed. It is sometimes suggested that the destruction of body image is the problem. Among the responses noted are phantom limb experiences by people who have had amputations, denial, clinical depression, and something that mimics the well-described pathways of grief.

These responses can be severe, potentially disabling, and, in some cases, psychologically morbid. Helping patients work though their feelings about loss is very important. It is just as important as helping them to acquire new skills in using their appliances or their new prostheses. Arguably, the importance of allowing patients undergoing such procedures the space and time to grieve for the loss or express and ventilate other emotions is a critical way of beginning the psychological as well as the physical healing process.

SOCIAL AND PSYCHOLOGICAL RESPONSES

A very useful way to conceptualize the overall social and psychological processes involved is to distinguish between the concepts of self and identity. The concept of self captures the idea that each and every human being carries a notion of what he or she is like as a human being. Some of these things will be attributes such as being friendly, vivacious, good looking, and hardworking. Other elements will refer to social roles and group membership. Some individuals may think of themselves as a man, father, husband, lover, writer, black, and middle-aged. Still other parts of the concept of self will refer to skills the individual thinks he or she possesses: "I can play basketball, I can drive a car, I can paint, I can play the piano," and so on. Some of the elements relate to more fundamental human skills and competencies: "I am an able bodied adult in control of my body and of my life."

Many of the procedures focused on here critically change the core aspects of self and very frighteningly result not only in the loss of control of some aspect of the body and its functions but also the ability to be in control of one's own destiny. Given that in Western society, control and self-control are highly valued, their loss is of considerable import. Not only that, their loss affects primal understandings of who or what we think we are. The assaults on basic activities such as eating, drinking, evacuation, walking, and talking are attacks on the very definition of what the able-bodied world takes to be human. This is because these skills and competencies spill over into and define other aspects of our sense of what we are and our place in the world.

It is not just the obstacles that arise because of the loss of function that are important. Physical barriers are significant because they prevent the postoperative patient doing things and participating in social activities. But also important is the meaning that not doing these things has for the personal biography. So no longer being able to have an erection and to have sexual relations, for example, is not just about not being able to father children or enjoy sexual relations—it is about what that means for the individual's sense of being a man, a husband, a father, and lover. Not being able to talk is not simply about learning new ways of communicating—it is about conversation, chatter, social intimacy, friendship, and being a member of the human community.

Consequently, because of the changes, postoperative patients have to develop a new or altered sense of self, a new sense of who and what they are, a new sense of their place in the world, and a new way of making sense of the world and of their lives. This is not an inconsiderable undertaking. We are basically setting the expectation that the patient will become, in effect, a different person. Not surprisingly, patients often resist and doggedly cling to their earlier sense of self, very reluctantly give it up, mourn its loss, and take a considerable time to embrace new aspects of their new self.

Another useful concept to help articulate the mechanisms involved is identity. The term *identity* is used to mean that public aspect of the person as it is known to others. Identity refers to the elements of role, social position, group membership, and personality as they are known to others. The labels that others apply to us are the key points of reference that we also use to categorize and organize the myriad of others with whom we come into contact. For ordinary able-bodied adults, the key aspects of public identity are usually things such as gender, age, appearance, ethnicity, style of dress, occupation, and all the well-known social signifiers that surround us most of the time. The important point about the kinds of surgery of interest here is that in certain circumstances, the sequelae of surgery are plainly visible to others and constitute a significant aspect of public identity. Amputation and radical face and neck surgery, for example, are immediately visible social signifiers to others. Some authors have talked about stigma in this context, arguing that certain external bodily markers are so significant that they constitute both ways of organizing perceptions (in the same way that things such as age and gender do) and also organizing public identity in very negative ways. In effect, the discrimination to which many disabled people are subject can be understood as a consequence, at the personal level, of the negative labeling and stereotyping and the stigmatizing response of others toward the functional impairment. This is distinct from the social level of discrimination that exists in legal codes and environmental and physical barriers to integration and full involvement in social matters. It is, generally speaking, a much more straightforward matter to change legal arrangements, to outlaw discrimination in the workplace, and to modify the physical environment than it is to change underlying stigmatizing attitudes and stigmatized public identities.

Some of the surgical conditions referred to in this section are invisible when someone is fully clothed. Someone who has had a mastectomy or a colostomy is like this. For them, the problem of public identity is slightly different. They of course have to manage their bodies, their functions, their appliances, and their prostheses. However, others who are not intimate and knowledgeable about the condition—strangers, fellow travelers on public transport, and fellow customers in a shop—would not be aware of the functional difference in their bodies. The question for those with these postoperative states is the extent to which they wish to tell others about their condition, their operation, or indeed the extent they might be compelled to reveal their situation. At these points, they face the possibility of their true identity being found out and their being labeled negatively.

COPING

A number of types of coping are at the heart of learning to live with a disability that arises as a consequence of surgery. The first of these is technical. Technical coping relates to the specific management of the way the body now functions and to managing any associated prostheses, appliances, and drugs. It relates to the skills that are required to keep functioning despite the consequences of surgery.

The second type of coping skill is *intrasubjective,* meaning within the individual. This is the thinking, feeling, and emotional response to the situation. Having a chronic condition such as cancer, in which the patient has to deal with a sudden diagnosis, surgery, radiation, chemotherapy, rehabilitation, and perhaps reconstructive surgery, is a disruptive and emotionally charged experience. The patient has a lot to deal with, and for many, there will be varying degrees of intense emotional response. Dealing with these feelings and working them through is an important process the patient has to go through and cope with.

The third type of process relates to interpersonal relations. Because of changes to self and identity, interpersonal relations are inevitably disrupted and renegotiated with intimates and with a broader circle of friends and acquaintances. Just as the body is not the same after surgery as it was before, so too are relationships shifted. The size of the shift may well depend on the surgery; patients may also only experience a shift in their patterns of social contacts in the short run, but shifts in interpersonal relations are part of the process.

Finally, there is a process that is called *intersubjective,* which is about rendering the experience meaningful. All of us, to a greater or lesser extent, seek to make sense of our circumstances, our life, and our place in the scheme of things. When people experience life events that arise from these operations, not only will they find that their previous sense of what they thought and what the future holds will need to significantly reappraised, but new meanings for the new circumstances in which they now find themselves will also have to be found.

Some people find hope and great comfort in what they learn about themselves in such experiences; for others, it an experience devoid of anything positive, and they see the whole thing in personally tragic terms. Of course, it may matter a great deal if someone takes a very positive attitude versus someone who does not, not least because of the impact on quality of life and return to ordinary everyday things. But just being positive is not the whole answer by a long way.

The experience of the surgery, which alters the way a human body functions and looks and creates a disability, is physically and emotionally painful. Human suffering on a grand, albeit personal, level is involved. People going through these procedures do sometimes feel despair before they can experience and see things positively. This makes it all the more important to allow time and space for those emotions to be ventilated and the opportunity for the person to do his or her grieving. Even then, of course, if the harsh external world assigns these individuals a stigmatized and negative label and identity, the task is hard indeed. We should not seek to find out from a psychological point of view which personality types cope best, nor should we blindly encourage a positive attitude. We should instead recognize that there are stages in the process of coming through this type of surgery, and the various coping processes have to come into play at different times.

▣ SWITZER, MARY ELIZABETH (1900–1971)

Developer of U.S. disability and rehabilitation policy

Mary Elizabeth Switzer, distinguished public administrator and developer of U.S. disability and rehabilitation policy, was born in Newton, Massachusetts, on February 16, 1900. In 1921, as Radcliffe College’s first graduate in International Relations, Switzer began a lifetime of increasing public service responsibility in Washington. Her career paralleled the development of social programs in the United States, stretching through the tenures of Presidents Harding to Nixon. Mary Switzer believed that bureaucracy existed to serve people and directed the forces of government to include persons with disabilities in the work and play of the nation.

Public Law 565 is the capstone of Mary Switzer’s career. Switzer’s effect on the quality of life for millions of persons with disabilities and their families is memorialized in bricks and mortar (the Switzer building in Washington and Switzer buildings at the Helen Keller Center, Assumption College, and the Woodrow Wilson Rehabilitation Center), in scholarships, by annual lectures and seminars, in 17 honorary degrees, and in dozens of awards she received during her lifetime.

▣ SYDNEY PARALYMPICS

Some 20 years after the 1981 International Year of Disabled Persons, Sydney hosted an exceptional Olympic and Paralympic Games, in which people with disabilities were competitors, spectators, volunteers, media, or employees. At the Sydney 2000 Paralympic Games, some 4,000 athletes from 125 countries competed in 18 sports. Of these sports, 14 are common to the Olympic Games, with the sports of wheelchair rugby, boccia, goal ball, and power lifting being specific to the Paralympics. People competing were from the following disability categories: Amputee, Cerebral Palsy, Intellectual Disability, Vision Impaired, Wheelchair, and Les autres (literally, the "others"). The Sydney Paralympics claimed a number of records, including the following:

- the most number of spectators to witness a Paralympic Games,
- the most number of tickets sold, and
- the Paralympic Opening Ceremony being the most watched television program in the history of the Australian Broadcasting Commission.

Why was this so? The Paralympics followed the undoubted success of the Olympic Games and the party atmosphere created. People enjoyed themselves tremendously and wanted to continue enjoying themselves. The Sydney Paralympic Organising Committee (SPOC) had also undertaken a very successful Reaching the Community Program that targeted schoolchildren and seniors. The program was regarded as important to raise awareness of disability in the community and was essential to weekday crowd numbers because, unlike the Olympics, the Paralympics were not held during school holidays.

There was no research carried out in Sydney investigating the effect of the Paralympics on attitudes to disability. However, the positive images of athletes with disabilities competing in sport were empowering and challenged the stereotypes of disability portrayed in the media and film. Yet, the representations of athletes with disabilities by the SPOC and the athletes themselves were diametrically opposed. The Australian Paralympians identified themselves as highly trained elite athletes, whereas SPOC marketing sought to evoke the sympathy of the nondisabled public to support the "poor cripple." This image was based on the public finding inspiration in "the disabled" overcoming their "deficits" through sporting participation.

This polemic was epitomized by the words of the mayor of the Paralympic Village, who referred to the athletes as "Bravehearts." This term was viewed by the Australian Paralympians as patronizing and led to a debate in the Sydney media about the perceptions of the Paralympics. The debate discussed the merits of Paralympians as elite athletes and not "disabled people," the merit of the Paralympics as a "true" sporting spectacle, and the language of disability. Yet, it was the inspirational message that the majority of media focused on.

The Paralympics provided athletes and spectators with disabilities with an unprecedented accessible experience. However, while the games were heralded for their inclusive planning practices, there were documented discriminatory practices. These involved

spectator and volunteer services,

general mobility and sensory access issues,

equality of transport provision,

the ticketing program not providing people with disabilities with appropriate seating, and

information, ticketing, and online resources not provided in accessible formats.

Most recognize that the major legacy of the games was the provision of accessible infrastructure that was developed in a relatively short timeframe. The professionals involved in the planning of the venues, the common domain, and transport now understand the principles and practices required for an inclusive planning process. One tangible outcome of the Paralympics was the development of an online access resource for planning accessible environments and events. The resource has incorporated the games' planning, development, construction, and operations experiences for disability and access. However, what was overlooked was that most of the inclusive practices could not have been delivered without a human rights framework and the blood, sweat, and tears of the Australian disability community. The Paralympics were made better by the social changes instigated by people with disabilities and disability advocacy organizations in consultations, lobbying, and advocacy that occurred in the lead-up to the games.

SYLE, EDWARD W. (1817–1890)

Missionary and scholar

The learned and genial English clergyman, Dr. Edward Syle, was a missionary, scholar, and founder of formal vocational work with blind people in China, at the Shanghai Asylum for the Blind. He worked with the American Episcopal Mission at Shanghai from 1845 to 1860 and kept a detailed journal, incidentally noting many aspects of disability. The journal gave much thoughtful description of Chinese life and customs and was serialized in the Episcopalian serial *The Spirit of Missions.* Syle studied the occupations of blind Chinese people and, in 1856, noticed an old woman "twisting some long sedgy grass into strings, such as are used for holding together, by hundreds, the copper 'cash' which are in such constant use." Syle asked her to teach his blind pensioners this craft, and "thinking, perhaps, that I was slightly deranged," she agreed. The craftwork soon expanded, as did the idea of elderly blind people being active contributors in the community. Syle later worked for seven years in Yokohama and Tokyo. His son, Henry Winter Syle (1846–1890), who lost his hearing at the age of six, became a deaf activist in Pennsylvania and was also ordained as a priest.

SYPHILIS

For half a millennium, syphilis was a feared and stigmatized disease. Known as "the great imitator" for its ability to mimic the symptoms of other illnesses, left untreated, it can damage any organ of the body. Beginning as a small genital chancre or sore, syphilis can lay seemingly dormant for weeks to decades. Then its reappearance could bring a range of ills from rashes and gummas across the body, deafness, blindness, perforated palates, madness, mania, excruciating joint pains and deteriorating bones, damage to the aorta of the heart, and death. Its visual components were frightening to see and its debilitating effects devastating.

Secrets and silences often accompanied the disease as its transmission through sexual intercourse or congenitally from mother to fetus trailed moral judgments and state intervention in their wake. Seen as the grand disease of the "other," its appearance often reached epidemic levels after wars and invasions and was usually blamed on someone else. Explanations for its existence, from heavenly wrath to promiscuity to betrayed innocence, underlay its power to evince interventions by priests, doctors, scientists, and healers alike. Both experimentation on patients, willing and unwilling, and self-experimentation by doctors in search of understanding and cures has characterized its long history.

Syphilis is caused by a microscopic spirochete called *Treponema pallidum.* Its modern name comes from a character in a poem by physician Girolama Fracastoro that was written in 1530 in Verona, in what is now Italy. Having offended the gods, Syphilius the shepherd was sent the disease as punishment for his sins and his name given to all who suffered as he did. The disease's common appellation often changed as it moved, labeled as the great pox, *lues venerea,* the French sickness, the Spanish disease, the Italian disease, Chinese ulcers, plum-tree poison, or sometimes bad blood.

The origins of syphilis are still being debated. Arguments have ranged for centuries on whether it was a disease of the Old World brought to the island of Hispaniola by Columbus's men in 1492 or a New World disease sent back in European bodies as revenge by the peoples who had been plundered. In 1495, the disease appeared in epidemic form during an invasion of the Kingdom of Naples by a French army with Spanish soldiers and sailors. Over sea and trade routes and following invading armies, the disease spread rapidly throughout the Mediterranean world to India, China, and Japan. Even before the spirochete was identified at the end of the nineteenth century, the various stages of the disease began to be mapped.

The primary infection appears usually on the genitals as a chancre that disappears, but not so the infection. In the secondary stage, rashes and sores, hair loss, swellings, and growths are common. In various parts of the latency stage, the disease's progress is often invisible, but chancres and rashes are possible. In the late stage, when the disease is not transmissible, the damage to major organs and death can occur. Pregnant women can pass the disease on to their fetuses with the risk of stillbirth, early death of a newborn, or serious medical problems. Reinfection can also occur.

By the sixteenth century, syphilis was widespread in the European population, counting as its victims both princes and paupers. The use of mercury, known to Arabic physicians for centuries as a cure for skin diseases, began to make its European debut. Those in the aristocracy could afford the ministrations of the learned doctors and were treated to a range of cures that usually involved purges, sweats, and rubs made from the bark of the gaiac tree as well as mercury. For those whose sexual conquests were a badge of honor, syphilis was more of an expected consequence than a sign of debauchery.

For the commoners, however, the stigma of the disease was much greater and shaming more widespread. Kept from the great physicians, such sufferers often found themselves locked in the back wards of institutions. They were treated by barber-surgeons and pox doctors who provided a wide variety of eclectic and often violent remedies, especially preparations of the frequently toxic mercury in the form of blue pills, rubs, and vapors. Historian Kevin Siena argues that in London between 1600 and 1800, a "gendered geography" was created, with men given admittance to the hospitals, women to the workhouses, while inventive efforts were made by all to hide their ills.

The adage that "a night with Venus might mean a lifetime with Mercury" reflected the connection that linked sex, syphilis, and the heavy metal "cure." With the rise of a more bourgeois sense of morality, as historian Owsei Temkin (1977) noted, by the seventeenth century, "acquisition of lues is proof of offence against morality, of an alliance with vice."

By the nineteenth century, syphilology was becoming a crucial branch of Western medicine. In search of understanding and cures, various kinds of experiments were carried out, often involving injecting both humans and animals with pus or blood. By the end of the century, syphilis and gonorrhea were shown to be separate diseases and the links between syphilis and a wide variety of other ills documented. In 1909, after a series of experiments in Berlin, Paul Ehrlich and Sahachiro Hata found that arsephenamine (an arsenical compound) would kill the treponema. By the early 1920s, mercury, neo-arsephenamine, and bismuth were used as cures (often taking more than a year to evince relief), and malaria was induced to create fevers for those with neurological complications.

In the United States, the twentieth century brought more research, the emphasis on statistical accounting for the disease, the opening of specialty clinics in major urban hospitals, and the beginnings of more open discussion of the disease in theatrical productions. In 1913, the American Social Hygiene

Association was formed to combat venereal diseases and the silences surrounding them. Posters, motion pictures, and educational campaigns began as Americans were warned to find marriage partners with "good blood." Blood tests required before marriages are a result of these efforts.

Syphilis became the focus of intense research. Under the leadership of the U.S. Public Health Service (PHS), a Cooperative Group Study in major hospitals was organized in the late 1920s to understand the disease. In the 1930s, Surgeon General Thomas Parran, having been kept off the radio for attempting to use the word *syphilis,* wrote extensively about the disease and encouraged public education campaigns to make the warnings about venereal diseases more widely known and to open discussions. The PHS's Venereal Disease division lent doctors to local and state public health departments and provided clinics for indigent patients.

In both World Wars I and II, emphasis was placed on prophylaxis for soldiers and the rounding up and incarcerating of assumed to be diseased prostitutes and "khaki-wackies," young women who followed the soldiers around. After experiments done by the PHS in the mid-1940s, penicillin proved to be a drug capable of curing syphilis in its early stages extremely quickly, and its widespread use followed.

Perhaps syphilis's most enduring legacy, however, was research done by the PHS in the counties in and around Tuskegee, Alabama. The PHS thought it had a situation that would allow for a study of the "natural history" of the disease, especially in African Americans who were assumed to have higher incidences and perhaps even a different disease than whites. What was supposed to be a short study stretched on for 40 years (1932 to 1972) as approximately 399 African American men who were in the late latent stage of the disease and 201 controls were followed as their symptoms worsened and deaths began to occur. But the men were never told they were in an experiment or that the rubs, tonics, and aspirins they were being given were not treatment for their disease. Even when penicillin became widely available, efforts that were not completely successful continued to keep most men from treatment.

Public outcry against the research in Tuskegee rose in 1972, when a newspaper story spread knowledge about its existence outside the confines of the medical and public health communities. What followed was a federal investigation, Senate hearings, a lawsuit, histories, plays, poems, music, and, finally in 1997, an apology from President Bill Clinton. Rumors persist that the PHS infected the men, although there is absolutely no evidence for this. Tuskegee's legacy has continued, however, as a metaphor for the fears in the black community over research, and Tuskegee's story is told over and over again as a warning to scientists about the ethics of research.

With the rise of HIV and AIDS, concern with syphilis has reappeared and coinfections not uncommon. Syphilis may no longer be the scourge it was half a millennium ago. But it remains a stigmatized, debilitating if untreated, and dangerous systemic illness that should be either prevented or cured.

T

▣ T4 PROGRAM

The T4 Program (also called "T4 Action" or "euthanasia") was the camouflage name for the mass murdering of thousands of mentally ill and disabled people during World War II in Germany. The name stemmed from the postal address of the central executive agency, the Tötungsbehörde (literally: "killing office"), at 4 Tiergarten Street in Berlin. The T4 Program was not officially legalized, but Adolf Hitler, the leader of the Third Reich, issued an authorization that was originally written in October 1939 but was dated back to September 1, 1939, the very day when World War II started. Hitler wanted to indicate that the beginning war was aimed not only against external but also against internal enemies.

The T4 Program was bureaucratically organized. It started with the registration of patients using specially designed forms. Every psychiatric hospital, medical institution, and charitable home in Germany had to fill out these forms about each of their patients, inmates, and clients. About 60 physicians recruited by the T4 agency served as experts. They reviewed the documents and decided who would live and who would be killed. After this step, the T4 agency sifted through the forms once more and made the final decision about life or death. Finally, the T4 bureaucrats compiled patient lists for each institution involved. The T4 agency also set up a special transport unit whose personnel were recruited from the SS, the notorious Nazi organization. This transport unit used seemingly neutral grey buses and was responsible for the victims' deportation to the six sites selected as the places where the killing of the victims in gas chambers occurred. At these institutions, special registration offices were also set up; they had the task of issuing official declarations of death and sending the urns with the ashes of the cremated to their families. T4 locations existed in Brandenburg, Brandenburg; Bernburg, Saxony-Anhalt; Sonnenstein, Saxony; Hartheim, Austria; Grafeneck, Württemberg; and Hadamar, Hesse.

The T4 Program started in the autumn of 1939 and officially stopped on August 24, 1941. The reasons for this sudden stop were manifold. One important reason was that although the Nazis originally intended for the measures to be kept secret, the spread of rumors in the villages surrounding the extermination sites could not be prevented. People living near the buildings observed that a continuous stream of patients entered the institutions, but nobody ever came back. Neighbors saw the smoke that arose when the dead were cremated. Families also became suspicious when a family member had been physically healthy before he or she came to one of the "euthanasia" institutions. Often, "weakening" or "debilitation" was indicated in the death certificates issued by the registration offices. The Nazi propaganda machinery could not prevent the T4 Program from being debated in public, when Clemens August von Galen, a Catholic bishop of Munster in Westphalia, took up the issue in a prayer in his church. He openly condemned the measures. After this event, the national socialist government decided to reduce the mass murder program.

However, the official ending did not mean that "euthanasia" measures stopped. The extermination sites in Bernburg, Sonnenstein, and Hartheim stayed open and continued the killing. Furthermore, after August 1941, the so-called "wild euthanasia" started. One main target group was prisoners who had become ill in the concentration camps. On one hand, the centralized murdering in special institutions lost its importance; on the other hand, ordinary physicians in various psychiatric hospitals and medical institutions all over the country participated in the murdering. They killed their patients mostly with drugs or poison, often in combination with strategically aimed underfeeding of inmates. A further "euthanasia" measure was directed at children with inborn impairments; it had been put into operation before the official start of the T4 Program and was continued after that.

In summary, more than 70,000 disabled persons were killed prior to August 1941. When World War II ended in May 1945, about 120,000 "euthanasia" victims had lost their lives at the extermination sites and through the various measures carried out by the T4 agency in Berlin.

TELEREHABILITATION

Telerehabilitation is the delivery of rehabilitation services via information technology and telecommunication networks. It is related to the more general field of telemedicine. During a real-time consultation, clinicians can see and talk with the client by means of a remote video camera and can record still images and measurements from sensors.

Interest in delivering care remotely has been driven by demographic changes due to increased numbers of people living with chronic diseases and disability and high costs of hospital and clinic visits. Furthermore, rural areas may lack local specialists, and extended travel wastes time and increases costs even more.

Typical applications include post-discharge follow-up of newly disabled people by physiatrists and therapists, seating and mobility services (wheelchair adjustments, assistive technology prescription), monitoring and prevention of pressure sores, wound assessment, evaluation of home modifications, and training in the use of augmentative communication devices. Virtual reality simulations can be used to create an engaging environment for exercise, using games to alleviate boredom.

Initially, POTS (plain old telephone systems) were used, but their bandwidth (amount of data able to be transmitted in bits per second) is low, resulting in small picture size, low resolution, slow frame rates, and poor audio quality. These problems have been eliminated with fiber-optic cable networks, using integrated services digital networks (ISDNs) or digital subscriber lines (DSLs). A mathematical technique called compression also enables the available bandwidth to be used more effectively.

Wireless devices are now widespread, allowing caregivers and clients to stay in touch while moving throughout the community. Cell phones, pagers, and personal digital assistants (PDAs) support voice, text, and image communication. Wireless Ethernet (WiFi, IEEE802.11b), Bluetooth, and ZigBee transceivers facilitate transmission of data (telemetry) from wearable sensors for recording vital signs, movement, and other variables. Mobile wireless devices can also help caregivers to locate people who are at risk of wandering. Health management and rehabilitation information resources are also available through the wireless application protocol (WAP). Virtual reality may be used to provide a range of simulated environments for therapy.

Some limitations and challenges have become evident. Access to high-bandwidth networks is growing rapidly but is still not universal, and service coverage may be patchy, especially in rural areas. Display and interface design need more attention. Since the technology is new, there are often problems with interoperability, reliability, and lack of standardization. Training of clinicians as teletherapists will need to be instituted. Although prices continue to fall, cost is still a major consideration, and reimbursement is problematic because, currently, it is usually contingent on attendance by a caregiver. Security, patient rights, and privacy issues must be addressed, using encryption where appropriate. Theoretically, there may be a risk with medical equipment such as pacemakers and powered wheelchairs, although in practice this is rare. There is a need for more quantitative tools that can measure joint motion, pressure, and force (haptic) feedback. Finally, there may be a "fear factor" associated with the use of technology.

While telerehabilitation is unlikely to replace traditional therapy, it is likely to provide services to an increasing number of people in the future.

TELETHONS

The roots of telethons in the United States as a means to raise money to "cure" or "help" people with a variety of disabilities arose from charity efforts in the pretelevision era. According to the Disability History Project, the most direct precursors were the posters, speeches, radio spots, and movie star–studded events used by friends and associates of polio survivor President Franklin D. Roosevelt to raise funds for treatment and services for people with polio at Warm Springs, Georgia.

When television evolved as a mass medium in the late 1950s and early 1960s, it became the mechanism by which charities made their appeals for money. In their efforts to draw the sympathy of the TV audience, these telethons turned to those previously successful print charity campaigns by employing "poster children." Along with the other techniques employed by the pretelevision charity events, featuring disabled children became a mainstay of telethons as an effective strategy to inspire donations.

However, when these poster children grew into adults, some began to question the techniques of telethons that used pity appeals to gather money. By the late 1970s, disability rights advocates joined together in a cohesive civil rights movement, and the Rehabilitation Act made U.S. society more accessible to people with disabilities. With these efforts came an understanding that the images of people with disabilities in the media had a powerful impact on society's acceptance of disability issues and on the self-concept of people with disabilities. Telethon images further stigmatized people with disabilities in society, according to disability rights activists. Disability historian Paul Longmore explained in a 1993 *Vanity Fair* article, "The message of telethons is whatever condition people with disabilities have, that condition has essentially spoiled their lives, and the only way to correct that is to cure them. The message of the disability rights movement is that it's possible to be a whole person with a disability" (p. 92).

However, the most famous telethon host, Jerry Lewis of the Muscular Dystrophy Association (MDA), told *Esquire* magazine in 1991 that disabled people needed help because "God goofed, and it's up to us to correct his mistakes" (p. 100). This statement from the 1973 MDA telethon, according to *Esquire,* caused some outrage about his insensitivity. However, according to Mary Johnson of the *Disability Rag,* the first big wave of protests against telethons began in 1981, when the American Coalition of Citizens with Disabilities, which represented 126 disability organizations, and the Disability Rights Center in Washington, DC, put an ad in the entertainment trade magazine *Variety,* criticizing the MDA telethon. The director of the Disability

Rights Center, Evan Kemp (who later became head of the U.S. Equal Employment Opportunities Commission), wrote opinion columns for the *New York Times* and the *Washington Post* explaining that the telethon was a "pity-a-thon" that left an impression that people with disabilities are not capable or employable. Lewis, who began hosting the telethon in 1966, was angered by the criticism and debated Kemp on the Phil Donahue TV show. This event in 1981 kicked off more than 20 years of clashes between Jerry Lewis and disability rights activists.

Jerry Lewis and the MDA telethon became the focus of most antitelethon activists because they made few changes in their pity approach tactics, whereas other disability-related charities began retooling their telethon efforts as a result of criticism, financial resources, and changes in TV. For example, by 1984, no TV station in New York City would air the Easter Seals Society telethon. TV station directors said that even though the charitable organizations paid to use a station's studio and crew, the station lost money because those fees did not cover all expenses, and the station lost ad revenue it would have received during the telethon hours. The charitable organizations also began to see how costly telethons could be. A March of Dimes executive said in 1987 that the organization stopped its national telethon because it was spending 50 cents to make one dollar, so the cost became too high. In addition, by the late 1980s, cable TV had grown in popularity. With many more choices, TV viewers no longer had to watch a telethon.

By 1990, many national telethons went away. The efforts of disability rights activists paid off in other ways as well. Some disability charities understood their criticism and changed their fundraising tactics completely. For example, Easter Seals said in 1992 that it wanted to focus on public awareness and advocacy. It brought more people with disabilities into its decision-making processes. An executive from United Cerebral Palsy explained that the media-savvy general public did not want sappy, inspirational pitches any longer; they wanted to know what disability organizations were doing to make people's lives better.

However, the national MDA Jerry Lewis Labor Day telethon remained virtually unchanged, so disability rights advocates redoubled efforts to get it off the air. In 1990, Lewis himself solidified the efforts against him when he wrote a first-person *Parade Magazine* article titled, "What If I Had Muscular Dystrophy?" A 1992 *Newsweek* story on the controversy reported that after using a wheelchair, he called it a "steel imprisonment" and referred to "the courage it takes to get on the court with other cripples and play wheelchair basketball" (p. 29). He then reflected on what he believed life using a wheelchair was all about: "I realize my life is half, so I must learn to do things halfway. I just have to learn to try to be good at being half a person" (reprinted in the August 1992 *Mainstream* magazine, p. 12).

His offensive references reenergized efforts among disability rights activists to stop his involvement with the MDA telethon. Two disability activists in particular used Lewis's words to launch an antitelethon group called Jerry's Orphans. Mike Ervin and Cris Matthews, a brother and sister who had muscular dystrophy, had been MDA poster children in 1961 and organized Jerry's Orphans to lobby the MDA to change its fundraising methods and, most importantly, to drop Jerry Lewis from the telethon. In a September/October 1992 *Disability Rag* article, Matthews said the MDA was "expert in exploiting the worst side of disability and, with the eager assistance of Lewis, has made us out to be nothing more than pathetic burdens to society, whose only desire is to walk" (p. 5). The brother-sister team said they had no problem with research efforts or anyone's desire to seek a cure, but they disliked the patronizing methods used to raise money for those tasks. Jerry's Orphans organized antitelethon protests in seven cities. Other disability activists also began their own protests of the MDA telethon. Laura Hershey, another former MDA poster child in Denver, organized a "Tune Jerry Out" protest of the 1991 telethon.

Another issue regarding telethons was financial. Many activists and others were concerned by the small percentage of the funds raised that were actually used for medical research or disability services. The *Disability Rag* reported that the executive director of MDA was one the highest paid charity executives in the United States. Telethon protesters also targeted corporate contributors to telethons. They asked them to give their donations through some other venue. They never asked contributors to give less money to the MDA, just not to make donations via the telethon. Jerry's Orphans and the disability rights group ADAPT (American Disabled for Attendant Programs Today, also called American Disabled for Accessible Public Transit) spoke with many of the MDA's corporate sponsors and requested that they not appear on the telethon; however, most corporate sponsors did not honor the request.

The other major event that helped society at large to understand the stigma of telethons was the Americans with Disabilities Act (ADA) of 1990, which mandated equal rights for people with disabilities in most aspects of society from transportation to employment to building access. However, Jerry Lewis refused to change his language or behavior on post-1990 telethons and would not take the concerns of disability activists into consideration, according a *Vanity Fair* article. The article also cited some praise for Lewis from his "kids." Stephen Mikita, an assistant attorney general in Utah and one of "Jerry's kids," said that he was proud to be called one of "Jerry's kids." He said the term shows that Lewis cares about people with muscular dystrophy as if they are his own family. Mikita added that Lewis was one of the first people to bring disabled people out into the open. "Lewis spoke about persons with disabilities, and embraced persons with disabilities, long before it was politically correct or in vogue to do so," Mikita said in the 1993 *Vanity Fair* article (p. 92).

Although Jerry Lewis did not change his rhetoric, the MDA telethon began making some changes after 1990 to reflect a society that now had the ADA. For example, the 1992 telethon featured more empowering video profiles of adults with muscular dystrophy working and making their way in the world. One video profile featured Matt Schuman, a former poster child, working at his job as a sports reporter for the *Greeley Tribune* in Colorado. The MDA telethon also changed in length by the late 1990s. Depending on the TV station, the telethon shrunk to just a few hours, rather than a day and a night of programming.

However, controversies involving Jerry Lewis's comments continued. In 2001, while being interviewed by the CBS *Morning Show,* Lewis defended the pity approach to getting telethon donations. "I'm telling you about a child in trouble. If it's pity, we'll get some money. I'm giving you the facts. Pity. You don't want to be pitied because you are a cripple in a wheelchair, stay in your house," Lewis said on the May 20, 2001, CBS *Morning Show,* as reported in *The Washington Post* (p. C1). After these comments, he issued an apology, saying he did not mean what he said. The MDA issued a statement distancing itself from Lewis and his comments, explaining that they did not reflect the views of the organization or its leaders.

▣ TELEVISION

The portrayal of disability on television shares traits with that of literature, drama, and film. Most typically, a disabled character appears on the small screen as a background figure, to provide comic relief, or to increase a sense of crisis. Although a number of made-for-television movies feature disability as a predictably melodramatic central concern, requiring cure and mourning while representing loss or enhancing the seeming mental fitness of other characters, more widely watched television shows rarely have disability as a regular central theme. Interestingly, disability has more prominence within the science fiction genre on television, indicating that a higher degree of fantasy allows for a higher degree of disability representation. Exaggerating this feature, the wave of offbeat comedies, often animated, in the late 1990s and early 2000s, such as *South Park, Malcolm in the Middle,* and *Family Guy,* frequently represent disability in an openly aggressive, perhaps satiric way that depends highly on the genre's clear distance from realism.

There are a number of stock plots that incorporate disability on television. The most frequent involves cure, in part because so many television shows are set in medical environments (e.g., *St. Elsewhere, ER, Scrubs*). Another common plot involves disability fraud. This shows up both in situation comedies (such as *Seinfeld*) and in dramas, especially those that feature the legal professions, both police and law, prominently (e.g., *Hill Street Blues, LA Law, Law and Order, CSI*). Disability arising from tragic accident or illness surfaces throughout television shows to create new, compelling interest on the part of viewers (e.g., *ER, The West Wing, Diff'rent Strokes*). Though not quite as laughable as the dramatic jumping of the shark tank on *Happy Days,* now widely recognized as a moment of television desperation, this spectacular turn to disability plots reinforces a popular misconception of disability as outside the bounds of everyday life.

DISABILITY AND DRAMATIC TELEVISION

Although predictably rare as central figures, characters with disabilities make periodic appearances in dramatic television productions, usually in minor roles. In their study of a six-week period in which they viewed 1,286 dramatic prime-time British television shows, Cumberbatch and Negrine found that 1.4 percent of the shows portrayed a disabled character with a speaking part. A recent greater social awareness of the prevalence of disability, enhanced by the advocacy of such actors as Michael J. Fox, has increased the prominence of disability in television. However, as is the case in most narrative forms, disability is often present on dramatic television but is rarely adequately explored. Most often, disability invites humor, moves along a tired plot, or helps to provide insight into able-bodied characters.

Television dramas that do have a continuing character with a disability often turn to that trope to signify human fallibility. Wheelchair-using Robert T. Ironside's relationship with black caregiver Mark Sanger presents disability prominently as dependency. *Wiseguy*'s Daniel Burroughs, a mentor who is an apparent paraplegic and wheelchair user, plays on the stereotype of the intellect with the frail body. (Interestingly, on *Highlander,* the same actor also portrays a wheelchair user, in this case a Vietnam war veteran.) In *LA Law,* Benny's developmental disability allows other characters to seem helpful and sympathetic.

Television drama also takes the opportunity to turn to disabled characters to make a political point. For example, the 1992–1996 David Kelley vehicle, *Picket Fences,* Zelda Rubenstein portrayed short-statured receptionist Ginny Weeden (the show also included Marlee Matlin as a deaf character and Robert Cornthwaite as an elderly character with Alzheimer's disease). NBC's popular prime-time drama *The West Wing* debuted with a daring representation of the injured president predicting the physical fallibility encapsulated in a vague bad back the show continues to feature. Later, the president's controversial choice not to disclose his diagnosis of multiple sclerosis foregrounds the politics of disability identity along with the public signification of disability as a marker of fallibility. *Law and Order*'s repeated featuring of assisted suicide plots raises questions of disability rights, if not always constructively.

The depiction of cure, or desired cure, of disabling conditions dominates prime-time drama. Despite the subtle portrayal of Dr. Carrie Weaver as physically disabled, a remarkable instance since her disability is never a central issue on the show, *ER* focuses most of its attention on cure. This becomes clearest when Dr. Romano has an arm amputated by a helicopter and angrily seeks all surgical means to normalize himself. The intriguing subplot that had Grissom becoming deaf, as his mother had been, and put sign language onto the *CSI* screen was cut short by his surgery that has now cured the otosclerosis. As in *ER,* this cured disability is balanced by the presence of a continuing character with a chronic disability (in this case the chief pathologist with an amputated leg). Similarly, *Joan of Arcadia,* invested as it is in the miraculous presence of God, still portrays medical science as the only hope (though a dim one) for Joan's wheelchair-using brother.

SCIENCE FICTION

Science fiction, with its frequent investment in mutant body forms, provides a sometimes restrictive and sometimes liberating view of disability. The familiar themes of cure and pity recur, but they are accompanied by some creative interrogations into the social (and sometime literal) construction of the body.

Star Trek continuously considers questions of differing bodily form and repeatedly returns to the idea that disability is contextual. The original captain of the Enterprise appears as a paraplegic in an episode that tries Kirk for misconduct. Though nonverbal, he communicates through a red and green light implanted in his chest. The original *Star Trek* series also features the famous episode "Plato's Stepchildren," better known for offering television's first interracial kiss than for the portrayal by Michael Dunn of Alexander, the dwarf jester. Levar Burton's depiction of Geordie La Forge on *Star Trek: The Next Generation* continues a relationship between racialized and ableist representation on this science fiction drama. La Forge "overcomes" his birth blindness by means of a VISOR that painfully requires such great focus that it also lends him incredible skill with warp engineering. This depiction is innovative in that he is at times less able and at times more able than characters without the VISOR, thereby contributing to a social constructionist or at least contingent model of disability.

Most often, science fiction television shows take familiar disability plots and add larger questions about the mutability of bodily form to their typical opportunistic forms. *Dark Angel* features the disabled avenger plot line, with a paraplegic mastermind, but he is one among mutants—with super and animal powers—so that he is rendered less powerful by comparison. The *X-Files* "Humbug" episode develops the freak-show plot and plays on Tod Browning's well-known "one of us" scene by having the small-statured ring master look at the always-dapper Mulder and say, "Ugh, can you imagine having to live your life like that?" Similarly, *Buffy the Vampire Slayer* satirizes disability stereotypes when Spike uses a wheelchair and when Xander has an eye poked out, so that disability is again the site of humor, but without being objectified.

DISABILITY AND SITUATION COMEDY

Cumberbatch and Negrine found that only 9 percent of British sitcoms in 1980 featured characters portrayed as having a disability, and they did so usually to make the character the object of humor. This has also largely been the case in American sitcoms, where a disabled character, very frequently in a wheelchair, appears for an episode or two and is either the butt of many jokes, the means by which other characters learn about themselves and get to feel at first embarrassed and then altruistic or at least enlightened, or both. For example, on *Happy Days,* Fonzie, who had experienced temporary disability himself after tearing the ligaments in his leg during a TV motorcycle stunt, and temporary blindness after being hit over the head, hires a disabled mechanic with a stereotypical chip on his shoulder. A wheelchair user, Don Konig has worked as a mechanic before being hit by a drunk driver, and he now needs Fonzie's help both in giving him work and in signing a social security form. The family's straightforwardness cures Don of his bitterness, and the episode ends in a friendly family meal. On *Diff'rent Strokes,* Arnold's wheelchair-using friend shows up in episodes focused on Arnold's unhappiness with his short stature. He learns the hard way, by trying to support his friend, that disabled people are stigmatized, and the whole Drummond family becomes more smug as a result.

Also a sitcom but crossing over into drama, *M*A*S*H,* running for 11 years, from 1972 to 1983, follows and influences a big-screen pattern of depicting war veterans coming to terms with their disabilities. Not only do countless young soldiers come through the 4077th in the hopes of surviving their frequently mortal wounds, but this long-standing drama/comedy includes one of the most memorable cases of disability fraud on television. In the first season, Hawkeye fakes a mental illness to obtain a leave but fails to get a diagnosis. Later, Klinger joins the 4077th and cross-dresses in an attempt to convince psychiatrists that he is unfit for service.

These patterns continue through sitcom production, where disability is rarely an ongoing concern but shows up to move the plot along or just create a new site of humor. Almost every popular sitcom has an episode about a disabled guest character. *Becker* is unique in that it features a continuous character who is blind (played by a sighted actor).

ANIMATION

Disability plays an at times troubling role in a series of late 1990s and early 2000s adult animation television programs that are not only removed from the conventions of realism but also deliberately created in bad taste. *Family Guy* offers an easily duped ex-cop who is in a wheelchair. *South Park*'s Timmy, a young boy with cerebral palsy, is the butt of jokes because of his tendency to say his own name repeatedly. He propels plots that present disability themes, including a satire on Christopher Reeve as "fake disabled," but mostly he is even more ridiculous than other *South Park* characters because of his cerebral palsy. *Quads* focuses entirely on disability but does not forward any particular critique or expression of disability identity in doing so.

DISABLED ACTORS

The most well-known disabled television actors are Marlee Matlin, who has been on 19 television shows, including *ER, Seinfeld, Spin City, Gideon's Crossing, Law and Order,* and *The West Wing;* Jim Byrnes, who has been on more than 20 television shows, including *Sliders, The Outer Limits, Highlander,* and *X-Men: Evolution;* and the late Christopher Reeve, who started his career on a small-screen soap opera, played a disabled war veteran on stage, and then returned to television after he became disabled himself.

Chris Burke, an actor with Down syndrome, played Corky Thatcher on *Life Goes On,* a 1980s family drama that features Corky being mainstreamed and fighting his own battles at school. Burke has also appeared on *ER, Touched by an Angel, Promised Land,* and *The Commish.*

While their status as actors may remain in question, a number of people with disabilities have appeared on reality television shows. One show, *The Littlest Groom,* made disability its central device by having a short-statured groom choose among average-sized and little women as his future bride. *The Amazing Race* included a short-statured competitor whose size was a distinct advantage in competition. *Survivor* has included one deaf competitor, who received some negative publicity from her friends at Gallaudet University for not signing during the show, and one character with a partially amputated leg. As with most television formats, reality television reflects both an increasing representativeness by including these characters with disabilities and also an exploitative thirst for the spectacle they produce.

ADVERTISING

As Ganahl and Arbuckle together with Haller and Ralph demonstrate, people with disabilities do not have adequate representation in television advertisements, though it is increasing. The rise in prominence is not resulting in more positive images, however. The most troubling examples include Christopher Reeve, in the prime Super Bowl advertising spot, depicted as cured and able to walk again. Similarly, Mothers Against Drunk Driving sponsored an ad with a young walking man purchasing a wheelchair. The implication is that he plans to drink and drive, and this will have the apparently horrifying effect of landing him in a wheelchair. These advertisements together signal the white, male physically disabled figure as the disability representative most likely to appear in advertisements that play on the general public's desire not to become disabled. The lack of televised coverage of the Paralympics as compared with the inordinate attention to athletic achievements of Olympians reinforces this imbalance.

TENBROEK, JACOBUS

(1911–1968)

American Advocate for the Blind

Dr. Jacobus tenBroek, called "Chick" by friends and family, blinded at the age of seven in a hunting accident, was a charter member and the first president of the National Federation of the Blind (NFB), founded in 1940 in Wilkes-Barre, Pennsylvania. The NFB grew to become the largest advocacy group of blind people in the United States. TenBroek was a constitutional scholar who wrote academic monographs on the 14th Amendment, public policy (particularly as it pertained to welfare programs), and the nascent Social Security Administration and its impact on the blind. TenBroek waged a relentless war of words against publicly financed programs that purported to assist the blind but that were in fact, he asserted, institutions rife with paternalistic attitudes and designed to perpetuate the inferior status and indigency of the blind. TenBroek argued in favor of a pension for the blind that would not require means testing as did social security. After earning a law degree and a doctorate in public policy, tenBroek taught speech and political science at the University of California at Berkeley for 25 years.

As a boy, tenBroek studied with Newell Perry at the California School for the Blind in Oakland, California. Perry mentored a generation of leaders that would found the California Council for the Blind in the 1930s, along with a handful of other state advocacy groups that would coalesce into a nationwide movement of blind activists. TenBroek would galvanize this generation of activists and draw them into the NFB under his leadership.

TenBroek served as president of the NFB from 1940 to 1961, when he resigned at the NFB national convention in Kansas City amidst a firestorm of dissension among a number of NFB state affiliates. By resigning, tenBroek managed to quell this dissent and put in place the next generation of leaders who he felt best represented his vision for the organization and the broader movement.

TERATOLOGY

In the twenty-first century, freak shows are more about performance than somatic oddity. Suspension of disbelief must accompany the exhibit that purports to be a cross between species, and even the most naïve person knows that unusual physical features such as extra limbs or variant statures do not result from supernatural forces. In the ancient world, people were not equipped to understand physical configurations as we do in the modern world, and ancient scientific thought provided no reason to disbelieve the combination of a horse and a man or the existence of a human with a hundred hands. Monstrous beings—*terata,* in Greek—usually inhabited lands around the edge of the earth and the mythological past. Monstrous beings also inhabited the Roman imagination: Historians of the Roman world frequently reported monstrous births as portents.

A distinction must be drawn between people with disabilities and monsters. People with disabilities comprised a significant proportion of the ancient landscape, and an ordinary community member who had some sort of disfigurement would not have been considered to be a monster; indeed, the unknown characterizes the monster. In the ancient world as today, physical configuration alone does not make a monster; rather, a confluence of social forces defines what lies within the bounds of human normality and what lies outside it. Plutarch, the first century AD biographer, refers to a Roman "monster market," where one could buy human oddities such as people with three eyes. This may have been a market in which people with variant bodies were sold and may have doubled as a sort of freak show; it must have had as much to do with salesmanship and showmanship as with somatic variation.

Monsters lend order to the world by defining the boundary of normal human parameters. The ancient world was not guided by the statistical bell curve of the eighteenth century; instead, the monster delineated physical normalcy by reflecting its antithesis. In the fourth century BC, in *Generation of Animals,* Aristotle described *monstrosity* as the failure to resemble a human being at all. Monstrosities, in Aristotle's view, included aberrations such as animal heads on human bodies or humans with extra heads.

In addition to defining physical normalcy, monsters also reflect social and moral bounds of their culture. Robert Garland (1995), in *The Eye of the Beholder,* argues that the Roman emperors, often reported to have people with physical anomalies amongst their courtiers, were themselves in the category of the monstrous. Sexual ambivalence, too, was seen as a monstrosity, as argued by Luc Brisson (2002).

A collection of essays on monstrosity in the Graeco-Roman world (the majority on the Greek world) can be found in Catherine Atherton's (2002) *Monsters and Monstrosity in Greek and Roman Culture.*

THALAB THE GRAMMARIAN

(ca. 845–904)

Iraqi grammarian and philologist

Abu 'l-Abbas Ahmad ibn Yahya ibn Zaid ibn Saiyar, more briefly known as Thalab, became the foremost grammarian and philologist at Kufa in Iraq. Even in his youth, reference was made to him as a reliable source of accurate knowledge. In his later years, he lost most of his hearing. One Friday afternoon, he left the mosque and was walking along the street while reading a book "when a horse knocked against him and threw him into a deep pit, out of which he was taken nearly senseless." He died in Baghdad the next day.

TIMUR THE LAME (1336–1405)

Tatar Warrior

From 1369 until his death, the Tatar warrior Timur Lang (the Lame) led his army through north India and central and west Asia, enlarging his dominion from Aleppo through Baghdad, Shiraz, and Hormuz in the south, bounded eastward by the Indus, and stretching north to the Aral Sea and much of the Caspian coast. He died while marching on China. Contemporaries mention his lame right leg and arm, from battle wounds or a youthful sheep-stealing incident. Examination of his skeleton in the 1940s confirmed the lameness. Memoirs attributed to Timur include a description of leading troops through snowbound mountains and being lowered down a precipice in a wicker basket attached with long ropes. He experienced rheumatic pain during such campaigns but drove himself on. A story has Timur laughing at Sultan Bayazid, who he had captured. Bayazid reminded Timur that the rise and fall of kingdoms was in God's hands. Timur replied that he was laughing at their mutual ugliness, because God gave kingdoms indifferently to "such ugly Fellows as we are, you a squinting clown, and I a lame Wretch."

TOKENISM

In modern industrial societies, people with disabilities have been widely underrepresented publicly and in the workforce, especially within white-collar professional jobs and other high-status positions in the media, government, and business. Within labor markets based on segmentation and hierarchy, very few people with disabilities have been able to break through what feminist discourse has labeled the "glass ceiling," into the upper echelons of leadership and power. Indeed, in most developed societies, a large majority of people with disabilities are denied employment altogether, curtailing their cultural participation as effective and self-determined individuals.

Unfortunately, the underrepresentation of large numbers of people with disabilities inevitably puts tremendous pressure on those in the public eye to embody a type of disability overcoming. From a historical perspective, famous high-achieving individuals with disabilities, such as reformer and writer Helen Keller and U.S. President Franklin Roosevelt, have been represented as inspirational examples of success against great personal obstacles. Similarly, figures such as Vincent van Gogh and Virginia Woolf are appreciated for their tremendous genius, while their experience of mental illness is separated out as a tragic fate. In such cases, disability is understood as an impediment to be overcome, rather than as an intrinsic component of one's individual work, art, or social perspective. Of course, while overcoming narratives are misleading and destructive in their own right, social interpretations of the vast majority of people with disabilities revolve around discourses of dependency, tragedy, and victimization.

Within this framework, contemporary public figures with recognized disabilities tend to be positioned within a binary construct—as either an extraordinary role model or an embodiment of the tragic nature of disability. Stephen Hawking's scientific genius seems to "transcend" his disability. On the other hand, Jerry Lewis's telethons, which feature the tragic stories of "poster children" with muscular dystrophy, perpetuate a belief system that invalidates the agency of people with disabilities. These reductive perspectives are indicative of the way disability tokenism functions. Out of this socially manufactured binary, individuals with disabilities who do gain power and influence are represented within public discourse as the "truth" of disability. Within this framework, they are living in a problematic double bind: If they succeed, the media may broadcast false expectations of other people with similar or dissimilar impairments; if they fail, they can be used as a rationalization for further broad-based discrimination.

Feminist scholars have described gender tokenism as a process of granting power and privilege to a few while withholding it from the vast majority of women. In this way, it appears that if one is truly qualified, that person can achieve any position she desires. The tokenized person is used by the establishment as (faulty) evidence that a system of justice based on personal merit is intact. The visible success of very few people is used to displace the social reality that the vast majority of people with disabilities lack the resources, opportunities, and support to experience the kind of success promised by this gesture of tokenism.

In effect, without support from a community of allies and other people with disabilities, people who are put in positions and expected to represent disability are set up to fail themselves and their community, because either outcome distorts any real relationship to the diverse and complex heterogeneity that disability represents.

TRAINING SCHOOLS

In the United States, training schools were institutions erected to house some of the children designated as feebleminded. They appeared mainly during the later part of the nineteenth century and the early decades of the twentieth century. Historically, they emerged as in-between sites, formalizing generally after the earlier East Coast asylums and religious-based charity institutions and before the special education classes funded under the auspices of public school authorities. By the early 1900s, scholars such as Henry Goddard of the Vineland Institute of New Jersey on the East Coast and Lewis Terman of Stanford University on the West Coast were arguing that 2–3 percent of the U.S. population were classifiable as feebleminded.

Training schools were initially institutions to which parents, for the most part, had to be persuaded to send their children. For most social groups in the United States at that point, voluntary segregation of the young from immediate family was generally not a preferred cultural experience. As such, welfare experts, religious workers, and concerned donors established rigorous programs of persuasion to segregate feebleminded children and place them in the new institutions.

The overt nature of this effort indicated a refiguration of the relationships that constituted the state. The shift in relationship structures, especially within families, was often commented on in two key sites where the successes and failures of training schools were reported. Two national conferences held annually in the United States documented these efforts across states and are important to note (published proceedings are available): the National Conference of Charities and Corrections and the National Conference on the Education of Backward, Truant, Delinquent, Dependent, and Defective Children. In addition, journals focused specifically on feeblemindedness, such as the *Training School Journal* and the *Journal of Psycho-aesthenics,* stood alongside more broadly conceived journals concerned with education in general, such as G. Stanley Hall's *Journal of Genetic Psychology* and *Pedagogical Seminary,* both of which frequently contained articles on feeblemindedness and degeneracy. (G. Stanley Hall was a founder of the *American Psychological Association* and a leading exponent of the child study movement.)

The new relationship of children to statehood was borne out in such documentary sites. These sites of information exchange are particularly significant for understanding how feebleminded children were constructed and imagined in relation to training schools and, in turn, nationhood. Under discourses of scientifically managed citizenship and a competitive eugenic philosophy, the routes through which human bonding could proceed and the methods for getting things done had changed. The child-adult binary had been refigured through the establishment of a variety of institutions that separated the young from each other and their elders, such as children's hospitals, schools of different kinds, and youth clubs, all of which were often further segregated by race in their establishment or operation. While all the young were now to be thought of as vulnerable, ignorant, segregable, and delayed from responsibility, children designated as feebleminded were made to embody the perpetuity of these features symbolically and to represent an apparent threat to the strength of the nation.

The variety of training schools that existed indicated an uncertainty over the minutiae of this logic but reflected a common dedication to segregation. Different schools had different functions. In a 40-year period around the turn of the twentieth century, training schools were one of several sites to which children labeled feebleminded could be allocated, depending on local laws and availability. For example, children could be assigned to (1) publicly funded training schools, some of which taught manual labor tasks; (2) privately endowed training schools; (3) philanthropic institutions more overtly concerned with segregation and medicalization; (4) state-care medical institutions that did not assume themselves to have pedagogical functions, including asylums; or (5) special classes either attached to a public school or centralized in a separate building within a given school district. In regard to training schools specifically, some had more of a "warehousing" function, while others placed an emphasis on manual training designed to "mitigate" the effects of feebleminded children on the larger group of citizens. Training schools were thus also "in-between" institutions, not only in terms of when they emerged, but insofar as the children sent to them were sometimes considered to be liminal—trainable but not educable, with manual or vocational labor being the only kind offered, if at all.

Because training schools emerged as part of a proliferation of formal segregating institutions, their role has been viewed in ways that go beyond their specific or intended internal functions. Earlier forms of segregation, such as reservation systems and slavery, were followed by other forms, such as asylums, prisons, orphanages, schools for Deaf and Blind, industrial schools, centers for juvenile delinquents, and training schools. Historians of education such as John Richardson (1999) have suggested that compulsory attendance legislation would not have been possible without this prior experience of confinement. By 1918, all existing U.S. states had compulsory attendance legislation, which was less about a commitment to elementary public schooling and more about who was *not* allowed to attend. In sum, training schools, alongside other prior institutions, had several kinds of purification purposes: (1) reforming state relations: they were believed to purify the child of familial influence by removing them and opening them to expert governance; (2) production and reproduction: to purify the wider population from "having to see" feebleminded children, with the hope of ending the reproduction of feebleminded people while simultaneously molding cheap, productive laborers; and (3) defining the citizen and the public: to purify state-funded "regular" or mainstream schooling by offering segregated spaces that made possible a more narrow definition of who the public was in public schooling.

TRANSGRESSION

Transgression is a form of resistance involving the crossing of limits or boundaries. It is not antagonistic or aggressive, nor does it involve a contest in which there is a victor; rather, transgression is playful and creative. Among disabled people, transgression has been a significant means of challenging limits and disabling barriers. Disability activists have been involved in a long campaign of direct action against disabling barriers, whereas transgression has been a more indirect and subtle form of challenge by disabled people.

The concept of transgression has been elaborated extensively by Michel Foucault, who was interested in Kant's critique of limits but wished to pursue more practical (and political) forms of engagement. Foucault saw transgression as distinctively different from transcendence or transformation: He did not envisage individuals as gaining absolute freedom from limits, as transcending, or as finding a new self. Instead, he suggested that individuals, in crossing limits or boundaries, might find moments of freedom or of otherness. Foucault's account of where transgression takes place is somewhat complex. In his "Preface to Transgression" (1963), written as an introduction to the work of Georges Bataille, he argues that "it is likely that transgression has its entire space in the line it crosses" (Foucault, 1963/1984, p. 73). This implies a boundary that can only exist if it is crossed. The limit and transgression depend on each other, but the relationship is not a simple one; rather, Foucault explains the relationship as being like a spiral, with moments of crossing of the limit appearing as flashes of lightning in the night that give a darkening intensity to the night they obscure. He also describes the interplay of limits and transgression as being regulated by a simple obstinacy. The act of crossing the limit does not violate it, but simultaneously affirms and weakens it. Foucault regards this as a form of nonpositive affirmation, which has to be constantly repeated, and likens it to Blanchôt's notion of contestation, which does not imply a generalized negation, but an affirmation that affirms nothing. A more positive version of transgression was developed by Foucault in the shape of practices of the self, whereby individuals set about changing their own selves.

Derrida sees transgression as being achieved in deconstructive readings of texts, which cross the protective limit given by traditional readings. It involves going beyond the first reading of a text and examining its ambivalences, contradictions, and slippages. Deconstruction transgresses against the protection that a traditional reading affords, by reading against the grain, exploring alternative meanings, and considering how the text itself *performs.* The playful nature of deconstruction and the transgressive forms of writing that are often adopted has provoked some criticism about its acceptability as a form of scholarship and has even led to the publication in *Social Theory* of a hoax article by Alan Sokal entitled "Transgressing the Boundaries: Toward a Transformative Hermeneutic of Quantum Gravity." However, those practicing deconstruction maintain that the transgressive strategies may be playful, but their intent—to challenge assumptions, orthodoxy, and dogma—is deadly serious.

Foucault uses sexuality to illustrate transgression, arguing that since the writings of Sade and, more recently, Bataille, sexuality has been a fissure that marks the limit within us and designates us as a limit. Foucault has been criticized extensively for failing to provide empirical examples of his concepts, and indeed, his discussion of sexuality provides little guidance into the practical pursuit of transgression. It has been suggested by one of Foucault's biographers, however, that sexuality is one area in which he did in fact experiment, and his own testing of the limits of homosexuality involved promiscuous behavior that led to his premature death from an AIDS-related illness.

Nevertheless, transgression has been viewed as an attractive construct in relation to marginalized and oppressed groups, as Foucault points out, not least of all because "it serves as a glorification of what it excludes" and forces recognition of exclusion. For those who transgress, according to Boyne (1990), "otherness lies ahead" (p. 82), and this allows individuals to shape their own identities by subverting the norms that compel them to perform repeatedly as gendered or disabled subjects. They are not required to—and indeed could not—reject these identities entirely, but they can vary the way in which they have to repeat these performances. Researchers studying transgression have uncovered strategies in which new mothers have avoided both breast feeding and the wrath of the health visitors checking on them. Within disability, it has been suggested that self-help groups for "ME sufferers" (those with myalgic encephalomyelitis/chronic fatigue syndrome) enable them to transgress against the regulatory norms that inscribe their bodies differently. Research with disabled students by Allan in 1999 documented the ways in which they transgressed both in and out of disability. Transgressive strategies that moved the students away from a disabled identity included using humor to put peers at ease, pretending to be "blind drunk" rather than drunk, or avoiding going to the toilet; acts of transgression toward disability included claiming a more disabled label and requiring peers to provide help. Teachers were generally unsympathetic to, and critical of, the students' transgressive practices, tending to read these as evidence of students' failure to accept the "fact" that they were disabled. There appeared to be a clash of discourses within the school, between, on one hand, the students' discourse of desire, within which they practiced transgression, and, on the other hand, the teachers' discourse of special educational needs, within which they provided support.

Disability arts represent a particularly creative and innovative form of transgression. They celebrate difference but also seek to subvert the normality genre by using the body as a weapon to subvert and undermine disabling barriers. Disability arts deploy difference strategically and involve individuals portraying themselves as aesthetic objects, through dance, photography, art, and other cultural forms. One powerful example comes from Cheryl Marie Wade, who, in her poem "I Am Not One of the," reverses beauty and ugliness, portrays herself both as a sexual object, with lace panties, and as deformed, with a stub, and demands a presence that has hitherto been denied. In "Crip Pride," Jessie Aaron presents herself and her "family" of disabled people as subjects with sexualities. She offers solidarity and difference as a response to the rejection she and others have experienced. Both writers assert their sexual and gendered identities in playful ways that challenge the desexing discourses of disability. Their transgression, therefore, has an impact on their own identities, but also on those who read the poems and who are forced to examine their own normalizing and disabling knowledge and actions.

Foucault acknowledges a "difficulty with words" that hampers philosophy and sees the absence of a language with which to talk about transgression as inhibiting its practice. Nevertheless, he expresses his hope that one day transgression will be as much a part of our culture as contradiction was for dialectical thought. Bataille also looks forward to the normalization of transgression whereby silent contemplation would be substituted with language (Foucault 1984). It could be said that transgression is indeed part of everyday culture, albeit denoting some marginal activities: A web search suggests that transgression has become synonymous with forms of eroticism and "deviant" sex. Transgression is also prevalent in the arts: Anton Chekhov's short story, Kate Jordan's play, and a film written and directed by Michael diPaulo all have the title *Transgression,* and Joyce Carol Oates's collection of short stories is entitled *Faithless: Tales of Transgression.*

Transgression appears to provide an important way for disabled people to engage playfully with limits imposed on them by a disabling society. It seems to provide scope for challenging the very existence of some of these limits and for self-transformation. Transgression operates within a discourse of desire, and this discourse has to be extremely powerful to speak against the needs-based discourses that dominate disability services.

TRANSITIONS IN EDUCATION AND EMPLOYMENT

Transition generally refers to any process that characterizes an evolution resulting in something new or different from that which was before. It may express the process of change in form, as in the shape or structure of the human body as it grows or ages, or it may refer to the process of changing emotional states, as in the swing from a normal to a depressed emotional state. In any case, *transition* is the term we use to label the process of change, reflecting the movement from one set of identifiable characteristics of something or someone to a new set of identifiable characteristics.

In the past two decades, *transition* has been the term used in education, particularly vocational education, to refer to the process of helping secondary education students become "work ready." In this context, transition includes all of the efforts of schools to modify and improve their vocationally oriented practices that more directly and effectively prepare students for the world of work. It refers to system-level efforts, including curriculum reform, changes or additions to course offerings, and enhanced work experiences. It quite literally refers to any effort by schools to influence and improve the potential for their students to achieve positive vocational outcomes. Transition from school to work, as it is often called, is the application of those practices referring to the transformation process of being school oriented to being work oriented.

The term *transition* has a more specific and formal meaning in special education. In this context, transition not only refers to the general school-based process of preparing students for the world of work, but also denotes a component of the individualized education plan (IEP) of students aged 14 and older. Thus, transition refers to improvements in "system" practices as well as to the application of those practices to individual students. Students with disabilities (who have an IEP) are required to have a formal transition plan as part of their education plan. The purpose and focus of the transition plan are to ensure that appropriate steps are in place that will lead to successful integration of students with disabilities into adult living environments, with special emphasis on work and post–secondary education settings.

TRANSITION AND STUDENTS WITH DISABILITIES

The concept of transition in special education has its roots in the early 1980s, when parents and advocates of students with disabilities began to voice concerns about the employment prospects for their children. The U.S. Education for All Handicapped Children Act (P.L. 94–142), which called for a free and appropriate education for students with disabilities, had been in place for nearly a decade. Evaluation data regarding its lack of effectiveness in stimulating the schools to adequately prepare students with disabilities for adult living and the world of work were beginning to mount and raised serious concerns among parents and advocacy groups. The facts that schools were now required to provide appropriate education to students with disabilities together with the accumulating data revealing the apparent lack of preparation for work and adult living led to sustained advocacy efforts to get the schools to include school-to-work transition planning as part of the educational plan for every secondary-age student. That advocacy effort culminated in the Individuals with Disabilities Education Act (IDEA) of 1990, which also mandated schools to incorporate into each student's IEP an outcome-oriented statement about transition services.

IDEA describes a transition plan as an outcome-oriented process that leads the student to successful linkages with the adult community. Successful linkages include postsecondary education; vocational training, integrated employment, or continuing adult education; adult services; or independent living and community participation. The entire emphasis of transition planning is to ensure that when the student exits the school setting—thus absolving the school of any further IEP responsibility—he or she has a direction and is effectively engaged in the adult environment. Practically, given individual interests and abilities, that could mean the student is working (has a job), is engaged in vocational rehabilitation services, is enrolled at a college or university, or is doing all three. Equally important, transition planning is intended to convey that students are linked with the community and community services in such a way that they have as much control over their lives and daily living as possible or are moving toward self-directed independence and independent living.

THE FOCUS OF TRANSITION PLANS

Transition plans embody a comprehensive and often complex strategy for bringing about the successful movement of students with disabilities from school to work and adult living. Comprehensive plans consider the wide range of programs in the workforce development system (including the school) that should play a role in bringing individual student success. In doing so, successful transition plans are characterized by four common elements: They are student centered, incorporate input from and identify critical stakeholders in the transition process, reflect interagency collaboration in meeting student needs, and address the broad range of student needs that will lead to successful transition.

The foundation of a successful transition plan is a genuine student-centered planning process. Successful transition plans reflect a clear and strong commitment to the goals, interests, and dreams of the student. Schools are obliged to work with the student through testing and assessment to determine his or her strengths and interests in order to articulate the intent, focus, and chief outcomes of the plan. The more closely the plan is tied to the goals of the student, the more likely its success will be. As plans are developed and modified over time, the student's goals and interests remain the centerpiece in the planning process. Successful transition plans take on appropriate detail depending on the interests, abilities, and needs of the student. No two plans are alike.

Stakeholder input and participation in plan execution are key characteristics of successful transition plans. Stakeholders can include the student, family members, teachers and other relevant educators, adult service providers, and relevant community members (e.g., advocacy groups) as appropriate and needed. The challenging aspects of stakeholder involvement are identifying the individuals who can play a key role in the development and execution of the plan and the timing of their involvement.

The third characteristic of successful transition plans is interagency collaboration. Involving the schools alone in the transition planning process is considered to be shortsighted and ineffective when adult service providers can supply key insight and services that can offer the student real-world experiences. Thus, it is imperative that schools involve agency representatives in planning both content and timing. In addition, plans should describe the details of how students will be linked to adult and community service agencies. At a minimum, the plan should include representatives from vocational rehabilitation services and the local workforce development system. In the United States, these are now called the "one-stop" employment development agencies. Other agencies that may play a role in transition planning and execution include mental health services, developmental disabilities, local centers for independent living, and the myriad of community-based services.

The fourth characteristic of successful transition plans is the focus on the broad range of student development needs. All students, whether bound for college or sheltered employment, will need assistance to meet the broad range of adult living requirements. Thus, transition plans should reflect the activities that are needed to meet those requirements, including consideration of life skills instruction, career and vocational exploration, structured work experiences, and support services.

THE TRANSITION PLANNING PROCESS

Transition planning typically begins when the student reaches high school age. IDEA mandates the development of a transition plan at age 14. The general idea is that the plan is first articulated early in the student's high school experience and is refined over time to reflect new information, changing demands, and refined interests. Successful plans result from planning activities that are open and participatory, ongoing, and centered on the goals and interests of the student. The process is open in that it involves individuals who have and feel a stake in the success of the resulting plan. The planning process is controlled by interested stakeholders, including the student for whom the plan is designed. All stakeholders provide input to the plan and share in the responsibilities for carrying out the plan.

Successful transition plans are dynamic and undergo periodic review to assess progress. They rarely remain static from initiation to completion, as opportunities and environments change over time. To take advantage of new opportunities, stakeholders should periodically assess progress of the plan toward the intended goals, review activities and supports, and revise as appropriate.

TRANSLATING THEORY AND RESEARCH INTO PRACTICE

The issue of translating theory and research into practice is ultimately one of disseminating and utilizing research findings. Through the dissemination and utilization of theories, practical programs implement and test new theories on varieties of populations and situations. The iterative nature of this process requires a constant dialogue between researchers and practitioners. While so-called pure research may be valued in the quest for knowledge in and of itself, applied research on disability, for example, presumes that individuals with disabilities, their family members, researchers, policy makers, and activists will be able to utilize those theories and findings in their own lives or professional work. To those ends, translating theory into practice is an important issue for many applied fields that work with and serve members of disability communities.

This entry has three objectives. First, five dimensions of dissemination that influence the utilization of new knowledge will be explored to suggest factors that should be considered during the dissemination process. Second, two models of information integration will be detailed to explore how practitioners incorporate new knowledge and processes. Finally, the implications of these components for integrating research findings into practice will be briefly discussed.

DIMENSIONS OF DISSEMINATION

Based on a literature review, the National Center for the Dissemination of Disability Research (NCDDR) identified four key dimensions that affect the acceptance of new theories and knowledge. The first dimension is the source of new knowledge: Where is the information coming from? This dimension speaks to the information source's credibility. If the information is from a reputable institution or researcher, the findings may be more readily accepted and integrated into the daily activities of an individual or agency. However, if the information originates from unknown or dubious sources, the information consumer may quickly disregard the findings. Indeed, the source of information is often more important than the actual information presented.

Second, the content of the disseminated message impacts whether it is incorporated into practice. While the previous dimension focuses on the quality of the information provider, this dimension focuses specifically on the message. To gauge the quality of the information, an individual must weigh the content against existing knowledge to see whether their experience confirms the theory. As consumers of information, people are constantly weighing new theories and messages against preexisting knowledge. As these messages cohere with previous knowledge and experience, the information will be accepted and implemented.

Third, the medium through which the theory is conveyed can affect its utilization. This dimension concerns how the material is disseminated. Perhaps the largest breakdown in theory implementation occurs in this dimension. For researchers based at colleges and universities, their positions often require them to present research findings at academic conferences or in scholarly journals. These venues may not be appropriate locations or formats for members of disability communities, practitioners, or agency staff. Research findings must be presented and conveyed in accessible formats and locations to assist in broader practice implementation. During the past several years, the Internet has made knowledge dissemination much faster and more accessible through web pages and an increasing number of online journals. However, with so much information coming from so many sources, people are forced to critically evaluate the credibility of information now more than ever.

Fourth, the users receiving the knowledge affect how the theories are translated into practice. As the

NCDDR suggests, facilitating a user's utilization of knowledge can be accomplished in two primary ways. First, the materials need to be relevant to the user's daily life. Second, the user must be ready to accept the information. Thus, from the information receiver's point of view, knowledge is more likely to be implemented as its utility increases. Within some academic fields, researchers have addressed issues of utility through participatory action research that incorporates the potential users of the information not only in selecting research questions, but also in developing theories and methods to answer those questions. Research suggests that through this collaboration, users and agencies are more likely to utilize the research findings.

A fifth dimension to the implementation of information that the NCDDR did not mention is the speed at which the information arrives to practitioners. The time lag between the research project and the dissemination of research findings can make the information out-of-date by the time practitioners and agencies receive it. This time lag occurs at numerous stages of the research and dissemination process. For example, when looking at possible racial and ethnic discrimination in vocational rehabilitation (VR) services in the United States, many of the articles that were published in 2002 and 2003 relied on information from the 1996 and 1997 Rehabilitation Services Administration's database, RSA-911. This lag of approximately six years could make the findings useless to VR practitioners and agencies as policies and administrations remain in flux.

MODELS OF INFORMATION INTEGRATION

The literature suggests two primary models to explain how theory is adopted into practice. First, the agricultural extension model suggests that people adopt new models for pragmatic reasons. If the theory produces a more efficient and efficacious means of getting outcomes, then it should be utilized. Second, the constructivist model indicates that people will adapt new methods only when their old methods fail and the new method reflects their experiences. Therefore, the first model can be seen as more of an objective approach and the second model as more of a subjective approach.

Agricultural Extension Model

The agricultural extension model developed as a model of translating theory into practice following patterns established in agriculture. This model focuses primarily on spreading the word of successful interventions. For example, in pharmacology, Viagra initially began as a treatment for high blood pressure and was used on young, male medical students. While the drug was successful at reducing high blood pressure, it also had an adverse side effect of an erection. Now the drug not only is used generally for men with impotence but also is used for men with spinal cord injuries to enhance their sexual functioning. Through that process, the use of Viagra spread from people with high blood pressure to older men with erectile dysfunction to men with paraplegia and tetraplegia.

This agricultural extension model also establishes "best practices" paradigms in fields such as public health and medicine. However, this model presents a narrow notion of knowledge dissemination. For example, the agricultural extension model assumes that the environmental and individual factors will be the same despite any differences that may exist between the initial study site and future sites where the knowledge may be applied. For this reason, some researchers in the literature have called for "best practices" to be considered "best processes" so that environmental and individual variables can be better considered in utilization. Indeed, this transition contextualizes the processes within the specific situations and reminds users to consider that context when adapting those processes.

Constructivist Model

The constructivist model is primarily concerned with how dissemination fits into the process of learning. This model considers how individuals and groups assimilate knowledge based on how well it blends with previous experience. Essentially, learners accept knowledge if it meshes with their personal experience and reject knowledge if it does not mesh with their experience. As a consequence of this model, people are likely to maintain the status quo unless faced with a problem. This stagnancy further detracts from possible innovations that may develop during process improvements. A possible way to counteract this stagnancy and push for innovations is to maintain cross-disciplinary teams to introduce theories from different fields when considering new practices.

CONCLUSIONS AND SUGGESTIONS

This entry has examined important factors in the research dissemination process and models to explain why practitioners and agencies may utilize research findings. At least three suggestions can be made based on the dissemination literature. First, researchers need to make new information accessible to all levels of users (e.g., researchers, individuals with disabilities, families, activists, policy makers). Accessibility may mean publishing and presenting the materials differently to different groups. This implication follows one of the primary rules of writing: Always consider your audience.

Second, researchers need to ground their research in communities that may implement their findings. This activity accomplishes several goals. Not only does the researcher gain credibility in the community, but also the community will be more likely to utilize the research findings. Participatory action research has provided a useful model to assist with this process. By incorporating community members in all phases of research and maintaining this connection throughout the project, researchers may be able to disseminate their findings more quickly to the people who are most likely to utilize them.

Finally, researchers need to understand models that lead people to utilize research findings so their dissemination efforts can target those models. For example, if individuals only accept new theories when old theories fail them, then researchers disseminating new findings need to show why old theories no longer apply. This concentration on dissemination packaging is vital to increase the likelihood of translating theory into practice.

TRAUMATIC BRAIN INJURY

Traumatic brain injury (TBI) is defined as any damage to the brain from an applied force. The forces involved can be from direct contact, as in blunt or penetrating head injury, from a gravitational source such as fierce shaking, or from rotational energy, as in shaken baby syndrome. Often, a combination of these forces is involved (a motor vehicle collision can cause both direct blunt trauma and rotational and rapid velocity changes). These events cause a deformation of the brain tissue that results in several types of pathology. In addition to the *primary injury* (caused at the moment the force is applied), a series of events is set in motion that continue to cause cellular damage over the next days to weeks, or even longer. These *secondary injury* events include a complex set of biochemical reactions and molecular changes that extend cellular damage, brain edema, and inflammation in a self-perpetuating cycle that rapidly increases the extent of the brain damage.

PRIMARY INJURY

Direct contact with the skull or brain is classified as *blunt trauma* (caused by, for example, a baseball bat or windshield) or *penetrating trauma* (from gunshot wounds, shrapnel, and knives). Blunt contact causes injury directly below the contact point. The impact can also cause the brain to move or shift back and forth inside the skull, damaging the opposite side of the brain, in a "contracoup" injury. The base of the skull is bony and rough and can cause tearing and bruising to brain tissue when it bounces back and forth. The extent of the damage varies depending on the intensity of force applied. The primary injuries that result are contusions (bruising of the brain tissue), tearing of the tissue and blood vessels, bleeding, tissue shearing, and disruption of neuronal networks. There are multiple types of contusions. Blunt head injury may be *open,* if the skull has been compromised to the point that brain tissue is open to the environment, or *closed.*

In addition to the direct blow, blunt trauma to the head causes the transmission of forces throughout the brain tissue. If strong enough, they can cause shearing and disruption of tissue and neural networks deep within the brain. This type of damage tends to be diffuse and can result in axonal damage (*diffuse axonal injury* [DAI]), diffuse edema, and extensive neuronal death and can extend the toxic secondary injury throughout the brain to areas far from the point of original contact. The same acceleration forces that cause DAI can also cause stretching and tearing of blood vessels leading to subcortical hemorrhages, additional neuronal damage, and disrupted functional activity in otherwise intact neurons.

Penetrating injury results in different injury patterns from blunt injury. The biggest factors in the degree of damage from a penetrating injury are the velocity and mass of the projectile. Shells from high-powered rifles and other high-velocity projectiles can cause an enormous pressure wave that damages the brain tissue in predictable patterns and can be massive and devastating. Lower-velocity projectiles cause less pressure-wave damage and less direct shrapnel path damage. As with blunt TBI, penetrating injury sets off a secondary injury cascade.

SECONDARY INJURY

The initial trauma to the brain that kills or damages nerve cells is only the first step in a drawn-out and complex cascade of events that cause further cell death. Immediately after a TBI, some cells are mortally wounded, while others farther away from the injury insult receive lesser wounds. However, within hours to days after the injury, if the metabolic and cellular machinery in the nerves (*homeostasis*) is too perturbed, these cells swell and die (*necrosis*). Necrosis can be caused by inflammatory factors produced in the brain, by free radicals entering into the brain, or by the excessive release of excitatory neurotransmitters such as glutamate. Some cells that survive the initial injury may die days, weeks, or months later, when mechanisms inside the nucleus of the cell trigger a breakdown of its DNA. This process is known as *apoptosis,* or programmed cell death, because it is triggered by genes within the cell nucleus responding to external signals caused by the TBI.

Components of the secondary injury cascade include *anoxia* (absence of oxygen), *hypoxemia* (low oxygen content in the blood), *hypotension* (low blood pressure) and *anemia* (low blood count), *hemorrhages* (bleeding in the brain), *edema* (swelling), and increased intracranial pressure. Edema is a common component of TBI that occurs when disruption of the blood-brain barrier allows fluid to leak into the brain, or cellular swelling follows cell membrane damage and ion transport dysfunction. Edema increases intracranial pressure and can result in further damage to brain tissue. If intracranial pressure continues to increase, it leads to compression of the brain tissue and eventual herniation of tissue through the brain stem, resulting in death. In addition to edema any new lesion or mass that occupies space causes increased intracranial pressure after TBI, and if these masses continue to grow, permanent brain damage ensues.

OUTCOMES

Traumatic brain injury is broadly defined in terms of three categories of severity: mild, moderate, and severe, based on the Glasgow Coma Scale, a 15-point scale designed to measure the patient's ability to respond to environmental stimulus (visual, verbal, motor) after TBI. The degree of impairment depends on the extent of damage to critical brain areas. In the United States, approximately 80 percent of TBIs are mild, 10 percent are moderate, and 10 percent are severe. Outcome after TBI can vary widely depending on the locus and extent of damage, age and sex of the patient, prior medical conditions, socioeconomic and educational status, early treatment interventions, and subsequent extent of rehabilitation and medical therapy. An equally broad range of symptoms—loss of consciousness and coma, persistent vegetative state, seizures, disrupted motor functions, visual defects, dizziness, disordered language, executive functions and communication skills, lack of emotional control, diminished (or enhanced) sex drive, depression, changes in personality, inability to focus and loss of attention, and impaired memory, especially short-term processing of information—can occur in the successive stages after TBI.

There are currently no clinically effective treatments than can directly repair the damaged brain. Basic research in this area focuses either on developing drugs that can prevent swelling, necrosis, and apoptosis (neuroprotection), or on agents or physiological techniques that encourage intact nerve cells to grow new branches, or to increase or even change their activity to replace the neurons that have been lost (enhancing neuroplasticity). A third category of research, using stem cells or other genetically modified cells (glial cells) that are transplanted into the zone of injury, seeks to replace damaged cells with substitute neurons or other cells that can restore function.

In the current absence of treatments, symptoms can persist indefinitely, although there may be gradual amelioration that can sometimes be improved with rehabilitation therapy. Many patients diagnosed with mild TBI develop behavioral problems and symptoms that prevent them from returning fully to their preinjury lifestyles or work, and in about 30 percent of cases, they are accused of malingering, although this condition is not easy to verify. There is now accumulating evidence that even mild but repeated head injuries (e.g., those associated with sports such as boxing or football) occurring over time can result in cumulative impairments that can be very disabling or even fatal.

According to the Centers for Disease Control, each year in the United States, 1.5 million people sustain some form of TBI—8 times the number of people diagnosed with breast cancer and 34 times the number of new cases of HIV/AIDS. TBI is the leading cause of death in males aged younger than 35 years. Fifty thousand people die from TBI each year, and these account for one-third of all injury-related deaths. Eighty to ninety thousand people each year "will experience the onset of long-term or lifelong disability associated with TBI" (Thurman et al. 1999:612). TBI is a leading cause of death and disability in people aged older than 75 years, mostly from falls and related accidents.

TRAVEL

Travel can narrow or widen gaps among people with disabilities (PWDs) and gaps between disabled and nondisabled people. As with the political, economic, and social development that often fosters it, travel can (but sometimes does not) create an egalitarian civil society. For many of the world's PWDs, economic, social, and political factors compound structural barriers to travel. PWDs are tourists traveling for leisure, "hosts" for the tourist industry, migrant laborers, students in educational exchange, and travelers in search of refuge.

Travel has several definitions, with different implications for disabled people. A basic definition is in the *Cambridge English Dictionary:* "to make a journey, usually over a long distance." Especially in Commonwealth countries, reference to travelers is often to migrants who are excluded from many social services.

Many authors looking at globalization, disability, and travel examine the dualisms (e.g., rich and poor, urban and rural) affected by globalization. But for the most part, these analyses have looked at disability only tangentially. Since disability, travel, and globalization are inextricably linked, this is a shame.

LEISURE AND BUSINESS TRAVEL

On the upper side of the gap between the "haves" and "have-nots" among PWDs are most leisure and business travelers. Travel for leisure or business is most frequent and easiest in the United States, followed by Canada and Western Europe, and most infrequent and difficult in most of Asia and Africa.

Many books and organizations have emphasized the gains that disabled people receive from travel. In the United States, Jillian Magalaner's publication of a travel guide geared toward travelers with disabilities in 1994 (revised in a new edition by Fodor in 1996) was a landmark. The publications acknowledged the importance of legislation, especially the Americans with Disabilities Act (ADA) of 1990, in bringing about change, and acknowledged that laws worked most effectively when people held businesses accountable. In 2002, the American Automobile Association (AAA) published *Guides to Barrier-Free Travel* for New York City, Washington, DC, and other destinations.

Such publications indicate progress, but the need for them reflects the limited access for travelers. They also reflect extensive cooperation between individuals and groups designed to promote accessible travel by PWDs. The AAA publications, for instance, drew on "accessibility appraisers" that included for-profit and nonprofit entities such as Access-Able Travel Source in Colorado, Accessible San Diego, and a Canadian company, Beyond Ability International.

Travel for disabled people has had an impact in the travel industry. This is reflected in growth and development of organizations such as the Society for Accessible Tourism and Hospitality (SATH) and estimates such as one from a 1999 publication of the European Commission: "an unserved potential of 35 million overnight travelers and 630 million nights could be generated (p. 4). Globally, that potential is much greater.

The global travel industry may have negative effects on tourist destinations. High disability expectancy characterizes some parts of the tourist industry. Deborah McLaren (2003) observed that "the general health of people in tourist destinations is declining, and locals are the least likely to be able to afford treatment" (p. 82). She offers specifics, such as the rise of HIV/AIDS in Thailand. Global travel and urbanization affects both the scope and the nature of disability.

TRANSPORTATION

Air, rail, cruise ship, and highway travel are all impacted by disability. In each, there have been many standards and aspirations for disability access but fewer enforceable rules.

In the United States, air carriers are regulated under the Air Carriers Access Act (ACAA). The ACAA's adoption in 1986 was unevenly implemented, however, and was aided by Department of Transportation's rule-making regarding matters such as service animals, boarding, and seating. That major problems remained was evident in a 1999 report of the U.S. National Council on Disability. In 2000, the ACAA's provisions were extended to foreign carriers landing in the United States. Writing in 2002, Curtis Edmonds suggested the need for a private right of action, allowing for individual lawsuits to bring about the promise of the ACAA.

Cruise lines attract many PWDs. Plaintiffs hoping that a U.S. court would order imposition of ADA standards on foreign-flagged cruise ships were ultimately successful. In *Spector v. Norwegian Cruise Lines,* the appellate court reversed a district court ruling where people faced barriers making access to services and evacuation equipment difficult or impossible. The ship flew the Bahamian flag, so the cruise line argued that it was not bound to comply with the ADA. Then, on June 6, 2005, the U.S. Supreme Court reversed the appellate court's decision and sided with the plaintiffs in their argument that the ADA's guarantees of access were applicable.

The concept of universal design has been applied to transportation systems, with the design of bus, rail, and air facilities intended to accommodate everyone.

Accessible transportation solutions exist but often are not adopted by industries and public authorities alleging budgetary restraints.

LODGING

Bathrooms, signage, elevators, telephones, transportation, staff training, parking, and other factors may determine how accommodating a hotel or motel will be for travelers with disabilities.

In the United States, lodgings are "public accommodations" covered under Title III of the ADA. Through the Access Board, there are specific requirements that lodgings should meet. Some adaptations have been made voluntarily, and some of the requirements have been enforced through the courts and through settlement agreements. However, requirements such as choice of rooms (e.g., twin, double double, or suite) and access to public areas (e.g., breakfast room, patio) continue to be violated. So do simple and widely known requirements for service dog access and placement of furniture to accommodate travelers with mobility impairments. As evidenced by numerous guides, though, accessible lodging exists, and some establishments have made major improvements.

ACCESS TO RECREATION

As with lodging, many recreational sites are "public accommodations" and are covered by legislation such as the ADA. Technological developments, such as all-terrain wheelchairs, can make accessible recreational attractions that were not accessible before.

Travelers' access to recreation may be purchased at the expense of high rates of disability in the host community, which becomes a basis for discrimination. In Pakistan, Kenneth MacDonald found that local porters had increasingly short careers aiding outside mountaineers, often because of chronic disability.

TRAVEL FOR EDUCATION, CIVIC ENGAGEMENT, AND MEDICAL SERVICES

People may travel for study in boarding schools, educational exchanges, study trips, Elderhostels, or other programs. Travel may be within a country or to another country.

Protections for U.S. citizens studying abroad were litigated in *Bird v. Lewis and Clark College,* where the court held that the guarantees of the ADA did not extend to overseas travel programs of U.S. universities.

Travel may catalyze civic engagement. In Zimbabwe, Rosangela Berman Bieler (one of Jim Charlton's [2000] respondents) said that she got involved at her rehabilitation center because she "wanted to travel, do sports, and other social things" (p. 13). Often, travel and involvement are mutually reinforcing. Many travel programs deliberately promote foreign study as equal exchange, rather than as a reflection of global inequalities. They involve PWDs as participating students and in host countries.

People may travel in search of medical services. Differing laws and economic, social, and cultural factors mean that different drugs, services, and barriers to access to care exist in different places. "Suicide tourism" was reported in accounts of physician-assisted suicide—actual in Switzerland and the Netherlands, hypothetical in Oregon. In India, the lure of tourism induced several poor people to sell kidneys. Medicinal marijuana and pharmaceuticals are more available in some jurisdictions than in others. More travel by PWDs is the likely result.

REFUGEES, ASYLUM, MIGRATION, DISABLED PEOPLE, AND TRAVEL

Millions of people, many of them PWDs, travel because of political, social, or economic conditions that push them away from their homes and pull them voluntarily or involuntarily to new homes. Some of these people are disabled when they leave their old homes; more will become disabled because of conditions during and after their travel.

Refugees and Asylum

Disability may affect an individual's getting asylum or extended departure. To claim refugee status, a person needs to show "well founded fear of persecution" on account of group membership (Convention Relating to the Status of Refugees 1954). Membership in a racial or religious group is more often useful in claiming refugee status than membership in an "other social group" (Convention Relating to the Status of Refugees

1954), which Arlene Kanter and others have persuasively argued should be read as including PWDs. Immigration officials often disagree, however. Disability also influences claims to asylum, which governments often deny on economic grounds.

Nongovernmental organizations (NGOs) and governments distinguish “refugees” from “internally displaced people” according to whether their travel was across national boundaries. In each case, many previously nondisabled people become disabled through travel, and disabled people are disproportionately likely to bear the consequences of unequal access. In Cambodia, Danilo Delfin (another Charlton [2000] respondent) observed that “if you are disabled, you automatically have people after you” (p. 102). The government and Khmer Rouge would each assume that a PWD was the enemy.

Migration

Millions of people each year migrate, often for employment or to follow tradition. The Commission for Racial Equality (2004) in the United Kingdom recently bemoaned that the “last ‘respectable’ form of racism” (para. 4) was against Gypsies (Rom) and travelers. Consequences include a life expectancy of 11 years less than average, diminished access to education, and poorer access to health care, all issues that disproportionately impact PWDs.

Several observers have noted a significant connection between the classification of mental disability and the immigration or refugee experience. In addition to the impairments that accompany migration, professionals may attach the “disability” label to the range of reasons why immigrants might not “fit in.”

REGULATION OF TRAVEL

Many changes easing PWD travel result from pressure exerted by PWDs and allies in the disability rights movement. Kanter (2003a) described encouraging legislative developments as the “globalization of disability rights law.” A common focus is access to buildings and transportation, which sometimes (not always) includes explicit mention of PWDs’ right to travel.

National Governments

National governmental laws, such as the ADA in the United States, are mentioned above. Many countries have legislation acknowledging disability rights; in most cases, travel is indirectly implicated in provisions on transportation and access to public and, in some cases, private facilities.

The United Nations

Within the United Nations (UN), PWDs have participated in the development of rules, hoping to move them from aspiration to binding law. The 1982 World Programme of Action Concerning Disabled Persons included a section on recreation. It linked PWDs’ having equal opportunities for recreation to use of hotels, beaches, restaurants, travel agencies, holiday resorts, and other facilities.

In 1993, the UN General Assembly adopted the Standard Rules on the Equalization of Opportunities for Persons with Disabilities. The Rules are not compulsory but provide goals, including Rule 11 on Recreation and Sports. This Rule mandates that travel services and hotels should offer their services and opportunities to all.

Despite the lofty objectives agreed to by national governments, achievements do not match aspirations. Arlene Kanter (2003a) noted that “disability remains invisible and marginalized as a human rights issue, even among human rights organizations and NGO’s” (p. 266). With a Convention (treaty), parties would be legally bound to comply, and the public would be in a stronger position to pressure nonparties.

The Convention was the subject of a Mexican United Nations General Assembly resolution and ad hoc conferences on a “Comprehensive and Integral International Convention to Promote and Protect the Rights and Dignity of Persons with Disabilities.” Adoption of a Convention with provisions related to (although not necessarily explicitly mentioning) travel is probable; as with other human rights conventions, implementation will be uneven.

Regional Organizations

Regional organizations, especially the European Union and the Organization of American States (OAS), also are arenas where disability and travel are discussed. The first intergovernmental disability rights convention was a regional one, the Inter-American Convention on the Elimination of All Forms of Discrimination against Persons with Disabilities, adopted by the OAS in 1999. Parties agree to promote integration "by public authorities and/or private entities" and eliminate discrimination "gradually" in transportation, recreation, services, and other areas (Inter-American Convention 1999). Mexico and Costa Rica are among the countries bound by this treaty; Canada and the United States are not.

NONGOVERNMENTAL ORGANIZATIONS AND TRAVEL

Prominent NGOs include organizations devoted to the travel industry, seeking to entice PWD travelers; organizations promoting the well-being of displaced people, many of whom are PWDs; and organizations devoted to participation by disabled people in all sectors of life, including travel.

Society for Accessible Tourism and Hospitality

SATH was founded in 1976 as the Society for Advancement of Travel for the Handicapped. Its mission is "to raise awareness of the needs of all travelers with disabilities, remove physical and attitudinal barriers to free access and expand travel opportunities in the United States and abroad" (Society for Accessible Tourism and Hospitality n.d., para. 1). SATH members include PWD consumers, but the organization's primary appeal is to travel professionals.

Independent Living Institute

The Independent Living Institute (ILI) was founded in Sweden in 1993 as the Institute on Independent Living. Since its inception, the ILI has worked across borders in Europe and disseminated information worldwide. It deals with a full range of independent living issues. Some, such as personal assistance, are unrelated to travel. The ILI website has a useful Recreation & Travel heading in its online library, recently added a section on Study and Work Abroad for All, and has long had an international Vacation Home Exchange.

Mobility International USA

Mobility International USA (MIUSA) was cofounded in 1981 by Susan Sygall (currently the executive director) and Barbara Williams. Its programs and services include the National Clearinghouse on Disability and Exchange (NCDE); International Development and Disability; International Exchange and Leadership Development; and Loud, Proud and Passionate!—International Women with Disabilities Leadership and Networking Projects. It promotes travel as empowering, particularly for disabled women facing sexism and ableism. MIUSA promotes a central role for PWDs in the development process. Travel is both an effect of and part of that process.

Other Nongovernmental Organizations

Travel and PWDs are touched upon by many NGOs, including the International Organization for Migration and Disabled Peoples' International. Travel is central to the mission of other NGOs, such as Access Exchange International. Together they influence perceptions of the connection between disability and travel. As NGOs become stronger, more PWDs should be participating in travel for leisure or business and fewer because of the "push" and "pull" factors generated by economic inequality.

TREDGOLD, ALFRED F.

(1870–1952)

British physician and eugenicist

Alfred F. Tredgold was an influential writer and medical expert in the early decades of the twentieth century, both in Great Britain and—through his influential textbook—throughout the English-speaking world. His book, *Mental Deficiency (Amentia),* first published in 1908, went through some eight editions before Tredgold’s death in 1952, continuing to be revised by new editors through 1979.

In the Edwardian era in England, Tredgold was also a prominent eugenicist, writing and testifying on the social importance of dealing with the “problem of the feeble-minded” (Tredgold 1911) and arguing that “morbid heredity . . . is present in 80 percent of cases [of amentia]” (Tredgold 1908:38). During this period, Tredgold testified for the Royal Commission on the Care and Control of the Feeble-Minded and served as consulting physician to the Littleton Home for Defective Children and the National Association for Promoting the Welfare of the Feeble-Minded. Along with other British eugenicists of the era, Tredgold warned the government to act aggressively to counter the burgeoning birth rates of intellectually disabled mothers. Only through segregation and sterilization, Tredgold argued, could Britain successfully arrest the “manner in which feeble-mindedness is permeating the country and swamping the mental and moral vigour of the community” (Jackson 2000:140).

TROPICAL DISEASES

The nosological category of tropical diseases grew out of the colonial expansion of European nations and the United States at the end of the nineteenth century. In less than a hundred years, *tropical medicine* became a term increasingly devoid of meaning, as scientific research, deteriorating public health infrastructures, and rapid, large-scale human displacement (among other reasons) produced the identification of new vector-borne infections in temperate climates and the reemergence of others long gone. In addition, the largest proportion of diseases found today in tropical countries are not due to parasites or vector-borne agents but to globally distributed causes such as tuberculosis, HIV, and smoking, whose prevalence and severity are increased by the conjunction of poverty, hunger, and lack of medical care.

The list of infections with a primary locus of transmission in tropical areas is vast, so this entry will comment only on the most important causes of disability (short- or long-term incapacitation on a mass scale). Those selected by Murray and Lopez in their analysis of the global burden of disease include four diseases transmitted by the bite of a mosquito (malaria, dengue hemorrhagic fever, Japanese encephalitis, and lymphatic filariasis); four transmitted by other arthropods (onchocerciasis, trypanosomiasis, Chagas disease, and leishmaniasis); two acquired by contact with a contaminated environment—soil (intestinal nematode infections) or water with infected snails (schistosomiasis); one acquired through contact with contaminated secretions or by flies (trachoma); and leprosy, for which close, prolonged personal contact is the suspected mode of transmission. A succinct exposition of the natural history, preventive measures, and drug therapy for these diseases can be found elsewhere. In all of these diseases, treatment (if available) to cure the infection will partially or not at all reverse the long-term disability produced by the disease. In almost all of these diseases, the initial infection usually produces a short, undifferentiated febrile illness or may be asymptomatic. Only malaria, dengue, and Japanese encephalitis are likely to produce life-threatening syndromes on first infection, and the resulting long-term disability (other than the incapacitation due to malarial relapses) mostly depends on the severity of the initial episode and sequelae from shock or respiratory compromise. Among all these diseases, the major producers of days of illness and early death according to Murray and Lopez are malaria (by far the most common), filariasis, leishmaniasis, and intestinal nematodes, so they are considered in the short space allowed by this entry. It must be emphasized, though, that the true illness burden is underestimated because of the lack of local resources, even for data collection.

Malaria is caused by any of four protozoan *Plasmodium* species (*falciparum, malariae, ovale,* and *vivax*) and produces fever, chills, sweats, and headache for a week to a month or longer, with relapses at irregular intervals for years thereafter, unless the proper antibiotic is provided. Falciparum malaria may progress to jaundice, shock, renal and liver failure, encephalopathy, and coma, with case-fatality ratios of 10–40 percent if untreated. Cases of cerebral malaria may recover with significant neuromotor deficits.

In contrast, the severe manifestations of lymphatic filariasis are usually the result of repeated infections that are active for years. *Wuchereria bancrofti, Brugia malayi,* and *Brugia timori* larvae, transmitted by mosquitoes, lodge in the lymph tissue and the lungs and may produce paroxysmal nocturnal asthma, chronic lung disease, renal disease, arthritis, adenitis, lymphangitis, chyluria, and elephantiasis of the genitalia or limbs. Drug treatment clears most microfilariae from the blood but may not destroy all adult worms, so it must usually be repeated at yearly intervals. The principal goal in the treatment of these patients is to prevent secondary bacterial infections in areas swollen with lymph, which can be accomplished through good hygiene, prevention and cure of skin lesions, exercise, elevation of affected limbs, and wearing of appropriate shoes. Hydrocele (collection of fluid inside the scrotal sac) can be treated with surgery. A very useful guide for management of areas with lymph swelling (lymphedema) has been recently published (Dreyer et al. 2002).

Onchocerciasis (river blindness) is also produced by filarial worms (*Onchocerca volvulus*) but transmitted by the bite of infected *Simulium* (black) flies. The microfilariae migrate through the skin and produce a chronic systemic illness with skin edema and atrophy, subcutaneous or periosteal fibrous nodules, and, if they reach the eye, visual disturbances or blindness. The introduction of ivermectin for onchocerciasis in 1987 was a milestone of disease treatment in less developed countries because of the efficacy and safety of the drug and because the manufacturer (Merck) decided to donate it without charge. This gift provided the incentive for establishing community-based distribution networks in affected areas (even if they had no established public health systems), stimulated similar donations by other pharmaceutical companies, and is seen as an example of what could potentially be accomplished for AIDS therapy.

Leishmaniasis, caused by a number of species of the protozoan genus *Leishmania,* is transmitted by the bite of sandflies and produces cutaneous and mucosal lesions that may last weeks or months and then heal spontaneously, only to recur even years later with dissemination and nasopharyngeal tissue destruction. Visceral leishmaniasis (kala-azar), characterized by fever, diarrhea, abdominal pain, hepatosplenomegaly, pancytopenia, and progressive emaciation, is usually fatal within 3–20 months if untreated.

The principal intestinal nematode infections are hookworm disease (uncinariasis, by *Ancylostoma duodenale, Ancylostoma ceylanicum,* and *Necator americanus*), roundworm disease (*Ascaris lumbricoides*), and trichuriasis (*Trichuris trichiura*). Hookworm eggs passed with feces hatch in the ground. Larvae penetrate human skin (usually the bare feet) and migrate through lymphatics and blood to the lungs, up the trachea, and then down the esophagus to the small intestine, where they attach to the wall, feed off the patient's blood, and produce thousands of eggs each day. This process may result in pulmonary infiltrates, cough, and tracheitis, but the major cause of disability in heavy infections is iron deficiency, with hypochromic microcytic anemia, hypoproteinemia, and retarded mental and physical development of children. *Ascaris* and *Trichuris* are acquired by the ingestion of eggs through pica or contaminated vegetables. The larvae attach to the mucosa of the intestine, and heavy infections may produce bowel obstruction, bloody stools, diarrhea, nutritional deficiency, and growth retardation in children.

The principal specialized medical care required by the long-term sequelae of these "tropical" infections can be grouped as follows: neurological and physical rehabilitation for cerebral malaria, encephalitis due to dengue or Japanese encephalitis virus, lymphatic filariasis, and leprosy; skin care and reconstructive surgery for lymphatic filariasis, leprosy, leishmaniasis, and onchocerciasis; ophthalmologic treatment for onchocerciasis, trachoma, and leprosy; gastroenterological expertise in hepatic schistosomiasis and Chagasic megacolon; and cardiological, urological, and pulmonary care for Chagasic cardiomyopathy, urinary schistosomiasis, and filarial interstitial lung disease, respectively. Unfortunately, these services are required by populations with other highly endemic severe diseases, such as HIV, that have little access to education and medical attention and are also burdened by poverty and malnutrition.

TUBERCULOSIS

Tuberculosis is a communicable disease caused by a mycobacterium. Its most common form is pulmonary tuberculosis, what used to be called *consumption.* A chronic disease, tuberculosis was endemic in Western countries until the post–World War II period. It is now endemic in developing countries, with the World Health Organization declaring a global emergency in 1992. Without antibiotic treatment, in the past in the West, and currently elsewhere, individuals have been disabled for many years by this long-term illness. In countries such as Germany, the United Kingdom, and Australia, the massive problem of tuberculosis prompted some of the earliest experiments in government welfare in the late nineteenth and early twentieth centuries. These early disability allowances, insurance programs, and pensions were often the basis on which later sickness, welfare, and disability support programs developed.

Tuberculosis has not always been understood as a communicable disease. In the nineteenth century and earlier, it was sometimes thought to be hereditary and at other times thought to be an effect of environment or constitutional weakness or a combination of these factors. Indeed, although the tuberculosis pathogen was identified by Robert Koch in 1882, the question "Is consumption contagious?" continued to be asked well into the twentieth century. In Victorian literature and visual culture, the aestheticized, chronically weak and bed-ridden consumptive was a stock figure. Partly but not wholly as a response to the identification of the causative organism, comprehension of the disease shifted from this individualized understanding to being an issue of public health. It became a disease associated with poverty and urbanization, disproportionately affecting minority groups, especially in cities.

Toward the end of the nineteenth century, a therapeutic regimen known as "open-air treatment" was developed. Typically, this involved several months' stay in an isolated institutional environment. The first British institutions opened in Edinburgh in 1889, modelled on German private institutions for open-air treatment. In the United States, similar institutions began about 1884. There was a phenomenal proliferation of tuberculosis sanatoria over the next few decades and well into the interwar period. Still understood within climatic theories of health and ill health, sanatoria for open-air treatment of tuberculosis were often built in carefully selected rural, mountain, or seaside locations. Following the basic principle that fresh air was itself curative, people were enjoined to undertake as much of their daily activity as possible outside: school, rest, sleep, exercise. At the height of its popularity, sanatorium treatment involved a radical, sometimes coerced and tightly controlled regimen of rest and incremental exercise. A person might be brought to the sanatorium and forced into total bedrest and, in some systems, total silence. Gradually, and sometimes over a period of six months, the patient was permitted to sit, move, and exercise in controlled ways, from small walks, to inclines, to long walks. Progress was measured by the person's temperature at specified times during the day, by appetite, and by capacity for exercise.

The idea of open-air treatment was to control rather than to cure the disease, but in doing so, the therapy temporarily "disabled" patients sometimes more than the disease itself. The major twentieth-century sociologist Erving Goffman's classic study on segregation and institutionalization, *Asylum,* was based on his time and observations in a tuberculosis sanatorium. The nature of these sanatoria ranged from versions of health resorts to versions of government workhouses, according to the social position of patients, usually depending on their class or race. The correlation of tuberculosis with urbanization and poverty meant that many indigent people were disabled by the disease and were institutionalized in sanatoria. In these instances, the tuberculosis sanatorium was also a place of detention, of unwilling institutionalization and segregation. In the United States, there is a particular history of the institutionalization of indigent African Americans on the grounds of their infection with tuberculosis.

Tuberculosis is arguably the most significant illness in the history of the development of welfare and health insurance programs over the twentieth century. At a population level, tuberculosis mattered greatly, because it typically disabled men and women in the middle years of life; it was not usually a disease of old age. Thus, as was noted over and over again until the antibiotic era, tuberculosis struck men and women in their "prime" productive and reproductive years. These people were usually, though not always, chronically disabled. This made the disease an economically significant one and prompted major new experiments in welfare, insurance, and disability allowance programs.

Because tuberculosis was so endemic in Western countries, the idea and sometimes the legal concept of disability itself were constructed specifically in relation to it. In Germany, novel programs for work-related insurance were developed in the late nineteenth century. In the United Kingdom in the early twentieth century, governments took financial responsibility for treatment of this disease in an unprecedented way. Often, "disability," and therefore eligibility for a pension, free treatment, or insurance payment, was determined by a person's capacity or incapacity to work. To qualify for the invalid pension in Australia, for example, an individual had to be deemed "totally and permanently incapacitated": disabled and, as it was then seen, unfit for work. These employment-oriented systems of insurance and welfare were problematically devised around the idea of a male breadwinner and a female dependent.

Over the twentieth century, the treatment for tuberculosis changed dramatically. Following the principle of rest to arrest the disease, physicians in the 1930s and 1940s sometimes surgically collapsed one lung for long periods. From late 1940s, chemotherapy began to replace previous therapies, dramatically changing the incidence of the disease in countries where the drugs were available: streptomycin in the 1940s, isoniazid and para-aminosalicylic acid (PAS) in the early 1950s, and rifampicin from the late 1960s. Once considered powerful enough to eradicate tuberculosis, chemotherapies have proven effective for populations with access to them. However, for nations and subpopulations without access to antibiotics, the tuberculosis problem escalates. This has been compounded by the emergence of multidrug-resistant strains. In countries such as Russia, the problem of coinfection with HIV and multidrug-resistant tuberculosis is an extremely serious one. Elsewhere, the issue of tuberculosis and global migration have become intertwined: For many nations, a central aspect of global movement and border control has been the strict screening of migrants, asylum seekers, and travelers for tuberculosis.

TUBMAN, ARAMINTA ROSS (HARRIET) (1820–1913)

American abolitionist

Born into slavery in Dorchester County, Maryland, Harriet was said to be of purely African ancestry. Raised under harsh conditions, she was subjected to whippings and heavy labor at an early age. At the age of 12, a blow to the head by her master resulted in constant blackouts and periods of narcolepsy throughout her lifetime. At the age of 25, she married John Tubman, a free black man, but when her master's slaves were put up for sale five years later, she escaped, and, with the help of white antislavery sympathizers, Harriet made her way to Philadelphia. There, she became acquainted with William Still, founder and Philadelphia stationmaster of the Underground Railroad. With the assistance of Still and other members of the Philadelphia Anti-Slavery Society, she learned about the workings of the Underground Railroad. She remained in Philadelphia for two years, working and saving money to return to Maryland for her husband, but when she reached him, she found that he had taken another wife and had no interest in returning north. At this juncture, Harriet dedicated herself to a life as a "conductor" on the Underground Railroad.

As the "Black Moses," Tubman "delivered" 300 slaves safely to the Free States or to Canada. Every time she traveled south, the dangers increased. This was partially due to her habit of falling into deep sleep-like states during the journey. Throughout her life, Tubman was subject to periods of seizures and periods of falling into a deep sleep. The slaves (and later soldiers) who traveled with her to freedom came to understand and expect that behavior. It was even rumored that during those sleeplike periods, she was receiving messages from God as to which route was the safest to lead her charges. In 1860, being too well-known and constantly hunted by slave catchers, she went into the South for the last time to bring back slaves.

During the Civil War, Tubman was a soldier, a spy, and a nurse, serving for a time at Fortress Monroe, which would later become the prison of Jefferson Davis. She slipped through enemy lines to bring back valuable information to the Union Army. She led soldiers through the Southern lines, bringing them back as safely as the slaves she had once led to freedom. While guiding a group of black soldiers through South Carolina, Tubman met Nelson Davis, who she would marry after the Civil War. The couple moved to Auburn, New York, where Tubman stayed active in support of the women's rights movement.

In 1908, Harriet Tubman built a house for the aged. It was there that she worked and was cared for in the years before her death in 1913. After her death, she was buried in Fort Hill Cemetery in Auburn, with military honors. She has since received many honors. On June 14, 1914, a large bronze plaque was placed at the Cayuga County Courthouse, and a civic holiday was declared in her honor. Freedom Park, a tribute to the memory of Harriet Tubman, opened in the summer of 1994 at 17 North Street in Auburn, and in 1995, the U.S. Post Office honored Harriet Tubman with a commemorative stamp. Tubman is widely remembered as a trusted spy, "conductor," and activist in the abolition and woman's rights movements.

U

▣ "UGLY LAWS"

In May 1881, the Chicago City Council enacted the first American "ugly law" forbidding "any person, who is diseased, maimed, mutilated or deformed in any way, so as to be an unsightly or disgusting object, to expose himself to public view." National networks of ministers, charity organizers, city planners, and municipal officials followed Chicago's ordinance with efforts to enact similar laws elsewhere: in Denver and Lincoln in 1889, in Columbus in 1894, in New York (unsuccessfully) in 1895, and in the entire state of Pennsylvania in 1891. The ordinance, wrote one Chicago reporter, would stamp its author, Alderman Peevey, as a public benefactor: "He proposes to abolish . . . the woman with two sick children who was drawn through the carding-machine in a woolen mill and who grinds 'Mollie Darling' incessantly on a hurdy-gurdy on a street corner." Remembering the woman who played "Mollie Darling," contemporary disability activists cite the extremity of "ugly law" as a signal reminder of the sometimes less obvious but still persistent forms of disability oppression today.

Most of these citations derive from a single and partly misleading paragraph in a landmark work of legal scholarship, Marcia Pearce Burgdorf and Robert Burgdorf Jr.'s "A History of Unequal Treatment: The Qualifications of Handicapped Persons as a 'Suspect Class' under the Equal Protection Clause," published in 1975. The Burgdorfs coined the phrase "ugly law" and placed it in "Chicago 1911," the date and place most commonly used when people quote it now. "Ugly," it should be noted, appears nowhere in the wording of the actual ordinances. "Unsightly beggar" ordinance is more accurate historically, since some of these laws, though not all, appear under that heading in the code books. Inventing "ugly" law, the Burgdorfs performed an act of advocacy probably inspired by the title of a newspaper article they footnoted concerning the last known arrest (in Omaha in 1974), "Begging Law Punishes Only the Ugly."

Unsightly beggar laws were enforced unevenly and perhaps rarely, as historian Brad Byrom has argued. Nonetheless, they had both concrete and chilling effects. A 1916 report by the "Committee on Cripples of the Welfare Federation of Cleveland" records the story of an unnamed man who sold newspapers until "the enforcement of a statute which prevented cripples from exposing their deformity by selling on street corners abolished [his] job. . . . Although it seemed rather hard," the Cleveland Cripple Survey reports, "he appreciated the meaning of it, but considered it ill-advised unless some step went with it for providing other opportunity for work for cripples." Understanding the meaning that this man, in his guarded, strategic protest, is said to appreciate requires placing the "ugly laws" within a complex set of vectors. These include the "tramp scare" and fears of vagrancy; the influence of the charity organization movement; new conditions of visibility in modern urbanity; labor unrest; social Darwinist theories and the rise of eugenics; and, not least, the concurrent development of institutions for the blind, deaf, feebleminded, and generally "dependent and defective classes."

UNION OF THE PHYSICALLY IMPAIRED AGAINST SEGREGATION (UPIAS)

The initiative to form the Union of the Physically Impaired against Segregation (UPIAS) was taken by Paul Hunt in 1972 when he called for a consumer group to promote the views of actual and potential residents of institutional homes for disabled people in the United Kingdom. The aim was to formulate and publicize plans for alternative forms of support in the community.

Exploring what support was needed to enable the most severely impaired people to live in the community encouraged UPIAS to completely rethink the prevailing interpretation of *disability*. In 1974, UPIAS published its detailed policies. This proposed the examination of "ways of *changing our conditions of life*, and thus *overcoming* the disabilities which are imposed on top of our physical impairments by the way this society is organised to exclude us."

This interpretation of *disability* was taken a step further in 1975 when it published "Fundamental Principles of Disability" and set out its radical definitions:

> *Impairment*—lacking part of or all of a limb, or having a defective limb, organ or mechanism of the body.
>
> *Disability*—the disadvantage or restriction of activity caused by a contemporary social organisation which takes no or little account of people who have physical impairments and thus excludes them from participation in the mainstream of social activities.

This interpretation of *disability* came to be known as the social model of disability. It radically transformed the way disabled people came to see themselves and their place in society.

UNITED NATIONS

The United Nations was established on October 24, 1945, by 51 countries. Today, UN membership totals 191 countries. The United Nations has four purposes: to maintain international peace and security; to develop friendly relations among nations; to cooperate in solving international problems and in promoting respect for human rights; and to be a center for harmonizing the actions of nations for peace and development based on the fundamental principles of human rights for justice, human dignity, and well-being of all people. The United Nations affords the opportunity for countries to balance global interdependence and national interests when addressing international problems to pursue these goals. The current 191 members of the United Nations meet in the General Assembly, the highest decision-making organ within the UN system, in which each country, large or small, rich or poor, has a vote and voice in this process; however, the decisions taken by the assembly are not legally binding. There are six main organs of the United Nations: the General Assembly, the Security Council, the Economic and Social Council, the Trusteeship Council, the Secretariat, and the International Court of Justice (The Hague in the Netherlands). Six official languages are used at the United Nations: Arabic, Chinese, English, French, Russian, and Spanish.

The UN global Programme on Disability is the lead program concerning disability—the focal point within the UN system. It is housed in the Division for Social Policy and Development at the Department of Economic and Social Affairs of the UN Secretariat. The mandate of the UN global Programme on Disability emanates from the 1982 World Programme of Action Concerning Disabled Persons and the 1993 Standard Rules on the Equalization of Opportunities for Persons with Disabilities as well as other relevant international instruments, such as the UN Charter, the Universal Declaration of Human Rights (UDHR), the International Covenant on Civil and Political Rights, and the International Covenant on Economic, Social and Cultural Rights.

The major objectives of the World Programme are (1) to support the full and effective participation of persons with disabilities in social life and development, (2) to advance the rights and protect the dignity of persons with disabilities, and (3) to promote equal access to employment, education, information, goods, and services. Since 2001, the UN global Programme on Disability also serves as the substantive secretariat for the General Assembly Ad Hoc Committee on a comprehensive and integral international convention to promote and protect the rights and dignity of persons with disabilities.

In its early period, the United Nations focused on improvement of the well-being of persons with disabilities to meet their needs in the social context.

In the 1960s, initiatives within the disability community and adoption by the United Nations of the international human rights conventions both in civil and political and economic, social, and cultural realms resulted in a fundamental reevaluation of the rights of persons with disabilities within the context of development. In the 1970s, the evolution of thinking on disability issues at the United Nations resulted in a number of initiatives embracing the growing international concept of human rights of persons with disabilities and equalization of opportunities for them. These include the 1971 Declaration on the Rights of Mentally Retarded Persons and the 1975 Declaration on the Rights of Disabled Persons.

These efforts were intensified within the framework of the UN Decade of Disabled Persons (1983–1992). A major outcome of the International Year of Disabled Persons, which preceded the Decade of Disabled Persons, was the World Programme of Action Concerning Disabled Persons, the most comprehensive global strategy, which took "equalization of opportunities" as its guiding principle. The Standard Rules, a major outcome of the Decade of Disabled Persons, provide an instrument for policy making and a basis for technical and economic cooperation. The international frameworks to promote the rights of persons with disabilities were further advanced by a series of 1990s UN development conferences and their respective five-year reviews, such as the 1993 Vienna Declaration and Programme of Action for human rights, the 1995 Copenhagen Declaration and Programme of Action for social development, the 1995 Beijing Declaration and Platform for Action, the Millennium Development Goals, and other relevant international commitments.

To implement the World Programme and the Standard Rules, the United Nations' global comparative studies suggest that disability is a quintessential cross-cutting development issue. The international community is witnessing a significant expansion of constituencies concerned with disability and the situation of persons with disabilities. In part, this can be attributed to the aging of the world's populations and the increased number of persons surviving diseases or conflicts with a disability. Disability issues and the situation of persons with disabilities within the context of overall national development need to be addressed. Examining these issues contributes to a growing awareness of universal design concepts globally and to recognition of the importance of incorporating universal design principles in international policies and programs for social infrastructure, social services, and promotion and development of accessible environments and institutions. While universal approaches to policy design and program planning represent a somewhat new trend, they reflect the concern of the United Nations not only with social and economic development but also with fundamental human rights.

While the means chosen to promote full realization of economic, social, and cultural rights of persons with disabilities will differ from one country to another, there is no country in which a major policy or program effort is not required. The commitment of member states to realization of the fundamental human rights of all persons would require governments to take all possible measures to make further progress in protection and promotion of the rights of persons with disabilities.

More recently, the initiative on a comprehensive and integral convention to promote and protect the rights of disabled persons resulted from a proposal made by Mexico during the 56th session of the UN General Assembly, which called on the international community to combat poverty and social exclusion. The importance was highlighted to involve all citizens as stakeholders and that a just world must be inclusive of all groups. For that reason, Mexico proposed the establishment of a special committee to study the elaboration of an international convention on promoting the rights and dignity of persons with disabilities, which was endorsed by General Assembly resolution 56/168.

The Ad Hoc Committee of the General Assembly on a comprehensive and integral convention on the rights of persons with disabilities was established in 2001 by assembly resolution 56/168. It was established in the context of addressing poverty and promoting social integration so as to create just and equitable societies based on participation of all citizens as stakeholders. The elaboration of a convention and its future adoption and implementation are expected to provide for a normative basis not only for implementation of the rights of persons with disabilities within the existing legal frameworks but also for formulating strategic options for policies and programs and evaluating measures to promote full and equal participation of persons with disabilities in society and development. National, regional, and international consultations concerning the potential convention are resulting in the emergence of new disability- sensitive networks of policy makers, program specialists, academics, and advocates.

UNITED NATIONS DECLARATION ON THE RIGHTS OF DISABLED PERSONS

In December 1975, the United Nations (UN) General Assembly adopted the Declaration on the Rights of Disabled Persons, which states that all persons with disabilities have the same rights as other persons. Provisions of the declaration include (1) defining a “disabled person” as anyone who cannot ensure the necessities of a normal individual and/or social life, as a result of a deficiency in physical or mental capabilities; (2) a nondiscrimination clause applying the rights to all disabled persons regardless of race, color, sex, language, religion, political or other opinions, national or social origin, state of wealth, or birth situation; (3) a right to respect for human dignity; (4) civil and political rights; (5) the right to measures to enable self-reliance; (6) the right to medical, psychological, and functional treatment; (7) the right to economic and social security and to a decent level of living and, according to capability, to employment; (8) the right to have their special needs taken into consideration at all stages of economic and social planning; (9) the right to live with family and to participate in all social, creative, or recreational activities; (10) the right to be protected against all exploitation/discrimination/abuse/degradation; (11) the right to qualified legal aid; (12) a clause stipulating that organizations of disabled persons may be consulted regarding the rights; and (13) a clause urging that persons with disabilities, their families, and communities be fully informed of the rights contained in the declaration. This act culminated the beginning of a new conceptual approach to disability issues as human rights issues.

Prior to 1970, the United Nations approached disability issues from a social welfare perspective. Little attention was paid to obstacles created by social institutions and society in general. The late 1960s became a time for reevaluation. In 1969, the General Assembly adopted the Declaration on Social Progress and Development, which, in Article 19, advocated the provision of health, social security, and social welfare services for all persons, including the provision of measures to rehabilitate the mentally and physically disabled to facilitate their integration into society. Education, vocational/social guidance, and job training and placement provisions were included. On December 20, 1971, the General Assembly proclaimed the Declaration on the Rights of Mentally Retarded Persons, which stated that the mentally retarded person has, to the maximum degree of feasibility, the same rights as other human beings, a right to proper medical care and education, to economic security, to a qualified guardian if required, to protection from exploitation, and to legal procedures. The declaration stressed that mentally retarded persons should live with their families and participate in the community. These declarations led up to the movement to create the Declaration on the Rights of Disabled Persons, which, in some sense, represents an attempt to delineate that the 1948 UN Declaration of Human Rights clearly applies to persons with disabilities.

Though nonbinding, the declaration led to several subsequent UN initiatives, such as the UN Year of Disabled Persons, the World Programme of Action Concerning Disabled Persons, the UN Decade on Disability, and the Standard Rules on the Equalization of Opportunities for Persons with Disabilities. These initiatives have comprised policies specifically to address the situation of persons with disabilities.

A parallel movement has occurred related to the incorporation of disability issues in UN policy initiatives designed to address the needs of all persons. For instance, in 1993, the World Conference on Human Rights in Vienna reconsidered universally recognized human rights issues and produced the Vienna Declaration and Programme of Action to guide human rights efforts. The conference declared that all human rights and fundamental freedoms are universal, and, hence, people with disabilities have these rights. Thus, any discrimination, intentional or unintentional against persons with disabilities, is viewed per se as a violation of human rights.

Since this declaration, the UN system has monitored the incorporation of disability issues into broader human rights initiatives. In 1998, the UN Commission on Human Rights adopted resolution 1998/31, which clearly recognizes that any violation of the fundamental principle of equality or any other discrimination or other negative differential treatment of persons with disabilities inconsistent with the United Nations Standard Rules is an infringement of the human rights of persons with disabilities. It encouraged all human rights treaty- monitoring bodies to monitor the compliance of nation-states with their commitments under human rights instruments to ensure the rights of persons with disabilities. Though expectations from this resolution were high, concerns were present when the commission met two years later. As a result, the commission adopted another resolution asking the UN High Commissioner for Human Rights to examine measures to strengthen the protection and monitoring of the human rights of persons with disabilities.

The incorporation of disability-specific policies within broader human rights instruments, combined with instruments specifically targeting persons with disabilities, has led to the creation of the UN Ad Hoc Committee to consider a Convention on the Rights of Disabled Persons. This represents a movement toward a legally binding human rights instrument for states that ratify it, as opposed to the Declaration on the Rights of Disabled Persons, which was not legally binding.

Nevertheless, the movement toward such a convention can be attributed in part to the original declaration.

UNITED NATIONS DISABILITY CONVENTION

Human rights are basic rights to which every human being is entitled irrespective of age, merit, sex, race, disability, or any other status. Human rights cannot be given or taken away by governments or other entities. They cannot be gained through status or merit nor can they be lost through "inhuman," "deviant," or criminal behavior. Human rights contain the moral values on which modern societies that believe in peace are founded. This is why we often find them in the constitution or some other fundamental legal source of a country. While the history of human rights is much longer, the most affluent period of human rights policy and law began after World War II with the establishment of the United Nations (UN). Human rights are one of the core values mentioned in the Charter of the United Nations and are the topic of one of the first legal instruments adopted by the United Nations, the Universal Declaration of Human Rights of 1948.

The development of UN human rights policy and law is a direct answer to the atrocities of German national socialism during World War II. Since disabled persons were one of the groups victimized by Nazi elimination programs, human rights are an important subject to disability for historical reasons. However, during the first three decades of international human rights law and policy disabled persons were invisible citizens. None of the core UN human rights instruments that were adopted during this time address the situation of disabled persons. Despite the fact that more than 600 million people, or approximately 10 percent of the world's population, have a disability, UN human rights discourse neglected and ignored persons with disabilities. Vice versa, in disability policy human rights were not an issue for a long time. Disability was treated as an issue of medical rehabilitation and welfare policy, issues that also were not regarded as human rights issues during the first decades. Similarly, it was ignored that two-thirds of disabled persons live in developing countries and that the link between poverty and disability is direct and strong. And while many disabled persons live in institutions under conditions that are overt examples of cruel, inhuman, and degrading treatment, they were not seen as victims of human rights violations but as victims of their own personal tragedy caused by their impairments. Neither was the situation of disabled women, who are at a much higher risk of sexual violence and exploitation, dealt with in a human rights context.

A dramatic shift in perspective has taken place over the past two decades from an approach motivated by charity toward the disabled to one based on rights. This shift can be described as a paradigm shift from the medical/individual model of disability to a human rights model. Thus, the issue of human rights has become important to the subject of disability rather recently as a milestone of perspective change. In essence, it means viewing disabled persons not as objects but as subjects. It entails moving away from seeing disabled persons as problems to viewing them as right holders. Importantly, it means locating problems outside the disabled person and looking at the manner in which economic, social, civil, and political processes are structured and whether they accommodate differences, such as disability. With the paradigm shift, a whole set of values that have not yet been applied to disability policy and law become available. Those are the values that underpin human rights: the inestimable dignity of each and every human being, the concept of autonomy and self-determination that demands that the person be placed at the center of all decisions affecting him or her, the inherent equality of all regardless of difference, and the concept of solidarity that requires society to sustain freedom of the person with appropriate social supports.

The shift from a medical/individual model of disability to a human rights perspective is a slow process, but it takes place at every level of modern society. The human rights model of disability has been authoritatively endorsed at the level of the United Nations over the past two decades. The process has led to the current drafting process of a UN treaty on human rights of persons with disabilities. Governments are clearly moving in the direction of the human rights perspective on disability. Recent research shows that more than 40 nation-states in all regions of the world have adopted nondiscrimination or equal opportunity legislation for their disabled citizens. National institutions for the promotion and protection of human rights in many countries take an active interest in disability issues. This helps to bridge the international human rights debate on disability to domestic discourses on disability law and policy reform. Finally, civil society is taking part in the change process. Disability organizations at international and national levels have come to characterize themselves as human rights organizations and have started to use human rights law and human rights mechanisms to foster their cause. Within a short time, disability organizations have become experts in the field, presenting hard facts on human rights violations against disabled persons all over the world, monitoring projects, and becoming actively involved in the drafting process. Disability organizations also have started to involve nongovernmental organizations (NGOs), which are mainstream human rights organizations that have in the past neglected disabled persons.

New human rights laws for disabled persons have emerged at the national as well as at the supranational and international levels. Today, we have binding and nonbinding instruments of international human rights explicitly for disabled persons that have been adopted by the General Assembly of the United Nations as well as by some of the specialized UN organizations, notable among them the International Labour Organization. At the regional level, the Organization of American States (OAS) and the European Union (EU) have passed strong equality legislation on disability. The OAS is the first intergovernmental organization that has a binding human rights treaty on disability. In 1999, the Inter-American Convention on the Elimination of All Forms of Discrimination Against Persons with Disabilities (IACPWD) was adopted.

Most of these human rights laws on disability have been adopted during the past two decades. Developments within the main bodies of the United Nations had a strong impact. These started with two resolutions adopted by the General Assembly in the 1970s. These were the 1971 Declaration on the Rights of Mentally Retarded Persons and the 1975 Declaration on the Rights of Disabled Persons. They are the first signs of a shift from a “caring” to a “rights-based” approach. The International Year of Disabled Persons (1981) was followed by the Decade of Disabled Persons (1983–1992), and the guiding policy instrument was the landmark World Programme of Action Concerning Disabled Persons (WPA), adopted in 1982 by the General Assembly. While the first two aims of the WPA reflect a more traditional approach to disability in that they focus on rehabilitation and prevention, the third aim—“equalization of opportunities”—is sign of a slow but sure shift to a human rights–based approach. The WPA has been prolonged and is still the guiding policy instrument on disability within the United Nations today. It is reviewed every five years (1987, 1992, 1997, 2002). The next review is due in 2007. During the Decade of Disabled Persons, two significant studies on human rights and disability were carried out under the auspice of the UN Commission on Human Rights and its subcommission. The first was a report prepared by Erica-Irene A. Daes, who was appointed special rapporteur by the Sub-Commission on Prevention of Discrimination and Protection of Minorities. It was titled *Principles, Guidelines and Guarantees for the Protection of Persons Detained on Grounds of Mental Ill-Health or Suffering from Mental Disorder* (1986). The report led to a 1991 resolution titled *Principles for the Protection of Persons with Mental Illness and the Improvement of Mental Health Care*. These principles have been hailed as a new departure in the perception of the role of law in this area. In recent years, however, this instrument has been criticized by some NGOs.

The second report was prepared by Leandro Despouy, who was also appointed a special rapporteur by the subcommission in 1984. His thoughtful and comprehensive report was titled *Human Rights and Disabled Persons* (1993). The Despouy report chronicles widespread human rights abuses in the area of disability and cites a number of such abuses as causes of disability.

The UN Disability Decade also led to the first efforts to adopt a human rights convention on disability. Such a recommendation was made by a global experts meeting in Stockholm in 1987, which had the mandate to review the WPA. Similarly, the Despouy report emphasized the need for a convention in order to put disabled persons on an equal footing with women, children, or migrant workers. Unlike these groups, who have their own thematic convention, disabled persons were left with what is called soft law. Unlike conventions, which are binding treaties to those member states that have signed and ratified them, declarations and resolutions adopted by the General Assembly have no binding legal effect.

Following these recommendations, Italy in 1987 and Sweden in 1989 proposed the drafting of a convention to the General Assembly, but did not succeed. As an alternative, a different kind of instrument was adopted by the General Assembly. The 1993 Standard Rules on the Equalization of Opportunities for Persons with Disabilities (StRE) are unbinding soft law, but they have become the guiding principles for disability policy within the United Nations and its member states. They mark a clear shift from the rehabilitation and prevention paradigm to the human rights perspective on disability. Unlike the aforementioned instruments, the StRE have their own monitoring mechanism. A special rapporteur who is supported by a panel of experts, composed of representatives of the main international disability organizations, is assigned the task of monitoring implementation of the StRE. The special rapporteur reports to the Commission on Social Development. The first special rapporteur of the StRE was a disabled person. Bengt Lindqvist of Sweden held office from 1994 to 2002. In 2003, Sheika Hissa K.A. Al-Thani from Qatar was appointed second special rapporteur.

With respect to hard human rights law, disability has been an issue to some extent during the past decade. There are currently seven human rights treaties, which also apply to disabled persons. The two core treaties are the International Covenant on Civil and Political Rights (ICCPR) and the International Covenant on Economic, Social and Cultural Rights (ICESCR), both of which were adopted in 1966. Another treaty, adopted in 1984, deals with torture, the Convention against Torture and Other Forms of Cruel, Inhuman or Degrading Treatment and Punishment, whereas the other four treaties deal with specific groups: the 1965 Convention on the Elimination of All Forms of Racial Discrimination (CERD), the 1979 Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), the 1989 Convention on the Rights of the Child (CRC), and the 1990 International Convention on the Protection of the Rights of All Migrant Workers and Members of Their Families (CMW). While only the CRC addresses disabled children in the text of the treaty, some of these treaties have been officially interpreted with respect to disabled persons. Such an official interpretation takes place when "General Comments" or "General Recommendations" to these treaties are adopted by their monitoring bodies. Thus, the Committee on CESCR adopted in 1994 General Comment No. 5 on disabled persons. Similarly, the CEDAW Committee mentioned disabled women in two of its general recommendations.

Despite these efforts to include disability into the monitoring process of hard human rights law, disabled persons have remained marginalized. The study *Human Rights and Disability: The Current Use and Future Potential of United Nations Human Rights Instruments in the Context of Disability* (Degener and

Quinn 2002a) has shown that treaty-monitoring bodies do not have the resources or the expertise to deal with disability comprehensively and on a general basis. The study, which was commissioned by the High Commissioner for Human Rights, entails a number of recommendations on how to improve the current human rights system with respect to disability. In addition, the need for a new disability rights convention is emphasized.

The idea of a thematic convention has been taken up by many NGOs in recent years again. On the initiative of Mexico, the issue was put on the General Assembly agenda again in 2001. GA Resolution 56/168 of December 19, 2001, established an Ad Hoc Committee

> to consider proposals for a comprehensive and integral international convention to promote and protect the rights and dignity of persons with disabilities, based on the holistic approach in the work done in the fields of social development, human rights and non-discrimination.

The Ad Hoc Committee, which is open to all UN member states and observers, met twice (2002 and 2003) before it established a working group with the aim of preparing a draft text of a convention, which would be the basis for negotiation by the Ad Hoc Committee. The working group would take into account all previous contributions submitted to the Ad Hoc Committee by states; observers; regional meetings; relevant UN bodies, entities, and agencies; regional commissions and intergovernmental organizations; and civil society including NGOs, national disability and human rights institutions, and independent experts. The working group met in January 2004 for 10 working days and was composed of representatives of 27 member states, 12 NGOs, and 1 National Institute on Human Rights. For the first time in the history of UN law, NGOs had an equal status to member states in the drafting process of a treaty.

The drafting process revealed many yet unresolved issues that have to be negotiated by the member states in future Ad Hoc Committee meetings. How to define disability and disability-based discrimination are examples of these issues. Today, there is no universal definition of disability. The debate about the medical versus social model of disability has raised concern about medically oriented definitions. The well-known World Health Organization (WHO) definition of disability, the ICF (formerly ICIDH), is not seen as appropriate for a legal text by many experts.

The question on how to define disability-based discrimination is closely linked to the equality concept at stake. A more formal equality concept does not tackle all forms of discrimination, that is, not those caused by structural barriers. A more material equality concept would, however, include that governments need to actively take steps to build an inclusive society that accommodates differences. The key words are "reasonable accommodation" (or "effective adjustment").

Other controversial issues are whether the treaty should include third-generation rights (i.e., the right to development and the duty of international cooperation) or new human rights that are not enumerated in the two core human rights treaties (ICCPR and ICESCR) or others. An example for a new right would be the right to be different. Since disability is closely linked to poverty and two-thirds of all disabled persons live in developing countries, the right to development is endorsed by many member states from developing regions as well as by NGOs. Not surprisingly, member states from richer regions are reluctant to include such a right in a human rights treaty that is not supposed to protect governments but people. Similarly, "new" human rights will not easily find consensus among member states, in times when international politics are in turmoil.

Finally, the implementation and monitoring mechanism of the treaty will cause much debate in the Ad Hoc Committee. The current UN treaty-monitoring system is in the process of reform for various reasons, such as overload of state reporting obligations and lack of resources. Some member states are reluctant to accept yet another treaty-monitoring body. Others prefer the StRE monitoring mechanism with a special rapporteur and a panel of experts. Another, related question is which role national human rights institutions shall play. These institutions are a rather modern development of human rights promotion and implementation, and there are vast differences between countries regarding mandate, independence, and competency of these institutes. There is some likelihood that the issue of monitoring and implementation will be postponed to a later drafting stage, to await the outcome of the reform process.

While many controversial issues remain to be resolved, the fact that a human rights convention for disabled persons is now finally being drafted is a tremendous progress in human rights and disability policy.

UNITED NATIONS DISABILITY STATISTICS

The collection and dissemination of disability statistics, by the United Nations Statistics Division (UNSD), started in the early 1980s in response to an increasing international interest in issues pertaining to disability. For example, 1981 was declared the International Year of Disabled Persons and the period 1983 to 1992 the Decade of Disabled Persons. The World Programme of Action Concerning Disabled Persons was adopted as an international guide for use in monitoring the situation of persons with disabilities. This Programme of Action called on the United Nations to develop, on a continuous basis, suitable systems for the collection and dissemination of information on disability necessary for program evaluation at all levels. UNSD therefore has been collecting and disseminating national disability statistics based on censuses and sample survey results, including administrative records. This has involved a worldwide review of published reports and direct communication with national statistics offices and relevant government ministries.

FRAMEWORK FOR DATA COLLECTION AND CLASSIFICATION

The United Nations encourages countries to use the conceptual framework of the International Classification of Functioning, Disability, and Health (ICF) for collection and classification of data on disability. The use of the common framework will facilitate the comparability of data at both the national and international levels, which is currently lacking within and among many countries.

In view of the problems of comparability of disability statistics, the international community is currently working to standardize and harmonize concepts and measures, for use in collecting and reporting disability data based on the ICF conceptual framework. The ICF provides a framework that describes health and health-related domains as body functions and structures, activities, and participation. The domains are classified from body, individual, and societal perspectives. The use of the ICF would result in better measures of disability compared to the use of strictly a severe impairment model. The ICF is multidimensional and has multiple domains and as such presents a framework to collect and present data on impairments, activity limitations, and participation restrictions as well as on the role of the environment. It places disability on a continuum of health with established thresholds for defining decrements of health that constitute disability. It also recognizes the impact of the environment on levels of functioning.

In the "Guidelines and Principles for the Development of Disability Statistics" (United Nations 2001), it is recommended that the ICF be the basis for defining the population with disabilities, developing questions, and classifying the data resulting from such measurements. Before the ICF was developed, the framework and terminology of the International Classification of Impairments, Disabilities, and Handicaps (ICIDH) were recommended so as to harmonize concepts used in disability measurement and classification.

THE UNITED NATIONS DISABILITY DATABASE

The United Nations Disability Database (DISTAT) is meant to promote wider dissemination and use of disability statistics. This database apart from providing statistical data and prevalence rates gives textual information or metadata from surveys and censuses conducted in a number of countries, such as questions used in studies, coverage, and sources of data. Metadata are particularly important in the area of disability statistics because currently different studies use different definitions and concepts of disability as well as conceptually different questions to identify the population with disabilities.

DISTAT-1, which was published in 1988, presents statistics from 63 national studies covering 55 countries. This information is published in the "Disability Statistics Compendium." The database contains national statistics on disability status of the population as well as socioeconomic characteristics of the population with and without disability such as marital status, education, and economic status.

DISTAT-2 shows a relative increase in the number of countries collecting and disseminating data on disability. The 2001 publication has 111 national studies from 78 countries worldwide. Common sources of disability data are censuses and surveys. The majority of countries in Africa and Asia collected disability data through censuses. Only a few countries in the database have statistics on disability that were compiled from administrative records.

ISSUES OF COMPARABILITY

The major problems in comparing disability prevalence rates among countries and within countries, over time, are the absence of internationally standardized definitions, concepts, classifications, and measures of disability. For example, some countries, which collected disability statistics through surveys, have included relatively detailed questions in the survey instruments that focus on activity limitations and participation restrictions. On the other hand, most countries, which collected data on disability through censuses, focused on persons with severe impairments, such as blindness, deafness, and mental retardation. Prevalence rates calculated on the basis of the two different approaches result in wide variation. Countries using questions based on the latter approach have relatively lower rates compared to countries using the former approach.

This wide disparity among prevalence rates has initiated a debate in the field of disability statistics where some people argue that there is no point in maintaining a database with seemingly incomparable prevalence rates. Others argue that the data serve their purpose by showing how prevalence rates are affected by concepts used and questions asked in various studies. The metadata included in the database therefore help readers to discern the inherent conceptual differences underlying the prevalence rates.

Statistics in DISTAT show wide variations among estimates of the prevalence of disability based on various studies and for different countries because of the use of different concepts and definitions among countries and studies. For example, the disability prevalence rate for Zambia based on the 1990 census was 0.9 compared to 20 percent for the 1996 survey in New Zealand. Methodological differences in the measurement of disability therefore constrain the straightforward comparisons of disability prevalence rates among studies and countries.

DEVELOPING STANDARD MEASURES OF DISABILITY

Efforts are under way to identify minimum common questions that can be used, by countries, in censuses and sample surveys. In June 2001, the United Nations hosted an international seminar on disability measurement. The purpose of this seminar was to review and assess methods used in data collection activities related to the measurement of disability in national statistical systems and to develop recommendations and priorities. The seminar recommended establishment of a forum called the Washington Group on disability measurement. The objectives of the group are (1) to guide the development of a small set of general disability measures suitable for censuses, national sample surveys, or any other source that will provide basic necessary information on disability worldwide; (2) to recommend one or more extended sets of survey items to measure disability or principles for their design, to be used as components of population censuses or as modules to specialized surveys; and (3) to address the methodological issues associated with the measurement of disability as identified by the group.

The first meeting of the group covered various methodological issues related to disability measurement including purposes of measurement. The group also reviewed the ICF model, disability tables in the United Nations census recommendations, global measures of disability, relationship of global measures to the ICF, the confounding function of assistive device use, cultural practices that influence the nature of the environment or proscribe participation, cultural issues that act as barriers to collecting data, and cross-national comparability of information.

The second meeting discussed a matrix that linked the characteristics of questions on disability to purposes for collecting the data and results of methodological testing of general measures of disability. At the third meeting, it was agreed that disability was multidimensional, therefore it was not possible to ascertain the single "true" disabled person, and therefore different purposes were related to different dimensions of disability. The fourth meeting agreed on a draft set of questions on disability for use in population censuses.

TRAINING WORKSHOPS

To encourage countries to use the ICF and improve data collection methodologies, UNSD has conducted regional/subregional workshops on disability statistics, one in Africa and the other for the countries in the Economic and Social Council for Western Asia (ESCWA). Apart from covering the sources and uses of disability statistics, the workshops covered the elements and concepts of the ICF as a basis for statistical measurement of disability. This approach encourages the use of common definitions and concepts, which would eventually generate internationally comparable data. In the Economic and Social Commission for Asia and the Pacific (ESCAP) region, they conducted a similar workshop on improving disability data for policy use. The next workshop, on improving disability statistics and measurement, was held in Bangkok, September 2004.

REGULARIZING INTERNATIONAL DATA COLLECTION

In October 2005, the UNSD will initiate a systematic and regular national collection of basic disability statistics as part of the Demographic Yearbook data collection system.

UNITED NATIONS STANDARD RULES

The Standard Rules on the Equalization of Opportunities for Persons with Disabilities have their origin in the passage by the United Nations General Assembly of the World Programme of Action Concerning Disabled Persons on December 3, 1982. The World Programme outlined three goals: the prevention of disability, rehabilitation for persons with disabilities, and the equalization of opportunities for disabled persons. While not abandoning the more traditional efforts regarding disability, its inclusion in the World Programme placed equalization of opportunities on a par with the more traditional concerns. Care was taken to define equality as a parity of opportunities with those of the whole population. This parity was viewed not as a static phenomenon but one that would be fostered and maintained as countries engaged in economic and social development. Thus, the concepts would apply equally to both developing and developed countries.

In December 1992, the General Assembly wanted to continue implementing the World Programme and passed a resolution urging expedited elaboration of standard rules on the equalization of opportunity for persons with disabilities. The Standard Rules were adopted on December 20, 1993. Their purpose was “to ensure that girls, boys, women and men with disabilities, as members of their societies, may exercise the same rights and obligations as others” (United Nations General Assembly 1993, Resolution 48/96, paragraph 15, p. 8). The Standard Rules, although not compulsory, offered an instrument for policy making and action to persons with disabilities and their organizations, while providing a basis for technical and economic cooperation.

The Standard Rules delineated UN member states’ responsibilities in three areas. The first area, preconditions for equal participation, included member state responsibilities to (1) raise awareness, (2) provide effective medical care to persons with disabilities, (3) provide rehabilitation services, and (4) ensure the development and supply of support services, including assistive devices. The next area, target areas for equal participation, comprised the following rules: (5) accessibility, (6) education, (7) employment, (8) income maintenance and social security, (9) family life and personal integrity, (10) culture, (11) recreation and sports, and (12) religion. Rule 7 for employment, for example, stipulated that persons with disabilities must have equal opportunities for productive and gainful employment in the labor market in both rural and urban areas. The final group provided implementation measures for member states on (13) information and research, (14) policy making and planning, (15) legislation, (16) economic policies, (17) coordination of work, (18) organizations of persons with disabilities, (19) personnel training, (20) national monitoring and evaluation of disability programmers in the implementation of the Standard Rules, (21) technical and economic cooperation, and (22) international cooperation.

Member states were urged to establish national coordinating committees to monitor the Standard Rules and to coordinate implementation efforts with organizations of people with disabilities. The rules recommended the establishment of a special rapporteur to monitor the rules at the international level and this feature was implemented. A panel of experts established by nongovernmental organizations (NGOs) consults with the special rapporteur to monitor implementation of the rules.

UNITED WAY OF AMERICA

The United Way of America (UWA) traces its beginnings back to 1887, when the Charity Organization Society began in Denver, Colorado. While this organization did not provide any direct human service provisions, it did conduct regular fund-raising campaigns for 22 local social service agencies and served as an intermediary between philanthropists and human service agencies. This sort of fund-raising role became the hallmark of what would become the UWA as it continued to develop throughout the twentieth century. By 1974, the UWA raised more than $1 billion in the United States and Canada, becoming the first charity to raise that much money.

In recent years, UWA has sought to evolve from strictly a fund-raising organization to a community empowerment organization. Three factors may have contributed to this evolution. First, widely publicized embezzlement scandals in not-for-profit organizations, including the UWA, have led contributors to demand greater transparency from these organizations. The UWA, however, provides no aggregate information about how much of the total money raised by United Way organizations across the United States goes to programs versus overhead costs. Second, following the terrorist attacks of September 11, 2001, on New York City, individuals and foundations donated large amounts of money to relief organizations such as Red Cross International and the Salvation Army. These contributions were targeted specifically for the victims of September 11 and left little money for other human services and other not-for-profit organizations in America. Finally, as a consequence of the first two factors, new philanthropists wanted to be more involved with agencies and wanted see how these agencies spent their donations.

To this day, as UWA transitions into a community empowerment agency, it maintains its identity as a fund-raising organization. For example, in 2002–2003, the United Way organizations across the United States raised $4.44 billion to target broad-impact areas such as strengthening families, building safe communities, supporting self-sufficiency, supporting vulnerable populations (e.g., people with disabilities and the elderly), and helping youths succeed. During its current transition period, UWA began referring to "member agencies" (i.e., agencies receiving money from the UWA) as "partner agencies." UWA's change in nomenclature from "member agencies" to "partner agencies" hints at the initial actualization of the organization's community empowerment vision.

This vision emerged further through UWA's greater emphasis on program evaluation among partner agencies. Now agencies must demonstrate both a need for program funding through a needs assessment and the program's effectiveness through formative and summative evaluations. To assist with these increased reporting requirements, the agency has created an innovative and informational web page, as well as developed numerous trainings concentrating on empowering social service agencies with greater program evaluation skills. These evaluation skills and the requirements the UWA developed necessitate greater transparency among agencies. Furthermore, once agencies develop the capacity for formal evaluation, they can use those skills to find grants outside the UWA. Indeed, UWA has shown that social service agencies now not only need to do good work, but they must also prove they do good work to remain viable.

UNIVERSAL DESIGN

See Accessibility; Aids for Activities of Daily Living; Assistive Technology; Visitability

UNIVERSALISM

The word *universalism* is sometimes not found in dictionaries, yet it is in current use. In the sphere of disability, it stands in opposition to an overly specialized perspective that would leave some people as exceptions and in marginalized status. But the term also has a more general meaning, derived from the word *universal*. Here it refers to the totality of reality, to that which extends to the entire collectivity.

The term is employed in the domain of disability to focus attention on the fact that we must above all make social spaces accessible—physical space, educational space, and mental space. As a consequence, it is a matter of reforming society so that it is receptive to the greatest possible number of disabled persons. The phrase "universal design" sums up this vision. The term is then in opposition to a particularist conception that would authorize intervention in social spaces only in the event of this or that specific deficiency. For example, instead of planning for maximum accessibility in the construction of an apartment building—for the entire building (universalism)—provision is made for one or two apartments outfitted for people in wheelchairs (particularism). It is quite clear that it will never be possible to foresee everyone's needs in every case and circumstance. But the very fact of setting accessibility as a goal for the majority of cases lowers the level of difficulty for a very great number of people and precludes handicap, or at least surplus handicap. This is one of the meanings of the word universal, as a synonym for general: what extends to the greatest number. Striving for universalism dictates working on and with the common everyday environment to avoid detours through specialist institutions or social stigmatization. Everything that enables disabled citizens to participate without obstacle in the life of the community must be attempted.

The limitation that has been recognized, that total accessibility cannot be achieved, will assist us in better understanding what *universal* and the doctrine of *universalism* really mean. Universal designates that which extends to the entire universe, to the total reality of the world or of the human collectivity. Apart from the laws of physics (an apple falls in the same way in Beijing as in New York), we may ask whether there are rules that are valid for humanity in its entirety. One could doubtless assert, for example, that some fundamental proscriptions seem common to all societies (the ban against killing, in particular one's kin; the ban against incest; the ban against generalized lying). But we must immediately add that the modalities, boundaries, and sanctions affecting these forbidden areas are extremely diverse. We more often encounter resistant particularisms, deeply anchored in culture, than common norms, customs, and conceptions. This is why it is perhaps better to view universalism in the narrow sense of logicians. They speak of a "universal term," that is, a term understood in its fullest extension, encompassing all the individuals in the category of individuals under consideration. The universal deals with a human group—a set—but not with the whole of humanity.

Philosophy has not always understood the universal in this sense. We should recall the celebrated "Dispute over Universals" that raged in the Middle Ages. Behind the diversity of beings, is there something that can be called "being"? Behind our ideas and the varied forms of what we call beauty, goodness, truth, is there a heaven where ideas of the beautiful, the good, the truthful exist? More recent is the question whether behind the diversity of languages there are laws that apply without exception to the totality of languages. This was the debate between linguists such as Sapir, on the one hand, and Chomsky, on the other, to cite but these two names. The universal, be it ontological, formal, or linguistic, is still being debated. Perhaps the most telling "last word" in the medieval debate was that of the fourteenth-century philosopher William of Ockham, who said, "The universal is an intention of the mind, susceptible of being attributed to a great number of subjects" (*Ordinatio sive scriptum in librum primum Sententiarum*, distinction II, question 6).

In this quick review of meanings of the words *universal* and *universalism*, we should also note the religious signification, Christian in particular, that makes universalism the doctrine of those who believe that all human beings are saved, whatever their religious views and thus without the mediation of Jesus Christ, while mainstream theology affirms that no one is saved without that mediation. Here universalism has a pejorative shading, even though the Christian religion lays claim to a universal calling, addressing all people of all times, to teach them of the promise of universal salvation through Christ. This, it may be noted in passing, is a neat reconciliation between the universal and the particular: Salvation is available to everyone but is mediated by the singular person of Christ.

Last, a more sociological signification for the word *universalism* should be noted. Social or cosmic reality is a whole on which individuals are dependent. In this context, the word emphasizes the social totality that precedes and determines individuals. The universal is primary with respect to the particular; it proceeds as a deduction and is not the result of a kind of induction from particulars toward a general level. Societies that have been called holistic operate on the basis of this primacy of the totality, of what dominates individuals and constitutes the common law to which they must submit. This sense of the word does not characterize modern societies, in which the point of departure is always individuals, their rights and their claims. Yet, on the other hand, our contemporary societies are borne along by the movement called globalization. Here we cannot analyze the different meanings and different levels of globalization. It will suffice to note that one of its aspects is the forcible application, often initiated by the countries most powerful in terms of demography and economy, of canons, standards, styles, technologies, which tend to be imposed on everyone, everywhere. The English language, to take a single example, is progressively becoming the universal language, the one in which the inhabitants of the culturally most remote countries will communicate, the one that will serve as the medium of exchange in all four corners of the world. This globalization is realized, by the very coercive nature of things, to the detriment, greater or lesser, of distinctive collective identities and ancestral traditions.

To summarize, the word *universalism* can have many meanings (religion claiming to address all humans; a doctrine that views reality as a totality, preceding all individuals; a philosophy in search of universals; a science that seeks laws without exception; a culture that imposes itself on other, earlier cultures), but it always comes back to the question of knowing whether we should focus on singularities in order to move to a higher level or posit a universal that subsumes these singularities. The problem of the universal will always be that of the relationship between the particular, always certifiable, and a superior level that transcends it, one established by the mind but not empirical.

In this general, abstract question, it is important to distinguish among a multitude of concepts. What is constant is not fully universal, because a constant is not susceptible, at a given time, to exceptions, although it does not rule out surprises. The general is not a synonym for the universal, because generality is the product of a statistical, probabilistic perspective and cannot claim to be valid for the whole of reality or society. Nor is global a synonym for universal, since globalization refers to the international without our being able to predict its universality.

This discursive tour of semantics, in the context of an encyclopedia devoted to disability, is not intended to make a full exposition of the problems of the universal. What stands out is that the universal has never been realized and never will. Its role is to establish, as some philosophers put it, a “horizon,” that is, a kind of ideal in front of us that we must not drop from sight, one with which we must constantly concern ourselves without getting lost in the restrictive, sequestering detail of particularist views and special interests. The status of the universal, and consequently that which must sustain universalism, stems from a double necessity: to refuse to believe that the universal is something that has already been achieved, and to refuse to renounce attaining it. This only appears to be paradoxical. In fact, anyone who claimed to have realized the universal would only have imposed his or her particularism on others. We have seen this in colonialism; we see it now in the standards of various technologies. It was seen in the Marxist ideology that sought to subject the world; it is seen now in the pretentions of the cultures of developed countries to regulate, and thus to reduce, other cultures (under the cover of universal human rights, nonetheless indispensable, or under the cover of democracy on the American, French, or British model). On the other hand, anyone who renounces the universal as goal opens the way to all kinds of excess, all kinds of cowardly tolerance and imprisonment in archaism. This is evident when no one speaks to the exploitation of women by certain religions, or when one accords this or that fanaticism the same respect and rights as the defense of human dignity, or when one fails to affirm that there are rights to be recognized for all humans, in their simple capacity as human beings.

To return, in conclusion, to the specific problem of disabled people, it seems important to claim that all of society be open to them and that the same real rights and responsibilities be recognized for them. At the same time, it is equally important not to neglect to insist that certain specific measures be taken, in particular for certain onerous or rare deficiencies, for instance. Aiming for universality in these measures and arrangements prevents us from siding with any one category of disadvantaged citizens, but believing that generalized accessibility is in itself sufficient would leave us the victims of illusion, since this would also entail abandoning certain people. Universalism remains a horizon, a perspective, a stimulating goal. The worst that could happen to it would be to believe that it is no longer worth pursuing.

—Henri-Jacques Stiker

URBANIZATION

Most people in the Western world live in cities, and increasingly people living in developing countries are moving to urban areas. In this urbanizing world, the majority of job opportunities, access to goods and services, entertainment, and other functions are found in cities. Since the late nineteenth century, the city has been viewed as a source of social alienation and anomie, characterized by fragmentation and the dissolution of traditional (often rural) social networks. Urbanization over the course of the twentieth century has witnessed, some commentators suggest, the emergence of unsustainable cities and modes of living. In this view, the city is conceived of as dystopia, increasingly plagued by environmental pollution, poor health for its inhabitants, social polarization between rich and poor neighborhoods, land degradation, and crime.

Such observations resonate with many disabled people whose experiences of urban environments are far from positive and are conditioned, in part, by their difficulties in moving about and getting access to places in the city. From sidewalks cluttered with street furniture such as benches and other physical obstacles to the absence of clear signage, urban areas are constructed in ways that do not contribute to the mobility of disabled people. In this respect, urban areas may be regarded as reproducing inequalities between disabled and nondisabled people (see Allen, Milner, and Price 2002; Imrie 1996, 2005; Imrie and Hall 2001). For some, urbanization is characterized by a design "apartheid" in which the design of the built environment actively disables disabled people, which, in turn, prevents them from accessing facilities such as shops, parks, transport, and dwellings without help.

For instance, common experiences of the effects of urbanization for disabled people who use wheelchairs include the following: ramps that are installed but prove to be too steep to be used safely, dropped curbs that are present but are badly placed; a government office on the second floor of a building but with no elevator; a shopping center without a disabled person's toilet; streets without clear signage or tactile walkways or means of way finding; a "wheelchair friendly" restaurant that has two steps at the entrance; a museum that has ramps and a disabled person's toilet but no elevator, so that wheelchair users can visit only the ground floor; and a municipal building with a ramp that is so steep that most wheelchair users prefer to go down it backwards. Such features are commonplace, so much so that they are broadly accepted by the population as a whole as normal and inevitable parts of everyday life.

An important theme in the study of the city and disability is that the disabling nature of the urban built environment is, in part, related to the purposive plans and policies of urban planners who have the responsibility for the production of cities. Urbanization, as product and process, takes shape through the context of the values of and actions by professionals, who, in Western societies, have rarely acknowledged disabled people and their needs. Rather, the urban subject—those whom planners seek to plan for—is conceived of as an abstract generalization and is rarely thought of in terms of differences in relation to the body, ethnicity, gender, or sexuality. Disability, as a descriptor or category of social reality, has rarely figured in architectural or planning education, and, as Greed (1999:270) suggested, the subcultures of design, property, and construction professionals are resistant to change in not permitting "much space for wider strategic and holistic approaches to . . . social factors."

While building regulators and officials have some scope to influence the form of the urban environment, the physical shape of urbanization is largely determined by the values and practices of property developers and builders. The values of property professionals are usually impervious to disability, and they tend to perpetuate problematical, and erroneous, assumptions about disabled people in relation to the design of their buildings. Professionals in the building industry continue to argue that there is insufficient demand by disabled people for an accessible built environment and that the provision of accessible buildings is prohibitively expensive. While both assumptions have been shown to be false, they persist as blocks to a progressive urbanism characterized by barrier-free environments.

Disabled people's experiences of urbanization are not just related to the form of the physical environment but are also determined, in part, by what Ellin (1996:252) referred to as the city with "a confluence of meanings rather than functions." Thus, many of the symbols and images of the city do not provide disabled people with the means for self-expression or autonomous behavior, but rather encourage a retreat into private spaces (or out of sight and off the streets). For instance, steps into shops or nightclubs not only prevent a wheelchair user ease of access to the facility but also create a context of dependence on others for assistance while transmitting a sense that those without "able" limbs, or independent use of body parts, are unwelcome. Likewise, for many wheelchair users, "back door treatment" is the norm, in which the entrance to a building is often through side doors, back doors, or everywhere but the front. In this sense, the built environment is marked out by spatial signifiers or symbols of difference that serve, potentially, to separate disabled people from their "normal" counterparts (see Hawkesworth 2001).

What are the possibilities for an urbanization that will facilitate livable places for disabled people? Most forms of urban renewal are characterized by a property-based approach to development, in which people-based issues are sidelined. However, recent debates about the "good city" revolve around principles of new urbanism, in which it is suggested that cities should be constructed as compact spaces with an emphasis on accessible, safe, and inclusive spaces. Its emphasis on small-scale, localized forms of urbanization, based on diverse neighborhoods and human scales of interaction, provides potential for crafting urban spaces based on human need rather than profit. In this respect, the people-centered design philosophy of new urbanism, while not a panacea, gives some hope that urban renewal will be attentive to some of the needs of disabled people (see Talen 1999).

Its translation into the lived realities of urbanization will depend, in part, on shifts in social attitudes and practices in relation to disability and a greater willingness of building professionals and others to recognize and respond to disabled people's intrinsic rights to access and mobility and movement in cities. In the United States and the United Kingdom, legislation is an important part of requiring much more provision of accessibility features than was hitherto the case, and city governments are adopting diversity agendas that require urban renewal policies and plans to incorporate the needs of disabled people. For instance, in the United Kingdom, all new dwellings have to be constructed to minimum levels of accessibility, while in the United States, many state and local governments have adopted ordinances that require developers to provide access in single-family dwellings. While legal measures, in and of themselves, cannot guarantee barrier-free environments, they provide the possibilities for a new era of urbanization characterized by the breakup of social and physical barriers in cities.

URINARY TRACT INFECTION IN SPINAL CORD–DISABLED PATIENTS

Urinary tract infection (UTI) refers to infectious diseases of the kidneys (pyelonephritis), ureters, bladder (cystitis), and urethra (urethritis). The most common way for bacteria to enter the urinary tract is through an ascending route from the genitourinary region through the urethra, counter to the usual flow of urine. Thus, the typical causes are bacteria from the gastrointestinal tract and vagina given their close proximity to the urethra.

Patients with disabilities are particularly at risk for UTI. The most notable group includes individuals with spinal cord dysfunction (SCD) including spinal cord injury and multiple sclerosis. Important complications of the urinary tract include kidney failure and infection. They have traditionally been ranked as leading causes of death in those affected with SCD. Prior to the early 1990s, diseases of the urinary tract accounted for two-thirds of deaths in this group of people. While medical care of patients with SCD has dramatically improved over the past one to two decades, UTI still ranks as the second most common medical complication. Increasing disability in patients with SCD increases the risk of UTI whereby 75 percent of patients with paraplegia and over 85 percent with quadriplegia experience UTI. As a result of recurrent UTI among patients with SCD, the medical costs are substantial; rehospitalization for complications can cost in excess of $12,000.

The basis for increased rates of UTI among patients with SCD is principally two-fold: (1) the decreased ability to completely empty urine from the bladder, producing static urine where even small numbers of contaminating bacteria can replicate, and (2) the requirement for either intermittent or indwelling catheterization for drainage of the urine, each of which can provide direct access for bacteria to the urinary tract. The use of catheters has dramatically improved the care of patients with SCD; however, catheters also substantially increase the risk of UTI especially when indwelling catheters are employed. Undoubtedly, antibiotics have had a major impact on treatment of serious UTI in patients with SCD, decreasing morbidity and mortality. Unfortunately, the diagnosis and the appropriate treatment for UTI in people with SCD are exceptionally difficult because individuals can have bacteria persist in their bladders without disease and can have dramatic cases of infection without fever or pain (as a result of their spinal cord injury). Antibiotics given prophylactically decrease the persistence of bacteria in the urine and delay the time until the development of a UTI; however, patients on prophylaxis still experience the same number of bona fide infections. The constant use of antibiotics also increases the occurrence of infections with antibiotic-resistant bacteria, a public health challenge.

In the future, medical advances may produce tests that differentiate true UTI from persistent bacteria in the urine. Examples of preventive therapies include colonization of the bladder with benign bacteria that block the disease-causing agents from gaining a foothold and vaccination against the most important causes of UTI. Improvements in rehabilitation may improve patients' sensation and thus their ability to appreciate pain and other symptoms of urinary infection while improving bladder function, decreasing their dependence on catheterization.

V

VALLATHOL (1878–1958)

Indian poet, essayist, and cultural architect

Vallathol Narayan Menon was a South Indian poet, essayist, and major contributor to the renaissance of the Malayalam language and culture. He lost much of his hearing as a young man. In his early 30s, he wrote *Badhira Vilapam* (*Lament of a Deaf Person*) expressing a sense of loss and deprivation as he became deaf. Vallathol had earlier translated Valmiki's *Ramayana* into Malayalam, and in his 70s he completed a translation of the *Rig Veda*. His eight-volume "Bouquet of Books" appeared successively from 1917 to 1970, after his death.

The dream of his mature years was to initiate the revival of Kathakali dance drama. He opened the Kerala *Kalamandalam* in 1930 to teach all the classical arts of Kerala, and his cultural crusade was recognized and honored after India's independence. The American danseuse La Meri (1941:27) studied gestural communication in Kerala in the 1930s and noted that "Vallathol, the great poet who has revived the Kathakali form in Malabar, is deaf and so converses entirely by means of the beautiful gesture-language of India."

VALUES

Any discussion of disability as a social phenomenon must also include the issue of values. Values are a set of principles or standards concerning the relative worth, utility, or importance of things and experiences. Often values appear in everyday life as judgments or points of view on behaviors and social problems. Disability as a category or a label is not value neutral. The term itself—*dis*-ability—implies a value judgment. All individuals vary in the skills and abilities they possess. Yet for a whole class of individuals, society considers their physical limitations to be a defining characteristic. Therefore, discussions of disability must be mindful of how values shape our attitudes and actions toward those with disability in society.

Social values are significant for how we, as a society, interact with, think of, and provide services for individuals with disabilities. However, the experience of disability is highly variable. The ways that individuals value (or devalue) their experience of disability is dependent on a wide range of factors. These factors include the age at onset of disability, the cause of their limitation, its visibility to others, and the degree to which it poses functional challenges or impediments in their daily lives. Each factor influences the value one places on his or her own life as well as the value of his or her life to others. Beyond individual values, society also values (or devalues) disability. Society's values are reflected in public policy initiatives and in the physical and social environments. This entry highlights the importance of values, as they influence behaviors and actions at both an individual and social level.

A person may experience disability at any point in life. The point of onset of disability may have a profound effect on how individuals think about and value their lives and their disability. Individuals who experience the onset of disability later in life must address their loss of physical function. Even more, they may perceive a loss of self. People who experience the onset of disability during adulthood often grapple with the loss of physical function and reconcile their current abilities with their ideas about who they were and the role they served. The ability to perform social roles such as wife, father, or employee might be limited by the physical experience of disability. This inability to fulfill their familiar roles may lead people not only to resent their disability but also to regard themselves as less valuable members of society.

Those who experience the onset of disability at an early age are faced with another set of social and personal challenges. Children may be unaware of their disability and how others perceive them. Many children without disability are not taught how to talk about disability. Rather than acknowledging children's curiosity, many parents hush them when they inquire about another child's disability in public, furthering the stigma that disability is something to be devalued. Furthermore, because children do not know what/how to talk about disability and difference, it makes social interactions all the more awkward for children with disabilities. As children age, they may realize that they do some things differently from their peers or cannot participate in some activities. As a result, they may see themselves as less socially valued. Alternatively, children may be able to incorporate their disability into their self-concept or identity from the start, thus avoiding the difficult transition experienced by many adults.

The visibility of one's disability could also play a role in how individuals think about and value their disability. Those with more visible disabilities—paralysis, amputeeism, severe forms of mental retardation—may experience more prejudice than do those whose disabilities are hidden, such as chronic pain. Alternatively, those with hidden disabilities may experience insensitive treatment from individuals who, unaware of their disability, do not anticipate the need for accommodation. More visible disabling conditions create an opportunity for the general public to pass judgment on and label those who experience disability. These judgments and associated labels indicate how society values disability.

Our discussion here focuses on the American experience of disability; however, how disability is valued is context dependent. The experience of disability depends on the social, cultural, economic, and political context in which a person lives, as well as the norms and beliefs associated with these dimensions. For example, some Middle-Eastern Muslim societies view those with mental retardation as "saints." Likewise, the economic circumstances of an area can influence social perceptions of disability. In a hunter-gatherer society, physical disabilities may be seen as exceptionally detrimental to the well-being of the tribe. Overall, there are very different cultural reactions toward those with disability. These cultural reactions shape the values of a society and thus influence the way those with disability are labeled and cared for in society.

The words that we use to talk about a phenomenon not only describe it but also shape the nature of the phenomenon itself. Language reflects the social values of the times. Today, many use *disability* and *impairment* interchangeably, yet they have profoundly different indications for how we are to think about the very nature of the state itself. The World Health Organization (WHO) has tried to reconcile these definitions in its International Classification of Impairments, Disabilities, and Handicaps (1980) and more recently in its International Classification of Functioning (2001). *Impairment* refers to problems in physical function, loss, or abnormality. *Disability* occurs when there is a mismatch between the physical capabilities of a person and the demands of the environment. In other words, the environment does not accommodate the limitation or inability of the person to perform such tasks as boarding a public bus or entering some buildings, creating "disability." Therefore, the WHO definition suggests that disability should not be viewed as a problem located solely within the individual, but rather as a problem in how society and the physical environment are structured.

Disability rights activists have long argued this point. They suggest that disability is a condition created by society and how it is arranged. They reject that disability is a personal inability to perform tasks because of a physical or mental deviation from "normal." These activists see disability as the result of an environment that is not accepting or accessible to people with abilities that stray from "normal." The concept of universal design taps into this notion. Universal design refers to an architectural approach that is accepting of all variants of physical ability. Stairs are replaced by gradual inclines; floors are neither so smooth to make it difficult to walk nor so coarse that it impedes mobility in a wheelchair. Disability activists' social model of disability favors environmental change rather than personal change. That is, environments should be accessible to all people, regardless of their physical and mental levels of function. This principle views disability as value neutral or even value added. Overall, this type of environment would better the lives of those with disability as well as those without disability.

Along with shifting the responsibility of disability away from the individual and toward society by altering the physical environment, changing language is also important in valuing disability. To say an individual "suffers" from deafness or mental retardation is to make a judgment about the worth and value of these experiences, and of those individuals who have such conditions. The importance of language in shaping the meaning and worth of disability has been emphasized by the "person first" campaign within the disability rights movement. This movement has argued that the term *disabled person* should be replaced by *person with a disability.* That is, the former term emphasizes disability as a master status—as the most salient and defining characteristic of an individual—whereas the latter stresses that people with disability are first and foremost *people* and that their disability is only one aspect of their personhood. This person-first campaign has empowered those with disability while at the same time raising their value in society. However, disability rights activists have launched a backlash against the person-first language that has come to permeate the field of disability studies on the basis that it undermines the importance of their disabilities to their lives. This movement argues that person-first language is a politically correct approach instituted by individuals who claim to speak for those with disability. Both sides of this debate, however, provide evidence that increased social value has been placed on disability. In turn, this is reflected in current public policy initiatives.

At a societal level, we may infer social values by analyzing public policy about disability. A glance at disability policy in the United States, as well as in other developed countries, depicts a formidable change in the way people with disability have been valued in society over the past century. In the past hundred years, we have moved from a society that promoted the principles of eugenics to one that incorporates people with disabilities more fully in social life. Again, this discussion emphasizes the American experience; however, it is, in many ways, typical of most developed Western countries' experience.

Public policy is strongly shaped by social values, and disability policy is no exception. In the United States, we can trace the evolution of social policy and social values regarding those with disabilities. Disability has been a stigmatizing characteristic throughout history, and people with disability have experienced oppression to various degrees. This oppression has resulted from and been legitimized by social policy and has ranged from eugenically driven attempts to eliminate those with disability from our society to extremely paternalistic attempts to protect those with disabilities from the larger society.

Disability was strongly devalued by society in the late nineteenth and early twentieth centuries. Individuals with disabilities were viewed as deviants to be kept away from society at best, as a fatal flaw in society that required elimination at the worst. We have moved past this phase in our history. Beginning in the 1950s but coming to a head in the early 1970s, parents, professionals, and disability rights activists began to demand policy changes. In the 1950s, parents began to form organizations around the specific disability categories that affected their children. These groups soon became instrumental in advocating for disability rights, most particularly for quality schooling for children with disabilities.

Throughout the 1960s, Congress expanded programs to fund education, rehabilitation, and social services for those with disabilities. During 1975, two crucial pieces of legislation were passed: the Education for All Handicapped Children Act (EHCA) and the Developmentally Disabled Assistance and Bill of Rights Act (DD Act). The EHCA guaranteed all school-age children with disabling conditions the right to a free and appropriate public education.

Though these policy advancements indicated a dramatic shift in our social conception of disability, the most significant legislative event was the 1990 passage of the Americans with Disabilities Act (ADA). This act formally outlawed all discrimination on the basis of disability, including discrimination in the workplace, in businesses, schools, transportation, and the like. Furthermore, it mandated, when economically feasible, that public spaces be made accessible to those with mental and physical disabilities. This sweeping legislation was the most profound indication that our society no longer found it appropriate to marginalize those individuals with disabilities. At the heart of the ADA was the aim of making all dimensions of public life available to those individuals with disability and to allow them to participate fully in society.

This is not to imply that the ADA has alleviated all forms of discrimination, nor does it suggest that, as a society, we have eliminated all stigma associated with disability. The ADA is worded so as to allow significant discretion in its interpretation. Still, a trend toward inclusion permeates current policy. This legislative shift is a further indication that society has become more accepting of disability. Rather than deliberately excluding individuals with disabilities from the public sphere of everyday life, the ADA protects the rights of people with disabilities to live their lives fully without environmentally imposed limitation.

Values, then, are clearly significant for how we, as a society, interact with, think about, and provide services for individuals with disabilities. Moreover, these social values play an important role in shaping the ways that individuals value (or devalue) their experience of disability. Culture also influences the social valuation of disability, and the ways in which these values translate into public policy and environmental change. During the past century, society has undergone a notable shift in the ways we value disability. We have moved from a society that has oppressed and hidden those with disabilities to a society that is more accepting of the disability experience. This shift in values has been reflected by a shift in public policy. Moreover, the personal experience and valuation of disability have likely changed as well over this period. People with disabilities are able to accept their disabilities and live in the public sphere in a way that earlier generations of people with disabilities were not. People with disabilities are now legally afforded educational and employment opportunities that were, in earlier times, systematically denied to them. Changes in policy and social values, in turn, have altered how individuals evaluate their bodies and their mental or physical abilities. More accommodating environments and a social awareness of the diversity of human abilities has begun to reduce the stigma associated with the disability experience for many. In the future, these social values may continue to provide those with physical or mental disabilities the ability to live life fully.

VAN GOGH, VINCENT (1853–1890)

Dutch artist

Vincent van Gogh was born in Zundert, the Netherlands. At age 27, after years spent in various failed professions, he decided to become an artist with the help of his brother Theo. In 1886, he moved to Paris to live with Theo, and there he met the Impressionist group. His palette lightened, and in 1888 he left Paris for Arles, a small, picturesque town in the south of France where he achieved full maturity as an artist. In 1888, he had the first of several epileptic seizures and mutilated his ear by severing an artery. In 1889, he voluntarily stayed at St. Remy, a mental hospital, where he was treated for seizures. In the last months of his life, he stayed at Auvers-sur-Oise near Paris and was treated by Dr. Gachet, who was willing to be paid in paintings. Also diagnosed with chronic sunstroke and intoxication from turpentine and absinthe, van Gogh died at age 37 by his own hand. He sold only one painting during his lifetime, yet left behind 1,600 paintings and drawings. His letters to Theo reveal the depression and elation of Vincent's life as a painter as well as his gentleness, love of humanity, and clarity of thought about his art.

—*Katherine Sherwood*

VAN LANDEGHEM, HYPPOLITE (fl. 1865)

European disability activist

The blind polemicist Hyppolite (sometimes given as Hippolyte) Van Landeghem published ca. 1863 a long denunciation of the "exile system" that "immured" blind youths in segregated schools (he had spent 12 years in one), wasting huge sums on buildings and "salaries of sighted officials, who are totally unfit to educate the blind" while the number of blind people thus (mis)educated was tiny compared with those for whom nothing was available. Van Landeghem keenly advocated home education, yet he was severely critical of William Moon's Society for Teaching the Blind at their own homes and of other evangelistic organizations using embossed books: "Restore to a blind man his social rights, give him an opportunity of achieving his own support," and only then expect him to attend to religion (Van Landeghem 1863). He railed against fund-raising to teach blind people in Asia, when 27,000 blind people in the United Kingdom lacked education or employment. Van Landeghem advised blind people to dispense with guides and walk the streets by themselves, after trying this himself for two years in London. A book by Mrs. Hippolyte Van Landeghem (1865) reinforced the message with life histories of notable blind people from Europe and America.

VEECK, BILL (1914–1986)

American businessman

Bill Veeck was one of the greatest innovators of baseball management while serving as owner and/or manager of four different major league baseball teams. The son of a sportswriter turned president of the Chicago Cubs, Veeck began working in baseball at age 11 as a ticket seller, vendor, and groundskeeper. He was famous for introducing gimmicks and marketing stunts including the exploding scoreboard, giving away live animals, scheduling morning games for late-shift workers, having marriage ceremonies on home plate, and his famous Grandstand Managers Day where he asked fans holding placards with a “yes” or “no” to vote on whether to hit, bunt, steal, or other managerial choices. He once presented his manager with a huge birthday cake, out of which popped a much-needed left-handed pitcher. In 1952, Veeck arranged for midget Eddie Gaedel to bat for the St. Louis Browns. Veeck also introduced innovations that became part of baseball management; shortly after taking over the Chicago White Sox he created a media event by setting up an office in a hotel lobby and purchasing contracts from players from other clubs, introducing free agency into major league baseball.

While still part owner of the Brewers, Veeck served three years in World War II in the U.S. Marines. An accident cost him his right foot and, despite 36 operations over the rest of his life, he lost his leg as well. Veeck never let the loss limit his work, and in one of his most creative stunts, in 1976 Veeck staged a bicentennial-inspired Spirit of ’76 parade on Opening Day—with himself as the peg-legged fifer.

Veeck is also credited for being a major management force toward integrating major league sports. Before entering the military, Veeck secured backing to buy the Philadelphia Phillies and had a plan to stock the club with stars from the Negro leagues, a plan rejected by the baseball commissioner. However, after the war, in 1947, Veeck integrated the American League by hiring Larry Doby, weeks after Jackie Robinson joined the Brooklyn Dodgers of the National League.

VESTIBULAR DISORDERS

Vestibular disorders refer to a group of problems affecting an individual’s sense of balance. Dizziness, vertigo, unsteadiness, light-headedness, and disequilibrium are some of the words people may use to describe a feeling of imbalance. Most vestibular disorders are transient and improve with observation and occasional symptomatic treatment. However, in rare instances, imbalance can be a sign of a potentially serious disorder.

The vestibular system is composed of a set of balance organs within each inner ear (collectively referred to as the *labyrinth*), nerves connecting the labyrinth to the brain, and various nuclei within the brainstem, cerebellum, and cerebral cortex that interconnect at multiple levels. The brain uses the input from both labyrinths to help determine one’s position in space. If there is a disturbance in input from one side, the asymmetry may be perceived as imbalance. Vision, *proprioception* (the ability to sense one’s position in space with the eyes closed), and *central integration* (the processing by the brain of input from the eyes, ears, head, trunk, and extremities into a meaningful whole) also significantly influence balance and are considered part of the vestibular system.

In addressing complaints of dizziness, physicians must first consider whether symptoms arise from true vestibular dysfunction or from a more general medical cause. Diabetes, cardiac arrhythmia, and hypotension are some of the many disorders that can cause dizziness or exacerbate a true vestibular disorder. Complaints of frank *vertigo* (the illusion of a turning motion) or the presence of *nystagmus* (an involuntary linear or rotary movement of the eye) on physical exam denote a vestibular problem. Once a vestibular lesion is suspected, a distinction is then made as to whether the site of the lesion is inside the brain or brainstem (*central*) or outside (*peripheral*). The pattern of onset (acute, subacute, progressive, intermittent), the duration of dizziness (seconds, minutes, hours, days), and associated signs and symptoms (hearing loss, tinnitus, head trauma) can further help to localize the lesion.

The diagnosis of most vestibular disorders is through a careful history and physical exam. A neurological exam is essential to identify disturbances in gait and balance and to uncover the presence of cranial nerve neuropathies, which may help to localize a lesion. The head-and-neck exam is focused on identifying the presence and direction of nystagmus and ruling out evidence of otologic pathology (a draining ear, mass, membrane perforation), which may suggest the cause of the problem. Once a differential diagnosis is established, additional testing such as an electronystagmogram (ENG) can then help to rule in or out a specific diagnosis.

Vestibular dysfunction can be caused by vascular events (migraine, stroke, hypotension), infections (labyrinthitis, otitis, mastoiditis), trauma to the temporal bone, autoimmune disorders (Cogan syndrome), metabolic derangements (diabetes, hypothyroidism), or neoplasms (vestibular schwannomas). Some diseases are idiopathic, such as benign positional vertigo (BPV) and Meniere's disease. Common peripheral vestibular disorders include BPV, Meniere's disease, vestibular neuronitis, acoustic neuromas, and labyrinthitis. Central vestibular disorders include migraine, multiple sclerosis, vascular insufficiency, cerebellar dysfunction, and Arnold-Chiari malformation, among others.

VETERANS

War has been credited as an impetus for change. Within many fields, war has been responsible for new methods, materials, and organizations. Clearly, war has been responsible for a mass of injuries that result in numbers of disabled people but has also acted as a catalyst to improve medical knowledge and techniques in the treatment of disability. During war, many different types of therapy have been developed that have primarily ensured the survival of those injured and also have produced innovative methods of treatment that have ensured a better quality of life for disabled people.

While wars in the previous centuries produced disabled men, World War I is the one noted for creating enormous numbers of disabled men. Estimates suggest that at least 1.5 million people were left with some sort of disability. Physical and sensory disabilities were augmented by those suffering from neurasthenia or shell shock. Innovations in medicine such as orthopedic surgery ensured that permanent disability was lessened, and often servicemen were made well enough to return to the battlefield and risk being killed once more.

Those who returned home with a disability became the government's responsibility; the Ministry of Pensions was established in 1917. In the United States after the war, three different agencies administered veteran's benefits: the Veterans Bureau, the Bureau of Pensions of the Interior Department, and the National Home for Disabled Volunteer Soldiers. Programs included compensation, insurance, and vocational rehabilitation. Advocate agencies in the United Kingdom such as the British Legion and the Returned Sailors and Soldiers Imperial League of Australia were established in 1921 and 1916, respectively, to look after the interests of disabled ex-servicemen. There were constant disagreements over pensions for disabled ex-servicemen, and the British government was criticized by organizations such as the British Legion for their lack of fiscal support. The United States established its own Veterans Administration in 1930, although there had been provision for disabled veterans since 1776 when, to increase enlistment for the Revolutionary War, pensions were offered to anyone who was disabled in the fighting.

Although World War II was not as devastating in terms of numbers killed as World War I, numbers of people were disabled as a result of the war. As the fighting line was more fluid, civilians were drawn into the field of battle and became disabled as a result of enemy action. New regimes were established to ensure that those who had been permanently disabled were able to be employed elsewhere to assist the war effort. Termed *rehabilitation*, its purpose was to ensure that the effect of the manpower shortage due to mass mobilization was lessened. The Disabled Person's Employment Act of 1944 in Britain established guidelines for the employment of disabled people after the war.

As well as being workers, disabled people were viewed as heroic. Douglas Bader, the famous double amputee, was feted for his bravery flying Spitfires for the Royal Air Force. Some of the most important work on disability was that of neurosurgeon Sir Ludwig Guttmann, at Stoke Mandeville in Aylesbury, England, who worked with servicemen and servicewomen who had incurred spinal injury with resultant paralysis. His efforts to prevent them from sinking into depression and work toward building a stronger body with compensatory muscles through sports had far-reaching implications, as these early competitions evolved into the contemporary Paralympic Games.

In the second half of the twentieth century, wars were conducted on a smaller scale, but numbers of people were disabled as a result of the conflicts. About 75,000 Americans were severely disabled in the Vietnam War. Later conflicts saw complicated disabling conditions such as Gulf War syndrome, which was reported to be caused by exposure to a cocktail of chemical agents. While there were fewer battle casualties in the latter decades of the twentieth century due to advances in technology that distanced the warring parties, the disabling effects of war continue.

VICTOR OF AVEYRON
(ca. 1790–1828)

French "feral child"

Victor is perhaps the best known and most important of the long list of so-called feral children. Often referred to as "the wild boy of Aveyron," Victor is forever associated with the name of his teacher, Jean Marc Gaspard Itard (who also gave Victor his name). For an entire generation of French intellectuals, Victor represented a chance to study what could not ethically be created: a "noble savage" raised in a state of nature uncontaminated by human culture. What could such a child show about the essence of human nature, human capacity? In what some have called the "forbidden experiment," Itard and Victor (and a caretaker, Madame Guerin) spent five intensive years together testing the empiricist notion that the human mind was a blank slate, dependent on the sensory experiences to develop all knowledge and socialization.

Victor was first brought to Paris in 1800 after being captured by townspeople in the region of Aveyron in the south of France. After an initial swirl of public attention and excitement, however, the French *alieniste* Philippe Pinel pronounced his diagnosis that Victor was not the suspected noble savage, normal in faculty but uncontaminated by human society. Pinel declared the child to be an incurable idiot, unimprovable in any way. It was Itard, however, who persisted, obtaining permission to work intensively with Victor, carefully exploring just how much the child could learn and approach normal development.

Itard's account of this five-year experiment, documenting Victor's progress in language, behavior, and other functional skills, is often regarded as one of the earliest attempts at systematic instruction of children with intellectual disabilities. Reminders of the many devices and techniques created by Itard for use in Victor's instruction can still be seen in such settings as Montessori classrooms and in the precise language of behavioral observations.

By 1805, Itard concluded that Victor did, in fact, have unalterable limitations to what he could learn, and Itard abandoned his efforts to document Victor's education. Itard went on to work for several more decades in the education of deaf children. Victor spent his remaining days with his devoted caretaker, Madame Guerin, living an apparently quiet life. Victor died in 1828 of unknown causes.

▣ VIOLENCE

No country or generation has been unscathed by violence. It is a phenomenon that has been continuously a part of human history. The universality and pervasiveness of violence are evident in our homes, playgrounds, schools, neighborhoods, worksites, places of public gathering, and nations. More than 1.6 million people die each year worldwide because of violence. Approximately half of these deaths are suicides, one-third are homicides, and one-fifth are related to armed conflict. Many more people are injured as a result of violence. For instance, it is estimated that for every death due to gun violence, three more people sustain gun-related injuries. In 1996, the World Health Assembly adopted a resolution declaring violence a leading worldwide public health problem requiring immediate attention from the professional community. *Violence* is defined by the World Health Organization (WHO) as "The intentional use of physical force or power, threatened or actual, against oneself, another person, or against a group or community, that either results in or has a high likelihood of resulting in injury, death, psychological harm, maldevelopment or deprivation." With this far-reaching definition, the WHO recognizes that violence may manifest in a variety of ways. According to the WHO, violence can be categorized as

1. Self-directed violence (self-destructive and suicidal behavior)
2. Interpersonal violence (family/intimate partner violence and community violence that occurs among acquaintances and strangers)
3. Collective violence (violence by a group of individuals against another group)

Given the magnitude of violence, it is not surprising that there is a direct relationship between violent behavior and disability. Violence has affected the field of disability in four distinct ways. First, there are individuals who have acquired a disability as a result of violence. Typically, these acts have been related to warfare, civil unrest, street violence, and interpersonal disputes. Second, people with disabilities are at an increased risk of being targets of violence and abuse both inside and outside of their homes. Third, there is a belief among the general public that people with certain disabilities (i.e., severe psychiatric disabilities such as schizophrenia and bipolar disorder) are likely to exhibit physically aggressive behavior. However, this belief is not entirely accurate. Individuals who are taking medication for a psychiatric disability are not at an increased risk to exhibit violent acts. Fourth, suicide (self-directed violence) is closely linked to psychiatric disabilities, particularly mood disorders. According to the National Institute on Mental Health, approximately 60 percent of individuals who commit suicide have had a mood disorder (such as major depression, bipolar disorder, or dysthymia). In addition, the field of disability has been embroiled in the controversial debate of physician-assisted suicide, whereby physicians provide individuals who are diagnosed with terminal illnesses or severe/incurable physical pain with the means to end their lives.

ACQUIRING A DISABILITY THROUGH VIOLENCE

Violence is related to disability when one considers the disablement of individuals because of violent acts. Although mortality is commonly used to indicate the magnitude of intentional violence, many more individuals sustain injuries that require medical attention, and a significant proportion become permanently disabled. Prevalence and incidence rates are difficult to determine due to a lack of systematic reporting procedures. Nonetheless, the relationship between violence and disability has been evident throughout human history. Violence-related disabilities occur under a wide range of circumstances, including self-injurious behaviors, suicides, domestic disputes, crime, community violence, civil unrest, political upheaval, and warfare.

War, violence, and disability have a long-standing relationship. One obvious consequence of war is death; another is injury and disability. The outcome of war-related disability was particularly evident during World War I, where an estimated 1.5 million people became disabled. Types of disabilities that were acquired included loss of limbs, blindness, deafness, traumatic brain injuries, and emotional traumas.

War holds a unique position in the disability rights movement because it helped transform attitudes toward those who are disabled. Prior to World War I, individuals with disabilities were often isolated and viewed with pity or apathy. After the war, these attitudes changed as many soldiers acquired their disability while serving their country. Upon their return from military duty, these soldiers were treated with respect by the general public. These changing norms began to influence how people with disabilities were treated in general. Disabled soldiers also brought to their home country a sense of responsibility to assist those with disabilities. In the United States, the Soldier's Rehabilitation Act and Smith-Fess Act were passed in 1918 and 1920, respectively. The Soldier's Rehabilitation Act provided vocational rehabilitation for military personnel, whereas the Smith-Fess Act did the equivalent for civilians.

In addition to warfare, civilians have acquired disabilities as a result of civil unrest and political upheaval. Such circumstances are evident throughout the world (e.g., Afghanistan, Angola, Cambodia, Ethiopia, Kosovo, Rwanda, and Vietnam). These countries have experienced years of internal political conflict, which have led to acts of violence and the disablement of thousands of civilians, including children and women. Given that these individuals typically reside in third world countries, their disabilities are often complicated by conditions of poverty and a lack of assistance and social services. During recent periods of political conflict, land mines have been used with high frequency. These weapons continue to pose a threat even after conflicts have been resolved. For example, as a result of three decades of violence related to political unrest, wars, and international border disputes, Cambodia has more than 30,000 people who have lost limbs following land mine detonation.

Spinal cord injuries as a result of violence have also risen in countries experiencing sociopolitical conflict. In the Republic of South Africa, a recent review of records from a spinal cord injury rehabilitation program indicated that gunshot wounds accounted for 36 percent of spinal cord injuries, a dramatic increase from the past. Similarly, during the 1990s, the United States experienced an extraordinarily high rate of violence-related spinal cord injuries. By 1994, violence accounted for 30 percent of new spinal cord injury cases. The United States has also experienced a rise in youth violence, with shooting sprees occurring across a variety of settings including homes, schools, and city streets.

VIOLENCE AGAINST PEOPLE WITH DISABILITIES

People with disabilities are also at a greater risk of being victims of violence and abuse compared to those without disabilities. This is particularly true for disabled women, children, and elderly persons. Historically, these three groups have been targets for abuse even when the disability status is not considered. In addition, those with disabilities that are considered severe (e.g., intellectual disabilities) are more likely to be abused than those with nonsevere disabilities. Severe disabilities can affect the person's ability to comprehend and/or report the abuse.

Prevalence and incidence rates of violence toward people with disabilities are difficult to determine because of underreporting and varying definitions for violence. Some definitions focus solely on the physical force that is exerted for the purpose of violating, damaging, or abusing. Other definitions extend beyond physical force to include verbal aggression, neglect, and financial exploitation. For the nondisabled population, 10 to 69 percent of women around the world have reported physical abuse by an intimate male partner, approximately 20 percent of women and 5 to 10 percent of men have experienced sexual abuse as children, and 4 to 6 percent of elderly individuals have experienced some form of abuse in their homes. For the disabled population, these abuse figures are even higher. For example, studies of women with intellectual disabilities have reported rates of sexual abuse from 30 to 90 percent.

A number of factors have been associated with violence, abuse, and disability. First, negative attitudes toward people with disabilities may contribute to abusive behavior. For instance, if people with disabilities are judged to be nonintelligent or weak, such beliefs may be used to justify abusive behavior. Second, when abuse occurs, social isolation among people with disabilities may affect their ability to report and/or identify the situation as abusive. Third, the nature of one's disability may pose barriers to reporting (e.g., people with speech disabilities may have difficulty reporting the abuse by telephone). Fourth, people with disabilities may be hesitant to report abuse if they depend on the abuser for care, fear retaliation from the abuser, and/or experience personal shame over the abuse.

The relationship between violence and disability is further complicated when one considers that people with disabilities can be abused in a number of settings, including their homes, schools, hospitals, residential centers, and social service agencies. Thus, potential perpetrators may include spouses, family members, friends, teachers, personal assistance providers, transportation employees, and health care workers. Such abuse is difficult to comprehend because the very individuals who are expected to provide protection and care pose a threat to those who are disabled.

Last, responses to reports of violence and abuse may vary by setting. For example, within social service settings, there may be ineffective procedures to investigate reports of violence. As a result, responses to violence and abuse may be affected by prejudiced attitudes, ignorance of proper protocol, and inadequate investigative skills. Within legal settings, police may harbor prejudiced attitudes toward persons with disabilities, which in turn may affect their investigations. In addition, the rights of people with disabilities may be impinged upon due to inaccessible courtrooms and courtroom proceedings (e.g., the lack of sign language interpreters for those with hearing disabilities during a trial; judges' reluctance to accept testimony of persons with intellectual disabilities). Because of these variables, people with disabilities may have difficulty obtaining justice, support, and other constructive organizational responses when they are violently victimized. Thus, they may be less likely to seek assistance to address instances of abuse.

PERPETUATORS OF VIOLENCE?

A third connection between violence and disability centers on how society views people with psychiatric disabilities. Historically, the general public has harbored the belief that individuals with severe psychiatric disabilities are dangerous and violent. Such perceptions are stronger today than they have been in the past and have been perpetuated by sensationalized headlines and popular media. However, such perceptions are misguided. There are three primary predictors of violence: past history of violence, drug and alcohol abuse, and a serious psychiatric disability *combined* with a failure to take medication. Individuals with severe mental illness who *are* taking their medication are no more dangerous than the general population.

Of the three predictors of violence, a past history of violence is the single most critical piece of information to examine regardless of disability status. The second important predictor is drug and alcohol abuse, and this is also true whether the person does or does not have a psychiatric disability. The third important predictor is the failure to take medication. Individuals who do not take prescribed medication for a psychiatric disability are more likely to commit violent acts than those who take their medication. Specifically, individuals with untreated schizophrenia and bipolar disorder are at risk to exhibit violent behavior.

Another possible predictor of violence is the type of delusion (or irrational belief) a person with a severe psychiatric disability is experiencing. Mental health professionals have long viewed paranoid delusions as a potential precursor of violence. However, the relationship between paranoid delusions and violence is not straightforward. For example, persons may experience delusions that they are famous. Yet this delusion is unlikely to lead to violent acts. Instead, a stronger predictor of violence is the feeling that others are out to cause physical harm, coupled with a feeling that one's mind is dominated by forces beyond one's control. An additional factor that may predict violence is *command auditory hallucinations*. Command auditory hallucinations involve voices telling an individual what to do; such voices may encourage violent behavior. In sum, the relationship between psychiatric disabilities and violence is complex, with a number of factors affecting the potential to act aggressively.

SUICIDE AND DISABILITY

The final link between violence and disability relates to suicide. The relationship between suicide (self-directed violence) and disability is twofold. First, each year approximately 800,000 people die by suicide worldwide, with the highest rates occurring in Eastern European countries and the lowest rates in Latin American countries and a few countries in Asia. Approximately, 30,000 suicides occur in the United States. Although determining the definitive causes of suicides have proven difficult, suicides in many nations are associated with mood disorders. For example, over 90 percent of suicides in the United States are associated with psychiatric disabilities (including depressive disorders, bipolar disorder, schizophrenia, personality disorders, and substance abuse disorders). Advances within psychopharmacology have helped with the treatment of psychiatric disabilities, which in turn help curb suicide ideation and behavior. However, despite medical advances, suicide remains a worldwide problem. In India and China, psychiatric disabilities are less important risk factors. For instance, cross-cultural research indicates that humiliation, shame, economic hardship, examination failure at school, and family disputes were the greatest risk factors for suicide in India.

Second, the fields of disability, medicine, and law have been divided by the issue of physician-assisted suicide. In 2001, the Netherlands became the first country to legalize such a procedure. The law allows individuals who are "suffering unbearably" with "no prospect of improvement" to end their lives, with the assistance of doctors. In the United States, Dr. Jack Kevorkian was the most vocal advocate of assisted suicide. Kevorkian assisted at least 130 individuals with ending their lives, despite legislation prohibiting such action. After much debate and controversy in the United States, physician-assisted suicide was legalized in the state of Oregon by a slim margin, with the passage of the Death with Dignity Act in 1994.

The medical and legal communities remain divided on the issue of physician-assisted suicide. Some medical and legal professionals argue that people should have the option to end severe and incurable physical pain and suffering, highlighting respect for individual autonomy. Others argue that such a legal option perpetuates the erroneous notion that people with untreatable medical conditions lead lives that are not worth living. From the start, prominent disability rights groups have opposed legalization of assisted suicide. They argue that providing such a legal option to individuals with terminal illnesses may generalize to others with treatable conditions (and people with disabilities) who are leading productive and fulfilling lives.

CONCLUSION

Violence has a clear connection to disability. This connection is evident when one considers (a) acquiring a disability through violent acts, (b) abuse and violence against people with disabilities, (c) the misguided belief that people with disabilities are perpetuators of violent behavior, and (d) self-directed violence and suicide. Given the history and extent of violence worldwide, these unfortunate trends are unlikely to dissipate in the near future. However, with the recent recognition of violence as a global public health problem by the World Health Assembly, the professional community worldwide is being urged to discuss and design prevention and intervention efforts to tackle these significant issues.

VISIBILITY AND INVISIBILITY

Some physical and mental impairments are clearly visible in the bodies and behavior of people with disabilities, while others are not. The latter are often referred to as “invisible disabilities.” The equally common expression “hidden disabilities” has been criticized for its implication that the disabled person is actively choosing to conceal his or her impairment. Within contemporary disability studies and political movements, *invisible disability* is sometimes used as an umbrella term meant to include all those who have not been represented by the first wave of activism and scholarship: people with mental illnesses, cognitive and learning disabilities, developmental disabilities, and/or chronic physical illnesses. Yet not all of those disabilities are invisible, and not all disabilities traditionally recognized as such are visible. Some of the most compelling accounts of passing as nondisabled, for example, have been written by blind people—yet blindness is not included in the “invisible” umbrella because of a long history of cultural recognition of blindness as disability. Thus, the phrase “invisible disability” carries both a literal and metaphoric meaning—literally referring to impairments that are not visible on a person’s body or behavior, and metaphorically referring to impairments that have not been well represented or recognized in the disability rights movement or scholarship. Some have advocated severing these meanings by referring to literally invisible disabilities as “nonvisible.” However, in current usage, there continues to be considerable overlap and inconsistency in the use of these terms.

People with highly visible impairments, such as amputees, wheelchair users, people with facial markings, and people of short stature, tend to share a common experience of being stared at, often in the context of being pointed out, mocked, touched without permission, or asked intrusive questions. Disability theory, thus, has been deeply concerned with analyzing and counteracting “the stare,” while disability activism has often sought to subvert or reverse this dynamic, as in the title of the 1997 anthology *Staring Back: The Disability Experience from the Inside Out.* The “hypervisibility” experienced by many people with disabilities, which continues to have a significant impact on everyday experience, employment, and relationships, has also been creatively adapted and challenged by many artists and performers with disabilities.

Many other people with disabilities exist in a fluid state of intermittent *invisibility*—as when using a prosthesis, when sitting down, when not communicating, or when taking medication that temporarily conceals an impairment, and *visibility*—as when using a cane, brace, or splint; when speaking in sign language; when asking for assistance with a specific task or activity; or when fluctuating symptoms such as a limp or tic temporarily appear. Even a person traditionally defined as visibly disabled, such as a full-time wheelchair user, can transfer to a sofa, fold her chair away, and join the ranks of the invisibly disabled for a time.

HISTORICAL BACKGROUND

Both social and medical models of disability have traditionally emphasized visible disability, while the status of invisible disability remains contested on many fronts. This emphasis on visibility is part of the overall focus on visualizing the body within Western medicine beginning in the late eighteenth century. The focus of diagnosis and treatment shifted at this time from listening to a patient's descriptions of symptoms to examining the patient's body for visible signs of disease. This shift has been translated into contemporary medicine through the distinction between "subjective" symptoms and "objective" signs, with objective signs taking precedence in determining diagnosis, treatment, accommodations, and benefits.

Historians of medicine and disability have noted that this emphasis on objectivity meant that patients were increasingly treated like objects on display. For example, by the late nineteenth century, many surgical operations in England took place in theaters observed not only by doctors but also by an audience of curious laypeople. The bodies of people with visible disabilities were of particular interest to this audience, and such institutions as the freak show and the "cabinet of oddities" became popular in both Europe and the United States. "Human curiosities" such as amputees, conjoined twins, people of small or large stature, and people with microcephaly were displayed in these settings to audiences whose sense of their own "normality" was produced and reflected through the freakishness projected on people with visible disabilities.

During the same period, Freudian psychoanalysis, with its theories of hysteria and psychosomatism, was gaining credence among a broad group of professionals, including physicians, authors, and crafters of social policy. These theories eventually produced a new explanation of invisible impairments as "all in your head," thus categorizing these impairments as both less exotic than visible ones, and also somehow less "real." In addition, the experience of invisible impairment became highly feminized at this time (such that even men with such impairments were seen as effeminate), and women's reports of their bodily experiences became subjugated to the expertise of the male medical professional. This dynamic continues in the experiences of contemporary women with invisible disabilities, as both studies and anecdotal evidence indicate that women's physical symptoms are taken less seriously and treated less aggressively than those of men and that women are much more likely than men to be referred for psychological evaluation when reporting an invisible physical symptom such as pain or fatigue.

The binary understanding of visible and invisible impairment has influenced even the contemporary social model of disability, which explicitly seeks to refute medical models. Social scientists have suggested that individuals with visible disabilities are more likely to develop a positive disability identity than are invisibly disabled people who can "pass" as normal. Scholars in the humanities have argued that disability itself is defined by a disruption in the visual field. Challenges to these claims have emerged from invisibly disabled scholars who suggest that the dynamics of visibility that oppress some people by "enfreaking" them, oppress others by "invalidating" them. Understandings of disability as "performative" and "rhetorical" are beginning to nuance the emphasis on visible disability prevalent in the first wave of British and American disability studies.

FORM VERSUS FUNCTION

Much of the cultural tension that exists around the questions of visible and invisible disabilities is based on the assumption that form reflects function. In other words, modern society has developed around the ideal that each of its citizens is able to perform in a "normal" capacity unless he or she looks somehow "abnormal." A woman who walks up to an airline counter to request a wheelchair, for example, will usually receive curious glances directed at her legs. The idea that a person can walk ten feet but not a hundred is just as foreign to modern conceptions of disability as the idea that a person can have limbs that look "normal" but do not function normally.

In contemporary systems of entitlements and access, immense suspicion exists that unethical or lazy citizens will take advantage of those systems. Thus, accusations of faking, malingering, or cheating are reported frequently by people with invisible disabilities across a broad range of impairments, including chronic physical illnesses, blindness and low vision, deafness, mental illnesses, and learning disabilities. In many cases, benefits and accommodations are denied to such people, resulting in significant social and economic disadvantage. For this reason, people with invisible impairments tend to remain more closely tied to the medical community, since they must often rely on doctor's certificates to obtain benefits and accommodations. This may be one reason why this population is perceived by some as having a less positive disability identity, according to the social model.

The assumption that form is tied to function also significantly affects people with visible disabilities, as their competence and intelligence may be challenged based on their bodily appearance or assistive devices. Many people with physical impairments that affect only certain functions can be treated as if completely incapacitated. For example, people whose legs are affected by paralysis, cerebral palsy, or multiple sclerosis report being denied driver's licenses in the United States despite their competence with hand controls. People who are nonverbal, communicate through assistive devices, or have speech impairments report being treated as "stupid," "slow," or developmentally delayed due to others' perception of their mental function as tied to their form of communication. This assumption has a serious impact on these individuals' social experience, as well as access to education and employment. Even individuals whose impairment is entirely formal with no effect on function, such as people with facial markings or skin differences, can face discrimination in these areas, thus demonstrating how issues of visibility affect all aspects of disability experience.

VISITABILITY

Unlike home modifications, where supportive features are incorporated to address residents' individual needs, visitability strives to provide a baseline level of accessibility in all new home construction, in hopes of benefiting the entire population. Therefore, *visitability* is an affordable, sustainable, and accessible design approach that targets single-family homes, the only type of housing not covered by the Fair Housing Act or any other federal or state legislation. Originating in Europe, the visitability movement was initiated in the United States in 1986 by Eleanor Smith, a disability rights advocate, and her group Concrete Change. Smith initially used the term *basic home access*, but in 1990 adopted the word *visitability*. Her ultimate goal is to make all new homes not covered by current access regulations "accessible enough" for a visitor with a disability. Thus, a visitable home is not necessarily intended to have a level of accessibility needed by a person with a disability. It is intended to be a residence for *anyone* and to provide access to *everyone*.

THREE PRINCIPLES OF VISITABILITY

There are three fundamental principles of visitability. First, visitability is based on the idea that inclusion of basic architectural access features in all new homes is a civil right and improves every person's ability to live productively and comfortably. People with disabilities should be able to visit their neighbors for mutual assistance, friendship formation, and child care. In most neighborhoods, however, a major barrier to social participation for individuals with disabilities is the lack of opportunity to visit other homes. When only a few houses have full access, people with mobility impairments are confined to their homes for socialization in the neighborhood and segregated from others; when people develop impairments, they must find new places to live or wait for expensive renovations; and when accessible entrances, in particular, are built as renovations, the results are often awkward solutions that reinforce the stereotypes and stigmas often associated with disabilities and accessibility. In response to these circumstances, visitability strives to create an opportunity for all neighbors in a community to socialize, help each other, and interact more effectively. It attempts to break down attitudinal as well as physical barriers to social integration of people with disabilities.

Second, visitability rests on the notion that, through good design, basic accessibility to single-family housing can be provided in most cases with minimal financial cost. The design philosophy contends that access is cost-effective if planned in advance. Incorporating accessible architecture features into housing designs during the early stages of development and before construction remains affordable. Although only a limited number of studies actually have analyzed the specific costs associated with visitability, these studies agree that introducing visitability through retrofitting results in significantly higher costs.

The third principle of visitability suggests that simplicity promotes implementation. Prioritizing access features ensures that the supply of accessible homes will increase more rapidly. Visitability advocates argue that a long list of demands can create the misconception that all access features are equally urgent and therefore must all be included in a home. Many builders and designers may currently perceive this as too difficult to even attempt. However, visitability advocates argue that not everything is of equal urgency. Some access features are more important than others in helping individuals visit with their neighbors.

VISITABILITY AS AN INNOVATION

Visitability's simplicity as a means to promote adoption is compatible with lessons learned from the study of innovation and its diffusion. Everett Rodgers (2002) defines *innovation* as "anything perceived to be new." He argues that it is not the reality that matters but the perception. Although visitability may not require new technology or look radically different, if it is *perceived* as something new, individuals will respond to it as if it *were* new. Because visitability is a new concept to most people, they consider it innovative. Therefore, those who wish to promote visitability need to understand the components of the innovation-decision process. According to Rodgers (2002), "The innovation-decision process is the process though which an individual (or other decision-making unit) passes from first knowledge of an innovation, to the formation of an attitude toward the innovation, to a decision to adopt or reject, to implementation and use of the new idea, and to confirmation of this decision" (p. 216). Rodgers proposes that the adoption of an innovation is a cyclical decision-making process with five activities: obtain knowledge, persuasion of the key decision makers, decision to act on the new idea, implementation, and confirmation.

Moreover, Rodgers argues that the pace of innovation adoption varies greatly. According to him, there are five attributes of innovation that enhance its adoption or diffusion rate: *relative advantage,* in which the diffusion rate is enhanced if there is a clear financial or social advantage for the new idea as compared to the idea or product it would supersede; *compatibility,* whereby if the innovation is congruent with current values, experiences, or needs, its rate of adoption will be faster; *trialability,* an innovation will be adopted more rapidly if it can be experimented with at relatively low cost of time, money, and commitment; *observability,* where the more an innovation is visible to others, the higher its rate of adoption will be; and finally, research by Rodgers's and others discovered that the pace of an innovation is affected by its *complexity*—the more an innovation is perceived to be relatively easy to understand and use, the higher the expected adoption rate (Rogers 2002:223–259).

This last characteristic specifically applies to visitability. In keeping with Rodgers's theory that simplicity promotes implementation, a visitable home is one that meets only three conditions: one zero-step entrance, doorways that are 32 inches wide, and basic access to at least a half bath on the main floor. These three features are considered the most essential for a person with mobility impairments to visit or live in a home, at least temporarily. In response to criticism that these three features are insufficient, Eleanor Smith argues, "What I'm after here is radically changing the way all new houses are built . . . and if you're going to do that, you can't have a long list of demands"

(Truesdale and Steinfeld 2002:3). Visitability advocates believe that once builders learn that visitability is easy to achieve and they receive positive confirmation through sales and consumer acceptance, they will be more likely to expand the list of universal design features they include in the next generation of housing.

VISITABILITY AND NEIGHBORHOODS

Along with individual single-family homes, many advocates and researchers view visitability as a major step toward achieving universal design on a neighborhood level. In acknowledging the valuable role of visitability in developing active communities, Truesdale and Steinfeld (2002) contend that

> visitability, although less than the ideal of a universally designed home, is actually universal design practiced through community and neighborhood planning. It ensures that a basic level of accessibility will be provided in all housing and it opens opportunities for participation in community life. (pp. 7–8)

Visitability provides benefits to a wide range of users, including those with disabilities, their nuclear families, friends, and other relatives who may, from time to time, need to use wheelchairs or other adaptive equipment. Consequently, rather than forcing individuals to remain isolated and confined to their personal surroundings, visitability allows individuals with a variety of abilities to interact with each other and participate in community activities outside of their homes.

THE VISITABILITY MOVEMENT

Recognizing the benefits and growing need for more accessible housing, many state and local jurisdictions have joined the visitability movement. In fact, several municipalities and states across the country have already formalized and enacted visitability programs. Despite their common goal of increasing the supply of accessible housing, these visitability programs vary significantly. The three primary ways they tend to differ are the geographic regions they cover, the scope of features they include, and the strategy by which they are implemented and enforced. For instance, some visitability programs cover housing within an entire state, while others only have jurisdiction over cities and/or counties. In addition, some programs strictly adhere to the three basic accessible features (stepless entrance, wider doorways and hallways, and a half bathroom on the main floor), while others include additional architectural elements such as lever handles, blocking for grab bars in bathroom walls, and accessible environmental controls.

Visitability programs also vary in how they are enforced. Some visitability initiatives are mandatory, whereby builders and homeowners are required by a law or ordinance to include the three visitable features during new construction, while other programs are voluntary. With voluntary programs, builders and consumers are encouraged to include the visitability features (stepless entrance, wider doorways and hallways, and basic access to a half bath on the ground floor), but they are not obligated to do so. There are additional variations within mandatory and voluntary programs. Although the majority of mandatory initiatives apply only to homes built with public funds, a few of these programs apply to both public and private homes. Moreover, with respect to voluntary programs, some programs offer monetary incentives while others involve certification or public awareness campaigns.

Whereas most visitability initiatives specifically apply to new housing, initiatives in all three types of jurisdictions (state, county, and city) do not preclude coverage of substantial renovations and retrofits in their respective guidelines. Incorporating renovations in visitability programs extends the housing market affected by the program to include existing homes. Although this expands the opportunity to increase the supply of accessible housing, it also could retard the advancement of the visitability movement. Encouraging consumers and builders to incorporate accessibility features after initial construction results in higher costs and ultimately reinforces the common misconception that visitability demands substantial spending.

Besides the more than 40 mandatory and voluntary programs already in place, there are numerous efforts to establish visitability programs in other states, counties, and cities across the country. Recent research identified 12 state and 15 local initiatives currently under way (Maisel 2004). While the final outcomes of these initiatives remain uncertain, their emergence symbolizes a growing interest in incorporating more accessibility elements in both public and private housing.

VOCATIONAL REHABILITATION

Vocational rehabilitation (VR) is practiced by rehabilitation counselors employed by the state-federal system, business and industry, insurance companies, and private agencies. The purpose of VR is to enable individuals with disabilities to acquire, resume, or maintain employment, an outcome that is in some way affected by a physical, intellectual, or emotional condition limiting one or more life functions. Rehabilitation counselors assist people in achieving their vocational goals by providing counseling, guidance, and placement services and by arranging for medical, accommodation, and assistive technology services.

Important emphases in the history of VR include vocational training, a civilian program based on eligibility criteria, professionalism, and civil rights. Historians trace the emphasis on vocational training to the industrialization of America. As were all citizens, people with disabilities were poorly prepared for roles in this new industrial society. After considerable political debate, the state-federal VR system emerged as a means for helping people with disabilities become employed following counseling, guidance, and vocational training services.

The state-federal VR system is a major provider of VR services to eligible individuals. Eligibility criteria include the presence of a disability and the presumption of benefit. Although these criteria have not always been applied in an equitable manner, the intention to do so is a strong force motivating the practices of the state-federal VR system.

The commitment to quality services is nowhere more evident than in the growing professionalism in VR. A *qualified provider* of VR services holds both a master's degree in rehabilitation and certification as a rehabilitation counselor (CRC). VR counselors complete a rigorous curriculum, receiving training in medical and psychological aspects of disability, vocational evaluation, independent living, placement, rehabilitation research, counseling, and multicultural/gender issues.

Given the breadth of their training, VR counselors are well prepared to serve individuals with severe disabilities. The theme of severe disability is another important "defining moment" for VR. It is reflected in (a) early legislative commitments to serve people with physical disabilities who wanted to return to work, (b) later legislation that included services for physical restoration and for people with psychiatric and mental retardation diagnoses, (c) emphases in the Rehabilitation Act of 1973 on serving people with severe disabilities, and (d) order of selection priorities in the state-federal system to serve people with the most severe disabilities first.

For a time in VR, the concept of severe disability was viewed primarily from a medical/economic model. The dominant service mode involved medical services to "fix" the person so that he or she could return to a job consistent with residual capacities. Income maintenance via Social Security's disability program represented the only other alternative. Reactions to the medical/economic model and to discriminatory practices eventually gave rise to assertion of civil rights by people with disabilities. Assertion of civil rights in response to paternalistic treatment provided the foundation for the Americans with Disabilities Act (ADA) with its hiring and accommodation protections. It gave rise to a new respect for people with disabilities as individuals with rights to participation and informed choice. It gave rise to consumer protection via Client Assistance Projects (CAPs). It gave rise to an acknowledgment of the importance of multicultural/gender issues and to the need for counselor sensitivity to the impact that these differences have on VR outcomes.

In conclusion, VR is about people and their desires to become and/or remain productive citizens. VR interventions involving vocational evaluation, vocational planning, physical and psychological restoration, and placement have become more comprehensive and professional. They have focused increasingly on meeting the vocational needs of those with the most severe disabilities. Finally, they have become more and more reflective of the agendas of those seeking services, rather than of those providing services.

VOCATIONAL REHABILITATION: LAW AND POLICY

Vocational rehabilitation (VR) is a process that enables individuals with disabilities to secure, retain, and advance in suitable employment and thereby further their integration or reintegration into society. Services to individuals with disabilities with a vocational or employment emphasis began before the turn of the twentieth century. They were often custodial in nature, and provided in the context of a caretaking role, thereby promoting segregation and exclusion from mainstream activities, including employment. The early perception of people with disabilities as subjects of health, welfare, and charity programs began to be seriously questioned in the early 1900s. Legislatively mandated changes began to occur around the time of World War I. These changes were initially spurred both by the need to train individuals for technical war occupations and replace workers called to fight in World War I, and later the need to return veterans to civilian careers.

Since then, a string of related legislation has added new services and new populations for coverage. A parallel development of services simultaneously occurred in other industrialized countries. Increasingly over the past century, we have moved to a model that highlights independence, equality of opportunity, recognition of unique talents and contribution, environmental and attitudinal barriers to success, and rights-based approaches that contribute to overcoming these barriers, such as workplace accommodation.

Modern VR policies grew out of the feeling that the federal government had an obligation to those who were wounded and became disabled in defense of their country. In 1918, the Veterans Rehabilitation Act (P.L. 65–178) was passed, authorizing VR services for World War I veterans. Services would be provided by the states, supported by federal grant money. Civilians with disabilities were excluded from receiving services under this act, but were provided for in 1920 with the beginnings of the civilian VR program (Smith-Fess Act, P.L. 66–236).

Parallel legislative developments were evolving at this time in other parts of the industrialized world. In Great Britain, the aftercare of disabled soldiers and sailors moved from being one principally of private initiative and financial support pre–World War I to a state matter with the Military and Naval War Pensions Act in 1915. Germany was in a better position than many countries to deal with the issue of VR, although VR was similarly the province of private charity or individual states pre–World War I. Germany was a leader in orthopedic surgery and rehabilitation and therefore had a well-developed network of disability centers, many of which had workshops teaching a variety of trades.

In the United States, the Social Security Act of 1934 (P.L. 74–271) established state-federal VR as a permanent program that could be discontinued only by an act of Congress. This action, however, did not guarantee continuing congressional appropriations. In 1943, the Barden-LaFollette Act (P.L. 78–113) broadened eligibility for rehabilitation services to include people with mental illness and retardation. *Vocational rehabilitation services* were defined as "any services necessary to render a disabled individual fit to engage in a remunerative occupation." This act also brought services for the blind under the umbrella of the state-federal VR support system, where previously they had been handled solely at the state level by state commissions for the blind.

In the post–World War II environment, the growth of VR slowed somewhat. The program was underpublicized and suffered from a lack of finances and of qualified rehabilitation professionals. The Vocational Rehabilitation Act Amendments of 1954 (the Hill-Burton Act, P.L. 83–565) began a new era for rehabilitation. This act provided funding to colleges and universities for the preparation of rehabilitation professionals and expanded services to people with mental illness or mental retardation. It provided funds for the expansion of rehabilitation facilities, extension and improvement of state agencies, and research and demonstration programs. Further amendments during President Lyndon Johnson's War on Poverty in the 1960s expanded programs, provided more federal funding to the states, and allowed states more flexibility in setting up rehabilitation agencies. In a parallel international effort, the International Labour Organization (ILO) Vocational Rehabilitation (Disabled) Recommendation No. 99 was adopted in 1955. This international instrument served as the basis for all national legislation and practice concerning vocational guidance, vocational training, and placement for persons with disabilities.

The next major piece of U.S. legislation affecting rehabilitation was the Rehabilitation Act of 1973 (P.L. 83–112). It introduced the Individualized Written Rehabilitation Program (IWRP) and postemployment services, made provision of services to people with severe handicaps a first priority, and provided special consideration for public safety officers injured in the line of duty. It authorized demonstration projects for independent living, established client assistance pilot projects, and mandated consumer involvement in state agency policy development. It also initiated the first legislation to prohibit discrimination in employment on the basis of disability and to provide access to federally funded programs for persons with disabilities. Subsequent amendments to the Rehabilitation Act have expanded and strengthened services for blindness and deafness and have added support for supported employment as a goal. Consumer empowerment was advanced in 1992 when consumer-controlled State Rehabilitation Advisory Councils were established and clients were given increased choice of employment objectives, providers, and services. In 1983, the ILO adopted the Vocational Rehabilitation and Employment (Disabled Persons) Convention No. 159, requiring member states to formulate national policies on VR.

Most recently, the Workforce Investment Act of 1998 (WIA) (P.L. 105–220) included amendments to the Rehabilitation Act. WIA changed the name of the IWRP to the Individualized Plan for Employment (IPE) and enhanced the collaborative relationship between the consumer and counselor, increased consumer control so customers could develop their own plans, stressed the concept of "presumptive eligibility" for Social Security Disability Insurance (SSDI) beneficiaries and Supplemental Security Insurance (SSI) recipients, expanded access to services promoting linkages with One-Stop Centers and other programs. VR services were expanded to include technical assistance for individuals to pursue self-employment, telecommuting, or small business operation as well.

The evolution in VR legislative and service structure changes over the past century reflects increasing sophistication and advances in medical and technological sciences. Even more profoundly, it represents a change in philosophy toward persons with disabilities. Twenty-first-century models of VR include recognition of the inherent worth of all individuals, including individuals with disabilities, in contributing to society and to the productivity of a national economy. This has changed how we interact with individuals with disabilities in service provision, from a patronizing and caretaking posture to one that is client driven, consumer focused, and personally empowering. This evolution in the way we prepare for, attach to, and advance individuals with disabilities in work has led a push toward quality, integrated, and paid employment. This movement was further supported by other federal laws, policies, and court actions, including the 1999 *Olmstead* decision, the Americans with Disabilities Act of 1990, further reauthorizations of the Rehabilitation Act of 1973, the Individuals with Disabilities Education Act of 1990, and the Ticket to Work and Work Incentives Improvement Act.

As segregated programming options decrease and integrated employment opportunities expand, person-centered planning, self-determination, and consumer-directed services and supports lead the way. As a result of these developments and a paradigm shift in the way we prepare people for work, individuals with disabilities have greater access to competitive and integrated work environments.

Looking forward, there are several significant trends emerging in VR practice. There is increasing recognition that VR services must be provided in a career development context if successful employment outcomes for people with disabilities are to be realized. Therefore, the role of VR counselors must move beyond just initial training and job placement, and include helping people maintain employment and advance in their careers, including home-based small businesses. Populations the VR process is being applied to are also changing, including people with hidden disabling conditions such as mental illness, diabetes, multiple sclerosis, cancer, HIV/AIDS, fibromyalgia, and heart disease, as well as people with age-related conditions such as arthritis and vision, hearing, and orthopedic-related impairments. There also must be an increasing emphasis on providing consultative services to employers and attention to interpersonal and organizational factors that contribute to long-term vocational success.

The contemporary VR process necessitates knowledge and use of workplace supports and accommodations, workplace disability management, and innovative strategies for building partnerships with employers. In addition, VR practitioners must increasingly be aware of the dynamic workplace ecology factors that shape the attitudes and behaviors of coworkers and supervisors toward workers with disabilities.

▣ VOCATIONAL REHABILITATION ACT (UNITED STATES)

See Rehabilitation Act of 1973 (United States)

▣ VOTING

People with disabilities have made tremendous political strides over the past few decades, most notably with the passage of the Americans with Disabilities Act (ADA) in 1990. Despite these policy gains, however, recent research suggests that the voice of people with disabilities in American electoral politics is faint. Several studies over the 1992–2000 period showed that voter turnout was 6 to 21 points lower among people with disabilities and was especially low among people with disabilities who are older, nonemployed, or have difficulty in going outside alone.

Voter turnout is the most basic form of political participation in a representative democracy. The turnout of people with disabilities can be important for electoral outcomes and politicians' attention to disability issues. Voting may also have important personal and social effects for individuals with disabilities, affirming their equality as citizens and integration into mainstream society and increasing perceived personal efficacy.

The factors affecting political participation can be divided into three categories: resources ("Are you able to participate?"), psychology ("Do you want to participate?"), and recruitment ("Did anyone ask you to participate?"). Resources include time, money, and civic skills; psychological factors include political interest, civic values,

Table 1 Studies of Voter Turnout (in percentages)

Election Year	*Disability Sample*	*Disability Turnout*	*Nondisability Turnout*	*Gap*
1. 1992	People with SCIs	56	71	15
2. 1994	Nonemployed	33	54	21
3. 1992–1996	Nonemployed	57	71	14
4. 1996	Nonemployed	44	65	21
5. 1996	Disability households	33	49	16
6. 1998	Broad disability sample	54	60	6
7. 2000	Broad disability sample	70	82	12

Note: SCIs = spinal cord injuries.

efficacy, group consciousness, and commitment to specific policies; and political recruitment occurs through formal and informal networks (e.g., work or voluntary organizations). Research on the general population demonstrates that factors in each of these categories strongly influence the likelihood of voting.

Disability can affect voter turnout in a number of ways. Limited resources can depress voter turnout among people with disabilities. They have lower average income and education levels than people without disabilities, and their financial resources are often further constrained by higher expenses for medical care and special equipment. Political recruitment among people with disabilities is limited by their relative isolation. They are more likely than people without disabilities to live alone and face transportation problems, and they are less likely to be involved in community and social activities. Physical isolation can be exacerbated by discriminatory practices such as states' disenfranchisement of some individuals with disabilities, frequent neglect of candidates and parties to recruit people with disabilities, and negative messages about disability conveyed through public policy.

In addition, the psychological effects of living with a disability can be important. The stigma and discrimination faced by many people with disabilities may combine with isolation and diminished resources to decrease feelings of personal efficacy and control, and in turn depress voter turnout. The stigma attached to disability, however, may motivate some individuals to engage in political action, as shown by the growth of the disability rights movement.

EVIDENCE ON VOTER TURNOUT

Voter turnout is generally lower among people with disabilities, as shown in seven studies summarized in Table 1. These seven data sources use very different samples. The first is based on a survey of New Jersey residents with spinal cord injuries (SCIs); the next three are based on nonemployed respondents to national surveys who answered an employment question by saying they have a disability; the fifth is based on a national survey of respondents who said that someone in the household has a disability (although the respondent may not have had a disability); and the final two are based on broader samples of people with disabilities (identified by questions based on the 2000 U.S. Census).

Despite important differences in the samples and disability measures, the results consistently show lower voter turnout among people with disabilities. The first five indicate gaps in the range of 14 to 21 percentage points, while the final two (using broader samples) show gaps of 6 and 12 percentage points. The smaller gaps in the last two samples, which are more representative of the full disability population, reflect a higher proportion of senior citizens, who are generally more likely to vote. After adjusting for differences in age and other demographic characteristics, people with disabilities were found to be 20 percentage points less likely to have voted in 1998. These estimated gaps are large in a practical sense: Based on the 2000 election study, if people with disabilities had voted at the same rate as those without disabilities, there would have been an additional 3.2 million voters in 2000.

The above studies are based on data from the United States. Electoral participation of people with disabilities has become a salient issue in a number of other countries, where there have been a variety of initiatives to decrease the barriers they face in voting. These efforts indicate that people with disabilities are less likely to vote in many countries, but systematic comparisons of turnout are not available outside of the United States.

Absentee voting can be an attractive alternative for people with mobility impairments or other transportation difficulties. Four of these U.S. voting studies indicate that absentee voting is higher among people with disabilities, particularly for those with mobility impairments. Voters with SCIs in 1992 were five times as likely as voters in the general population to vote by absentee ballot (35 vs. 7 percent), while other samples show that voters with disabilities were about twice as likely as those without disabilities to vote by absentee ballot (13 vs. 7 percent in 1994, 14 vs. 8 percent in 1998, and 20 vs. 11 percent in 2000).

TURNOUT PATTERNS AND POSSIBLE EXPLANATIONS

Several studies indicate that turnout continues to be lower on average for people with disabilities even after controlling for a variety of demographic and economic characteristics, but the size of the voting gap varies along several dimensions—particularly age. While voter turnout increases strongly with age in the general population, it rises only weakly with age in the disability population. The result is that voter turnout is slightly depressed among young people with disabilities and much more strongly depressed among senior citizens with disabilities (e.g., in 1998 the turnout gap between people with and without disabilities was less than 10 percentage points among people under age 45, but 30 points among people age 65 or older).

In addition, employment appears to be important: The 1992, 1994, and 1998 election studies found lower turnout among nonemployed people with disabilities, but the 1992 and 1998 studies found that turnout was almost identical between employed working-age people with and without disabilities. Employment may raise voter turnout among people with disabilities due to resource effects (such as higher income), recruitment effects (through increased social contacts at work), psychological effects (such as increased identification with mainstream society and an increased sense of efficacy and interest in public issues), and other reasons. The voting gap is reduced but still exists after controlling for several income, recruitment, and psychological variables in the 1998 study, indicating that the role of employment requires further investigation.

Mobility problems also appear to contribute to the low turnout of people with disabilities. Turnout in 1998 and 2000 was lowest among people who reported difficulty going outside their homes alone. Also, the 1992 and 1998 election studies found that 30 percent of people with disabilities were not able to drive, and voter turnout was 15 to 20 percentage points lower among this group (after controlling for other personal characteristics). Voting clearly does not depend on being able to go outside alone (since one can vote by absentee ballot, or be taken to the polling place by others), suggesting that greater ease of mobility may have important social and psychological effects through increased interaction, feelings of efficacy, and identification with mainstream society.

Turnout of people with disabilities may be discouraged by problems in getting to or using polling places. A 2001 study by the General Accounting Office found that only 16 percent of polling places in 2000 had no potential impediments to access by people with disabilities. In the 2000 election survey, 6 percent of people with disabilities who had voted in the past 10 years reported encountering problems in voting at a polling place, while one-third (33 percent) of all others with disabilities said they would expect problems, compared to only 2 percent of people without disabilities. Based on these figures, an estimated 3.0 million citizens with disabilities either encountered or would expect to encounter difficulties in voting at a polling place. Reported problems include difficulty in getting to or inside the polling place, difficulty once inside the polling place, and general mobility limitations. Inaccessible polling places, apart from the practical difficulties they present, may make people with disabilities feel like second-class citizens who are not fully welcome in the political sphere.

Direct measures of recruitment are available in the 1992–1996, 1998, and 2000 election studies, where people were asked whether they had been contacted or otherwise encouraged to vote by a political party or anyone else. While recruitment is a strong predictor of voter turnout in general, and people with disabilities had fewer such contacts, this accounted for little of their lower turnout.

Psychological factors have been directly examined in several studies. One finding from a 1987 Harris poll indicated that interest in politics is a strong predictor of turnout among people with disabilities, similar to the general population. Feelings of political efficacy—that one is qualified to participate in politics and that the political system is responsive to individuals like oneself—are lower on average among people with disabilities. Regardless, this accounts for only a small part of the turnout gap between people with and without disabilities. The perception that people with disabilities are a minority group was linked to lower voter turnout among people with disabilities in 1984 but not in 1986. Finally, voter turnout in 1998 was especially low among those who had recent onset of disability, suggesting there are psychological effects of learning to live with a disability. These results indicate that psychological factors are important in voter turnout among people with disabilities but do not point to factors that fully explain the turnout gap.

INCREASING VOTER REGISTRATION AND TURNOUT

The voter turnout gap associated with disability is also reflected in voter registration rates: Only 62 percent of citizens with disabilities were registered to vote in 1996, compared to 78 percent of citizens without disabilities. This raises the question of whether people with disabilities face special barriers to registration.

In an effort to decrease barriers to voter registration, the National Voter Registration Act (NVRA) was passed and signed into law in 1993. The NVRA is often called the "Motor Voter Act" because it mandates that citizens be given an opportunity to register at motor vehicle agencies when their driver's licenses are obtained or renewed. More broadly, the NVRA requires states to offer voter registration in conjunction with any business at public service or assistance agencies as well as at offices providing state-funded programs for people with disabilities. In addition, states must provide for mail-in registration procedures, which can be especially helpful to people with mobility limitations.

The NVRA went into effect on January 1, 1995, but full implementation was delayed by the requirement for costly computerized communications between election officials at the state and national levels, and legal challenges by several states. Even in 2000, a survey showed that many agencies were not aware of their NVRA responsibilities. Some states had already implemented similar provisions by the time of the 1994 elections, but those changes did not substantially increase the turnout of nonemployed people with disabilities in that year; also, in 1998 and 2000, only 1 percent of people with disabilities who were registered since the NVRA took effect had done so at a disability or other social service agency. So far, the ability of NVRA reforms to increase voter turnout has been limited, but several studies suggest that registration among relatively uninvolved groups, such as African Americans and young people, has increased. Whether these newly registered citizens capitalize on their eligibility to vote may depend on other factors such as recruitment efforts and the salience of campaign issues.

New computer technologies have expanded the options for accommodating voters with disabilities. The Help America Vote Act (HAVA), passed in 2002, encourages adoption of these technologies, requiring each polling place to have at least one fully accessible voting system by January 1, 2006. In addition, HAVA promotes election access by requiring that each state allow electronic voter registration at disability agencies, all voting-related materials are available in alternative formats, and poll workers are provided disability etiquette training. The implementation and effects of HAVA remain to be seen.

CONCLUSION

In sum, voter turnout is lower among people with disabilities than among the general population. The research has identified several reasons but has not been able to fully explain this gap, indicating that there is still much to learn. While existing research provides only limited insights, it seems likely that both individual and contextual factors—including accessibility problems, legal and policy barriers to participation, and the marginalizing effects of disability policy—play a role in depressing voter turnout among people with disabilities. Policies such as HAVA, aggressive enforcement of polling place accessibility, and increased voter recruitment among people with disabilities could make an important difference.

Higher voter turnout among people with disabilities—which could raise the number of voters in U.S. elections by up to 3.2 million—could have a major impact on electoral outcomes. Such increased turnout could reshape the political landscape, increase the responsiveness of public officials to disability issues, and further contribute to the personal and social empowerment of people with disabilities by affirming their equality and rights as citizens.

VYGOTSKY, LEV SEMYONOVICH (1896–1934)

Russian psychologist

Lev Semyonovich Vygotsky was born in 1896 in Orsha, Belorussia. He was a clinical psychologist, researcher, and theoretician, developing an avant garde approach to disability (defectology, or the general science of deficiency) that grouped together neurobiological, psychological, social, and educational aspects. By bringing new blood to special education, this new science led to the creation of several institutes in Eastern Europe, including Moscow's Institute of Defectology, which Vygotsky directed from 1929 to his death in 1934. He left behind numerous writings, which, under Stalin, took some time to reach Western countries.

Unlike his Western contemporaries, whose conception of disability he found to be negative, static, and too focused on the disabilities themselves, Vygotsky offered a dynamic and multidimensional model of the development of nondisabled and disabled children. The disability may be put to positive use by stimulating compensatory processes that allow development to take new paths. The dynamic forces of compensation, enabled through the flexibility of psychic functions, also require mediation of the sociocultural environment. Indeed, it is the interactions of living with others that form the substrate of development. A disabled child who lacks a sufficiently positive social environment, or who benefits from such an environment too late in life, will encounter greater difficulties.

The richness of this socioconstructivist approach to development has inspired new generations of research in the fields of disability and special education.

▣ WAR

Except perhaps for the grinding, daily toll of industrial accidents in modern societies during the last two centuries, there has been no more constant a source of disability, whether due to injury or to chronic illness, than war, one of the oldest of human practices. Although this fact is widely acknowledged, it is largely underanalyzed. In the case of both civilians and members of armed forces disabled as a consequence of war, there has been an evident reluctance to come to terms with the price that military conflict has exacted on the bodies and minds of both participants and bystanders. Within the context of that neglect, however, governments, researchers and scholars, and the general public have paid much more attention to the male disabled veterans of military service in conventional, national armed forces than to civilians disabled by war. (We know much less about the historical treatment of disabled veterans in non-Western countries and about those male and female alike who served in unconventional military forces, such as guerilla armies.) Even then, the intensity of this emotional and material generosity shown toward the Western male disabled military veteran has generally declined with time after the war in which the veteran was disabled.

In contrast to disabled veterans, the bystander is not easily assimilated into the romanticized and heroic depictions of warriors that form part, although by no means all, of the representation of those disabled in war, and that provide some of the luster by which wars seem at some emotional and ideological level more acceptable. Relatedly, more resources and energy have been devoted to providing medical, rehabilitation, and reintegration services, including pensions, for disabled military veterans than for civilian war victims. Although disabled military veterans have been pioneers on the frontiers of the welfare state, such that the programs created for them and the methods of organizing assistance by states have later been applied to the general disabled population, there remains in most societies an abiding gap between the social provisioning of the two disabled populations, greatly favoring the veterans. Yet, even the disabled veteran of military service has been a neglected figure in the writing of history and official memories of war. Civilization may indeed require a short memory if it is willing to engage in large-scale violent conflict to resolve its problems. Consequently, we have a subject riddled with gaps and difficulties.

THE DISABLING OF CIVILIANS

Evidence of impairment due to war is at least as old as the narratives of antiquity, but it has grown enormously in modern times. In the more distant past, the lack of highly destructive technology probably limited the number of war victims, while the poor state of medical care doomed large numbers of the injured and ill to a relatively quick death. War-related disability, moreover, could be claimed as one source of misery among many that doomed people to short, unhealthy, and impaired lives. In the modern era, the violence of warfare has spread outward into ever-larger populations, especially because of strategic aerial bombing, which has never been—and probably will never be—precise enough to avoid claiming large numbers of innocents as well as combatants. At the same time, however, medical therapeutics and rehabilitation techniques have become more effective at saving and reclaiming lives, so the number of survivors has grown alongside the number of victims. Yet, in the midst of such trends, the various difficulties, whether moral, psychological, or evidentiary, of coming to terms with the numbers and conditions of civilian victims continue.

To some extent, the problem of neglect is wrapped up in the dense moral fog that surrounds war itself. The calculus of victimology exerts endless pressure on the process of making sense of the consequences of war, as loser and winner contest their claims to both virtue and unjust suffering. World War II provides an illustration of this. The world waited almost 60 years for a study of the lethal and decisive Allied bombing of German cities and towns that concentrated not, as in British and American studies, on the strategy and logistics of aerial campaigns, but on their terrible human consequences. A sustained discussion was certainly needed because while on the official level it was stated that the targets were war industries and military concentration, it was well understood that the bombings were rarely precise and thus, in effect, targeted the civilian population. When that study was finally conducted, it was quite logically written by a German historian, Jorg Friedrich. However, every step of Friedrich's interpretive process, from his estimate of civilian casualties to his effort to establish a moral context for evaluating crimes against the noncombatant German citizens, was littered with the question of German guilt—for beginning the European war, for an especially lethal style of warfare that often targeted civilians, and for the Holocaust. It could hardly be claimed that Hitler's Luftwaffe, and toward the end of the war V-1 "buzz bombs" and V-2 rockets, failed to take their own lethal toll on British urban dwellers. Friedrich's claims that Winston Churchill, an uncompromising exponent of the strategy of aerial assault on urban centers, was a war criminal certainly rang hollow in the United Kingdom and elsewhere.

The same remorseless moral logic has characterized evaluation of the lethal World War II aerial campaigns over Japan, another aggressor nation brutal in the treatment of its adversaries, civilian and military alike, and responsible for the devastating surprise attack on Pearl Harbor that dragged a reluctant United States into war. Even such conventional assaults, comparable to similar raids over Germany in terrorizing civilian populations, as the devastating fire bombing of Tokyo in 1945 that is considered to have killed at least 87,000 civilians and injured 41,000, were dwarfed by the consequences of the deployment of the two atomic bombs in August 1945. There were perhaps 200,000 deaths in Hiroshima and Nagasaki attributable to the blasts by early November 1945. The majority of the dead and injured were civilians. The uniquely alarming injuries sustained by the *hibakusha* (A-bomb survivors), especially those tens of thousands exposed to radiation, have been well known since the immediate aftermath of the war. Their ranks included not only Japanese civilians but also Korean, Chinese, and other Asian forced laborers who were brought to Japan to work in war industries. Fetuses exposed to radiation in the womb were born with severe mental and physical impairments, and severely burned individuals, including most evidently those who were facially disfigured, were seen everywhere on the streets of Hiroshima and Nagasaki.

Americans have never been comfortable with sorting out the human consequences of the atomic bombs. During the occupation of Japan until April 1952, the American victors restricted research and publicity about radiation disease and other consequences of the bombs. The visit to the United States of 25 severely burned and facially disfigured young women, the so-called "Hiroshima maidens," for treatment marked not only a recognition of the civilian victims but a low-intensity, largely private effort to come to terms with the moral problem of these civilian casualties. Organizers of the visit included the Japanese Hiroshima Peace Center, American Quakers, Norman Cousins (the editor of the mass circulation weekly *Saturday Review*), and surgeons at New York's Mt. Sinai Hospital, with the cooperation of the American government, which provided air transportation for the women.

Such private efforts stopped well short of a formal acknowledgment of the toll the atomic bombs took on civilian lives. There is still resistance to such a national accounting. A major debate erupted in the United States as the 50th anniversary of the deployment of the bombs approached. The Smithsonian Institution, in planning for the commemoration of the bombings, stated that it would evaluate the necessity of the bombs and their human consequences and their role in bringing a speedy end to the Asian conflict. Veterans and patriotic groups and conservative politicians and journalists, angered by the seemingly moral equivalence being established between Japan and the United States, combined to create a storm of controversy over any effort to represent the larger issues presented by civilian targets and casualties, and they were successful in scaling back the goals of the exhibit.

Amid such ideological and partisan pressures and the general denial that surrounds the subject of civilian victims of modern warfare, it is perhaps to be expected that what has been done to help them has largely gone unheralded and unanalyzed, especially in nations suffering defeat, and has been done within budgetary constraints that were often tighter for civilian than military war victim programs. Following the two world wars, the spread of rehabilitation facilities and the creation of disability pension schemes served European civilians and military veterans. The programs bore the mark of specific historical circumstances, national traditions, and the qualities of national political leadership, as the examples of post–World War II Britain and Germany suggest. Because British industrial and agricultural workers had been drafted into their jobs and subject to injury, not only in war work but like other civilians in bombing raids, extending to them the same vocational rehabilitation programs created for disabled military veterans seemed just to both planners and the general population, especially in the context of Britain's emergent postwar social democratic mood. The Allies sought to install this sort of program in defeated Germany, but for rather different reasons. To combat militarism, at first the Allies insisted that there be no separate benefit system for disabled German veterans, whose needs the occupiers assimilated into the civilian disability system, then composed heavily of war victims. Because of a continuing national pride in the armed forces and feelings of obligation to those who had fought for their fatherland, even in the face of defeat and the taint of Nazism, the policy was so unpopular among Germans that it threatened to hinder efforts to win over the population in the emerging Cold War rivalry with the Soviet Union, and was gradually compromised. When Germans in the Western zone were allowed to govern themselves in 1949, the new government's first important accomplishment was the reconstruction of the relatively generous war veteran benefits program that had existed in the post–World War I Weimar Republic. In Japan, the restoration of self-government allowed the Japanese to push ahead in developing special services for the *hibakusha,* at first with activities on the local level by doctors in Hiroshima, and then with national legislation in 1957 and 1968 that provided medical, health, and welfare services to victims of the atomic bombs.

Although civilian war victims continue to lack access to the range and quality of services and income subsidies available to disabled military veterans, the moral grounds for debating the effects of war shifted notably in the late twentieth century toward much greater consideration of the consequences of war for the innocent bystander. Counterinsurgency wars, such as the Vietnam War, were especially criticized for insensitivity to casualties among civilians, who were often caught in the crossfire between guerilla and conventional forces. As with the burns caused by napalm in Vietnam, maiming resulting from unexploded ordnance, such as cluster bombs and especially land mines, became the basis for global campaigns of protest and remediation. There was no more powerful symbol of the damage such weapons caused bystanders than the iconic photo taken in 1972 of the nine-year-old Vietnamese girl, Kim Phuc, who was severely burned over 35 percent of her body. A South Vietnamese pilot had dropped napalm on her, members of her family, and other villagers, believing they were involved in an attack on ground troops he was sent to support. Growing awareness of the disastrous effects on civilians of aerial bombing campaigns and strategic missiles put considerable pressure on the United States to develop more precision weaponry and to use it with greater restraint in wars in Afghanistan and Iraq in the early twenty-first century. It was in this moral context, which highlighted the impersonal and random violence of terror from the skies, that it became possible for Jorg Friedrich to offer a moral reevaluation of the Allied bombing campaigns that for years had been viewed as the triumph of Allied air power in pursuit of victory against Nazism.

DISABLED MILITARY VETERANS

Representation

There is no doubt that disabled combat veterans have long been recognized as a source of special moral concern by the societies for which they have fought. They have also evoked intense anxiety and fear. To understand these contradictory responses, it is necessary to understand the ways in which in Western cultures, both warrior and disability discourses influence the understanding of the disabled veteran. The representation of disabled veterans is largely a product of the conflict and negotiation of these discourses, which lie in a state of constant tension, as we see in the ancient Greek narrative of Philoctetes. The root of these tensions lies in gendered assumptions about manhood. On the one hand, like Philoctetes, the warrior may be valorized as a symbol of male power and honor; on the other hand, pity and fear, the common emotions associated with our response to disability, serve to subvert honor and either infantilize and feminize the male or demonize him.

The ideal traits of the warrior have been steeped in ideas of masculine honor because war is the archetypical male experience, forming one of the borders of male and female. The warrior's character traits of courage, toughness, endurance, and a capacity for action have been fairly stable throughout the centuries, although the grounds for heroism have shifted from a chivalric emphasis on individual valor to peer groups' codes of behavior, emphasizing individual obligations to the combat group. Injury and disability incurred in war have been frequently viewed as, in Stephen Crane's ironically intended phrase, a "red badge of courage" for a warrior engaged in the worthy cause. Although wartime governments have sometimes been divided about allowing civilians to learn the extent of death and traumatic injury experienced by fighting men, in the belief that such knowledge was bad for morale, the disabled veteran as warrior hero has served as a particularly potent, public symbol for inspiring war efforts and loyalty to the state. When war ends, however, and memories of it begin to fade amid the general desire to return to a normal peacetime existence, the warrior hero gradually loses his luster and is reduced in stature to a beleaguered disabled man, whose needs may be perceived as both intrusive on the peacetime agenda and expensive. Thus, the generosity that his government and the public showed him through preferential public employment, pensions, vocational rehabilitation, prostheses, and education also begins to be challenged and, in time, even to recede.

As a disabled man, the veteran increasingly comes to be seen not as a warrior, but through the images by which people with disabilities have been conceived. For centuries in Western cultures, people have responded to disability and to disabled veterans with pity and fear. The veterans may evoke pity as innocent sufferers: In the case of veterans conscripted into armies, they are injured through no fault of their own and thus made to experience pain, a loss of autonomy, and exile from the community of the able-bodied, just as the wounded Philoctetes suffered physical exile on an isolated island. While the impulse to feel, if at times excessive, sympathy for the disabled veteran may be quite understandable, it has frequently been manipulated for instrumental purposes, thus popularizing pity. Twentieth-century veterans' organizations, such as the American Legion and a broad array of World War I–era German organizations, learned how easily a democratic polity can be manipulated through the potent, guilt-inducing symbolism of badly injured or ill veterans, especially when backed by powerful veterans' lobbies and bloc voting. Pity would not go unchallenged, however, for during World War I the idea of aggressive normalization through physical restoration and vocational training, which had been propagated first on behalf of the rehabilitation of injured and ill industrial workers in the late nineteenth century, spread among all of the major belligerents, allies and enemies alike. By the final year of that war, it came to constitute a counterdiscourse to traditional ways of conceiving of disabled veterans' postwar prospects; it insisted that every effort be made to return the disabled veterans to the community and to the workforce, and thus to oppose those influences that cast him as a feminized shut-in, lacking a man's place in the world.

The disabled evoke fear because physically and mentally impaired people have historically suggested sinfulness, deformity of the soul, and loss of moral autonomy. These conceptions cast the impaired individual as, alternately, revengeful, bitter, and self-absorbed; dependent, irresponsible, and parasitical; or monstrous. Neuropsychiatric disability also raises more immediate fears, given that it is associated with a direct physical threat to the observer and to social order itself. Although Americans have associated the enraged, antisocial, unpredictable madman possessing advanced weapons training with the Vietnam War veteran suffering from post-traumatic stress disorder, in fact, as Shay and others have suggested, societies have long been haunted by fears of the disruptive potential of men schooled in violence and possessing unpredictable mental states. Two of the earliest domiciliary institutions established for the care of aged and disabled veterans, France's Hôtel des Invalides (1633) and Britain's Chelsea Hospital (1685), were founded partly in the belief that there were many such men and that it was necessary to remove them from the streets in the name of public safety. Impoverished as many of them were and unable to reintegrate themselves into society, they were believed to have turned to begging, picking pockets, and violent thievery.

Public Policy

Protecting society against the disabled veteran, however, has not been the primary reason for the increasingly elaborate and frequently, at least at their inception, generous programs of social assistance that have come to characterize the response of modern societies to disabled veterans. Most Western societies historically have had at least two parallel tracks for assisting those construed to be in need, one for veterans and one for the general civilian population. The former is not only older than the general welfare state, but has been governed by different principles and rules and has been more generous in its provisions. The veterans' provision itself has not been a single entity. Although assistance for both groups has been governed by a common justification, disabled and able-bodied veterans have not been provided for equally. Disabled veterans consistently have been treated better than able-bodied veterans and indeed than perhaps any other cohort in society, including impaired civilians, whether disabled in peace or as bystanders in war. The liberal veteran provision is a consequence of the understanding—widely articulated in seventeenth-century England, in the era of the French Revolution, during the American Civil War by both North and South, and then universally accepted in the twentieth century—that assistance for and recognition of veterans must not be considered charity. Instead it is a reward for—and implicitly, too, an incentive to inspire—service to the state. In the case of disabled veterans, it is also a repayment for a personal sacrifice that is greater than simply time served. Thus, assistance is conceived as earned and a right. While assistance for disabled veterans generally came before that for the general population of veterans, in twentieth-century modern mass democracies, it has been increasingly given generously to all veterans, who now in some societies have life-long entitlements to medical care and education long after they have left the armed forces.

While programs of pension assistance and medical and domiciliary care for injured and ill veterans can be traced back to antiquity and appear here and there in early modern Europe, the dawn of the modern system of assistance for disabled veterans appears in history alongside the appearance of mass conscripted armed forces in the late eighteenth century and thereafter.

In the 1790s, in response to both egalitarian ideology and the invasion of the country by opponents of the Revolution, Revolutionary France briefly democratized pensions and qualifications for residence at the Hôtel des Invalides, which under the Bourbon monarchy had been largely limited to officers, before the pendulum swung backward toward elite privilege under Napoleon. Following the American Civil War, the federal government developed an elaborate and expensive pension system, which was administered by a centralized bureaucracy in Washington that, anticipating the modern welfare state, created a complex process for inspecting and classifying the bodies of disabled veterans of the Union Army. Also established were a network of domiciliary institutions for homeless and disabled veterans (the National Home) throughout the northern and western states, and a program providing prosthetic devices for thousands of amputees. The major European military pension systems, especially the French system adopted in 1831, established pension rates based on the nature and degree of physical injury. Although it borrowed from this practice, the American system departed from European models in allowing popular politics to mold the continuing evolution of its disability pensions. Large budget surpluses resulting from tariff revenues and a competitive electoral politics that thrust the veterans' vote into a position of prominence in national and state elections, led to an enormously expanded population base of the American pension system. It became, in effect, an old age pension for all veterans older than 62 that cost, by 1914, $5 billion annually.

The American pension system served as a negative reference point for efforts in the World War I era that ultimately created the modern system of care and assistance for disabled veterans in Western societies. Its costs, partisan manipulation, and refusal to examine possibilities for disabled veterans' lives other than as permanent clients of the welfare state, all were rejected by those planning and implementing the national programs that emerged out of the unprecedented scope and scale of needs created by men injured in the Great War. At the war's end, 752,000 British veterans, 1,537,000 Germans, just over one million French, 70,000 Canadians, and 200,000 Americans, among others, were classified as disabled or chronically ill as a consequence of service. The positive reference point was provided by the progressivist efficiency ethic of modern industrial society, which conceived of the individual as a social and economic resource to be formed and conserved through rational state planning and, relatedly, by the experience of the successful vocational rehabilitation of victims of industrial accidents.

Although national variations in implementation and administration existed, the conceptual unity among the major belligerents began with a consensus around the goals of both the most complete physical restoration of the individual as possible and aggressive socioeconomic normalization. These goals were conceived of as a *right,* an entitlement that the veterans had earned through sacrifice. However, the ground on which this right was to be constructed shifted subtly from the "sacred debt" to maintenance by the state proclaimed by Revolutionary France. The disabled veteran possessed the right to be restored to the position of a self-supporting, productive modern citizen. The state and cooperating private agencies were to approach the disabled man with practical programs that encouraged him to be rehabilitated. The medical phase of treatment would be accompanied by occupational and physical therapy to accustom him to doing practical, worklike activities while gaining strength and agility. Even before completing medical treatment injured men might be put to useful industrial work, which helped some of the European belligerents to deal with acute wartime labor shortages. The most complete physical restoration possible must have its complement in social and economic restoration in civilian life, an argument recently advanced by civilian rehabilitation specialists, who had begun decades before World War I to apply these same ideas to disabled children and victims of industrial accidents in Britain, Belgium, France, and Germany. The United States had just made a national commitment to civilian rehabilitation in legislation passed only months before the country entered the European war.

Opportunities were to be presented to the disabled veteran for vocational rehabilitation geared to what he could do in spite of his losses. A man's options for work should be fitted not only to physical condition but also to his prior occupation and class origins and to such aspects of the larger social and economic context as local job markets where he was likely to reside. Analogous arrangements were to be created to assist neuropsychiatric casualties and those suffering from chronic illness, the most common of which at the time was tuberculosis. Pension systems, free prosthetics that emphasized function over aesthetics, preference in government employment, and fully subsidized medical care were promised as a reward and as an aid to—not a substitute for—normalization.

During the balance of the twentieth century, public policy sought to improve and to elaborate on, rather than find substitutes for, this program. Everywhere it was installed, the program faced similar problems. Three were especially pressing. First, there was the problem of impersonal administration. The large masses of disabled men dependent on state services came to feel demeaned as cogs in a vast bureaucratic machine, even while they were lauded as heroes. One way of confronting the perpetual complaints about bureaucratic administration, as was done in Canada and the United States, was to include disabled veterans and their organizations in planning and administering programs in the belief that they could do the job more compassionately and efficiently, with more credibility than career civil servants. Second, the problem of containing long-term costs was persistent, especially as the men whom the state was obligated to assist aged and experienced health crises. Governments found that commitments made in the flush of patriotic obligation and in times of economic expansion and fiscal stability ultimately became a burden in hard times. The political costs of cutting benefits were enormous, so governments attempted in World War II to learn one lesson from World War I: The armed forces inducted many men with existing medical and psychological conditions, and these conditions were often worsened by military service. When and where circumstances allowed for systematic manpower planning, as in Australia, Britain, Canada, and the United States, governments raised induction standards to exempt or, in line with wartime labor shortages, provide national service opportunities for men who were already feeble, sick, or emotionally unstable. This policy was geared especially to weeding out those vulnerable to neuropsychiatric breakdowns. Even with pre-induction screening, it was increasingly recognized that neuropsychiatric problems were caused not only by combat, but also by military service that pulled men out of their normal lives and subjected them to psychological pressures that many could not handle. Once viewed as evidence of malingering or cowardice, neuropsychiatric illness became one of many new illnesses and impairments that late twentieth-century armed forces and governments had to take into account. This was the third problem, and it grew more insistent in the late twentieth century. The changing nature of warfare created new sources of disability, such as exposure to radiation among those military personnel ordered to be present near nuclear weapons tests in the 1940s and 1950s, exposure to the chemical poisons that resulted in Agent Orange illness among troops deployed in Southeast Asia, and Gulf War syndrome.

Throughout the twentieth century, governments in the developed world succeeded in achieving improved subsidized medical care, improved vocational rehabilitation, and innovations in prosthetic and assistive devices for disabled veterans. But the way forward was by no means even. Economic contractions limited the ability of governments to fund assistance programs for growing numbers of veterans. In part, fears of escalating costs led to resistance to acknowledging responsibility for the new chronic illnesses caused by the changing conditions of war. Disabled and able-bodied alike, veterans often found that the state was less generous to them than it had been to their grandfathers and fathers who were veterans of previous wars. During the twentieth century, however, the outstanding development in the field of public policy was the growth and improvement in all facets of the disabled veterans' provision.

The Experience of Solidarity

So often is the disabled veteran portrayed in popular culture, journalism, and scholarship as a client of the welfare state that there is a tendency to believe that the ultimate source of his social identity and group formation is his relationship to the state. Disabled veterans' organizations have formed for the purpose of pressuring the state to be more generous in financing entitlements and giving symbolic recognition, and these groups have built solidarity around activity as a political pressure group. While the state has been deeply involved in the lives of disabled veterans, the point is easily exaggerated. There are three distinct sources of the process by which disabled veterans have come to understand themselves as a group and to organize as such: an historical event (participation and injury in a war, in specific historical, cultural, and political contexts); an experience of medical treatment, rehabilitation, and reintegration; and an ongoing relationship with government as a source of material benefits and symbolic recognition. The state is, of course, implicated in all of these, for it is the state that has put men in uniform, cared for them when injured or ill, and assisted them on the path toward normalization. However, each of these sources also owes a great deal to interactions with the able-bodied public, to cultural representations of both disability and veterans, and above all, to a solidarity born of collective experience. While disabled veterans have had a singular and broadly ramifying relationship with the state, they have also had especially close relations with one another, and these relationships have been crucial in forming their identities and political orientations. This collective orientation contrasts with the experience, at least until recently in Western societies, of disabled civilians, which has been individual rather than collective.

At the heart of the collective nature of the disabled veterans' experience is disability itself; those injured in adulthood, after a lifetime of normal activity, have multiple psychological, social, and emotional needs that arise during medical treatment, rehabilitation, and reintegration. These needs hardly can be satisfied by government alone. The veterans' solidarity was built initially on the collective experience of military service, war, and injury. For reasons of efficiency and with an eye to inspiring high morale, military medicine developed the practice in the twentieth century of putting men with the same injuries and illnesses together for treatment, so that alongside the combat unit, the hospital ward and rehabilitation facility have been a *locus classicus* of disabled veterans' identity and group formation. It was in such facilities, through discussions with one another and not simply with doctors, that men came to understand the limits and possibilities of their situation and reached understandings about what for them might be a normalized existence. Lacking the psychological counseling that became widely available in the late twentieth century, disabled veterans of the world wars acted as their own counselors, talking about such essential issues as establishing new relations with parents, wives, children, and girlfriends; dealing with staring and other types of unwanted attention; confronting fears about sexual intimacy; learning to use prosthetics and assistive devices; overcoming environmental obstacles; framing realistic employment aspirations; and above all, avoiding the roleless, self-pitying, and anger-driven life that led frequently to alcohol abuse, probably the most common maladjustment of disabled veterans throughout history.

Cohorts were formed in these institutional settings that ultimately became the basis for smaller veterans' organizations composed of men with common injuries, such as the *Bund Erblindeter Kreiger* in Germany after World War I and, after World War II, the Blinded Veterans Association (BVA) in the United States and the Canadian Paraplegic Association (CPA). Disabled veterans have belonged to the larger veterans' organizations—both the mixed organizations, composed largely of the able-bodied majority of veterans, and the composite organizations, which brought together men with a wide variety of disabilities. It was, however, in these smaller, single-population organizations, built on shared experience and camaraderie, that the most complete synthesis of disabled veterans' needs and aspirations for normalization might be found. In such organizations, too, the struggle against the limitations imposed on people with disabilities was fought. The BVA led protests against New York City municipal health regulations that barred guide dogs from restaurants. One of the CPA's founders, Lt. John Counsell, a spinal cord–injured veteran, successfully campaigned to have the lightweight, self-propelling Everest & Jennings wheelchair made available to Canadian veterans to enhance their mobility.

We are now in a position to see that the disabled veteran's history and self-understanding is significantly more complex than may be grasped by merely considering him a client of the welfare state. At the core of his experience is disability—the negotiations and struggles of living with a disability in societies that frequently resist, at varying levels of consciousness, integrating people with impairments into the social systems of daily life. In this sense, although much—including particularly generous state assistance—has separated the experience of disabled veterans from that of disabled civilians, both populations have taken part in common struggles to win a broader place in the world.

WHEELCHAIR

A wheelchair is any seating surface (e.g., a chair) that has wheels affixed to complement or replace an individual's ability to move from place to place. This includes everything from large, bulky, manually powered wheeled wicker chairs to high-tech, electric-powered wheelchairs that can climb stairs. In 1932, Herbert A. Everest, a mining engineer with a disability, and Harry C. Jennings, a mechanical engineer, collaborated to design and patent the cross frame wheelchair. They later formed Everest & Jennings, Inc., one of the largest international wheelchair manufacturers. Their design became the standard for the wheelchair industry that exists to this day.

Typically, a wheelchair consists of four wheels: two large wheels in the rear that are used for propelling the wheelchair, and two small wheels in the front that swivel, called casters. The large wheels support the majority of the individual's weight and provide the primary means of propulsion. The casters facilitate maneuverability; they are similar to the casters found on the front of grocery carts. Traditionally, wheelchairs are divided into two categories: manual and electric-powered. These categories are defined by the mechanism used to propel the wheelchair. A manual wheelchair is propelled by human power, and an electric-powered wheelchair is propelled by an electrically based power source (typically a battery and electrical motor).

A manual wheelchair is powered either by the individual using the wheelchair or by an assistant.

The most commonly recognized manual wheelchairs are seen at hospitals and nursing homes. Individuals who have the strength and endurance to independently propel the wheelchair typically use manual wheelchairs. They can propel the wheelchair in different ways. For instance, individuals with a spinal cord injury can use their upper extremities. Individuals who have had a stroke that affects only one side of their body can use one upper extremity and one lower extremity. Individuals who no longer have the strength to walk without a walker or cane or the endurance to walk with one can use their lower extremities. An assistant or attendant propels the manual wheelchair when individuals cannot do it themselves.

Manual wheelchairs can be divided into numerous categories based on their intended use and design. The most basic characteristic that distinguishes manual wheelchairs is the frame design, but wheelchairs are also categorized by style, material, and weight

Style

A standard folding wheelchair has a cross-brace design (X-frame), which allows the wheelchair to fold laterally via a scissor-like action. These wheelchairs are very popular because they can be easily folded for transportation. The limitation to folding frame wheelchairs is that they tend to be heavy and have reduced performance characteristics compared with a rigid frame manual wheelchair. A rigid frame does not incorporate a folding mechanism into the design, thereby significantly improving aesthetics, performance, strength, and weight.

Material

Another feature that distinguishes wheelchairs is the type of material used. Initially, manufacturers used steel in all manual wheelchairs (primarily mild steel) because of its low cost and ease of machinability. The last 20 years has seen numerous advances in the materials used to manufacture wheelchairs. Now they are made using primarily steel, aluminum, and titanium. Steel is limited to standard wheelchairs that have folding frame mechanisms. Aluminum is now used throughout the wheelchair industry, primarily in ultralight wheelchairs and some lightweight wheelchairs. Aluminum has a higher strength-to-weight ratio than mild steel, thereby reducing the overall weight of the wheelchair, and it has the added advantage of being resistant to corrosion. Finally, titanium has begun to appear in ultralight manual wheelchairs, further reducing the weight because of its high strength-to-weight ratio. Titanium also is resistant to corrosion. The key limitations to titanium are its relatively high material costs compared with steel and aluminum and the greater difficulty in machining or welding titanium.

Weight

In general, there are three wheelchair weight categories: standard, lightweight, and ultralight.

Standard wheelchairs are typically folding frame wheelchairs that are manufactured using mild steel. They are the heaviest of manual wheelchairs, usually weighing more than 18 kilograms with limited adjustability in components. These wheelchairs are designed most often for temporary use and are usually found in medical facilities (e.g., hospitals and nursing homes).

Lightweight wheelchairs also are typically folding frame wheelchairs. They have many adjustable components and are available with many features. They also tend to be lighter than standard wheelchairs (typically between 13 and 18 kilograms) because they are usually manufactured using aluminum.

Ultralight wheelchairs have the best performance characteristics of the three weight categories. As expected, these are the lightest-weight wheelchairs (typically less than 13 kilograms) because they are manufactured using aluminum, high-performance steel, or titanium. However, the key difference between lightweight and ultralight wheelchairs, besides weight, is an adjustable rear wheel axle. A horizontally adjustable rear wheel allows for the optimal placement of the rear wheel on the frame. This makes it easier for the individual to reach the rear wheels during propulsion, reducing stress and strain on the upper extremities.

The frame is the most basic unit of a manual wheelchair and the most influential in terms of performance. However, the components that are attached to the frame to generate a functional manual wheelchair are significant as well. The key components are the tires, the wheels, the axles, the casters, the leg rests, and the armrests.

Tires

Wheelchair tires are either solid rubber or pneumatic (air-filled). Solid rubber tires are almost always used with standard wheelchairs and sometimes with lightweight wheelchairs. These tires provide a hard ride and have a high rolling resistance, but they have low wear rates and are low maintenance. Pneumatic tires are almost always used with ultralight wheelchairs and sometimes with lightweight wheelchairs. These tires provide a softer ride, lower rolling resistance, and are lower in weight, but they have high wear rates and are high maintenance (particularly in maintaining appropriate air pressure).

Wheels

The wheels are usually spoked (wired) or molded (mag). Wheel sizes range from 12 to 26 inches in diameter, depending on the purpose of the wheelchair. Molded wheels have low maintenance requirements; however, they are significantly heavier and less responsive than spoked wheels.

Axles

Rear wheel axles are either fixed or quick-release. Like solid rubber and pneumatic tires, fixed axles are almost always used with standard wheelchairs, quick-release axles are almost always used with ultralight wheelchairs, and either fixed or quick-release are used with lightweight wheelchairs. Fixed axles are a bolt and locknut that require tools to remove and attach the rear wheel to the frame. A quick-release mechanism has a button on the end of the axle that allows for easy removal of the tire without any tools. This may be critical for disassembling a wheelchair when transporting it in an automobile. The fixed axle is low maintenance, while the quick-release axle requires frequent monitoring.

Casters

The casters range in size from 3 to 9 inches in diameter, with the majority falling in the 5- to 8- inch range. The caster tires can be solid rubber or pneumatic but are limited to either mag or solid hub wheels.

Leg Rests

The leg rests are fixed, swing-away, or elevating. They consist of a hanger that is attached to the frame and a footplate that supports the individual's feet. Fixed leg rests are integral to the frame; they produce a lighter-weight system since there are fewer components. Swing-away leg rests allow for the removal of the leg rests from the frame in order to facilitate transfers into and out of the wheelchair. Elevating leg rests allow the lower extremities to be positioned at different angles with relation to the seat surface, thereby raising and lowering the leg position. This is often critical to address an individual's specific physiologic issues (e.g., swelling in the lower extremities).

Armrests

The armrests are either fixed height or adjustable height. Armrests facilitate transfers by providing a hand-hold for the individual. They support the upper extremities when the individual is not propelling the wheelchair, and they provide a means for weight-shifting if the individual has the strength to lift his or her bodyweight using the upper extremities.

WHEELCHAIR, ELECTRIC

An electric-powered wheelchair (EPW) is propelled by an electrically based power source, typically motors and batteries. An EPW is also referred to as a power wheelchair. The first powered wheelchair appeared during World War I when an engine was added to a manual wheelchair. The demand for the wheelchairs, however, did not exist until nearly 30 years later.

A joystick, similar to that used with a computer game console, is the most basic and common device used to control an EPW. Advancements in control systems allow individuals to control a wheelchair using any voluntary movement. For example, a wheelchair can be controlled using head movement, breath actuation, tongue movement, or lower extremity control. Initially, EPWs were merely heavy-duty, manual folding frame wheelchairs that were powered by lead-acid batteries, motors, drive belts, and pulleys. These conventional power wheelchairs were very simplistic systems. They required the use of the joystick to control the wheelchair's movement, and programmability did not exist. The seating system typically consisted of a sling seat and back upholstery, which significantly limited postural support for the individual.

The advent of the power base allowed for significant mechanical advancements in EPWs. The power base separated the EPW into two components: the base, which provided the mobility, and the seating system, which provided the postural support. At the same time that a shift from a conventional power wheelchair to a power base wheelchair was taking place, significant advancements were occurring in electronic systems. Some of these mechanical and electrical advancements included the ability to add power tilt and recline systems and programmable performance settings (forward speed, turning speed, and acceleration).

Two types of drive mechanisms are used on EPWs: indirect drive and direct drive systems. Indirect drive systems (pulleys and drive belts) are used on conventional EPWs. Direct drive systems (gear box) are used on power base wheelchairs. Today, the vast majority of power wheelchairs use a power base with a direct drive system. Twelve V wet cell and 12 V gel cell batteries are used to provide the current required for EPWs. Typically, two 12 V batteries in series (24 V total) are required. Because of the maintenance requirements of wet cell batteries, gel cell batteries are the battery of choice. Although these batteries are similar in size to batteries used in the automobile industry, automobile batteries cannot be used for EPWs.

EPWs also can be classified based on the location of the drive wheels. There are three types of wheelchairs: front wheel drive, mid- or center wheel drive, and rear wheel drive. Traditionally, rear wheel drive EPWs were preferred because of their similarity to manual wheelchairs in design and maneuverability. However, center wheel drive wheelchairs have gained popularity because they provide increased maneuverability.

Push-rim–activated power assisted wheelchairs (PAPAWs) incorporate features of both manual and electric-powered wheelchairs. A PAPAW typically consists of an ultralight manual wheelchair with an external power source (batteries and motors). It complements an individual's ability to manually propel the wheelchair rather than replaces that ability, as is done with an EPW. The push-rim contains sensors that detect the direction and magnitude of force applied to it by the individual. The motors are then activated and assist in the propulsion of the wheelchair.

WHEELCHAIR, HISTORY OF

Wheeled chairs have a long history. The earliest representation of a wheeled chair is an image on a sixth-century Chinese sarcophagus, although like the wheel and the chair, the history of wheelchairs probably dates back to 3500 B.C. It is possible that wheeled chairs entered Europe around the twelfth century, along with the wheelbarrow, but the first recorded use of self-propelled chairs by disabled people was not until the seventeenth century. Johann Hautsch made several rolling chairs for occasional use in Nuremberg during the early 1600s, and a disabled watchmaker named Stephan Farfler made a three-wheeled chair that he could propel by use of a rotary handle on the front wheel in around 1655. Mechanical "invalid chairs" (*wheelchair* is an idiom of the twentieth century) that employed a range of cranks and rotary devices increased in use from the late seventeenth century. They were designed as a means of transport primarily for the wealthy. By the beginning of the eighteenth century, wheelchairs began to appear in surgical and medical instrument catalogues as vehicles to transport patients. Styled like armchairs, these wood, wicker, or iron machines, with large wheels at the front and one caster at the rear for balance, were ornate, heavy, and cumbersome.

A variety of forms of the bath chair, originally designed around 1750 by James Heath of Bath to transport the sick to take the waters at the pump room or to bathe in the baths, dominated the British scene in the nineteenth and early twentieth centuries. The bath chair was halfway between an apparatus for injured, sick, or disabled people and a rickshaw-like mode of transport used by wealthy Victorians. Toward the middle of the nineteenth century, wooden wheelchairs with caned seats and backs also appeared, especially in the United States, where Civil War veterans used them. However, despite the introduction of wire-spoke wheels and rubber tires (borrowed from the bicycle) at the end of the nineteenth century, few wheelchairs during the first half of the twentieth century facilitated independent mobility outdoors.

The 1950s in both Britain and the United States saw the ascendancy of the relatively lightweight, tubular-steel folding wheelchair. The most celebrated example of this design is probably the Everest & Jennings (E&J) single X-brace folding wheelchair, first developed in 1933 by Herbert Everest (a wheelchair user since 1919 after a mining accident) and his partner Harry Jennings. However, the "invention" of the E&J wheelchair was not an isolated event. Chester Hockney had patented a tubular-steel folding wheelchair in 1907, and in Britain J. and A. Carters offered a wooden "folding" wheelchair in 1902. An American contemporary of E&J, Samuel Duke, also developed a tubular-steel folding wheelchair in 1934 from which he started the American Wheel Chair Co., and Dingwall & Son (Engineers) Ltd. marketed the first British tubular-steel folding wheelchair in 1948.

In contrast to earlier wheelchair designs, the folding tubular-steel wheelchairs afforded wheelchair users the ability to leave the home and travel for the first time. In addition to their ability to interface with other forms of transportation, folding tubular-steel wheelchairs were around half the weight of their wooden predecessors, and with large propelling-wheels at the rear and casters at the front, they were better able to negotiate steps and curbs.

In both North America and Britain, the rise to dominance of the tubular-steel folding wheelchair was due in no small part to the actions of the state. Shortly after World War II, both the U.S. Veterans Administration and the Canadian Department of Veteran Affairs began to supply E&J wheelchairs to disabled veterans. These lucrative contracts enabled E&J to grow into the most successful wheelchair company in the United States, holding a near monopoly on the North American prescription market by the 1960s. In Britain, too, the monopoly of the state-run wheelchair service, with its concentration on standardization, facilitated the ascendancy of the tubular-steel folding wheelchair when the Ministry of Health designed and distributed its own version (the Ministry Model 8).

Equally important, however, the ascendancy of the lightweight folding wheelchair design was due to wheelchair users' increasing control of the technology. Whereas World War I produced colossal numbers of soldiers returning with missing limbs, to which the technical solution was the prosthesis, World War II and the mass production of penicillin by 1945 resulted in a new constituency of *active* wheelchair users: people surviving with spinal injuries. The burgeoning of state-organized resettlement and rehabilitation services, including rehabilitation engineering, raised expectations among this group of being independent. The polio epidemics of the late 1940s and early 1950s, thalidomide in the 1960s, and the Vietnam War in the 1960s and 1970s all had a similar effect.

In matters of wheelchair design, wheelchair users were predominantly concerned with making the technology lighter, more reliable, and higher performing. Although wheelchair manufacturers in both Britain and the United States adopted this innovative path, it was from wheelchair sports that the ultralightweight revolution drew inspiration. Emerging from independent shifts in rehabilitation practices and philosophy following World War II (initiated by Ludwig Guttmann in Britain and Tim Nugent in the United States), wheelchair sports generated groups of wheelchair athletes who began to tinker with their wheelchairs to improve performance. During the next 40 years, this experimentation eventually challenged dominant thinking about wheelchair design and set the tone for manual wheelchair technology at the end of the twentieth century. The symbol of this sea change was Motion Designs' Quickie, an ultralightweight rigid-frame wheelchair developed by Marilyn Hamilton, Jim Okamoto, and Don Helman in 1979. Quickie transformed the orthodoxy of what an "everyday" wheelchair should look like and how it should function. Reworking innovations developed by wheelchair athletes such as Jeff Minnebraker, Motion Designs introduced color, aesthetics, and high performance to the mass wheelchair market.

Powered wheelchairs first emerged in a form that people with severe impairments could use in the late 1940s and 1950s. Despite a range of designs that existed during this period, it was George J. Kline's development of a friction motor and joystick in 1953 that influenced the form of powered wheelchairs for the next two decades: standard wheelchairs with motorized attachments. Designs for powered mobility progressed through the 1950s and 1960s, and more robust indoor/outdoor designs such as Raymond Biddle's BEC wheelchair emerged. The late 1960s also saw the introduction of proportional controllers by the Motorette Corporation and Penny & Giles, along with the greater use of microprocessors and computer technologies in wheelchair controllers.

Special or adaptive seating was another important innovation in wheelchair design that emerged from pediatric services in both Europe and North America during the early 1970s. Innovators in special seating were motivated by finding technological solutions to the problem of pressure sores and support for skeletal deformities, joint instability, and unusual body dimensions, but inextricably linked with those solutions was the idea that this technology would facilitate social inclusion for people with severe and complex physical impairments. Originally, seating engineers designed their seats as inserts, but during the 1980s, they worked with wheelchair manufacturers to develop a separate chassis on which to mount either standard or special/adaptive seating. This innovation led to one of the most significant design changes in powered wheelchairs in the 1990s: the power chassis, which divorced wheelchair design from the anthropometric and ergonomic considerations of seating.

In the early twenty-first century, wheelchair design is reaching for the stature of high technology with the introduction of the IBOT and the push-rim–activated power-assisted wheelchair (PAPAW). The IBOT, developed by Independence Technology, is a powered wheelchair that incorporates gyroscopes and computer technology to enable it to stand, be in motion at standing height, negotiate steps and curbs, and travel over a variety of uneven terrains. The PAPAW, currently marketed by a number of large wheelchair manufacturers, is a hybrid of powered and manual wheelchair technologies that employs motors to supplement the power applied by the user to one or both push-rims during propulsion or braking. It remains to be seen whether either design will dominate wheelchair provision in the future.

WILHELM II, EMPEROR

(1859–1941)

German emperor

Wilhelm II was, from 1888 to 1918, the last German emperor and Prussian king. Under his reign, the German Empire, the so-called Wilhelmian Empire founded in 1870/1871, was transformed from a backward agrarian country into one of the leading industrial nations of Europe. However, the great European and global ambitions of Germany led to World War I, which in turn led to 10 million casualties. The end of the war was essentially also the end of the German monarchy.

Emperor Wilhelm II was born on January 27, 1859, as Prince Friedrich Wilhelm Albert Victor. He was the first child of Prince Friedrich Wilhelm of Prussia, later Emperor Friedrich III, and his wife, Victoria, Princess Royal of England. Because of a difficult breech birth, Wilhelm II's left arm was paralyzed and about 15 centimeters shorter than the right. It was debated whether or not his brain was damaged during birth because of a lack of oxygen. His physical impairment had great biographical and historical consequences because it did not fit with the social image of a crown prince. His mother, in particular, could never come to terms with it. Numerous often cruel attempts at therapy and a merciless education from his tutor shaped the childhood of Wilhelm II and most likely led to his later rejection of his parents and their liberal outlook. His cruel tricks and violent verbal attacks, which occasionally had serious consequences for foreign policy, were well known. Early in his life, Wilhelm II's psychological health was doubted by his own family, as well as by contemporary psychiatrists.

After studying law and political science in Bonn, marrying Auguste Viktoria in 1881, and receiving military training, Wilhelm II took over the reign from his father, who had ruled only briefly. His political influence varied during his 30-year reign. Wilhelm II embodied the many ambivalences of his epoch: He encouraged scientific and technical development and enlarged the Navy to satisfy his global militaristic ambitions. His relentless fight against the Social Democrats, his antiparliamentary stance, and his unrealistic sentiment about the God-given rights of the monarchy exacerbated internal political conflicts. In November 1918 Wilhelm II fled to Doorn, in the Netherlands, to escape the first German Republic and, most likely, to avoid being indicted as a war criminal.

He lived there until his death on June 14, 1941. He hoped until the last that the monarchy would be reinstated, and apparently he could not see any fundamental contradictions between National Socialism and his own political views. Not least his notorious anti-Semitic diatribes made clear that there were important ideological continuity lines in German politics.

WILLOWBROOK STATE SCHOOL

Willowbrook State School in New York was conceived in the late 1930s by parents and professionals concerned about those who were then called "mentally deficient." When proposed, it was intended to be a state-of-the-art facility to care for and educate such persons. As such, it joined the ranks of many large American institutions that were also proposed and built for such purposes. These had begun to be constructed in the United States during the mid-nineteenth century and continued to be built into the twentieth century. Such places were part of society's overall efforts to provide for the welfare of people who, before around 1850, had no avenues for education and self-betterment. At first, the schools tended to be relatively small places whose basic purpose was to educate residents and, if possible, return them to their communities. Over time, with the advent of the scientific movement of eugenics—a viewpoint that created fear of people who were seen as having genetic abnormalities—institutions became less educational and more custodial. In the 1920s and 1930s, they regularly practiced sterilization of residents as part of society's solution to what was called "the menace of the feebleminded." Conditions in New York institutions worsened significantly during the Depression and again during World War II.

The immediate reasons for Willowbrook State School's construction on Staten Island stemmed from parents' perceived need for such an institution near New York City. A multipurpose hospital located on Randall's Island had been closed down. Parents in New York City in the 1930s began to lobby for a school to be built and formed a coalition with professionals from the American Association on Mental Deficiency. Staten Island was considered the ideal place; it was within the City of New York but geographically isolated since no bridge or tunnel linked it to the other boroughs. Staten Island was physically near, yet socially isolated and invisible, a clear pattern in the location of many institutions across the country. Despite community resistance, $12 million was allotted for construction at the Willowbrook site.

Thus, Willowbrook State School was built in the late 1930s, an era when the government provided resources for many public works. This explains why its buildings are similar to other institutions built at the same time, to some degree sharing certain basic architectural features. Willowbrook was designed to serve as home, school, and work for as many as 2,000 residents. It was to take mainly residents from the city, but also it was intended to house those who lived in other New York State institutions and schools, which during the 1930s and 1940s had become increasingly overcrowded. It was to have state-of-the-art facilities and training for staff.

Just before Willowbrook was to open, World War II began. From 1940 until 1947, the grounds served as Halloran Veterans Hospital, which was operated by the military. After the war, a prolonged battle emerged between New York State and the Chiefs of Staff about returning the facility to New York State for its original purpose. In 1947, the Chiefs of Staff relented to public pressure, and Willowbrook State School received its first students with developmental disabilities. Between 1947 and 1954, veterans and disabled persons shared the facility. Governor Dewey found himself in a difficult position of having to be sympathetic to both the pleas of veterans who wanted Willowbrook to remain their home and those of parents who needed placements for their children. Eventually the veterans were forced to leave but not without resistance.

The school's initial years of operation were documented in the only borough-specific daily newspaper in New York City, the *Staten Island Advance.* Some articles also appeared in the *New York Times* and *New York Post.* These articles reveal the hopefulness of the situation when the school first opened. Willowbrook quickly became the largest employer on Staten Island, and the care of the residents, while perhaps primitive and scientifically naïve by current standards, bore no resemblance to the neglectful and abusive conditions that came later in its history. In its early years Willowbrook was one of the more progressive and well-informed institutions of its type. There was even a staff-training manual, a rarity for the era. This is not to say that there was no abuse in these early years, as evident from oral histories of persons who came to Willowbrook during this time. The first major case of abuse reported in the newspapers occurred in 1952.

Willowbrook accepted "patients" quite easily. All that was needed was a physician saying that the child or adult required evaluation. This could be done at the facility itself, which resulted in a "drop-off" policy.

Census figures taken from newspaper accounts indicate a rapid initial growth in Willowbrook's population, including the admission of many young children. During the 1950s, there was evidence of some overcrowding, and with federal funds, the facility built additional buildings in the early 1960s to accommodate a larger and younger population. During this same period, the quality of life on the wards at Willowbrook appeared to deteriorate significantly. This occurred for primarily two reasons. First was the broadening of the admission criteria so that almost any person, with or without disability, could and would be admitted. Willowbrook began to be used as a warehouse for the "socially undesirable" of New York City, and this led to a great increase in the number of people living there. As many as 6,000 patients lived on the grounds, and at least a substantial minority had no disability. The second reason for deteriorating conditions was that New York State experienced a terrible budget shortfall during the 1960s, and the City cut the budget in all service sectors. This combination of census increases and financial cuts led to an increase in the resident-to-staff ratio at Willowbrook. In 1965, Robert Kennedy compared conditions at the school to a "snake pit." Given the number of patients at Willowbrook, the manipulation of parents to consent to medical research, and many family members' relative lack of concern, the staff used the residents during this era in various forms of medical experimentation, which while technically legal at the time were by today's standards illegal and unethical. This included the purposeful infection with hepatitis of children who had intellectual disabilities.

With so many people living at Willowbrook, with so few people taking care of them, and with a lapse in government support or oversight, a social disaster occurred. In fairness, such disasters occurred not only at Willowbrook but also at institutions all over the United States during this period. There appears to have been an epidemic lack of social conscience. As bad as conditions were at Willowbrook, it may not have been the worst of institutions in the United States. During this period, children and adults with and without disability who found themselves in institutions such as Willowbrook were systematically subjected to the most abusive and neglectful living conditions, outside of the concentration camps in World War II and the Civil War, perhaps ever created in the history of the United States. Because of overcrowding and inadequate resources, conditions on the wards at Willowbrook became "sub–kennel-like." Neils Erik Bank-Mikkelsen, a Danish visitor to the school in the 1960s, remarked, "In Denmark we don't let our cattle live this way."

In the early 1970s, additional budget cuts created nearly unbelievable conditions at Willowbrook. Staff-to-resident ratios were as low as 1 or 2 to 70. This essentially meant that no supervision at all was possible on many wards. The feeding time for children who could not feed themselves fell to approximately three minutes. Many "patients" were starving, and some died from asphyxiating food while being fed. During the early 1970s, a situation already completely unacceptable on moral or legal grounds became exacerbated, intolerable, and without precedent in American civil society.

Despite newspaper articles that exposed the conditions at Willowbrook, nothing was done. Jane Curtin of the *Staten Island Advance* wrote several articles about Willowbrook and documented the conditions there with photographs. Parents who had children at Willowbrook, particularly the Parents Benevolent Association, began to protest the intolerable situation. In the early 1970s, these parents were joined by professional staff employed at the school.

Finally, in early 1972, at the invitation of Dr. Michael Wilkins, one of the physicians allied with the parent group, a young television reporter for the ABC network, Geraldo Rivera, was given a key to one of the wards and "invited" to Willowbrook to record conditions (Rivera 1972). This event was to change the course of history for people with developmental disabilities. Rivera arrived on the Willowbrook campus unannounced and with a television crew. Without permission, he and crew entered building number six and videotaped. Rivera's tapes were broadcast nationally. They graphically depicted the neglect and abuse of children and adults. The images were accompanied by a narrative describing the smell of feces, urine, and death. The videos showed children and adults unclothed, lying in their own filth, and some restrained in straitjackets, sitting on the floors in crowded, unsupervised "day rooms." Rivera's tapes were so graphic, so condemning, that their national broadcast virtually began a movement to close institutions like Willowbrook overnight.

The parents who had been demonstrating, but "shouting in the wind" as one of them put it, were joined by various groups and filed a lawsuit in federal court over the inhumane living conditions. This lawsuit began the legal processes that resulted in the signing of the Willowbrook Consent Decree in 1975. Lawyers for the plaintiffs, that is, individuals and organizations representing the interests of the more than 5,000 residents who lived at Willowbrook at the time, and lawyers for New York State spent several years working out a detailed agreement about the process for and conditions of closing Willowbrook. The consent decree, a monumental legal agreement, became a model for similar decrees around the nation. The signing into law of the Willowbrook Consent Decree by Governor Hugh Carey is another chapter in the legacy of Willowbrook and one of the most significant events in the civil rights movements by and for people with developmental disabilities. Its history is documented in the 1984 book *The Willowbrook Wars* by Rothchild and Rothchild. It is important to consider not only the negative heritage of Willowbrook but also its positive legal impact on the civil rights of this population.

The Willowbrook Consent Decree created what is known as the Willowbrook class. The class contained anyone who resided at Willowbrook at the time the decree was signed into law. The consent decree described the conditions of placement that had to be met for anyone in the class, down to the number of towels he or she was to have. The decree created a very detailed system of monitoring and oversight of the class members, including the Commissioner's Task Force on Willowbrook that directly evaluated class members' current living situations. The obligations specified in the consent decree are to be met until the last of the "class clients," as they are sometimes referred to, pass on. This means, incidentally, that the Willowbrook case, in some form or another, is one of the longest open cases in American legal history. Since March 1993, the Willowbrook Consent Decree has been legally known as the Willowbrook Permanent Injunction.

Partly because New York State had decided to decrease its populations in all state institutions and state schools, in 1978 it created the Office of Mental Retardation and Developmental Disabilities (OMRDD). It was the OMRDD that oversaw the closure of Willowbrook. The late 1970s through Willowbrook's closure on September 17, 1987, represents yet another important story in Willowbrook's legacy. During this time, a partnership among the State, OMRDD, and not-for-profit agencies created neighborhood and community-based supports and services for former residents of institutions such as Willowbrook. This was the era of "communitization" and "normalization," when huge steps forward were made in the civil rights movement for people with developmental disabilities. This is a particularly fascinating period and one not well documented either in books or in films.

It is very difficult to generalize about the current welfare of persons who lived at Willowbrook. How people have coped with their experiences at Willowbrook varies widely. Some were broken, perhaps irretrievably. Others were deeply scarred, and these scars are still visible in their behavior today. Still others have seemingly left Willowbrook behind in their lives. From their behavior, one cannot tell they were ever there.

In 1993, the College of Staten Island moved to its current location, the converted campus of the Willowbrook State School. The State spent more than $400 million for redesign and reconstruction. Some old buildings were torn down, and new ones were built. Almost all of the old structures have been refaced, and there is very little indication of the site's previous use. One sees instead a beautiful and expansive college campus. While such a refitting is both remarkable and praiseworthy, perhaps the one thing we should take away from the history of Willowbrook is to "never forget."

WITCHCRAFT

Technically, the term *witchcraft* hinders an understanding of the phenomenon that it intends to identify. Rather than a descriptive term referring to the practice of magical or diabolical arts, most scholars prefer *witch-hunting* because it redirects attention to those better understood as persecuted on behalf of economic, gender, racial, physical, and cognitive differences. *Witch-hunting,* then, identifies the practice of attempting to slander individuals—almost always women—on the basis of social transgressions. One can find episodes of witch-hunting throughout history, but often epidemics of witch-hunting broke out during times of extreme social duress. Specifically, charges of witchcraft were made against an individual who challenged established authorities—those who violated entrenched codes of appearance, economic stability, or belief. While such practices of slanderous accusation originated in Europe, this entry focuses on the variant strain of such behavior as it evolved in seventeenth-century United States.

SEVENTEENTH-CENTURY NEW ENGLAND

Perhaps because witch-hunting was common in Europe, the Euro-American colonies participated in similar accusations from the very beginning of settlement life. Laws on witchcraft in the colonies all evolved from the 1604 English Statute (1 Jac. I, c. 12) that made "being a witch" punishable by death. Accusations of witchcraft were closely related to the experience of personal misfortune or a significant fall in social status. One consistent characteristic of witchcraft inquiries revolved around the accused and the accuser's health. Witches were often individuals who practiced midwifery in secret. Medical efforts by women led to suspicions among male authorities that the accused were exceeding their assigned roles in the domestic sphere. While mothers were expected to care for family members, treating others beyond that circle was considered illegal. Furthermore, the onset of inexplicable illness, bodily pains, and disability played key parts in the trial of witches; marks on and bodily ills in children, for instance, often prompted parents to worry about the source of such afflictions. In other cases, bodily blemishes discovered upon investigation of the accused's naked body provided convincing evidence of impropriety. In this sense, witch-hunting finds its grounding in interpretations of bodily vulnerability and difference. Those charged as witches were often accused of "looking different," and thus a hierarchy of appearance and functionality serves as a context for suspicions of witchcraft.

One of the earliest records of witch-hunting (1638) reveals that the case of Jane Hawkins of Boston turned on the fact that she had performed as a midwife during the "monstrous birth" in that year (Hall, 1991: 19). Since the Puritan magistrates considered "deformed fetuses" a sign of disfavor from God—therefore continuing the most ancient of ideologies about congenital disability—those present for such events were sometimes accused as a group. In Hawkins's case, she had been under suspicion for some time because she gave community women oil of mandrakes to facilitate their ability to conceive. Such acts angered a patriarchal establishment in that they violated conventions of gender-based authority. As a result, Hawkins was expelled from the colony with the consequent order that she not "meddle in surgery, drinks, plasters, or oils, not to question matters of religion, except with the elders' satisfaction" (Hall, 1991: 20). The mother of the disabled fetus, Mary Dwyer, also left the colony but returned to profess her faith as a Quaker in 1657. She was executed by the government in 1660 for heresy. While suspicions ran high during the seventeenth century toward women practicing the "medical arts," the birth of a visibly disabled child served as material evidence against those women who challenged the status quo. Two other Quaker women, Mary Fisher and Ann Austin, were stripped and searched for demonic "marks" during the 1650s. In each of these cases, bodies considered "deviant" prompted invasive investigations and secured the fate of those involved.

Symptoms considered disabling, such as seizures, deafness, vomiting, violent pains, or sickness, did not necessarily lead to accusations against the individuals affected; rather, such "disturbances of the body" often prompted others in the vicinity to be accused of supernatural manipulation. During outbreaks of witch-hunting, the different body itself was targeted as a sign and symptom of one's confederation with demonic forces. In 1648, Margaret Jones was hanged for causing disabling symptoms in those she touched; like Jane Hawkins, she too was suspected of practicing midwifery on the margins of colonial society. Jones's trial consisted of neighbors testifying that the accused had exchanged angry words with them for various reasons. One is struck while reading court testimonies from this period by the degree to which an accusation of witchcraft could be prompted by ordinary conflicts between residents—a missing utensil, a dropped dinner, or disagreements over land borders. All of these mundane events serve as legitimate evidence for an inquiry into witchcraft during this period.

Besides disease, disability, and congenital "deformity," charges of witchcraft also accompanied those who experienced bouts of severe mania, depression, or other psychiatric conditions. While such swings of emotion and cognitive states must have been relatively common among those living on the edge of what Puritan writers referred to as a "waste and howling wilderness," altered states of perception could lead to persecution. For instance, in 1641, colonist Mary Johnson was convicted of thievery. This conviction led the accused to confess to forming a compact with the devil and witnessing visions of the devil encouraging her while working in the fields and performing labors for her. This "voluntary" admission was the first recorded confession of witchcraft in the colonies, and Johnson was executed as a result (Hall, 1991: 23). Furthermore, one woman who was tried for slandering another with the accusation of witch was found not guilty based on the fact that she was "deprived of natural reason when she expressed those words charged on her" (Hall, 1991: 134). In 1671, Elizabeth Knapp was accused of being possessed because of her bodily mannerisms such as uncontrolled shrieks and outbursts of wild laughter. Readers of these transcripts encounter a number of individuals who profess their consort with demons in order to establish a state of mind that differed radically from that of most community members. Thus, some individuals went to their deaths while embracing the truth of an alternative psychiatric state of mind (what we might term "mental illness" today) in the guise of a confession of witchcraft. During these trials, the accused had no recourse to legal representation.

As mentioned earlier, once a charge of witchcraft was made credible through corroborating testimonies of malfeasance or "strange behavior," most individuals were physically searched for "witches' teats" or other discernible stigmata. Those who believed in witchcraft thought that witches met with devils at night, taking on the form of shape-shifting animals to suckle the devils. In other cases multiple bruises, moles, or visible blemishes could serve as physical confirmation of one's guilt.

By 1692, these relatively individual and isolated cases of consort with the devil turned into an unabashed rout of Satan as a conspiratorial presence controlling certain community members. The majority of charges during the Salem witch trials were similar to the previous cases cited here: seizures, possessions, monstrous babies, blemishes and deformities, personal misfortunes, and mental illness. When a group of girls experienced symptoms of "diabolical possession," the community hunted down scapegoats. The first three to be arrested—Sarah Good, Sarah Osbourne, and a West Indian slave named Tituba—led to a wider net of conspiracy, and ultimately, at least 19 individuals were executed for their presumed roles in these events. Early on in the public panic, evidence presented suggested that the conspiracy was so great that witching practices included formal meetings in the woods with Satan, the observation of black Sabbath, and covenant signings.

Witch-hunting brought together a powerful social alchemy of physical and spiritual realms. While disability status proved central to nearly every witching episode, disability itself did not automatically result in condemnation. While all witches presumably had "marks" that exposed their allegiance to the devils, many of the accusers used their own experiences of bodily vulnerability as the impetus for charges against another. Such instances help to describe the degree to which communities will pursue extravagant explanations for the existence of bodily, sensory, and cognitive variations. As with many other phenomena, bodies seem to cycle through periods of greater or lesser vulnerability; such perceptions seem, in part, to be based on our socially derived investments in homogeneity and the contingencies of health. They also condition ways in which we experience our own bodies as sources of discrimination, ridicule, and fragility. Of course, the witch trials resolved nothing that they set out to cure. Rather, they succeeded in deepening cultural obsessions with disability as a marker of maligned social identities.

WOOLF, VIRGINIA (1878–1941)

British writer

Virginia Woolf wrote experimental novels, essays, and political tracts that reflect on British traditions, Victorian behaviors, and the myriad changes that occurred in the modern era prior to World War I. She also wrote about her reflections on the root causes of a series of mental breakdowns that she experienced throughout her life, and linked her experience of collapse to creative output. Her first recorded episodes of mental anguish occurred around the deaths of each of her parents, although throughout her life she sought extended rest cures in nursing homes. During the same time period that the father of psychoanalysis, Sigmund Freud, was expatiating on a "talking cure," Woolf herself wrote about the creative potential to be found after periods of bleakness. Much of her writing depicts characters experiencing their environment in oppressive ways. Characters find it necessary to creatively resolve social and artistic undertakings, from paintings, to relationships, to dinner parties, and these efforts are salves that also supply readers with reasons to live. Many of her contemporaries and acquaintances, including her husband, believed that Woolf experienced bouts of manic depression, which might today be labeled as "bipolar disorder."

Woolf herself would seemingly indicate the material causes of mental anguish. *A Room of One's Own* (1929) focuses on the material necessities that would enable women to make more significant contributions to social thought and academic work. With male privilege a paramount feature of intellectual life, Woolf theorizes that feelings of suffocation in women likely derive from patriarchy. Particularly in her first novel, *The Voyage Out* (1915), she implies that the constraints of femininity result in suffocating mental illness. Exclusion from voting, education, governance, and citizenship results in women achieving much less than their potential. Judith Shakespeare, a character invented by Woolf to express this idea, lies buried at the crossroads while her male counterpart, William, achieves an "androgynous mind" and goes on to write masterful drama.

The later *Mrs. Dalloway* (1925) connects the depression of a conservative politician's wife who feels the pressures and demands of staging a successful dinner party to a disabled veteran's death wishes as he undergoes a rehabilitation regime that requires him to avow manliness. Many of Woolf's works concern the dissolution and restructuring of identity as a matter of social imposition. She puzzles over how female identity requires acquiescence to domination and the role of reflecting back an image to a man of twice his natural size. Catering to masculine cultural biases prevents women from undertaking their own careers, either as individual subjects or as artists in their own right.

In "On Being Ill," Woolf contends that illness merits as much literary attention as love, warfare, and jealousy; she delves into the separate experience of the world that is the vantage of the bedridden. Her work sits at the cusp of a series of literary narratives that seek to vivify body travails, mental anguish, and artistic resolutions to such psychic troubles. Although

Woolf records feeling intense personal negation and depression, she is not immune from the eugenicist ideas of her own era. Feminist scholar Cora Kaplan recounts Woolf's recording of her own repulsion toward her "vacant-eyed" and "idiot" sibling Laura (1870–1945) (Caplan, 2000: 314), who died in an institution. This kind of disavowal expresses what contemporary theorists consider a social hierarchy, under eugenics, of passable—as opposed to offensive—disabilities. Disability disavowal, or the participation in a hierarchy of functional "severity," has always troubled efforts at collective organizing for both feminist and disability politics.

WORK INCENTIVES

Work incentives can take many forms. To understand their application, one must first understand that there are three primary stakeholders in the employment process—the employment candidate, the employer, and any third parties that may support the employment placement process. While most employers would state that securing a qualified employee is incentive enough, often various incentives are available to support the employment outcomes of certain groups in the employment sector that are either not represented or underrepresented. These incentives are intended to encourage the employment candidate to seek work, encourage third party service providers to support the placement of specific types of employment candidates, and encourage the employer to make certain accommodations in the workplace or underwrite additional costs associated with providing certain types of work supports.

Incentives for employment candidates that support individual career development, job placement, and employment retention and advancement take many forms. These incentives are typically offered by federal or state government agencies in recognition of the fact that a person who receives certain types of disability benefits and public entitlements and who returns to work will be more self-sufficient and less reliant on public programs. The benefit is not only to the individual, who is able to be more self-sufficient, but also to the government through savings associated with decreased or terminated entitlements and the communities in which the individual is now working and contributing. The Social Security Administration (SSA) offers a few of these types of incentives as part of their return-to-work agenda for people with disabilities. In addition to the examples illustrated below, similar work incentives exist for individuals who receive veterans' benefits, subsidized housing, Temporary Assistance for Needy Families, and other public entitlements.

The SSA administers two benefit programs for individuals with disabilities: Supplemental Security Income (SSI) and Social Security Disability Insurance (SSDI). SSI is a means-tested disability benefit program that provides benefit assistance to individuals who demonstrate economic need and who are 65 or older or have a disability. SSDI benefits are paid to individuals, and their dependents, who have been employed and have paid Social Security taxes under the Federal Insurance Contributions Act (FICA). The legislative history of both the SSI and SSDI programs reveals the desire of Congress to provide every opportunity and encouragement to the blind and individuals with disabilities to return to gainful employment. During the past 20 years, legislative and regulatory changes in the SSI and SSDI programs have been enacted to incorporate work incentives aimed at reducing the risks and costs associated with the loss of benefit support and medical services as a result of returning to work.

Work incentive provisions administered by the SSA can help people with disabilities in three significant ways. First, they can help individuals pay for services or items that they need in order to work and help them to maintain, or in some cases even increase, their cash benefits until they are stably employed. Second, work incentives such as the Plan for

Achieving Self Support (PASS), Impairment Related Work Expense (IRWE), and Blind Work Expense (BWE) enable people with disabilities to recover expenses they incur while working. Finally, extended Medicaid provided under Section 1619(b) of the Social Security Act and the Medicaid Buy-In Program and Medicare Extensions incorporated into the Ticket to Work Act remove disincentives associated with working and possibly losing health care. The goals of the work incentive programs are to assist individuals to achieve gainful employment, increase independence, facilitate empowerment, and acquire self-support.

Incentives for employers fall into two primary categories: (a) tax credits and deductions for providing specific accommodations and removing physical barriers to the workplace, and (b) financial reimbursement for wage and training offsets. However, these should not overshadow the myriad of other incentives that exist for hiring individuals with disabilities. A study by the Dupont Corporation in 1990 reported several incentives, among them the fact that 97 percent of workers with disabilities rated average or above in safety and 90 percent rated average or above in performance of their specific job duties. Second to the contributions of a qualified employee with a disability are other financial incentives for diversifying the workforce.

Tax deductions and credits offered to employers as incentives are administered by the U.S. Internal Revenue Service (IRS). The Removal of Architectural Barriers Tax Deduction allows employers to deduct expenses from their tax liability for making a worksite facility or public transportation vehicle more accessible to both the elderly and individuals with disabilities. The maximum deduction is $15,000. The Disabled Access Tax Credit is a financial incentive for eligible small businesses that for the preceding year did not have more than 30 full-time employees or more than $1 million in gross receipts. Eligible expenses under this credit are those that enable the business to comply with requirements set forth under the Americans with Disabilities Act. The maximum credit in any given year is $5,000, and the credit cannot exceed the tax liability for the year. There is a $250 deductible, and only 50 percent of the eligible access expenses after the deductible is applied are allowed. The Work Opportunity Tax Credit (WOTC) is another incentive authorized by the Small Business Job Protection Act of 1996. The WOTC is a federal tax credit that encourages employers to hire certain protected groups of job seekers (including individuals with disabilities that meet certain eligibility criteria) by reducing the employers' federal income tax liability by as much as $2,400 per qualified new worker. Provisions are also allowed for part-time workers and qualified summer youth workers. A final group of incentives for employers are those classified as On-the-Job Training Programs. These are typically administered by the Workforce Development System or State or Federal Vocational Rehabilitation System and provide the employer a financial offset to cover wages during certain training periods of new employment.

A final group of stakeholders in the employment process are service providers. These are community private and public for-profit and not-for-profit entities typically charged with assisting and supporting individuals with disabilities in securing, retaining, and advancing in employment. Incentives for this important stakeholder typically take the form of reimbursement for services and supports rendered. Service providers are usually engaged in contractual relationships with state agencies to accept referrals and deliver employment-related services and supports. However, many service providers are not solely reliant on these fee-for-service structures and may be benefactors of philanthropic trusts, charities, and other fund-raising activities. Deviating from this more traditional fee-for-service structure are outcomes-based models or incentives. Under this paradigm, service providers are paid for specific employment outcomes achieved, not the actual services and supports rendered leading to the outcome. Some systems weight the amount of the actual incentive based on the outcome achieved, and variations in this paradigm place value-added emphasis on the self-determination and empowerment of the individual being supported. One example of this new paradigm is the Ticket to Work and Self-Sufficiency Program administered by the SSA.

The Ticket to Work and Work Incentives Improvement Act of 1999 included a provision to establish the Ticket to Work and Self-Sufficiency Program, which allows SSDI and SSI beneficiaries to seek employment services, vocational rehabilitation services, and other supports of their choosing needed to obtain, retain, or maintain employment and reduce their dependence on cash benefit programs. The Ticket to Work Program is voluntary, and a beneficiary who has been issued a ticket may use it to obtain services and jobs from any Employment Network (EN) he or she chooses or to the State Vocational Rehabilitation Agency (SVRA), so long as that EN or SVRA is willing to accept the ticket. In turn, once the ticket is accepted, the EN or SVRA provides employment services, vocational rehabilitation services, and other support services to assist the beneficiary in obtaining, regaining, and maintaining self-supporting employment as specified in the beneficiary's Individualized Work Plan (IWP), if developed with an EN, or Individualized Plan for Employment (IPE), if developed with the SVRA. The EN or SVRA will receive payment only if the beneficiary achieves certain work-related outcomes. At any time, a beneficiary can retrieve his or her ticket from an EN or SVRA and reassign it to another, so long as ticket eligibility requirements continue to be met.

WORKERS' COOPERATIVES

A worker cooperative is a business owned by some or all of its employees. Members of the worker cooperative work in the business and govern and manage it. Worker cooperatives are democratically run. Each worker-member has one vote in decisions about business policies, working conditions, and other matters related to how the business is run. This contrasts with other business structures in which the number of votes corresponds to the number of shares owned in the company. In larger cooperatives, members elect representatives to the board of directors. Some worker cooperatives employ workers who are not worker-owners.

Worker cooperatives have a long international history and have developed in different regions as a result of different influences. The consistent theme is the intent to create and maintain meaningful work at fair wages, in businesses that are owned and run by the workers as well as being part of the social and economic fabric of the community. Worker cooperatives are one type of cooperative business; others include supplier cooperatives (e.g., agricultural cooperatives) and consumer cooperatives (e.g., housing cooperatives).

Global and national associations and federations such as the International Co-operative Alliance (ICA) and the Canadian Co-operative Association (CCA) have articulated the principles and values followed by worker cooperatives. In addition to the democratic nature of the business, these principles include open and voluntary membership and the equitable sharing of income and profits with members after some reinvestment in the operation of the co-op. Emphasis is also placed on education, training, and information for members and the public.

A strong emphasis in these businesses is "cooperation among cooperatives." Each cooperative aims to use services and products created by other cooperatives. Cooperatives share a concern for their communities and try to contribute socially and economically to the sustainable development of their respective communities locally, nationally, and internationally.

Worker cooperatives operate in many sectors, from farming to manufacturing, home care service to auto repair. Worker co-ops can be set up as for-profit or not-for-profit operations, with any surpluses returning to members. They can be small or large: The Mondragon worker cooperatives, founded in Spain in 1956, have grown to be one of the largest complexes of cooperatives with more than 60,000 workers and 150 businesses.

There are three ways that worker cooperatives can directly benefit persons with disabilities:

1. The cooperative may include people with disabilities in its membership and give specific attention to policies and practices that support workers with disabilities. For example, attention may be given to disability benefits, the inclusion of support personnel, or flexible work hours.
2. The cooperative may be set up specifically by or with people with disabilities to create meaningful work for them. Worker cooperatives may be initiated by social service agencies attempting to help their client obtain more meaningful work, with the intention that the cooperatives will become independently operated over time.
3. The cooperative may be structured to provide services to people with disabilities. Recent examples include Cooperative Home Care Associates in New York, Home Care Associates in Philadelphia, and Cooperative Care in rural Wisconsin.

Some countries have promoted cooperatives through economic and social policies. In several countries, worker cooperatives and other business models sharing some of the characteristics or values of worker cooperatives have developed for people who have experienced long-term unemployment or underemployment, including those with disabilities. These include the self-help cooperatives of the 1930s, social firms, and consumer businesses. In contrast to these, Employee Stock Ownership Plan businesses are more than 50 percent employee owned and do not have mandates to support workers with disabilities.

Currently, worker cooperatives appear to be enjoying renewed interest and growth, and cooperative businesses are evolving with support from governments interested in assisting workers from vulnerable groups or locales to achieve economic success in several countries around the world.

WORKSITE MODIFICATION

Worksite modification represents an area of assistive technology that combines the principles of human factors, ergonomics, safety, and disability. Worksite modification has become an important strategy in the provision of reasonable accommodation required under the Americans with Disabilities Act (ADA). As a result, worksite modification services may be requested by employers or vocational rehabilitation counselors with state or community agencies. They may also be requested in worker's compensation situations when a worker is trying to return to a jobsite.

An accurate job description is necessary when considering worksite modification services. The description should not merely tell how the job has been physically done in the past but should describe the functional requirements of the job. For example, "transporting shipping boxes to pick-up area" would be more accurate than "carrying shipping boxes. . . ." The job description should also include expected productivity levels so that the outcomes of worksite modification efforts can be quantified.

Other key components of worksite modification services are an analysis of how the elements of the job description are being performed and an accurate description of consumer abilities. These components enable the consumer and service provider to consider different work techniques or a different layout of the equipment, so that the consumer can use his or her abilities to do the job.

Human factors and ergonomics are useful in analyzing the relationship between the worker and elements of the workstation. For office applications, the addition of seating that provides adequate support and adjustability is often involved. Being able to vary one's position throughout the workday can help reduce the development of discomfort such as low back pain. Also, adequate arm support and positioning can address issues faced by individuals with carpal tunnel syndrome.

When equipment is involved, it may involve modifying equipment already at the workstation or introducing new equipment. When changes are made to existing equipment, consideration must be given to shared use of tools or machinery and maintenance of all safety features designed into the original equipment.

New equipment may include commercially available devices made for the public and perhaps not used for the specific job, or devices made specifically for individuals with disabilities. Use of commercially available devices enables the benefits of mass production and quality control to be realized.

Where there is no commercially available device to use or modify, custom-designed, custom-fabricated devices are an option. These custom devices are often low-tech and low-cost. Jigs and fixtures may be used, for example, to stabilize parts being worked on or to reduce the number of steps involved in performing repetitive work tasks.

Worksite modifications are often valuable to all workers present at the jobsite. This may become evident at shared workstations or when several workers are doing the same job. Professionals involved in worksite modification may include rehabilitation engineers, occupational therapists, physical therapists, or ergonomists. The Rehabilitation Engineering and Assistive Technology Society of North America (RESNA) has a special interest group on Job Accommodations.

WORLD BANK

The World Bank is an international organization that provides long-term loans, grants, technical assistance, and advice to help developing nations reduce poverty and increase their economic growth. The World Bank is one of the largest sources of aid to developing nations, annually providing more than $20 billion to fund hundreds of projects. The bank's loans and grants are given primarily to the poorer nations of the world to fund projects that are often not attractive to private investors. Many of these nations use the funds to establish industries, implement environmental programs, and conduct infrastructure projects, including the construction of dams, electrical facilities, and roads.

The World Bank is a family of institutions technically known as the World Bank Group. Originally, the World Bank consisted of only one institution, the International Bank for Reconstruction and Development (IBRD), which began operating in 1946. Later, four other affiliated institutions were formed and joined the group. They include the International Finance Corporation (ICF), established in 1956; the International Development Association (IDA), established in 1960; the International Center for Settlement of Investment Disputes (ICSID), established in 1966; and the Multilateral Investment Guarantee Agency (MIGA), established in 1988.

The World Bank Group provides aid principally through the IBRD and the IDA. The IBRD raises most of its funds on the world's financial markets and lends to developing nations at interest rates that tend to be somewhat below those of commercial banks and with longer maturities. By comparison, the IDA aims to promote economic development through providing concessionary finance from funds contributed every three years by individual donor nations. The IFC promotes private sector investment by supporting high-risk sectors and countries. The MIGA provides political risk insurance (guarantees) to investors in and lenders to developing nations. The ICSID settles investment disputes between foreign investors and their host nations.

Member nations own the World Bank Group, and they are jointly responsible for how the bank is financed and how its money is spent. Specifically, the IBRD is owned by 184 member nations, while the other agencies of the bank are owned by 140 to 176 members.

A president and board of 24 executive directors manage the day-to-day operations of the World Bank Group. The member nations of the bank or their constituencies appoint the executive directors. The executive directors elect the president of the bank. The president is traditionally an individual from the United States because it is the largest economy in the world and has the greatest share of investments in the bank. The president is elected for a five-year renewable term. He or she chairs meetings of the board of executive directors and is responsible for the overall management of the bank. The current president of the World Bank Group is Paul D. Wolfowitz, who has been president since 2005.

The World Bank Group employs approximately 9,300 people, including economists, financial analysts, educators, environmental scientists, and engineers. The bank's employees work in the organization's Washington, DC, headquarters or in one of its 109 country offices.

During the World Bank's 60-year history, its focus has changed a number of times. Initially, the bank was almost exclusively concerned with the reconstruction of Europe and Japan after World War II. During the 1950s and 1960s, the bank's funds were relatively limited, and they were largely directed into infrastructure projects such as building electric power stations and transportation systems. During the 1970s and 1980s, the bank's funds greatly increased, and the magnitude of its lending commitments rose. There was a new interest in alleviating poverty, and the bank began lending more funds to developing nations. During the 1990s, with the fall of the Soviet Union, the bank increasingly made loans to fund new developing markets and private economic activities in Eastern Europe.

THE MISSION, PRINCIPLES, AND VALUES OF THE WORLD BANK

Mission (last updated June 30, 2003)

> Our dream is a world free of poverty.
>
> To fight poverty with passion and professionalism for lasting results.
>
> To help people help themselves and their environment by providing resources, sharing knowledge, building capacity, and forging partnerships in the public and private sectors.
>
> To be an excellent institution able to attract, excite, and nurture diverse and committed staff with exceptional skills who know how to listen and learn.

Our Principles

> Client centered, working in partnership, accountable for quality results, dedicated to financial integrity and cost-effectiveness, inspired and innovative.

Our Values

> Personal honesty, integrity, commitment; working together in teams—with openness and trust; empowering others and respecting differences; encouraging risk-taking and responsibility; enjoying our work and our families.

Over the years, the World Bank has been strongly criticized by academics, political activists, and nongovernmental organizations. Some believe the bank has been too conservative in its lending practices and has not done as much as it could to help the poorer nations of the world. Others believe the bank has given too many loans to poor nations and saddled them with inordinate debt, which they cannot possibly afford to repay. When they do not repay, the bank has mandated draconian structural changes to their economies without giving due regard to the effects of such changes on the nation's social progress and political stability.

In the United States, both the political left and right have criticized the World Bank. Some on the political left want the bank to allow the poorest nations to cancel repayment of their loans so they can devote more of their resources to health and education. Debt forgiveness, however, shrinks the bank's income and thus perhaps its future loans. In contrast, some on the political right want to leave all development to private enterprise. The World Bank, however, receives most of its income from loans to middle-income nations and then turns some of the modest profit on these loans to help poorer nations.

Starting in 2000, the World Bank has become increasingly concerned with how to include disabled persons in the economies and societies of developing nations. To address this issue, the bank has undertaken several activities. For example, the bank is working to expand and improve the collection of disability data in developing countries. It established an online clearinghouse to make documents concerning the disabled readily available to its member nations and the general public. It sponsored several international conferences on disability and development. The first conference was held in December 2002 and the second in December 2004. The bank also recently launched an educational program aimed at incorporating the various dimensions of disability into development policies and practices at the urban and municipal levels. The bank's first course on disability issues, held in Guatemala in May 2004, emphasized the inclusion of the disabled in urban transportation, housing, financing, and other areas.

In the future, the World Bank will face many daunting challenges. It will have to reduce poverty in developing nations while their populations continue to grow. The bank will also need to increasingly address the growing plight of poor nations in sub-Saharan Africa. Many of these nations are experiencing the effects of the HIV/AIDS pandemic, which is rapidly reversing many of the economic and social gains made during the past 50 years. As a result of HIV/AIDS, an entire generation of people is being lost, the number of persons with disabilities is increasing, average life expectancy is decreasing, and infant and childhood mortality is increasing. To reverse the effects of this devastating disease, the economies, health care, and educational systems of these nations will need to be greatly strengthened—and in some cases totally rebuilt.

▣ WORLD HEALTH ORGANIZATION

The World Health Organization (WHO) is the specialized agency within the United Nations (UN) concerned with protecting and improving the world's public health. WHO's main objective is to attain the highest possible level of health for all people of the world. The organization very broadly defines health as "a state of complete physical, mental, and social well being and not merely the absence of disease or infirmity." WHO improves health by setting norms and standards, providing countries with technical advice and assistance, and advocating changes in public health policies. WHO is also the world's foremost source of international information concerning demographic and health trends, the occurrence and burden of chronic and infectious diseases and disabilities, and the provision of public health, medical, and environmental health services by countries.

HISTORY

A number of international public health organizations preceded the World Health Organization. The WHO can trace its history back to 1851 when 12 countries met at the first International Sanitary Conference held in Paris, France. Other organizations that were forerunners of WHO include the International Office of Public Health established in 1907 in Paris and the League of Nations' International Health Organization established in 1923 in Geneva, Switzerland. After World War II, when the League of Nations was broken up, the members of the newly formed United Nations met in New York to discuss establishing a new international health organization. They drafted the constitution of the WHO, which stated that the proposed organization's overall purpose was the promotion and pursuit of "the attainment by all people of the highest possible level of health." With the ratification of its constitution by member nations, the WHO came into formal existence in 1948.

During its initial years, WHO focused its activity on the demands of post–World War II reconstruction, including the rebuilding of health services in war-affected countries. In the 1960s and early 1970s, WHO worked primarily on mass campaigns for the prevention, control, and eradication of malaria, tuberculosis, and sexually transmitted diseases. It also conducted activities to improve maternal and child health, environmental sanitation, and nutrition. In the late 1970s, WHO worked with other national and international organizations to help stop the spread of the ancient deadly infectious disease smallpox. Through its efforts, smallpox was the first disease in human history ever to be eradicated. Starting in the early 1980s and continuing to the present, WHO has broadened its focus to include treating and preventing chronic diseases, improving environmental conditions caused by air and water pollution, providing health care technology, and ensuring the production and distribution of essential pharmaceuticals to member states. WHO has also become the world's "health conscience" by actively promoting human rights and the principle of equity in health among all people of the world, including persons with disabilities. According to WHO's constitution, "The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political, economic, or social condition."

ORGANIZATIONAL STRUCTURE

The organizational structure of the WHO has changed little since its establishment in 1948. WHO is open to all member states of the United Nations, along with other nonmember nations or states that are invited to participate. Since its inception WHO has attempted to have universal membership, reflecting the belief that health concerns cannot be confined within national boundaries but require cooperation across all countries. Currently, the WHO is organized into four divisions: the World Health Assembly, the Executive Board, the Secretariat, and the Director General.

The World Health Assembly is the supreme decision-making body of WHO. It is composed of representatives from 191 member states. All member states are represented in the assembly's plenary and legislative body. Delegations of member states consist of not more than three delegates most qualified by their technical competence in the field of health, preferably representing the national health administration of each member state. Representatives of relevant international organizations and recognized nongovernmental organizations are also permitted to attend the assembly as observers. The Health Assembly's main functions are to decide major public health policy questions and to determine the overall policy direction of WHO's six-year General Programme of Work. The assembly also supervises the financial policies of WHO and reviews and approves the organization's budget. The assembly has the authority to adopt regulations in such fields as sanitary and quarantine requirements; determine the nomenclature for diseases and causes of death; and establish standards with respect to safety, purity, and potency of biological, pharmaceutical, and similar products. These regulations are binding unless member states choose to opt out from them. The assembly meets annually, usually in May. Each member state has one vote. In practice, the majority of the World Health Assembly's decisions are presented as recommendations or resolutions, and most decisions are made by consensus.

The Executive Board is the executive body of WHO that works to put into action the decisions and policies of the World Health Assembly. It consists of 32 members. Specifically, the board prepares the agenda and program of work for the next meeting of the Health Assembly. The board also is empowered to take emergency measures in case of epidemics or disasters. The World Health Assembly elects member states that will sit on the Executive Board. It is customary that at least three of the five permanent members of the United Nations Security Council (i.e., China, France, Russia, the United Kingdom, and the United States) serve on the Executive Board at any given time. Upon election, board members serve in a personal capacity as health experts rather than as representatives of particular governments. Executive Board members serve a three-year term. Each year there is a rotating turnover of one third of the membership. The board meets twice yearly, in January and after the World Health Assembly meeting in May.

The Secretariat is the administrative and technical staff of the WHO. It consists of about 5,000 public health, medical, economic, and support staff and other experts. Members of the Secretariat work at WHO's global headquarters, in the organization's six regional offices, and at field offices in countries throughout the world. WHO's Secretariat focuses its work on articulating consistent, ethical, and evidence-based policy and advocacy positions; managing information by assessing trends and comparing performance; setting the agenda for and stimulating research and development; catalyzing change through technical and policy support in ways that stimulate cooperation and action and help to build sustainable national and intercountry capacity; negotiating and sustaining national and global partnerships; setting, validating, monitoring, and pursuing the proper implementation of norms and standards; and stimulating the development and testing of new technologies, tools, and guidelines for disease control, risk reduction, health care management, and service delivery.

The Director General heads the Secretariat. Nominated by the Executive Board and elected by the World Health Assembly, the Director General is appointed for a period of five years. Among the primary responsibilities of the Director General are appointing Secretariat staff, preparing annual financial statements, and drafting WHO's proposed program budget.

The global headquarters of the World Health Organization is located in Geneva, Switzerland. The organization also has six regional offices: WHO Regional Office for Africa, located in Brazzaville, Republic of the Congo; WHO Regional Office for Europe, located in Copenhagen, Denmark; WHO Regional Office for South-East Asia, located in New Delhi, India; WHO Regional Office for the Americas/ Pan-American Health Organization, located in Washington, DC; WHO Regional Office for the Eastern Mediterranean, located in Cairo, Egypt; and WHO Regional Office for the Western Pacific, located in Manila, the Philippines.

The regional offices were created because of the early recognition that effective international health cooperation requires both global and local actions, and because some of the regions already had international health organizations (i.e., the Pan American Health Organization), which were incorporated into the WHO. Each region is managed by a director and has its own staff. The regions are responsible for the policies and activities in their respective geographic areas.

DISABILITY-RELATED ACTIVITIES

The WHO undertakes many activities to identify, help, and protect people with disabilities. Specifically, it works to ensure the human and legal rights of persons with disabilities, provides community-based rehabilitation services to treat the disabled, conducts various surveys to estimate the worldwide extent of disabilities, and develops, tests, and widely disseminates measures of disability.

The WHO's Disability and Rehabilitation team (DAR), for example, attempts to ensure equal opportunity and promote the human rights of people with disabilities by supporting member states in framing and implementing policies and involving community participation. Major activities of the DAR include establishing methods to quickly identify and reduce the impact of impairment, improving access to rehabilitation facilities and services, integrating rehabilitation services into nations' primary health care systems, promoting community-based rehabilitation programs, and strengthening the interactions among people with disabilities, health care workers, professionals, and the community.

To measure the extent of disabilities in populations and to determine worldwide trends in the occurrence of disabilities, the DAR periodically conducts surveys. Based on the results of a recent survey (2003), the DAR estimates about 600 million people, or up to 10 percent of the world's population, experienced some type of disability that caused difficulties in common daily activities. It found that 80 percent of the world's disabled lived in low-income countries. In addition, the majority of people with disabilities are poor and lack access to basic services, including rehabilitation facilities. The survey also found that the world's disabled population is increasing because of such factors as population growth, medical advances that preserve and prolong life, war injuries, landmines, the spread of HIV and AIDS, malnutrition, chronic disease conditions, substance abuse, accidents, and environmental damage. These factors are creating an overwhelming global demand for health and rehabilitation services.

The DAR publishes a number of guidelines, technical documents, and reports on disabilities and rehabilitation. Many of its publications are available in hardcopy and online. All of them are in English, and some are also available in Arabic, French, and Spanish.

To measure the extent, severity, level of impairment, and treatment of mental health disorders, the WHO World Mental Health Consortium is currently conducting the largest cross-national mental health survey ever undertaken. This face-to-face household interview survey of adults representing the general population of several countries asks respondents to assess if, during the previous 12 months, they had or were treated for a variety of mental disorders (i.e., anxiety, mood, impulse control, and substance abuse disorders). The ongoing survey will interview nearly one-quarter of a million people in 28 countries.

Survey results from more than 60,000 respondents from 14 countries indicate that mental disorders are common and often undertreated. In developed countries (Belgium, France, Germany, Italy, the Netherlands, Spain, Japan, and the United States) between 36 and 50 percent of people with serious mental disorders were untreated in the year prior to the interview. In less-developed countries (China, Columbia, Lebanon, Mexico, Nigeria, and Ukraine), the problem was even greater, with 76 to 85 percent receiving no treatment. The level of impairment associated with serious mental disorders in all countries was found to be staggering. Persons with serious disorders reported they were so debilitated that they lost their ability to function for between 30 and 80 days during the same period.

The WHO also periodically attempts to determine the global burden of disease by measuring the impact of the loss of healthy life from a large number of infectious and chronic diseases and injuries. The global burden of disease combines the loss of life from premature death with the loss of healthy life from disability. Disability is measured in units of disability-adjusted life years. Calculation of the disease burden is based on a number of assumptions that involve decisions about ethical values or social preferences. The key factors are the potential years of life lost from death; the discount rate, or extent of time preference for human life and health; and the disability weights used to convert life lived with a disability to a common measure of premature death. The concept of the global burden of disease has been widely used by developing countries to calculate the relative cost effectiveness of health interventions as a basis of policy reform.

Finally, the WHO has developed and promoted several standardized measures of disability. It first issued a standardized classification of disability in 1980 when it published the International Classification of Impairments, Disabilities, and Handicaps (ICIDH). The ICIDH, however, suffered from several conceptual and technical problems and was difficult to use. In 1993, the WHO began an international collaborative process for substantially revising it. With the participation of 65 countries, the group developed various drafts of a new classification of disabilities and extensively field-tested them to ensure reliability, validity, and comparability across cultures, languages, age groups, and genders. In 2001, the WHO issued the International Classification of Functioning, Disability, and Health (ICF).

The ICF provides a common framework for describing and measuring disability at both the individual and the population levels. It incorporates both a medical and a social model of disability. Briefly, the ICF identifies three dimensions of human functioning: body function (physiological functions of body systems including psychological functions), activity (the execution of a task or action by an individual), and participation (involvement in a life situation). Decreases in these dimensions are viewed as dimensions of disability. Disability is broadly defined in terms of impairments (problems in body function or structure such as a significant deviation or loss), activity limitations (difficulties an individual may have in executing activities), and participation restrictions (problems an individual may experience participating in life situations). The ICF can be used to classify specific categories of functioning in these disability dimensions, with qualifiers to assess severity and to identify whether the category is being used as a capacity or a performance. The ICF is available from the WHO in English, French, Spanish, Arabic, Chinese, and Russian. A multilingual CD-ROM version is also available.

WULFF, HILDE (1898–1972)

German social worker and children's advocate

Hildegard Wulff was a German social worker who founded and ran homes for children with physical impairments. In addition, she was active in the Women's and Disability Rights movements. Wulff was born on January 7, 1898—the daughter of an industrialist family in Ruhrgebiet, West Germany—and contracted polio at the age of two years. Her father exhausted all medical possibilities hoping for her stabilization and recovery. Indeed, her long clinic and hospital stays caused a separation between Hilde Wulff and both of her sisters and excluded her from educational possibilities. These essential childhood experiences later turned Wulff toward the vocation of social work and the foundation of homes for physically disabled children. In 1921, she established the pediatric home "Urdenbach" in Düsseldorf. From 1923 onward, she involved herself with the "Selbsthilfebund der Körperbehinderten" (Self-Help Alliance of the Physically Handicapped; 1919–1931), the first emancipatory self-help organization representing the interests of the physically disabled in Germany.

At this time, Wulff was already fighting for an inclusive education of both disabled and "healthy" children in public schools. In April 1933, just a few months after the National Socialists seized power, Wulff founded the Children's Home "Neu-Westend" in Berlin. From 1935 until the mid-1960s, she ran the home "Im Erlenbusch" in Hamburg. During the Third Reich, she probably housed political and racial victims of Nazi persecutions in both places. For political reasons, Wulff resigned from the "Selbsthilfebund der Körperbehinderten," which had developed into the National Socialist and racial hygienic–oriented successor organization "Reichsbund der Körperbehinderten" (Reich Organization of the Physically Disabled). She and the children she cared for all survived the National Socialist period. On July 23, 1972, Wulff died in her home in Hamburg.

X

XENODISABILITY

The neologism *xenodisability* (*xeno* meaning foreign) is designed to be synonymous with *zoodisability* (*zoo* meaning animal). Both terms refer to disability in the animal world—that is, foreign from the human.

In 1995, a group of schoolchildren on a field trip near Henderson, Minnesota, found that 11 of 22 frogs they encountered had limb and eye deformities. Since that time, biologists across North America have noted that frogs with limb anomalies—absent, deformed, or extra legs—are being born at a prodigious rate. Evidence now suggests that farming techniques have changed soil contents, promoting the growth of a parasite that induces these deformities in frogs. Like the canary's extreme sensitivity to gas, which made it an early warning system for coal miners, animal disability can be a harbinger of problems to come in the relationship between human beings and the environment. But the meaning of such problems is far greater for humankind.

The place of disabilities in the animal world, as it relates to humans, is many faceted. Humans' reasoning about animals with disabilities is sometimes indicative of humans' own social peculiarities. The thirteenth-century physician Aldebrandino of Sienna was curious about why humans are unable to walk when they are born, as other animals can. He concluded that the mother's menstrual blood poisons the human child, and only after the blood has been cleansed from the child's body is it able to walk. Disability in humans is partly revealed by comparison with animals, and vice versa. By comparing ourselves with other creatures, we have "determined" that our opposable thumbs have been critical to our developmental advantage, increasing our functional abilities in comparison with the species-level "disability" of nonprimates.

Animals are also widely used in more focused research, both as models for conditions that disable humans (e.g., the mouse model for Rett syndrome) and as test subjects for interventions, at either the mechanical or the cellular/molecular level (e.g., both large and small animals used in stroke studies).

At the cultural level, animals have been a ready symbolic or metaphoric venue for disabilities for millennia, as in descriptions such as "blind as a bat." Literature abounds with disabled animals, even stutterers, like the cartoon character Porky Pig. But observing the culture of real animals with disabilities has been equally valuable, if only more recent. Jane Goodall noted that chimpanzees exhibit some mutual wound-tending behavior when one of their number is hurt. Since the 1950s, Japanese macaques have been observed to have significant rates of physical disabilities. One study found the incidence at birth to be nearly 15 percent. Although the study found that infant mortality for macaques with disabilities was three times that of those without malformations, maternal "caretaking" evidently overrules natural selection, as many survive. One research team is now making a concentrated study of these mother-infant dyads.

While we study macaques and other primates with disabilities, these same species are trained as assistants to human beings with disabilities, just as dogs and other animals are. Xeno/zoodisability is a field with rich potential for increasing our understanding of the meaning of disability.

—Walton O. Schalick III
