The second notion of disability culture is based on social/political dynamics of group interaction. This notion is based on sociological notions of culture that look at minority groups and their solidarity and common goals of fighting oppression. The notion also includes common values of social/economic justice. From this way of thinking, disability culture stands *in resistance to* mainstream cultural expressions of disability as pathological and unproductive and stands *for* radical democracy and self-empowerment. In making disability a social/political issue, disabled people affirm the validity and importance of disability and represent a disability culture of dissent and struggle that includes material (economic) and temporal (body) dimensions.

The third general form that disability culture takes is personal and aesthetic. In this notion, culture is created from individual experience. The disabled person is an interpreter of cultural identity. The mind/body consciousness has the capacity to resist and transform values about disability in mainstream culture. Disability culture as personal/aesthetic is what disabled people acknowledge when they say, "I am proud to be Black and Disabled."

These three forms of disability culture take expression simultaneously. The boundaries between personal disability identity pride and notions of disability community are blurred. Identities forged from personal experiences may be supported and further developed by identity with a particular disability community—whether social, political, or academic. Disability culture as social/political coexists with personal values of disability pride. All of these forms of disability culture are expressed through textual, discursive, linguistic, and artistic forms.

LOOKING TOWARD THE FUTURE

Understanding disability culture offers several possibilities for future thinking, study, and practice. These possibilities might include (1) study of changes in the way disability and difference are defined and understood; (2) changes in thinking about disability identity in relation to society as a whole, as well as in relation to disability movements; and (3) changes in the ways we think about and develop supportive communities. These three possibilities open the way for furthering current notions of disability culture.

Defining Disability and Difference

Disability, disablement, and impairment are universal. They know no national, societal, or cultural boundaries. Anyone can become disabled—regardless of age, class, race, or gender—through birth, accident, illness, war, poverty, or advanced age. Most individuals, at some point in their lives, will experience disability, disablement, or impairment. The vast majority of the current 600 million disabled people worldwide live in developing countries. Most of these individuals live in rural areas and experience their cultural identity in traditional agrarian societies. It has been estimated that in some regions of the world, as much as 25 percent of the population have impairments. In fact, in some countries such as Mali, blindness is not considered a disability but just one of the many conditions of everyday life that all Malians experience in one way or another. Under these conditions, disability and impairment are not merely the experience of a minority group, but rather the normal condition of humanity. From this perspective, distinctions between disabled and nondisabled individuals that have formed the basis for developing disability culture become problematic. When all individuals are included—because they are frail, limited, mortal—there will be no distinct identity.

Study of disability culture also shows us that people who have impairments often define themselves not by their impairments, but in relation to disablement in cultural contexts, whether political, social, or aesthetic. These cultural contexts show us that different cultural beliefs and practices make biological impairment difficult to define (consider the example of deafness) or to separate from disablement. Notions of the impaired body shift and change, depending on the cultural context and historical times. Definitions of disability culture and the processes of enacting this culture (identifying as Disabled, or not) suggest a future in which *embodiment* (the experience of disability) may be a more effective way of understanding impairment than attempting to refine or develop universal descriptions and categories of impairment. Seeing disability and impairment as embodiment recognizes the historical and cultural aspects of impairment that are inseparable from the biological aspects.

Embodiment as a line of thinking in relation to impairment characterizes a small but growing number of recent scholarship in disability studies. Two examples are the books *Embodied Rhetorics: Disability in Language and Culture* (edited by James C. Wilson and Cynthia Lewiecki-Wilson) and *Semiotics and Dis/ability: Interrogating Categories of Difference* (edited by Linda J. Rogers and Beth Blue Swadener).

Recognizing Multiple Identities

Disability culture has been associated with identity politics because of its emphasis on collective identity to work for social change. This collective identity is based on an understanding of shared oppression and has the principle goals of forging positive images and changing society to meet the requirements of social justice and equity. Notions of disability culture that emphasize a collective identity have been criticized as the paradox of disability culture by disability activists and by disability scholars. The paradox lies in the argument that claiming unity against oppression is actually a source of oppression in itself. In other words, claiming unity leads to simple dichotomies of "Us" (Disabled) and "Them" (Nondisabled), ignoring and devaluing differences among disabled people.

All people have multiple identities. Gainer's statement "Now I am Black and Disabled" points to this fact. These identities take on different meanings and importance in different contexts. As an example, for many disabled people, being a woman, being gay or lesbian, or being Black is more disabling in relation to societal discrimination than having an impairment.

One of the core values of disability culture is acceptance of difference. At the same time, the social model of disability aims to fix the environment so that differences no longer make a difference. The paradoxes of unity and difference inherent in these values and goals need to be addressed in the future—both at a practical level and in theory.

Developing Communities

In industrialized countries of the North, the rule of thumb for counting the prevalence of disability is 10 percent of the population. In developing countries of the South, this number may be greater, due largely to conditions of poverty. All in all, disabled individuals the world over arguably represent one of the largest minority groups in the world. In today's globalized world, coalescing (coming together) as an oppressed minority—whether group membership is based on discrimination from full rights as citizens or on exclusion from social roles that define personhood—has become imperative.

The rise of disability culture has depended primarily on community building, either as a result of physical exclusion from society (as in Zimbabwe) or to resist social, political, or economic exclusion from basic human rights, employment opportunities, or from social roles and responsibilities connected to personhood. The social and political movements that have developed from community building have been composed largely of middle-class individuals from industrialized countries. These movements have also created social and political agendas within a disability culture that is based on Western assumptions about disability. The growing movement in developing countries exposes the limitations and narrow vision of these earlier movements.

The challenge for the future is to develop a broader cross-cultural and comparative vision of disability culture. This vision would take into account notions of personhood and "the body functional," as well as traditional models of disability and the broad vision of disability and development.

Globalization has brought with it advances in computer technologies and other scientific advances that have greatly benefited disabled people. For example, electronic devices for blind individuals, physical mobility devices, and opportunities for communication via the Internet have greatly contributed to the expansion of disability culture. At the same time, these technologies are not available to the majority of disabled people living in poverty. For this reason, globalization carries opportunities as well as dangers. The opportunities lie in including greater numbers of disabled people with access to disability culture. The danger occurs when these numbers represent mainly the privileged, creating a greater divide and exclusiveness in disability communities.

Whether disability culture is a state of mind, a place, or membership in a community, the ultimate goal of disability culture is for all disabled people everywhere to be at home in their country. Playwright and poet Neil Marcus (n.d.) puts it this way:

> If there was a country called disabled,
> I would be from there.
> I live disabled culture, eat disabled food,
> make disabled love, cry disabled tears,
> climb disabled mountains and tell disabled stories. . . .
> If there was a country called disabled,
> Then I am one of its citizens.
> I came there at age 8. I tried to leave . . .
> But found myself, in the end staying and living there . . .
> In my life's journey
> I am making myself
> At home in my country.

DISABILITY DISCRIMINATION ACT OF 1992 (AUSTRALIA)

See Disability in Contemporary Australia

DISABILITY DISCRIMINATION ACT OF 1995 (UNITED KINGDOM)

The Disability Discrimination Act 1995 (DDA) (as amended by the Special Educational Needs and Disability Act 2001), together with the Disability Rights Commission Act 1999, constitutes the primary source of antidiscrimination legislation for disabled people in the United Kingdom.

The campaign for antidiscrimination legislation in the United Kingdom began in earnest in the late 1970s, as a result of the emergence of the disability movement in the United Kingdom. This movement—a loose coalition of disabled individuals and organizations (influenced by disabled people and organizations in other countries and by other liberation movements both in the United Kingdom and abroad) with a common understanding and consciousness—developed a new way of understanding disability through what became known as the social model definition of disability. The term *social model* was coined by Mike Oliver in 1983 to reflect the growing demand by disabled people and their allies for “nothing more fundamental than the switch away from focusing on the physical limitations of particular individuals to the way the physical and social environments impose limitations on certain groups or categories of people.” In summary, the social model sought to understand the concept of disability as the result of the relationship between people with impairments and an oppressive society, as opposed to what became known as the medical model of disability, which placed disability within the framework of medicine. Accordingly, disabled people reframed the discourse so that their experiences and lives were explained as a reflection more of discrimination and oppression than of their impairments (their medical or quasi-medical condition). As a result, in 1981, the first attempt at antidiscrimination legislation for disabled people in the United Kingdom was made by Alf Morris MP. That attempt, together with the next 16, all failed. However, over the next 15 years, the campaign for antidiscrimination legislation grew, particularly with the passing of the Americans with Disabilities Act in 1990.

THE DDA

Until the DDA, disability legislation in the United Kingdom was primarily aimed at providing welfare support in the form of financial benefits or services and by establishing special homes and schools. The DDA, however, established requirements on employers, service providers including those disposing of or managing premises, transport providers, and (since September 2002) education providers to end less favorable treatment of disabled people and make “reasonable adjustments”: amend policies, practices, and procedures; provide auxiliary aids and services; and remove physical and other barriers.

Who Is Covered?

The act limits the protection afforded to those with impairments that have a substantial and long-term (which means at least 12 months) adverse effect on at least one of eight prescribed day-to-day activities. These activities are mobility; manual dexterity; physical coordination; ability to lift, carry, or otherwise move everyday objects; speech, hearing, or eyesight; continence; ability to concentrate, learn, or understand; and perception of the risk of physical danger. In addition, the act covers those who have had (but no longer have) such an impairment, those with severe disfigurements, those with symptomatic progressive impairments, and those with impairments that would have a substantial effect on one or more of the prescribed activities were it not for the fact that the effect is controlled or corrected by the use of prostheses, medication, or otherwise. On the other hand, drug addiction, hay fever, and certain mental illnesses that have antisocial consequences (such as pyromaniacs, kleptomaniacs, and voyeurs) are excluded. In total, more than 10 million people are covered—about 17.5 percent of the UK population. Those not currently covered by the legislation include those with impairments that do not have a substantial effect on a prescribed activity, those with short-term impairments, those with a genetic predisposition to impairment, those with impairments that have yet to manifest themselves symptomatically, those assumed to have an impairment, and those associated with or related to people with impairments.

The Employment Provisions

The DDA gives a general duty on employers to treat disabled applicants for jobs and employees no less favorably than they would treat nondisabled applicants and employees. In addition, the act requires that employers make what are known as "reasonable adjustments" to remove obstacles that substantially disadvantage disabled people. Such adjustments may be physical adjustments to premises to make them accessible or, for example, altering working hours or providing training. Discrimination is, however, lawful if it is for a reason that is both "material to the circumstances of the case and substantial." However, the employment provisions of the act do not currently cover certain categories of employment including the police service, fire service, prison service, armed forces, and partnerships.

The DDA abolished the quota system established by the Disabled Persons (Employment) Acts of 1944 and 1958. Until the DDA was brought into force, large employers—those with more than 20 staff members—were obliged to ensure that at least 3 percent of their workforce consisted of registered disabled people. That duty no longer remains. In any event, most large employers never met the 3 percent target. The rationale behind abolition of the quota system was, essentially, that with antidiscrimination measures, quotas were no longer necessary. In addition, even those companies that did meet the quota tended to employ disabled people at junior levels and the fines levied on those employers that failed to meet the quota were derisory. However, abolition was not universally supported as some believed that it provided a rare opportunity for a disabled applicant to be given an advantage over a nondisabled applicant in recruitment. It is hard to tell whether abolition has itself (without the DDA) affected employment opportunities for disabled people.

Discrimination in the Provision of Goods, Services, Facilities, and Premises

The DDA also affords some protection to disabled people in the provision of goods, services, and facilities. These include access to and use of any place that members of the public are permitted to enter (including shops, churches, courts, railway stations, and public parks); access to and use of means of communication; access to and use of information services (including advice agencies); accommodation in hotels and boarding houses; facilities by way of banking and insurance and for grants, loans, credit, and finance; facilities for entertainment, recreation, and refreshment (including bars, restaurants, theaters, and leisure centers); facilities provided by employment agencies; and the services of any profession and trade (including doctors, lawyers, and hairdressers) and any local and public authority. The act requires providers of such services not to treat disabled users less favorably than they would a nondisabled person and also to make such adjustments as may be reasonably required to remove or reduce obstacles for disabled people. Adjustments may be to policies, practices, and procedures to provide alternative means of communication (such as text phones, Braille, extra staff, and other equipment) and (from September 2004) to the physical environment and buildings. Discrimination is, however, permitted if it is related to health and safety, capacity, the need to be able to provide services to others, or additional expense unrelated to the duty to make reasonable adjustments. The provisions do not apply to aspects of the general environment (such as street furniture), some private clubs, the design or manufacture of goods, or anything related to national security.

There are similar obligations on those disposing or managing premises save that there is no duty to make any adjustment.

Transport

The act establishes time frames for meeting minimum requirements for access to public service vehicles (buses and coaches), trains, and licensed taxis. However, there are currently no directly enforceable antidiscrimination provisions.

Education

Until September 2002, most education was expressly excluded from the antidiscrimination provisions of the DDA. However, amendments brought by the Special Educational Needs and Disability Act 2001 extended the DDA into the provision of education in schools and colleges. Schools must not treat a disabled applicant or pupil less favorably than they would a nondisabled applicant or pupil and must make adjustments to policies, practices, and procedures (though not, necessarily, in the provision of auxiliary aids and services—which is dealt with by separate, education legislation—or in physical adjustments to premises). Colleges must also not treat a disabled applicant or student less favorably than a nondisabled applicant or student and must make adjustments to policies, practices, and procedures; in the provision of auxiliary aids and services; and (from September 2005) to physical features. Discrimination is, however, permitted in order to comply with permitted forms of selection, to protect academic or other standards, and where it is “material to the circumstances of the case and substantial.”

Two key recent cases have illustrated the extent of the effect of these new provisions. In *Ford Shubrook v. St Dominic’s 6th Form College* (2003)*,* the Court held that the refusal of a college of further education to permit a 16-year-old student with cerebral palsy to commence academic studies, because of concerns about his ability to access parts of the building, was, having regard to all of the circumstances, unlawful. The Court issued an injunction requiring the college to admit the student. In *Buniak v. The Governing Body of the Jenny Hammond Primary School* (2003)*,* a Tribunal held that a school acted unlawfully in discriminating against a six-year-old student in a variety of ways at school, including in excluding him from school activities and in refusing to secure adequate staffing support for him.

CHANGES FOR 2005

Recently, the government passed the Disability Discrimination Act 2005. The changes extend the protection against discrimination in job advertisements, group insurance, transport services, public authorities, and private clubs, among others. The changes also deem people with HIV infection, multiple sclerosis, or cancer to be disabled for the purposes of the DDA at the point of diagnosis (not simply at the point that the impairments become symptomatic).

DISABILITY IN CONTEMPORARY AFRICA

Africa is the second largest continent in the world with 40 countries and a population of 800 million people. Geographically, it is often divided into northern Africa and sub-Saharan Africa. Northern Africa is mostly Muslim, while sub-Saharan Africa is mainly Christian. Africa is a continent of contrasts—geographically, economically, and culturally. Geographically, Mount Kilimanjaro in northeastern Tanzania (the highest mountain in Africa) stands at 20,000 feet, while the Sahara Desert in Egypt sinks 436 feet below sea level. African countries range in size from Togo with a land area of 21,927 square miles to Sudan with 967,495 square miles. Economically, Africa is generally a poor continent—some of the poorest countries in the world are in Africa—and yet it hosts some very rich coastal trading countries and some of the wealthiest individuals. Add to these contrasts the extensive varieties of languages and ethnic groups; the South African government alone recognizes 11 official languages in the country.

What this means is that Africa has a mosaic array of cultures within which disability exists. It is important to understand disability in Africa within this context. Rich cultural heritages—indigenous, traditional, and modern—provide an essential context for understanding disability. Within this context, poverty and its implications are the major problems in Africa—both as a cause and as a consequence of disability. Nevertheless, disabled people and their organizations in Africa are pursuing a rich path to development that provides strength and spiritual force for economic self-determination and political empowerment at the individual and collective levels. They will need these forces for the "long journey towards inclusion in development as a contribution to the transformation of the African continent" (Lorenzo 2003:776).

CULTURAL CONTEXT OF DISABILITY IN AFRICA

Traditionally, disability was viewed suspiciously and negatively in Africa, but as Chimedza, Mpofu, and Oakland (2000) observed, the situation is changing to a certain degree. Africa today is made up of a rich cultural heritage, both indigenous traditional and modern. The majority of the millions of citizens of Africa live in rural areas, and in the main they hold indigenous traditional worldviews. A minority of Africa's citizens live in towns and cities, and in the main most of these people subscribe to modern scientific worldviews as a result of the continent's colonial heritage and modernization (Mpofu forthcoming). This affects the African people's understanding, definition of, and interaction with disability. For example, indigenous traditional African societies view or define disability as "a limitation in social role functions resulting from physical, sensory or emotional abnormalities and is of a spiritual nature" (Mpofu and Harley 2002:27). This view is reflected in the proverbs that are used in relation to disability (Devlieger 1999) and in the nature of the words they use to describe and to define disability (Burch 1989; Devlieger 1998; Mpofu 1999). Thus, the Bantu languages in sub-Saharan Africa, for instance, have the suffix *-rema* or *-lema* (i.e., becoming heavy, to fail, to experience difficulty or foolishness) in words that refer to disability. The implicit meaning is that having a disability makes one incapable of many roles. Moreover, in many of these languages the word *rema* or *lema* is prefixed by the object or animal referent *ki*, *chi*, or *isi* (for "it") as in *kilema* (e.g., in Lebe, Sanga, Songye languages: Angola, Congo, Zambia); *chirema* (Shona language: Zimbabwe, Mozambique); or *isilima* (Ndebele, Nguni, Zulu: Malawi, South Africa, Tanzania, Zimbabwe). Therefore, the traditional African view of disability places a person with a disability somewhere between a human being and an animal or object. This view is demeaning and pejorative even in those cultures and yet continues as acceptable everyday practice. Unfortunately, it promotes wrong messages, attitudes, and stigmas against people with disabilities by dehumanizing them as objects, things, and animals.

Generally, proverbs in the African cultures are used mainly as words of wisdom to advise and warn each other on topical issues and situations. Proverbs on disabilities in the African languages serve a similar function. Kisanji (1995) argued that

> in traditional Africa, proverbs generalize a community's experience and that each proverb was accompanied by a parable which provided a sketch of the original situation . . . understanding proverbs to do with disability in African languages helps understand the attitudes towards disability and persons with disability in the society.

It is therefore important to understand the nature of disability as portrayed in the African proverbs. Several themes tend to run across most proverbs in eastern and southern Africa (Devlieger 1999). There is fear by people without disabilities of becoming disabled. One sees a sense of insecurity related to disability in many of these proverbs. For instance, there are several proverbs that send strong warnings against laughing at disability or at persons with disabilities. The proverb "Tosepanga lemene, Efile kiakupanga" (Don't laugh at the disabled person, God keeps on creating you) is widely used among the Songye people. The theme is also expressed in many other countries in Africa, for example, Zimbabwe (Shona): "Seka hurema wafa" (Laugh at disability after you are dead); Tanzania (Swahili): "Cheka kilema, uzae kilema" (Laugh at a deformed person, and you will bear a deformed person); and Zambia (Chitonga): "Haaseka bacembele bulema buzya buseka" (To him who laughs at old people, a crippled state comes laughing). The implications of laughing at persons with disabilities make clear the insecurity of any person's life. This insecurity is obvious for the persons with disabilities, but the possibility of becoming disabled is emphasized as a possibility to everyone. The message "it can happen to you one day in life" is very clear.

The other theme that seems to characterize proverbs on disability in Africa especially in sub-Saharan Africa is that there seems to be a general acceptance of the limitations of disability. For instance, this acceptance is clearly illustrated not only concerning the vulnerability of being blind but the acceptance of the limitations of that condition. Examples of this can be found in Zimbabwe (Shona): "Bofu harimemi hunza" (A blind man does not inspect a game pit) and Senegal (Wolof): "Gumba du jiite yoon" (A blind person should not lead the way) (see Devlieger [1999] for more examples). These proverbs offer a different way of thinking in contrast to the rehabilitation approach to disability, according to which the disadvantages of disability may be reversed or compensated.

By contrast, the third theme shows that there appears to be a general acceptance of people with disabilities as a source of integrity and family connectedness in some of the proverbs. The point these proverbs make is that although persons with disabilities can face negative attitudes and laughter elsewhere, the family is one source of consideration and respect. People cannot laugh at or look down on a member of their family who has a disability. It is unacceptable. Examples of this can be found in Tanzania (Swahili): "Mama hawezi kumkana mtoto, hata akiwa na vilema" (A mother cannot repudiate her child, even if it has defects); Zambia (Chewa): "Mako ndi mako usamuone kuchpa mwendo" (Your mother is your mother even if she has a deformed leg); and Zimbabwe (Shona): "Benzi kunge riri rako, kudzana kwaro unopururudza" (If an idiot is a member of your family, you applaud his dancing).

One of the major challenges of understanding disability is to address the meaning of disability in a cultural context. Such meanings are no doubt situated in the tensions between language and the experience of disability. Language is the vehicle of our thoughts, feelings, attitudes, and ideas toward objects, ideas, and people. The language that people use to describe other people if negative shows the enshrined negative attitudes and stigmas that have been accepted as normal in that society. Through its language, the African traditional society perpetuates a mixed culture that generally looks down on people with disabilities. People with disabilities then continue to experience significant social stigmas. For example, studies in schools have revealed that students with disabilities are discriminated against by their peers and teachers and are more likely to be ascribed more negative characteristics (e.g., dirty, lazy, useless, dishonest) than their other classmates (Chimedza et al. 2000; Mpofu 1999; Barnatt and Kabzems 1992).

At the same time, it is important to note that in some traditional African communities disability is accepted as a positive attribute. People with disabilities are revered in some communities in Africa. Some disabilities are viewed as having extraordinary powers that influence the community (Mpofu 2000; Ingstad 1995). In such cases, positive attitudes and beliefs about disability exist. However, such communities are few and limited to specific disabilities (e.g., a one-eyed person is believed to see better than a two-eyed person and to possess extraordinary vision-based powers; some psychiatric disabilities are viewed as spiritual gifts). For instance, among the Chagga people of eastern Africa, children with disabilities are regarded as hosting evil spirits, thus guaranteeing the safety of the whole community from the same spirits (Devlieger 1995). In such situations, some African people with disabilities seem to enjoy much more acceptance among their community than elsewhere.

In contrast to these indigenous, traditional views of disability, modern African views of disability are emerging, largely influenced by the West—particularly through education and modernization. For example, a modern Zimbabwean definition of *disability* is "a physical, mental or sensory condition which gives rise to physical, cultural or social barriers inhibiting an individual from participating at an equal level with other members of society in activities, undertakings or fields of employment that are open to other members of society" (Government of Zimbabwe, Disabled Persons Act 1994, p. 51). Such definitions conform to modern worldviews of disability.

THE PROBLEMS OF DISABILITY IN AFRICA

Of the 800 million people living in Africa, estimates of the prevalence of disabled people range from 3 to 18 percent, or approximately 50 million individuals. The DISTAT (United Nations Disability Statistics Database) figures (as reported by Elwan 1999:6) provide high estimates of 18 percent of people under 15 years of age in Ethiopia, to low figures of 3 percent in Malawi, with several other African countries falling within the range of 10 to 15 percent. In some areas, this number may be higher, as in some villages in Zaire, where more than 30 percent of the population may be affected by river blindness (Coleridge 1996:106).

Poverty and disability are linked. Limited access to adequate health care, education, and employment increases the risk of illness, injury, and impairment. Perhaps one of the most dramatic examples is the AIDS pandemic. Worldwide, 39.4 million people are infected with HIV/AIDS. The World Health Organization (WHO) reports the highest rates of infection in Africa and estimates that disabled people—especially those with hearing and visual impairments—are two to three times at higher risk for infection than other groups because of their lack of access to education and health care. Disability is thus a life-and-death survival issue in many parts of Africa (Disabled People South Africa 2000). By world standards, the situation is bleak.

The main cause of disability in Africa today is poverty. Unlike developed countries, diseases that are otherwise preventable such as polio, measles, tuberculosis, and meningitis continue to cause impairments and disability in Africa. This situation exists because governments are too poor to afford preventive measures for these diseases, or they have not prioritized prevention in their development agenda. Another cause of disability that is poverty related is malnutrition. Both severe malnutrition and undernutrition cause disability. Children either die or become disabled due to malnutrition and starvation simply because there is no food to eat. This situation is more common in wartorn parts of Africa. Wars in such countries as Rwanda, Burundi, Angola, Congo, and Sierra Leone have resulted in significant numbers of injuries and disabilities. Because of wars, children and women suffer and become victims of death and disabilities. The United Nations estimates that 45 million land mines are buried in 11 African countries with Egypt, Angola, and Mozambique the most affected (Onasanya 2004). This situation will cause more disability if not managed properly.

Lack of resources due to poverty and war, in combination with cultural values, means that service provisions for people with disabilities in most African countries are very limited. For example, less than 1 percent of the approximately 6 million children with disabilities in sub-Saharan Africa who are school age attend school (Chimedza, Mpofu, and Oakland 2000). Until recently, the education of people with disabilities was left to missionaries, charitable organizations, and individual philanthropists with minimal support from governments. It is only recently that governments are beginning to participate in providing services to people with disabilities but still in a very limited way. Yet the education of people with disabilities in Africa has come a long way. In precolonial Africa, children with disabilities were educated with the rest of the community in the village under the tutorship of the elders. There were no special sessions or special institutions to educate children with disabilities. Everyone was integrated within the learning community. However, with the advent of postcolonial formal education, children with disabilities began to be educated in special schools isolated from the rest of the community. These usually were boarding mission schools. For a long time, this was the only model of special education available in Africa. Whereas special schools still exist and are used in most countries in Africa, most current practices favor the integration and inclusion models of special education.

It is important to note that the concepts of integration and inclusion as used in various countries in Africa may not necessarily mean the same both within and outside of Africa. For instance, the concept of integration in general suggests bringing the student with disabilities into the mainstream of the school system so that the student learns together with the regular students. Hence in the United States, the same concept is called mainstreaming. In integration—whether it be in schools or in communities—the focus is on changing the person with disabilities to fit into the mainstream of the system. Persons with disabilities are assisted to adapt and function so that they can cope with the system by provisions of back-up support and training. However, in real terms, in countries in Africa such as Zimbabwe, integration has often meant a geographical process of moving a child with disabilities physically into the mainstream school. This process ignores issues of whether the child with disabilities is learning or not.

Most African governments have accepted integration as the best form of education for people with disabilities without considering the implications. The issue of the integration of people with disabilities is one that has to be considered with care and detachment. Many teachers have expressed reservations about integration of people with disabilities despite its advantages. Some scholars have pointed out that the integration of children into ordinary schools has many implications for teachers and planners. For example, integration requires attitude change, additional teaching materials, resource teachers, and modification of infrastructure (Peters 2004). Placement of students with disabilities into ordinary schools without the relevant provisions is frustrating to both the school authorities and the student.

The other concept that is commonly used in the education of children with disabilities that needs unpacking for Africa is inclusion. Inclusion should not only be a policy but a practice. Inclusion should include inclusive schooling, inclusive education, and inclusive societies. Most African societies' inclusion practice is limited due to negative attitudes and stigmas that are prevalent in these communities. Inclusion should not aim to change the person with disabilities to fit the environment. Instead the aim is to change the environment to accommodate the needs of the person. In practice in most African countries such as Uganda, the inclusion of children with disabilities in schooling means all children with disabilities must go to the school nearest to their home. This is the school where their siblings, friends, and neighbors go irrespective of the accessibility and pedagogic appropriateness of the school. In other words, inclusion may mean placing the person with disabilities into the community with or without support. Unfortunately, most Africa economies are not able to support and sustain inclusion in the same manner as in the West. The idea therefore is to adapt these concepts to fit the sociocultural and economic contexts of Africa.

Governments' services and support to their citizens for education and other services are generally facilitated or enabled through legislation and budget allocations. This support is critical to ensure that the citizens get the required services. Most countries in Africa do not have legislation on disability. There are no acts of Parliament that give comprehensive attention to disability. This situation affects the funding of disability supports, and in most cases does not become part of the national budget. Disability issues are then funded through an external donor project or become a sidelined peripheral issue within a Ministry allocation. Generally, almost all national constitutions guard against the discrimination of their citizens on any grounds. Some of these constitutions (e.g., Zimbabwe) go on to enumerate the basis on which people should not be discriminated against (e.g., race, color, tribe, gender, poverty, political affiliation) and in the process they usually fail to include disability. While one can argue that disability is implied, the omission causes problems.

Finally, in terms of employment, the situation of people with disabilities in Africa is fraught with significant problems. In general, there are high rates of unemployment in the formal sector in Africa and people with disabilities are worse off than their nondisabled counterparts with regard to employment opportunities. In the past, the practice was to train people with disabilities in basic trades such as shoe mending, basketry, leatherwork, pottery, weaving and crocheting. Such trades are no longer viable. Moreover, some people with disabilities now have professional and higher academic qualifications to compete in the current professional job market. There is no country in Africa that has an affirmative action system of employment whereby people with disabilities have a certain number of jobs reserved for them in employment. Although some people with disabilities have been employed in professional and other high-level jobs, generally they are unemployed or underemployed, and they get very little promotion once they are hired. Some turn to begging for survival since there are no state "social security" benefits. The only social security for most of Africa is the family support system.

THE NEW AFRICAN RENAISSANCE

> Nothing about us without us.
>
> *Friday Mavuso*

Despite the problems, the disability rights movements in Africa have organized and grown, over the past 25 years, at a rapid rate. The activities of disabled people's organizations (DPOs) and their leaders provide much hope and lessons to learn for other regions of the world. Every country in Africa has organizations of disabled people that are growing in numbers and in power. In South Africa, Friday Mavuso (who became a paraplegic as a result of a gunshot fired by a police officer) became legendary in the township of Soweto for his charisma and political savvy. The organization that he founded during South Africa's struggle for liberation from colonial rule—Self Help Association of Paraplegics (SHAP)—became a model for bringing about economic empowerment and social transformation for disabled people throughout sub-Saharan Africa (Laclave 2004). The well-known slogan "Nothing about us without us" was popularized by Friday Mavuso and has been adopted by DPOs worldwide. Disabled People South Africa (DPSA) grew out of efforts like SHAP and now enjoys membership of more than 12,000 disabled people and is influential throughout Africa and the world. DPSA currently holds special consultative status with the Economic and Social Council of the United Nations. Disabled Peoples' International (DPI), one of the leading DPOs at the international level, benefited for several years from the leadership of another well-known African disability activist, Joshua Malinga of Zimbabwe.

In its 2002 Annual Review, Action on Disability and Development reported that in Burkina Faso alone, memberships of DPOs increased by 21 percent in that year. From the National Union of Disabled Peoples of Uganda, to the South African Federation of Disabled People, to the Federation of Disability Organizations in Malawi, much is happening at the country level in Africa. As a result of these groups' advocacy and development efforts, persons with visual impairment in Ghana and Sierra Leone now vote with tactile ballot guides, and most governments have developed not only accessible voting standards but a wide range of legislation and policies that address the basic rights of disabled people to quality of life and active participation in their communities. Some African countries now include disabled representatives in government at the national level. South Africa's 1997 *White Paper on Integrated National Disability Strategy* now guides government policy in all sectors of national initiatives.

In addition, UNESCO and UNICEF report growing numbers of community-based rehabilitation programs and inclusive education programs that seek to improve the quality of life of disabled people through education, employment, and access to health care.

The African Decade of Persons with Disabilities (2000–2009) was adopted by Declaration of the Organization of African Unity in July 2000, with its secretariat based at the South African Human Rights Commission in Johannesburg. Decade activities and Plan of Action are the responsibility of the Africa Rehabilitation Institute and are coordinated and monitored by the Pan-African Federation of Disabled People (PAFOD). Regional federations have been formed in the South, East, West, North, and Central Africa to oversee work at the regional level. The overall goal of the African Decade of Persons with Disabilities is full participation, equality, and empowerment of people with disabilities in Africa. Eight objectives have been formulated for the African Decade: (1) contributing to poverty alleviation; (2) combating causes of disability; (3) strengthening the African voice; (4) awareness raising and sensitization; (5) putting disability on the social, economic, and political agenda; (6) spearheading the implementation of the UN Standard Rules; (7) addressing issues pertaining to children, youths, and women with disabilities; and (8) using the UN Standard Rules as a basis for policy and legislation. The Plan of Action for the Decade, developed in Addis Ababa in 2002, targets 12 specific objectives, including (1) support of community-based service delivery; (2) programs to alleviate poverty; (3) ensuring representation of disabled persons at national levels; and (4) addressing the needs of the most vulnerable—women and children.

While it is impossible to adequately report the range and scope of activities related to the African Decade declaration and Plan of Action, some examples are illustrative. First, the plight of disabled women has received special attention. In Beijing, for the World Congress on Women's issues, disabled African women participating in the World Congress initiated the African Network of Women with Disabilities (WWD) formulated in 2001. The initiative focuses on reproductive health and HIV/AIDS for women with disabilities. Various disabled women's support groups throughout Africa have been formulated and have generated a variety of economic, health, and social support systems that address their specific needs.

The CBR Africa Network (CAN) was established in 2001 to promote community-based rehabilitation (CBR) as a participatory strategy in Africa (reported in *Disability World*, Issue No. 21, Nov.-Dec. 2003). CBR as a philosophy and practice has been in existence since at least the early 1970s. CBR is a "strategy within community developed for the rehabilitation, equalization of opportunities and social integration of all people with disabilities. CBR is implemented through the combined efforts of disabled people themselves, their families and communities, and the appropriate health, education and social services" (ILO/UNESCO/WHO 1994 as reported in Ingstad 2001:781). However, early CBR efforts focused on the individual rehabilitation component. The new wave of CBR efforts, as envisioned in Africa, focuses first and foremost on collective equalization of opportunity and social integration of disabled people. In Kenya, for example, itinerant CBR workers conduct an "open education" program in rural areas. These workers visit blind children in their homes and work with the parents to provide early stimulation activities that will assist them in entering school. The workers also provide Braille lessons in schools, and attend teacher staff meetings to assist in planning and curriculum adaptation. Tanzania uses a similar model of itinerant CBR workers in schools, funded by the Tanzanian Society of the Blind (Peters 2004:30).

However, CBR in some African countries has met with cultural problems. For instance, CBR is based on the concept of volunteerism. This concept rarely exists in African communities in the same manner as it does in the West. People do not just volunteer to work for nothing, especially when their families do not have enough to eat. Traditionally, they worked in the village or the chief's field for free because when there was hunger the chief used the produce from that field to feed them. They volunteered to assist in the fields of a neighbor because there was a beer-drink at the end. After all, in most of Africa, disability is a family and not a public issue. This view is one reason why early CBR foreign workers complained that African families were hiding their children with disabilities. The reality is that the families were protecting their children with disabilities from these outsiders. The situation changed once the families understood the mission of CBR. A case is given, for instance, in Botswana, where a daughter-in-law who was looking after her blind mother-in-law refused to have her trained in mobility and orientation so that she could move independently around, since her husband and his relatives would view her as very irresponsible to let the mother-in-law wander around guided by a stick.

In charting the way forward, the Office on the Status of Disabled Persons in Africa has targeted economic empowerment, social services, capacity building and empowerment of DPOs, and reinforcing policy and legislative frameworks for disability rights throughout Africa. Overall, the African renaissance approach to problems of disability and African solutions to the problems hold the promise of models for the rest of the world to learn from.

DISABILITY IN CONTEMPORARY AUSTRALIA

According to a 1998 national survey of disability conducted by the Australian Bureau of Statistics, there are more than 3.6 million Australians with disabilities. This number corresponds to 19 percent of the

Australian population. The census also found that there were another 3.1 million Australians who had an impairment that did not restrict them in their daily lives. This means that over one-third of all Australians live with some form of impairment. The vast majority of disabled Australians do not rely on government assistance. There were 658,915 Australians on the Disability Support Pension in 2002, of whom 406,893 (or 61.75 percent) were men and 252,022 (or 38.25 percent) were women. The most common primary medical conditions reported by people on the Disability Support Pension were musculoskeletal, psychological/psychiatric, and intellectual/learning impairments. The most commonly reported problems facing disabled Australians were a need for assistance with mobility, property maintenance, health care, self-care, and transport.

The overall rate of labor force participation for the entire Australian population is 76 percent, but only 53 percent of people with a disability are in the labor force (Australian Institute of Health and Welfare [AIHW] 2000). Disabled Australians are entitled to many different forms of government assistance, including income support (such as the Disability Support Pension, Sickness Allowance, and Mobility Allowance). State and federal governments also provide funding for employment programs, home and community care programs, aids and appliances programs, and other services. Work-related disability programs are also provided by the Commonwealth Rehabilitation Program, which receives more than $100 million in funding.

According to a study by the AIHW (2003), 1,737 800 people, or 48 percent of disabled Australians, used some form of aid in 1998. The sorts of aids used by disabled Australians include wheelchairs (both electric and manual), scooters, canes, crutches, walking sticks, seating and bedding aids, incontinence aids, nebulizers, dialysis machines, ventilators, and hearing aids. The AIHW reported that the use of aids was particularly prevalent among people with sensory, speech, and physical disabilities.

The commonwealth government first began providing financial support for disabled people in 1908, when it introduced the Invalid Pension and Old Age Pension. In 1944, the commonwealth government felt a need to establish a social security system that would protect citizens from the extremes of a market economy and began providing Sickness Benefit Payments and Unemployment Benefits. The period from the 1950s to the 1970s was characterized by economic and political stability, as well as full employment, and the idea of a comprehensive social security system was consolidated at this time.

Australia's modern disability policy took shape after the International Year of Disabled Persons in 1981. The 1980s saw a shift away from placing disabled people in institutions; the introduction of the Commonwealth Disability Services Act, which provided a framework for the provision of disability services; and the formation of a large number of disability organizations. In 1991, the federal Disability Reform Package was introduced, which aimed to maximize the employment of disabled Australians and a 10-year Commonwealth-State Financial Agreement clarified the roles of respective governments with regard to the provision of disability supports and services.

A number of legal mechanisms have been developed to protect the human rights of disabled Australians. The Human Rights and Equal Opportunity Commission is the main body charged with protecting the rights of disabled people and advocating on their behalf. It administers the Disability Discrimination Act, which was introduced in 1992 and which aims to eliminate discrimination against people with disabilities and to promote equal opportunity for disabled Australians. The Disability Discrimination Act covers a wide range of areas, including work, accommodation, education, and access to premises, clubs, and sports, and it prohibits both direct and indirect discrimination on the grounds of disability. There are also Disability Discrimination Act Standards, which specify in more detail rights and responsibilities about equal access in particular areas, such as employment, public transport, education, accommodation, and in the administration of commonwealth laws.

The Commonwealth Disability Strategy, first introduced in 1994 and revised in 2000, is designed to provide equal access to commonwealth government services for people with disabilities. It encourages organizations to provide information in flexible formats, purchase accessible services, employ disabled staff, and consult with people with disabilities to find out their needs.

National, regional, and local disability advocacy organizations are funded under the National Disability Advocacy Program. Some of the more influential disability organizations in Australia, which are represented in the Australian Federation of Disability Organizations, are Blind Citizens Australia, Deafness Forum Limited, the National Ethnic Disability Alliance, Women with Disabilities Australia, National Council on Intellectual Disability, Physical Disability Council of Australia, Head Injury Council of Australia, and the Australian Association of the Deaf.

A major review of Australia's welfare system (including the Disability Support Pension) was announced by the minister for Family and Community Services, Senator Newman, on September 29, 1999. The review was prompted by concern over the growth in spending on welfare payments and services (to a point where it had reached a third of total budget outlays). Also, the number of Australians in receipt of welfare had grown rapidly from 1.5 million people in 1989 to 2.6 million people (one in five Australians) in 1999. In particular, the number of Australians on the Disability Support Pension had grown from 300,000 in 1989 to 600,000 in 1999, and it was predicted to rise to 750,000 in 2006. This level of "welfare dependency" had created the urgent need for reform, Senator Newman said.

Despite the presence of this significant social welfare system, significant unmet needs have been identified within the Australian disability community. In 1998, the Australian Bureau of Statistics reported that more than 24,000 people with a profound or severe disability received no assistance at all, and more than 41,000 carers received no assistance or support. Also, many of the services that were designed to provide respite care are not able to perform those functions because they are being used by people in need of long-term solutions who cannot be housed elsewhere. An acknowledgment of this problem can be found in the 1998 report by the New South Wales Community Services Commission, which estimated that 40 percent of respite beds are not being used for this purpose.

Another of the major disability issues in Australia over the past five years has been the inappropriate placement of young disabled people in nursing homes. Approximately 6,000 disabled people under the age of 65, including 1,100 under the age of 50, currently reside in Australian nursing homes. The majority of these people have acquired brain injuries, multiple sclerosis, and other neurological conditions. A national summit on young people in nursing homes attracted 180 people in May 2002, and 500 people attended a national conference in 2003 titled Unlocking Potential: From Vision to Reality.

In recent years, a number of Australian disability rights groups have taken up the issue of discrimination against disabled immigrants and refugee seekers. Sometimes, lawsuits have been instigated around these cases. For instance, in the case of *Inguanti v. Minister for Immigration and Multicultural Affairs* (2001), a man with an intellectual disability was denied a visa that would have allowed him to live with his brother in Australia. His brother was his legal guardian, and the man had significant financial resources to support himself. However, the decision of the Migration Review Tribunal was that the man's intellectual disability was likely to require the provision of health care or community services that would result in a significant cost to the Australian community, and on this basis he was denied a visa. This decision was subsequently set aside after an appeal to the Federal Court of Australia.

The circumstances of this case were similar in some respects to another federal Court case, *Minister for Immigration & Multicultural Affairs v. Seligman* (2001). In this case, an application for a visa by a successful South African businessman and his family was denied because the family included a 22-year-old son who has a borderline intellectual disability. The son's intellectual disability was also deemed as "likely to require the provision of health care or community services which would result in a significant cost to the Australian community," even though a substantial trust fund had been established to support him, and he had an offer of employment as part of the Community Services provided by the Australian Jewish Welfare Society. The initial denial of a visa was subsequently overturned. Not all of the appeals in this area have been successful, however. The case of *Blair v. Minister* *for Immigration & Multicultural Affairs*, for instance, upheld the refusal of a visa to a 9-year-old boy, Michael Courey (who has a mild intellectual disability, hypothyroidism, and a hearing impairment), on the grounds that he would be likely to require health care or community services in Australia.

In recent years, the National Ethnic Disability Alliance (the peak body in Australia for disabled people from non-English-speaking backgrounds) has been advocating on behalf of the rights of disabled children in refugee detention centers. There were 16 children identified as disabled who were in detention centers in 2002, with impairments including cerebral palsy, hearing impairment, vision impairment, acute dwarfism, Perthes disease, and Fragile X syndrome. The National Ethnic Disability Alliance also suggested that the numbers of children with invisible disabilities may be much higher than these figures indicate. It has argued that keeping disabled children in refuge detention centers amounts to a fundamental violation of their human rights and is highly inappropriate. It also places this situation in the context of broader patterns of disadvantage and discrimination, suggesting that three-quarters of disabled people from non-English-speaking backgrounds do not receive any commonwealth-funded disability services.

Australian women with disabilities are particularly disadvantaged. Women with Disabilities Australia reports that although women make up half of the overall population of people with disabilities, they experience labor market marginalization and poverty at much higher rates than other Australians, including men with disabilities. More than half of all women with a disability in Australia earn less than $200 a week. Also, the rates of employment for disabled women are almost half those of disabled men. Entry into vocational rehabilitation programs is also more difficult for women with disabilities. However, the open employment services funded by the commonwealth government largely assist men rather than women: In 1997–1998, these services provided two-thirds of their services to disabled men. Compounding these vocational barriers, women with disabilities are also less likely to receive appropriate health services than nondisabled women, are more likely to be institutionalized than disabled men, experience higher rates of violence and abuse than other Australians, and are more likely than other Australians to experience barriers in access to telecommunications (Frohmader 2002).

The continuing, unlawful sterilization of women with intellectual disabilities is another major human rights issue in Australia. Some of the reasons given for the sterilization of women with intellectual disabilities include the need to prevent pregnancy, manage menstruation, and improve personal care. The unlawful nature of these sterilization procedures has been recognized in a number of reports from state and federal governments, as well as other organizations including the Human Rights and Equal Opportunity Commission. In 2000, a resolution was passed in the Australian Senate that called for a review into the legal, ethical, and systemic issues surrounding this issue.

Indigenous Australians have many unique experiences with regard to disability. Many Aboriginal and Torres Strait islander communities have different definitions of *disability* from those used by Western professionals. The difficulties measuring the extent of disability in Aboriginal and islander communities is compounded by the fact that there is a dearth of literature on this topic. However, one study in New South Wales conducted by Thomson and Snow (1994) found that Aboriginal people were more than twice as likely to be disabled than other Australians. This study reported that sensory impairments were most common, followed by musculoskeletal impairments, circulatory system disorders, and respiratory disorders.

DISABILITY IN CONTEMPORARY CHINA

China is a land of contrast and change. The world’s most populous nation (1.3 billion) is in the throes of rapid development, enjoying the benefits and suffering the stresses of integration in the world economy, with widening disparities between rich and poor, rural and urban, disabled and nondisabled. Communist China’s transition to a market economy has increased the marginalization of already vulnerable individuals through dismantling the “iron rice bowl” of a job and basic security for life, introducing a competitive labor market, and the gradual weakening of nonprofitable primary care services. Partly in response to this, the Chinese government has initiated a series of laws and programs to improve the life chances of disabled people. The driving force has been Deng Pufang, president of the China Disabled Persons’ Federation (established 1988), a wheelchair user and son of the late Chinese leader Deng Xiaoping. The benefits have mostly been felt in large cities, where access to education, employment, high-tech medical services, and community-based rehabilitation has increased for those with money, good social connections, and less severe impairments. In rural areas where most Chinese disabled people live, access to such services is severely restricted and in some areas, millions of disabled people live below the absolute poverty line. With per capita gross domestic product in 2001 of US$4,020 (compared to US$34,320 in the United States), China is still a developing country.

BRIEF HISTORY

The People’s Republic of China was founded in 1949. Mao Zedong, leader of the Chinese Communist Party, propelled China toward his vision of a self-reliant socialist state. The Mao decades were characterized by upheaval: organizing the masses into collectives and work units, exhorting them to rapid industrialization and repeated revolution, with some devastating effects. Even so, when Mao died in 1976, China had higher levels of adult literacy, life expectancy, and living standards and a more stable economic base. Isolationist in relations with the West, China seemed a model of socialist development.

The Cultural Revolution (1966–1976) left a deep scar and a readiness for new direction. Deng Xiaoping responded with far-reaching reforms embracing market economics and opening China’s doors to the world. Deng legitimized personal profit and ownership to achieve a prosperous China: What difference if the cat is black or white, so long as it catches mice? Collective farms were divided and allocated to individual households. Town and village commercial enterprise was encouraged. In cities, state work units gave way to a competitive labor market. Special Economic Zones to attract and control foreign investment powered economic growth in southern and eastern coastal regions.

The demise of work units marked the end of the so-called iron rice bowl of a job and basic security for life. Millions saw their standard of living rise. More experienced job insecurity and relative poverty. The potential for social instability, compounded by large-scale rural-urban migration, strengthened the government’s resolve to restrict population growth. The one-child policy was a response to fears of endless poverty due to overpopulation. The policy became less draconian over time but it remains, in modified form, part of Chinese life. China’s economic and social landscape had been transformed again, but political reform was absent, as shown by the repression of pro-democracy demonstrations in Tiananmen Square on June 4, 1989.

Since Deng’s death in 1997, China has become more liberal economically, socially, and culturally, but the Chinese Communist Party still represses those who speak openly against the government, seek independence (Tibet, Xinjiang), or may threaten social order (Falun Gong). The third generation of political leaders (Hu Jintao succeeded Jiang Zemin as president) has continued to focus on economic growth and social stability. Integration into the world economy has been accelerated by accession to the World Trade Organization. Economic growth has now averaged 10 percent for two decades. Urbanization is predicted to reach 45 percent by 2010. In some cities, population pressures and resource shortages mean that per capita availability of water is among the lowest in the world. Environmental degradation and industrial pollution are cause for global concern. The 2003 United Nations Human Development Report ranked China at 104 out of 175 countries, yet vast tracts of western inland China would rank with the world's least developed countries. In 1997, there were 58 million people estimated to be living below the international absolute poverty standard. The aging pyramid structure of China's population (one child supporting two parents and four grandparents) is a constant anxiety. China has a vibrant economy and a dynamic population, but it faces some of the world's most daunting social, economic, and environmental challenges.

DISABILITY ON THE AGENDA

There are 60 million disabled people in China (5 percent of China's population). They are disproportionately represented among the poor and unemployed. Yet since the 1980s, and compared with countries with higher gross domestic product per capita, there has been a demonstrable attempt to raise awareness and increase life chances. The most important legislation and initiatives are the 1991 Law on Protection of Disabled Persons (promoting the comprehensive rights of disabled people to participate in all aspects of life); 1994 Regulations on Education of Disabled Persons (making education for all disabled children compulsory mainly through special education schools and classes, also promoting adult, further and higher education); and a series of National Work Programs for Disabled Persons (1988, 1991, 1996, 2001), integrating disability into the government's Five Year Plans for national development.

Enforcement of antidiscrimination legislation in China is difficult (although there have been pioneers such as the Centre for Protection of the Rights of Disadvantaged Citizens at Wuhan University). Official evaluations of progress against national program targets suggest that China's disability initiative has affected hundreds of thousands of disabled people. For example, there was an 800 percent increase in the number of disabled children in segregated (special education schools or classes) or mainstream school in 1995 compared to 1980 and a 400 percent increase in the number of segregated schools over the same period; provision of speech and hearing training to 60,000 deaf children and surgery to limit impairment from polio for 360,000 children and young adults.

Deng Pufang has spearheaded China's disability initiative. Born in 1944, eldest son of the late Chinese leader Deng Xiaoping, he became paralyzed during the Cultural Revolution. Following his father's political rise, Deng Pufang went to Canada for medical rehabilitation, where he glimpsed a different future for China's disabled people. In 1984, he set up the China Welfare Fund for Disabled Persons. In 1988, he founded the China Disabled Persons' Federation (CDPF). The CDPF is a national government agency (a quasi-ministry) and has branches at provincial, municipal, country, and township levels. It is not a membership organization. The degree of activism varies; it has been described as having a strong dragon's head and a weak dragon's body. It incorporates numerous agencies including the China Deaf Association, China Blind Association, and the China Association of Friends and Relatives of People with Mental Disabilities. CDPF aims to serve and represent disabled people. It receives government budgetary allocations and raises funds from donors inside and outside China. Deng Pufang is a well-connected figurehead for the organization: In 2003, he received the United Nations Prize in the Field of Human Rights.

Aside from Deng Pufang, two other factors have helped put disability on the agenda: statistics and international collaboration. Matthew Kohrman's illuminating analysis of the 1987 First National Disability Sample Survey reveals a complex of anxieties, pressures, and motivations relating to categorization, scientific caliber, and national self-image. The final survey comprised 1,579,314 people and covered household characteristics, self/family-identified disability, and medically certified disability. The medical survey had six categories: speech/hearing, intellectual, visual, physical, mental health, and multiple impairments. It found that 4.9 percent of individuals living in 18.1 percent of households were disabled. The statistics were sufficiently striking to legitimize a unique program of social development.

Credible statistics also enabled Deng Pufang and CDPF to participate internationally. None could have predicted the extent of China's participation in the United Nations Decade of Disabled Persons (1983–1992) or the Asia Pacific Decade of Disabled Persons (1993–2002), which China initiated. There have been numerous collaborations with UN agencies (rehabilitation pilots, training programs, publications on Western medical rehabilitation, and more recently, on practical advice for legal and social workers), not to mention the 1994 Far East and South Pacific Games for the Disabled in 1994 and forthcoming 2007 International Special Olympics in Shanghai and 2008 Beijing Olympics. Such collaborations strengthen the capacity of China's disability initiative to survive the passing of Deng Pufang's powerful father in 1997.

DISABILITY POLICY AND PROVISION

China has a long history of disability policy and provision. Fiscal and administrative disability classifications date at least to the Tang Dynasty (618–907). Ordinances on emergency relief date to the Han Dynasty (206 BC to AD 220). In the nineteenth century, foreign missionaries established schools for blind and deaf children. Under Mao, disability provision included some vocational segregated schools, mental asylums, welfare institutions (institutional provision was minimal), and Soviet-inspired welfare factories providing sheltered employment. Data on numbers and scale vary and reflect the upheaval of the Mao years, but it is likely that hundreds of thousands of disabled men and women were employed in welfare factories with larger factories operating like other state work units, providing housing and basic health services.

The economic reforms of the 1980s had a severe impact on disabled people. In urban areas, the demise and profit-orientation of work units led to unemployment, cutbacks, and shutdowns of welfare factories. In rural areas, the dismantling of collective farms seriously disadvantaged households with one or more disabled person. Free access to school and health care has been replaced by school fees, fee-for-service medical care, private medical insurance coverage (unaffordable for most), and erosion of nonprofitable primary care services.

Reversing the decline of already limited provision as well as increasing and improving services has been the task of the CDPF and the Ministries of Public Health, Civil Affairs, and Education (brought together with other government agencies in the National Co-ordination Committee on Disability, headed by a vice prime minister). The relationships between these agencies have at times been fraught and competitive. Nonetheless, CDPF has produced successive National Work Programs for Disabled Persons (1988, 1991, 1996, 2001) in line with national Five Year Plans. Key elements have been prevention, rehabilitation, education, employment, poverty alleviation, facilities, leisure, and sports. (Official statistics on progress are provided by the CDPF.)

There are continuities with the past: welfare enterprises, vocational segregated schools, minimal institutional provision, reliance on families, and limited emergency relief. There are also new developments, although many of these have been unpopular, have struggled to get beyond pilot phase (especially in rural areas), or meet only a fraction of need and demand. Examples are an unpopular employment quota of at least 1.6 percent disabled employees (many employers prefer to pay the fine, which in turn funds vocational training and support for disabled people); rural poverty alleviation programs (80 percent of disabled people live in rural areas, half of whom live in poverty); community-based rehabilitation (which has remained largely limited to a few urban areas despite its potential in rural areas); and professional training in Western medical rehabilitation and social work. Among the defining characteristics of China's disability initiative are self-reliance, population, and visibility.

SELF-RELIANCE

Disabled people are exhorted to show self-respect, self-confidence, self-strengthening, and self-reliance. Self-reliance is about earning a living and becoming a national economic asset rather than a liability, in line with the emphasis on individual and household responsibility—the touchstone of the post-Mao reforms, and on work as the central signifier of adult personhood in China. For dependent adults and children, families are expected to carry full responsibility. Welfare provision is minimal and patchy, often one-time payments to coincide with festivals, if available at all.

Employment options are self-employment, welfare enterprises (tax relief with a workforce of 35 percent disabled people, mostly run by local governments including in towns and villages) and employment under the quota system for government agencies, commercial enterprises, and nonprofit organizations (comparatively few gain genuine employment under this system).

National targets for education also feed into the goal of self-reliance. Education for disabled children is highly vocational, often linked to a specific welfare enterprise or stereotyped profession. There has also been a concerted effort to set up adult vocational training centers, retraining those who lost their jobs when some of the welfare factories closed, and assisting disabled people to find a trade for self-employment. Restoring function and enhancing employability, based on exacting notions of normalcy, lie behind some of the national targets for medical rehabilitation (speech and hearing training for deaf children, remedial surgery for children with polio), while imparting a vocational skill is seen as a central component of medical rehabilitation.

POPULATION

In 1990, the Law on Protection of Disabled Persons became China's first comprehensive piece of disability legislation (implemented in 1991). Reflecting the UN World Programme of Action, it asserts disabled people's rights to participation in social, economic, cultural, and family life. The law has been promoted extensively although enforcement through legal channels is very difficult. The law provides a framework for the development of legal, social, medical, educational, and vocational services, initiatives to reduce disabling barriers in the environment, and to limit the incidence and impact of impairment (e.g., reducing easily preventable intellectual impairments caused by iodine deficiency). More controversially, the 1994 Law on Maternal and Infant Health Care promoting better prenatal and postnatal care also includes a requirement for a premarriage medical examination to identify serious genetic, infectious, or mental diseases and, through restricting childbirth, reduce congenital impairments. The measure is repressive, even eugenic. It is consistent with government efforts to "reduce population quantity, raise population quality" and the construction of disability as a social problem (*shehui wenti*). The solution is seen as two-fold: reduce the number of disabled people, and ensure that those who are disabled can contribute to the economy.

VISIBILITY

Since its inception, the CDPF has used the media to raise public awareness of disability, to combat negative treatment and verbal abuse of disabled people, and to encourage disabled and nondisabled people to volunteer their services and raise funds (in 2003, CDPF announced 50,000 liaison centers for volunteers and 1.69 million registered volunteers). This use of national and regional media has been part of a careful and strategic approach to ensuring the long-term sustainability of China's disability initiative, and particularly of the CDPF itself, beyond the passing of Deng Pufang's powerful father in 1997 and the future passing of Deng Pufang himself. Other components of the strategy have been the National Disability Sample Survey of 1987, high-level and well-publicized international participation and collaborative programs, and the regular showcasing of individual disabled men and women who exhibit qualities commensurate with China's construct of a modern and progressive state. The need to demonstrate clear success and make a mark on China's modern landscape has also influenced decisions to pursue high-tech, high-cost urban rehabilitation centers, such as the flagship China Rehabilitation Research Center (set up in 1988 under the CDPF). The center and its equivalents in other large cities are a visual reminder of the CDPF and of what China should aspire to in line with advanced economic countries. Traditional Chinese medicine (acupuncture, *qigong*, massage) is used alongside Western medical rehabilitation, social and vocational rehabilitation, but the emphasis is on importing and developing scientific and technological rehabilitation. The handover of Hong Kong in 1997 and increased international collaboration have facilitated this, although the approach has been strongly criticized by agencies interested in expanding the access to services of poor and rural disabled people.

PROSPECTS

The current rehabilitation target of full access to rehabilitation services for all disabled people, including in rural areas, by 2015 seems remote. Imported models of community-based rehabilitation have great potential in China, but the reforms of the 1980s have weakened service infrastructures and the capacity of government at all levels to implement top-down, extensive, and nonprofitable services.

Among urban educated élites, there are signs of a discourse of rights and respect, demand for services and opportunities, and an emerging civil society of charitable and self-help groups (many led by parents of disabled children and some by disabled adults). In an authoritarian state, the capacity and sociopolitical space for genuine community-led approaches are weak and contested. The challenges for the CDPF are to empower such social enterprise, without seeing it as a threat; to continue to keep disability on the agenda in the face of growing social development pressures (including an aging population and projected exponential increase in people living with HIV/AIDS); and to expand the benefits of the disability initiative to reach the poorest of China's disabled population.

DISABILITY IN CONTEMPORARY INDIA

The subcontinent of India lies in southern Asia, between Pakistan, China, and Nepal. To the north, it is bordered by the world's highest mountain chain, where foothills and valleys cover the northernmost of the country's 26 states. Further south, plateaus, tropical rain forests, and sandy deserts are bordered by palm-fringed beaches. The population of India as of 0:00 hours on March 1, 2001, stood at 1,027,015,247 persons. With this, India became only the second country in the world after China to cross the one billion mark. India is home to 16 percent of the world's population, who occupy 2.42 percent of its land area, which is 3.3 million square kilometers. It has a coastal length of 7,600 km.

DIVERSITY

India's significance lies not only in its physical attributes but also in the fact that it is the world's largest functioning democracy, with regular and freely contested elections. India serves as an excellent example of facing challenges of fostering the development of plural communities and multiple identities. It is a country in which there are 15 official languages, more than 300 minor languages, and some 3,000 dialects. Twenty-four languages have more than 1 million speakers each. The most widely spoken language is Hindi, but this is the mother tongue of only about 40 percent of the population. Often Indians cannot understand each other, and they frequently use English as a link or administrative language. About 80 percent of the population is Hindu. But Hinduism is an amalgam of pluralistic beliefs and forms, often containing conflicting elements. An additional 12 percent are Muslims, deeply aware of their Islamic faith. Hindu, Urdu, Bengali, Marathi, Tamil, Telegu, Punjabi, and other languages create minorities of their own. Tribal and neoaboriginal peoples number almost 40 million. No contestant for political office can be successful without an awareness of these constituencies. This mosaic is culturally extraordinary. However, it is also a source of divisiveness in a nation where particular loyalties have a deep meaning, both spiritually and physically. Given this diversity, it is remarkable that India has remained and grown, and continues to grow, as one nation. The consciousness of the great past and the newness of the present sometimes produce an abrasive reaction.

The very word *India* implies a unity, which exists more as a tentative political form than as a human and sociocultural reality. For many in the West, India is considered as a torpid and remote conglomerate of people, which represents a combination of the exotic and tragic, a land of both poverty and plenty, a nation both powerful and weak, ancient and modern. The history of India is the history of colliding cultures—agrarian and industrial, masculine and feminine, national and imperial. Gaining independence after 200 years of colonial rule, India's progress into modernity has been fraught with all manner of fascinating entanglements, beginning of course with its knotty caste system and its ambivalent relationship with Pakistan. It seems fair to say that the identity of this great and ancient nation is at least partially defined by conflicts between the identity it wants and the one history has thrust upon it.

In all its diversity, India presents a revolutionary argument about the subtle nuances of progress and its fluid relationship with tradition. Both historically and in modern times, India has been an animated and vivacious society with a vibrant internal psyche as well as an influential relationship with the world. Modern India is home both to the tribal with his anachronistic lifestyle and to the sophisticated urban jetsetter. It is a land where temple elephants exist amicably with the microchip. Its ancient monuments are the backdrops for the world's largest democracy where atomic energy is generated and industrial development is rapidly making India a world industrial and technological leader. It is not uncommon to find fishermen along the country's coastline with simple fishing boats in a centuries-old tradition while, a few miles away, motor vehicles glide off conveyor belts in state-of-the-art factories.

Internationally, modern India has represented a middle ground in the international politics. Believing as it does in nonalignment in international politics, India has attempted to create a balance that demonstrates a viable route for nations that did not want to take sides in local conflicts. India's significance has to be understood in context of the geopolitics of South Asia. Bordering the Indian Ocean into which the Persian Gulf flows, it is a key location in an era of oil logistics. Add the proximity of Russia, Afghanistan, Pakistan, and China, and India's situation becomes critical to the tensions and interactions of current global politics.

INDIA IN A GLOBALIZING WORLD

In the past decade and half, India's economic policies have also broken new ground. They were the first large-scale test of the modern mixed economy. While these policies did usher in spectacular hopes and optimism, and assisted in the market reforms, they have also created a resurgence of ethnic politics around cultural identity, which appears poised to threaten the present world order. In India, the rise of radical Hindu nationalism, represented by Hindutva resurfaced with the integration of India in the global market. Divisive forces, in the name of religious and political ideology, have wreaked violence, chaos, and destruction violating the aspiration for a more humane order. As Indian society has moved along the road to modernity, it has led to a paradoxical scenario by creating two distinct worlds within India. There are the cities of India, where 28 percent of the population lives, and rural India, where about 600,000 villages contain the rest of the population.

Urban India is the India of modern industry, national politics and foreign policy, government planning, the national media, the major universities, business, the armed forces, science and technology. Its products are rated as some of the best in the world. This India has shopping malls, amusement parks, bowling alleys, and large department stores that seem to be drawing on the boom in the new economy sector. On the other hand, there are both urban and rural belts in which clean drinking water and electricity are not available. The onslaught of private media with innumerable private satellite channels does not fail to raise the aspiration level.

However, the drive toward upward mobility is not contained within the developing fabric of both economic and social life, creating dilemmas and discontent. With the euphoria of globalization and “high-tech civilization,” concerns about poverty, hunger, and inequality are virtually dismissed as an obsession of ideologists. This attitude has generated dangerous consequences. Both first-generation and second-generation reforms overlook various crucial issues and objectives such as eradication of poverty, prevention of concentration of economic power in private hands, avoidance of regional imbalances, and promotion of small-scale industries and village crafts. Economic development actually ran counter to these objectives. While India does and must take pride in its information technology (IT) professionals and cyber cities, it has had to recognize that there are tragic deaths by the hundreds of farmers and weavers, besides starvation deaths, in the wake of neoliberalization policies. The story of modern India is thus not simply the story of well-fed, well-clothed men; it is also the story of intense agony—loss of self and communication and relatedness. The urgent task before the government and civil society is to recover these myriad relationships so that democracy can be transformed into a rights opportunity for multiple identities and communities if a more equitable world order is to emerge.

BLEND OF MATERIAL AND THE SPIRITUAL

The most significant feature of Indian culture has been its belief that life cannot be viewed solely in terms of materialistic realities. True actualization is possible only when the attempt is made to look within, and India at its core quests for spirituality as the ultimate search. The desire to know life through, for example, yoga, art, and philosophy, persists despite the country’s modernity. Thus, an ingrained and dominant spirituality, a creative zest for life, and an intelligent combination of the rational, ethical, and aesthetical mind characterize Indian culture.

GENDERED CHARACTER OF INDIAN SOCIETY

In terms of gender issues, historically, the dominant ideologies in Indian culture have continued to operate paradoxically. While in principle they might be postulated as complementary, their actual meaning/working is oppositional. Thus, there is a strong cultural belief that while the female is opposed to the male, female is at the same time encompassed in male. This is symbolized in the figure of lord Shiva called Aard Nareshewar, where the left side is depicted as female and the right side as male. Yet the lives of women do not reflect this inclusion; large sections of women are among the most underprivileged in India. While some women from the upper classes head political parties and command large followings, women’s representation in Parliament and in state legislatures has not been more than 10 percent. There are several clear indicators of the fact that Indian women continue to be discriminated against: The sex ratio is skewed against them, maternal mortality is the second highest in the world, more than 40 percent of women are illiterate, and crimes against women are on the rise. Yet the women's movement, which gathered strength after the 1970s, has led to progressive legislation and positive change, spurred on by the participation of women in local self-government.

The most serious issue of modern India is the changing sex ratio. An alarming drop in the number of girls born in India is being blamed on a strong cultural preference for sons—coupled with cheap and widely available medical tests that can tell parents the sex of their unborn child. Data from India's 2001 census show the sex ratio for 0- to 6-year-olds fell from 945 females per 1,000 males in 1991 to 927 in 2001. The new figures give India one of the world's lowest ratios of women to men; the statistical norm is 1,050 females for every 1,000 males. The drop is largely due to the widespread but illegal practice of using ultrasound scans to identify female fetuses and then aborting them. In 1994, the Pre-Natal Diagnostic Technologies (PNDT) Act banned the practice. But it has proved toothless—seven years after enactment, not a single conviction has taken place. This is yet another indicator that technological advances may not always denote progress and growth.

CASTE SYSTEM

According to the Indian Constitution, there is a separation between religion and state. Caste discrimination is thus legally forbidden. However, in modern India, caste identity has become a subject of political, social, and legal interpretation.

Affirmative action programs in education, employment, and other spheres have been undertaken. Yet it is doubtful whether these steps have resulted in the social uplifting of the marginalized categories as there is a backlash from the communities that were high in the social hierarchy. Caste thus remains a site of contest for modern India.

DISABILITY SCENARIO

India has approximately 70 million disabled people. The unwillingness of the government to include the domain of disability in the 2001 census to obtain a conclusive idea about prevalence reflects the attitudinal barriers in acknowledging the disabled identity. Disability issues have no space in the political agenda or the most forward-looking social movements of the country. Consequently, within the dominant Indian cultural ethos, labels such as "disability," "handicap," "crippled," "blind," and "deaf" are used synonymously. The assumption of the label's naturalness is unquestioned. The roots of this assumption lie in the ideology that conceives of disability as inherent in the mind or body. This corresponds with the idea of lack and inability that is associated with these conceptions. In a culture that valorizes perfection, all deviations from the perfect body signify abnormality, defect, and distortion. Conveying feelings of inability and uselessness, disability epitomizes "failure" and is conceived of as a personal tragedy. The common perception views disability as a retribution for past karmas (actions) from which there can be no reprieve. The popular images in mythology attest to extreme negativity associated with disability in India. While sex selection is a cause for concern for social activists, killing imperfect children will not even count as a crime. The general response of the nondisabled world ranges from pity and charity, to hostility, anger, banter, and ridicule. Within this pessimistic situation, a silver lining comes in the form of disabled people themselves and their struggles to resist the system. Along with their families, their strivings to chart out a different destiny saw the first legislation for equal opportunities being passed in 1996.

Notwithstanding the different realities of education and employment, the discourse of disability activism in India itself constitutes a meta-narrative that universalizes disability. The leaders of the movement are middle-class urban men who have been educated in public schools and are representative of an "elite" background. Their fight for "disability rights" is borrowed from their Western counterparts without any clear analysis of the inherent biases. Consequently, the imported packages of "nothing about us without us," while perfectly appropriate in some contexts, are universal solutions that ignore the specifics of the Indian dilemma.

Academic and social reflection on whether these programs borrowed from the West have the potentiality of understanding and responding to the diversity of

Indian culture and concomitantly is practically nonexistent within disability activism. The fight for rights thus ends up paying lip service to the needs of diverse groups, whereas in actuality the agenda remains dictated by the understanding/needs of the leaders. While poverty exacerbates the disabled existence, the leaders fight for agendas that are their own.

India, while having a specific interpretation of disability, still has lived with values of interdependence and reciprocity. While it has a lot to learn from the West, it can contribute by becoming a role model in negotiating with diversity. It has a history of a freedom movement and struggles for land, language, and gender rights. These approaches have maintained a separate identity while keeping a unity of spirit and purpose intact. India in this sense is a perfect example of highlighting the limitations and strengths of identity politics. It demonstrates that a lot can be gained from a revitalization and reformulation of culture and tradition. India can thus contribute to disability studies a viewpoint that emphasizes a closer look at how communities mobilize locally to create a grassroots movement that initiates a culture of resistance to oppressive practices. These agendas of resistance connect local, regional, and global efforts toward the ideal of not an independent, but an interdependent, existence. India can demonstrate to the global disability movement as well as to disability studies that research and practice have to work at these interconnected levels. While according the highest priority to the rights of disabled people, it continues to adopt a sensitive, reflexive, and critical approach, thus rendering a careful interrogation of traditional values.

DISABILITY LAW: CANADA

In 1982, the rights of persons with disabilities were given constitutional protection in the Charter of Rights and Freedoms, part of Canada's Constitution. As constitutional legislation, the charter applies to governmental action and legislation, including provincial and federal human rights statutes. The direct impact of the charter on the day-to-day lives of individuals is relatively limited. Indirectly, however, it has a significant impact, since it provides the framework within which provincial and federal human rights statutes operate. These statutes are considered quasi-constitutional and prohibit discrimination on a number of grounds, including disability, in areas such as housing, employment, education, and the provision of goods and services to the public.

The equality rights of persons with disabilities derive from Section 15 of the charter: "15**.** (1) Every individual is equal before and under the law and has the right to the *equal protection and equal benefit* of the law without discrimination and, in particular, *without discrimination* based on race, national or ethnic origin, colour, religion, sex, age *or mental or physical disability.*"

The charter does permit governments to implement programs that specifically help people in those groups protected by the charter. The rights of persons with disabilities are given the same degree or protection as other enumerated grounds such as religion and race.

If a statute or governmental action is found to be contrary to Section 15 of the charter, it may continue to operate if the government can demonstrate that it is justifiable in a free and democratic society. Section 1 states: "The *Canadian Charter of Rights and Freedoms* guarantees the rights and freedoms set out in it subject only to such reasonable limits prescribed by law as can be demonstrably justified in a free and democratic society." The onus is on the government to demonstrate that there is a significant societal justification for a distinction. A discriminatory provision may also stand if the government invokes Section 32 of the charter. That section states that Parliament or a provincial legislature may enact a declaration declaring that a statue or part of a statute will remain in effect despite the fact that it has been found to be contrary to

Section 15 of the charter. To date, no government has invoked this power.

The charter protections are enforced through individual actions brought in court. Administrative tribunals, including labor arbitration boards, also have the authority to interpret the charter where necessary to carry out their adjudicative functions.

Remedies available to the court under the Charter of Rights and Freedoms include declaring a statute or part of a statute invalid and therefore of no force and effect. Often when this is the result, the courts will give the government time to amend the legislation so that it complies with the charter. The court can also "read in" language to the statute so that it complies with the charter. Courts may also award damages for discriminatory treatment.

As constitutional legislation, the charter must be interpreted broadly and consistent with its overall purpose. The interests of society must be taken into account and the interpretation flexible rather than rigid. The broad purposive interpretation of the charter also extends to provincial and federal human rights legislation, which is considered quasi-constitutional.

One of the most important concepts running through recent decisions relating to discrimination on the basis of disability is the use of dignity and respect as fundamental interpretive principles. This is reflected in the duty to accommodate, the definition of disability, and the determination of undue hardship in both charter and human rights litigation. Starting with the decision of the Supreme Court of Canada in *Law v. Canada,* the courts have articulated the rights of persons with disabilities in relation to dignity. This applies not only to the underlying purpose of the charter, but it is used as a measure in determining appropriate accommodation. In *Law,* the Supreme Court of Canada set out the following steps to use in analyzing claims under Section 15 of the charter: Does the law specifically make a distinction between the individual and others or does it fail to take into account the individual's differences that may lead to disadvantage if the person is treated exactly like everyone else? Is the distinction based on a characteristic that falls within the grounds under Section 15 either those that are listed or that are considered to be analogous? Does the different treatment either impose an additional burden on the individual or does it deprive them of a benefit that others obtain from the legislation in a way that suggests that the person is a less worthy or valuable as a person or member of society or that they are less deserving of respect than others?

Some factors that may determine whether a person's dignity has been demeaned are the following: Does the individual belong to a group that has been subject to prejudice or stereotyping or is historically disadvantaged? Does the law take into account the person's own situation and needs or does it provide benefits based only on categories? Is the purpose of the law to improve the situation for people who are disadvantaged? How serious is the impact of the law and how defined is the group affected by it?

A second major aspect of charter litigation involved distinguishing between direct and indirect or adverse effects discrimination. Direct discrimination was described as intentionally treating people in one of the equality-seeking groups differently. Adverse effects discrimination in the employment context was said to occur when an employer had a policy or practice that was not intentionally discriminatory and did not treat people from equality-seeking groups differently, but nevertheless resulted in differential treatment creating a disadvantage for the individual.

In *British Columbia Government and Service Employees' Union v. Employees' Union (B.C.G.S.E.U.) (Meiorin),* the Supreme Court of Canada eliminated the distinction between the two types of discrimination in determining whether or not there was a duty to accommodate. In moving away from the bifurcated approach, the court in *Meiorin* wrote: "The distinction between a standard that is discriminatory on its face and a neutral standard that is discriminatory in its effect is difficult to justify, simply because there are few cases that can be so neatly characterized."

The Supreme Court of Canada set out a three-part test to determine whether a standard or policy is discriminatory: Is it rationally connected to the performance of the job? Was it was adopted in good faith with an honest belief that it is necessary to fulfill a work-related purpose? and Is it reasonably necessary to accomplish the work-related purpose?

The effect of *Meiorin* has been to move the inquiry from the question as to the type of discrimination to the duty to accommodate. In recent years, the Supreme Court of Canada has also expanded and clarified its approach to the duty to accommodate. The duty to accommodate is considered a significant human rights obligation. The obligation is on all parties to fully participate in the process. This includes the employer, the employee, and, where applicable, the union. The courts have been clear that unions have an obligation to participate in the process and to support accommodation measures.

An increasingly important component to the duty to accommodate is the process of determining accommodation itself. The employer has the primary responsibility because the employer controls all aspects of the work environment. However, the employee must also participate.

Accommodation must be provided to the point of undue hardship. The issue of undue hardship, however, does not arise until appropriate accommodation has been determined. The employer may not raise financial or other constraints during the initial process of deciding on the most appropriate accommodation. The onus is on the employer to demonstrate that an accommodation would result in undue hardship. What constitutes undue hardship depends on a number of factors including the jurisdiction in which the case is brought. In some jurisdictions, such as Ontario, the human rights legislation sets out specific factors that can be considered. In other jurisdictions the scope is broader. Among the factors that have been considered are the impact on a collective agreement, employee morale, the size of the employer's operation, and the operational requirements of the workplace.

In recent years, the courts have become much more demanding of the employer in terms of providing evidence of undue hardship. Concrete evidence must be provided; speculation is not sufficient. The courts have been clear that in terms of increased costs, such as insurance, there must be evidence from the insurer that the rates will in fact increase. The courts have also refused to consider the potential cost that may arise if others in the workplace seek similar accommodation, whether because of a disability or other enumerated grounds.

More recently, however, the Court has recognized that disability discrimination does not occur in isolation and that the social context and other factors must be taken into account. In *Quebec (Commission des droits de la personne et des droits de la jeunesse) v. Montréal (City),* known as *Mercier,* the Supreme Court of Canada considered three related cases involving stereotypical assumptions about disability that resulted in discriminatory treatment. The discrimination in these cases arose not because of their underlying medical condition, but because of the perceived disability in the minds of their employers.

As with the interpretation of Section 15 of the charter, and related human rights provisions, the definition of disability in Canadian jurisprudence is also broad. There is no definition of disability in the charter, and provincial human rights legislation defines it broadly. The prohibition against discrimination also applies to perceived disability, temporary disability, past disability, and association with a person who has a disability. In some jurisdictions, such as Ontario, the inclusion of these related concepts is explicit, while in others, the definitions are being expanded through the broad interpretation of Section 15 of the charter, particularly after the decision in *Mercier.*

Although there is no set list of conditions, diseases, or disorders that constitute disability, the courts have determined that alcoholism, drug addiction, smoking where it is a significant addiction, and obesity fall within the definition of disability. In determining whether a disability exists, the court is is increasingly looking at whether the condition complained of arises out of a perceived limitation, whether or not that limitation exists.

DISABILITY LAW: EUROPE

Disability has finally become a human rights issue in Europe. There is now a developing base of legislation in many European countries that sees its goal as the elimination of discrimination against people with disabilities, taking individual human rights as its baseline philosophy. In three countries (Austria, Finland, and Germany), the right not to suffer discrimination because of a disability is enshrined in the constitution itself, although this by no means guarantees the right is upheld, in the absence of meaningful enforcement machinery. Three constitutions provide for the general right of disabled people to be integrated into their society and place a concomitant responsibility on the state to ensure that all barriers to such integration are removed (Austria, Greece, and Italy). A number of other national constitutions also refer to the rights of disabled people in more specific, more narrowly defined contexts, for example, a constitutional right to social welfare/social security (Finland, Italy, and Portugal) or a constitutional right to appropriate education and financial support (Italy, Finland, Greece, and Portugal). In a number of countries (Austria, Finland, Greece, and Italy), the special needs of disabled people are addressed primarily through social and economic policy and associated welfare legislation, rather than through antidiscrimination laws. In other countries (Belgium, Ireland, Germany, the Netherlands, and the United Kingdom), substantive national laws have been passed developing legal rights for disabled people to equal opportunities in education, employment, or other settings. This latter trend will continue to develop apace within the European Union, at least in the context of employment and training, as EC Directive 2000/78/EC requires all member states to have introduced antidiscrimination laws in the fields of employment and training by the end of 2006 at the latest (see below), thereby marking a decisive shift within the European Union toward using the language and the tools of civil rights in the disability context.

If we look beneath the superficial modeling of legal approaches to human rights for people with disabilities, to search out the underpinning philosophy, a clear picture emerges. While all the legal approaches preach equality, and all have the potential to move toward a notion of equality, clear differentiation nevertheless exists. The basic model is premised on the concept of equal rights. This “equal rights” model ignores difference. It states that everybody has equal rights and should therefore be treated the same; for example, Article 3 of the German Basic Law states that “no person shall be disfavoured because of disability.” While it has proved a useful political tool for disability activists as a means of overcoming the medical model of disability, which remains particularly predominant in Eastern Europe, the equal rights model has severe limitations as a practical tool for reform, if only because granting equal rights to all citizens requires taking a look at difference and understanding that different people have different needs. To ignore differences helps to prevent stereotypes and stigmatization but at the price of failing to do justice to the reality of difference.

A more sophisticated model starts with equal rights and adds equal opportunities. This “equal opportunities” model accepts that where people with disabilities are at a disadvantage, for example, in their quest for employment, granting them formal equal rights without providing equality of opportunity to exercise those rights is an empty gesture. A typical manifestation of an adherence to the equal opportunities model is the requirement that employers make “reasonable adjustments” or “reasonable accommodations” to their workplaces, policies, and practices to ensure that a person’s disability does not reduce his or her opportunity to participate in the workplace on the same terms as the person’s nondisabled colleagues. Article 5 of EC Directive 2000/78/EC requires employers to make reasonable accommodations in the form of “appropriate measures where needed in a particular case” to ensure that disabled employees are not prevented from performing the essential functions of their job purely because of their disability. The directive also expressly permits these accommodations to be accompanied, if necessary by special measures or affirmative action policies, thereby recognizing that merely imposing minimal standards of nondiscriminatory conduct on employers may not be sufficient to promote equality in practical terms. Several European countries (Denmark, Finland, Ireland, Spain, and the Netherlands) have legislation in place permitting special measures of this nature to be taken in the context of employing people with disabilities. Others may follow.

The fully developed model of legal approaches to human rights for people with disabilities, which comes closest to achieving genuine equality, can be described as the "tripartite" model. This model combines equal rights with equal opportunities but adds a third and final ingredient of equal outcomes. This model recognizes, for example, that an employee with a disability who receives the same pay, and equality of opportunity, as his or her nondisabled colleagues remains disadvantaged so long as the person has to bear a disproportionate further burden of costs to support his or her personal needs. Another example is a young club-goer who uses a wheelchair and who is granted access to a nightclub at the same price, and through the same entrance, as fellow clubbers without wheelchairs but remains disadvantaged unless the dance floor itself is as safe and welcoming to the person using the wheelchair as it is to the other dancers. "Equal outcomes" builds in a redistributive balancing of resources to compensate individuals for their extra expenditure, whether it be in time or money or overcoming "attitude." By this tripartite commitment to rights, opportunities, and outcomes, the model can truly be said to have embraced a full conceptualization of equality.

The fully developed tripartite model can be deemed successful, however, only if it achieves a balance of all three factors, that is to say, rights, opportunities, and outcomes. To concentrate on equal outcomes, without equality of rights and opportunities, could lead to an undesired result that shackles other freedoms. For example, while a child with disabilities may achieve higher academic results ("outcomes") in a segregated special school, he or she may as a result have been deprived the right and the freedom to choose integrated education, notwithstanding the possibility of a lesser scholastic "outcome." Regrettably, it cannot be said that, at present, any European country has embraced the tripartite model approach to disability in any meaningful way.

EUROPEAN UNION

Article 13 of the European Community (EC) Treaty establishing the European Community (as amended by the Treaty of Amsterdam) gives the countries of the European Union (EU) powers collectively to take all necessary measures to combat discrimination. Article 13 also provides the first specific reference to *disability discrimination* within the EC Treaties. On November 27, 2000, the EU passed Directive 2000/78/EC, which seeks to establish a general framework for equal treatment in employment and occupation and to render unlawful discrimination on a number of grounds including disability. Directives reconcile the dual objectives of (1) securing the necessary uniformity of community law and (2) respecting the diversity of national traditions and structures. The goal of a directive is more that of harmonization than unification. A directive is binding on the member states as to the objective to be achieved, but it leaves it to national governments to decide how the agreed community objective set out in the directive will be incorporated within their own legal system. Each directive lays down a set time frame by which the directive must be transposed into the national law of each member state. Member states are liable to pay damages where loss is sustained by reason of their failure to transpose a directive in whole, or in part, into their national system of law (see *Joined Cases C-6 Francovich and 9/90 Bonifaci 1991, ECR 1–5403*).

By December 2003, the Non-Discrimination Directive should have been transposed into the national domestic laws of all 15 members states, although individual countries can opt to wait until 2006 before achieving full implementation. In addition, the *acquis communitaire* underpinning the accession of new countries to the EU (known as the "candidate countries") requires a specific undertaking that they will transpose directives into their national laws as a condition of entry. As a parallel initiative, the EU has established a six-year Community Action Programme (CAP), ending on December 31, 2006, aimed at promoting measures to combat discrimination. In addition, the EU Social Policy Agenda, adopted in June 2000 by the Social Policy Council, is committed to monitoring implementation of the *Communication from the Commission to Council, European Parliament, Economic and Social Committee, and Committee of the Regions. 2.05.2000COM: Towards a Barrier-Free Europe for People with Disabilities.*

The CAP to combat discrimination has three main objectives:

1. To foster a better understanding of issues relating to discrimination by improving knowledge of the problem and assessing the effectiveness of policies and practices
2. To develop the capacity to prevent and to tackle discrimination effectively, particularly by strengthening organizations' means of action and supporting the exchange of information and best practice across Europe
3. To promote and disseminate the values and practices underlying the fight against discrimination, including the use of awareness-raising activities

To achieve these objectives, the program is supporting a number of activities. First, it has established Groups of Independent Experts who assist the commission and the member states in monitoring the transposition of the antidiscrimination directives into national law. The groups, consisting of experts from all member states, meet on average twice a year and provide an annual report to the commission. The Group of Independent Experts on disability has produced a major report on the states of anti-disability discrimination legislation across the 15 member states, which became available in 2005 (European Commission 2005). In addition, the group has carried out extensive research into the particular problems associated with reasonable accommodation and its practical operation in the discrimination field, pre-employment medical testing including genetic testing, and reconciliation of health and safety measures. In 2004, the specialist groups working on each of the discrete areas of discrimination covered in the directive (religion or belief, age, sexual orientation, disability) were merged into one "supergroup" monitoring antidiscrimination legislation as a whole, across the enlarged EU. It was a major task.

Second, the program is supporting a range of sophisticated data collection initiatives to measure the extent and impact of discrimination in Europe (European Commission 2003d). Third, the program is sponsoring independent studies of the effectiveness of the various national bodies already established to promote equality and fight discrimination, looking also at the measures to combat discrimination in countries that have applied to join the EU (European Commission 2003c). These studies will focus particularly on additional steps that may need to be taken in order to take on board the provisions of EC antidiscrimination legislation. A feasibility study, on the establishment of indicators to measure the cost-effectiveness of diversity in companies, has also been carried out by the Centre for Strategy and Evaluation Services (European Commission 2003a). This study seeks to identify new ways of measuring diversity and the benefits it can bring to business and thereby makes a valuable contribution to promoting diversity programs and measures in companies and help to make EU law a reality on the ground. Other studies on barriers to access to assistive technology and other forms of obstruction to employment progress have also been carried out. Finally, the program is promoting a range of initiatives designed to strengthen the capacity of nation-states to build their own programs, independent of EU support.

The candidate countries that gained accession to the EU in 2004 (Cyprus, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia, and Slovenia) and those expected in 2007 (Bulgaria, Romania, and Croatia) are all moving slowly toward a rights culture similar to that which is developing within the EU. Many of the initiatives that form part of the CAP include candidate countries. The majority of the candidate countries already have specific legislation dealing with disability discrimination, although in these countries the predominant concept of disability is based on a narrowly defined medical model. There are "quota" systems (arrangements whereby employers must ensure that a percentage of their workforce have specified disabilities, or suffer financial penalties) of varying kinds in the Czech Republic, Cyprus, Lithuania, Malta, Poland, and Romania and specialized or sheltered employment programs in operation in Bulgaria, Cyprus, Hungary, Romania, and Slovakia. Enforcement machinery for discrimination claims is scant across all the candidate countries, with only Romania possessing a special body for hearing discrimination cases. Sanctions for noncompliance either with quotas or with antidiscrimination measures are also weak, and largely unenforced, although the directive requires that effective enforcement machinery is in place.

The European Union Charter of Fundamental Rights sets out in a single text, for the first time in the EU's history, the whole range of civil, political, economic, and social rights of European citizens and all persons resident in the EU. The Cologne European Council (June 3–4, 1999) entrusted the task of drafting this charter to a specially convened convention. The convention held its constituent meeting in December 1999 and adopted the draft on October 2, 2000. The Biarritz European Council (October 13–14, 2000) unanimously approved the draft and forwarded it to the European Parliament and the commission. The European Parliament gave its agreement on November 14, 2000, and the commission on December 6, 2000. The presidents of the European Parliament, the council, and the commission signed and proclaimed the charter on behalf of their institutions on December 7, 2000, in Nice. The rights set out in the charter are divided into six sections:

Dignity

Freedoms

Equality

Solidarity

Citizens' rights

Justice

They are based, in particular, on the fundamental rights and freedoms recognized by the European Convention on Human Rights (see below), the constitutional traditions of the EU member states, the Council of Europe's Social Charter (see below), the Community Charter of Fundamental Social Rights of Workers, and other international conventions to which the EU or its member states are parties. The issue of the charter's legal status—that is, whether to make it legally binding by incorporating it into the treaty—was raised by the Cologne European Council, which originally launched the charter initiative. The convention drew up the draft charter with a view to its possible incorporation, and the European Parliament voted in favor of incorporation. When the charter was proclaimed in Nice in December 2000, Romano Prodi, president of the commission, stated that "in the eyes of the EC, by proclaiming the Charter of Fundamental Rights the EU institutions have committed themselves to respecting the Charter in everything they do and in every policy they promote."

Disability is included in the charter's general nondiscrimination clause (Article 21), and Article 26 specifically states that the Union recognizes and respects the rights of persons with disabilities to benefit from measures designed to ensure their independence, social and occupational integration, and participation in the life of the community.

COUNCIL OF EUROPE

The Council of Europe (COE) is a political organization, founded in 1949. Its aims are to guarantee democracy, human rights, and the rule of law and to develop common responses to political, social, cultural, and legal challenges in its member states. There are currently 43 states that are members. The COE's main instrument, the European Convention on Human Rights and Freedoms, is the core treaty with enforcement powers through which the COE influences policy on human rights across Europe. Although disability discrimination is not specifically protected by the convention, Article 2 ("the right to life"), Article 3 ("no-one shall be subjected to torture or to inhuman or degrading treatment or punishment"), Article 8 ("everyone has the right to respect for their private and family life"), and Article 14 ("prohibition of discrimination") have been used in a number of creative ways to come to the assistance of people with disabilities whose rights to equal treatment are not being respected. For example, the case of *Botta v. Italy* (1998) established (see para. 32) that the right to a private life, guaranteed and protected by Article 8 of the convention, included the need for a state or public authority to protect a person's physical and psychological integrity. The Court held that Article 8 was primarily intended to ensure the development, without outside interference, of the personality of each individual in his or her relations with other people, a statement that has far-reaching implications for disabled people who are denied such development. The duty on the state or a public authority is clearly a positive duty.

Article 8 was argued in another case against the government of Italy, *Marzari v. Italy* (1999), where the applicant, who suffered from a series of complex disabilities, filed an action against the government for failing to provide him with accommodation suitable for a person with his disabilities. The applicant was unsuccessful, because the Court decided that the state had taken all reasonable steps to provide him with suitable accommodation, which he had rejected, notwithstanding the fact that an independent tribunal had determined that the accommodation was suitable, with modification. Although the applicant lost his case on the facts, the Court nevertheless left the door open for a different outcome, had the facts been more compellingly in favor of the applicant, holding that a state has obligations of this type where there is a direct and immediate link between the measures sought by applicants and their private life.

The European Social Charter (ESC) is a COE treaty, signed in 1961, which also is designed to protect the human rights of individuals including those with disabilities. In 1996, a revised and updated charter was opened for signature. It entered into force on July 1, 1999, and will progressively replace the 1961 Charter. Article 15 of the ESC 1961 deals with the right of physically or mentally disabled persons to vocational training, rehabilitation, and social resettlement, stating that with a view to ensuring the effective exercise of the right of the physically or mentally disabled to vocational training, rehabilitation, and resettlement, all state parties undertake the following:

- To take adequate measures for the provision of training facilities, including, where necessary, specialized institutions, public or private.
- To take adequate measures for the placing of disabled persons in employment, such as specialized placing services, facilities for sheltered employment and measures to encourage employers to admit disabled persons to employment.

Article 15 has been now amended as follows: With a view to ensuring to persons with disabilities, irrespective of age and the nature and origin of their disabilities, the effective exercise of the right to independence, social integration, and participation in the life of the community, the state parties undertake, in particular:

- To take the necessary measures to provide persons with disabilities with guidance, education, and vocational training in the framework of general schemes wherever possible or, where this is not possible, through specialized bodies, public or private.
- To promote their access to employment through all measures tending to encourage employers to hire and keep in employment persons with disabilities in the ordinary working environment and to adjust the working conditions to the needs of the disabled or, where this is not possible by reason of the disability, by arranging for or creating sheltered employment according to the level of disability. In certain cases, such measures may require recourse to specialized placement and support services.
- To promote their full social integration and participation in the life of the community in particular through measures, including technical aids, aiming to overcome barriers to communication and mobility and enabling access to transport, housing, cultural activities, and leisure.

Article 15 therefore no longer applies only to vocational rehabilitation but also to the right of persons with disabilities to independent social integration, personal autonomy, and participation in the life of the community in general. The words "effective exercise of the right to independence" contained in the introductory sentence to the provision imply, inter alia, that disabled persons should have the right to an independent life. Under this provision, state parties must aim to develop a coherent policy for people with disabilities. The provision takes a modern approach to how the protection of disabled people shall be carried out, for example, by providing that guidance, education, and vocational training be provided whenever possible in the framework of general schemes rather than in specialized institutions, an approach that corresponds to that of Recommendation No. R (92) 6 of the Committee of Ministers of the Council of Europe. It not only provides the possibility but, to a large extent, obliges state parties to adopt positive measures for people with disabilities.

An international monitoring system is in place to monitor the extent to which COE member states respect the articles of the charter. Governments must submit reports on the application of the provisions of the charter that they have accepted. Copies of the reports can be viewed and downloaded at http://www.humanrights.coe.int/cseweb/GB/GB1/GB1.htm. The reports are all examined by the Committee of Social Rights, comprised of independent experts, which examines the reports and gives a legal assessment of their conformity with the charter. In the light of this assessment, the COE Committee of Ministers can issue recommendations to any governments appearing to be in default. An Additional Protocol providing for a system of collective complaints was opened for signature on November 9, 1995, and entered into force on July 1, 1998. Its purpose is to improve the efficiency of the supervisory machinery of the Social Charter, by enabling collective complaints alleging violations of the charter to be dealt with, in addition to the existing procedure for examining governments' reports. A number of international organizations of employers and trade unions, and other international nongovernmental organizations (NGOs) with consultative status within the COE, are entitled to raise collective complaints. For a full list of those bodies entitled to raise a collective complaint, see http://www.humanrights.coe.int/cseweb/GB/GB3/GB31.htm. Collective complaints are examined by the Committee of Social Rights, which must first decide on their admissibility in the light of criteria listed in the protocol. In practice, the committee, after having collected information from the complainants, from the state concerned, from the other contracting parties to the charter and from both sides of industry, draws up for the Committee of Ministers a report containing its conclusions as to whether the contracting party against which the complaint is directed has, in a satisfactory manner, ensured that the provision of the charter which is the subject of the complaint is applied. It is then the task of the Committee of Ministers to address a recommendation to the contracting party concerned, in the event that the Committee of Social Rights finds that the charter has not been satisfactorily applied, or, should this not be the case, to adopt a resolution to that effect.

Finally, it should be noted that independent, state-financed bodies with a clearly defined role to educate, reform, and enforce legislation in the field of disability discrimination are an increasingly important phenomenon across the whole of Europe (European Commission 2002).

EUROPEAN DISABILITY FORUM

Created in 1996, the European Disability Forum (EDF) is now the largest independent, trans-European organization that exists to represent disabled people in dialogue with the EU and other European authorities. Its mission is to promote equal opportunities for disabled people and to ensure disabled citizens' full access to fundamental and human rights through their active involvement in policy development and implementation in the EU. EDF has national councils in 17 European countries, together with approximately 45 disability NGO members, and a number of associate group and individual members. One of the most important campaigns of the EDF in recent years has been to argue for a disability-specific directive, that covers a far wider range of discriminatory activities. EDF argues that discrimination does not occur in the field of employment only, as employment is closely linked to several other areas such as education, transportation, and access to services and goods. Therefore, a directive aimed only at employment is insufficient. For a disabled person to be an active member of society in all areas and to enhance a broad nondiscrimination approach, a new disability-specific directive is needed. EDF has prepared a draft for such a directive. For the full text of this draft directive, go to http://www.edf-feph.org/en/policy/nondisc/nond_ pol.htm.

DISABILITY LAW: GERMANY

Written in 1994, Section 3, Paragraph 3, Sentence 2 of the German Constitution (Grundgesetz) forbids the discrimination of people based on their disability. The concept of disability in Germany, however, is not uniformly regulated in legal documents. The most comprehensive definition can be found in Section 2 of the Sozialgesetzbuch IX-Rehabilitation und Teilhabe behinderter Menschen (SGB IX; Social Security Code IX-Rehabilitation and Participation of Disabled People, in effect since July 1, 2001) and is defined in an identical manner in Section 3 of the Behindertengleichstellungsgesetz (BGG; Disability and Equality Law, in effect since May 1, 2001):

> People are disabled if their physical function, cognitive ability, or psychological health significantly deviates from that of the typical, age-appropriate condition for longer than six months, and therefore interferes with their participation in society.

The German laws provide various instruments to prevent the discrimination of people with disabilities. Section 81, Paragraph 2 of the SGB IX, for example, forbids the discrimination against severely disabled people (*Schwerbehinderte*) at the workplace. Employers may not discriminate against people with disabilities in hiring, promotion, or termination practices. If an employee makes a believable argument that discrimination has occurred, the employer must use objective reasons to prove that the unequal treatment is or is not justified. Individuals who have an officially recognized disability can be terminated only upon approval of the Integrationsamt (Integration Office). Larger businesses are required to employ a fixed quota of severely disabled people or pay the state a specific lump-sum penalty. The regional income from this so-called Ausgleichsabgabe (equalization tax) is used to help support the gainful employment of the severely disabled.

The Behindertengleichstellungsgesetz (Disability and Equality Law) of the Federal Republic of Germany and the corresponding equality laws of individual states prohibit direct and indirect discrimination within state institutions. Official information must also be available for people with sensory disabilities. Hearing-impaired and speech-impaired individuals have the right to use sign language and communication help. The regulations also include guidelines for barrier-free new construction, public streets, paths, and public transportation and for equality in primary and secondary education. In addition, disability associations have the right to negotiate and bargain with economic enterprises for their services and products. The enterprises are not, however, obliged to come to a consensual, contractual agreement (a so-called Zielvereinbarung [target agreement]).

As yet, there has been no explicit legal sanction regarding the exclusion or discrimination against disabled people with respect to the purchase and use of economic goods and services. When private insurance companies, landlords, tour operators, airlines, restaurants, or other private businesses refuse disabled people as customers, individuals may claim illegal discrimination on a case-by-case basis. So far in such situations, however, disabled people have had to prove that they have been discriminated against. As of the beginning of 2004, a comprehensive civil antidiscrimination law had not yet been adopted. Access to medical, occupational, and social rehabilitation; nursing programs; pension payments; and social security benefits are regulated in various laws (e.g., Sozialgesetzbücher [Social Security Codes] III, V to IX, XI, as well as the Bundessozialhilfegesetz [Federal Public Welfare Law] and the Grundsicherungsgesetz [Basic Income Law]). The decision as to which benefit applies in individual instances is delegated in the German social law to various öffentlich-rechtliche Körperschaften (Official Statutory Corporations), semi-national organizations like the Gesetzliche Krankenkassen (Statutory Health Insurance Companies). The service provision is provided through social welfare organizations and private companies, for example, private nursing services, and nursing homes with ecclesiastic or associational sponsorship. According to the law, national social security only covers those who are gainfully employed or who have been in the past. Based on this fact, many disabled people are dependent instead on public welfare through the Bundessozialhilfegesetz and Grundsicherungsgesetz. These forms of benefits serve, above all, to protect an individual at the minimum income level necessary for survival. They only cover essential rehabilitation and integration assistance and only accept recipients who are indigent, people who have no or only a meager source of income, or who possess only a few assets.

At the beginning of the twenty-first century, German disability policies were newly conceived. Today, the long-term goal is to encourage the social participation and self-determination of disabled people. They should no longer be passive objects of social welfare, but should make, as much as possible, self-determined decisions regarding the forms in which to receive support. In addition, consideration is to be made of the needs of disabled women. These basic goals, however, have as yet been only partially realized in the law and in practice.

DISABILITY LAW: SWEDEN

The Swedish Disability Act (Lag om stöd och service till vissa funktionshindrade, SFS 1993:387) came into force in 1994. It is hereafter referred to as LSS, the standard Swedish abbreviation. LSS complements universal legislation such as the Social Services Act and the Health and Medical Services Act, giving priority to the social needs of persons with severe disability such as intellectual disability (mentally retarded from birth or young age; autism or conditions resembling autism; considerable and permanent intellectual disability after brain damage when an adult, caused by external force or illness), and other lasting physical or mental disabilities that are manifestly not due to normal aging, if these disabilities are major and cause considerable difficulties in daily life and, consequently, an extensive need for support and service. LSS succeeded an act of similar construction, the Special Services Act of 1985, offering social support only to persons with intellectual disabilities. In accordance with LSS, the target groups are entitled to 10 different support measures, one of the most important being the right to personal assistance. Local authorities are responsible for nine and county councils for one support measures. The same kind of social support can be given in accordance with the Social Services Act and LSS. However, because LSS is a human rights statute there are decisive differences: LSS has a higher level of ambition (”good living conditions” as opposed to the “acceptable standard of living” as decreed by the Social Services Act), there is an unconditional right to support when needs are not met, applications for support may not be turned down on the grounds of insufficient funding, and LSS measures are free of charge.

The political intention with LSS is to strengthen citizenship in the encounter with the public sector. Freedom from coercion and influence over assessment of needs are ways to guarantee the civil element of citizenship. Equalization of opportunities to live a life like others and be able to participate in society and the common welfare expresses the social element of citizenship. However, the reform has not been implemented to the extent that the politicians intended. Appraisals indicate that a smaller number, half of the expected 100, 000 or 1 percent of the population, have shared in the benefits of this reform. This result particularly applies to persons with mental disabilities. Thus, first, persons with severe disabilities have not, for different reasons, been able to exert their legal rights. Second, officials and experts, such as social welfare officers and physicians, seem not always to understand the intent of LSS and its precedence over the Social Services Act. Third, local politicians, who very well may understand the intent of LSS, giving persons with severe disabilities priority, still defend municipal self-government and follow their own priorities. The result has been several cases of judicial disobedience when favorable decisions in courts have not been enforced. The state tries to overcome this problem, earlier by fining disobedient municipalities, and since 2002 by using sanctions.

DISABILITY LAW: UNITED STATES

Disability law in the United States is at a pivotal point in its development. The past half-century has seen a move from the medical and vocational models, which addressed disability as either a medical issue to be cured or a justification for welfare and benefits, to a civil rights model, which seeks to remove the barriers that impede the full integration of people with disabilities into society.

The Americans with Disabilities Act (ADA) is the current prominent national policy and legal statement affecting the lives of persons with disabilities. Though the ADA is the largest and most sweeping legislation, it does not stand alone. Among others, the Rehabilitation Act, Individuals with Disabilities Education Act (IDEA), Fair Housing Act Amendments, and various state laws all combine to complete the American disability law landscape or framework. These laws, and the legal issues involved in narrowing or enlarging their focus, are explored below.

AMERICANS WITH DISABILITIES ACT

The ADA was signed into law on July 26, 1990. It is sweeping legislation, intended to create broad social change. At the signing ceremony, President George H. W. Bush described the ADA as

> the world's first comprehensive declaration of the equality of people with disabilities, and evidence of America's leadership internationally in the cause of human rights. With today's signing of the landmark Americans with Disabilities Act, every man, woman, and child with a disability can now pass through the closed doors, into a bright new era of equality, independence, and freedom.

The ADA has a preface section and three main parts. The preface section states Congress's goals and reasons for passing the ADA. This section of the law identifies people with disabilities as "a discrete and insular minority who have been faced with restriction and limitations, subjected to a history of purposeful unequal treatment, and relegated to a position of political powerlessness in our society," and sets the nation's proper goals regarding individuals with disabilities as ensuring "equality of opportunity, full participation, independent living, and economic self sufficiency."

The preface section also sets out the operative definition of disability for the entire statute. An individual with a disability is defined as someone with a physical or mental impairment that substantially limits one or more major life activities of the individual, a record of such an impairment, or being regarded as having such an impairment. In a series of cases, the U.S. Supreme Court has recently interpreted this definition to mean that individuals and their impairments must be considered in their mitigated states. Thus, for example, an individual with 20/200 vision who is rejected for a position as a pilot based on an employer's uncorrected vision requirement is not considered disabled for the purposes of the ADA, where eyeglasses can correct that individual's eyesight to 20/20.

The next three main parts of the ADA (commonly referred to as Titles I to III) cover nondiscrimination in employment, public services, and places of public accommodation, respectively. These will be discussed in turn.

Title I: Employment

Perhaps the most heavily litigated provisions of the ADA have been the employment sections. They impose comprehensive—from application to termination—obligations on covered employers.

The ADA's general rule of nondiscrimination in employment is that "no covered entity shall discriminate against a qualified individual with a disability because of the disability of such individual in regard to job application procedures, the hiring, advancement, or discharge of employees, employee compensation, job training, and other terms, conditions, and privileges of employment."

Covered Entity

An employer is a "covered entity" if that employer has 15 or more employees. Most recently, in *Clackamas Gastroenterology Associates, P.C., v. Wells,* the Supreme Court developed a six-part test to determine whether shareholder-directors are employees for the purposes of ADA Title I. The crucial element in this test is control.

In *Board of Trustees of the University of Alabama v. Garrett,* the Supreme Court held that Congress's abrogation or limitation of the states' Eleventh Amendment sovereign immunity was invalid insofar as Title I provided for suits against the states for monetary damages. Therefore, states are treated differently for ADA Title I purposes than are private employers. After *Garrett,* a state employee does not have a viable claim against his employer for monetary damages under ADA Title I.

Prohibited Inquiries

There is a substantial body of case law relating to the range of permissible inquiries (both before and during employment) under Title I. The general preemployment rule is that a potential employer may not try to learn if the applicant has a disability, unless it is legitimately necessary for the conduct of the job. Preemployment medical examinations are not permissible. This provision allows individuals with disabilities to be judged on their qualifications and not on their disabilities. After an employer has made a conditional offer, but before the start of employment, the employer may require a medical examination or ask disability-related questions if all employees—or a least all employees performing similar tasks—must take it and it can be shown to be related to the job qualifications. The examination is subject to rigid confidentiality restrictions. During the course of employment, an employer may not make inquiries or require a medical examination "unless such examination or inquiry is shown to be job-related and consistent with business necessity."

Reasonable Accommodation

The concept of reasonable accommodation is central to Title I's antidiscrimination provision. An employee is not a "qualified" person with a disability for purposes of Title I if he or she cannot perform the essential job functions with or without a reasonable accommodation. An employer's failure to make a reasonable modification, when asked, constitutes a separate claim of employment discrimination. A reasonable accommodation is a modification or adjustment to a workplace process or environment that makes it possible for a qualified person with a disability to perform essential job functions. Accommodations may include physical modifications to a workspace, flexible scheduling of duties, or provision of equipment, assistive technologies, and job training to aid in job performance.

To be eligible for an accommodation, an employee must make his or her disability known to the employer and request an accommodation. Once the accommodation request is made, the ADA requires a consultative "interactive process." In this process, the employer retains the right to choose the accommodation according to its reasonable effectiveness and the employee's good faith opportunity to participate in the process.

Undue Hardship and Direct Threat

A common critique of Title I is that accommodations for qualified individuals create economic hardships that are costly and burdensome for employers. The statutory mechanism for dealing with this criticism is the "undue hardship" defense. Employers only are required to make accommodations that do not impose undue hardships on them. An undue hardship is a significant difficulty or expense, in light of the firm's size and resources. Undue hardship is an affirmative defense that must be raised and proved by the employer.

Similarly, an employer does not need to make a requested modification if it creates a significant risk of a "direct threat" to the health or safety of the employee, applicant, or others in the workplace. In *Chevron v. Echazabal,* the Supreme Court interpreted this defense to include instances where the employee's disability creates a direct threat to his own health or safety.

Title II: Public Entities

ADA Title II requires that the services, programs, and activities of state and local government entities be accessible to people with disabilities. Before the ADA was enacted, the Rehabilitation Act of 1973 prohibited some public entities from discriminating on the basis of disability. This protection, however, was limited to public entities that received federal financial assistance. A primary purpose of Title II was to extend the existing prohibition on discrimination to state and local government entities, regardless of whether they received federal financial assistance. Title II is therefore the least revolutionary of the major titles of the ADA.

Title II's main antidiscrimination provision is that "no qualified individual with a disability shall, by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity, or be subjected to discrimination by any such entity."

To have a viable Title II claim, a plaintiff must demonstrate that he or she was either excluded from participation in or denied the benefits of a public entity's services, programs, or activities, or was otherwise discriminated against. The regulations promulgated by the U.S. Department of Justice pursuant to Title II offer extensive guidance on what this means. Conceptually, it is useful to think about the affirmative responsibilities of public entities in five areas: making reasonable modifications to policies, practices, and procedures; administering services, programs, or activities in the most integrated setting appropriate to the needs of qualified individuals with disabilities; modifications to facilities; communications modifications; and accommodations in transportation.

Until recently, it has been an open issue as to whether individuals can sue states for damages for violations of Title II of the ADA. In *Tennessee v. Lane*, the Supreme Court held that an individual could sue a state for damages for not providing access to courthouses. It is still an open question whether individuals can sue states for damages for the panoply of other rights that fall within Title II's scope.

Reasonable Modifications to Policies, Practices, and Procedures

The Title II regulations provide that a public entity must reasonably modify policies, practices, or procedures when necessary to allow participation by a person with a disability. Analytically, this is similar to the reasonable accommodation requirement of Title I.

The regulations set the outer limits of reasonable accommodations. The regulations provide that modifications must be made *unless* the public entity can demonstrate that making them would fundamentally alter the nature of the program, service, or activity.

Although the reasonable modification requirement of Title II does not include an undue hardship defense, the courts have read undue hardship into the fundamental alteration defense. Thus, courts determining whether a modification will constitute a fundamental alteration consider whether the change will cause an undue financial or administrative burden on the entity.

Even if a given program, service, or activity has an essential eligibility requirement, the plaintiff still can be a "qualified individual with a disability" if he or she can meet that requirement with or without "reasonable modifications to rules, policies, or practices, the removal of architectural, communication, or transportation barriers, or the provisions of auxiliary aids and services."

Integration

The regulations provide that public entities must administer services, programs, or activities in the most integrated setting appropriate to the needs of qualified individuals with disabilities. In *Olmstead v. Zimring,* the Supreme Court considered the interplay between this integration mandate and the "fundamental alteration" limit on reasonable modification of policies.

In *Olmstead,* two women with mental retardation and psychiatric conditions brought suit under Title II, claiming that the state of Georgia had discriminated against them by keeping them in institutionalized settings instead of community placements that were appropriate for their needs. The Court held that this unjustified institutional isolation constituted discrimination within the meaning of Title II. However, the Court recognized that the duty to accommodate was not absolute. In deciding whether this accommodation would fundamentally alter the state's mental health treatment program, the proper inquiry was *not* the cost of accommodating these two plaintiffs weighted against the states' overall mental health budget.

In July of 2001, President George W. Bush entered an executive order reinforcing the *Olmstead* decision and providing guidance to the U.S. attorney general, the secretaries of Health and Human Services, Education, Labor, and Housing and Urban Development, and the commissioner of the Social Security Administration in its implementation. As part of the administration's "New Freedom" initiative, the Centers for Medicare and Medicaid Services distributed more than $120 million in grants in 2001 and 2002 to help states increase community-based integration for people with disabilities. However, years after the *Olmstead* decision, states face a lack of coordinated community-based services and a shortfall of funds in carrying out the integration mandate.

Facilities Modification

Title II applies to a public entity's physical structures. Courts have interpreted this reach to include, among other things, city buildings, botanical gardens on the premises of a state university, publicly owned sporting arenas and theaters, and recently, city sidewalks. The regulations provide that each service, program, or activity conducted by a public entity, when viewed in its entirety, must be readily accessible to and usable by individuals with disabilities. This does not mean, however, that each existing facility must be physically accessible to and usable by individuals with disabilities.

The regulations set forth the "program access" standards for facilities. What a public entity must do to ensure program access to its facilities varies according to whether the facility is an "existing" facility, a new facility, or a facility that has been altered.

In ensuring program access in existing facilities, a public entity does not have to take action that will result in fundamental alteration in the nature of a service, program, or activity or cause an undue financial or administrative burden. The public entity has the burden of showing that compliance with the program access standard would result in such alteration or burden. The decision that compliance would result in such an alteration or burden must be made by the head of the public entity, in writing.

Notably, a program must be accessible "when viewed in its entirety." Therefore, if a government program offers identical services at more than one facility, not every facility must be accessible. To allow some facilities to remain unchanged, the alternative facilities must offer equivalent services in terms of type of service, hours of operation, convenience, and quality.

The regulations create a different set of responsibilities for public entities for construction of new facilities and alterations of existing facilities. For new construction, the regulations provide that each facility or part of a facility constructed by, on behalf of, or for the use of a public entity be designed and constructed in such manner that the facility or part of the facility is readily accessible to and usable by individuals with disabilities. Alterations to existing facilities are subject to a similar standard.

In contrast to the regulations governing existing facilities (where entities are exempted from making fundamental alterations and bearing undue financial burdens), the regulations for new construction and alteration are more stringent. There is no "undue burden" provision, with the regulations stating facilities "shall" be accessible.

Effective Communication

Like the program access standard, Title II's communications provisions have a statutory and regulatory component. Title II's definition of qualified person with a disability links the "provision of auxiliary aids and services" to the concept of reasonable accommodations. The Title II regulations have a separate section devoted to "Communication," which makes clear that communication is an integral part of a public entity's responsibilities under Title II.

The regulations provide that auxiliary aids and services be furnished when necessary to afford an individual with a disability an equal opportunity to participate in and enjoy the programs, services, or activities of the public entity. The effective communication obligation is owed to people with hearing, speech, and vision disabilities, as well as those with mental and physical impairments.

In terms of types of auxiliary aids and services, a public entity is to give primary consideration to the requests of individuals with disabilities. Auxiliary aids and services for people with hearing impairments include qualified interpreters, notetakers, written materials, amplifiers, captioning, teletypewriters (TTYs), telecommunications devices for the deaf (TDDs), and others. For people with vision impairments they include qualified readers, taped text, Braille, large print, assistance locating items, and others. For people with speech disabilities they include TTYs, computer terminals, speech synthesizers, and communication boards. The regulations provide that a public entity does not need to take any action that it can demonstrate would result in a fundamental alteration or an undue financial or administrative burden.

Transportation

Title II has a separate part dedicated to nondiscrimination in transportation provided by public entities. Transportation was an area where the ADA's framers recognized an existing pattern of discrimination and inequity.

The ADA explicitly states that "discrimination against individuals with disabilities persists in such critical areas as . . . transportation" and "individuals with disabilities continually encounter various forms of discrimination, including . . . transportation . . . barriers." The debates on ADA passage suggest that the framers viewed transportation as crucial to unlocking other opportunities that the ADA would help create.

Public transportation is especially important to people with disabilities because the evidence suggests that they are more reliant on public transportation than the general population. The legal and policy tensions specific to transportation issues are a microcosm of the entire act. These issues include mainstreaming of existing transportation to accommodate people with disabilities versus paratransit (i.e., transportation services usually performed by vans that are provided separate from mass transit's normal operations), and whether there should be a "threshold" or "necessary" level of spending on mass transportation options for people with disabilities.

ADA Title II's transportation provisions require accessibility standards for fixed-route systems (e.g., buses and rails that run on fixed schedules), paratransit, demand response systems (e.g., any system, such as taxicab service, that is not a fixed route), and rail service that is dedicated to commuters and that runs between cities.

Title III: Public Accommodations

Title III extends the ADA's antidiscrimination mandate to places of public accommodation and commercial facilities. Title III therefore is broader in scope than Title II. The goal of Title III is to integrate people with disabilities into the mainstream of American life.

The overarching requirement of Title III is set out in its antidiscrimination provision:

> No individual shall be discriminated against on the basis of disability in the full and equal enjoyment of the goods, services, facilities, privileges, advantages, or accommodations of any place of public accommodation by any private entity who owns, leases (or leases to) or operates a place of public accommodation.

The premise of Title III is straightforward: Places of public accommodation are barred from discriminating against people with disabilities in their use of facilities and the provision of goods and services. To this extent, Title III parallels Title II of the Civil Rights Act of 1964.

However, discrimination under Title III is defined broadly to include failure to make reasonable modifications of policies, practices, and procedures; failure to ensure effective communication; and failure to take steps to make facilities physically accessible. The defenses to a charge of discrimination rely on concepts of undue burden, fundamental alteration, and lack of "readily achievable" modifications.

Title III provides general and specific prohibitions on discriminatory conduct. General discrimination prohibited under Title III includes denial of participation, participation in unequal benefit, providing a separate benefit when separation is not necessary, failure to ensure that people with disabilities receive goods or services in the most integrated setting appropriate to their needs, denying an individual with a disability the opportunity to participate in an integrated benefit because of the availability of a separate benefit, using contractual or administrative methods that have the effect of discriminating or that perpetuate the discrimination of others who are subject to common control, and discrimination on the basis of association with a person with a known disability. Specific types of discrimination under Title III include discriminatory eligibility criteria; failure to make reasonable modifications of policy, practice, or procedure when necessary to permit a person with a disability to benefit from a place of public accommodation; failure to ensure effective communication through the provision of auxiliary aids; and failure to remove architectural barriers to access when it is readily achievable to do so.

A place of public accommodation may not assess a charge to a person with a disability for any action, aid, or service required by the ADA, even to cover the actual costs of the action, aid, or service. Rather, the cost of compliance must be considered an overhead expense.

The defense to the reasonable modification requirement is that the requested modification would fundamentally alter the nature of the goods or services being provided. The U.S. Supreme Court addressed the application of the fundamental alteration defense in *PGA Tour, Inc. v. Martin.* Casey Martin, a professional golfer, has a degenerative circulatory disorder that obstructs the flow of blood from his right leg to his heart. Martin requested that the Professional Golfers' Association (PGA) allow him to ride a golf cart in its tournaments, instead of complying with the normal rule that participants walk the course.

The PGA Tour conceded that a golf cart was necessary for Martin to participate in the tour, but argued that the requested modification would fundamentally alter the nature of the event in three ways: by altering "such an essential aspect of the game of golf that it would be unacceptable even if it affected all competitors equally," by giving the individual with a disability an unfair advantage over the other players, and by imposing administrative burdens on the operator of a place of public accommodation. The Court found that none of those possible alterations rose to the level of a permissible defense in this case, and held that Casey Martin was entitled to use a golf cart as a reasonable modification.

Title III provides an affirmative defense in situations where providing a modification would pose a direct threat to the health or safety of others. The statute defines "direct threat" as "a significant risk to the health or safety of others that cannot be eliminated by a modification of policies, practices, or procedures or by the provision of auxiliary aids or services."

The ADA regulations provide that the direct threat determination should be based on individualized assessment and on reasonable judgment that relies on current medical knowledge or the best available objective evidence. It must consider the nature, duration, and severity of the risk, the probability that the potential injury actually will occur, and whether modifications will mitigate the risk.

Title II also requires physical accessibility of public accommodations. For existing facilities, Title III requires architectural barriers to access to be removed "where such removal is readily achievable, i.e., easily accomplishable and able to be carried out without much difficulty or expense." If removal of a barrier or barriers is not readily achievable, a place of public accommodation must attempt to make its goods and services accessible to people with disabilities through alternative methods that are readily achievable. Examples of alternatives to barrier removal include providing curb service or home delivery, retrieving merchandise from inaccessible shelves or racks, and relocating activities to accessible locations.

Title III entities making alterations or renovations to existing facilities for other than barrier removal purposes must "make such alterations . . . in such a manner that, to the maximum extent feasible, the altered portions of the facility are readily accessible to and usable by individuals with disabilities, including individuals who use wheelchairs." New buildings, constructed for first occupancy after January 26, 1993, must be fully accessible to and usable by people with disabilities. The only exception to compliance occurs when the entity demonstrates that full compliance is structurally impracticable. Structural impracticability will be found "only in those rare circumstances when the unique characteristics of terrain prevent the incorporation of accessibility features."

SECTION 504 OF THE REHABILITATION ACT

The Rehabilitation Act of 1973, and Section 504 in particular, is in many ways the direct predecessor to the ADA. As originally passed, the primary focus of the Rehabilitation Act of 1973 was vocational training and rehabilitation. The stated purpose of the act was to "provide a statutory basis for the Rehabilitation Services Administration," an agency charged with carrying out the provisions of the act, and to authorize various rehabilitation programs.

The final part of the original 1973 act contains the portions of the Rehabilitation Act that over time have had the greatest impact. Section 501 requires affirmative action and nondiscrimination in employment by federal agencies of the executive branch. Section 502 established the Architectural and Transportation Barriers Compliance Board (Access Board), which also is responsible for developing accessibility standards for the ADA. Section 503 requires that to receive certain government contracts, entities must demonstrate that they are taking affirmative steps to employ people with disabilities.

The enduring hallmark of the Rehabilitation Act of 1973, however, is Section 504. This section provides that no otherwise qualified individual with a disability shall, solely by reason of his or her disability, be excluded from the participation in, denied the benefits of, or subjected to discrimination under any program or activity receiving federal financial assistance. This sweeping language was the first explicit Congressional statement recognizing "discrimination" against people with disabilities.

The regulations promulgated pursuant to Section 504 of the Rehabilitation Act introduced the concept of "reasonable accommodation" to disability discrimination law. The "employment" section of the Section 504 regulations states:

> A recipient [of federal funds] shall make reasonable accommodation to the known physical or mental limitations of an otherwise qualified handicapped applicant or employee unless the recipient can demonstrate that the accommodation would impose an undue hardship on the operation of its program or activity.

The regulations provide examples of reasonable accommodations, including altering facilities and modifying work schedules.

The Section 504 regulations' approach to facility access issues is similar to ADA Title II. The regulations provide that no qualified person with a disability be denied the benefits of, excluded from participation in, or otherwise subjected to discrimination because a recipient's facilities are inaccessible to people with disabilities. This is commonly known as the "program access" requirement. A recipient of federal funds does not have to make its facilities accessible; rather, accessibility is achieved when each program or activity within the facilities, viewed as a whole, is accessible. Examples of steps to ensure program accessibility include redesigning equipment, reassigning classes to accessible buildings, and home visits.

Another issue the regulations make clear is that education is covered by Section 504. The regulations provide that recipients of federal funds that operate public or secondary schools must provide a free appropriate public education to each qualified handicapped person, regardless of the nature of severity of that person's handicap. Similarly, the regulations provide that qualified persons with disabilities may not be denied admission or subjected to discrimination by postsecondary schools on the basis of disability.

The Rehabilitation Act and its accompanying regulations frame the issues of employment, and facility and educational access for persons with disabilities as a balancing test. Accommodation is desirable, when the methods of ensuring accessibility are reasonable. Although "reasonable" is not defined, a guiding principle is that a reasonable accommodation or modification does not require a change to the fundamental nature of the job, program, or facility.

Conceptually and doctrinally, the ADA and Section 504 of the Rehabilitation Act of 1973 have a close relationship. Both are premised on the belief that people with disabilities have a right to be included in society and that a denial of that right, including failure to make reasonable accommodations, constitutes discrimination. The ADA concepts that the courts have struggled with—reasonable accommodation, the definition of disability, and fundamental alteration—have their bases in the Rehabilitation Act. The ADA is explicit that Rehabilitation Act regulations and cases are instructive in interpreting the ADA.

SECTION 508 OF THE REHABILITATION ACT

The implementation of Section 508 of the Rehabilitation Act was designed to spur innovation throughout the e-commerce industry. Enacted as part of the Workforce Investment Act of 1998, Section 508 requires that electronic and information technology (EIT), such as federal websites, telecommunications, software, and information kiosks, must be usable by persons with disabilities.

Federal agencies may not purchase, maintain, or use EIT that is not accessible to persons with disabilities, unless accessibility poses an undue burden. The EIT Accessibility Standards, finalized on December 21, 2000, detail the requirements for federal entities. Section 508 does not require private companies that market technologies to the federal government to modify the EIT products used by company employees, or to make their Internet sites accessible to people with disabilities.

INDIVIDUALS WITH DISABILITIES EDUCATION ACT

The IDEA originally was passed in 1975 (under the name Education for All Handicapped Children Act). As originally passed, this act was an express recognition of the number and needs of children with disabilities in the school system. Congress found that "there are more than eight million handicapped children in the United States today," whose educational needs were not being met. To meet these educational needs, IDEA focuses on higher expectations, mainstreaming students where possible, and an increased federal rule in ensuring equal educational opportunity for all students.

Under the IDEA, schools have to provide a free and appropriate public education (FAPE) to eligible children with disabilities. The FAPE should take place in the least restrictive environment appropriate to the child's needs. IDEA requires schools to develop an individualized education program (IEP) for each child. Each child's IEP must be developed by a team of knowledgeable persons and reviewed annually. This team includes the child's teacher, parents, and if appropriate the child, and an agency representative who is qualified to provide or supervise the provision of special education. If the parents disagree with the proposed IEP, they may request a due process appeal hearing and a review from the state educational agency, and may appeal this decision to state or federal court. In 2005, the IDEA was reauthorized with the Individuals with Disabilities Education Improvement Act of 2004.

FAIR HOUSING ACT AMENDMENTS

In 1988, Congress introduced a series of amendments to the Civil Rights Act of 1968, including a prohibition on housing discrimination against people with disabilities. These amendments are known as the "Fair Housing Act Amendments of 1988."

The Fair Housing Act Amendments make it unlawful to discriminate in the sale or rental of housing, and the terms and conditions of such sale or rental, on the basis of disability. The Fair Housing Act Amendments have a broad scope, protecting not only a buyer or renter with a disability but also a person with a disability who lives with a buyer or renter, or any other person associated with the buyer or renter.

Discrimination under the Fair Housing Act Amendments includes a refusal to permit an occupant with a disability, at his or her own expense, to make reasonable physical changes to the existing premises; a refusal to make reasonable accommodations in rules, policies, practices, or services; and a failure to construct multifamily dwellings (which contain four or more units) so that specified portions of those facilities are accessible to individuals with disabilities.

STATE DISABILITY LAWS

Before the passage of the ADA, the primary responsibility for regulating discrimination on the basis of disability belonged to the individual states. Different states had laws covering nondiscrimination in employment, public accommodations, and state services. Many states covered one, but not all, of these areas. These pre-ADA state statutes generally regulated far less conduct than the ADA.

Congress's passage of the ADA was grounded on a recognition that stronger protection was needed than that offered by the states alone. The ADA was a shift toward a comprehensive federal model of protection for a wide range of people with disabilities. The ebb and flow between and among the U.S. federal and state laws is, of course, reflective of changing views about the role of the federal and state government in the lives of citizens. With the recent narrowing by the Supreme Court of federal civil rights laws, and the ADA in particular, states' civil rights laws take on a renewed importance for the protection of people with disabilities from discrimination.

Today, every individual state has some law relating to discrimination on the basis of disability. The scope and coverage of these laws run the gamut. Some state statues offer protection that is greater than, or equal to, the ADA, while others offer less protection.

One example of a state that offers more protection for people with disabilities is California. California had a history, even pre-ADA, of offering strong legal protections for people with disabilities. The California disability antidiscrimination statute, the

Fair Employment and Housing Act (FEHA), is comprehensive in scope. FEHA prohibits discrimination in public and private employment, and it contains a reasonable accommodation requirement. Another California statute, the Unruh Civil Rights Act, guarantees people with disabilities full and equal accommodations in business establishments.

In 2000, California amended the FEHA. The amendments expand on the ADA's protections in several significant ways. For example, as discussed, to be considered "disabled" for the purposes of the ADA, an individual needs to be considered in his or her mitigated state. The FEHA amendments reject that view, providing that "under the law of this state, whether a condition limits a major life activity shall be determined without respect to any mitigating measures." Similarly, while the ADA limits coverage to individuals whose impairments result in a *substantial limitation* of a major life activity, an individual is covered by California's FEHA if his or her impairment *limits* a major life activity.

CONCLUSION

The laws discussed above make up the American legislative landscape as it relates to the rights of people with disabilities. The political and judicial climate of the United States is split between those who believe the ADA represents the federal government reaching too far into the lives of states and private businesses and those who feel this is the most important civil rights law of the past several decades. Time will tell the direction and scope that judges and politicians allow the ADA to take.

DISABILITY LEAVE

In the United Kingdom in the early 1990s, a pioneering job retention program for disabled people was introduced under the title "disability leave." Designed to assist newly disabled people or people whose impairment deteriorates to retain their employment, the program provides for a period of leave with expert assessment, advice, rehabilitation, retraining, workplace adaptation, and, perhaps most important of all, job protection.

Disability leave was developed by the Royal National Institute of the Blind (RNIB) and has subsequently been adopted by a number of major employers across the United Kingdom. RNIB has pressed successive governments to put the scheme on a statutory basis, but to date this has not been accepted. Yet with recent changes to disability employment and benefit policies, some elements are now in place. What is missing is a clear policy for job protection.

BACKGROUND

RNIB developed disability leave as a response to the large number of people in their 40s and 50s losing their sight at work who through redundancy, resignation, or early retirement also lost their jobs. It was recognized that sight loss (or any other impairment) need not be an obstacle to staying in work but that all too often both employer and employee believed it was.

Disability leave offers major benefits to both employer and employee. To the newly impaired employee, the program provides support, retraining, rehabilitation, and crucially, the chance to avoid what is likely to be a long period of unemployment with the inevitable associated drop in income. To the employer, disability leave has many benefits including the retention of experienced staff, avoidance of unnecessary recruitment costs, lower staff turnover, and a reduced early call on occupational pension funds.

WHAT IS DISABILITY LEAVE?

Disability leave does not simply refer to a "leave" entitlement, but rather to a whole process of assessment, advice, retraining, and workplace adaptation including the provision of assistive technology and job protection. Typically, a company's disability leave plan will involve early intervention to identify and engage with employees who are experiencing sickness or disability. A home visit may be arranged as early as four weeks although eight weeks is a more typical period. If appropriate, a case manager is appointed who provides support and advice to the employee and the manager. Following an expert assessment, a range of options are considered to enable the employee to continue in his or her current job including retraining, workplace adaptation, and the provision of assistive technology. However, in certain circumstances the job itself may need to be modified with possible reallocation of duties among colleagues. As a last resort, it may be necessary for the employee to be redeployed elsewhere in the organization.

RNIB developed the policy of disability leave in the early 1990s in consultation with statutory, voluntary, and trade union organizations concerned with employment and disability. Subsequently, it has been adopted by a range of mainly larger companies including Barclays Bank, HSBC, Royal Mail, and the TUC. However the great majority of employers continue to respond to the onset of an impairment in an ad hoc and typically negative manner. This reflects widely held prejudicial views about the difficulties of employing disabled people and also worries about the additional costs that may be incurred.

In the absence of widespread adoption of disability leave on a voluntary basis, RNIB has pressed successive governments to put the scheme on a compulsory basis. RNIB wants disability leave to be as well-known as the statutory maternity leave program that provides job protection and income for women during pregnancy and the first year following birth. However, to date, this has not been accepted with the government arguing that disability leave should be provided by employers as a "reasonable adjustment" under the Disability Discrimination Act (DDA).

FOUR ELEMENTS OF A SUCCESSFUL POLICY

Disability leave is one way to assist newly disabled people to retain paid employment. But, as with any voluntary program, it can have only a limited impact. Disability leave needs to be put on a statutory basis and supported by a broader set of policies that promote job retention. Overall, four elements are critical to success: job protection, cost sharing, early and timely intervention, and a flexible and supportive benefits system.

Job retention through disability leave, or indeed any other program, is not possible if there is no job to return to. In the United Kingdom, this protection should be provided by the DDA with employers being required to retain newly disabled employees and to make "reasonable adjustments" to the work environment. However, typically the DDA comes into effect only when an individual makes a complaint of unfair dismissal on grounds of disability; that is, *after* the individual has lost his or her job. Even if an Employment Tribunal finds in favor of the disabled employee, it cannot under current legislation require the employer to reinstate. At best, the disabled person will receive substantial compensation from his or her ex-employer but will, nevertheless, still be out of work.

The second key element of any job retention strategy is cost sharing. Most employers are not convinced by the business case for retaining newly impaired employees. They believe that there will be substantial costs associated with retraining and workplace adaptation and that these will outweigh the benefits of keeping an experienced employee. Without a compulsory job retention program that allows for some element of cost sharing, employers will not keep on newly disabled employees.

In the United Kingdom, this issue has been partially addressed through the Access to Work program. This provides government funding for adaptation of premises and equipment, special aids, support workers, and travel to and from work. In many cases, Access to Work can cover all of the additional costs associated with retaining a newly disabled person, which should be enough to alleviate employer concerns. However, as many as three-quarters of employers have not heard of the program and the financial support it can provide.

While Access to Work is concerned primarily with funding changes to the work environment and equipment, the Employee Retention Grant Scheme introduced in the Republic of Ireland in the late 1990s provides financial support for the development and implementation of a job retention strategy for newly disabled workers. Under a two-stage process, employers receive funding to buy in expert skills to develop a written individual retention strategy and then further aid toward implementing the strategy including retraining and job coaching. In general, cost sharing is needed to ensure the provision of return to work services through individual casework and to fund workplace adaptations and equipment.

The third necessary element of a successful job retention strategy is early and timely intervention. Within disability leave programs, there is typically a home visit at eight weeks. This is in sharp contrast to the usual practice in the United Kingdom, which has been to allow newly sick or disabled employees to drift out of work and onto long-term benefit dependency. This is changing with a stronger focus on job retention in the Department for Work and Pensions (DWP) latest Five Year Plan (DWP 2005). But the United Kingdom is still some way from the early interventions required in countries such as Denmark, Sweden, and the Netherlands.

The fourth key element of a successful job retention strategy is a benefits system that is flexible and supports a gradual return to work after a period of disability leave. In the United Kingdom, benefit rules have tended to discourage the combination of sickness/incapacity benefit with a wage, allowing for part-time working. However, this also is starting to change as the findings of DWP Pathways to Work and job retention pilots show the advantages of flexible benefit/pay packages.

DE FACTO DISABILITY LEAVE

Despite the UK government's stated opposition to disability leave, key elements are now in place. There is cost sharing through Access to Work. Timely intervention and benefit flexibility is starting to be delivered through Pathways to Work and the proposed Rehabilitation Support Allowance. What is missing is effective job protection. This is not and will not be delivered by the type of disability discrimination legislation that exists in the United Kingdom and the United States. Yet, as both Bloch and Prins and Thornton have argued, this is *the* most important element in a job retention strategy.

DISABILITY MANAGEMENT

Disability management is used to refer to a wide range of concepts and approaches. Most commonly, the term is used in three areas: work and work discrimination, symptom/condition management, and resource management.

Within the area of work, disability management commonly refers to a field of practice that has focused on how employers manage disability overall within the workplace, including issues such as preventing disability, returning to work after a disability event, providing reasonable accommodations within the worksite, and cost-benefit and -effectiveness analyses of the management services. Within the United States, there is a national certification system for disability management specialists, referring primarily to human resource specialists with experience in managing work-related disability issues. Given the passage of the 1990 Americans with Disabilities Act in the United States, the Disability Discrimination Act in England, and other related civil rights legislation in many countries, the focus has shifted toward evaluating discrimination in the workplace experienced by disabled people, and the effect of this discrimination on the disabled person, the disability community as a minority group, employers, and society in general. The field of disability management has also focused on organizational health, that is, how disability influences cost, cost-benefit, and productivity within worksites as organizational units. The field of disability studies has instead focused on analyzing the oppression of disabled people as a minority group, particularly evident in the area of access to work opportunities, tracing the oppression to a capitalist political economy and ideology.

Disability management has also been used to refer to the management of symptoms, conditions, and impairments affiliated with disability. In this case, *disability* is used to refer to disease, medical or chronic conditions (e.g., diabetes, heart disease, arthritis, multiple sclerosis), or broader impairment categories (e.g., physical, cognitive, mental, sensory). *Management* refers to how people who are living with these conditions manage or control the symptomology, and the use of treatments affiliated with each. Research has focused on how people respond to symptoms and control them in emergency and acute situations as well as over their lifetime, treatment strategies for managing symptoms, and the relative outcomes, effectiveness, and long-term impact of treatments, primarily related to quality of life and cost/cost-benefit issues as framed within a medical approach.

The focus on condition or impairment management has expanded beyond symptom management to self or self-care management, that is, managing everyday self-care in the home given specific conditions or a long-term disability. Self-care is often linked with overall health promotion strategies, including nutrition and exercise to maintain or prevent declines in function. Intervention programming in this area has included a range of strategies, including self-care rehabilitation within traditional rehabilitation settings, community-based health promotion groups or intervention programs, telerehabilitation in which rehabilitation or medical professionals consult remotely with clients on specific self-care issues in the home, and use of Internet and/or self-paced learning modules for specific client populations. Most programming has focused on specific groups, such as people living with diabetes, asthma, chronic heart conditions, and back pain. The focus in this application is on finding effective strategies to help people manage themselves within the home setting and preventing or decreasing use of costly emergency medical care, long-term care, or institutionalization services. The approach centers on self-efficacy and the development of active problem-solving skills. Increasingly, the use of a peer mentor approach, that is, the use of people who have been through a disability experience to mentor other people new to it, is being emphasized. Peer mentoring is being shown to be as effective as or more effective than traditional patient education delivered by medical professionals in realizing outcomes related to symptom management, overall activity, and role participation, and reduced cost related to use of medical and health-related services. The effects of remote peer mentoring, using strategies such as peer Listservs and electronic mail support groups, are also being examined, showing similar positive outcomes.

A social learning and peer mentoring approach is also a guiding tenet for another application of disability management that focuses on the right to live in the community, and the right to have access to equitable supportive resources to live and participate long term. Coming from the independent living and disability rights movements taking place in many countries, the term *disability* is reconceptualized away from the individual, and the focus on the deficit or dysfunction in the individual assumed in prior approaches, to disability as the oppression of a minority group as a result of societal and environmental barriers, including access to community living resources. Resource management involves finding, accessing, controlling or coordinating, and troubleshooting supportive resources such as affordable and accessible housing, personal attendant services, transportation, assistive technology, and any other supports for community living. This involves accessing and coordinating these resources across many systems with different policies and eligibility criteria. The emphasis is both on learning self-advocacy skills, on an individual basis, and on collective activism to change systems, assert civil rights, and improve societal conditions and opportunities for the disability community as a minority group. Resource management has been emphasized within centers for independent living and other disability activism organizations, and it is being increasingly used as a model approach within the delivery of home and community-based waiver programs to support transition out of institutions and long-term community living choices. The movement has also expanded beyond resource management to focusing on disability experiences as lived by disabled people themselves, and the sharing and critical analysis of those experiences from multiple perspectives.

DISABILITY POLICY: INDIA

The history of a comprehensive disability legislation in India is fairly recent. It can be said to have begun with the ratification of the 1995 Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act (henceforth called PWD Act) by the Indian Parliament. Prior to that, disabled people in India were receiving services—both by the government and nongovernment agencies—but they did not have any legal protection. They could not claim these services as a matter of right. According to Ali Baquer, for the first time, through the PWD Act, it was impressed on society that it has a responsibility to accommodate its disabled citizens and treat them at par, as full and equal citizens—with respect and dignity.

The passage of the PWD Act marked a new dawn in the life of disabled in India. However, one cannot talk about this landmark act without briefly tracing the background in which this legislation became the law of the land and also at the responses of society and state toward the challenges faced by disabled in India—especially during the colonial and postcolonial period. In her pioneering work, which documents the history of disability policy and programs in India, D. Rama Mani has briefly touched on the perception of disability as an issue of charity in ancient and medieval India. She further suggests that with the inroads of Western civilization and the missionaries in the eighteenth century, the old order—of families supporting and providing for their disabled kith and kin—crumbled. If charity and welfare models were in place before the onset of India's colonization by the British, the medical/pathological/rehabilitation model was initiated during the colonial period, which again remained predominantly charity based. The efforts to rehabilitate the disabled were sporadic in the sense that certain categories were totally left out of the purview of services. The responses came from the voluntary sector and the missionaries, which started with the setting up of the hospitals and charitable homes for destitute and handicapped children in the 1880s. Special schools for hearing impaired at Mumbai in 1884 and for the blind in 1887 at Amritsar, Punjab, were opened by the Roman Catholic missionaries. By the time of independence, nearly 100 special residential schools and training centers for disabled people were running.

While echoing similar views, Maya Kalyanpur and Anuradha Mohit have stated that the institutions set up during the colonial period were patterned to perpetuate custody rather than care for disabled people. Their "asylum-like character . . . unleashed in its wake the process of dehumanization of the PWDs [people with disabilities]." In light of this statement if one looks at the responses of the state, they are manifested in the inclusion of disability in the census, which started in 1872 and continued until 1931, and the passage of the Indian Lunacy Act of 1912, which was established for the mentally retarded and mentally ill people. This act did not allow any medical or therapeutic intervention but entitled the judiciary to relegate mentally ill, then called people deemed of unsound mind, into prisonlike psychiatric institutions.

After independence, however, with India adopting a system of welfare state, policy makers started looking at disability as a rehabilitation issue. The focus was on prevention of disability and its causes, on one hand, and provision of services in the field of education and employment of disabled people, on the other. The disability groups, which were more organized and raising their voices, were able to get concessions and subsidies from the government. Special mention can be made of organizations of the blind, such as the National Federation of the Blind, which were able to obtain concessions in air travel. Like in other countries, disabled veterans were also given differential treatment compared to civilian disabled people. From the 1950s to 1981, the International Year of Disabled Persons, the government responded to the needs of the disabled by making meager budgetary allocations, to be given in the form of grants-in-aid, to nonprofit organizations, for delivering services to the disabled in the area of education, rehabilitation, training, and employment. These nongovernmental organizations (NGOs), however, remained dominated by able-bodied, philanthropic individuals and professionals. There was hardly any place for disabled people to plan the services and programs meant for them. At the same time, need was also felt to prepare a large pool of professionals who could train the disabled in different vocations and work in the national training institutes set up by the government of India. The four national institutes were the National Institute of Visually Handicapped at Dehradun, National Institute of Orthopedically Handicapped at Calcutta, National Institute of Mentally Handicapped at Secundrabad, and Ali Yavar Jung National Institute of Hearing Handicapped at Mumbai.

The year 1981 marked the beginning of change in the condition of disabled people in India. It was the International Year of Disabled Persons, and being a signatory to the UN resolution of 1976, the government of India had committed itself to mandates that provided for equal participation of disabled people in all walks of life and emphasized recognition of the rights of disabled and evolving strategies for their development. Statutory provisions were made and strengthened. For the first time in independent India, the disabled were counted in the decennial population census. The way the data were collected and questions framed, however, left out several categories of disabilities. Because of this, authentic figures could not be gathered, and, instead of improving on it, the practice was done away with in the next census, in 1991. It was in the decade of the 1980s that positive action started in favor of delivering services to the disabled—reservations in educational institutions and employment were given on extended, the Lunacy Act of 1912 was repealed, and the National Mental Health Act was passed in 1987. In the same year, the Justice Baharul Islam Committee was appointed to draft the legislation emphasizing the rights, equal opportunities, and full participation of disabled people. The new national education policy was implemented with focus on inclusive education for disabled children in integrated settings. The state governments also responded by running central government-sponsored programs for the disabled and starting their own programs as well. The public sector responded overwhelmingly by opening doors to disabled people.

Despite these developments, disability remained a marginalized issue until the early 1990s, when some young like-minded disabled advocates, prominent among them being Javed Abidi, Anuradha Mohit, Sarabjeet Singh, Ali Baquer (nondisabled advocate), A. K. Chowdhury (nondisabled advocate), and Lal Advani, formed the Disability Rights Group (DRG) in 1994 to lobby with India's policy makers to accept the recommendations of the Justice Baharul Islam Committee and accordingly pass the legislation. The NGO sector was still dominated by able-bodied people who were largely dependent on government funding for their existence; education of disabled children was still under the purview of Ministry of Social Justice and Empowerment rather than education; disabled people were still relegated to C- and D-category jobs in the government sector; and, with globalization, opportunities for disabled people in the job market were shrinking day by day.

The formation of this DRG was inspired by none other than the stalwarts of the American disability movement Judy Heumann and Justin Dart, who informed these young disability activists via a satellite conference that the Americans with Disabilities Act was a result of a sustained campaign and self-help advocacy movement of disabled people. After a prolonged campaign, several rounds of talks, lobbying, sit-ins, protest marches, press conferences, media mobilization, and agitations, the Persons with Disabilities Act was finally passed by the Indian Parliament on December 31, 1995, and became a law on February, 7, 1996, with the president giving his assent.

According to a conservative estimate, there are 70 million disabled people in India. The act places them on par with other citizens of the country in respect to education, vocational training, and employment. For the first time, the private sector was called on to respond to the disabled. It also streamlines the services existing for the disabled and extends them further; for example, the reservation of posts has been extended to groups A and B and it forces the state to ensure that every child with disability has access to free education up to the age of 18 years. The state has been entrusted with the responsibility to prevent disabilities and provide medical care, education, training, employment, and rehabilitation for persons with disabilities. Furthermore, the state must create barrier-free environments for them, protect their rights, and counteract any abuse or exploitation. It must also provide sufficient mechanisms to implement the intentions and provisions of the act through the constitution of coordination and executive committees at central and state levels with adequate representation of disabled people in them and the office of commissioner at the federal as well as state level. The act gives definition of disability and recognizes seven disabilities that are entitled to the benefits of the act. The categories that have been left out of this act have been included in the National Trust for the Welfare of Persons with Autism, Cerebral Palsy, Mental Retardation and Multiple Disabilities Act, 1999. The PWD Act is designed to encourage fuller participation of disabled people in the community and eliminate discrimination. The act may not yet have significantly affected the large number of Indian disabled people but definitely has highlighted disability as a development and human rights issue.

DISABILITY POLICY: UNITED STATES

In the United States, as in other countries, individuals with disabilities have historically lagged behind the remainder of the population in terms of key socioeconomic indicators and have been excluded from full—and often even partial—participation in society. And, like other countries, the United States has struggled to find the correct mix of policies to bring people with disabilities into the larger society and to equip them to participate meaningfully.

The United States first addressed disability as a health issue and attempted to ameliorate the circumstances of people with disabilities through treatment and care. In the past 30 years, however, policy has shifted. Instead of viewing disability as a medical condition that inherently prevents full engagement in society, today’s policies view society as an institution that has discriminated against those with particular medical conditions. Thus, disability law in the United States today focuses on preventing discrimination based on disability and breaking down the structural barriers to full participation.

A cautionary note: Disability policy in the United States is a dynamic mixture of federal and state laws, regulations, and cases. Often states are on the cutting edge, forcing the national government to catch up. Sometimes the opposite is true. This entry, however, focuses on federal laws, which must be dealt with in all jurisdictions. Moreover, the scope of this entry is limited in that it ignores much substantive disability law and the compelling policy issues that arise in connection with those laws. This article, for example, focuses on the Americans with Disabilities Act’s efforts to erase those impediments to full participation in society that exist today. Much thought, however, has gone into the ADA’s role in ensuring that new obstacles to full participation do not develop as society changes. One of the most fascinating current issues involves how the ADA’s mandates should function with respect to the accessibility of new technologies such as the Internet. Thus, though this entry explores the basics of disability policy, it leaves much uncovered.

The farthest-reaching statement on disability law and policy is found in the Americans with Disabilities Act of 1990 (ADA). In broad terms, the ADA extended to the private sector employment requirements placed on the federal government and federal contractors by the Rehabilitation Act of 1973. It also mandated access to public services—with special emphasis on transportation—and to “public accommodations and services provided by private entities.” This includes everything from hotels and amusement parks to laundromats.

Although the ADA has a broad focus, the component that is perhaps central and that has stirred debate is the accommodation mandate with respect to private employment embodied in Title I of the act. This title places much (but not all) of the initial cost of integrating people with disabilities into the workplace on the private employer. Academics have criticized the approach as inefficient and ineffectual, though whether either is true remains to be seen. Given the centrality of employment as a tool of economic independence and as a route to social integration, the success or failure of Title I may announce the success or failure of the ADA.

EXTENT OF DISABILITY IN THE UNITED STATES

Tens of millions of individuals in America have disabilities. And those going through life with a disability face myriad obstacles. Much of society has traditionally been, and remains, physically inaccessible to people with disabilities. While the lack of physical access to society is troublesome, it is only the most visible of an array of concerns. As shown by the statistics below, people with disabilities lag behind the nondisabled population in a variety of social and economic indicators.

- 27 percent of individuals with disabilities are employed, compared to 78 percent of their nondisabled peers.
- Employees with disabilities with full-time jobs had average annual earnings of $29,513 in 1998, which was more than $8,000 less than the $37,961 average earnings of their nondisabled counterparts.
- Fewer than 11 percent of individuals with disabilities have more than 16 years of education, while almost 24 percent of individuals without disabilities attain that level of education.
- Fewer than 10 percent of individuals with disabilities own a home, while homeownership for the population as a whole exceeds 70 percent.
- 34 percent of persons with disabilities live in households with a total income of $15,000 or less, compared to only 12 percent of those without disabilities.
- People with disabilities are roughly 20 percent less likely to vote than those without disabilities, even after controlling for demographic and other factors relating to voting.

All agree that society has a role in ameliorating the condition of the population of people with disabilities. But how best to respond has not been obvious. Over about the past quarter century, the thinking in the United States has undergone a transformation. Whereas traditionally the government saw itself as a caretaker for people with disabilities, it has recently embraced a disability policy that seeks to integrate those with disabilities into society. The former approach is often referred to as the medical model or charity model and the latter as the civil rights model.

MEDICAL MODEL

From the viewpoint of the medical model, disability is conceived of as an infirmity that inherently precludes full participation in the economy and society. It is the job of doctors, rehabilitation professionals, government bureaucrats, and social workers to take care of individuals with disabilities and to help them adjust to a society structured around the abilities and interests of the nondisabled.

Thus, society's role with respect to people with disabilities is paternalistic; its treatment of them is viewed as a form of welfare or charity. People with disabilities are seen as one component of a larger population that, for whatever reason, cannot fend for itself in society as currently structured. Importantly, this perspective never questions whether society is structured correctly; it merely seeks to help those who cannot function normally within it.

This perception of disability evolved following the Civil War, when the United States created a pension system, in part to manage a population of disabled former soldiers adjusting to postwar society. The legislation linked the definition of disability to an inability to work and established physicians as the gatekeepers of disability benefits.

To this day, many contemporary employment, health care, and rehabilitation programs for persons with disabilities are modeled on this theory. These are policy relics, however, for with the passage of the Rehabilitation Act in 1973 and the ADA in 1990, the United States signaled a significant shift toward the civil rights model.

CIVIL RIGHTS MODEL

The civil rights model conceptualizes persons with disabilities as a minority group entitled to the legal protections of equality that emerged from the struggles of racial minorities and women. Proposing "disability" as a social and cultural construct, the civil rights model focuses on the laws and practices that subordinate persons with disabilities. It insists that society secure the equality of persons with disabilities by eliminating the legal, physical, economic, and social barriers that preclude their equal involvement. The emphasis is not on giving any group special benefits; rather, the issue involves balancing the scales. As one commentator suggests:

> The configurations of the existing environment confer enormous advantages on nondisabled persons. Machines have been designed to fit hands that can easily grip these objects, steps have been built for legs that bend at the knee. . . . Everything has been standardized for a model human being whose life is untouched by disability. All aspects of the built environment, including work sites, have been adapted for *someone*; the problem is that they have been adapted exclusively for the nondisabled majority. (Hahn 1993:103)

Thus, while the medical model focuses on caring for a population of individuals whom society has left behind, the civil rights model focuses on changing society so it leaves behind fewer people.

The shift toward the latter conceptualization of society's role in the lives of people with disabilities started in the 1970s, when individuals with disabilities began to assert their right to be independent in pursuing education and housing. As a result of these efforts, national disability policy began to recognize the right and ability of individuals with disabilities to live independently. For example, Title VII of the Rehabilitation Act of 1973 initiated funding for centers for independent living (CILs). Those centers, which provide services *for* individuals with disabilities and are operated *by* individuals with disabilities, have been enormously successful over the past two decades: Only 10 centers existed in 1979, while in 2002 there were more than 350.

The focus on independent living led to a patchwork of federal and state laws addressing the accessibility of voting and air travel, as well as the right of people with disabilities to enjoy education and independent housing. Then, in 1990 the ADA was enacted. It embraced a range of disability rights issues and made specific findings that relied on the civil rights model.

In language reminiscent of law that addresses the civil rights of other minority groups, the ADA reported that

> historically, society has tended to isolate and segregate individuals with disabilities, and, despite some improvements, such forms of discrimination against individuals with disabilities continue to be a serious and pervasive social problem; . . . [and] individuals with disabilities are a discrete and insular minority who have been faced with restrictions and limitations, subjected to a history of purposeful unequal treatment, and relegated to a position of political powerlessness in our society.

To begin to rectify the history of discrimination, the ADA set out to ensure that, at least going forward, the disability population will enjoy "equality of opportunity, full participation, independent living, and economic self sufficiency."

THE ADA AND THE CIVIL RIGHTS MODEL

The ADA signals a shift in the underlying philosophy of disability rights law in the United States. Moreover, the legal mechanisms created by Congress and realized in the ADA to achieve these policy goals appear to be well designed to reflect the civil rights model on which the statute is based.

The ADA sets out nondiscrimination mandates and requires that society adjust to accommodate individuals with disabilities in virtually every corner of society. Those principles touch on many aspects of public life, but where they function most prominently and controversially is in the area of employment.

The ADA's treatment of employment is indicative of the structure of the ADA as a whole and can be seen as an example of how the ADA implements the civil rights model. This title sets out a general prohibition of discrimination in employment: "No covered entity shall discriminate against a qualified individual with a disability because of the disability of such individual in regard to job application procedures, the hiring, advancement, or discharge of employees, employee compensation, job training, and other terms, conditions, and privileges of employment." And the statute goes on to realize that goal by requiring "reasonable accommodation" by employers. The concept of reasonable accommodation mandates that an employer make changes to its work environment to accommodate a qualified candidate with a disability so long as the alterations would not be unduly burdensome to the business as a whole.

This legal structure flows logically from the civil rights model. According to the model, individuals with disabilities, like certain other groups, have been suppressed by long-standing, built-in societal discrimination. For them to become equal members of society, this discrimination must be extirpated. The ADA tackles this policy imperative by prohibiting discrimination based on disability. In seeking to cure the condition that the civil rights model posits as the root cause of the marginalization of people with disabilities, the act demonstrates its commitment to this perspective.

Arguably, the civil rights model only forbids discrimination between equally qualified people on the basis of irrelevant factors. To that extent, a "passive" ADA might be acceptable and avoid problems of distributive justice among people applying for the same job. It would also be wholly ineffectual. People with disabilities may have the same capabilities as nondisabled individuals, but they face a two-pronged challenge. Not only are there biased attitudes toward individuals with disabilities, but society has been constructed in a way that physical impediments also stand in the way of full participation. Thus, to achieve a level playing field, as called for by the civil rights model, disability policy must not only outlaw discrimination, but it must also address the physical obstacles. The reasonable accommodation principle is a response to these physical impediments.

The act thus goes further than typical civil rights legislation in that it requires employers to accommodate applicants with disabilities. While most legislation designed to protect a group from discrimination mandates that the regulated individuals or entities simply *not* discriminate, the ADA requires an affirmative duty on the part of society, and in the context of employment, private employers. This accommodation mandate, however, is not a departure from the civil rights model, but rather a logical extension of it.

By requiring that the workplace be physically reconfigured or a job assignment be altered (so as to make a barrier irrelevant) to create a work environment hospitable to a qualified individual with a disability, the accommodation mandate removes barriers to equality. Thus, the reasonable accommodation mandate, when coupled with the nondiscrimination principle, seeks to create the equality envisioned by the civil rights model.

In sum, the themes of nondiscrimination and accommodation that run through the employment provisions of the ADA, as well as the text of the document as a whole, implement the civil rights model of disability policy. Having solved the theoretical problem, however, people have begun to face the practical one: Does the structure of the ADA, particularly in the employment context, represent a fair and cost-effective outcome?

LAW AND ECONOMICS PERSPECTIVE

The ADA's treatment of employment has been the subject of examination. The prohibition against disability discrimination, as well as the requirement of reasonable accommodation, put much of the responsibility of integrating people with disabilities into the workplace on private employers. Commentators have questioned whether this is an equitable and efficient means of allocating the cost of a societal good.

Concerns about distributive justice arise with respect to the ADA because it burdens certain segments of society while benefiting others. Compelled to bear some of the burden of the employment sections of the ADA are nondisabled job applicants and employers. Nondisabled job seekers are now forced to share the employment market with qualified individuals with disabilities. Although it is true that this does impose a cost on this portion of society, it seems minimal (and inherently fair).

Whether employers are suffering net costs at the hands of the ADA, however, is a closer question. Businesses seek to make a profit. To do so, they presumably strive to operate in the most efficient manner possible. Legislation affecting private companies can either help or hinder this effort. Much analysis has gone into what effect the ADA's antidiscrimination and reasonable accommodation mandates have had in this regard.

One can make a compelling argument that the antidiscrimination principle of the ADA improves the efficiency of private employers. Historically, antidiscrimination law in the United States has aimed at ensuring that a person who fits a particular job is able to obtain that job, despite irrelevant personal features: A person's skin color, gender, sexual orientation, or religion generally have little bearing on the match between the person's skills and a particular job. By forcing employers to ignore these irrelevant criteria, civil rights policies should enable the employer to build a workforce better able to perform the required tasks, thereby increasing the employer's efficiency.

The antidiscrimination principle of the ADA is in line with these laws; it performs the same filtering function that traditional antidiscrimination law performs by removing misleading signals from the employers' information mix. An employer will no longer be able to ignore a qualified individual simply because of his or her disability. Thus, there is a plausible argument that the ADA's embodiment of the antidiscrimination principle should increase efficiency.

It is much harder—though not impossible—to show that the reasonable accommodation mandate inures to the economic benefit of the private employers required to implement it. The explicit command that employers accept the burden of paying for accommodations—up to the undue hardship ceiling—sets the ADA apart from other civil rights legislation and, in turn, has created significant theoretical disputes.

The Rehabilitation Act of 1973 imposed reasonable accommodation duties on the government and government contractors; the ADA extends those duties to private employers. The theory supporting the former does not necessarily justify the latter. Although the government may have aims beyond strictly maximizing its output, such as providing employment to those who might not otherwise find it, a private entity's overriding goal is to maximize its profits. And to reach that goal, it seeks to operate in the most efficient manner possible.

It is not yet definitively established what positive impact reasonable accommodation has had on this effort. One must first look at the practical costs to an employer of accommodation. Research has suggested that many people with disabilities require no accommodation, and of those who require accommodation, the cost is usually *de minimis*. For example, a study of workers with disabilities for the U.S. Department of Labor found that only 22 percent of employees with disabilities received some form of accommodation. Of those accommodations, roughly one-half cost nothing, and of the other one-half, more than two-thirds cost less than $100. Thus, at least according to this study, the reasonable accommodation requirement often imposes little or no actual costs on an employer.

Moreover, accommodation is required only when it is not unduly burdensome. Practically, therefore, it is only in the circumstance where a substantial, but not overly burdensome, accommodation is mandated that concerns about efficiency arise. And even in this circumstance, the costs to the employer are mitigated by a variety of tax incentives. There are several tax provisions set out in the Internal Revenue Code available to businesses to foster ADA implementation and compliance: a "disabled access credit" available for small business, a tax deduction available to any business when improving accessibility for customers and employees with disabilities, and a tax credit available to any employer for a percentage of the first- and second-year wages of a newly hired employee with a disability. Beyond this, there are state tax code provisions applicable to small businesses to foster the hiring and retention of employees with disabilities.

Even with these tax incentives, some (usually large) employers may at times be forced to endure significant direct costs under the reasonable accommodation requirement. Those costs must be compared against the benefits that inure to an employer from accommodation and hiring of an employee with a disability to determine whether accommodation increases a business's efficiency.

At first blush, reasonable accommodation may appear inefficient for an individual employer. Theorists posit two applicants with identical skills, one with a disability and one without. It would be inefficient for the employer to hire the applicant with a disability and pay for accommodation, when the employer could hire the applicant without the disability and not be forced to bear those costs.

Though this is a persuasive theory, it has been countered by scholars who contend that reasonable accommodations are efficient in many contexts because they carry hidden benefits. For example, studies support the proposition that employees with disabilities as a group tend to be more efficient workers in that they tend to have lower turnover, less absenteeism, and lower accident risks. Thus, the cost of accommodation may be offset by workplace attributes that individuals with disabilities tend to possess.

Moreover, certain accommodations may be efficient in that they improve the productivity of other employees without disabilities. For example, ramps and elevators assist workers with rolling carts, and accommodations involving technology improve productivity and workplace safety for all workers.

Finally, making reasonable accommodations may be efficient in that it reinforces what would otherwise be an economically rational decision. A certain individual may possess such unique abilities that the cost of altering the workplace may be more than offset by the increased profits realized by having the person contribute to the business venture. In this scenario, the cost of accommodation would be less than the increased efficiency realized by hiring this specific employee.

Whatever the reason, research indicates that accommodations often are a profitable undertaking. One study found that for every dollar invested in an effective accommodation, companies realized an average of $50 in benefits.

Even ignoring these micro findings, reasonable accommodation may work at the macro level by increasing the efficiency of society as a whole. This is because the costs of providing accommodations may be offset by the gains realized by greater employment of individuals with disabilities. According to this theory, government benefits paid to people with disabilities will decrease because fewer individuals with disabilities will be in need of government support. In addition, the more individuals employed, the more the government collects in the form of income taxes. In other words, it may be efficient to have individual employers "run" this social welfare program, so that even if there are net costs, they are smaller than if the government ran the program.

All of this is not to say that the federal government plays no role in the employment context. In fact, aside from the tax incentives mentioned above, legislation has been recently enacted that is designed to help individuals with disabilities transition into the newly opened work environment. In the Ticket to Work and Work Incentives Improvement Act (TWWIIA), Congress sought to remove two of the barriers that stand in the path of individuals with disabilities seeking employment: potential lack of health care coverage once employed, and lack of training for and access to certain jobs.

Individuals with disabilities have traditionally faced a severe disincentive to entering the workforce in that employment income would disqualify them from Medicaid and other benefits under the Social Security Disability Insurance program (SSDI) and the Supplemental Security Income program (SSI), which have been available to individuals who could not engage in "substantial gainful activity." Thus, once individuals with disabilities gained employment, they could lose government-provided health benefits. Yet their new jobs often did not provide insurance and did not pay enough for individual coverage. And, even when insurance was available or affordable, many individuals were denied coverage because of their disabilities. This led to a situation where, among working Americans with disabilities, almost one in five had no health insurance.

TWWIIA addresses these issues by allowing states to permit qualified individuals with disabilities to purchase Medicaid health insurance after entry into the workplace even though their income may be above the poverty level. In addition, TWWIIA has provisions that address the potential loss of health benefits by those returning to work after a disabling injury.

Moreover, the lack of skills training and access to job sites often makes finding employment especially difficult for individuals with disabilities. To address this issue, TWWIIA's Ticket to Work and Work Self-Sufficiency Program provides recipients of disability insurance with a "ticket" to purchase employment training services from qualified Employment Networks (ENs). ENs are public or private entities that provide services such as workplace accommodations, peer mentoring, job training, and transportation assistance to ticket participants seeking employment.

TWWIIA and the ENs work in conjunction with broader welfare-to-work transition programs such as the Workforce Investment Act (WIA) and the

Temporary Assistance for Needy Families Programs (TANF), which provide incentives and training to help low-income individuals (including those with disabilities) find employment. The ADA requires that services provided by ENs or through the WIA or TANF be accessible to those with disabilities. Thus, TWWIIA, working alongside the ADA, has created a situation whereby individuals with disabilities are now able to access a range of job-related services to help them find and retain employment.

Such policies demonstrate America's commitment to integrating people with disabilities into the workforce. However, the costs of these programs need to be considered when determining whether the ADA's employment construct is efficient for society as a whole. This is especially relevant since some economists have questioned whether the ADA creates a net increase in employment. It has been argued that the accommodation requirement, because it hypothetically increases an employer's hiring costs, may lead to less overall employment, and thus *less* employment of people with disabilities. If indeed fewer individuals with disabilities are employed, this would defeat the argument that accommodation helps to relieve the social welfare system.

Whichever way one evaluates the efficiency argument, it is important to note that the efficiency of the program was not an overriding consideration at the time of the ADA's adoption. The ADA as a whole, and the accommodation requirement in particular, represented a national policy that costs and economic efficiency are dispensable (within limits) if more people with disabilities are employed. As explored below, it is a subject of debate whether the ADA has accomplished this goal, and conclusions are influenced by how one defines disability for purposes of the law.

IMPACT OF U.S. DISABILITY LAW

People with disabilities have been employed at substantially lower rates than people without disabilities, although the rates tended to fluctuate with overall economic conditions. The ADA was aimed at this employment gap. It came into effect for most private businesses in 1992, but as early as 1996 some commentators suggested a deterioration in the employment situation of individuals with disabilities in relation to other groups.

The period following the enactment of the ADA has been one of rapid changes in the economic structure of the United States. Manufacturing sector jobs have declined in favor of service industry jobs; job mobility has increased; and the economy has seen an upsurge and, at the end of the decade, a substantial retrenchment. In the face of those large-scale changes in the economy, researchers have attempted to determine the impact of the ADA on the employment of people with disabilities. The studies, several of which are discussed below, have yielded contrary interpretations of employment trends among people with disabilities.

One recent study attempted to trace the employment of individuals with disabilities over time using national survey data. People were identified as having a disability if they answered the following question in the affirmative: "Do you have a health problem or disability which prevents you from working or which limits the kind and amount of work you can do?" The study attempted to evaluate the ADA's impact by looking at the change in the number of weeks worked and the average weekly earnings of this group over the course of the 1990s. Based on this analysis, the authors argue that the ADA had a negative causal impact on the number of weeks worked by individuals with disabilities and had no impact on the wages of those individuals.

Other studies with similar survey data have suggested similar results, even while employing a different methodology. In one study, the authors examined the impact of the ADA on three groups of U.S. states: (1) states that, prior to the ADA, had no disability discrimination law; (2) states that, prior to the ADA, had only a "traditional" disability discrimination law—one that prevented discrimination on the basis of disability (nonaccommodation states); and (3) states that had an ADA-like statute—one that prohibited discrimination and also required reasonable accommodations (accommodation states). The authors theorized that by comparing results among the states grouped in this manner, one could better isolate the effects of the ADA, and the accommodation requirement in particular.

The authors found that for this sample the employment of people with disabilities declined. Moreover, when comparing the decrease in employment between the non-accommodation states and the accommodation states, the study found that the decrease in employment was more severe in the former group. The finding that states that had no accommodation requirement saw a decline that surpassed the states that already had an accommodation statute suggests that this mandate was the component of the ADA that was largely responsible for the employment decline.

Thus, some studies suggest that the ADA, and the accommodation provisions in particular, have a *negative* impact on the employment of people with disabilities. But other authors question the methodologies used by previous scholars, and in particular their failure to focus on people the act was designed to help—*qualified* people with disabilities—rather than all people who answered yes to the broad question: "Do you have a health problem or disability which prevents you from working or which limits the kind and amount of work you can do?"

Studies that have sampled individuals the ADA more likely covers have reached more encouraging results. When focusing on the ADA target group (i.e., those individuals who are not work limited but are functionally limited), one study found an increase in employment rates. Another study, examining a population of "disabled" individuals drawn from a Social Security Administration survey, found that the ADA had a positive impact on certain people with disabilities, although it may have had a negative impact on those people with disabilities who were not already, at the time the ADA became effective, participating in the labor market.

Authors of those later studies identify aspects of prior studies that may have skewed their results. For example, reports finding that the ADA had a negative impact may have underreported the positive influence of the ADA because, if more people with disabilities have jobs, fewer may view themselves—and report themselves—as having disabilities that limit their ability to work. Thus, the number of employed people with disabilities would not accurately be reflected.

While the studies may have underreported the number of employees with disabilities, at the same time, they may have inflated the number of individuals with disabilities who are unemployed. Increasingly stringent welfare requirements coupled with more generous federal disability laws create incentives for unemployed individuals to classify themselves as having disabilities. This effect may have caused certain individuals to exaggerate their disabilities, which would in turn inflate the number of unemployed labeled as having disabilities, possibly rendering research findings inaccurate.

It is evident that, even a decade after the ADA's enactment, the results of its employment provisions remain unclear. Some studies find that the statute has led to diminished employment. But those findings may result from limited methodologies and data sets that fail fully to account for the inherent problems with the definition of disability and the measurement of that population.

Nevertheless, even if one discounts research that suggests a negative impact on employment, the studies, when looked at as a whole, indicate that the ADA is serving its antidiscrimination and integration mandates, albeit perhaps as not in regard to large numbers of people with disabilities. Given that the ADA came into being during a time of economic prosperity, it will be important to track its results in the slow growth period that has defined the recent economy.

Broadly, the ADA raises the policy issue of the proper scope of such antidiscrimination laws as applied to private entities—necessarily enforced by private litigation—to bring people with disabilities into the mainstream. Would employment rates improve significantly if the initial costs of accommodation were shared among employers, persons with disabilities, and the government? And, at what point would a system including greater government support create an unwieldy bureaucracy?

These broad questions, concerning the proper mix of public and private endeavors, color the debate with respect to the public accommodation provisions of the act as well. And though the answers are not clear yet, it is the passage of the ADA that has allowed us to begin to ask those important questions.

DISABILITY PRIDE

Disability pride represents a rejection of the notion that our physical, sensory, mental, and cognitive differences from the nondisabled standard are wrong or bad in any way and is a statement of our self-acceptance, dignity, and pride. It is a public expression of our belief that our disabilities are a natural part of human diversity, a celebration of our heritage and culture, and a validation of our experience. Disability pride is an integral part of movement building and a direct challenge to systemic ableism and stigmatizing definitions of disability. It is a militant act of self-definition, a purposive valuing of that which is socially devalued, and an attempt to untangle ourselves from the complex matrix of negative beliefs, attitudes, and feelings that grow from the dominant group's assumption that there is something inherently wrong with our disabilities and identity.

Dr. Martin Luther King Jr. (1967) once wrote,

> One must not overlook the positive value in calling the Negro to a new sense of manhood, to a deep feeling of racial pride and to an audacious appreciation of his heritage. The Negro must be grasped by a new realization of his dignity and worth. He must stand up amid a system that still oppresses him and develop an unassailable and majestic sense of his own value. He must no longer be ashamed of being black.

Although there are many barriers facing people with disabilities today, one of the single greatest obstacles we face as a community is our own sense of inferiority, internalized oppression, and shame. The sense of shame associated with having a disability has, indeed, reached epidemic proportions. Disability rights movements in different countries have made many gains in the area of civil rights over the past decade, but what good is an Americans with Disabilities Act or a Disability Discrimination Act if people will not exercise their rights under these laws because they are too ashamed to identify as being disabled? "As long as the mind is enslaved," King wrote, "the body can never be free." As long as people with disabilities remain ashamed of who we are, we will never realize the true equality and freedom we so desire. We must first take pride in ourselves as a community. We must no longer be ashamed of being disabled.

Dismantling centuries of internalized oppression, however, and promoting a widespread sense of disability pride are easier said than done. Unlike other civil rights movements, people with disabilities do not always have the benefit of a generational transfer of disability history and pride through the family structure. There are no "disability churches" per se, neighborhood enclaves, or other communal institutions where people with disabilities can come together by choice and consistently receive positive messages that counteract the depredation wrought by the onslaught of cultural terrorism. There is a tremendous need to create a counterculture that teaches new values and beliefs and acknowledges the dignity and worth of *all* human beings. Disability pride is a direct response to this need.

DISABILITY RIGHTS EDUCATION AND DEFENSE FUND

The Disability Rights Education and Defense Fund (DREDF), with offices in Berkeley, California, and Washington, D.C., has been a leading cross-disability civil rights law and policy center since it was established in 1979. DREDF carries out its mission through training, legal assistance, advocacy, policy and legislative development, litigation, and research. DREDF is unique in the disability rights movement in the United States because it was founded and continues to be led by people with disabilities and parents of children with disabilities, and it achieves social change by organizing and training at the grassroots level, crafting and promoting legislation and policy, and defending those policies in the courts.

DREDF identifies economic and social disenfranchisement of people with disabilities as the result of prejudice and discrimination rather than as an inevitable consequence of the physical and mental limitations imposed by disability. This worldview closely aligned DREDF with other civil rights struggles, thus leading to an invitation in 1981 to join the executive committee of the nation's largest coalition of civil rights groups, the Leadership Conference on Civil Rights (LCCR).

DREDF plays a central role in articulating the principles of disability rights law and developing and disseminating strategies for groundbreaking disability civil rights legislation and litigation. DREDF is best known for advocating successfully for federal civil rights laws, representing members of Congress and leading disability organizations in amicus curiae briefs in cases argued before the U.S. Supreme Court, and national grassroots training and empowerment for thousands of parents of children with disabilities and adults with disabilities.

DREDF laid the groundwork for enactment of the landmark 1990 Americans with Disabilities Act (ADA) by preserving and advancing its predecessor law, Section 504 of the 1973 Rehabilitation Act when it came under attack by the Reagan administration and in the courts in the early 1980s. Similarly, DREDF organized to preserve regulations implementing the Education for All Handicapped Children Act. DREDF is also credited with playing leading roles in the passage of the ADA and other groundbreaking laws such as the Handicapped Children's Protection Act of 1986, the Civil Rights Restoration Act of 1987, and the IDEA Amendments Act of 1997.

In 1987, DREDF established the Disability Rights Clinical Legal Education Program and began teaching disability rights law at the University of California, Berkeley, Boalt Hall School of Law and supervising law students in the practice of law. DREDF litigation seeks not only to enforce existing laws but also to clarify and advance disability rights through the pursuit of law reform cases, such as by filing the first full-inclusion special education case that went to the U.S. Supreme Court, *Holland v. Sacramento City Unified School District* (1994).

Since 1990, DREDF has worked internationally in 17 countries with advocates who seek assistance in the development of law and policy reform strategies. Ongoing future challenges include restoring, sustaining, and preserving the ADA from further erosion in the courts, and meaningful enforcement of IDEA. As DREDF works in coalition with racial, economic, and environmental justice groups, future challenges will broaden the reach of DREDF's expertise to key areas such as equitable and accessible health care services.

DISABILITY STUDIES

DISABILITY STUDIES AND DISABILITY RIGHTS

Disability studies functions as the theoretical arm of disability rights movements. As an interdisciplinary field of study and scholarship, disability studies analyzes the meanings attributed to human corporeal, sensory, and cognitive differences. Participants examine the role that disability serves in expressive traditions, scientific research, and social science applications. They study the status of disabled persons, often by attending to exclusionary scholarly models and professional structures. Interestingly, a key aspect of disability studies has involved focusing on the privilege that accrues to nondisabled persons within built environments. Implicitly, then, researchers question the ethics of inbuilt social exclusions by tracing out their origins. As a result, they track down many historical "genealogies" of practices and attitudes concerning disabled persons.

In seeking to understand the variety of interpretations that make disability an evident facet of human diversity, the field includes many methodologies such as quantitative assessment, qualitative interpretation, critical analysis, and historical genealogies. Nonetheless, because disability studies marks a departure from fields of knowledge and professional training that may have sustained exclusionary practices and mandated social shame, participants in disability studies primarily engage in efforts to reevaluate the implications of traditional approaches to disability. New scholarship proposes research topics that allow disability perspectives to emerge. As a result, the experiences that infuse life with a disability are valued for insights that can be culled for innovative strategies to assist new generations of disabled persons. Such disability perspectives bring to the forefront of cultural commentary a body of insight previously marginalized within many universities during an era of scholarship in which eugenics ideas prevailed.

It should be emphasized that disability studies initiatives, research projects, and curricula have been developed worldwide, with formations primarily in global urban centers and wealthy nation-states. This entry, however, will be limited to the United States, and to an extent, Canada, the United Kingdom, and Australia. Disability studies takes place when groups of committed advocates, activists, and scholars pursue work locally to make the persistence of disability exclusions across a variety of regional and global contexts better understood, documented, and interpreted. Only very recently, during the last decade of the twentieth century, did disability studies begin to be more generally recognized as an area of academic inquiry, while the moniker "disability studies" came into usage during the1980s. The new term sought to differentiate its concern with the well-being of disabled persons from what one scholar has termed the "disability business." The disability business was perceived as a megalithic operation of management interests and government surveys that were frequently answerable to the goals of nondisabled persons at the expense of their disabled clients, family members, or neighbors.

At present, disability studies consists of a nascent, yet rapidly expanding scholarship that draws researchers from across a diversity of academic fields. Most universities have been inaccessible to disabled persons; as a consequence, scholars in disability studies observe the ways in which curricular ideas also suffer from this central exclusion, taking as a given that disability experiences offer a substantial vantage upon human existence. Because aspects of fields of study may reiterate the perpetuation of "able-ist" bias, disability studies can sometimes involve a rejection of habits, methods, and undertakings of universities in the past in their assumptions about bodies and capacities. Thus, disability studies also entails studying the myriad ways that traditional fields have been willing to study their topic from a distance without embracing the insights and critical perspectives of disabled persons concerning their own predicament. The distinction entails making claims for critical insights to be gained by partaking of disability-based experiences, knowledge, and lifestyles.

Disability studies scholars distinguish their undertaking as "new" in order to mark a distance from the viewpoint of modern eugenics that sought to "improve human stock." At the beginning of the twentieth century, such an enterprise targeted the eradication of disabilities from human populations. Not only are many events and public spaces of modern life organized by policies that effectively segregate persons with disabilities from a civic mainstream, but traditional responses to disabled persons, termed the "study of disability" as opposed to "disability studies," also see disabled persons as clients, informants, or research objects to be treated, managed, regulated, controlled, and investigated. So not only must social barriers to the inclusion of disabled persons be broken down, as disability rights proclaims, but the sources for misperceptions about disability experiences need to be redressed. These objectives require studies of discourse, and of the etiologies and histories of the definitions of pathology and aberration, in addition to study of the histories of the development of environments and communication modes that privilege some players and exclude others.

Universities, such as renowned Stanford University, whose first president David Starr Jordan promoted eugenics ideas about the obvious inferiority of disabled persons' lives and bodies, may not be perceived as immediately welcoming of disability perspectives. Recently, for example, Princeton University garnered international press coverage for hiring eugenics theorist Peter Singer. Singer argues not only that parents should decide whether disabled infants should be killed at birth but also that adult disabled persons have no evaluative criteria to contribute to a discussion over the value of a life lived by a disabled infant. Able-ist biases in top-flight universities, from their physical plant specifications to their presumptions about body qualifications, make them chilly places for disabled persons. Many note how ideas for gas chambers, first developed as a means to ease the difficulty for health practitioners in administering lethal injections, were developed within academic settings and with demonstration project methodologies. When Harriet McBryde Johnson, a disability rights lawyer and noted disability rights commentator, visited Princeton for a series of forums with Peter Singer, she reflected on the ethical conundrum such a visit provokes. On the way out, she thought about her "brothers and sisters," the 14 arrested protestors for Not Dead Yet, who "were here before me and behaved far more appropriately than I am doing." Johnson's statement recalls that of Virginia Woolf, who, when invited to speak at an Oxford college, still could not access the Bodleian Library to review a manuscript on the basis of her gender. "And I thought how it was better to be locked out than to be locked in," Woolf commented with a similar ambivalence.

Just as they were previously closed to the participation of women or as they discriminated against members of racial or ethnic groups, universities have not immediately embraced the influx of "out" disabled persons into their hallowed halls. As a result, many well-worn ideas and representational practices await critical reexamination with the supposition that patterns of interpretation likely uphold unrecognized investments concerning the inferiority of disabled persons. Research conducted to endorse ideas about eugenic segregation, the sterilization of those assessed as "feebleminded" or hereditarily deficient, or prevention of disabled persons on the premise of the social burden they present simply support oppressive disability ideologies of a previous, yet not quite antiquated, era. Old-school disability research may verify reasons that disabled persons should be excluded from public forums and civic roles. Furthermore, many technologies have been developed as means for containing unruly bodies and punishing the disruptions associated with bodies that "deviate" from the normal.

A key issue for disability studies, then, has been to determine the extent to which newer professionals who work within these frameworks can update disciplinary practices to make their research feasible for progressive disability goals. Similar questions had been asked about psychiatry, for example, after Holocaust genocide and medical experimentation implicated practitioners who had been schooled in the field and proceeded to generate from it violent medical interventions on disabled children and adults. Were premises in the field corrupting or did these perverse practices simply represent a complete aberration from mandated formats of investigation and hence only reflect violent impulses in the practitioners themselves? A similar revolutionary questioning guides disability studies as it surveys the current state of the university and interrogates fields such as behavioral and abnormal psychology for their routine support of evaluation practices designed to condemn disabled persons for their differences.

Scholarship in disability studies affords a unique and divergent vantage point from the paradigms that sustain traditional study, management, and interventions. For example, disability studies research would interview clients not to determine who would make the best fit for counseling or special education services, but to find the unique worldview that disabled persons have imbibed as a result of their marginalized social predicament. Those who endure demeaning cultural practices can often best assess the sources and mechanisms of their operation.

Following the advent of disability studies in the 1980s, many academic approaches toward disability were routinely put to the side as simply too "medical" in nature. What the first generation of scholars meant by this criticism of a "medical model" was that the research upheld an exclusively interventionist and individualized approach to disabled bodies. All insufficiency appeared localized within the dysfunctional body itself. A medical model approach proceeds on the assumption that the only valuable knowledge concerning disabilities would need to be directed toward curing, concealing, or fixing bodies so that individuals could be made to "pass" as normal. For a first generation of disability studies scholars, cure approaches reinforced social ideas that impaired bodies should be rejected. At the very least, these scholars focus on social barriers that disabled persons face and leave aside fields that pay attention to the repair of impaired bodies.

Importantly, the limitations of a medical model that early disability studies references may itself have little relation to actual practitioners of medicine. Instead, concepts of a "medical model" refer to the social premise, frequently held outside of medicine, that disability requires referral to the purview of medical practitioners. Several disability studies scholars have shown how factions of physicians in the American Medical Association initially resisted the idea that insurance decisions should be assigned to clinical assessments. Nonetheless, legislatures in Germany and the United States, for instance, decided that physicians would function as the gatekeepers for disability verification. They thus inaugurated a class of medical authorizers to diagnose and certify the validity of all disability claims. This professional gate-keeping, the practice of which often divides disabled people from the services they need, has become one of the foremost obstacles addressed by disability studies today—particularly in countries that lack universal health care systems such as the United States.

This system of evaluation requires disabled persons to endlessly submit to professional gazing to qualify for social supports. But the enforcers of this policy, that is now a habit of thought in many Western countries, may trickle down to the shoe store clerk who will not sell a shoe to a person with lower-limb muscle spasticity prior to obtaining a doctor's note. In an increasingly bureaucratized social state, the medical model has left disabled persons frequently vulnerable to the whims of general practitioners in spite of the fact that such professionals may have little knowledge about the condition in question. Consequently, one often finds practitioners invested with the power to assess patients for the purpose of qualifying for benefits, supports, and general consumer services such as airline travel or equipment.

In contrast, a rights era of disability studies endorses a cross-disability and nonspecialized approach to meaningful inclusion for disabled persons. Subsequently, as this entry observes, disability studies will ask for the modification of practices that are premised on privileging some bodies and excluding others.

Prior to the rights-based disability platform of the 1960s, a focus on disability in society entailed advocating for charitable contribution and safekeeping for persons with particular kinds—even "brand names"—of disabilities. For instance, mid-nineteenth-century institutions governed their populations so that they housed only the least severe. This ensured patient success and further supported ideas behind the rejuvenating mission of cures in benevolent nature. A return to the community for each institutionalized individual formed a key objective. More difficult disabilities were left to the family where they sometimes received local support in the form of outdoor relief or made up a large percentage of those housed in indoor relief efforts such as almshouses. A widely accepted international theory of disability at this time, established by the French educator Eduoard Séguin, argued that those diagnosed as idiots suffered from a weak will. Training schools sought to correct this insufficiency—or at least ameliorate it—by subjecting disabled individuals within their charge to extensive rituals of personal hygiene tasks of rote repetition. Patients found themselves locked into an inflexible regimen of care and engaging in tasks that demanded concentration for extended periods of time. In cultivating such habits, training institutions aimed to improve a "defective" internal landscape by targeting the external body as a site of personal management.

From the 1920s onward, rehabilitation era disability professionals emphasized the acquisition of personal adjustments and skills that could enable a disabled person to survive in a society that was not built to accommodate them. In the United States, France, and Germany, for example, special schools that aimed to "salvage" human beings by educating the physically weak emerged in urban centers. These schools for "crippled children" pre-date legislation for disabled children that provides rights for a free and appropriate formal education (prior to 1974, 80 percent of disabled children did not have access to a formal education). Federal mandates in the United States continue to update this effort at social inclusion and the necessity of public education for schoolchildren with differing bodies, minds, and emotional habits alongside all others in a "least restrictive" environment.

In the 1920s, evolving from hospital schools, and offering an alternative to segregated warehousing, special schools for children with physical disabilities offered a curriculum that included rehabilitation services; in-house dentistry; occupational, physical, and speech therapies; Franklin Delano Roosevelt (FDR) era swimming pools; and a variety of wheeled transport and home-styled modification devices—all within the confines of a one-stop educational facility. Special schools explained their mission as a matter of "salvaging" the educable from the disability mix that had simply been consigned to training schools and workshop labor under the expansive eugenics era category of "feebleminded."

In this mold, special schools accompany the expansion and professional credentialing enterprise of other helping industries, in addition to nursing. Participants at schools for handicapped children also underwent continual assessments in specialized quadrants of the schools, for example, physical, emotional, dental, personal hygiene, and small and large motor control. But like rehabilitation medicine itself, special schools also sought distance from medical environments and fix-it approaches to disability. They too critiqued a "medical" approach in favor of education and rehabilitation. It is important to differentiate the agonistic distancing of professional service industries from medical approaches and the medical model critiques of disability studies. Unlike professionals who advocate for rehabilitation as a solution to a problem presented by disabled persons, disability studies represents the social and material predicament of disabled persons as a matter of inclusion, recognition, and social change. Furthermore, disability attends to the environmental resistance to inclusion—attitudes and the enforcement of normative expectations upon bodies—as opposed to individual adjustments.

Disability studies, uniquely, must put the status and experience of disabled persons prior to its own success as a professional operation. Thus, whereas rehabilitation and a rehabilitation movement could oppose disability rights in favor of principles of intervention, service, and care, disability studies aims to place the perspectives of the objects of scrutiny and remediation front and center to its concerns. One is reminded that even in the closing of the most inhumane institutions, a variety of interests will come forth to oppose such efforts: Care worker unions will protest out of a desire to keep their jobs in a specialized field; family members will often ally themselves with care workers and claim that the work of keeping a disabled person at home lacks sufficient social supports to be feasible; local businesses catering to institutional living complain that their economic livelihood will be undermined; nearby neighborhoods will resist under the argument that "freeing the inmates" poses threats to everyone's well-being. Yet disabled persons themselves, on the verge of emancipation, offer up ambivalent and less certain opinions. Few yearn to keep institutions open in that they represent sites of state-sponsored incarceration, but neither does it seem appropriate to look forward to life where one may be viewed as a persistent burden, economic drain, and social misfit. Scholars in disability studies seek to expand on the limited choices offered to disabled persons to live meaningful lives by redressing the social constraints that continue to underwrite such hostile public beliefs. Rather than individual insufficiency, disability studies aims its critique at the material social conditions—such as poverty, unemployment, and disability insurance restrictions on wage earning—that produce abject dependency.

Historically, populations of dependents have found themselves concentrated in poor houses, workshops, and almshouses with others who cannot effectively sell their labor in a competitive market rife with prejudice toward functional and aesthetic differences. One function of this lumping of the unemployable was the development of large bin categories of disabilities; such classification strategies emerged in the mid-twentieth century—an era dominated by rehabilitation and charity model approaches. Bin categories include "muscular dystrophy," a label that represents more than 37 manifestly different etiologies of neuromuscular disorders, or "cerebral palsy," a general term for hugely divergent muscular rigidities. Etiological clusters, such as paralyzed veterans or people with epilepsy, receive attention and management from agencies designed to attend to their lesser social opportunities. Thus, children with vision impairments might be sent to a blind school to acquire different skills such as Braille along with white cane techniques or canine companion assistance. Deaf children might be channeled to a deaf school where they acquire sign language or vocalization skills in the press to access regular educational curriculum. Multiply disabled children, those who have been projected to be low achieving by means of newly minted evaluation tools such as intelligence tests, and ranging from those termed "retarded" to those negotiating cultural barriers or nonstandard literacy, undergo institutional referral and placement throughout the twentieth century. A substantial number of infants and children with all kinds of disabilities continue to be abandoned and placed as "wards of the state." Individuals located within such sweeping categorizations represent not only disabled people, but rather the fallout from modern standardization practices that prove inflexible and unduly narrow when it comes to the rote expectations of all bodies within capitalism.

While pointing out the permeability of these categories of human differences, disability studies reassesses the historical solutions that have been arrived at in terms of placement, tracking, and a deterministic foreclosure on social possibilities. Yet the advent of the field has also been theorized as developing from experiences that issue from clustering together kinds of bodies that share designations of deviance. Collectivities can better foment collective action for improved social situations. Strongholds for initiatives in disability rights have come from collectivities of individuals who may have endured segregation at one time and now resist oppressive protocols. In other words, disability studies is also linked in history to the predominance of kinds of disabled living and the social opportunities afforded to highly particular groups. These include veterans groups, who sometimes claimed exclusive rights to remediation services but also precipitated the development of technologies such as power wheelchairs and curb cuts that benefited others. Not only did a post-polio president, FDR, seek to include disabled citizens as beneficiaries of services for disabled veterans, but in the late 1940s, disabled Canadian veteran John Counsell formed the Canadian Paraplegic Association, an advocacy group that demanded the supply of accessible cars outfitted with hand controls to all who could use them. Furthermore, in the 1960s "person first" advocates sought to upgrade social awareness by interrogating the linguistic implications of referring to persons with disabilities as handicapped, crippled, or disabled. In Britain during the early 1970s, the Union of the Physically Impaired Against Segregation (UPIAS) was formed as a coalition among those who had fought to escape confinement in nursing homes. The members of this organization may have been the first to formulate what would come to be recognized as the "social model of disability": one that viewed impediments as the product of social rather individual liabilities. UPIAS (1974/1975) put forth mandates about the social nature of disability experience that merit repeating:

> In our view, it is society which disables physically impaired people. Disability is something imposed on top of our impairments, by the way we are unnecessarily isolated and excluded from full participation in society. Disabled people are therefore an oppressed group in society. It follows from this analysis that having low incomes, for example, is only one aspect of our oppression. It is a consequence of our isolation and segregation, in every area of life, such as education, work, mobility, and housing.

Likewise, the 1990s saw the rise of disability groups comprised of former poster children who critiqued the proliferation of telethons for those with muscular dystrophy and other disabilities and tendering the exhibition of disabled bodies as pity-ridden social capital for raising research and cure funding.

These efforts all paralleled various other civil rights agendas seeking to redress the invisibility experienced by devalued lives. Such movements shared a key strategy: to place distance between their own bodies and the belief that lack of success could be attributed to biologically located deficiencies.

INSTITUTIONALIZING DISABILITY STUDIES

As further evidence of political piggy-backing by various civil rights agendas, one witnesses a surge of interest in disability studies research and scholarship immediately following the passage of legislative initiatives such as the Americans with Disabilities Act in 1990 in the United States. As a result of this legislation and that which came before it (Section 504 of the Rehabilitation Act in the 1970s), a new generation of disabled students made their way to universities. Yet, despite the implementation of policies, codes, and mandates for inclusion, college students with disabilities often found themselves involved in highly individual struggles with able-ist barriers in the pursuit of their own education. After all, laws may exist but that does not mean that institutions and professions comprehend the barriers that their own fields of operation have put into play. This generation, the inheritors of legislation and ideas about the social nature of disability, committed itself to bringing the insights gleaned from struggles for disability rights into every avenue of social organization and thought. As many in disability studies have put it: "If disability studies didn't come along I would have had to invent it."

Put quite simply, many younger disabled persons became attuned to the fact that disability studies offered them further grounds for social theorizing and policy action toward their own predicaments. Disability studies affords students with disabilities a basis for asserting the right to accessible classrooms, libraries, and laboratories that had previously seemed off-limits due to prohibitive scheduling, inaccessible locations, and discriminatory attitudes. This post-ADA generation of students with disabilities forced opportunities for advocacy regarding obstacles that many took for granted as inevitable barriers. Suddenly, excessive work hours, timed tests, small print, fluorescent lights, inadequate table heights, flights of stairs to stages for ceremonies, and expectations about presentable appearance appeared as unnecessary barriers that by design excluded many disabled persons.

In addition, disability studies allows students and researchers to examine the buried able-ist exclusions that inform research premises. The research that has ensued tackles issues such as objectivity in nondisabled research perspectives and pathologizing ideas about human variation that sometimes inform premises. For example, disability perspectives require us to rethink assumptions that a bus with high stairs represents a democratic and publicly available mass transit objective accomplished. Deaf studies, likewise, asks us to rethink assumptions about oral eloquence and the aesthetics of sound that condition so many of our daily encounters. And in a basic way, disability studies demands reconsideration of dubious general public educational requirements such as the expectation that children will be able to hop on one foot as a mandated qualification to graduate from kindergarten. Just as universal design asked that we think about the ways architectural exclusions get inserted into a built environment, so disability studies asks us to analyze the assumptions about normalcy that go into validating educational, business, and civic practices. The field of disability studies seeks to expose the ways that naturalized exclusions have seeped into every cranny of modern social life.

Nearly 100 disability studies courses are currently offered at colleges and universities, while many curricular and research plans continue apace. Universities offer degrees, concentrations, minors, or simply courses of study in disability studies. Examples include Canadian programs in disability studies at Ryerson University; a master of arts degree in Critical Disability Studies at York University; a concentration in disability studies for a master's or PhD in the Cultural Foundations of Education program at Syracuse University; undergraduate and interdisciplinary minors in disability studies at universities that include Ohio State University in Columbus, Ohio, and the University of California, Berkeley; and an interdisciplinary PhD in disability studies at the University of Illinois at Chicago.

In addition, a web search currently yielded more than 50 affiliated programs, centers, clusters, and research institutes at universities. University-affiliated centers crisscross the globe from the Centre for Developmental Disability Studies at the University of Sydney in New South Wales to the Program in Disability Studies at Rutgers University where coursework has been revised so as to include the topic of disability geography. As mentioned earlier, the Centre for Disability Studies at the University of Leeds has been principal in setting the agenda and commitments of disability studies globally by publishing a journal in disability studies and establishing a research track to accompany degrees at all levels. Faculty at Leeds assist in publishing the international journal *Disability & Society* and pilot the list serve on disability research known simply as "the UK Listserv" by international participants. In addition, the Center on Disability Studies at the University of Hawaii emphasizes cultural approaches to disability and maintains commitments to working with disability coalitions in the Pacific Rim. Organizers recently launched an online periodical titled the *Review of Disability Studies: An International Journal.* And the Centre for Research into Disability and Society in New South Wales offers PhD scholarships to enroll at Curtin University while Temple University has launched courses and a graduate certificate program in disability studies proper.

In the United States, disability studies originates with the formation of the Society for the Study of Chronic Illness and Disability in the early 1980s. Chair of the Sociology Department at Brandeis University, Irving K. Zola, began distributing a newsletter from his office that collected together and advertised new initiatives on behalf of disability as a social experience. The photocopied newsletter publication contained a letters column, featured book reviews, and opinion columns. Significantly, early issues feature Zola's review of Erving Goffman's *Stigma: Notes on the Management of Spoiled Identity* and thus inaugurated a discussion of the disability coordinates of self-perception and social interaction that continues to fuel one aspect of the field. Zola, and his family and colleague's newsletter, which gained library subscriptions and an international mailing list, eventually grew into the current online academic journal *Disability Studies Quarterly.*

In 1986, at the urging of its membership, and as the push for an Americans with Disabilities Act gained momentum, the Society for the Study of Chronic Illness, Impairment, and Disability (SCIID) changed its name to the Society for Disability Studies (SDS). Other methodological models also developed alongside the strict social model advanced by UPIAS. For instance, at this time and prior to the ADA, Harlan Hahn pioneered a minority group model of disability contending that disabled people represented a distinct minority. The effort to study and analyze disability as culture, one that gives impetus to unique institutions, art, and perspectives, arose from the minority model. In the United States, the claims of Deaf studies to emerge from a unique heritage and to constitute a linguistic minority influence the claims made on behalf of disability culture, crip culture, or simply subcultures. Pioneering studies of predominantly deaf communities in disparate locations such as Martha's Vineyard and Varna had shown the cultural variability of signed languages and regional differences in expectations about normalcy and self-expression. Deaf communal forms such as sign language, deaf poetry performance, and investments in the merits of segregated deaf communities all influence disability studies but conflict with many precepts. These surround questions of disability hierarchies, language facility, and discriminatory ideas about self-expression whether spoken or signed. Nonetheless, many counterdiscourses interrogate the premises of a dominant "normal" culture through the examination of developed subcultures, many geographically isolated or disenfranchised as pockets within urban spaces.

Increasingly, disability studies has found itself needing to emphasize diversity as a key factor in the social desirability of having disabled persons represented at universities and across educational forums. The emphasis on disability as a diversity category emerges from research efforts to find commonality in variation without losing the divergent vantage points that such conditions afford. Disability studies scholars have contended that just as race, gender, and sexual preference can be demonstrated as either neutral difference or as productive characteristics as opposed to tragic implications, disability itself comprises a form of embodiment artificially constructed as flawed. Yet alliances between multicultural agendas and disability studies efforts to include disability as part of human diversity education have been slow in coming. For instance, one initiative to allow disability to fulfill the multiculturalism requirement at Hunter College met with fierce opposition from race and gender scholars. Multiculturalism is beset by its own able-ist premises in having exceptionally high-achieving exemplars of one's ethnic or native traditions serve as singular justifications for cultural equality. Perhaps disability studies might inevitably discover that diversity as exemplified by multiculturalism can arrive with very narrow ideas about bodies in tow. Yet, at the same time, many scholars in these fields have embraced disability as a deepening of multicultural pedagogies.

As a new area of scholarship that has thus far resulted in a wealth of publications and collaborative projects, as opposed to university posts, disability studies bears much in common with other "identity" fields such as queer studies and gender studies. These fields of scholarly endeavor also feature an incredible output in scholarship and quality of thought while having received less in the way of material recognition such as degree-granting programs or funded faculty lines. The older industries of a "disability business" still largely hold the purse strings to disability undertakings. And these industries have been built up by means of a "charity model" that likely depicts disabled persons as incompetent and needy—a representation that is anathema to disability rights, which points out that the predicament of validating disabled persons as the "deserving poor" reinforces the idea of a natural state of unemployment and dependency for all disabled persons. Concepts of a charity model run deep. Ironically, practitioners of disability studies have been accused of "biting the hand that feeds them"—a criticism that upholds the idea of disabled persons as parasitic and ungrateful by comparison to the common lot of human beings.

In addition to curricular innovations, many access and accommodations offices have sprung up to manage new generations of disabled students who anticipate accommodation, as opposed to exclusion, from educational settings. These offices sometimes support a disability cultural mission and/or active disability support networks. Staff for disability offices may lack the authority that comes from having gained knowledge through a standard credentialing mechanism, such as that offered by special education or communication disorders under the auspices of a previous "disability business." A field offers credentials in an education that guarantees training in requisite areas and study in a centralized knowledge base. Access and disability awareness may be subsumed as components of occupational therapy or policy studies. Only disability studies forces a convergence of the historical study of social management, human rights categories, and access strategies as a matter of group survival—a mosaic approach that recognizes these aspects as mutually supportive and inevitably interwoven. At present, resident disability experts on campuses often represent homegrown and creative talent. Offices are staffed by individuals who share expertise in areas ranging from a judicial history of the ADA to experience in disability sports such as wheelchair basketball. One should also point to the cultural and academic sway exerted by two offices for disability services located at major state universities during the 1970s, University of California, Berkeley, and University of Illinois, Urbana–Champaign, as fulcrums for university accessibility plans based on the insights generated among disabled and nondisabled students who participate at those sites.

At present, many disability services offices at universities become sites where the interests of budget-conscious bureaucracies collide with the rights and goals of disabled persons. Services offices may need to enforce policies that test, retest, and validate impairments so that individuals may qualify, on a case-by-case basis, for "extra" services such as captioning, sign language interpreters, relocation of classes in accessible spaces, lighting modifications, and extra test-taking time. While the redesign of curriculum to meet accessibility differences is significant, even a new area opened up by technological possibilities to which faculty need to dedicate time and attention, disability services quickly become overburdened by the necessity of serving in all these capacities. In general, under state bureaucracies that operate many educational settings, it becomes easier for offices to test and evaluate students for disability status than to theorize the modifications necessary to promote an inclusive learning environment. Still, many have risen to the challenge of this multitasking necessity and offer content-based national conferences on the topic of disability studies among an array of disability issues necessarily bound up in working toward the maintenance of inclusive community forums.

It has been pointed out that disability studies first emerges alongside the insights obtained by participants in disability rights movements and activities during an era that fiercely advocates for deinstitutionalization. As a result, many scholars surface from a first generation of families who refused to institutionalize their disabled children and family members. Along with their traditional research plans, these scholars conduct research into the new experience of living at home with disabled persons and the reaction of a mainstream society to this new choice. In addition, in literary circles, authors such as the Japanese Nobel Prize winner Kenzaburo Oe are celebrated for their open and honest address of the efforts to live at home with disabled family members. Oe's autobiographical memoir, *A Personal Matter,* discusses the entirely altered coordination of household affairs that occurs as a result of living at home with his autistic, musically gifted son, Kikura. Oe's partner contributes to his books with watercolor portraits of family scenes.

The topic of living at home with disabled family members may have previously been the purview of talk show entertainment but not of academic study. One can clearly see from this approach that disability studies benefits from the insights of women's and gender studies that the personal is political. But also the personal is a matter for redress by professions. Professionalism itself, in its rebuke of any personal attributes from kinds of hairstyles to habits of facial expression, stands in the way of the integration of disabled persons' entrance into the workplace.

In addition to alternative family arrangements, many centers for independent living (CILs) have become cultural powerhouses for the talents and insights of disabled persons in the community. Several CILs have even formed their own research think tanks to rival the funding streams traditionally poured into legitimated university research locales. They sponsor events and training sessions to bring about disability awareness in the community and to enforce accessibility standards that remain little understood. CILs have sought to introduce universities to the rich field of disability studies proper. The Ohio-based Ability Center of Greater Toledo worked with representatives across an array of academic disciplines to endow a faculty position to chair a disability studies program at the University of Toledo. At the University of Illinois, Chicago, disabled students apply from across the globe in order to pursue work in disability studies at the master-of-science level. Many scholars in disability studies, facing a lack of pathways yet to be put into place in curricula and university recognition, may leave to ply their research and social insights in community education. Such an eventual exodus at the level of higher education, as has occurred at CILs, continues to perpetuate a separate location for the focus on social barriers to disability living. In short, such mini "brain drains" occur in newly minted academic programs because of a resistance to the ideas about disability emancipation held by those in traditional academic disciplines who consider disability to be their exclusive purview. At community centers, scholars who have now benefited from university coursework sponsor disability pride parades, promote projects on digital storytelling, and coordinate data banks on disability images, disability history archives, and autobiographical archives from movement participants and key leaders. This shift to CILs as alternative research and employment domains is also evidenced by their active cultivation of disability-based archives. For instance, instead of donating his papers to a university library, FDR historian and disability policy activist Hugh Gallagher left his papers with Toledo's Center for Independent Living.

RECENT RESEARCH TRENDS

Whereas clusters of professionals, previously charged with maintaining records and oversight of institutional warehousing, found themselves declared increasingly irrelevant, and since rapid-paced deinstitutionalization in the 1980s promoted community care initiatives, the traditional privilege accorded to expert oversight has been roundly rejected by disability studies. This rejection has occurred in the midst of active efforts to seek models self-governance and a reevaluation of the principles of guardianship.

Whether indigenously cultivated or generated from universities in the "first world" and translated to those societies deemed "less enlightened," disability studies scholars have increasingly found themselves participating in knowledge dissemination strategies as an effect of postcolonial contexts. Since many countries participated in cross-cultural comparisons of eugenic practices, disability studies has found it necessary to follow suit and use successes in one national milieu to pressure results in other cultures. Yet this situation of political cross-referencing often results in scholars from developed countries preaching to the "unconverted." Such power imbalances situate developing countries as less "modern" in comparison to industrial powers. In addition, they also find themselves promoting or imposing products and policies devised in contexts alien to specific disability needs of various global regions. Thus, one can find Western-manufactured wheelchairs running aground in geographies without paved roads, curb cuts, or nonurbanized environments. Finally, there are few opportunities offered by scholars in developed countries to participate in a reciprocal exchange of ideas about disability innovation. Thus, even disability studies has been caught up in reifying inequities on a global scale.

Consequently, the postmodern and international coordinates for disability studies analysis cannot be underestimated. While disabled persons have faced many barriers to higher education, access to discussions and materials on the Internet have shifted the terms by which individuals in diverse locations acquire interpretive skills about their home contexts. In other words, the Internet opened up participatory forums to a social group that had found schooling prohibitive and the negotiation of public environments frequently dangerous. In the public sharing that occurred on the Internet, disabled persons and disability advocates could share notes on disability predicaments globally while evaluating their own local sense of key obstacles to an equitable and inclusive society: public transportation; access to education; employment; stigma; and common prejudices about bodily, emotional, and mental differences. Likewise, these virtual communities encouraged individuals to swap bodily and social strategies for more successful navigations of hostile or indifferent environments. At present, online discussion groups pursue topics that range from social justice, bioethics, scholarship in the humanities, prosthetic supplementation, personal assistance concerns, and issues of sexuality as appropriate conversation topics for disability-based community. They have also generated a growing global sense of history that provides points for contrast and comparison between the cultural situations of disabled people.

New kinds of study modes and information transmission such as the development of digital media, availability of captioning techniques, keyboarding and voice recognition software have all played a part in getting formerly home-bound or segregated disabled persons into a more participatory cultural mix. Less expensive visual transmission modes such as digital video are making some of the more erased pockets of disability experiences available to the ways we imagine alternative human existences. Histories of institutionalization have shown us that disability oppression occurs not just in violent practices but also in their relegation behind walls, in confinement practices, and as a result of assumptions about bodies in clinics or institutions properly deemed "private." As a result, disability studies has helped to forward media as an powerful venue for accessing personal narratives and multiple voices. International film festivals in Australia, Russia, England, the Balkans, Toronto, and other sites have all sought to use digital formats as an opportunity to educate general populations and legislative agendas in their home countries.

Yet disability studies continues to face up to how inclusion occurs at the expense of the newly included subject. The classroom may be suddenly desegregated but nothing that disrupts the operation of business as usual can occur. Postcolonial studies, with its focus on the internalized oppression of the subaltern and the ultimate silencing of counterdiscourses, has proven integral to current trends in disability studies scholarship. Rather than repeat the error of turning disabled people into passive victims of inhumane social practices, for instance, disability studies has borrowed from theories of international resistance efforts to keep its own interpretive strategies relevant and less marginalizing in and of themselves. In doing so, disability studies—now christened "critical disability studies" by some to remind the field of its radical orientations—pursues analytical approaches based on insights gleaned from comparative disabilities, disability as a subcultural form of alliance, and even the internal fractures precipitated by the advent of disability hierarchies as manifest of more internal forms of social oppression.

Contemporary formations of disability studies analyses have also taken on cooperative research strategies to de-emphasize the singular nature of much scholarly work. As in women's studies and some social science-based research, one witnesses the rise of greater self-consciousness about issues of research interdependencies and the privileges that result in scholarly success based on individual genius models. One now regularly finds research attributed to coauthorship and collaborative research teams circulating in the published literature. Such efforts are not merely the fortuitous results of disciplinary practices, but rather an active effort to re-imagine the collaborative effort invested in research efforts.

For a time, participatory action research enjoyed popularity with disability studies. However, while it integrated disabled persons, they were left as informants but not essentially engaged in the more critical tasks of knowledge production. While disability studies generates new questions, projects, and politicized research agendas, the field must continue to be mindful of the fact that it also potentially replicates the exhaustion of research-based practices on disabled people's bodies. Even the most liberating research models run the risk of treating disabled persons' time and resources as readily and freely available to investigators.

One common future goal would be to offer real choices in collaboration and a legitimate role in the creation of research-based knowledge generation. Such efforts need to occur without the enforcement of exclusive, delimited contact on the part of research subjects who share conditions for example. Thus, disability studies is faced with the challenge of formulating new disability-based insights that engage dominant modes of thinking without simply reproducing traditionally oppressive modes of research conduct. Such an elusive objective continues to guide much current thinking in disability studies.

DISABILITY STUDIES: AUSTRALIA

Disability studies has emerged as a growing area of academic research and professional education and training in Australia as it has in many other developed and developing countries (Green and Meekosha 2004; Meekosha 2004). This is a consequence of the rise of the disability movement and the more vocal demand for relevant curricula by disabled people and their allies. It also reflects the impact on universities of the Australian Disability Discrimination Act (1992), which covered issues of discrimination in education. The growing presence of people with disabilities in society—in particular their presence in the community following decades of deinstitutionalization—has further contributed to an awareness of the responsibilities of educational institutions to disabled citizens. In addition, the demonstrated failure of medical and individual pathology models of disability to explain and "liberate" people with disabilities from constraining and repressive modes of treatment has resulted in many alternative arguments for including disabled people in wider social relations.

However, disability studies remains fragmented with individual scholars scattered across universities and departments. These individuals may have little support from their colleagues, and the institutions demonstrate only a limited understanding of the growth of disability studies overseas. Disability studies as a discipline thus remains fragile in the Australian context, especially given a political climate of neoconservatism and a significant political backlash against minority agendas. The traditional interventionist disciplines such as special education, health sciences, occupational therapy, and rehabilitation have begun to use the language of disability studies, in effect rebadging their courses, without necessarily changing their individualized, medicalized approach or incorporating the ideas of the disability movement into their curricula. A similar phenomenon has been documented in the United States (Linton 1998). Other than the audits referred to below, there is currently no critical literature examining disability studies in Australia. Thus, in Australia we have not seen the growth of departments created around disability studies. Unlike in the United States (Thomson 2001), neither women's studies nor Australian studies has incorporated issues of disability. There is no scholarly journal catering specifically for disability studies, and we have yet to see any collections of readings in disability studies unlike the United Kingdom where there have been several (Shakespeare 1998; Barnes 1999; Barnes, Oliver, and Barton 2002), or the United States where collections in the humanities are widespread (Davis 1997; Snyder, Brueggemann, and Thomson 2002). Key Australian analyses of social movements continue to exclude any mention of the disability movement (see, e.g., Burgmann 2003).

An audit of 26 of 37 Australian universities undertaken in 1999 (Social Relations of Disability Research Network 1999) sought to document the extent and type of subjects addressing disability in a social context taught across various professional and disciplinary areas. No relevant subjects were found in seven of these universities. In those universities where there were subjects, the range of professional programs affected the likelihood of relevant subjects appearing—disability studies, rehabilitation studies, and special education courses were the most likely to have subjects that reflected social issues. It was rare to find any reference to disability studies or issues in general arts degrees or indeed to find a social analysis of disability in professions such as nursing or medicine (as discussed in Wilson 2000).

Most subjects about disability outside law and sociology reflected service delivery priorities and interventions relating to specific impairments, through an individualized perspective that focused on disabled persons and their experiences and relations with professionals. These subjects would clearly be seen as "not disability studies" as defined by Simi Linton (1998). However, there were a significant number of subjects that reviewed changes in social attitudesto disability, and the expansion of human rights approaches to disabled people.

In 2004, a follow-up audit (Green and Meekosha 2004) revealed that there has been an overall fall in subjects dealing with social dimensions on disability. In particular, Deakin University and University of New South Wales had lost a significant number of relevant subjects, perhaps a consequence of cutbacks in overall subject offerings in an increasingly financially constrained environment, or the moving on or retirement of specialist teachers with a commitment to this perspective.

On the other hand, there had been some promising improvements. Some professional programs that had not done so in the past, such as occupational therapy at Curtin University, had begun to identify the social dimensions of disability as an important component of study. Also, subjects exploring the social dimensions of disability were more evident—though still a rarity—in general arts degrees.

DISABILITY SURVEYS

A survey is a method for collecting information about a population. The survey method has several components: a sample of persons that accurately represents the population; standard data collection procedures, including a standardized questionnaire; summary estimates of statistics for the population based on the information collected; and estimates of the sampling error of the statistics. A *disability* survey uses the survey method to collect information about disability. In some disability surveys, disability is the primary topic in the questionnaire; in others disability is a secondary topic.

THE VALUE OF DISABILITY SURVEYS

The main value of disability surveys is that they are relatively inexpensive, unobtrusive, and accurate. Disability statistics can be produced in other ways: in a census that enumerates *all* persons in a population, not just a sample, or in administrative records that include all members of a population, such as the medical care system for elderly people in the United States. However, producing statistics from censuses and administrative records systems is more expensive, more burdensome, or less accurate than producing them from surveys.

Surveys can produce a variety of useful disability statistics. One important use of disability statistics is to formulate and evaluate disability policy. Proponents and opponents of disability policies in employment and transportation use survey statistics in debate. Disability statistics are also used by manufacturers and distributors of disability-related products and services (e.g., assistive devices, disability insurance plans), as they plan for production, advertising, and sales. Scientific researchers use disability statistics to investigate the causes and consequences of disability.

DESIGN AND ANALYSIS OF DISABILITY SURVEYS

Samples for disability surveys are selected in several ways. In a *scientific* sample, the sample persons are selected at random with known probabilities of selection. A scientific sample can be selected from a preexisting list of persons; for instance, if most people have listed telephone numbers, a sample can be selected randomly from telephone directories. Also, a sample can be selected by randomly selecting residential areas, listing the addresses of dwellings in those areas, and then randomly selecting addresses from the list.

Samples for disability surveys may also be selected by establishing quotas for sample categories with selected characteristics. The quotas are set so that the resulting sample will have the same proportions of persons in each category as the population. For instance, if it is known from a census that 10 percent of a population is African American, then a sample of

1,000 persons would be designed to include 100 persons in that category. Data collectors contact people in the population until the quota for each of the categories has been achieved.

While all disability surveys use standardized data collection techniques, they may use different *modes* of data collection. Frequently used modes are face-to-face interview, telephone interview, and self-administered questionnaires distributed by postal mail. Many survey organizations have begun to use self-administered questionnaires distributed by electronic mail or postings on the World Wide Web. Modes differ in quality of data and cost of administration: Generally, face-to-face interviews yield better quality but cost more, while electronically distributed questionnaires yield poorer quality but cost less. To optimize data quality and costs, disability surveys may use combinations of modes.

Once disability data are collected from a sample, they are *weighted* to produce estimates of population statistics, and the sampling errors of the estimates are estimated. If the sample persons were selected with a known probability, the weight for producing estimates of population statistics is the inverse of the probability of selection. For instance, if the probability of selecting a particular case was one in a thousand (1/1000), then the weight for that case would be the inverse (1000/1), or one thousand. If the weights of all sample persons with a particular characteristic (e.g., mobility limitation) are added together, the sum is an estimate of the number of people in the population with that characteristic.

Sampling error is the variability in a population estimate that arises because it is based on a sample rather than a complete enumeration. It is often stated in this form: "It is estimated that 15.4 percent of the population has a disability, plus or minus 1.2 percent." If the sample was selected scientifically, statistical theory and computer software are available to estimate sampling error accurately. If the sample is not scientific, estimates of sampling error have a weaker theoretical basis and may be less accurate.

ILLUSTRATIONS OF APPROACHES TO SURVEYS

Two surveys will be described to illustrate approaches to disability surveys: Canada's Participation and Activity Limitation Survey (PALS) and the U.S. National Health Interview Survey on Disability (NHIS-D). PALS was conducted by Statistics Canada in 2001. It was a "post-censal" survey, meaning that the sample for PALS was selected from persons enumerated in the 2001 census; persons who were homeless or living in institutions were not included. The census included these questions: "(1) Does this person have any difficulty hearing, seeing, communicating, walking, climbing stairs, bending, learning or doing any similar activities? and (2) Does a physical condition or mental condition or health problem reduce the amount or the kind of activity this person can do?" The PALS sample was selected at random from persons who answered "yes" to either census question. At the beginning of the PALS interview, the census questions on disability were repeated, and then a series of disability screening questions were asked. If these questions elicited no report of disability, the case dropped from the sample. About 43,000 persons with disabilities were included in the sample, and they were interviewed by telephone.

The PALS questionnaire was consistent with the World Health Organization's International Classification of Functioning, Disability, and Health (ICF). The ICF definition of disability includes restrictions to participation in societal activities (e.g., school, work), limitations in personal activities (e.g., walking, talking), and impairments of body functions (e.g., hearing, seeing). The title of the survey—*Participation* and Activity Limitations—emphasizes this multiaxial definition. PALS' predecessor was the 1991 *Health* and Activity Limitations Survey (HALS). The title change reflects a trend toward a social rather than a medical definition of disability in surveys.

PALS estimated that 12.4 percent of the household population of Canada had a disability in 2001. The rate was 3.3 percent among children and youths (0–14 years) and 14.6 percent among adults (15 years and over).

In the United States, the NHIS-D was based on the annual National Health Interview Survey (NHIS). The NHIS uses a *clustered area probability sample*—small geographic areas are selected at random with probability proportionate to population size; survey staff then lists the addresses of dwellings in the sample areas, and small clusters of households are selected at random from the lists. Survey staff then visit sample households and conduct face-to-face interviews with members of sample families.

The first phase of the NHIS-D was a supplemental questionnaire to the NHIS in 1994 and 1995. In those years, more than 220,000 persons were included in the NHIS sample, and an extensive questionnaire module was administered to determine if they had any indication of disability. The definition of disability in the NHIS-D was not based on a single concept of disability; rather, it was based on a variety of disability definitions used in national programs and policies. In the second phase of the NHIS-D, persons identified in the first phase as having a disability were contacted, and a face-to-face interview on consequences of disability was conducted. About 36,000 persons (16 percent) were eligible for a second-phase interview, and about 33,000 interviews were completed. A variety of estimates of disability prevalence have been made using the NHIS-D, most falling in the range of 10 to 15 percent.

ISSUES, PROBLEMS, AND OPPORTUNITIES

A major issue in disability surveys is measuring disability. Disability is an inherently complex concept that is difficult to define and measure. When the paradigm for disability changed from medical to environmental, measurement became more difficult. Disability surveys have good measures of many impairments and simple activities, but they are only beginning to develop measures of complex activities and participation, and measures of environmental factors are still over the horizon.

Another problem is survey accessibility for respondents with disabilities. Conventional survey design assumes that sample persons are able-bodied, or that an able-bodied proxy respondent can accurately answer questions about a disabled sample person. These assumptions lead to standard survey practices that systematically exclude full participation in surveys by persons with disabilities, undermining the quality of disability survey data. Survey methodologists are now beginning to recognize and address this problem.

New information technology is creating opportunities for disability surveys by making it cost-effective to measure complex concepts (e.g., computerized adaptive testing) and to administer questionnaires in a variety of accessible formats (e.g., screen readers, voice recognition). On the other hand, some information technology is making it more difficult for surveys to yield complete interviews (e.g., telephone "caller ID," electronic mail filters).

DISABLED PEOPLES' INTERNATIONAL

Established in 1981 in Canada, Disabled Peoples' International (DPI) is a leading international cross-disability organization of and directed by persons with disabilities working in human rights advocacy. Around the world, disabled people total approximately 600 million with 80 percent living in developing countries. They represent the diversity of all humanity. DPI recognizes this and works through building consensus on issues by gathering together to discuss them.

Each year, 135 National Assemblies meet to identify priorities for countries and regions of the world. The DPI World Council, made up of six representatives from each region, meets every two years to discuss disability in a global context at the World Summit. DPI's largest gatherings are World Assemblies, which are held every four years to develop a multiyear action plan. For example, at the most recent 2002 assembly, held in Sapporo, Japan, delegates from more than 100 countries came together and identified priority issues for immediate action. The result was the prioritization for a campaign for a UN Convention to protect the rights and dignity of persons with disabilities.

In addition to its main priority of human rights, DPI works in other important areas, among them sustainable livelihoods, independent living, and inclusive education. In recognition of DPI as an international authority on disability, the United Nations has conferred Special Consultative Status with the Economic and Social Council of the United Nations (ECOSOC). Through its work, DPI is committed to achieving full participation of all disabled people in society.

DISABLED PERSONS' FUNDAMENTAL LAW OF 1993 (JAPAN)

The Disabled Persons' Fundamental Law (DPFL) is one of 27 fundamental laws in Japan. Ranked between the Constitution of Japan and various substantive or procedural laws, a fundamental law stipulates basic principles in each policy area. The purpose of DPFL is to establish the fundamental principles regarding measures for persons with disabilities and designate the responsibilities of the national and local governments to comprehensively and systematically promote measures for persons with disabilities, and thereby to promote their independence and full participation in society.

DPFL was enacted in 1970 through an initiative of members of the Diet across party lines to establish better coordination between policy areas, such as education, employment, social welfare, and transportation. Major revision was made in 1993 reflecting a progress of guiding principles in disability policy that were deeply influenced by international movements, such as the International Year of Disabled Persons (1981) and the UN Decade of Disabled Persons (1983–1992). Lobbying from the disability community also played an important role in this amendment.

With the 1993 revision, DPFL now provides, among other things, that (1) "disabled persons" means persons whose daily or social life is substantially limited over the long term due to a physical, intellectual, or mental impairments (first official recognition of persons with mental illness as the target of disability services); (2) national and local governments are responsible for establishing a long-term development plan for disability services; and (3) persons with disabilities have a right to take part in the formulation of this plan. DPFL, however, is not well-known to general public. The disability community has asked to revise it to include the antidiscrimination principle.

DISABLED VETERANS

Killing and maiming are not only the unfortunate by-products of combat. They are crucial to war's very aims. Since the beginning of time, enemy armies have sought to develop ever more lethal weaponry to injure and eliminate the opposing force. Some soldiers recover from their wounds or recuperate from their diseases and are able to return to battle. They may eventually return home with little lasting physical damage. Others, who are not so fortunate, join the ranks of the permanently disabled. Of course, civilians as well as soldiers are injured in wars. However, the term *disabled veteran* is generally taken to encompass only those injured while in the military. Because most fighting forces have been disproportionately male, the term *disabled veteran* refers primarily to men.

Disabled veterans have always been war's most conspicuous legacy. From the earliest Stone Age conflicts to modern warfare, the human aftermath of war has been measured in decades, not months. At a fundamental level, disabled veterans of today's wars still share a great deal with their forbears two centuries ago. Both are forced to adapt to infirmities incurred as adults in the service of their country. The emotions they experience—pride, despair, fear, and anger among them—are common threads that link the American soldier disabled in the Iraq War to the disabled veterans of the Napoleonic campaigns. Both have needs that are, on the face of it, similar: medical care, a job, and, if they cannot work, some form of subsistence.

Yet, despite these important similarities, the way in which disabled veterans are treated and viewed has changed significantly over time. With the rise of the modern nation-state, the conscription of mass armies, and the development of welfare programs, disabled veterans became a subject of new concern to governments. They have been the targets of innovative social policies that have expanded the state's scope of responsibility, and the recipients of novel benefits that have taxed treasuries. Disabled veterans have proven an important constituency to be courted for states intent on establishing their patriotic concern for the fighting man and, in some cases, their legitimacy to govern. At various points in history, disabled veterans have become disruptive when their demands are not met. As a consequence, the lot of disabled veterans, though often difficult, has, in general, been superior to that of the civilian disabled. Especially since the twentieth century, disabled veterans in many countries have established a privileged place at the heart of the welfare state.

The treatment of disabled veterans has varied not only across history but also, in important ways, between countries. While the questions that the care of the disabled veteran raises are often similar—On what basis should pensions be awarded? What should be the role of voluntary organizations in their care? How should they be employed?—the answers that individual nations have offered differ dramatically. The solutions that countries have offered are a product, in the first instance, of national patterns of welfare provision. They reveal much about the relative weight accorded state versus charitable authorities, and the tendency to resort to compulsory versus voluntary means of enforcement. Care for the disabled also depends on public attitudes toward the armed forces, as well as feelings surrounding the particular war—and its resolution.

While soldiers have always been injured in wars, it was not until the wars of the nineteenth and twentieth centuries that disabled veterans existed in massive numbers and constituted a highly visible special category for attention. Research on the ancient world indicates how very differently disability was construed in a period in which many wounds were simply incurable. It does not appear, for instance, that the Greeks honored the wounded or disabled in speeches or special ceremonies. While Plutarch records that the Athenian state provided some support to men wounded in battle, these were likely payments to the indigent, rather than honoraria for service.

With the rise of the early modern state, from the sixteenth through the eighteenth centuries, came new attitudes toward the disabled. Some governments recognized the need to provide the disabled with statutory benefits so that they were not forced to rely on charity. To better raise a mass army, or so the logic went, the state had to prove its commitment to the injured man. Europe's first state system of benefits for rank-and-file disabled veterans was initiated by the English Parliament in 1593, which hoped by this measure to improve recruitment and reduce desertion. The first veterans' homes—France's Hôtel des Invalides (1633) and Britain's Chelsea Hospital (1685)—were founded in the following century to care for the aged and the disabled. Although the care that men received was superior, in most cases, to the treatment meted out in poor houses, these institutions, and those that followed such as Frederick the Great's Invalidenhaus in Berlin (1748), nonetheless distinguished sharply between officers and other ranks. In the Invalidenhaus, for example, officers were accorded sumptuous living quarters, complete with private gardens sheltered by high hedges, while ordinary soldiers had to settle for a room or two.

So long as armies remained professional fighting cadres, recruited or impressed for service, there was little incentive or need to equalize treatment across the ranks. Even those measures accorded by the state were not secure; within a few decades of the English Parliament's introduction of state-sponsored pensions, the benefit had been restricted to those disabled veterans incapable of work, and devolved on the individual counties. However, the idea of the nation in arms, pioneered by the French revolutionaries, made every citizen a potential soldier—and disabled veteran. Before the introduction of universal conscription, only a very small percentage of the population would have served in the military. In France, on the eve of the Revolution of 1789, the army numbered only 156,000 out of a total population of 29,100,000. In the U.S. Civil War, by contrast, the North mobilized 2,000,000 out of a total population of 32,000,000. From the nineteenth-century conflicts forward, the circle of those who would fight was dramatically expanded, even as the ability to inflict harm was magnified by technological advances in weaponry, such as the Gatling machine gun used in the Civil War and improved, recoilless artillery pieces.

The American Civil War, the bloodiest of the nineteenth-century conflicts, inaugurated a new age in warfare and in the history of disabled veterans. Scholars have called the Civil War the first "total war," by which they mean that the entire populace was mobilized: men in the field and noncombatants (women, children, and the aged) in supporting roles at home. By the war's end, 620,000 American lives had been lost—more than were killed on the U.S. side in the Korean and Vietnam Wars combined. Figures from the Union army indicate that the North alone had treated more than 7 million cases of disease and 250,000 wounds; 30,000 amputations were performed. As a consequence, after the Civil War, the U.S. federal government faced a veritable avalanche of claims. The government responded with a system of veterans' homes, preference in government hiring, land grants, free prosthetics, and above all else, pensions. Although southerners were not entitled to federal pensions (they were provided for, usually scantily, by state governments), the cost of pensions skyrocketed, as these entitlements were politicized by parties eager to court the veterans' vote. By the end of the nineteenth century, the federal pensions bill amounted to $150,000,000 a year, or 38 percent of the entire federal budget.

Although the European governments looked with horror on the rapidly escalating pensions bill in the United States, the Civil War would prove, in some senses, a trial run for the twentieth-century's two world wars. More men were mobilized to fight World War I than ever before in history. Both the total losses sustained and the rate of loss (calculated as a proportion of the mobilized populace) were unprecedented. More than 9.5 million soldiers died over a period of 52 months; on average, the war claimed the lives of 5,600 men every day that it continued. Twenty million men were severely wounded; 8 million veterans returned home permanently disabled. As a consequence of dramatically increased firepower, they had suffered some of the worst injuries ever seen. Shrapnel from the new exploding shells tore ragged paths through flesh and bone; poison gas (first used by the Germans in 1915 and quickly reciprocated by the British) seared eyes and lungs, creating the spectacle that the painter John Singer Sargent captured in his heartrending painting *Gassed*. Under the threat of constant shellfire and ubiquitous death, some men lost their minds. After months of exposure in rat-infested trenches, others contracted debilitating illnesses that eventually shortened their lives.

As firepower became more destructive, medicine's ability to mend bodies improved in tandem. As a consequence of sanitary innovations, World War I marked the first war in which injury, rather than disease, claimed the largest number of British casualties. Improvements in the delivery of medical services behind the lines, a host of surgical innovations (especially in orthopedics and in plastic surgery), and improvements in the treatment of infectious diseases ensured that more men returned home than ever before, swelling the ranks of the permanently disabled. Medical science's advances continued through the twentieth century. The widespread introduction of antibiotics during World War II (penicillin had been discovered in 1929) cut mortality rates in hospitals dramatically. It has been estimated that during World War II, 60,000 American, Canadian, and British soldiers survived a hospitalization that would have killed them two decades earlier.

More disabled veterans meant greater pressure on the states that had sent them to fight. World War I forced all of the belligerent nations to deal with disability on a scale never before experienced. The overwhelming numbers of casualties, combined with the widespread expectation that the war would be short, meant that none of the European states was prepared to deal with the problems that disabled men faced. All were forced to develop solutions amid wartime budgeting constraints and, in some instances (as in Russia and Germany), political turmoil. Some responses were common. Governments largely acknowledged the need to provide nationally funded pensions, even in those countries (such as Britain), where charitable organizations had, during the nineteenth century, played a leading role. In most countries, rehabilitation, training, and employment were also of central concern to the state, as officials sought to return men to the workforce. Integration into the labor market, rather than segregation in veterans' homes, was the call of the day.

Despite these commonalities, however, important differences remained in the treatment of disabled veterans after World War I. The cases of Britain and Germany indicate the range of government responses. While commentators in both countries agreed that it was the responsibility of the state, supplemented by the efforts of its citizenry, to provide for the disabled, British and German veterans fared very differently. In Britain, civil servants in the new Ministry of Pensions charged with their care sought to limit the state's obligations toward disabled veterans. Pensions assessments were based solely on the degree of physical disfigurement or illness and did not take account of a man's capacity to return to work. Successive British governments proved notably reluctant to institute programs that provided disabled men with a chance at gainful employment. As a consequence, the tasks of rehabilitation and employment were left largely to philanthropy and voluntary effort. In Germany, by contrast, state officials embraced the rehabilitation of the disabled as their foremost duty, and largely eliminated charities for the disabled. Pensions were intended to compensate men for the loss of earning capacity, as well as for the physical fact of disability. The Weimar Republic's National Pension Law (1920) accorded the disabled more than a right to pensions; they were also entitled to an occupational retraining course and free medical care for all service-related ailments. Under the Law of the Severely Disabled (1920), most employers were required to hire and to keep them. It was very difficult to fire a disabled man.

In general, most countries hewed closer to the German model than to the British and, in the aftermath of World War II (even in Britain), the tide had turned against predominantly voluntarist solutions to the needs of disabled veterans. The privileged position of veterans in relation to other categories of the disabled was well established. In Soviet Russia, for example, disabled veterans of World War II were entitled to privileges that distinguished them from the peacetime disabled: a free automobile (to be replaced every seven years), a gasoline subsidy, free public transportation, priority in housing, and the free installation of telephones. To a limited extent, the civilian disabled profited from wars' creation of an entirely new populace of disabled people. Medical advances made in connection with disabled veterans, such as new prosthetic devices, could be translated into improved care for the rest of the population. Some social legislation, such as Germany's Law of the Severely Disabled, was extended to peacetime disabled as well. However, in general, veterans jealously guarded their prerogatives, and protested vehemently against any attempt to integrate their care with other categories of the poor or disabled.

While disabled veterans throughout history had usually defined themselves as a group bound together by shared experiences, the massive numbers generated by the twentieth century's wars, and their favored place in the welfare state created new kinds of political organizations. The first mass veterans' associations dated to the late nineteenth century, with the Grand Army of the Republic (organized by Civil War veterans in the North) and the Kyffhauser Bund (founded by veterans of the Franco-Prussian War). These were mixed organizations of disabled and nondisabled veterans, of officers and enlisted men.

Although many of the veterans' associations founded in the twentieth century adhered to this model, with World War I also came the formation of organizations whose membership was restricted to war victims, defined as the disabled, their dependents, and the survivors of the dead. Some of these organizations, as in France, were nonpartisan, focused chiefly on securing improved benefits. Others, as in Germany, though ostensibly apolitical, were in fact deeply politicized along the spectrum of left to right; the country's largest war victims' organization, the National Association of Disabled Soldiers, Veterans, and War Dependents, enjoyed close ties to the Social Democratic Party, while one of its challengers, the Central Association of Disabled German Veterans and War Dependents, was thoroughly conservative. By 1919, there were seven national organizations of war victims in Germany, with a total membership, at the high point in 1921, of nearly 1.4 million. Through the 1920s, these organizations were involved in an increasingly bitter battle with their fellow citizens, whom they accused of neglecting them, and the state, which despite its innovative welfare programs, could not fully compensate veterans for their sacrifices. By the early 1930s, disabled veterans in Germany had become a constituency ripe for the picking by the Nazi Party. In Britain and France, by contrast, where veterans could take pride both in their victory, and in their fellow citizens' grateful response to soldiers' sacrifices, veterans remained bulwarks of the established order.

Throughout the twentieth century, disabled veterans came to occupy a position of great symbolic significance in the lands to which they returned. Not only were the disabled present in the greatest numbers ever seen, but they had become, in most countries, the state's favored wards, the subjects of costly and path-breaking social legislation. Where disabled veterans had once been isolated in institutions such as the Invalidenhaus, they were now, quite literally, more visible on the street, in the workplace, and even on the movie screen, in films such as the Academy award-winning *Best Years of Our Lives* (1946). Changing attitudes toward disability, both furthered by disabled veterans and reflected in their situation, meant that an injury sustained in battle no longer necessarily stripped a man of his expectations for a well-paying job, marriage, or a family.

Yet, at the same time, the public image of the disabled veteran has often been an ambivalent one. Societies have tended to treat all veterans with caution, as men who have endured the fire of battle, have killed, and perhaps still contain within them the potential for violence. Because they carry the scars of war on their body, disabled veterans have been seen as an exaggerated instance of the general phenomenon. The civilian populace's guilt toward the disabled has undoubtedly played a role in stigmatizing these men as unstable. In novels and films in which disabled veterans appear, images of pathos have coexisted with threatening visions of danger. With rare exceptions, the quotidian struggles of disabled veterans are seldom depicted.

DISCREDITED THERAPIES

Alternative or discredited therapies are those that exist outside the framework of professionally accepted remedies as determined by mainstream medical systems. While one could speak of allopathic medicine as an alternative system in eighteenth-century China, this entry considers the context to be contemporary Western medicine. Among those therapies generally considered alternative, for example, are acupuncture, magnet therapy, and many herbal remedies.

Nevertheless, it is important to recognize that alternative or discredited therapies can also become mainstream or accredited, while previously approved interventions can be later discredited. Applying leeches to remove a plethora of one of the four humors, for example, was a mainstay of conventional medicine from antiquity into the nineteenth century. In 1833, some 40 million leeches were imported into France for medical purposes. By the end of the century, leeching therapy was overturned with successive changes in medical theory and practice. Over the past two decades, however, leeches have found new roles in postoperative management for plastic and reconstructive surgery; they have reentered accredited use, although for different theoretical purposes. Thus, the designation of alternative is a moving target.

The term *alternative*, or discredited, therapy fundamentally exists on the sociological level with allocation of resources—mainstream/licit therapies have the support of, for example, governmentally endowed institutes or departments at major universities; the alternative intervention often exists as a grassroots enterprise. Nevertheless, popular alternative therapies can command enormous market forces, which at times can overturn the traditional domination of mainstream medicine. Such changes are often full of social controversy.

Alternative or discredited medicine in Western Europe and North America may be said to have begun with the rise of mainstream medicine. Defining the latter means defining the former as “the other” kind of practice. Thus, in the early Western Middle Ages, magicians and sorcerers offered an alternative means of healing often sought by people with chronic conditions when doctors trained in humoral medicine or Catholic healing interventions were unsuccessful. At times, the Church and the more formal physicians joined forces to limit the appeal of such magical healers. By the thirteenth century, after the invention of the medical schools within the newfangled universities, physicians, lay governmental authorities, and the Church established regulations requiring that medical practice be certified by a license granted only after examination by the university faculty. In 1322, an illiterate woman, Jacqueline Félicie de Almania, and four of her colleagues were tried and excommunicated for unlicensed practice in Paris by the Medical Faculty, despite witnesses asserting her salutary effect in the face of mainstream impotence. Similar examples exist for medieval Spain, Italy, and England.

As university medicine grew in authority and prestige, its physicians entered medical service in the courts of the powerful. By the sixteenth century, figures such as Paracelsus (ca. 1493–1541) could be chased out of town after town for offering medical care that did not fit into the confines of the now codified theory and practice of the universities. In the late eighteenth century, some therapies, such as mesmerism, enjoyed a period of wild enthusiasm only to be officially and permanently discredited by a panel of experts. Others, such as electrotherapeutics for conditions such as stroke and insanity, were used with initial enthusiasm, followed by a period of discredit and but are now being investigated again and used by biomedical scientists.

In the United States, the slow absorption of proprietary, freestanding medical schools into the universities delayed the process of a more consistent division between accepted and discredited therapies until the late nineteenth century. This process was enhanced by the acceptance of the scientific method into medicine, though that acceptance was highly variable both chronologically and geographically. By the beginning of the twentieth century, requirements of verifiable proof of efficacy began to limit the social penetration of alternative medicine and increased the lists of discredited therapies. The ongoing "successes" of scientific medicine, from aseptic and antiseptic surgery to anesthesia to antibiotics to immunomodulators, generated a popular perception that scientific medicine would eventually be able to cure most, if not all, conditions.

Coincident with the shift from the acute- to the chronic-disease model in the second half of the twentieth century, the slow gains with respect to cures for cancer, HIV, and other objects of "wars on disease," as well as the social revolutions of the 1960s and early 1970s, popular acceptance of non-biomedical/university therapies grew. By the 1990s, the groundswell of use of such treatments had grown to the point that reportedly 42.1 percent of American patients acknowledged using such therapies. The National Institutes of Health (NIH) created the Office of Alternative Medicine (OAM) in 1993, which became the current National Center for Complementary and Alternative Medicine (NCCAM) in 1998. Such an official endorsement for the field has blurred the distinction between mainstream and alternative therapies in their classic definition.

As different cultures with a less professionalized medical history endorse the Western biomedical model to a greater or lesser extent, the relationship between "alternative" and "discredited" therapies varies. In China, for example, traditional Chinese medicine (TCM) shares a relatively coequal status with allopathic medicine. In Brazil, prayer competes with native remedies and allopathy**.** In addition, sociological relationships established by professionalized markets can reverse as one moves across cultural boundaries. Thus, in the United States, different alternative remedies have been embraced by both higher and lower socioeconomic groups, whereas in China, the likelihood of a person choosing TCM over allopathy decreases as one ascends to higher socioeconomic statuses.

Conditions, which include chronically disabling features, can fall into those with gradual functional "deterioration," no change, or slow gains, after the model of cerebral palsy, cancer, and HIV. Thus, people with strokes, traumatic brain injuries, amputations, chronic pain, and many others have sought out alternative therapies when biomedical science has not helped. In this way, modern people with such chronic conditions echo their medieval predecessors who, frustrated with the mainstream healer, sought out magicians, sorcerers, and the nonlicensed healers. While the salubrious claims of these complementary healers have not always been proven by science, more intense investigation may prove many of them and so embrace them as accepted therapy.

In the United States, over the past decade, such market forces have pressured both the government and insurance companies to accept in part previously marginalized therapies. In addition, certain medical disciplines, physical medicine and rehabilitation (PM&R) among them, have traditionally employed alternative therapies, from hippotherapy to acupuncture, in advance of more traditional allopathic specialties, further blurring the boundaries between accepted and discredited.

DISEASE

Disease is a pathological state of a part of an organism. Disease may be brought about by multiple causes such as genetic, infectious, or environmental factors. Distinct symptoms usually indicate the presence of disease.

The concept of disease is at the heart of biomedicine. The purpose of biomedicine, also referred to as allopathic medicine, is to diagnose and cure physical pathology. Historically, disease has been understood in different ways. Before the use of the scientific method and the rise of biomedicine, disease and its symptoms were usually attributed to spirits, witchcraft, humoral processes, or other causes in the social world. In contrast, biomedicine tends solely to consider organic causes and aspects of disease. Discoveries such as the germ theory of disease and the existence of entities such as viruses and bacteria did much to bolster this latter understanding. Discovering the root physical cause of the disease is considered essential to treating, curing, and preventing it. For example, if a patient has a bacterial infection, an antibacterial medication is given. When a medication like penicillin was discovered to fight the disease process, it changed the health outcomes of entire populations. Similarly, when it was discovered that diseases could be transferred by germs, handwashing became a common practice. This simple behavior changed obstetrical practice and reduced infant mortality rates when babies started to be delivered into clean hands. In addition to curative medications and behavioral changes, biomedicine has discovered vaccines that can prevent diseases that were otherwise disabling or deadly such as measles and diphtheria. Because of the power of the biomedical approach to disease, medical research continues to flourish with the promise of curing an increasing number of diseases.

Biomedicine has made staggering improvements to the prevention and treatment of a myriad of diseases. However, the emphasis in this type of medical system is on disease rather than health or well-being. *Allopathic* means “against suffering or disease” and overwhelmingly focuses on removing pathology rather than sustaining health. In this disease-focused system, a person is often stripped of psychosocial or spiritual aspects and effectively becomes a set of body parts to fix. While this emphasis on pathology is changing to encompass health promotion to some extent, the Western medical system is still predominantly one of crisis management. Other systems, such as several Eastern medical models, focus on regular practices to sustain health in addition to disease treatment.

Current controversy exists over whether some conditions should be considered diseases or not in allopathic medicine. For example, a long-standing area of disagreement is addictions. Alcoholism, once considered a moral failing, is increasingly thought of as a disease with genetic factors related to the malfunctioning of neurotransmitters. Many psychiatric disorders have also been redefined as diseases rather than bad behavior such as Tourette’s syndrome, eating disorders, and obsessive-compulsive disorder. For many in Western societies, having a troubling condition defined as a disease rather than a character flaw removes stigma and aids the solicitation of professional help.

Medical anthropologist Arthur Kleinman identified an important distinction between disease and illness. He argues that disease refers to the biological pathology as well as health care practitioners’ understanding of the pathology according to biomedical models. On the other hand, illness refers to a broader set of experiences around the disease including the patient’s and family’s subjective recognition, naming, and experience of the problem. Whereas disease is presented as acultural in a medical model,[1] illness includes the sociocultural context of a problem. The social and cultural components of the experience of a condition have been identified as crucial to the course of the condition. Therefore, medical sociologists and anthropologists point to the importance of examining the illness in addition to the disease, even in biomedical contexts. In the study of disability, several anthropologists such as Robert Edgerton, Benedicte Ingstad, and Susan Reynolds Whyte proved that cultural context makes a significant difference in the identification, experience, and outcome of a condition. The disease/illness distinction is also especially relevant as allopathic medicine expands transculturally and as heavy transnational immigration creates multicultural communities. In such cases, experiences of illness and disability as well as symptom reporting may vary greatly, and it is crucial that important cultural differences are not dismissed in the professional health care setting.

—Eileen Anderson-Fye

Note

1. Many have convincingly argued that even biological pathology is shaped by culture. For example, heart disease and obesity-related health problems have been found to vary in their prevalence depending on a diet common to a particular culture or region.

DISPARITY

The term *health disparity* is widely used to indicate inequalities in health status and health care services, as it relates to minorities. For example, a disproportionately high number of people in certain ethnic and socioeconomic groups have illnesses such as heart disease, obesity, and cancer. In addition, observed differences exist between Hispanic Americans and the general population in the proportion of having a usual source of care. Ethical judgments of such inequalities (fair or unfair) depend largely on a person's perception of the reasonableness of the underlying reasons for the inequalities, such as differences in income and access to insurance. Other inequalities are often considered unfair when race is the main reason for inequalities. For example, research has shown that the race/ethnicity of a patient is the main factor that affects primary care physicians' decisions on specialist referral or the use of expensive treatment.

Racial disparity in health surfaced in 1985, when the U.S. Department of Health and Human Services issued the first comprehensive national minority health study, known as the Secretary's Task Force Report on Black and Minority Health. The task force focused on differences in mortality for six key areas between minorities and the white population (cancer, cardiovascular disease and stroke, cirrhosis, diabetes, homicide and unintentional injuries, and infant mortality that collectively accounted for more than 80 percent of the mortality from 1979 to 1981) and concluded that the difference in mortality was not acceptable. Following the report, federal and state governments created agencies, such as the Office of Minority Health, to address these issues of health disparity. However, comparisons of the findings in the 1985 report to information released in *Health, United States 1990* showed very little change in the health status of minority populations.

By 1998, studies indicated that racial disparity had not improved as much as hoped. The long-standing considerable differences in death rates for infant mortality, heart disease, cancer, and HIV/AIDS between minorities and whites made a compelling case for a federal response. Consequently, President Bill Clinton launched a initiative that set a national goal of eliminating disparities in six key areas by the year 2010: infant mortality, diabetes, cancer, heart disease, HIV/AIDS, and immunizations.

In 1999, Congress authorized the Institute of Medicine's (IOM) study on the prevalence and impact of ethnic bias. Unlike previous governmental studies, the IOM report, titled *Unequal Treatment: Confronting Racial and Ethnic Disparities in Health Care*, focused on quality of treatment by examining provider-patient clinical encounter itself rather than mortality or prevalence of diseases. The report documented the prevalence of lower-quality treatment of minority patients, and concluded that minorities received unequal treatment because they are, in fact, minorities.

Policy makers started to express concerns related to the sole focus on racial and ethnic minorities as opposed to a more generally defined population, such as those whose health care needs are not well met. Concerns led to addition of the definition of *health disparity population* into a new federal law, the Minority Health and Health Disparities Research and Education Act of 2000: A population can be designated as "a health disparity population if there is a significant disparity in the overall rate of disease incidence, prevalence, morbidity, mortality, or survival rates in the population as compared to the health status of the general population."

Specification of certain segments of the population in the health disparity definition provides insight as to which segments are of greatest interest for policy makers. The National Healthcare Disparity Report, developed by the Agency for Healthcare Research and Quality (AHRQ) to meet the mandate by Public Law 106–129, the Healthcare Research and Quality Act of 1999, identified persons with disabilities and persons who use long-term care, among others, as priority populations worthy to track health care disparities. According to the U.S. Census (2000), nearly one in five persons, or 49.7 million people, had some type of long-lasting condition or disability. They represented 19.3 percent of the 257.2 million people who were age 5 and older in the civilian noninstitutionalized population.

Some disparities were documented based on national survey data, such as the Medicare Current Beneficiary Survey, the National Nursing Home Survey, and the National Home and Hospice Care Survey. However, other national survey data were not usable for reporting on racial/ethnic and socioeconomic disparities related to disability. Many data collections do not capture disability and, when collected, do not have adequate sample sizes of the disabled to examine racial/ethnic and socioeconomic disparities.

In general, the Medicare Current Beneficiary Survey (MCBS) findings indicated the presence of racial/ethnic and socioeconomic disparities in the quality of health care among disabled persons. According to the disabled elderly, the percent of persons who reported problems with the quality of care is higher among Asian and Pacific Islanders (11 percent) when compared with whites (4 percent), and higher among persons in poor households (6 percent) when compared with persons in high-income households (3 percent). Small sample sizes precluded assessment of disparities in the quality of health care among the disabled nonelderly. Similarly, access to care also indicates disparity among disabled persons. For example, among the disabled elderly, the percentage of persons with a problem getting to the doctor from their home was higher among Hispanics (16 percent) when compared with non-Hispanic whites (7 percent). In addition, there is an income gradient with this measure of physical access to a doctor: Persons in poor (11 percent), near-poor (9 percent), and middle-income (7 percent) households experienced more difficulty than persons in high-income households (4 percent).

The National Nursing Home Survey and the National Home and Hospice Care Survey data were used to examine racial, ethnic, and socioeconomic disparities in nursing home care. Within the survey data, differences in the management of pain and the receipt of rehabilitative services among nursing home residents were demonstrated. Significant disparities in influenza vaccination were not observed, but disparities in pneumococcal vaccination among some nursing home residents were present. Among persons ages 18 to 64, rates of nursing home discharges were higher among blacks (22 per 10,000 population) when compared with whites (16 per 10,000). In addition, when discharged from a nursing home, the percentage of persons who stabilized/recovered was lower among blacks (22 percent) than whites (34 percent).

Health disparities can be examined from the point of view of public health purposes. This approach follows the 1986 World Health Organization definition of health, which states, "Health is a state of complete physical, mental, and social well-being, and not merely the absence of disease or injury." *Healthy People 2010* and similar state initiatives have committed the nation to the goal of eliminating health disparities by 2010. *Healthy People 2010* defines health disparities as differences that occur not only by gender, race or ethnicity, education, or income but also by disability, geographic location, or sexual orientation. Of 28 focus areas that cover both health care and health status measures, the sixth focus area addresses disability and secondary conditions with one of three goals being the elimination of disparities between people with and without disabilities in the U.S. population.

The disparity findings suggest that people with disabilities tend to have lower rates of physical activity and higher rates of obesity. They tend to report more anxiety, pain, sleeplessness, and days of depression, and few days of vitality when compared to people without activity limitations. Health promotion activities are important for people experiencing a disability regardless of race or ethnic group, gender, or primary condition or diagnoses (e.g., major depression, arthritis, cerebral palsy, diabetes, spinal cord injury, or fetal alcohol syndrome).

A 2003 national survey that updates the Disability Supplement to the National Health Interview Survey (NHIS-D) conducted nearly 10 years ago examined health care use, costs, and access among people with disabilities. More than 33,000 households were contacted; 3,687 of which were identified as including a household member with a disability. According to the survey findings, people with disabilities are often confronted with socioeconomic and health-related disadvantages, compared to the rest of the general population. Commonly, disabled people, both mentally and physically, have lower incomes, are older in age, are more likely to be female, are more likely to be unemployed, and are often poorer in health. Thus, because of these disadvantages, people with disabilities are more likely to use the health care system exhaustively: (1) 90 percent of the sample reported employing physician services six months prior to the survey, (2) approximately 33 percent reported frequenting emergency room services six months prior to the survey, and (3) 90 percent reported taking at least one prescription drug on a daily basis. These numbers indicate higher health care use rates for people with disabilities when compared to the general U.S. adult population. Although those living with disabilities are often profound and intense users of health care services, they obtain these services much less regularly than is normally recommended.

The survey findings highlight barriers to care among the uninsured and those with gaps in coverage within persons with disabilities. For example, the uninsured were four times as likely to have postponed care because of cost when compared to those with insurance coverage. Also, the uninsured were three times as likely to go without needed supplies or medication. Those insured primarily by Medicaid were less likely to postpone care or go without necessary medication compared to those covered by Medicare or private insurance companies. In addition, the disabled, covered solely by Medicare, fared worse than people with private coverage (12 times as likely to postpone care, and 7 times as likely to forgo medication). The findings suggest that Medicaid provide the most important financial protections when compared to other sources of coverage such as Medicare and private insurance.

On the other hand, the Medicare Current Beneficiary Survey (MCBS) data allow comparison of health status between two groups of Medicare beneficiaries: the disabled under age 65 and the elderly population. In general, the survey concluded that disabled beneficiaries have poorer physical, mental, and functional levels than the elderly. The study also reported that the disabled were twice as likely to be in fair or poor health (59 vs. 23 percent), and twice as likely to have trouble performing one activity of daily living (44 vs. 26 percent) or instrumental activity of daily living (36 vs. 16 percent). The survey also noted that disabled persons bear heavier disease burdens and are more likely to report having three or more chronic conditions. Furthermore, the disabled are often poorer: They are more than twice as likely as seniors to live under the federal poverty level (45 vs. 20 percent); nearly 80 percent live on modest incomes under 200 percent of the poverty level. Mentally disabled beneficiaries are the most vulnerable: They are more likely to have incomes below poverty level.

Differences in health status and disposable income seem to lead to differences in health care utilization between the disabled under age 65 and the elderly Medicare beneficiaries. In 1998, the average number of prescriptions filled by disabled users (34) was much higher than for elderly prescription users (25). In addition, the disabled spend almost 50 percent more than the elderly on prescription spending ($1,284 vs. $841).

A recent Commonwealth Fund study singled out a vulnerable subgroup within persons with disabilities: Severely disabled persons enrolled in Social Security Disability Insurance (SSDI), waiting the mandated two-year waiting period before their Medicare coverage takes effect. Medicare provides coverage for individuals whose disabilities are severe and permanent enough, qualifying them for SSDI, even if they are not age 65 and older. However, unlike the elderly beneficiaries, federal law requires these individuals to wait two years after they receive SSDI before their Medicare coverage takes effect. Many of these individuals are no longer eligible for Medicaid when they receive SSDI payments that push them over the financial limits for Medicaid. Some may still be eligible for Medicaid benefits but are unaware of their potential eligibility. In 2002, a total of 1.2 million people with disabilities under age 65 were in the mandated two-year waiting period. About 400,000, or one-third, of all these individuals likely were estimated as uninsured. Thus, many, particularly those in the waiting period, report enormous problems: skipping medications, putting off needed care, feeling depressed and anxious about the future, and believing they were not in control of their own lives. The study findings call for eliminating the current Medicare two-year waiting period and beginning Medicare coverage concurrent with that of SSDI.

Mental disorders are disabling conditions. Former Surgeon General David Satcher's 2001 report on health disparities, titled *Mental Health: Culture, Race, and Ethnicity*, documents the existence of several disparities affecting mental health care of racial and ethnic minorities compared with whites: Minorities have less access to, and availability of, mental health services. Minorities are less likely to receive needed mental health services. Minorities in treatment often receive a poorer quality of mental health care. Minorities are underrepresented in mental health research.

Studies mentioned above tend to focus on disparity in access to care. We may need more research related to quality and outcomes in health care for the disabled. Another observation relating to the studies mentioned above involves little research on racial disparity relating to disability. With the exception of mental health, most disparity studies mentioned above do not report on racial/ethnic and socioeconomic disparities related to disability. Many survey data conducted or sponsored by federal agencies do not capture disability and, when collected, the definition of disability is often not consistent across data or over time. Even when disability status is captured, in many cases, the data do not provide adequate sample sizes of the disabled to examine racial/ethnic and socioeconomic disparities. The 2004 National Academy of Sciences' report, titled *Eliminating Health Disparities: Measurement and Data Needs*, recommended the use of state-based data such as vital records, administrative data from Medicaid and the State Children's Health Insurance Program, and data from registry systems for analyzing disparities in health and health care. Although those types of data provide information on race and ethnicity and socioeconomic status, disability information may not be available, limiting their use for studying racial and socioeconomic disparities relating to disability.

DISSOCIATIVE DISORDERS

Dissociative disorders are disturbances of normally integrated mental functions such as identity, memory, consciousness, or perceptions of environment. These can occur suddenly or gradually and may last a short time or become chronic. Dissociative phenomena, on the other hand, are seen in normal subjects and may result from hypnosis or a trance state. About 90 percent of the population is hypnotizable. Trance refers to altered state of mind during which a person performs uncommon physical feats, such as standing on one leg for hours or walking on a bed of nails. Dissociative phenomena have been recorded in the temples of Aesculapius in ancient Greece, in Native American culture, and among Indian monks. Dissociative phenomena can also be seen in various religious and cultural ceremonies internationally where the process of celebration induces a group dissociative phenomenon.

Dissociative disorders are usually psychopathological and include the following subtypes: dissociative amnesia, dissociative fugue, dissociative identity disorder, depersonalization disorder, and dissociative disorder not otherwise specified.

Dissociative amnesia is characterized by an inability to recall important personal information of stressful or traumatic nature. It may be *localized* (inability to recall events during a circumscribed time), *selective* (can recall only some aspects of an event), *continuous* (ongoing amnesia following a specific event), or *systematized* (inability to recall certain categories of events). Dissociative amnesia can occur at any age but is rare in children. Its incidence is higher in soldiers in combat. It is reversible, usually beginning and ending suddenly. Recurrences are not uncommon. Hypnosis and amobarbital interview may be helpful in retrieving lost memory.

Dissociative fugue presents as a sudden, unexpected travel away from home with inability to recall some or all of one's past. Onset is sudden, usually following severe psychosocial stressors. This state usually lasts for minutes to days, but may be prolonged for months. Although confusion may be present, most individuals appear quite intact and do not draw attention.

Dissociative identity disorder (formerly called multiple personality disorder) is characterized by the presence of two or more distinct personality states or identities that recurrently take control of the person's behavior. The patient may be unable to recall important personal information. This is a chronic and complex disorder, which may result from severe childhood abuse (physical, emotional, or sexual) or neglect. It is diagnosed three to nine times more frequently in adult females. It is more common among the first-degree biological relatives of patients with this disorder.

The person may have different personality states or identities, that is, the child, the angry person, the protector. Most patients are unaware of their disorder and may seek treatment for depression. Many patients receive other diagnoses prior to treatment and may not respond to medications. The transition ("switch") from one personality to another is usually quite sudden. The degree of impairment depends on the manner in which various personality states interact with each other. The switching is a vulnerable time. Patients may attempt suicide, mutilate themselves, or become violent toward others. Long-term psychodynamic psychotherapy using an integration approach is helpful.

Depersonalization disorder presents as recurrent episodes of depersonalization in which a person feels detached or estranged from one's self. He may feel as if he is an observer watching himself as if in a dream or movie. Reality testing remains intact. The prevalence of this disorder is unknown. It usually occurs in adolescence or adulthood. Most patients present with anxiety, panic, or depression. Clinical course may be chronic with recurrences following stressful events. Impairment is usually minimal and most patients function well, but some become incapacitated from fear of going insane.

Dissociative disorders not otherwise specified do not fit in any of the above categories. Ganser's syndrome (in which the person gives approximate answers) falls in this group.

DIVERSITY

Although *diversity* is a much overused term within multiculturalism, its potential for promoting social transformation—particularly with respect to disability—remains significant. At base the term suggests difference, or rather, the recognition and acceptance of difference; however, even this formulation does not adequately address the term's importance. Instead let us say that diversity represents not a point of acceptance but a stance toward the world that refuses to foreclose on the question of who counts among the ranks of humankind. Diversity, then, becomes a more active ethical position, available for adoption as opposed to a goal to be fulfilled.

This distinction is important at the outset because the overuse of *diversity* in contemporary politics and rhetoric has reduced the term's meaning to an objectively achievable goal. If we have human "differences" represented at any one point in time—African American, Jewish, women, gay—then we have achieved "diversity" and we can go on from there. Such a position cultivates certain forms of tokenism where the one stands in for the many and, as a consequence, the plurality of the many drops out. Pure efforts to operationalize diversity inevitably miss the point of the concept, and therefore, this entry sets out a philosophical overview of the term's important meanings.

Properly understood, then, *diversity* means a plurality of singularities working together toward collective understanding and action. The realization of diversity, which can never occur once and for all, must constantly be renewed and implies a recognition that beneath any collective banner those who comprise it must also retain their specificity. Consequently, diversity should not be viewed as a question of representation; particularly in the sense of one perspective effectively embodying a diverse whole. Instead, efforts to achieve diversity seek to avoid rhetorical efforts in the name of false unity. The goal is not a subsumption of differences beneath a singular identity—whether that identity be women, African Americans, disabled people, the working class—but rather a cultivation of shared participatory space where differences remain recognizable. Nor can diversity be adequately identified with more outdated political groupings of "the people," "the masses," "the proletariat." If this were so, and diversity functioned merely as another synonym for designations of group identity, the term's significance would prove much less consequential.

Diversity has come to stand in as an alternative form of identification—one that ultimately attempts to suspend the need for singular group identity overriding dynamic differences across populations. As Ernesto Laclau and Chantal Mouffe have pointed out, political formations coalescing beneath an identity (no matter how large the potential grouping) inevitably experience the fracturing of differences residing just below the surface of a unifying banner. One might say that efforts to unify a plurality of identities beneath a nodal point of belonging find themselves inevitably beset by the demands of diversity. The specificity of individual differences ultimately makes demands on the larger category charged with organizing shared modes of belonging. Conceived in this way diversity can be understood as a disruptive presence at work in all efforts at totalizing allegiance.

At the same time, diversity does not involve surrendering to relativism either. The existence of particularities among collective gatherings does not necessarily mean that organizing devolves into irredeemable difference. Philosophies of political organizing, as Michael Hardt and Antonio Negri point out, have often offered formulas that result in a false choice between unwieldy plurality or authoritarian singulars. Diversity's alternative philosophical gambit resides somewhere in between these extremes. Instead diversity focuses on forms of collective action taken in common among the individualities that comprise it. The effort of diversity is not to forge "unity" of identity based on a shared interest or essential quality, but rather to achieve an open process respectful of differences born of intellectual, social, geographic, and embodied experiences. While there is a defining nonallegiance to national boundaries, diversity actively recognizes the specificity of place and culture. Within this formula there is no need to negate local differences; rather the creativity of differences interacting with each other express the ideal of diversity. The conscious goal of diversity is to produce alternative routes of belonging that bypass more worn down points of group organization.

Yet this formulation is not without conflict. Nor is its achievement simple to pull off. One inevitably finds exclusions occurring even in the most "diverse" gatherings. Disability, for one, often finds a difficult time inserting itself into political efforts claiming to be diverse for a variety of reasons. First, modern liberation movements have traditionally sought to undermine social designations of inferiority by distancing themselves from criteria of "biologically based" insufficiencies. The contemporary history of women's weaker constitutions or biological racism, for instance, situates a population's inferiority as having a bodily basis. By way of refuting such ascriptions modern concepts of femininity and race have rightfully exposed the social underpinnings informing such beliefs. However, in the wake of these liberation formulas, disability functions as a remainder of true "inferiority" in that it continues to operate within the parameters of biology.

Furthermore, disabled participants in politicized identity movements have often found themselves left out of traditional activist practices. On the basis of inaccessibility that exists within political organizations—for example, lack of audio description and/or alternative print formats for people with visual impairments, lack of sign language interpreting and/or captioning for deaf participants, lack of physical accessibility for those with mobility impairments—disability itself has not been recognized as a legitimate constituency with issues in need of political redress. Thus, divisions often surface based on insensitivities in Leftist movements to the forms of marginalization that disabled people face. In addition, within disability groups one could also point out that lack of active recruitment of other marginal identities results in a failure of diversity among disability movements as well. Within this matrix of insensitivities, inadequate recognitions, and exclusionary practices little space is left for the exploration of the substantial overlaps that exist between disability, race, class, gender, queer, and other identities seeking political change. One basis for social claims of marginalization eclipse other equally pressing oppressions, and disability often finds itself holding the least status among competing discourses of social redress. Diversity and disability, it would seem, do not mix.

Thus, disability as diversity continues to function as oxymoronic. Disability and its intersections with other identities have not yet been adequately recognized as a cultural attribute with something to contribute to our understanding of social disenfranchisement, political organization, or collective well-being. In fact, disability often appears as the identity claim that will ultimately expose all identity claims as false. If people with disabilities who have obvious "things wrong with them" (or so goes this rationale) can also claim the political terrain of social constructivism, then all identity-based claims are in jeopardy. With the arrival of disability we have somehow reached the end point of identity politics because claims to social disenfranchisement based on prejudicial beliefs about inferior biologies must be disallowed from growing too sweeping (and, therefore, ludicrous). If disability gains recognition as a minority like any other, then it instantly metamorphoses into the largest minority group (some 20+ million in the United States alone). Difference becomes mere variation; disability threatens to re-biologize socially derived inequalities; minority status itself becomes a joke when one has to work in such large demographic quantities; and anyone could ultimately become a resident of minority landscapes. Claims to social justice become impossible, incoherent, and, ultimately, unwieldy.

Diversity undermines (or, depending on your point of view, exacerbates) such fears in that it endeavors to attribute differences differently. Differences are not so much based on one's possession of discrete characteristics (femininity, homosexuality, color, disability); rather, diversity seeks coalitions among those who use difference as a tool to analyze structural inequalities. Diversity is a shared methodological tool more than a static mode of being. Such an approach does not mean a rejection of biological and social identities. Instead, diversity cultivates a common-ness across previously segmented identities based on annunciations of common objectives. As a result, diversity cannot be achieved beforehand or a priori. It is a dynamic and ever-shifting product of politicized identity constituencies as they interact with each other to formulate and imagine another world where differences could be signified as wealth rather than lack.

In April 2005, for instance, the Perth Social Forum in Australia adopted the slogan "Another World Is Possible." A three-day symposium included environmentalists, feminists, aboriginal rights advocates, disability rights advocates, theorists of organizational behavior, anthropologists, Marxists, globalization philosophers, "slow food" proponents, and antiwar protestors. Diversity operated as the expressed goal in that participants were encouraged to pursue multiple activist interests without privileging any singular aspect of their identity interests. In other words, the inter- and intragroup efforts explicitly discouraged a single basis for belonging or legitimate activism. Instead, coteries of interests became the norm and participants found themselves teaching and being taught across a variety of perspectives. By the conclusion of the event, five key themes surfaced as interests identified "in common" among all attendees: the insufficiency of existing forms of political participation, the global ruination of environments (both natural and artificial), the continuing proliferation of poverty, increasingly narrowing criteria of meaningful human inclusion based on variation rather than homogeneity, and strong commitments to global peace agendas. These shared investments signaled not unity of identity but common political and social capacities among those gathered.

Critics of diversity might say that, inevitably, every identity group is formed on the basis of its exclusions—those who do not fit based on fetishized traits strategically reclaimed to counter mainstream devaluation. Diversity sets out to undo this limiting logic by inserting a more expansive formula for involvement. Even when a historical moment is dominated by a variety of unifying identity rubrics, diversity responds to the indefinite nature of dispersed networks—those intersected by myriad differences of race, class, gender, disability, age, sexuality, and cultural/geographic specificities. Because the multiple interests of the Perth Social Forum could still manage to define agendas in common based on the five themes identified above, one recognizes that diversity does not necessarily undermine the ability to exist in common. Diversity is not a devolution into incoherency; instead it seeks to transform the appearance of incoherency from the outside into an organizational strength. Consequently, diversity grapples openly with the need for alternative organizational strategies that do not cover over differences but rather cultivate them openly as desirable—a politics based on variation as a commonality of our embodied, political lives.

DIX, DOROTHEA (1802–1887)

American social reformer

Dorothea Dix was a renowned social reformer and vocal advocate for the humane treatment of people with psychiatric disabilities. During her lifetime, Dix traveled extensively throughout the United States and abroad, visiting jails and almshouses to document the inhumane treatment of those with mental illness. She used these notes and observations to fight for the use of "moral treatment" in their care. Her reports regarding the treatment of those with severe mental illness were presented in numerous state legislatures, leading to the creation or enlargement of many hospitals designed specifically for the needs of this group. Dix believed that it was important to provide a place that focused specifically on assisting people with mental illness. She felt that the current system of care, one that focused on trying to address the needs of many disparate populations, including orphans, criminals, and paupers, was not specialized to adequately address of all these issues. Dix believed that a therapeutic setting, focusing on recovery, without restraint or confinement of patients, would be most helpful in restoring mental health.

Dix rose to prominence after submitting a petition to the Massachusetts General Court, titled the *Memorial to the Legislature of Massachusetts,* which documented the horrific conditions of people with mental illness living in confinement throughout the state. As a result, Massachusetts enlarged its state mental hospital to provide specialized treatment to low-income individuals with psychiatric disabilities. As an outcome of her successful efforts in Massachusetts, Dix became involved in conducting surveys and inspections of almshouses and prisons in other states, and she lobbied other legislatures to enact similar reform legislation. She played an instrumental role in the creation of 32 mental hospitals and became nationally known for her reform efforts.

Although Dorothea Dix was progressive in her views about psychiatric disability and specialized treatment for people with mental illness, she did not embrace reform in many other areas. As a woman, she did not feel that it was appropriate to engage in public speaking herself. So instead of addressing legislative bodies and other groups, she wrote speeches that were read on her behalf by prominent men who supported her efforts to create mental health care facilities. In addition, unlike many reformers and activists of the 1800s, she was not an abolitionist, and she maintained close ties with prominent slaveholder families. Some historians have argued that she was more effective in her advocacy of humane treatment for the mentally ill because she followed the strict social conventions of the time. She presented herself as a reluctant activist moved to action by the plight of people with mental illness. However, her conservative views in many areas have made her less appealing as a role model for subsequent generations that have rejected many of her beliefs.

Dix was born on April 4, 1802, in Hampden, Maine, a small village on the Massachusetts frontier. During her youth, there was significant tension within her family, particularly between her parents and grandparents. Dorothea's father lacked much of the ambition and drive that had characterized her grandfather's success. In addition, her father married a woman that his parents felt was beneath him. At age 12, Dix ran away from her parents and went to live with her grandmother in Boston. At 14, she moved in with the family of a prominent physician and became semi-independent from her family. While living with this family, Dix opened a private school. She continued to teach for the next 20 years, in various locations, at her grandmother's home and at the Female Monitorial School, and she also provided private tutoring. In addition, she published a number of books for children, including her most famous *Conversations on Common Things.*

Dix's focus on social reform was in part influenced by her strong commitment to the Unitarian faith. In the early 1820s, Dix began attending sermons every Sunday and Thursday, and focused her life increasingly around church lectures, sermons, and humanitarian projects. Dix seemed particularly influenced by the church's emphasis on the poor and unfortunate and its efforts to create a more socially just community. Dix regularly attended a Unitarian church led by William Ellery Channing, and over time developed a personal relationship with the pastor. Dix began tutoring his children and eventually began to accompany the family on summer trips and on a lengthy journey to the Caribbean.

During the late 1820s and the early 1830s, Dix developed significant health problems, including a chronic respiratory condition. In the winter of 1836, she experienced an episode of severe depression. Seeking rest and a change of scenery, she sailed for England in the spring. However, upon her arrival, her symptoms worsened and she became bedridden and despondent. Dix was taken in by a Unitarian philanthropist, William Rathbone II, and his wife, who were acquainted with William Ellery Channing. During her stay with the Rathbones, Dix continued to experience severe symptoms of depression, in addition to an episode of pneumonia. She consulted with William Rathbone and Oxford physicians regarding her symptoms. Dix was often confined to her room by chronic fatigue; however, she enjoyed frequent visits from the Rathbone family. Dix convalesced in England for a year and a half and, as she became stronger, she socialized increasingly with the numerous guests that visited the Rathbones. Through these interactions, Dix was probably exposed to the "reform movement of moral treatment" that was becoming increasingly popular in Europe. Upon receiving news of her grandmother's death, she returned to New England in the summer of 1837.

Dix's philosophy regarding treatment reform for individuals with mental illness was strongly influenced by the moral treatment movement. Originating at the York Retreat in England, this treatment focused on encouraging patients to use self-control instead of using physical and mechanical restraints. The York Retreat was a private hospital in which seven staff cared for 30 patients. Patients were expected to take part in daily activities, such as reading, writing, sewing, socializing, and gardening. Work also was considered an essential part of developing self-control. Exercise, warm baths, and a generous diet were believed to be important to calm and reassure patients. Privileges were granted to individuals who behaved in a desirable manner. This new philosophy emphasized that patients could be rehabilitated and cured, particularly if early treatment was provided.

During the nineteenth century, public hospitals provided treatment only for low-income individuals and those who had exhausted their financial resources. Hospitals were viewed as the option of last resort and were associated with moral degeneracy and poverty. In addition, hospitals exposed patients to contagious, infectious diseases such as sepsis. In general, families cared for members with physical and/or mental illnesses at home. The asylum movement sought to change the role of hospitals in American society. The movement focused on creating institutions that would provide specialized care in pleasant, homelike environments. The asylum movement subscribed to the belief that the increasing complexity, dislocation, and urbanization of American life had detrimental effects on people's physical and mental health. Asylums provided safe havens where people could recover from these effects.

Moral treatment in the asylums used a system of incentives and punishments to treat mental illness. Asylum staff developed an individualized regimen of various activities for each patient that included grooming, exercising, meeting with the physician, dining, recreation, educational activities, and some work activities. The regimen was changed as an individual's symptoms improved or declined. Individuals were discharged from the asylum when they no longer experienced symptoms of mental illness, exercised sufficient control over undesirable impulses, and demonstrated a determination to lead a productive life. Asylum superintendents would often send inquiries in the years following discharge to former patients to see how they were doing. Generally, hospital stays lasted a number of months while, for a smaller number of people, hospitalizations occurred for a period of years.

When Dorothea Dix returned to Boston, she met Samuel Gridley Howe, who encouraged her interest in humanitarian work at a local prison. Together, they worked on strategies to bring more public attention to the situation of people with severe mental illness. Dix began visiting jails and almshouses in Massachusetts, documenting what she found throughout the state. During her visits, she conducted a census of each institution's inmates with mental illness, documented their general condition, and intervened in particularly dire situations to alleviate suffering. She noted the availability of religious instruction and literature. Howe, who had recently been elected to the state legislature, encouraged Dix to summarize her findings in a petition to the legislature. Dix completed her petition, *Memorial to the Legislature of Massachusetts,* including the names and dates of the various places she had visited, for the opening session of the legislature, where it was presented on January 19, 1843.

In her *Memorial to the Legislature of Massachusetts,* Dix detailed graphic portraits of men and women living in filth; she described people living in "cages, closets, stalls, and pens!" who had been beaten and whipped. She gave case examples of individuals kept isolated in dark cellars, naked, and covered in human excrement. Many confined individuals had no clothing, heat, or furniture. Through the *Memorial,* Dix recommended legislative action to create asylums for those with severe mental illness. She advocated separating them from criminals, asserting that those with mental illness needed care, not punishment, and that by confining them in prisons, their conditions only worsened.

A pamphlet of the *Memorial* also was circulated throughout the state, causing considerable controversy, as some of the institutions included in her petition disputed her findings. However, a few prominent politicians and attorneys spoke out in her defense. As a result, Dix became increasingly influential and met with many legislators in an effort to lobby her cause. In the spring of 1843, the Massachusetts legislature allocated funds to greatly expand the State Mental Hospital at Worcester. Dix conducted similar investigations and engaged in lobbying efforts in other states, including New York, New Jersey, Pennsylvania, Kentucky, Illinois, Tennessee, Louisiana, Mississippi, North Carolina, Alabama, and Maryland. Her advice and assistance often was sought by state politicians because she was viewed as an objective outsider who could assess the plight of people with mental illness and provide guidance regarding legislation to address these concerns.

By the late 1840s, Dix focused on developing a national plan to address the treatment of people with mental illness. She created a federal memorial in which she described the plight of those with mental illness in various towns and villages throughout America. She argued that mental illness was increasing, and that other countries were experiencing similar problems. She focused on the potential for treatment to cure some individuals, and its ability to make those individuals whose conditions were thought to be "incurable" comfortable and socially useful. Her petition led to a bill proposing a federal land grant for 12,225,000 acres to be set aside as a public endowment. The income from this land was to be used to provide services for people with mental illness, as well as those who were blind, deaf, and mute. From 1848 to 1854, Dix continued to lobby for her plan, and the legislation was successfully passed by both the U.S. House and Senate. President Franklin Pierce, however, vetoed the bill and ended Dix's pursuit of securing funding for current and future state programs to address the needs of the people with mental illness. In a written defense of his action, Pierce stated that he did not want to establish a precedent in which the federal government was responsible for funding state programs.

Discouraged by the failure of her effort to provide a national endowment for treatment of mental illness, Dix returned to Europe. She traveled extensively to many countries, including England, Scotland, France, Austria, Italy, Greece, Turkey, Russia, Sweden, Denmark, Holland, Belgium, and Germany. During her two years there, Dix visited prisons and almshouses, again documenting her findings and advocating for reform.

When Dix returned to the United States, she continued to lobby and advocate on behalf of her cause. Within a few years of her return, the Civil War began. She was appointed superintendent of United States Army Nurses by President Abraham Lincoln. In this position, however, Dix was often in conflict with the Army Medical Bureau. She had difficulty adjusting to the bureaucracy and organizational structure of the military establishment. Since her previous work had been conducted more autonomously, she faced constant challenges to her authority. With Dix's reserved and distant manner, in addition to her unorthodox ways, many critics emerged, leading to a decline in her public image.

After the war, Dix again returned to advocacy work for people with psychiatric disabilities. However, she was disappointed to see that mental hospitals had become overcrowded, understaffed, and run down. Most of the facilities lacked adequate funding to provide the type of treatment originally envisioned by those advocating moral treatment. Many rural communities where asylums were located objected to funding treatment for predominately urban populations. In addition, the economic depression of 1857 and postwar depressions further depleted hospital funds. Asylum facilities were also strained by the huge influx of immigrants, who had few financial resources. These facilities became merely custodians of people with mental illness, not the therapeutic, tranquil environments for which she had fought.

Dorothea Dix died in 1887, at the age of 79. She is buried in Mount Auburn Cemetery in Cambridge, Massachusetts.

DO NOT RESUSCITATE (DNR) ORDERS

Do not resuscitate (DNR) orders are advance medical directives that request that doctors do not attempt cardiopulmonary resuscitation (CPR) if a person's heart stops or the person stops breathing. A DNR order is then placed on the individual's medical chart, and sometimes a colored bracelet is also put on the person's wrist stating, "Do Not Resuscitate." In these cases, when the person's heart stops or the person stops breathing, doctors then abide by this directive, and the individual is likely to die in the hospital.

A DNR order may be applied before, during, or after a cardiac or respiratory arrest. Individuals may write their own advance directive, indicating a desire to have a DNR order placed on them, if they are considered rational and able to communicate their wishes in a clear manner.

A DNR order does not mean that no medical assistance will be given to the individual. For instance, emergency care and other health care providers may continue to administer oxygen, control bleeding, splint or immobilize, position for comfort, provide pain medication, and provide emotional support. However, they will not administer chest compressions, inset an artificial airway, defibrillate or cardiovert, or initiate cardiac monitoring.

DNR orders can be particularly controversial when the individual is incapable of expressing his or her own wishes, for instance, if the person is in a coma. In these circumstances, when the individual is unable to give informed consent, the authority to make such decisions passes to a surrogate decision maker, such as a legal guardian, spouse, or parent. Often there are conflicts between surrogate decision makers and other family members or friends who disagree about the treatment the individual would have wanted.

Doctors often discuss the need for DNR orders when a person has malignant cancer or a severe infection such as pneumonia, or if the person's kidneys do not work well. People who ask for a DNR order in these circumstances often express a desire to let nature take its course.

Although some doctors may raise the issue of DNR orders with people who are likely to become disabled, their use in these circumstances is far more controversial. It cannot automatically be assumed that because someone is disabled, or is likely to become disabled, that quality of life will automatically decrease, and it certainly cannot be assumed that disability is an automatic justification for a DNR order. Disability rights activists often campaign on this issue—they argue that it is wrong to suppose a person will have a lower quality of life simply because he or she is disabled—and condemn doctors who promote DNR orders as a reasonable medical response to disability.

Another issue that is of concern to disability activists is whether the person who is subject to the DNR order actually consents to this order. In some cases, it has been argued that an individual with a DNR order did not consent to such an order and did not even know that such treatment decisions had been made.

DOCUMENTARY FILM

Since the beginnings of film, disabled people have been central subjects of the documentary genre. The evolution and subgenres of disability documentaries provide insight into shifting social attitudes toward people with impairments. In addition, different constituencies have used the documentary's association with empirical "objectivity" as a means to serve a variety of social and political ends. Disability documentary can be divided into the following subgenres: medical, eugenic, inspirational, and activist. Individual films tend to fall into one primary subgenre while exhibiting characteristics of others.

The medical subgenre can be traced to the earliest film technologies. Medical practitioners used film in the early twentieth century as a tool to document the symptoms of individuals with impairments for multiple purposes: archival, research, diagnostic, and educational. For instance, in addition to making multiframed images of normative walking, standing, and crouching movements, the pioneering photographer Eadweard Muybridge made chronophotographs of "abnormal" gait patterns in the United States during the 1870s. Audiences for these early films primarily consisted of the medical community and researchers, rather than the general public. Currently, this subgenre thrives in the form of films created as professional development material for medical and social service providers. These films provide information on matters ranging from the latest therapeutic techniques to understanding the daily obstacles faced by disabled people to updates on disability legislation. This subgenre also includes documentaries intended for general audiences. For example, popular, current-day versions of the medical subgenre have proliferated on television, showing the miracles of modern medicine to cure, or at least markedly improve, the lives of the ill and disabled. These documentaries contribute to the popular understanding of the medical model of disability, which casts disabled people as individual, pathological patients in need of medical care or cure.

The eugenic subgenre emerged in the late 1920s through the 1940s. Eugenicist documentary filmmakers created propaganda aimed at both the medical community and the general public to justify the treatment of people with a variety of impairments, including institutionalization and other forms of segregation, sterilization, and in the most extreme cases, euthanasia including medical murder. A notorious American example of such films is *Are You Fit to Marry?* (1928), which warned against allowing disabled children to grow, marry, and give birth to ever-more impaired progeny. The film functioned as a health propaganda film that drew direct equations between individual citizen's bodies and the health of the nation. In doing so, *Are You Fit to Marry?* popularized eugenics ideology and made it the responsibility of individuals and family to strictly police their reproductive fitness. Nazi propaganda films produced between 1935 and 1937 (with titles such as *Straying from the Path, Hereditarily Ill,* and *Sins of the Fathers*) promoted the sterilization of people with mental impairments or psychiatric labels. Furthermore, British films released after World War I such as *War Neuroses: Netley, 1917, Seale Military Hospital, 1918,* as well as U.S. propaganda films during World War II demonstrated modern applications of psychiatric therapeutic techniques deployed to integrate traumatized veterans back into society.

The eugenic subgenre in its most blatant form has mostly died out; however, elements can still be found on television documentaries exploring the ethical complexity of end-of-life issues, such as the Public Broadcasting Services' series titled *Before I Die: Medical Care and Personal Choices* (1997). In addition, a number of films recording decisions about medical surgery decisions surrounding conjoined twins have been released.

The inspirational subgenre documents the trials and tribulations of life as a disabled person, focusing on either the ability of the individual to overcome impairments or the tragic inability to do so. Such films are often created by nondisabled filmmakers and geared to a nondisabled general audience. These films focus on disabled people of notable or extraordinary accomplishments. These accomplishments are often attributed to individual courage and acts of great willpower. Such films include Jessica Yu's *Breathing Lessons: The Life and Work of Mark O'Brian* (1994). O'Brian, a poet and journalist, was an American polio survivor who lived 40 years in an iron lung. Susan Hannah Hadary and William A. Whiteford's *King Gimp* (1999), which documents 13 years in the life of Dan Keplinger, a young American painter with cerebral palsy, can also be included in this subgenre. While such films explore many facets of their subjects' lives—including their work, friendships, family lives, and romantic aspirations—they ultimately tend to cast such issues sentimentally, rather than politically. These works evoke easy emotions of sympathy, pity, tragedy, or triumph by unveiling how their protagonists strive to achieve beyond their presumed incapacities to produce art. In doing so, they portray disability as an individual phenomenon that is divorced from the wider struggles of disability civil rights agendas and often neglect the degree to which class status provides an enabling context for their accomplishments.

Often in direct contrast to the inspirational subgenre, the activist subgenre includes documentaries that explore the social and political dimensions of disabled people's lives and advocate, explicitly or implicitly, for systemic liberatory change. Early activist films, such as the controversial American film *Titicut Follies* (1967) by Frederick Wiseman, documented the abusive treatment of people with disabilities in criminal psychiatric institutions. More recent films continue this theme by exposing past and current atrocities against people with disabilities such as Mat Fraser's *Born Freak* (2002), Snyder and Mitchell's *A World without Bodies* (2002) and *Disability Takes on the Arts* (2004). Furthermore, activist films tend to situate their disabled subjects in community with one another rather than as products of independent genius. The Israeli film *Liebe Perla* (2000) exposes Nazi medical experiments on a short-statured Hungarian family. This history is unvieled as Perla, the only living survivor of this family, is assisted by Hannelore Witkofski (who was born in post-World War II Germany and is also short statured) in finding evidence about her family from Josef Mengele's gruesome "studies." Another example is the French film *Forbidden Maternity* (2002) by Diane Maroger. Maroger documents the transition to independent living of a couple with cerebral palsy, Nathalie and Bertrand. The film explores the couple's efforts to deal with the effects of childhood institutionalization, the lack of liberty available to those under disability guardianship laws, and Nathalie's forced sterilization approved by her mother. In all of these efforts, independent disability documentary filmmakers seek to expose a debilitating history as the source of their collective impediments.

The 1990s to the present day have witnessed an upsurge of activist films by and about people with disabilities. The focus on disability oppression as a human rights issue coincides with the passage of civil rights legislation such as the U.S. Americans with Disabilities Act (1990). These films also participate in the creation and dissemination of disability culture and disability arts. For example, David E. Simpson and Billy Golfus's film, *When Billy Broke His Head . . . And Other Tales of Wonder* (1994), documents Golfus's recovery from a traumatic brain injury. Endless medical and social service bureaucracies seemingly designed to keep people with disabilities a permanent underclass as well as debasing attitudes shared among nondisabled friends and family thwart Golfus's reentry into society. Golfus learns to navigate these obstacles through the discovery of the disability civil rights and culture movements in interviews and friendships with disabled leaders. Other examples include Mitchell and Snyder's documentary, *Vital Signs: Crip Culture Talks Back* (1995), which features leading scholars, artists, and activists with disabilities presenting myriad viewpoints on disability culture, civil rights, and the politics of representation. Whereas the inspirational subgenre often captures one exceptional individual's struggles for acceptance, new disability documentary cinema steers away from more singular tales of disability prowess in order to foreground the shared and sometimes contentious perspectives among those who comprise contemporary disability communities.

Increasingly, there has been a renaissance of disability documentary filmmaking from locations across the globe. Just in the past few years, an explosion of new works in this genre have been released. What characterizes these films as revolutionary is the degree to which they move from introductory lessons in the humanity of disabled people for predominantly nondisabled audiences to nuanced explorations into the intimacies of interdependent lives. Many of these works explore close relationships between disabled people and others, such as Martin Taylor's *Berocca* (UK, 2004), which details the experiences of a father with cerebral palsy with his son in northern England; South African filmmaker Shelley Barry's recent work such as *Whole–A Trinity of Being* (United States, 2004), which features an ode to a woman's tracheostomy site; the Korean documentary film *Turtle Sisters*, which details the efforts of a small group of disabled women trying to set up a viable living situation for themselves; and *The Silent Wedding* (Russia, 2004), which portrays deaf laborers in St. Petersburg making a bell that they will never hear ring. This brief catalog of works suggests the increasingly global scope of disabled people's rights movements seeking to use film as a medium for effecting social change.

DOPING IN PARALYMPIC SPORT

Doping is defined as the use of certain prohibited substances and methods intended to enhance and/or having the effect of enhancing athletic performance (as described in the World Anti-Doping Code Prohibited List). Use is considered to have occurred when there is evidence of the application, ingestion, injection, or consumption by any means whatsoever of any prohibited substance or method.

In Paralympic sport, the International Paralympic Committee (IPC) established the IPC Anti-Doping Code, in compliance with the general principles of the World Anti-Doping Code (WADC), to prevent—in the spirit of fair play—doping in sport for athletes with a disability. The code applies to the Paralympic Games and all competitions sanctioned by the IPC and to all sports practiced within the context of the Paralympic movement, including during preparation for competition. All participants (athletes and athlete support personnel) accept these rules as a condition of participation and are presumed to have agreed to comply with the code.

Doping control has been conducted at all Paralympic Games since 1988 and most World Championships organized by the IPC. Since 2004, and the introduction of the WADC, all IPC-sanctioned competitions are required to conduct doping control. In addition, the IPC conducts out-of-competition testing in cooperation with the World Anti-Doping Agency (WADA). In the event of an anti-doping rule violation, sanctions are applied, which include disqualification from competition, forfeiture of all medals, points, and prizes, and ineligibility from competition for a set period depending on the type of anti-doping rule violation and number of violations committed by an athlete.

The WADC Prohibited List is published and revised by the WADA. In recognition that there may be instances where athletes seek to use substances on the Prohibited List for therapeutic purposes, exemptions may be sought from the IPC Therapeutic Use Exemption Committee. Exemption is granted on the basis that an athlete would experience a significant impairment to health if the prohibited substance or method were withdrawn from the course of treatment and the athlete would gain no additional enhancement of performance other than that which might be anticipated by a return to a state of usual health following the treatment of a legitimate medical condition.

Doping control is conducted for two reasons, first, to protect athletes from the potentially harmful effects that some drugs may produce, and second, to ensure fair and ethical competition by preventing athletes from taking drugs in an attempt to increase performance.

DORRIS, MICHAEL AND REYNOLD ABEL ("ADAM")

(Michael, 1943–1997; Abel, 1968–1991)

American writer (Michael) and Native American fetal alcohol syndrome victim (Abel)

Michael Dorris was a young unmarried academic when he adopted three-year-old Abel, a Lakota Sioux child with apparent developmental delays. Abel Dorris was eventually diagnosed with the condition now called fetal alcohol syndrome (FAS). Michael Dorris's book about Abel's childhood and diagnosis, *The Broken Cord,* was an award-winning critical success, though its ethical and rhetorical dimensions remain troublesome to many. Abel Dorris died in New Hampshire in 1991, after being struck by a car. Michael Dorris also died in New Hampshire, nearly six years later, in the last of several suicide attempts. Michael Dorris's own struggles with depression, substance abuse, and abusive behavior were widely noted after his death. Michael Dorris's passionate activism toward prevention of FAS, especially among Native Americans, and posthumous revelations about his own mental illness, are perhaps as much a part of his legacy as his several novels and the Native American Studies Program he founded at Dartmouth College.

—Penny L. Richards

DOWN SYNDROME

Down syndrome is the common name for a genetic anomaly, trisomy-21–nondisjunction of the 21st chromosome during meiosis, resulting in a zygote carrying an extra 21st chromosome. Down syndrome occurs in one out of every 600 to 800 live births, making it by far the most common form of chromosomal nondisjunction in the living human population.

Humans with Down syndrome have existed for at least as long as *Homo sapiens* and its immediate ancestors, but trisomy-21 was not identified until 1866, when British physician John Langdon Down associated it with phenotypical facial features such as epicanthal folds in the eyelids and flattened noses. Since these features can also be found in certain Asiatic populations, Down syndrome was for many decades referred to as "mongolism," and Langdon Down's discovery played a minor part in nineteenth-century debates over the question of evolutionary "polygenesis"—that is, the question of whether humans evolved from different ancestors corresponding to the different human "racial" subgroups (Down himself understood trisomy-21 to be evidence of human monogenesis). The genetic principles behind Down syndrome were not understood for nearly another century; until 1959, when French physician Jerome Lejeune identified the nondisjunction responsible for the syndrome, conventional wisdom held that Down syndrome was caused at some point in fetal development, and some researchers speculated that fetuses with "mongolism" were "throwbacks" to earlier stages of human evolutionary development.

Down syndrome is associated with mental retardation as well as a wide range of systemic health problems, ranging from congenital heart defects to childhood leukemia to a vastly increased risk of Alzheimer's disease in later life. In 1900, the life expectancy for people with Down syndrome was under 10 years, largely because of their increased susceptibility to infection; the discovery of antibiotics helped push the life expectancy beyond 20, and with the advent of open-heart surgery, saving innumerable children who would have died in infancy, the average life expectancy for people with Down syndrome increased to 55. The average quality of life for people with Down syndrome, at least in industrialized nations, has increased more dramatically still. Long considered ineducable "idiots" (when that term was considered to be a diagnosis rather than an insult) incapable of acquiring basic skills regarding speech and reading and therefore best consigned to mental institutions, people with Down syndrome have lately demonstrated significant capacities for learning and expression. It is no longer uncommon to find adolescents and young adults with Down syndrome graduating from high school, or older persons with Down syndrome working and living independently or in assisted-living environments involving other persons with developmental disabilities. At the same time, however, advances in prenatal fetal screening, combined with a widespread sense in the medical profession that "prevention" is superior to palliative care, have led many people to see Down syndrome as a human anomaly that is potentially eradicable, and whose eradication would be an unqualified benefit to the species as a whole. Accordingly, advocates for people with Down syndrome—and many people with Down syndrome themselves—have tended to applaud the social advances that have incorporated people with Down syndrome into the fabric of public life while remaining suspicious of new forms of eugenics that threaten to render those social advances moot.

DRAMA AND PERFORMANCE

The discussion of disability in drama and performance can include widely varying, even diametrically opposed, types of representation: the literal representation of disability used toward metaphorical ends in canonical drama; plays, solo performances, and community-based theater projects created by disabled artists with disability themes at their core; and performance modalities created with a disability aesthetic in mind.

Drama and performance are vital and powerful parts of disability culture for several reasons. Disabled bodies have been on display in performance at several points throughout history. As sideshow freaks, mendicants, poster children, and medical subjects, disabled people's bodies have been deployed within highly specific kinds of spectacle and put on display in ways heavily circumscribed by the expectations of nondisabled audience members. The pervasive presence of disabled people in traditional dramatic literature is somewhat more complicated; while there are many examples of disabled characters that reinforce stereotypes, there are still other representations that simultaneously represent and resist traditional ways of understanding disability. The work of contemporary playwrights and performers from within disability culture, therefore, has been a powerful way in which the disability community has reclaimed and redefined disability identity in performance. At once influenced by and carrying forward the confrontational spirit of disability activism, these artists have placed the disability experience at the center of their work, claiming the public space of the stage as location to which they have a right of access, and within which they can confront the voyeuristic stare. The disabled performer can no longer be hidden or looked away from; because the stage allows this direct challenge to the traditional relationship between the disabled person and the nondisabled spectator, it is a particularly powerful place for disabled artists to give visibility and voice to the disability experience. Within the space of the theater, the disabled artist can perform the reality of disability, model new ways to imagine the place of disability within contemporary society, and posit disability as a catalyst for artistic creation. This last aspect, reflective of much recent thought, opens the way for disability to be the conduit toward a more general invigoration of theater and performance.

The disabled body has been as consistently on display in Western theater as it has in other literary and artistic genres. For example, Sophocles' play *Oedipus Rex,* William Shakespeare's *Richard III,* Tennessee Williams's *The Glass Menagerie,* and Margaret Edson's *Wit,* although spanning diverse eras and countries, all depend heavily on the presence of disabled bodies to motivate the action and to serve as metaphors. These examples likewise bookend a long dramatic tradition of using both moral and medical models of disability. According to the former model, the disabled body bears moral meaning: It can stand for extremes of evil or innocence, mark a tragic fate or punishment, underscore the mystical or all-knowing sensibilities of a character, embody the outcome of violence or neglect, inspire nondisabled characters to some personal transformation, or symbolize some internal foible or personal failing of a character. The latter model posits disability as a condition that is either cured or heroically overcome at best, and as tragic fate at worst.

The kinds of disability represented throughout theatrical history include a full range of cognitive and physical disabilities, and their depictions are historically contingent. It is important to remember this contingency in fully evaluating the representation of disability in canonical theater; some plays, while bound to the audience expectations of their times, have also been able to challenge simultaneously the moral and medical models of disability. For example, George Henry Boker's *Francesca da Rimini,* while in many ways a typical mid-nineteenth-century American melodrama, critiques the prejudice and pity directed at the humpbacked protagonist, even though he is finally the drama's villain. Plays have shown the intersection between disability and other identity categories; Tony Kushner's *Angels in America,* for example, shows how homophobia and the stigmatization of AIDS patients in 1980s America were intimately interwoven. Indeed, there have been periodic plays within traditional theater that have directly challenged stereotypical ideas about disability and identity, such as Mark Medoff's *Children of a Lesser God.* This does not mean that disability always intersects successfully with theater that purports to challenge social constructions. For example, although disability is a social construction like race and gender, some plays of political protest created by multicultural and feminist playwrights have distanced themselves from the stigma popularly associated with disability, instead using disability metaphorically to illustrate the destructive quality of social oppression. Yet in so doing, such plays reinscribe that oppression as it is enacted against disabled people.

Today, there is a vital and wide-ranging body of drama and performance coming from within disability culture, a tradition that traces its roots to the contemporary disability rights movement. As disability and theater scholar Victoria Ann Lewis (2000) points out, it is a wave of creativity that originated in "the rag-tag comedy troupes, the stand-up (or more accurately, sit-down) comics, the agit-prop collectives, and rowdy performance artists that were the inevitable camp-followers of the political activists and legislators who changed the social reality of disabled Americans" (p. 93). Disability in performance is no more a monolith than disability as an identity category; therefore, to consider disability in contemporary drama and performance is to consider the work of playwrights, community-based theater groups, monologists, performance artists, and dancers with a full range of visible and invisible disabilities. In using the disabled body as a subject of and catalyst for creative expression, these artists have aimed for goals such as creating solidarity through affirming the presence of disability culture, articulating emotions from sharp wit to righteous anger, relating specific experiences with disability, recounting disability history, promoting advocacy and activism, revealing the intersections of disability and other kinds of identity, and interrogating traditional ideas about normalcy and looking.

Among the earliest groups formally to place the disability experience at the heart of their creative endeavors were the National Theatre of the Deaf, established in 1967; the National Theatre Workshop for the Handicapped, begun in 1977 under the direction of Brother Rick Curry; and the Other Voices Project, founded at the Mark Taper Forum in 1982 under Lewis's direction. While representative of diverse performance goals and creative styles, these groups have been joined by others working along similar lines. For example, Wry Crips Disabled Women's Theater (Oakland, California), Actual Lives (Austin, Texas), and the DisAbility Project (St. Louis, Missouri) have created dialogues about disability within their own communities. Many individual playwrights from within disability culture have likewise written plays which address diverse subjects; among the best known of these is John Belluso, whose work includes *Gretty Good Time* and *The Body of Bourne.* Mike Ervin and Susan Nussbaum are likewise playwrights of note who have written about physical disability, while Willy Conley has created plays about Deaf culture. Perhaps the most prolific and multivaried work within disability culture has come from solo performers. Monologists such as David Roche and Mary Duffy have challenged the idea of the stare, and criticized the imposition of a disability identity on themselves that is pathologized or writ tragic. Still other performers have explored the intersection of disability with race; Lynn Manning's *Weights,* for example, recounts his life as a blind African American man. And artists such as Cheryl Marie Wade have lyrically portrayed disability pride in bodily difference. Building on that last element, dance artists such as Catherine Cole and dance companies including AXIS have used the movement of the disabled body as a means of expression that invites audiences to see disabilities, in the words of disability and theater scholar Carrie Sandahl, as "states of being that are in themselves *generative* and, once de-stigmatized, allow us to envision an enormous range of human variety—in terms of bodily, spatial, and social configurations" (p. 22).

That final point marks cutting-edge thinking in disability drama and performance, as artists and scholars currently explore the idea of a disability aesthetic that would lead to a more broad re-envisioning of theater; after all, as Sandahl observes, "just as the disabled body challenges widely held beliefs about what constitutes the human form, disability theatre poses similar challenges to the form that theatre itself takes." Deaf/West Theater, for example, mounted its production of the musical *Big River* on Broadway in 2003, in which it integrated American Sign Language completely into the visual landscape of the performance itself. In playing with different configurations of signers and speakers, and of Deaf and hearing actors, the production not only disrupted the hierarchical relationship between speaking and signing extant in society, but it created a kind of choreography for the musical in which actors' bodies—whether Deaf or not—expressed in new ways. This and other uses of a "disability aesthetic" in contemporary direction, playwriting, and performance of all kinds posit the possibility that through a disability perspective, a more general broadening of our culture's understanding of representation and performance might be accomplished. In this way, performance—and ideally, the society that it reflects—would be thus reinvigorated by disabled people claiming their rightful place on the stage.

▣ DU PRÉ, JACQUELINE (1945–1987)

English musician

Jacqueline du Pré was born in Oxford, United Kingdom, on January 26, 1945, and died October 19, 1987, at age 42 She was diagnosed with multiple sclerosis (MS) in 1973.

Du Pré has been called the world's greatest cello player. At the height of her popularity, she worked with Sir John Barbirolli and the London Symphony Orchestra, Itzhak Perlman, Zubin Mehta, Pinchas Zuckerman, and Daniel Barenboim. Many music critics consider her interpretation of Elgar's *Cello Concerto in E Minor* to be the finest ever recorded. In 1967, she married Daniel Barenboim and in the glamour world of the 1960s, the couple achieved rock star iconic status. But her MS caused her much anxiety and grief. Her marriage with Barenboim collapsed as her condition deteriorated. In the public image, she was the ultimate beautiful disabled heroine touched by tragedy.

The film *Hilary & Jackie* is based on the book *A Genius in the Family* by du Pré's sister Hilary and her brother Piers. In the book, her decline into "madness" is chronicled, but people familiar with MS will instantly recognize the exhaustion, ambivalence toward work and career, depression, strange and numbing bodily sensations, lack of coordination, and incontinence. Thus, her life did have many tragic elements—the degeneration of her body confronted her continually with the loss of the powerful person she saw herself as being. Her life became a series of struggles in trying to retain her power, and as each element was eroded, she sought some other way to affirm herself. She was not a victim of MS but a passionate musician battling her impairments. These personal battles are as important for our understanding of disability as those more publicly known because they reveal her individual encounters with the realities of disabling societies—issues that received much less attention during her lifetime.

▣ DÜRER, ALBRECHT (1471–1528)

German artist

Albrecht Dürer, born on May 21, 1471, was the third of 18 children born to Albrecht Dürer, a goldsmith who had moved to Nuremberg, Germany, from the

Kingdom of Hungary, and Barbara Holfer, the daughter of Albrecht Dürer the Elder's master. Albrecht Dürer the Younger became a highly celebrated artist in Germany and many of the contemporary German humanists were his friends. To demonstrate their respect, the Germans chose Dürer as the first artist to have a public monument erected in his name and the first artist to have his home and tomb restored. Over the centuries he also became internationally known, especially throughout Europe, in the United States, and in Russia.

During his education and training, Albrecht Dürer learned a number of skills that later became highly valuable to him. After attending a Nuremberg school for a few years, at the age of 13 he went into an apprenticeship with his goldsmith father. Later he completed an apprenticeship with Michael Wolgemut where he learned to design landscape backgrounds, panel painting, and the craft of woodcut illustrations.

Throughout his life, Dürer had significant contact to individuals with health problems and with disabilities. First, it is noteworthy that most of his siblings did not survive beyond the first few years of life. Second, his brother Albert suffered from severe arthritis after having worked in a mine for four years to support Albrecht's training and education. In honor of his brother Albert, who had forfeited his own dreams of becoming an artist to support Albrecht, Dürer painted *The Hands,* which later was renamed as *The Praying Hands.* Third, after his father's death, Dürer became the caregiver for his disabled and blind mother.

DWARFISM

Dwarfism is a rare phenomenon that nevertheless seems to have occurred in every recorded human society, as evidenced by images and records from ancient Egypt, Greece, and Rome; Renaissance and Baroque Europe; the nineteenth-century freak show; and contemporary cinema. The role, status, and cultural representation of dwarfs have varied: While many have traditionally been employed as jesters, pages, or entertainers, others have been successful soldiers, diplomats, or even rulers. In the modern world, self-help groups or representative organizations tend to favor terms such as *restricted growth* (United Kingdom) or *little people* (United States) or *short stature* (Australia), rather than the word *dwarf.*

From a medical perspective, there are at least 200 separate forms of skeletal dysplasia, and short stature can also be a consequence of other syndromes. The most common cause of disproportionate short stature is achondroplasia, a dominant genetic condition involving a mutation in the FGFR3 gene that leads to the characteristic short arms and legs and different skull shape. Restricted growth affects approximately 1 in every 20,000 births, with around 60 percent occurring in average-height families. While rare forms of skeletal dysplasia are fatal, and in most others there can be medical complications such as sleep apnea and spinal stenosis, people with skeletal dysplasia do not usually experience intellectual impairment, shortened lifespans, or major health problems.

The growth of support groups and improving social acceptance has meant that most people with restricted growth now lead normal lives and achieve the same social goals as average-height people. For example, members of this community have worked as doctors, lawyers, politicians, businesspeople, academics, and teachers and in many other occupations. While the world is not configured well for people who average just over 4 feet, most environments can be negotiated independently.

Public fascination is perhaps the most debilitating problem for people with restricted growth. While making fun of other minorities is proscribed, laughter at the expense of dwarfs seems to remain socially acceptable. Traditional images of dwarfs—including the paintings of Velasquez and the Brother Grimm stories—are more dignified than the infantilized characters portrayed in Walt Disney's *Snow White and the Seven Dwarfs* and subsequent pantomimes.

Perhaps because of cultural devaluation, extensive limb lengthening (ELL) has been attractive to some families affected by skeletal dysplasia. Orthopedic surgeons can achieve increases of around 6 inches in height, using metal fixators on the legs, and sometimes the arms. The procedure is painful and expensive and immobilizes the patient for months or years during early adolescence. Controversy surrounds the practice, which is denounced by many adults with restricted growth. Human growth hormone (HGH) has also been prescribed to some affected children. While it brings on the growth spurt and changes the growth curve, there is doubt as to whether it contributes to any increase in adult height. Genetic screening is not viable for such a rare condition, and antenatal ultrasound rarely detects skeletal dysplasia in utero until the third trimester of pregnancy, which is too late for selective abortion in many jurisdictions. For these reasons, dwarfism will remain part of the human experience, and the emphasis should be on acceptance and inclusion.

DYBWAD, GUNNAR (1909–2001)

American (German-born) author and civil rights advocate

Gunnar Dybwad was born in Leipzig, Germany, on July 12, 1909, and received his doctor of laws degree in 1934 from the University of Halle in Germany. He also earned a degree from the New York School of Social Work in 1940. His career in special education and human services spanned eight decades. During that time, he was made a fellow in several prestigious professional organizations including the American Association on Mental Retardation, the American Sociological Association, the American Orthopsychiatric Association, and the American Public Health Association. He was also an honorary fellow in the American Academy of Pediatrics.

Dybwad published several books and monographs in the field of mental retardation. In addition, his work has been published in more than 20 journals including the *Journal of Rehabilitation*, *CHILDREN*, *International Rehabilitation Review*, *Policy Studies Review*, *Journal of Rehabilitation in Asia*, and *International Journal of Religious Education*.

He was executive director of the National Association for Retarded Children from 1957 to 1964, served as a consultant to President John F. Kennedy's Presidential Panel on Mental Retardation, and was an expert witness in several landmark court cases in educational rights and institutional abuse, including *Mills v. Board of Education* and *Wyatt v. Stickney*.

He and his wife Rosemary were instrumental in the formation of the International League of Societies for Persons with Mental Handicap, which later became Inclusion International. He was president of Inclusion International from 1978 to 1982.

Dybwad was twice recognized with honorary doctorates: first a doctor of humane letters from Temple University in 1977 and then doctor of public services from the University of Maryland.

Dybwad's academic career included professor of human development at Brandeis University from 1967 to 1974, visiting professor at Syracuse University, and visiting scholar at the Canadian Institute on Mental Retardation.

Dybwad was at the center of the development of thoughts that are now taken for granted: normalization, deinstitutionalization, inclusive schooling, self-advocacy, and self-determination. Considered by many to be the grandfather of the self-advocacy movement, Dybwad worked in support of self-advocacy literally until his death September 13, 2001, at age 92.

DYBWAD, ROSEMARY F.

(1910–1992)

American author and civil rights advocate

Rosemary F. Dybwad was born on May 12, 1910, in the town of Howe, Indiana. The daughter of a missionary, she spent her teen years in Manila, Philippines. She spent her college years in Oxford, Ohio, at Western College for Women where friendships with international students led her to apply for a fellowship with the Institute of International Education.

She was a graduate student in sociology at the University of Leipzig from 1931 to 1933. During those years, she met Gunnar Dybwad and in 1934 they were wed and returned to the United States briefly. In 1935, she entered the University of Hamburg, receiving her doctorate in 1936. In 1939, she gave birth to their son, Peter, and 1941 their daughter, Susan. She was as proud of her accomplishments as a mother as she was of her work as a scholar and an advocate.

When her husband became director of the National Association for Retarded Children in 1957, Rosemary volunteered to assist with the voluminous international correspondence as similar parent groups were forming all across the globe. She began an international newsletter and became a driving force in the establishment of the International League of Societies for Persons with Mental Handicap.

In 1964, Rosemary and Gunnar became codirectors on an international mental retardation project in Geneva, which took them as consultants to some 30 countries. Upon returning to the United States, she began publishing an international directory of mental retardation resources. The third and final edition was published in 1989.

In her later years, she was a tireless advocate, supporter of self-advocates, and social change agent, spending time on picket lines, in demonstrations, and writing and speaking in support of self-advocates and in opposition to segregation.

Rosemary F. Dybwad died of cancer in 1992. Her memory lives on in the Rosemary F. Dybwad International Fellowship Trust Inc., which supports international travel for scholars and self-advocates.

DYSARTHRIA

Dysarthria is primarily a medical term. It is used to describe speech that is difficult to produce and/or difficult to understand as the result of lesions or damage to the nerves that send messages to the muscles involved in speech production. This includes the muscles for articulation or pronunciation (such as lips, tongue, jaw) as well as the muscles controlling nasality, phonation, and respiration. The muscles may be weak, be uncoordinated, move slowly, or not move at all. People with dysarthria may also have difficulty swallowing.

People may be born with dysarthria (such as individuals with cerebral palsy or muscular dystrophy). It may also result from a stroke, brain injury, tumor, infection, or a progressive neuromotor disease, such as Lou Gehrig’s disease (amyotrophic lateral sclerosis; ALS), multiple sclerosis, or Parkinson’s disease.

Dysarthria can be characterized in many different ways depending on the extent and location of the lesion. It may be localized, affecting only one muscle or muscle group (such as only respiration) or it may be generalized affecting many components, respiration, nasality, and phonation as well as articulation. People with dysarthria may experience limited lip, tongue, and jaw movement, slurred speech, slow speech or rapid mumbled speech, soft or inaudible speech, breathiness, hoarseness, and drooling.

People with dysarthria (primarily adults with cerebral palsy) report that they are often mistaken for "retarded" or deaf. If someone is unable to understand them, they may walk away, talk loudly, or talk to others about them.

Some people with dysarthria choose therapy to learn compensatory strategies for improving swallowing, improving the functionality, intelligibility of their speech or to learn augmentative, alternative methods of communication. To improve the functionality, intelligibility of their speech, someone may learn to talk slower and more deliberately. Also, communication partners may learn listening strategies (e.g., choose a quiet place, let the person know what part of the message you understood and parts you need clarified). Some people choose to use communication aids. If someone has difficulty producing adequate volume for speech, he or she may benefit from a speech amplifier. To clarify speech, people may learn to use letter or word boards to introduce the topic they want to talk about and/or to point to the initial letter of each word they say as they speak. People unable to produce speech may also consider an electronic augmentative communication device with voice output so that they can communicate on the phone and talk to unfamiliar people.

DYSLEXIA

Dyslexia is characterized by an unexpected difficulty in reading in children and adults who otherwise possess the intelligence, motivation, and schooling considered necessary for learning to read. Dyslexia is the common and most comprehensively studied of the learning disabilities (LD). The prevalence of dyslexia is now considered to range between 5 to 10 percent of the school-age population.

The cardinal signs of dyslexia observed in school-age children are an inaccurate and labored approach to decoding and reading words either in isolation or in text. For example, when asked to read aloud, most children with dyslexia display a labored approach to decoding ("sounding out") unfamiliar words. This laborious and slow approach to reading words makes it difficult to understand what is read. This is because the more time spent in reading words the less time can be dedicated to remembering what is read. Typically, in contrast to the difficulties experienced in decoding single words, individuals with dyslexia have adequate vocabulary and listening comprehension abilities. Indeed, one sign of dyslexia is that the individual who has difficulty comprehending what is read because of labored reading can understand the same material when it is read aloud by another person. Parents of dyslexics frequently report that although their child enjoys the opportunity to be read to, reading aloud to the parent or reading independently is resisted.

In contrast to conventional wisdom, individuals with dyslexia do not see letters and words "backwards." The letter reversals that are observed in some children below age six or seven reflect normal variations in development. Persistent difficulties reading words and text, with or without letter reversals, are caused primarily by circumscribed language difficulties rather than deficits in visual perception. Rather, dyslexics have difficulties developing an understanding that words, both spoken and written, can be segmented into smaller elements of sound. This ability is termed *phonemic awareness* and is an essential ability given that reading an alphabetic language (i.e., English) requires that the reader map or link printed symbols to sound.

Children at risk for dyslexia can be identified as early as five years of age. Kindergarten assessments that measure awareness of phonemes and other language skills, such as rhyming ability and the rapid naming of letters and numbers, are highly predictive of later reading difficulties. Family history is also important in the diagnosis of dyslexia. Approximately half the children with a parent with dyslexia will also have reading difficulties. However, the specific mechanisms by which genetic factors predispose someone to dyslexia are not clear.

Effective intervention programs for school-age children with dyslexia provide direct, explicit, and systematic instruction in phonemic awareness, phonics, reading fluency, vocabulary, and reading comprehension strategies and ample opportunities for writing and reading. The teacher's knowledge and experience in assessing and treating dyslexia are critical.

The treatment of dyslexia in students in high school, college, and graduate school is typically based on accommodation rather than remediation. College students with a childhood history of dyslexia frequently require extra time in reading and writing assignments as well as examinations. Other accommodations include the use of laptop computers with spelling checkers, tape recorders in the classroom, access to lecture notes, tutorial services, alternatives to multiple-choice tests, and a separate and quiet room for taking tests.

DYSPHAGIA

Dysphagia, or difficulty swallowing, is a common condition with many etiologies, including stroke, neurological disorders, and cancer. Dysphagia may cause malnutrition, weight loss, dehydration, airway obstruction, or aspiration pneumonia, resulting in potentially serious morbidity or mortality. Dysphagia due to oral or pharyngeal dysfunction is often amenable to rehabilitation and is the focus of this discussion.

Swallowing requires activity of 31 muscles and 6 cranial nerves and must be coordinated with breathing, speaking, and mastication. For descriptive purposes, the process of swallowing is commonly divided into four phases: oral preparatory, oral propulsive, pharyngeal, and esophageal. The oral preparatory phase includes mastication and oral food transport. In the oral propulsive phase, the tongue squeezes the food against the palate, pushing it through the faucial pillars into the oropharynx. In the pharyngeal phase, the bolus is transported to the esophagus during a rapid sequence of events that includes tongue base retraction, soft palate elevation, pharyngeal constriction, hyolaryngeal elevation, laryngeal closure, and opening of the upper esophageal sphincter (UES). During the esophageal phase, the bolus is transported downward by a peristaltic wave; the lower esophageal sphincter relaxes, allowing the bolus to enter the stomach.

Clinical evaluation of swallowing requires a comprehensive history and physical examination that includes assessment of cognition, voice, speech, cranial nerves, oral sensory and motor function, respiration, and trial swallows. If esophageal dysphagia is suspected, a routine barium swallow or endoscopy is generally indicated. The videofluorographic swallowing study or VFSS (also known as the modified barium swallow) is the "gold standard" for assessment of oral/pharyngeal dysphagia. This study is typically performed jointly by a physician (usually a radiologist or a physiatrist) and a speech-language pathologist. The purpose of the VFSS is to evaluate the structure and function of the oral cavity and pharynx. If aspiration is noted, compensatory maneuvers to reduce or eliminate aspiration are tested empirically during the VFSS, to determine the circumstances for safe and efficient swallowing. Fiberoptic endoscopic evaluation of swallowing (FEES) is often used to assess swallowing when VFSS is not feasible. Although it is a sensitive method for detecting aspiration, the FEES is less useful than VFSS because it omits assessment of critical aspects of the swallow (e.g., tongue base retraction, opening of the UES).

Rehabilitation of swallowing disorders aims at eliminating aspiration, improving oral intake so it is safe and adequate to maintain hydration and nutrition, and improving sensory and motor function to optimize the strength and speed of the swallow mechanism. Therapeutic exercises may address deficits in flexibility, strength, and coordination of oral, pharyngeal, and laryngeal structures. Compensatory maneuvers such as alterations in head position, respiration, or food consistency may eliminate aspiration and improve swallow efficiency. Designing the rehabilitation program requires understanding the underlying cause of the dysphagia and its unique manifestations in the individual with dysphagia.

CHRONOLOGY

1500 BCE Egypt: The Ebers Papyrus, a medical textbook, devotes an entire chapter to eye diseases. It also shows that deafness is well understood and that clinical knowledge has developed.

400 BCE Graeco-Anatolian Hippocratic writings coin the word e*pilepsy* for a convulsive condition they view as a disease rather than a possession or punishment. Today, it is estimated that more than 80 percent of the 40 million people who currently have epilepsy throughout the world have little access or no access to contemporary treatments.

300 BCE China: *The Yellow Emperor's Internal Classic* is the first text to outline acupuncture. Ordinances on emergency relief for the disabled date to the Han Dynasty, 206 BCE–AD 220. Fiscal and administrative disability classification date at least to the Tang Dynasty, 618–907.

1250–1350 High point of medieval medicalization during which theoretical explanations for conditions gain currency in Western Europe. Prior to this time, in the most general of terms, lay explanations held more sway, ranging from the superstitious to the spiritual to the vindictive. With the founding of the universities, medical theory, typified by the four humors, became more influential in governmental, legal, and elite social circles. Disabling conditions like epilepsy, strokes, and paralyses, as well as psychiatric conditions, increasingly fell under the social control of doctors.

1400 Turkey: Deaf people work in the Ottoman Court from the 15th to the 20th centuries. Sign language becomes a recognized means of communication among both hearing and deaf courtiers.

1593 England: The origins of disability as a social and political category emerge with the first state disability benefits being enacted by Parliament for those disabled in war.

1593 Europe and the United States: English Parliament initiates Europe's first national system of benefits for rank-and-file disabled veterans. The first veterans' homes—France's Hôtel des Invalides, Britain's Chelsea Hospital, and Frederick the Great's Invalidenhaus in Berlin—are established in 1633, 1685, and 1748, respectively. Following the American Civil War, the U.S. government responds with a system of homes, preferences in government hiring, land grants, free prosthetics, and pensions for disabled veterans (however, southern veterans were limited to usually scanty state pensions).

1601 England: The Poor Law is passed to provide family and community support for those unable to make a living for themselves.

1604 Laws on witchcraft in the colonies all evolve from a 1604 English Statute that makes "being a witch" punishable by death. During outbreaks of witch-hunting, the "different" body itself is targeted as a sign and symptom of one's confederation with demonic forces.

1697 England: The first English workhouse for people with mental and physical disabilities is established in Bristol in 1697.

1704 Bethlem Hospital in the United States has 130 residents housing the "furiously mad."

1714 Canada: The Bishop of Quebec opens the first building in Canada exclusively for the confinement of mentally disturbed individuals. It is adjacent to Quebec General Hospital.

1749 France and England: Denis Diderot pens one of the most influential treatises on the blind and education in his *Letter on the Blind* in which he argues that the blind can be educated. In 1784, Valentin Haüy opens the first school for the blind in Paris. He perfects a system of raised *letters* to enable the blind to read. In 1828, Louis Braille modifies a raised *dot* system invented by Charles Barbier, which is used today by blind persons to read and communicate. In 1847, William Moon, an Englishman, develops an embossed script based on Roman capitals that blind adults can learn to read in a few days. It is the first reading system for the blind to be widely adopted across the world, but because it is costly to print, the Braille system, which can be produced by blind individuals for themselves, overtakes Moon's system.

1755 France, the United States, and Germany: The Abbé Charles-Michel de l'Épée establishes the first state-supported school for the training of young deaf children, where he teaches sign language. The school serves as an inspiration for the establishment of other European schools and has a dramatic impact on social attitudes toward the deaf. In 1817, Thomas Gallaudet and Laurent Clerc establish the Asylum for the Deaf (now American School for the Deaf) in Hartford, Connecticut. Clerc imports the French sign system, which influences the makeup of contemporary American Sign Language (ASL). In 1778, Samuel Heinicke establishes a school in Leipzig, Germany, where the "oral method" is used.

1800 France: Victor of Aveyron, a "feral child" found in southern France, is brought to Paris. Jean Marc Gaspard Itard, a French physician, develops a systematic training program for the boy and works intensively with him for five years. Itard considered his attempt at educating Victor to be a failure because the boy did not learn to use a language. Nevertheless, Itard's disciples, including Edouard Séguin, Maria Montessori, and Alfred Binet, continue his work by establishing classes for children considered to be "mentally retarded."

1802 France: The world's first pediatric hospital, L'Hôpital des Enfants Malades, is founded.

1817 The American School for the Deaf is founded in Hartford, Connecticut. It is the first school for disabled children in the Western Hemisphere.

1817 James Parkinson, a London physician, describes what is to become known as Parkinson's disease.

1817 Thomas Gallaudet and Laurent Clerc open the American Asylum for the Education of the Deaf and Dumb in Hartford, Connecticut.

1828 Frenchman Louis Braille, blind from childhood, modifies a raised-dot system of code, one of the most important advances in blind education. It not only allows the blind to read at a much faster rate but also makes it possible for the blind to be teachers of the blind. UNESCO creates the World Braille Council in 1952.

1829 France: Louis Braille publishes an explanation of his embossed dot code.

1832 Samuel Gridley Howe is chosen to direct what is later to be called the Perkins School for the Blind in Boston. It becomes the model for schools around the nation. Laura Bridgman and Helen Keller attend Perkins. In 1837, Ohio establishes the first state-sponsored school for the blind.

1834 England: The English Poor Law Amendment stipulates five categories of those unable to work: children, the sick, the insane, defectives, and the aged and infirm. This sets the stage for the development of specialty institutions that isolate the disabled from the community.

1841 P. T. Barnum purchases Scudder's American Museum in New York City. This moment is considered to be the beginning of the "Golden Age" of freaks, which persists until the 1940s. The tension

between freaks and disability rights comes to a head in 1984, when disability rights activist Barbara Baskin successfully lobbies the New York State Fair to remove Sutton's Incredible Wonders of the World Sideshow, featuring a limbless man who performs as the "Frog Boy," from the midway.

1843 Due to the influence of Dorothea Dix, an American social reformer, the Massachusetts legislature allocates funds to greatly expand the State Mental Hospital at Worcester. Dix also plays an instrumental role in the creation of 32 mental hospitals and becomes nationally known for her reform efforts. By the late 1840s, Dix focuses on developing a national plan that addresses the treatment of people with mental illness.

1846 William Thomas Green Morton discovers anesthesia and in 1867 Joseph Lister provides a model for antisepsis. These new technologies play a central role in the future of aesthetic surgery as well as surgical intervention for every type of disability that calls for it. Penicillin is discovered in 1929, cutting mortality rates in hospitals dramatically.

1848 The North Carolina School for the Deaf begins the first publication for Deaf persons with its school newspaper, *The Deaf Mute.* First published in 1907, the *Matilda Ziegler Magazine for the Blind* is an ongoing Braille publication.

1848 Samuel Gridley Howe founds the first residential institution for people with mental retardation at the Perkins Institution in Boston.

1851 In the United States there are 77 residential institutions for children, 1,151 by 1910, and 1,613 by 1933. By the 1950s and 1960s, family members and politicians throughout Western Europe, Canada, and the United States push for the deinstitutionalization of people with disabilities.

1851 The first International Sanitary Conference is held in Paris, France, with 12 countries participating. It leads to the World Health Organization, the WHO, which formally comes into existence in 1948.

1857 Edward Miner Gallaudet, youngest son of Thomas Hopkins Gallaudet, establishes the Columbian Institution for the Instruction of the Deaf, Dumb, and Blind, located in Washington D.C. Its college division, eventually known as the National Deaf-Mute College, is the world's first institution of higher education for deaf people. Abraham Lincoln signs its charter on April 8, 1864; today it is known as Gallaudet University.

1857 English philosopher Herbert Spencer is first to use the expression "survival of the fittest." The application of his idea in combination with Charles Darwin's theories in his 1859 book, *The Origin of the Species,* is called Social Darwinism. It is widely accepted and promoted in Germany in the 1920s and leads Adolf Hitler to express prejudice against the weak, sick, and disabled.

1863 Louis Agassiz, a significant American naturalist, advocates the permanence of different races and worries about the "tenacious influences of physical disability" if races were mixed.

1864 Germany: Karl Ferdinand Klein, teacher for deaf-mutes, and Heinrich Ernst Stotzner are considered the founding fathers of the *training school,* which calls for schools to be created for less-capable children with the goal of improving their lot. Training schools remain in effect today, but critics maintain that there is an over-representation of socially and economically underprivileged students in this type of setting experiencing little academic success.

1868 Sweden: The Stockholm Deaf Club is the first recorded organization of people with disabilities.

1870 England and Wales: Education for children with disabilities begins when universal elementary education is first introduced around this time. From 1895 onward, schools for "defective" children spring up. In 1899, Alfred Eichholz, an inspector of special education, draws up key recommendations, which leave their mark on the historic 1994 Education Act legislation. In 1978, the Warnock report

introduces the term *special needs education,* which soon gains acceptance worldwide. With the 1994 UNESCO Salamanca Statement and Framework for Action on Special Needs Education, a major shift in organizing educational services for children with disabilities is confirmed internationally.

1876 ◆ Isaac Newton Kerlin, Edouard Séguin, and others establish the Association of Medical Officers of American Institutions for the Idiotic and Feeble-Minded Persons. Today, it is known as the American Association on Mental Retardation. Séguin, who staunchly believes in the educability of those with significant cognitive disabilities, is styled as "apostle to the idiots," by Pope Pius X, reflecting the attitude of the time.

1880 ◆ The United States National Association of the Deaf (NAD), the first organization of deaf or disabled people in the Western Hemisphere, is established. In 1964, the Registry of Interpreters for the Deaf (RID) is formed to establish a national body of professionals who are trained and certified to enable communication between deaf, signing persons and nondeaf, speaking persons.

1880 ◆ Helen Keller is born in Tuscumbia, Alabama. An illness at the age of 19 months leaves her totally deaf and blind. In 1887, Anne Sullivan, recently graduated from Perkins Institution for the Blind, joins the Keller household as Helen's teacher and remains Keller's companion for nearly 50 years. For many, Keller's story is the quintessential overcoming narrative.

1881 ◆ The Chicago City Council enacts the first American "ugly law" forbidding "any person, who is diseased, maimed, mutilated or deformed in any way, so as to be an unsightly or disgusting object, to expose himself to public view."

1882 ◆ The first major federal immigration law in the United States, the Immigration Act of 1882, prohibits entry to "lunatics," "idiots," and persons likely to become unable to take care of themselves. Most of the restrictions that apply specifically to disability are removed from U.S. law in 1990. Today, disabled immigrants are still denied an entry visa if they are deemed "likely to become a public charge."

1887 ◆ Walter Fernald serves as superintendent of the Massachusetts School for the Feeble-Minded (now known as the Fernald Center) from 1887 to 1924. Unlike most of his colleagues, Fernald moderates some of his earlier extreme views and eventually develops one of the country's largest "parole" systems for moving institutional residents back into smaller, community-based residences.

1887 ◆ The American Orthopaedic Association is founded. German and British counterparts are founded in 1901 and 1918, respectively.

1895 ◆ The chiropractic profession is founded. This type of care is used to relieve musculoskeletal pain, one of the most common causes of disability.

1899 ◆ Maria Montessori and a colleague open the Scuola Magistrale Ortofrenica in Rome, an educational institute for disabled children and a training institute for instructors. Her method relies on the concept of sensory-based instruction as a means for developing intellectual competence. Her methods allow the child the greatest possible independence in order to foster his or her own development (the child's own inner "building plan").

1904 ◆ Sir Francis Galton, half first cousin of Charles Darwin, defines the term e*ugenics* (which he coined in 1883) in a paper he presents to the Sociological Society on May 16. He argues for planned breeding among the "best stock" of the human population, along with various methods to discourage or prevent breeding among the "worst stock." Galton also develops the idea for intelligence tests. The term *feeblemindedness* is defined as broadly as possible and is widely used by eugenic social reformers to conflate myriad social problems. Further naming, classification, and labeling provides eugenicists with a troubling rationale for treating people with coercion, disrespect, and profound inhumanity. Persons within the various categories of sub-normality become particularly vulnerable

to state-sanctioned segregation, institutional confinement, and enforced sterilization. Eugenics is widely practiced in Europe, the United States, and Canada, culminating in the systemic murder of more than 260,000 disabled people by the Nazis between 1939 and 1945. Today, the so-called new eugenics, known as "human genetics," appeals to the needs of the individual. Critics (some of the first in Germany), however, criticize individualistic eugenic approaches and disclose the connections between human genetics, national socialist racial hygiene, and eugenics.

1905 Alfred Binet and Theodore Simon publish the first intelligence scale, known as the Binet-Simon Test.

1908 The publication of Clifford Beers's *A Mind That Found Itself* initiates the mental health hygiene movement in the United States. Speaking out against mistreatment and neglect within the system, Beers establishes the Connecticut Committee of Mental Hygiene, which expands in 1909, becoming the National Committee for Mental Hygiene and is now known as the National Mental Health Association. In 1940 there are 419,000 patients in 181 state hospitals. In 1943, the patient-doctor ratio is 277:1, and by the mid-1950s in New York state alone, there are 93,000 inpatients. The Bazelon Center for Mental Health Law, founded in 1972 by a group of committed lawyers and professionals in mental health and mental retardation, attempt to improve mental health service provision through individual and class action suits. In 1980, a group of these lawyers form the National Association of Rights Protection and Advocacy (NARPA). One-third of its board of directors must identify themselves as current or former recipients of mental health care. The association is committed to the abolishment of all forced treatment.

1908 Pastor Ernst Jakob Christoffel establishes a home in Turkey for blind and otherwise disabled and orphaned children. This grows into Christoffel-Blindenmission (CBM), an independent aid organization of Christians of various denominations united to help disabled people in third world countries. Today, it supports more than 1,000 development projects in 108 countries. In 1999, CBM, other agencies, and the World Health Organization initiate VISION 2020: The Right to Sight, a global initiative for the elimination of avoidable blindness by the year 2020.

1909 Germany: The German Organization for the Care of Cripples is created as an umbrella organization for the care of the physically disabled. The Prussian Cripples' Care Law of 1920 for the first time provides a right to medical care and scholarly and occupational education for this group.

1912 Henry H. Goddard publishes *The Kadikak Family,* supports the beliefs of the eugenics movements, and helps create a climate of hysteria in which human rights abuse of the disabled, including institutionalization and forced sterilization, increases. In 1927, the U.S. Supreme Court, in *Buck v. Bell,* rules in favor of forced sterilization of people with disabilities, further fueling eugenics movements—the number of sterilizations increases.

1914 By this date, Sigmund Freud develops his most enduring influence on the study of disability, namely, the theory of psychosomatic illness in which a psychopathological flaw is given corporeal form as a symptom, thereby establishing the notion that people succumb to disease or disability because they feel guilty about past or present repressed desires.

1918 The Smith-Sears Veterans Rehabilitation Act passes, authorizing VR services for World War I veterans. In 1916, the National Defense Act marks the beginning of the U.S. government's supportive attitude toward rehabilitation. In 1920, the Smith-Fess Act marks the beginnings of the civilian VR program. The Social Security Act of 1935 establishes state-federal VR as a permanent program that can be discontinued only by an act of Congress.

1919 Edgar "Daddy" Allen establishes what becomes known as the National Society for Crippled Children. In the spring of 1934, the organizational launches its first Easter "seals" money-making campaign. Donors place seals on envelopes containing their contributions. The seal is so well-known that it

becomes part of the organization's official name. Today, Easter Seals assists more than one million children and adults with disabilities and their families annually through a nationwide network of more than 500 service sites. During the 1920s, Franklin D. Roosevelt inspires the March of Dimes.

1920 At about this time, the Shriners open hospitals for the care of crippled children. President Herbert Hoover establishes a "Children's Charter" in 1928 highlighting the need to attend to the needs of crippled children.

1921 Franklin D. Roosevelt contracts poliomyelitis. Despite damage to his legs (which makes him a wheelchair user) and deep depression, through enormous rehabilitative effort, he eventually re-enters politics and becomes president of the United States. His triumph over personal disability becomes legendary. Critics, however, fault him for choosing to minimize his disability in what is called his "splendid deception." He establishes a center for the treatment of polio patients in Warm Springs, Georgia, called the Georgia Warm Springs Foundation (1927), which hires medical specialists from Atlanta to direct orthopedics. In 1937, President Roosevelt becomes the prime mover behind the National Foundation for Infantile Paralysis Research.

1921 Mary L. McMillan (Molly) establishes the American Women's Physical Therapeutic Association, which is known today as the American Physical Therapy Association (APTA).

1921 The American Foundation for the Blind is established.

1921 Canada: Researchers isolate the hormone insulin. In 1922, Frederick Banting, Charles Best, J. B. Collip, and J.R.R. Macleod produce and test the pancreatic extract on people with diabetes, for which they are awarded a Nobel Prize. Insulin becomes a wonderful treatment for diabetes, but not a cure.

1921 France: Three historical waves of advocacy movements can be identified beginning with the National Federation of Injured Workers (FNAT) in 1921 and other organizations that focus essentially on the protection of rights. Another factor that stimulates advocacy groups in the first wave is the wounded veterans of World Wars I and II. A second wave dates from the period after World War II. Many advocacy groups form between 1950 and 1970, such as the Union of Associations of Parents of Maladjusted Children (UNAPEI) in 1960. A third wave finds a gradual emergence of three types of associations: those that run specialized facilities (for example, Living Upright, which, in 1970, leads to the creation of the first group living facility); those interested in trade unions; and those represented by user-advocate associations. Financing comes in large part from public funds, thereby creating a government-association partnership.

1922 The founding of Rehabilitation International sets the stage for the establishment of other international organizations of and for people with disabilities that link together throughout the world. Later international organizations include, among numerous others, the World Federation of the Deaf (1951), Inclusion International (1962), the International Association for the Scientific Study of Intellectual Disability (1964), Disabled Peoples' International (1981), and the International Disability Alliance (1999).

1925 The American Speech-Language-Hearing Association, today the American Academy of Speech Correction, is established to provide high-quality services for professionals in speech-language pathology, audiology, and speech and hearing science, and to advocate for people with communication disabilities.

1928 Charles Nicolle is the first deaf person to be awarded a Nobel Prize.

1929 Seeing Eye establishes the first dog guide school in the United States.

1930 The Veterans Administration is created to administer benefits, promote vocational rehabilitation, and return disabled veterans to civil employment. There is a record of provision for disabled veterans in the United States since the Revolutionary War and the Civil War. After World War I, three agencies administer veteran's benefits.

1932 ◆ Herbert A. Everest, a mining engineer with a disability, and Harry C. Jennings collaborate to design and patent the cross-frame wheelchair, which becomes the standard for the wheelchair industry that exists today. Developed during World War I, the first powered wheelchair appears, but doesn't gain popularity for another 30 years.

1935 ◆ President Franklin D. Roosevelt signs the Social Security Act of 1935 on August 14. Beginning in 1956, SSA amendments provide disability benefits.

1935 ◆ By 1935, in the United States more than 30 states pass laws allowing for the compulsory sterilization of those deemed genetically unfit in state and federal institutions. By 1970, more than 60,000 people are sterilized under these laws.

1935 ◆ As a result of being denied participation in the Works Progress Administration (WPA), six young people with disabilities hold a sit-in at the offices of New York City's Emergency Relief Bureau, demanding jobs in non-segregated environments and explicitly rejecting charity. The League of the Physically Handicapped is born out of this activism and operates in New York from 1935 to 1938. The League identifies social problems that remain issues today.

1935 ◆ Peer support in the United States is traced to the establishment of Alcoholics Anonymous in this year. Interest in peer support increases in the 1960s and is adopted by the disabled community. Movements, such as the Center for Independent Living, and groups, such as the National Spinal Cord Injury Association, make peer support one of their major activities.

1936 ◆ The American Academy of Physical Medicine & Rehabilitation is founded, leading to the approval of the American Board of Physical Medicine & Rehabilitation by the American Medical Association in 1947.

1937 ◆ The Fair Housing Act of 1937 passes with a mandate to assist the poor, a group that includes people with disabilities, by creating public housing. However, it is not until the Rehabilitation Act of 1973 that housing law specifically deals with discrimination faced by individuals with disabilities in housing programs that receive federal funding. The 1988 amendment to the Fair Housing Act of 1968 extends protection for people with disabilities beyond those of Section 504 of the Rehabilitation Act to include private housing.

1939 ◆ The Nazi regime institutes the Aktion T4 program in Germany. Children and, later, adults with disabilities are selectively killed both in hospitals and in special centers. The program was officially terminated by Adolf Hitler in August 1941, but practitioners "informally" continued it through a phase historians have called "wild euthanasia."

1940 ◆ State activists for the blind, including Jacobus Broek, come together in Wilkes-Barre, Pennsylvania, to charter the National Federation of the Blind (NFB). In 1957, the NFB publishes the first edition of the *Braille Monitor,* which is still in print today. In 1960, dissatisfied NFB members form the American Council of the Blind (ACB).

1940 ◆ Paul Strachan establishes the American Federation of the Physically Handicapped, the nation's first cross-disability, national political organization.

1942 ◆ The American Psychiatric Association develops a position statement in favor of the euthanasia of children classified as *idiots* and *imbeciles.*

1943 ◆ The LaFollette-Barden Act, also known as the Vocational Rehabilitation Amendments, adds physical rehabilitation to federally funded vocational rehabilitation programs.

1943 ◆ The United Nations is established on October 24 by 51 countries. The global Programme on the Disability is the lead program concerning disability. Many other types of programs, activities, and instruments include the 1975 Declaration on the Rights of Disabled Persons, the 1981 International Year of

Disabled Persons, the 1982 World Programme of Action Concerning Disabled Persons, the 1983–1992 UN Decade of Disabled Persons, and the 1993 Standard Rules on the Equalization of Opportunities for Persons with Disabilities. In 1988, the first UN Disability Database (DISTAT) publishes statistics from 63 national studies covering 55 countries and the 2001 publication presents 111 national studies from 78 countries, indicating a growing interest worldwide for the collection of usable data. In 2005, a UN Ad Hoc Committee continues to consider a Convention on the Rights of Disabled Persons that is a legally binding human rights instrument. Today the UN membership totals 191 countries.

1943 ◆ Sweden: In possibly the first reference to the concept of normalization, the most significant driving force in the ongoing closure of state-run or state-funded institutions for people with a disability is made by the Committee for the Partially Able-Bodied, established by the Swedish Government. Through the advocacy of people such as Niels Erik Bank-Mikkelsen, normalization, with its profound positive effect on the lives of people who were once removed and segregated from society, remains relevant today.

1944 ◆ Richard Hoover invents long white canes known as Hoover canes that are used by many blind people.

1944 ◆ The word *genocide* first appears in a book by a Polish lawyer Raphael Lemkin titled *Axis Rule in Occupied Europe* in which he describes Nazi Germany's practices but also seeks the adoption of legal restrictions so that genocide will not occur. In 1948, the United Nations adopts a declaration and then a convention on genocide that describe both against whom genocide might be directed and acts constituting genocide. Article 6 of the Rome Statute of the International Criminal Court (ICC), established in 2002, uses language identical to that in the UN convention to define genocide. More than 90 countries are parties to the ICC, but not the United States.

1945 ◆ President Harry Truman signs into law an annual National Employ the Handicapped Week. In 1952, it becomes the Presidents' Committee on Employment of the Physically Handicapped, a permanent organization, which reports to the President and Congress.

1945 ◆ Canada: Lyndhurst Lodge, the first specialized rehabilitation center for spinal cord injury (SCI) in the world, and the Canadian Paraplegic Association, the first association in the world administered by individuals with SCI, are established.

1946 ◆ The first chapter of what will become the United Cerebral Palsy Association, Inc. is established in New York City. It is chartered in 1949, and along with the Association for Retarded Children, it becomes a major force in the parents' movement of the 1950s.

1946 ◆ The National Mental Health Foundation is founded by attendants at state mental institutions who aim to expose abusive conditions. Their work is an early step toward deinstitutionalization.

1946 ◆ The National Institutes of Mental Health (NIMH) are founded in the United States.

1946 ◆ Europe: The European Union is founded on September 17 in Paris. It consistently shows its commitment to eliminating discrimination on many fronts through joint declarations, resolutions, directives, and action programs. With regard to disability, the European Union supports actions in favor of people with disabilities, principally in the form of European Social Fund interventions. Action programs aim at facilitating the exchange of information between member states and nongovernmental organizations with a view to identifying good practices, integrating people with disabilities into society, and raising awareness of related issues. The EU Council of Ministers Recommendation on the Employment of Disabled People (1986) calls on member states to "eliminate negative discrimination by reviewing laws, regulations and administrative provisions to ensure that they are not contrary to the principle of fair opportunity for disabled people." Further

steps are taken in 1996 when a communication on equality of opportunities for disabled people sets out a new European disability strategy that promotes a rights-based approach, rather than a welfare-type approach. This is strengthened in 1997 when the heads of state act to strengthen Article 13 of the European Community Charter of Fundamental Social Rights of Workers (1989), giving the European Community specific powers to take action to combat a broad spectrum of discrimination that includes disability.

1948 ◆ The National Paraplegia Foundation is established as the civilian branch of the Paralyzed Veterans of America.

1948 ◆ The World Health Organization is established. The WHO actively promotes human rights and the principle of equity in health among all people of the world, including persons with disabilities. Today it consists of 191 member states, but strives for universal membership. In 1980, the WHO publishes the International Classification of Impairments, Disabilities, and Handicaps (ICIDH) and issues a revised version in 2001, the International Classification of Functioning, Disability, and Health (ICF).

1948 ◆ The United Nations General Assembly adopts the "Universal Declaration of Human Rights," which promotes and affirms the fundamental rights to life, liberty, and security; to medical care and social services; and to the benefit from scientific progress and its uses.

1948 ◆ Sir Ludwig Guttmann organizes the first Stoke Mandeville (England) Games for the Paralysed, thus launching the Paralympic movement. The Games become international in 1952. In 1960, the first Paralympic Summer games are held in Rome and the first Paralympic Winter Games follow in 1976. The Paralympic Games are multi-disability, multi-sport competitions and have become the second-largest sporting event in the world, only after the Olympic Games.

1948 ◆ World War II bomber pilot and war hero Leonard Cheshire establishes what is to become the largest charitable supplier of services for disabled people in the United Kingdom. In the 1960s, the resistance of disabled people who live in one Leonard Cheshire home, Le Court, plays a major role in establishing the British disabled people's movement. In the late 1990s, the Leonard Cheshire organization establishes the Disabled People's Forum, which is run by disabled people and supports disabled people's involvement and empowerment.

1949 ◆ Timothy Nugent founds the National Wheelchair Basketball Association, and the first Annual Wheelchair Basketball Tournament takes place.

1949 ◆ Europe: The Council of Europe, an intergovernmental organization, is founded. Its activities cover all major issues facing European society other than defense. Human dignity, equal opportunities, independent living, and active participation in the life of the community form the heart of the Council of Europe's activities in relation to people with disabilities. The European Social Charter of 1961 and its revision in 1996 include specific wording and expand the rights of individuals with disabilities.

1950 ◆ The Social Security Amendments of 1950 provide federal-state aid to the permanently and totally disabled (APTD), which serves as a limited prototype for future Social Security assistance programs for disabled people.

1950 ◆ The National Mental Health Association is formed with the mission to continue 1908-advocate Clifford W. Beers's goals of "spreading tolerance and awareness, improving mental health services, preventing mental illness, and promoting mental health."

1950 ◆ The National Association for Retarded Children (NARC) is established by families in Minneapolis. It is the first and most powerful parent-driven human-services lobby in the nation to emerge in the 1950s.

1950 Amniocentesis is developed by a Uruguayan obstetrician. Later, advanced prenatal testing provides a battery of powerful medical tools to predict risk of disability and provide information to parents about their pregnancies.

1951 With the founding of the World Federation of the Deaf, the deaf community becomes international.

1953 Francis Crick and James Watson propose a three-dimensional structure for the DNA molecule. The paper they publish also gives clues to genetic mechanisms. Today, more than 6,000 monogenic disorders have been identified, and these affect approximately 1 in 200 live births.

1955 The polio vaccine, developed by Dr. Jonas Salk, becomes available, thus ending polio epidemics in the Western world. A new oral vaccine, developed by Dr. Albert B. Sabin, is approved for use in 1961.

1956 Social Security Disability Insurance (SSDI) becomes available through amendments to the Social Security Act of 1935 (SSA) for those aged 50–64. Other important amendments to SSA include the following: 1958: provides for dependents of disabled workers; 1960: removes age limit; 1965: Medicare and Medicaid provide benefits within the framework of the SSA (until 1977); 1967: provides benefits to widows and widowers over the age of 50; 1972: Supplemental Security Income (SSI) establishes a needs-based program for the aged, blind, and disabled; 1984: the Social Security Disability Reform Act responds to the complaints of hundreds of thousands of people whose disability benefits have been terminated; 1996: President Clinton signs the Personal Responsibility and Work Opportunity Reconciliation Act, making it more difficult for children to qualify as disabled for SSI purposes.

1959 The UN Declaration of the Rights of the Child is adopted; the UN Convention on the Rights of the Child is adopted in 1989. A central principle of both documents is access to education for all children including those with disabilities. In 1993, a related UN document, the Standard Rules for the Equalization of Opportunity, extends this to preschool children, and in 1994, UNESCO's Salamanca Statement and Framework for Action specifies the provision of special education for children with disabilities or learning difficulties. These documents constitute a universal bill of rights that can serve as a framework in the development of national policies worldwide.

1961 The American Council of the Blind is established.

1961 Europe: The European Social Charter (ESC) protects "the right of physically and mentally disabled persons to vocational training, rehabilitation and social resettlement." In 1996, it is revised, updated, and expanded to take account of social changes.

1961 Michel Foucault's work *The History of Madness in the Classical Age* becomes obligatory reading for those concerned with the archaeology of madness and its treatments. It continues to be an academic *rite de passage.*

1962 Battered child syndrome is defined. Researchers estimate that the incidence of maltreatment of children with disabilities is between 1.7 and 3.4 times greater than of children without disabilities.

1962 Russia: The Moscow Theater of Mime and Gesture is the first professional deaf theater in the world. It has been in continuous operation for more than 40 years and has staged more than 100 classic and modern plays.

1963 Congress enacts new legislation to ensure funding for a comprehensive program of research on mental retardation through the National Institute on Child Health & Human Development. In 1965, the Office of Economic Opportunity launches the Elementary and Secondary Education Act (ESEA), commonly known as Project Head Start. The goal is to prevent developmental disability by providing increased opportunities for disadvantaged children in the preschool years.

1963 The Developmentally Disabled Assistance and Bill of Rights Act (DD ACT) is authorized, with its last reauthorization in 1996. It focuses on individuals with developmental disabilities such as intellectual disability, autism, cerebral palsy, epilepsy, and hearing and visual impairments, among others.

1964 The Civil Rights Act is passed. It becomes the model for future disability rights legislation.

1964 France: L'Arche is established. By the beginning of the twentieth-first century, it includes more than 113 communities in 30 countries. "The Ark" is a distinctive style of community living, based on "core members" and "assistants," who view their commitment as sharing life *with* people with disabilities, rather than as caregivers.

1965 Newly enacted Medicare and Medicaid provide national health insurance for both elderly (over 65) and disabled persons.

1965 The Vocational Rehabilitation Amendments of 1965 are passed. They provide federal funds for the construction of rehabilitation centers and create the National Commission on Architectural Barriers to Rehabilitation of the Handicapped.

1965 The Autism Society of America is founded.

1967 Deaf actors establish the National Theatre of the Deaf (NTD). It is the world's first professional deaf theater company and the oldest continually producing touring theater company in the United States. Today, after almost 40 years, the NTD chronicles over 6,000 performances. The National Theatre Workshop for the Handicapped begins in 1977 and the Other Voices Project in 1982. These groups are among the earliest groups formally to place the disability experience at the heart of their creative endeavors.

1967 Heart transplantation is introduced. This technology is preceded by open-heart surgery developed in the 1950s and coronary bypass and internal pacemakers in the1960s. The Framingham Heart Study begins in 1948. It collects data over the next decades that help identify major risk factors contributors to heart disease.

1967 Paul Lemoine in France in 1967 and Kenneth Jones and David Smith in the United States in 1973 independently describe the condition fetal alcohol syndrome (FAS), which comprises a recognizable pattern of birth defects attributable to the adverse effects of maternal alcohol abuse during pregnancy.

1967 England: St. Christopher's Hospice in South London opens. It is the first attempt to develop a modern approach to hospice and palliative care.

1968 Congress enacts the Architectural Barriers Act. The ABA requires access to facilities designed, built, altered, or leased with federal funds.

1968 The Fair Housing Amendments to the Civil Rights Act of 1968 guarantees civil rights of people with disabilities in the residential setting. The amendments extend coverage of the fair housing laws to people with disabilities and establish accessible design and construction standards for all new multifamily housing built for first occupancy on or after March 13, 1991.

1968 Sweden: The origins of People First® go back to a meeting of parents of children with intellectual disabilities whose motto is "we speak for them." However, the people with disabilities in attendance wish to speak for themselves and start their own self-advocacy group. Similar groups quickly spread to England and Canada. The name People First is chosen at a conference held in Salem, Oregon, in 1974. People First is an international self-advocacy organization run by and for people with intellectual disabilities to work on civil and human rights issues.

1970 ◆ Landmark legal cases such as *Diana v. State Board of Education* (1970; Latino students) and *Larry P. v. Riles* (1971–1979; minority students) challenge biases inherent in standardized testing procedures used to identify students as eligible for special education. Both cases call into question the widespread use of "scientifically" objective measures to gauge intellectual ability. Today, despite reforms, a disproportionate number of students from racial, ethnic, and linguistic minorities continue to be placed in special education classes.

1970 ◆ Japan: The Disabled Persons' Fundamental Law (DPFL) becomes one of the 27 fundamental laws that stipulate basic principles in each policy area. Major revision takes place in 1993 reflecting a progress of guiding principles in disability policy that are deeply influenced by international movements such as the International Year of Disabled Persons (1981) and the UN Decade of Disabled Persons (1983–1992). Disability Studies as well as modern disability movements are born this same year, when members of Aoi Shiba, a group of people with cerebral palsy, protest publicly for the first time against sympathetic views toward the killing of disabled children by their parents. Aoi Shiba and other disability movements join in the establishment of Disabled Peoples' International in 1981. In 1986, the Rehabilitation Engineering Society of Japan (RESJA) is established. In 1992, disability movements in Japan initiate the Asian and Pacific Decade of Disabled Persons 1993 to 2002. The Japan Society for Disability Studies is established in 2003 and a unified national organization, Japan Disability Forum (JDF), is established in 2004.

1970 ◆ United Kingdom: The Chronically Sick and Disabled Persons Act (CSDPA) strengthens the provisions in the 1948 National Assistance Act (NAA). Later, the Disability Discrimination Acts of 1995 and 2005, together with the Disability Rights Commission Act of 1999, constitute the primary source of antidiscrimination legislation for disabled people.

1971 ◆ A U.S. District Court decision in *Wyatt v. Stickney* is the first important victory in the fight for deinstitutionalization.

1971 ◆ WGBH Public Television establishes the Caption Center, which provides captioned programming for deaf viewers.

1971 ◆ Gerontologist M. Powell Lawton defines *functional assessment* as any systematic attempt to objectively measure the level at which a person is functioning in a variety of domains. Over 30 years later, functional assessment, in combination with *outcomes analysis,* is considered one of the "basic sciences" of rehabilitation. In 1980, the World Health Organization proposes a series of definitions, which have a profound impact on the assessment of functional status and outcomes in rehabilitation. It is modified and revised in 1993 and 2001.

1971 ◆ The Declaration on the Rights of Mentally Retarded Persons (UN 1971), the Declaration on the Rights of Disabled Persons (UN 1975), and the World Programme of Action Concerning Disabled Persons (UN 1982) indicate the emergence of a global discourse of rights for disability.

1972 ◆ A group of people with disabilities (including Ed Roberts, John Hessler, and Hale Zukas), known as the Rolling Quads, living together in Berkeley, California, formally incorporate as the Center for Independent Living (CIL). This first CIL in the country becomes the model for Title VII of the Rehabilitation Act of 1973. In the late 1980s and early 1990s the group's advocacy efforts help pass the Americans with Disabilities Act (ADA). CILs are always controlled by disabled people. Accepted by most people as the birth of the modern independent living movement, the Berkeley concept migrates to other countries. In 1999, a global summit on independent living is held in Washington D.C. The summit brings together more than 70 countries. The Washington Declaration that comes out of the conference establishes a set of basic principles. In 1996, the Ed Roberts Campus, an international center and a service facility, is created in Berkeley, California, in memory of Edward V. Roberts, founder of the independent living concept.

1972 A young television reporter for the ABC network, Geraldo Rivera, is given a key to one of the wards at Willowbrook State School on Staten Island, New York. Established in the late 1930s as a state-of-the-art facility for the “mentally deficient,” by 1972, Willowbrook becomes a warehouse for the “socially undesirable” of New York City, with a substantial minority having no disability at all. The inhumane conditions deteriorate to the extent that a visitor remarks, “In Denmark we don’t let our cattle live this way.” Rivera’s exposé leads to a lawsuit that results in the Willowbrook Consent Decree of 1975, which creates a detailed system of monitoring and oversight of all residents living there at that time, to be met until the last of the “class clients,” as they are sometimes referred to, pass on. The property has since been sold to a college.

1972 Paul Hunt’s call for a consumer group to promote the views of actual and potential residents of institutional homes for the disabled in the United Kingdom results in the establishment of the Union of the Physically Impaired against Segregation (UPIAS). The group’s aim is to formulate and publicize plans for alternative forms of support in the community. Hunt is regarded by many disability activists as the founder of the modern disabled people’s movement.

1972 New Zealand: Three key pieces of legislation pass have long-term effects on the disabled community: the 1972 no-fault Accident Compensation Act that provides monetary compensation to victims based on level of impairment suffered; the 1975 Disabled Persons Community Welfare Act, giving assistance to disabled people, parents, and guardians, as well as voluntary associations; and the Human Rights Act of 1977, which does not include disability as a recognized grounds for discrimination. Today, disabled populations in New Zealand continue to fight to establish an identity as disabled people rather than a group needing “welfare.” One task is to promote legislation that includes disability as a group against whom discrimination is outlawed.

1973 The Rehabilitation Act of 1973 lays the foundation for the disability rights movement. Its Section 504 asserts that people with disabilities have equal rights that prevent discrimination based on their disability in programs or activities that receive federal funding. This is the first major nationwide antidiscriminatory legislation designed to protect disabled Americans. These rights are further protected with the landmark Americans with Disabilities Act (ADA) of 1990.

Section 501 of the Act requires affirmative action and nondiscrimination in employment by federal agencies of the executive branch. Section 502 creates the Access Board, which grows out of the 1965 National Commission on Architectural Barriers to Rehabilitation of the Handicapped. As a result of the commission’s June 1968 report, Congress enacts the Architectural Barriers Act (ABA). Section 503 requires that to receive certain government contracts, entities must demonstrate that they are taking affirmative action to employ people with disabilities. The enduring hallmark of the act, Section 504, provides that no otherwise qualified individual with a disability shall, solely by reason of his or her disability, be excluded from the participation in, denied the benefits of, or subjected to discrimination under any program or activity receiving federal funds. However, it would take five years of lobbying and protesting before the American Coalition of Citizens with Disabilities (ACCD) wins the release of regulations that allow Section 504 to be implemented.

The Act is in many ways the direct predecessor to the ADA. However, the primary focus is vocational training and rehabilitation, and over the next half-century, disability law and advocacy move from the medical (medical issues) and vocational (often a justification for welfare and benefits) models to a civil rights model, which seeks to remove the barriers that impede the full integration of people with disabilities into society.

1973 The term *mainstreaming* emerges within the educational jargon associated with the Education for All Handicapped Children Act (EHA), the early U.S. legislation subsequently reauthorized as the Individuals with Disabilities Act (IDEA) in 1990.

1973 Ronald Mace is the driving force behind the creation of the first accessible state building code in the United States (North Carolina, 1974) and in the drafting of national accessibility codes and

standards. He coins the term *universal design* to capture and promote his expanded philosophy of "design for all ages and abilities"—curb cuts being his favorite example.

1973 Washington D.C. introduces the first handicap parking stickers. The Federal-Aid Highway Act funds curb cuts.

1974 First Lady Betty Ford and investigative reporter Rose Kushner are diagnosed with breast cancer. They help break the public silence on this topic. In 1954, Terese Lasser begins Reach to Recovery, a program of volunteers who have previously undergone radical mastectomies who provide emotional support to hospitalized women who have just had the operation. Today, one in eight women is diagnosed with breast cancer during her lifetime.

1975 The Education for All Handicapped Children Act, the first separate federal legislation authorizing special education for children and youth, passes, due, in part, to the advocacy efforts of a group of parents. In 1990, it becomes known as the Individuals with Disabilities Education Act, or IDEA.

1975 The Developmentally Disabled Assistance and Bill of Rights Act, providing federal funds for programs that provide services for people with developmental disabilities, passes.

1975 The Association of Persons with Severe Handicaps (TASH) is founded. It calls for the end of aversive behavior modification and deinstitutionalization of people with disabilities.

1975 The UN General Assembly adopts the Declaration on the Rights of Disabled Persons, which states that all persons with disabilities have the same rights as other people. This document is not legally binding and can be attributed in part to a UN Ad Hoc Committee set up in 2001 to consider a Convention on the Rights of Disabled Persons that is legally binding.

1975 United Kindom: The Union of the Physically Impaired against Segregation (UPIAS) publishes a paper that redefines the term *disability,* which becomes known as the social model of disability as it radically transforms the way disabled people see themselves and their place in society.

1976 The Higher Education Act of 1965, which establishes grants for student support services aimed at fostering an institutional climate supportive of low-income and first-generation college students, is amended to include individuals with disabilities. In March 1978, the Association on Handicapped Student Service Programs in Post-Secondary Education is founded. It later becomes the Association on Higher Education and Disability (AHEAD).

1976 Sponsored by Ralph Nader's Center for the Study of Responsive Law, the Disability Rights Center is founded in Washington D.C.

1977 Protesting the federal government's delayed enactment of the rules and regulations for the implementation of the Rehabilitation Act of 1973, disabled activists on April 1 organize protests at the federal offices of the Department of Health and Human Services in various cities across the United States. In San Francisco, protesters hold the regional offices hostage for 28 days, gaining national attention and resulting in an agreement with federal officials for the rapid establishment of the rules and regulations to implement Section 504 of the Act.

1977 Max Cleland is appointed to head the U.S. Veterans Administration. He is the first severely disabled person to hold this post.

1977 S. Z. Nagi defines *disability* as an individual's performance of tasks and activities related to achievement of social roles—a distinct concept, different from *impairment*. It is further formalized with the introduction of the World Health Organization's International Classification of Impairments, Disabilities, and Handicaps in 1980 and further refined in 2001 in its International

Classification of Functioning, Disability, and Health. Nagi's model is used as the basis for the Americans with Disabilities Act, for almost all disability social policy in the United States, and for statistics at the United Nations and in Europe.

1978 ◆ The Child Abuse Prevention and Treatment and Adoption Reform Act of 1978 and the Adoption Assistance and Child Welfare Act of 1980 promote the adoption of children with special needs, including disabilities.

1978 ◆ The Atlantis Community, the second independent living center in the country after Berkeley, is established in Denver, Colorado, in 1975. On July 5–6, 1978, twenty disabled activists from the Atlantis Community block buses with their wheelchairs and bodies and bring traffic to a standstill at a busy downtown intersection. This act of civil disobedience results in the American Disabled for Accessible Public Transit, the original name for the American Disabled for Attendant Programs Today, or ADAPT.

1978 ◆ Legislation creates the National Institute on Handicapped Research. In 1986, it is renamed the U.S. National Institute on Disability and Rehabilitation Research (NIDRR). Its mission is to contribute to the independence of persons of all ages who have disabilities. It is located in the Department of Education under the Office of Special Education and Rehabilitation Services.

1978 ◆ The World Health Organization starts to promote the concept of community-based rehabilitation (CBR) as a means of helping people with disabilities in the developing world. It emerges, in part, from the WHO primary health care campaign Health for All by the Year 2000. Around the same time, in Western countries, home-visiting programs in which a trained worker regularly visits the family to advise on ways of promoting child development become one of the success stories of modern disability services. Among the best-known programs are those based on a model originating in Portage, Wisconsin, and now used in many countries.

1978 ◆ England: The Warnock report introduces the term *special needs education.* It marks a major shift in organizing educational services for children with disabilities and results in the new conceptualization of special needs education. This change is confirmed internationally by the Salamanca Statement and Framework for Action on Special Needs Education at the UNESCO's Conference held in Salamanca in 1994. This theoretical shift is marked with the change of the term *integration* to *inclusion* or *inclusive education.*

1978 ◆ USSR: The Action Group to Defend the Rights of the Disabled is established to advocate for legal rights for Soviets with disabilities.

1979 ◆ The Disability Rights Education and Defense Fund (DREDF) establishes itself as a leading cross-disability civil rights law and policy center. It is founded by people with disabilities and parents of children with disabilities. Because its philosophy is closely aligned with other civil rights struggles, in 1981, DREDF is invited to join the executive committee of the national's largest coalition of civil rights groups, the Leadership Conference on Civil Rights. In 1987, DREDF establishes the Disability Rights Clinical Legal Education Program and begins teaching disability rights law at the University of California's Boalt Hall School of Law.

1979 ◆ The National Alliance for the Mentally Ill (NAMI) is founded. NAMI is an advocacy and education organization.

1979 ◆ Germany: The first Cripples' Group is founded as a cross-disability group with emancipatory aims. In an attempt to reinterpret disability in positive terms, the cofounders choose the term *Krüppel* over handicapped or disabled.

1979 ◆ Nicaragua: The Organization of the Revolutionary Disabled is set up in the wake of the Sandinista victory.

1980 ◆ The California Governor's Committee on Employment of People with Disabilities and entertainment and media industry professionals establish the Media Access Office (MAO).

1980 ◆ About the time Congress is considering passage of the ADA (1990), marketers begin to acknowledge the economic potential of the disabled community; consequently, the appearance of disabled characters in consumer goods advertising mushroom and ability-integrated advertising becomes much more commonplace. Organizations such as MAO and NOD (National Organization on Disability) provide advertising strategies and guidance.

1980 ◆ The Rehabilitation Engineering and Assistive Technology Society of North America (RESNA), an interdisciplinary association composed of individuals interested in technology and disability, is founded.

1980 ◆ The World Health Organization's International Classification of Impairments, Disabilities, and Handicaps (ICIDH), a groundbreaking, but controversial, classification system is tentatively released for trial purposes with the goal of uniform information collection worldwide. It has a negligible impact on disability statistics or data collection; however, researchers argue that it is a vast improvement over available tools. It is renamed and vastly revised in 2001.

1980 ◆ England: Graeae Theatre Group, composed of disabled actors, directors, and other theater professionals, is founded in London by Nabil Shaban and Richard Tomlinson. It takes its name from the the Graeae of Greek mythology, three gray-haired sisters who shared one eye and one tooth. Graeae's first production is *Sideshow*.

1980 ◆ Netherlands: The Liliane Foundation starts by assisting 14 children. In 2002, it helps 31,982 children spread over 80 countries. The Foundation's efforts are directed primarily toward children with disabilities living at home. Its aim is to have direct contact with the child within the home situation and to assist the personal growth and happiness of the child, thus providing "tailor-made" assistance.

1980 ◆ Taiwan: The Physically and Mentally Disabled Citizens Protection Law is promulgated. It guarantees legal rights for the disabled and creates a significant improvement in their welfare. Although most of the disabled people in Taiwan still struggle to earn their due respect, today, public awareness of this group is emerging gradually and significantly.

1980 ◆ United Kingdom and Europe: The Black Report (*Report of the Working Group on Inequalities in Health)* is published. Among other groups it targets disabled people for better conditions that lead to better health. The report does not find favor with the Conservative government, but begins to be implemented under the Labour government in 1997. With its central theme of equity, the report plays a central role in the shaping of the World Health Organization's Common Health Strategy of the European Region.

1981 ◆ The Reagan Administration begins to amend and revoke disability benefits, a policy that continues throughout his administration and leads several disabled people who are in despair over the loss of their benefits to commit suicide.

1981 ◆ Justin Dart, recognized as the founder of the Americans with Disabilities Act (ADA, 1990), is appointed to be vice-chair of the National Council on Disability. The council drafts a national policy on equal rights for disabled people; the document becomes the foundation of the ADA.

1981 ◆ The Committee on Personal Computers and the Handicapped is established in Illinois, an indicator of the disabled community's interest in information technology (IT) accessibility, but in order to stimulate the development of suitable products, activists lobby for legislative protections, which are included in the Americans with Disabilities Act of 1990. In 2000, a suit brought by the National Federation of the Blind against AOL is suspended when AOL agrees to make its software accessible by April 2001. The World Wide Web Accessibility Initiative (WAI) launches in 1997. It raises the level of awareness of disability accessibility issues within the Internet community, especially among those who design and implement web pages.

1981 ◆ The first reported cases of AIDS in the United States appear in June. Today, the World Health Organization estimates that worldwide, approximately 40 million people are living with HIV/AIDS; 22 million men, women, and children have died; and 14,000 new infections are contracted every day. Around the world, in the year 2003, the AIDS epidemic claims an estimated 3 million lives, and almost 5 million people acquire HIV, 700,000 of them children. Currently, 6 million people infected with HIV in the developing world are estimated to need access to antiretroviral therapy to survive, but only 400,000 have this access.

1981 ◆ Disabled Peoples' International (DPI) is officially founded at a meeting in Singapore. The establishment of such international organizations around this time represents the disability movement becoming a global social movement instead of a national one. DPI is directed by persons with disabilities working in human rights advocacy. It sponsors World Assemblies, which are held every four years to develop a multiyear action plan. The most recent one is held in 2002 in Sapporo, Japan, where delegates from more than 100 countries come together. A leading slogan for DPI and other disability groups, coined in the early 1990s, is "nothing about us without us."

1981 ◆ The International Year of Disabled Persons encourages governments to sponsor programs that assimilate people with disabilities into mainstream society. Despite the positive worldwide effects it has, the UN program also creates some angry activists with disabilities who protest against the charity approach officially adopted for the event. Consequently, the activists build their own infrastructure consisting of counseling and advocacy facilities as well as job creation programs.

1981 ◆ Australia: Australia's modern disability policy takes shape after the 1981 International Year of Disabled Persons. Examples: The 1980s see a shift away from institutional care; the Commonwealth Disability Service Act provides a framework for the provision of disability services; and in 1991, the federal Disability Reform Package maximizes the employment of disabled. In 1995, a legal decision represents a watershed in telecommunications policy for people with disabilities when a commission's inquiry finds the national carrier, Telstra, guilty of discrimination against people with severe hearing or speech impairments. The success of the action results in the Telecommunications Act of 1997, which includes new provisions for the deaf community.

1981 ◆ Mexico: The Program of Rehabilitation Organized by Disabled Youth of Western Mexico begins as a rural community-based rehabilitation program.

1981 ◆ Soweto: The Self Help Association of Paraplegics begins as an economic development project.

1981 ◆ United Kingdom: Disabled people set up the British Council of Disabled Persons (BCOPD), the United Kingdom's national organization of disabled people, to promote their full equality and participation in UK society.

1981 ◆ Zimbabwe: The National Council of Disabled Persons, initially registered as a welfare organization, becomes a national disability rights group.

1982 Disability Studies originates with the formation of the Society for the Study of Chronic Illness, Impairment, and Disability. In 1986, it officially changes its name to the Society for Disability Studies (SDS). Disability Studies is a critical field of study based in human and social science.

1982 *In re Infant Doe* (commonly known as the Baby Doe case) launches the debate as to whether parents or medical authorities should choose to let a disabled infant die rather than provide the necessary medical treatment and nourishment essential to sustain life. In response to this and other cases, the U.S. Department of Health and Human Services creates a rule maintaining it unlawful for any federally funded hospital to withhold medical treatment from disabled infants. In 1984, the U.S. Congress enacts the Child Abuse Amendments, which calls for the medical treatment of newborns with disabilities unless the child would die even with medical intervention. The issue makes it to the U.S. Supreme Court in 1986 with the *Bowen v. American Hospital Association* case. The Court holds that denying treatment to disabled infants does not constitute legally protected discrimination under Section 504 of the Rehabilitation Act and that hospitals and physicians are to implement the decision of the parents. The decision results in the passage of the Child Abuse Prevention and Treatment Act Amendments of 1984. In the year 2000, a scholar argues that the Amendments, presidential commission writings, and disability advocates "have all combined to ensure that most babies who can benefit from medical interventions do receive them."

1982 Disability Awareness in Action (DAA) and other groups such as the Disabled Peoples' International (DPI) and International Disability Alliance (IDA) are the driving force behind the globalization of disability issues through the World Program of Action (1982), the United Nations Standard Rules of Equalization of Opportunities for People with Disabilities (1993), the World Summit for Social Development (1995), and the Education for All Framework for Action (2000), as well as the current campaign to secure a UN convention on the rights of disabled people.

1982 The National Council on Independent Living (NCIL) is formed in the United States. It provides an excellent example of leadership for people with disabilities by people with disabilities.

1982 Canada: The Charter of Rights and Freedoms section of the Constitution provides protection to persons with disabilities.

1982 France: Handicap International is founded in Lyon. It is active in various areas associated with all the causes of handicaps, both traumatological (land mines, road accidents) and infectious (polio, leprosy). In the 1990s it begins working on mental disability issues as a result of experience with Romanian orphanages and the war in the Balkans. In 1992, Handicap International creates its first two mine clearance programs and in 1997 it is the joint winner of the Nobel Peace Prize for its leading role in the fight against landmines.

1983 Rights-based approaches to disability rapidly gain currency in many developing countries since the UN Decade of Disabled Persons, 1983–1992. UNESCAP's Biwako Millennium Framework for Action towards an Inclusive, Barrier-Free and Rights-Based Society for People with Disabilities in Asia and the Pacific sets the priorities for the extended Decade of Disabled Persons, 2003–2012.

1983 Access and accessibility are concepts discussed throughout the World Programme of Action Concerning Disabled Persons passed by the UN General Assembly. The General Assembly in 1993 passes the Standard Rules on the Equalization of Opportunities for Persons with Disabilities.

1983 England: The first Covent Garden Day of Disabled Artists is held in London.

1983 Thailand: DPI-Thailand is established.

1984 The Access Board issues the "Minimum Guidelines and Requirements for Accessible Design," which today serves as the basis for enforceable design standards. The 1990 Americans with

Disabilities Act (ADA) expands the board's mandate to include developing the accessibility guidelines for facilities and transit vehicles. The Rehabilitation Act Amendments of 1998 give the Access Board additional responsibility for developing accessibility standards for electronic and information technology. In 2001, Section 508 of federal law establishes design standards for federal websites, making them accessible to individuals with disabilities.

1985 ◆ The U.S. Department of Health and Human Services issues the first comprehensive national minority health study, which shows racial disparity in health and concludes that the difference in mortality is not acceptable. In 1998, studies indicate that racial disparity has not improved as much as hoped; consequently, President Bill Clinton launches an initiative that sets a national goal of eliminating disparities in six key areas by the year 2010. Some of these areas include diseases and conditions considered to be disabling as well as life threatening.

1986 ◆ The Air Carrier Access Act (ACAA) passes. It requires the U.S. Department of Transportation to develop new regulations that ensure that disabled people are treated without discrimination in a way consistent with the safe carriage of all passengers. The relevant regulations, Air Carrier Access rules, are published in March 1990.

1986 ◆ The National Council on the Handicapped publishes its report *Toward Independence.* It recommends that "Congress should enact a comprehensive law requiring equal opportunity for individuals with disabilities" and suggests that the law be called "the Americans with Disabilities Act." In its 1988 follow-up report, *On the Threshold of Independence,* the council takes the somewhat unusual step of publishing its own draft of the ADA bill.

1986 ◆ The Equal Opportunities for Disabled Americans Act allows recipients of federal disability benefits to retain them even after they obtain work, thus removing a disincentive that keeps disabled people unemployed.

1986 ◆ Australia: The Disability Services Act provides that a person with disability has the right to achieve his or her individual capacity for physical, social, emotional, and intellectual development. In 1992, the Disability Discrimination Act supports nondiscrimination in education and training. It also makes it unlawful to discriminate in relation to access to premises, including public transportation.

1986 ◆ Canada: The Employment Equity Act mandates the institution of positive policies and practices to ensure that persons in designated groups, including persons with disabilities, achieve at least proportionate employment opportunities.

1986 ◆ England: The first issue of the magazine *Disability Arts in London* (DAIL) is produced in London.

1986 ◆ Southern Africa: The Southern Africa Federation of the Disabled is formed as a federation of nongovernmental organizations of disabled persons.

1988 ◆ The Technology Act (Technology-Related Assistance for Individuals with Disabilities Act of 1988 and its 1994 amendments), and, in 1998, the Assistive Technology Act (AT) provide financial assistance to states to support programs of technology-related assistance for individuals with disabilities of all ages. The1988 act defines *assistive technology* (AT). The Americans with Disabilities Act of 1990 prohibits discrimination against people with disabilities in employment, public institutions, commercial facilities, transportation, and telecommunications, which includes accessibility to all entrances, bathrooms, program areas, and parking spaces as well as interpreters for the deaf and Braille and large-print materials for the blind. The Telecommunications Act of 1996 requires the telecommunication industry to make equipment that will support transmission of information in forms accessible to people with disabilities including broadband and television program captioning. By 2000, approximately 10 percent of the U.S. population uses AT devices and/or modifications to their home, work, or school that allow them to participate in major life activities.

1988 ◆ Congress introduces a series of amendments to the Civil Rights Act of 1968, including a prohibition of housing discrimination against people with disabilities. These amendments are known as the Fair Housing Act Amendments of 1988.

1988 ◆ China: Deng Pufang, a wheelchair user and son of the late Chinese leader Deng Xiaoping, is the driving force behind a series of laws and programs initiated to improve life for the disabled. In 1984, he sets up the China Welfare Fund for Disabled Persons and, in 1988, the China Disabled Persons' Federation, which endeavors to improve public images of disabled people. Today, there are 60 million disabled people in China.

1989 ◆ The European Network on Independent Living (ENIL) is set up. It focuses on personal assistance as a key component of independent living.

1990 ◆ ADAPT, the American Disabled for Attendant Programs Today, originally called the American Disabled for Accessible Public Transit, continues to gain public awareness through tactics of civil disobedience until regulations are finally issued with the passage of the Americans with Disabilities Act (ADA).

The ADA passes, after ADAPT uses tactics of civil disobedience, in the tradition of other civil rights movements, in one of the largest disability rights protests to date (600 demonstrators), the "Wheels of Justice March," during which dozens of protesters throw themselves out of their wheelchairs and begin crawling up the 83 marble steps to the Capitol to deliver a scroll of the Declaration of Independence. The following day 150 ADAPT protesters lock wheelchairs together in the Capitol rotunda and engage in a sit-in until police carry them away one by one.

George H.W. Bush signs the ADA on July 26. It provides employment protections for qualifying persons with disability. It is the most prominent and comprehensive law prohibiting discrimination on the basis of disability in the United States, expanding the mandate of Section 504 of the Rehabilitation Act of 1973 to eliminate discrimination by prohibiting discrimination in employment, housing, public accommodations, education, and public services.

In June 2000, the National Council on Disability issues a report, *Promises to Keep: A decade of Federal Enforcement of the Americans with Disabilities Act,* which includes 104 specific recommendations for improvements to the ADA enforcement effort. On December 1, 2004, the council issues a final summary report, *Righting the ADA,* in order to address "a series of negative court decisions [that] is returning [Americans with disabilities] to 'second-class citizen' status that the Americans with Disabilities Act was supposed to remedy forever."

1990 ◆ The ADA requires public entities and businesses to provide effective communication to individuals with disabilities. Title IV of the ADA mandates that nationwide telecommunication systems be accessible to persons with speech or hearing disabilities. The Federal Communications Commission (FCC) requires relay services to be in place by July 26, 1993. The Telecommunications Act of 1996 adds provisions to the Communications Act of 1934 that requires manufactures and providers of telecommunications equipment and services to ensure accessibility to persons with disabilities. In 2000, President Bill Clinton establishes regulations governing the accessibility to people with disabilities of the electronic and information technology used within the federal government.

1990 ◆ The Individuals with Disabilities Education Act (IDEA) is enacted. It guarantees the right to free and appropriate education for children and youth with disabilities and focuses on higher expectations, mainstreaming students where possible, and an increased federal rule in ensuring equal educational opportunity for all students. IDEA requires schools to provide a free and appropriate public education to eligible children with disabilities. It also requires schools to develop an individualized education plan (IEP) for each child and placement in the least restrictive environment (LRE) for their education. IDEA is amended in 1997 and reauthorized again in 2004 as the Individuals with Disabilities Education Improvement Act.

1990 ◆ Legislation establishes the National Center for Medical Rehabilitation Research (NCMRR), whose mission is to foster development of scientific knowledge needed to enhance the health, productivity, independence, and quality of life of persons with disabilities. It has primary responsibility for the U.S. Government's medical rehabilitation research that is supported by the National Institutes of Health (NIH).

1990 ◆ The World Declaration on Education for All (EFA) is adopted in Jomtien, Thailand, by more than 1,500 persons representing the international community. Article 23 of the UN Convention on the Rights of the Child states that disabled children have the right to a "full and decent life" and that member nations provide free education and training to disabled children whenever possible in order to provide the "fullest possible social integration and individual development." UNESCO is the lead UN organization for special needs education.

1990 ◆ Korea: The disability movement celebrates the passage of the Employment Promotion Act for People with Disabilities. The government imposes control over the disabled population in the 1960s and 1970s by forwarding institutionalization under the banner of "protection," promoting sterilization, and violating the rights of disabled people in general. The 1981 International Year of Disabled Persons influences the government, and new laws, such as the Welfare Law for Mentally and Physically Handicapped, are enacted, and the human rights of disabled people becomes the dominant rhetoric of the disability movement.

1990 ◆ United Kingdom: The National Disability Arts Forum is launched at the UK-OK Conference at Beaumont College in Lancashire, UK.

1991 ◆ The Resolution on Personal Assistance Services is passed at the International Personal Assistance Symposium. Personal assistance services are the most critical services for individuals. Critical aspects of these services are that they must be available up to 24 hours a day, 7 days a week, to people of all ages, and with access to governmental payments. In the United States alone, personal assistance services affect the lives of more than 9.6 million citizens with disabilities.

1991 ◆ Australia: The federal Disability Reform Package is introduced; the Disability Discrimination Act, which covers issues of discrimination in education, is enacted in 1992; and the Commonwealth Disability Strategy, designed to provide equal access to government services for people with disabilities, is first introduced in 1994 and then revised in 2000. During the 1990s similar discrimination legislation emerges in other countries, such as New Zealand's Human Rights Act, the U.K.'s Disability Discrimination Act, Israel's Disabled Persons Act, Canada's Human Rights Act, and India's Disabled Person's Act.

1991 ◆ China: The most important laws and initiatives reside in the 1991 Law on Protection of Disabled Persons and a series of National Work Programs for Disabled Persons (1988, 1991, 1996, 2001), which integrate disability into the government's Five-Year Plans. China participates heavily in the United Nations Decade of Disabled Persons, 1983–1992, and initiates the Asia Pacific Decade of the Disabled Persons, 1993–2002. China continues to collaborate with UN projects involving the disabled and will host the 2007 International Special Olympics in Shanghai.

1991 ◆ Serbia and Montenegro: From the 1960s to the 1980s, post–World War II Yugoslavia is lauded for being a socially advanced nonaligned nation, but the contemporary wars that decimate Yugoslavia begin in 1991, and today there are more than one million disabled citizens, refugees, and casualties due to the wars. Disabled people in Serbia and Montenegro (formally named the Federal Republic of Yugoslavia—FRY) are left with shattered pieces of the spent past with little hope for the near future. Although the FRY constitution prescribes special protection of disabled persons in accordance with legal provisions and Serbia is party to numerous UN documents and acts, a disabled expert in 2004 admits that discrimination against persons with disability in Serbia and Montenegro is a

long-term problem that people without disability tend to ignore. Two of the most effective advocacy groups making in-roads today are the Association of Students with Disabilities and the Center for Independent Living in Belgrade.

1992 ◆ The UN Economic and Social Commission of Asia and the Pacific (ESCAP) proclaims a 10-year program known as the Asian and Pacific Decade of Disabled Persons 1993–2002 with goals of full participation and equality for persons with disabilities.

1993 ◆ The United Nations publishes the Standard Rules on the Equalization of Opportunities for Persons with Disabilities, which becomes the international legal standards for disability programs, laws, and policies. Although not legally enforceable this instrument sets an inclusive and antidiscriminatory standard that is used when national policies are developed. It marks a clear shift from the rehabilitation and prevention paradigm to the human rights perspective on disability.

1993 ◆ Slovak Republic: The Czech and Slovak Republics separate into two independent countries. They both join the European Union in 2004. In Slovakia, a large number of highly innovative and resourceful grassroots nongovernmental organizations emerge to address the human rights, quality-of-life, and independent living priorities of citizens with disabilities. They pursue this mission, however, with extremely limited resources and with varying degrees of support from a multiparty parliament.

1993 ◆ Sweden: The Independent Living Institute (ILI) is founded.

1994 ◆ Two networks, one for elderly persons and the other for persons with disabilities, join together to form the U.S. National Coalition on Aging and Disability. In following years, policy makers and advocates begin to see the benefits of merging some services.

1994 ◆ Germany: The disability rights movement is successful in using for its own aims the reform of the German constitution, which is made necessary by the reunification process. An amendment to the constitution forbids discrimination on the grounds of disability. Other such laws as the Rehabilitation of Participation Law (2001) and the Federal Equal Rights Law (2002) are formulated with the active contribution of disability rights activists, and in 2003, the official German program of the European Year of People with Disabilities is organized by a prominent activist.

1994 ◆ Sweden: The Swedish Disability Act (LSS) comes into force. It expands the 1985 Special Services Act. The LSS is also more ambitious than its predecessor, calling for "good living conditions" rather than just an "acceptable standard of living."

1995 ◆ The National Council on Disability, a federal agency, makes recommendations to the president and Congress on disability issues. Among other issues, it calls for the end to the use of aversives (techniques of behavior control such as restraints, isolation, and electric shocks) because they are abusive, dehumanizing, and psychologically and physically dangerous. Other organizations follow, such as the Autism National Committee in 1999, TASH in 2004, and the International Association for the Right to Effective Treatment in 2003.

1995 ◆ The Commission for Case Management Certification (CCMC) incorporates. Case management is a process of care planning and coordination of the services and resources used by people with disabilities and their families.

1995 ◆ Europe: The Association for the Advancement of Assistive Technology in Europe (AAATE) is founded as an interdisciplinary association devoted to increasing awareness, promoting research and development, and facilitating the exchange of information. AAATE is composed of more than 250 members from 19 countries. It interacts with sister organizations in North America, Japan, and Australia to advance assistive technology worldwide. The Tokushima Agreement, signed in 2000 by AAATE, the Rehabilitation Engineering and Assistive Technology Society of North America

(RESNA), the Rehabilitation Engineering Society of Japan (RESJA), and the Australian Rehabilitation and Assistive Technology Association (ARATA), promotes exchange of information and collaboration.

1995 ◆ United Kingdom: The campaign for antidiscrimination legislation begins in earnest with the emergence of the disability movement in the late 1970s. The Disability Discrimination Act of 1995 (DDA) together with the Disability Rights Commission Act of 1999 constitute the primary source of antidiscrimination legislation for disabled people in the United Kingdom. The Disability Discrimination Act 2005 extends the protection.

1996 ◆ There are 1.4 million fewer disabled older persons in the United States than would have been expected if the health status of older people had not improved since the early 1980s.

1996 ◆ Advocates for mental health parity such as the National Alliance for the Mentally Ill (NAMI; 1979) believe that mental illnesses are real illnesses and that health insurance and health plan coverage for treatment should be equal with coverage of treatment for all other illnesses. Due in part to advocacy, the Mental Health Parity Act becomes law in 1996. In 1999, mental illness ranks first in causing disabilities among many industrialized nations, including the United States, which experiences a loss of productivity in this year of $63 billion. In the United States, 5 to 7 percent of adults suffer from serious mental disorders and 5 to 9 percent of children suffer from serious emotional disturbances that severely disrupt their social, academic, and emotional functioning.

1996 ◆ Costa Rica: Approval of a law called Equal Opportunities for People with Disabilities is a turning point for the population with disabilities, which is among the most excluded sectors of society. The law is inspired in part by the United Nations Standard Rules on the Equalization of Opportunities for Disabled People (1993). Disability experience in Costa Rica is definitely transformed as a result of the mandates of this generic law, as people with disabilities and their families start to use this legal instrument as a strategy to empower themselves.

1996 ◆ Europe: Created in 1996, the European Disability Forum (EDF) is today the largest independent, trans-European organization that exists to represent disabled people in dialogue with the European Union (EU) and other European authorities. Its mission is to promote equal opportunities for disabled people and to ensure disabled citizens full access to fundamental and human rights through its active involvement in policy development and implementation in the EU. The EDF has national councils in 17 European countries and has 127 member organizations. The European Year of People with Disabilities 2003 is one of the EDF's most important campaigns.

1996 ◆ India: The Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act, 1995, becomes law. It is the first legislation for equal opportunities for disabled people. Prior to this, disabled persons receive services but not legal protection. Improvements in conditions begin in 1981 with the International Year of Disabled Persons. India is a signatory to the UN resolution of 1976 establishing it and is thereby committed to improving the lot of the disabled. The Lunacy Act of 1912 is repealed and the National Mental Health Act is passed in 1987. Nonetheless, with approximately 70 million disabled people residing in India (in a population of over a billion), the government does not include the domain of disability in the 2001 census, which reflects the attitudinal barriers in acknowledging the disabled identity.

1997 ◆ Government expenditures on behalf of persons with disabilities may total as much as $217.3 billion (taking into account the costs that would be expected among persons with disabilities in the absence of the disability), the equivalent of 2.6 percent of the gross domestic product in the United States for 1997.

1997 ◆ The landmark 1997 UNESCO Universal Declaration on the Human Genome and Human Rights frames the actual application of the new scientific developments raised by genetics. As a policy

statement, it provides the first signs that genetics will be applied in ways that maintain human rights. In 2003, the Council of Europe and the council's Steering Committee in Bioethics issue policy statements in a working document titled Application of Genetics for Health Purposes. In the case of gene therapy, in 1994, the Group of Advisors on the Ethical Implications of Biotechnology of the European Commission voices concern regarding equity, maintaining that all genetic services that are available for the entire population should be equally available for persons of disability. Today, UNESCO's Human Genome Organization's Ethics Committee, the World Health Organization, the Council of Europe, and consumer organizations such as Inclusion International, Rehabilitation International, and Disabled Peoples' International play major roles in translating genetic innovations into health service and public health fields, helping develop policies that focus on the general recognition, respect, and protection of the rights to which all people, whether disabled or nondisabled, are entitled. Concerns related to the possible undermining of human rights are expressed in 2003 when Disabled People's International demands a prohibition on compulsory genetic testing.

1997 ◆ Colombia: The General Act for People with Disabilities, also known as the Disability Act: Law for Opportunity, passes. The 2003–2006 National Plan of Attention to Persons with Disabilities estimates that 18 percent of the general population has some type of disability. Despite the existence of at least 37 disability-related legal policies (2001), the government provides limited spending on programs that protect the rights of people with disabilities, and the lack of enforcement of rights remains a major concern. Today's awareness efforts include marathons with the participation of the general population to raise money for educational programs for children with special needs, Special Olympics, new organizations such as the Colombian Association for the Development of People with Disabilities, and media awareness campaigns.

1998 ◆ President Bill Clinton issues an executive order ensuring that the federal government assumes the role of a model employer of adults with disabilities.

1998 ◆ President Clinton signs into law the Rehabilitation Act of 1973 Amendments. Section 508 requires that electronic and information technology (EIT), such as federal websites, telecommunications, software, and information kiosks, must be usable by persons with disabilities.

1998 ◆ Ireland: The Irish Employment Equality Act entitles all individuals, including disabled persons, equal treatment in training and employment opportunities. The Education Act of 1998 requires schools to provide education to students that is appropriate to their abilities and needs. The Education for Persons with Disabilities Bill passes in 2003. A Disability Bill published in 2001 fails to underpin a rights-based approach and is withdrawn amid a storm of protest in 2002; a redrafting of a new Disability Bill is suffering from continuing delays. Traditionally, Irish voluntary organizations play a reactionary role in the development of services for people with disabilities and a key role as pressure groups trying to keep disability issues on the political agenda.

1999 ◆ The National Center on Physical Activity and Disability (NCPAD) is established as an information and resource center that offers people with disabilities, caregivers, and professionals the latest information on fitness, recreation, and sports programs for people with disabilities.

1999 ◆ Established by a panel of experts brought together to evaluate the UN Standard Rules on the Equalization of Opportunities for Persons with Disability, the International Disability Alliance (IDA) encourages cross-disability collaboration and supports the participation of international disability organizations in the elaboration of a proposed UN convention on disability.

1999 ◆ England: The first disability film festival, Lifting the Lid, is held at the Lux Cinema in London.

2000 ◆ The National Telability Media Center collects documentation of 3,000+ newsletters, 200 magazines, 50 newspapers, 40 radio programs, and 40 television programs dedicated to disability in the United States alone. *The Ragged Edge, Mainstream* (Internet-based), and *Mouth* are examples of disability rights-focused publications.

2000 ◆ *Healthy People 2000,* the second edition of the Surgeon General's report on health promotion and disease prevention (the first edition published in 1979), includes some reference to the health and well-being of people with disabilities, but few data are available. In the mid-1990s, the U.S. Department of Health and Human Services begins a dialogue with the Centers for Disease Control and Prevention to include people with disabilities in the third edition, *Healthy People 2010.* The resulting report includes more than 100 objectives that include "people with disabilities" as a subpopulation for data gathering.

2000 ◆ The World Bank, increasingly concerned with how to include disabled persons in the economies and societies of developing nations, establishes an online clearinghouse to make documents concerning the disabled readily available to member nations and the general public and holds its first course on disability issues in 2004 in Guatemala.

2000 ◆ Africa: The African Decade of Persons with Disabilities, 2000–2009, is adopted by the Declaration of the Organization of African Unity. The African Network of Women with Disabilities (2001) and the community-based rehabilitation organization CBR Africa Network (CAN) are examples of the many activities that result from the African Decade.

2000 ◆ Brazil is one of the few countries to include an entire section on disability in its 2000 census. Results show that 14.5 percent of the population, roughly 24 million people, report having some form of disability, the poorest region, the northeast, reporting the highest percentage and the richest, in the south, the lowest. People with disabilities in the first half of the twentieth century have no voice or representation. In 1932, the first Pestalozzi Society, a community-based school for children with intellectual disabilities, is founded. By the end of the twentieth century, there are 146 Pestalozzi Societies and more than 1,700 chapters of the Association of Parents and Friends of the Exceptional. The first center for independent living is established in 1988 (CVI-RIO). In 1992 and 1995, CVI-RIO organizes two international conferences on disability issues called DefRio, out of which comes "Goals of the ILM," a document that delineates the basis for the independent living movement in Brazil; however, financial support is not provided by the government, creating a struggle for sustainability. Brazil has progressive policies toward disability. The constitution includes sections on the rights of people with disabilities, and laws have been passed with regard to accessibility, education, and employment.

2000 ◆ Europe: A European Community directive requires all member states to have introduced antidiscrimination laws in the fields of employment and training by the end of 2006. It seeks to establish a general framework for equal treatment in employment and occupation and to render unlawful discrimination based on, among other categories, disability. The European Union Charter of Fundamental Rights sets out in a single text, for the first time in the EU's history, the whole range of civil, political, economic, and social rights of European citizens. Disability is included in the general nondiscrimination clause (Article 21), but Article 26 specifically states that the Union recognizes and respects the rights of persons with disabilities to benefit from measures designed to ensure their independence, social and occupational integration, and participation in the life of the community.

2000 ◆ The Human Genome Project (HGP), an international effort to specify the 3 billion pairs of genes that make up the DNA sequence of the entire human genome, produces its first draft in June 2000. Formally begun in October 1990, it is completed in 2003.

2001 President Clinton declares in Executive Order No. 13217 the commitment of the United States to community-based alternatives for individuals with disabilities. This ensures that the *Olmstead v. L.C.* decision (1999), which mandates the right for persons with disability to live in the least-restrictive setting with reasonable accommodations, is implemented in a timely manner. The executive order directs federal agencies to work together to tear down the barriers to community living.

2001 In the United States, census data indicate that only 48 percent of citizens 25 to 64 years old with severe disabilities have health insurance compared with 80 percent of individuals with nonservere disabilities and 82 percent of nondisabled Americans. Women with disabilities in general are more likely to live in poverty than men. Minorities with disabilities are more likely to live in poverty than nonminorities with disabilities. In 2003, in the United States, about 28 percent of children with disabilities live in poor families compared with 16 percent of all children.

2001 A UN Ad Hoc Committee begins discussions for a legally binding convention under the draft title Comprehensive and Integral Convention on the Protection and Promotion of the Rights and Dignity of Persons with Disabilities. Its fifth session is held in early 2005.

2001 A new World Health Organization classification of people with disabilities, the International Classification of Functioning, Disability, and Health (ICF), replaces the old International Classification of Impairments, Disabilities, and Handicaps (ICIDH). The ICF definition shifts the focus from disability as an innate deficit ("medical model") to disability as constructed through the interaction between the individual and the environment ("social model"). This shift encourages a focus on the kinds and levels of interventions appropriate to the needs of individuals.

2001 UNESCO launches pilot education projects for disabled children in Cameroon, the Dominican Republic, Egypt, Ghana, India, Madagascar, Mauritius, Nicaragua, Paraguay, South Africa, Vietnam, and Yemen. The global initiative Education for All 2000 has as its primary millennium development goal universal education by the year 2015.

2002 The U.S. Supreme Court rules that executing persons with mental retardation is unconstitutional.

2002 Disabled Peoples' International's 2002 Sapporo Platform, developed by 3,000 delegates from more than 90 countries, urges members to take every opportunity to seek publicity and awareness in order to change negative images of disabled people.

2002 Canada: The Canadian International Development Bank announces the approval of the Canada-Russia Disability Program, a four-year $4 million project, focusing on education, disability studies, social work practice, social policy, and information dissemination.

2003 A national survey that updates the Disability Supplement to the 10-year-old National Health Interview Survey highlights barriers to care among the uninsured. The uninsured are four times as likely to postpone care and three times as likely to go without needed supplies.

2003 The National Association of Social Workers (NASW) issues a policy statement that discusses their core values with respect to working with people with disabilities, including self-determination, social justice, and dignity and worth of the person. The statement emphasizes that social workers are responsible to take action with people who have disabilities in advocating for their rights to fully participate in society.

2003 The Disability Awareness in Action (DAA) database contains a total of 1,910 reports of known abuse affecting nearly 2.5 million disabled people. In the area of education alone, it documents

118 cases affecting 768,205 people in 67 countries. Responding to this documentation and other reports, the United Nations Commission on Human Rights creates the Global Rights campaign to address human rights abuses. Disability rights organizations use this information to insist on a UN convention on the rights of disabled people that would be legally binding on nation-states.

2003 The International Association for the Study of Pain has more than 6,700 members, representing more than 100 countries and 60 disciplinary fields. Chronic pain is one of the leading causes of recurrent and permanent disability in the developed world today, yet less than 1 percent of the U.S. National Institutes of Health's budget supports research into mechanisms and management of pain. The U.S. Congress declares 2000–2010 the Decade of Pain Control and Research.

2004 The *Journal of Gene Medicine* (January) reports that 636 gene therapy clinical trials are completed or ongoing, involving 3,496 patients. The first gene therapy clinical trials begin in the early 1990s.

Today Seventy to eighty percent—approximately 400 million—of the world's disabled people (600 million, or 10 percent of the world's population) live in the developing world, and of the world's poorest of the poor, 20 to 25 percent are disabled. In most countries, 1 out of 10 persons has a disability. Many international efforts are under way to address poverty and disability, such as those of the Action on Disability Development and the Chronic Poverty Research Centre.

Today E-health is the use of emerging interactive telecommunications technologies such as the Internet, interactive TV, kiosks, personal digital assistants, CD-ROMs, and DVD-ROMs to facilitate health improvement and health care services, including those with disabilities. E-health relies on environments that use a variety of technologies that can compensate for the lack of sensory ability. Telerehabilitation is an example of services delivered information technology and telecommunication networks.

Today Celebrating difference is the mantra and visible manifestation of disability culture in all regions of the world.

SEARCHING FOR AND EVALUATING WEBSITES

Anne Armstrong

The Internet, or Web, provides a vast number of channels through which researchers can find information on virtually any subject. The expansiveness of the Web can be daunting to new researchers. On the other hand, researchers often assume that they have mastered the Web in its entirety when indeed they have merely scratched the surface in terms of the numbers of resources they have consulted and searches they have performed.

Because the field of disability studies is continually evolving and inherently multidisciplinary, Web searchers can draw on previously conducted research from disciplines within the humanities, social sciences, and health sciences. This guide aims to expose beginning researchers to a mixture of general and subject-specialized Web-based search tools, as well as strategies for performing sophisticated Web searches and criteria for evaluating websites. In addition to its broad subject coverage, the field of disability studies differs from most fields in that many researchers may themselves have disabilities affecting their ability to perform research on the Web. For this reason, this description concludes with an overview of accessibility issues on the Web and suggestions for further reading.

OVERVIEW OF WEB-BASED RESEARCH TOOLS

When approaching Web searching, researchers should be aware of the multitude of search tools available to them, in addition to the varying purposes of these tools. Many users approach Web searching with the assumption that "everything is in Google," but this is a limiting misconception. No single search engine contains everything on the Web. Furthermore, all search engines function differently and rank results differently. Therefore, sampling various search tools increases the comprehensiveness of results on any topic. This discussion outlines multiple types of search tools available on the Web and offers potential starting points for Internet research on issues related to disability studies, whether from a health sciences, social sciences, or humanities perspective.

The Web-based search tools outlined in this chapter include general search engines, subject-specialized search engines, directories, indexes, catalogs, and Listservs. It is important to note that different types of search tools cover different parts of the Web. The Web is composed of layers. The top layer is detectible by general search engines, while a deeper layer termed "the invisible Web" can be penetrated only by specialized search engines, indexes, and catalogs. Readers should be aware that because the Web is in a constant state of flux, currently available resources may become obsolete over time, and newer, more sophisticated search tools will undoubtedly evolve.

General Search Engines

Most people who have searched the Web are familiar with sites such as Google, HotBot, or Lycos, which allow them to enter a string of keywords into a search box to retrieve a list of relevant websites (see Table 1). These sites, referred to as search engines, search the Web by means of a program called a *spider* (also

Table 1 Selected General Search Engines

Name	*URL*
AltaVista	www.altavista.com
Excite	www.excite.com
GO	www.go.com
Google	www.google.com
HotBot	www.hotbot.com
Lycos	www.lycos.com
Yahoo!	www.yahoo.com

called a *robot* or *crawler*). Since search engines tend to index millions of websites, they are most useful for entering specific search terms rather than broad concepts such as disability studies.

While Web searchers tend to pick a favorite search engine and return to it repeatedly, it is important to note that different search engines produce varying results, and that a truly comprehensive Web searcher should compare the results of multiple search engines. The variation between search engines can be attributed to differences between the spiders fueling the search engines as well as differences in the level of indexing and the order in which results are ranked. While some search engines index the full text of documents, others may index only the first page, or merely the *meta-tags*, which are lines of code containing keywords. Web searchers should be aware that developers of websites may intentionally increase their usage of certain words or meta-tags to increase the prominence of their website among search results. This practice has been referred to as *spamdexing* and is most prevalent among the developers of commercial websites advertising products and services. Due to the constant fluctuation of the Web, no search engine is entirely up-to-date; results produced by identical searches can vary greatly from one day to the next, even when one is using the same search engine.

Subject-Specialized Search Engines

Subject-specialized search engines (also referred to as subject portals) developed by educational institutions, associations, government agencies, and corporate entities narrow the broad scope of the Web, providing a focused channel by which researchers can search for information when they have determined the discipline from which their topic stems. Examples of such search engines are listed in Table 2. While subject-specialized search engines index considerably fewer websites and documents than general search engines, the information contained within them has been preselected, ideally by experts within a given field. Many subject-specialized search engines expose searchers to parts of the "invisible Web" not indexed by general search engines. Subject-specialized search engines can ease the research process by whittling down the Web to a more manageable size. However, researchers who use them should take the time to view the criteria for selection of

information contained within them. This information is usually posted within online "help" or "about" pages on the home page.

Table 3 contains search tools that have been developed distinctly for the purpose of locating specialized search engines by subject.

Directories

Directories are hierarchically arranged subject guides composed of websites chosen by or recommended to editors of the directory (Table 4). Usually, directories follow a template in which major subject categories such as health, sciences, social sciences, or humanities are posted on the top-level page. Each of these links leads to lists of narrower subcategories. The links on the second level lead to narrower subcategories, and so on. A sample hierarchy from the directory created by Google (available at http://directory.google.com) lists the following subject breakdown: Society → Disabled → Disability studies.

Directories provide Web searchers with the ability to browse recommended resources in various subject areas without having to enter specific search terms. Other useful attributes of directories are that they often contain summaries and evaluations of websites.

Article Indexes

Article indexes allow researchers to search by topic for published articles in magazines and scholarly journals. Researchers could certainly locate journal and magazine articles using a freely available search engine such as Google, but they would merely be skimming the surface of what has been published. While the Web provides access to *more* content, it does not provide comprehensive access to research published in journal articles. Article indexes are for the expressed purpose of finding journal articles. With a few exceptions (such as PubMed, an article index of health sciences journals developed and maintained by the National Library of Medicine), article indexes are not freely available on the Web. Libraries purchase subscriptions to multiple article indexes covering a wide spectrum of disciplines. The indexes available through a given library are often dictated by the curriculum of the college or university that the library serves. Thus, large research institutions offer a greater number of specialized article indexes than smaller institutions and public libraries. Due to licensing agreements between article index providers and libraries, off-site access to indexes is usually limited to faculty and students of a college or university. However, there are many libraries that allow members of the public to use their article indexes from within the library. A local public library would be a good starting place for those not connected with academic or commercial organizations.

Since article indexes are proprietary products developed by companies for sale to libraries, they tend to offer specialized search features that are not always available on freely available search engines. These features include subject headings, thesauri, abstracts (summaries of articles), and frequently the full text of articles. Researchers should familiarize themselves with online tutorials, "help" screens, and "about" pages to increase the effectiveness of their searching.

Freely available article indexes relevant to disability studies include the following:

- PubMed: A product of the National Library of Medicine, which includes more than 14 million citations for biomedical articles dating back to the 1950s. URL: http://www.ncbi.nlm.nih.gov/entrez

- CIRRIE: Center for International Rehabilitation Research Information and Exchange, a database containing more than 24,000 citations of international research published from 1990 to the present. URL: http://cirrie.buffalo.edu

Catalogs

While researchers can search indexes to find articles on specific topics, they can search online catalogs to find books. Some catalogs list the books available at individual libraries, while others contain the holdings of multiple libraries and institutions. The individual catalogs of public libraries and universities are usually freely available on the Web. The most comprehensive catalog is called WorldCat, developed by an organization called OCLC (Online Computer Library Center). WorldCat lists books available at public and academic libraries throughout the world. Like most article indexes, WorldCat is not freely available on the Web and must be accessed through a library.

Listservs

Listservs are mailing lists on the Internet that facilitate online discussions on various subjects. They allow researchers within a given field to communicate about scholarly issues via email. People customarily sign up for Listservs by sending an e-mail to the Listserv address stating that they wish to subscribe. Several Listservs related to disability studies are listed in Table 5. In addition, Web searchers can perform a search on a database called tile.net to search for Listservs by topic.

SEARCH STRATEGIES

Since search capabilities vary from site to site, Web searchers should use online "help" screens and tutorials to learn search tips and strategies for improving their search results. Some search techniques common to several Web-based search tools are summarized below.

Quotation Marks

When entering a search, users should enter phrases in quotation marks to stipulate that they would like the results to contain a specific word combination and order. For instance, multiword concepts such as "disability studies," "adaptive technology," and "section 508" should be entered within quotation marks. Proper names can also be entered within quotation marks.

Truncation

Truncation symbols allow Web searchers to simultaneously search for multiple endings of a given word. For instance, assuming that the asterisk is the designated truncation symbol in a search engine, entering the word "impair*" would produce results including all forms of the word after the root, including "impair," "impaired," "impairment" and "impairments." In addition to adding truncation symbols to the end of words, users may also insert internal truncation symbols if there are potential variations for the spelling of the middle of a word. For instance, entering the word "colo*r" would simultaneously search for the words "color" and "colour." "Help" screens or "search tips" usually list the designated truncation symbol for a given database.

Boolean Logic

Developed by the English mathematician George Boole, Boolean logic is a mathematical framework that Web searchers can apply to broaden or refine their searches. There are three words, or *operators*, that Web searchers can use to combine their keywords to perform more complex searches: AND, OR, and NOT. The three Boolean operators are summarized below, along with potential applications. It is important to read the online "help" section of a database before performing a Boolean search, as Boolean searching does not work in all databases.

Using the Boolean Operator "AND"

Combining words with "AND" narrows a search, as the database retrieves only items that contain *all* the words entered. The second search example below will produce fewer results than the first, since there are three keywords that must appear within the content of each result.

"disability studies" AND theory
"disability studies" AND theory AND history

Using the Boolean Operator "OR"

Entering the term "OR" between keywords stipulates that any, but not all, of the words entered must appear within the search results. Using "OR" is a way of searching for synonyms or related terms when there are multiple words for the same concept. The example below shows how you could broaden your search if you wanted to search for multiple adaptive technology applications in a search engine. The second search example will potentially produce more results than the first, since there is an additional keyword that the results could include.

JAWS OR "Ruby OpenBook"
JAWS OR "Ruby OpenBook" or "window eyes"

Using the Boolean Operator "NOT"

Entering the Boolean operator "NOT" after a word stipulates that the word should not appear within the results. Using "NOT" in a search can be particularly useful if a word is frequently used in multiple contexts and you wish to eliminate results dealing with a particular topic. In the example below, the second search will ideally eliminate items relating to the state of New Mexico, given that the researcher is looking for information on legislation related to disabilities in the country of Mexico. The use of NOT can be too limiting. The second search would eliminate results that discussed both Mexico and New Mexico.

Disabilities AND legislation AND Mexico
Disabilities AND legislation AND Mexico NOT "new mexico"

Nesting

Nesting allows Web searchers to simultaneously search for multiple search terms relating to the same topic. The grouping of synonymous terms within parenthesis is referred to as nesting, as multiple terms relating to the same idea are clustered together as a single concept. When using nesting, the words within the parenthesis are connected by the Boolean operator "OR."

To find information about software for people who are visually impaired, search results are increased by using nesting to group multiple words for each facet of the topic:

(software or "adaptive technology") AND ("visually impaired" or blind)

Plus and Minus Signs

Most general search engines allow users to enter plus or minus signs before a particular word. Entering a plus sign before a word (e.g., +ADA) stipulates that the word must appear within the search results. A minus sign before a word (e.g.,–mobility) stipulates that the word should not appear within the results. Since some search engines also use plus and minus signs as substitutes for Boolean operators, it is important to view online "help" or "search tips."

Search Limits

Most search engines allow users to limit their results by date, language, or document type. Limiting capabilities vary from site to site and are customarily outlined in online "help" screens. In general, article indexes have more sophisticated limiting capabilities than search engines that are freely available on the Web.

EVALUATING WEBSITES

A researcher weighing the quality of a journal article faces a lesser challenge than a researcher considering a website as a potential resource. The publishing industry applies labels to periodicals of varying type: Scholarly journals, popular magazines, trade publications, and newspapers comprise the major categories. Articles submitted to scholarly journals undergo a peer review process by experts in a given field. If in doubt as to the suitability of journal for scholarly purposes, a researcher can consult a directory of periodicals such as *Ulrich's Periodicals Directory,* which indicates whether or not a journal is peer reviewed.

The fact that the Web has no comparable methods of control complicates the task of determining whether a website is appropriate for research purposes. While websites produced by certain types of agencies and organizations certainly undergo a form of *internal*

review, the Web is a free forum; people can post anything they want, and no one has the right to force to take it down if it fails to meet certain standards of quality or accuracy. To complicate the matter, inaccurate or inexpert information can hide like a wolf in the sheep's clothing of sophisticated graphics, layout, and design. The Web has no peer review process to ensure quality. While none of the evaluation criteria outlined below can provide the final word as to the suitability of a website for scholarly use, a researcher who searches the Web with multiple evaluation criteria in mind expedites the process of finding quality information.

Authorship

When determining the credibility of a website, researchers should use multiple techniques to determine the credentials of the author as well as the character of the organization hosting, or sponsoring, the site. If individuals are listed as authors, researchers should take steps to determine their credentials and reputation in the field by performing a search in a general search engine to find biographical information or other documents written about the author. This will also produce references to the author on the sites of other authors within a field. Researchers can also consult a number of biographical sources available at libraries, such as *Who's Who in the America* or sources tailored to particular fields of study, such as *Who's Who in Science and Engineering.*

Website addresses, or URLs (Uniform Resource Locators) can also provide hints as to author affiliations and potential bias. Personal websites are often hosted on commercial ISP (Internet Service Provider) Web servers such as aol.com, or geocites.com. URLs of personal websites often contain first or last names, as well as percent (%) or tilde (~) signs. While personal websites may contain authoritative information, researchers should question why the same content does not appear on a site sponsored by an educational or research organization.. Was the site created as a pastime or to serve as a forum for airing personal views? Or does the site reflect serious scholarship backed up by other credentials and research published in scholarly publications?

Every website URL ends with a *domain name*, usually a series of three letters preceded by a period. The domain name denotes the type of institution that hosts the website and can often provide clues as to the purpose or potential bias of a site. Common domain names include the following:

Educational sites: .edu
Government sites: .gov, .mil, or country codes (e.g., .uk = United Kingdom, .au = Australia, .do = Dominican Republic)
Nonprofit organization sites: .org
Commercial sites: .com

Most URLs contain multiple levels separated by slashes (e.g., http://www.nod.org/stats/). To learn more about the sponsor or publisher of a particular site, you can remove levels of the URL one by one to see where the site is hosted and determine the character of the sponsoring entity. For instance, if a site is hosted on the site of an association, viewing the mission statement on the home page of the association can provide clues as to the bias or purpose of the content. When judging the credentials of the publishing entity, researchers should look for contact information and institutional logos. In general, sites devoid of identifying information or contact numbers and addresses should raise suspicion.

Audience

When evaluating a site, researchers should determine whether the content succeeds in addressing the stated audience through tone and presentation. Sites for adults should not have a childlike appearance or tone. Likewise, sites may be deliberately overrun by technical language or jargon to confuse or mislead a particular audience. High-quality sites clearly define their intended purpose.

Currency

Medical research findings or population statistics may become obsolete at a faster rate than research in the humanities. Web researchers should check sites for copyright dates and the date of the last update. Broken links are a sign of neglect, as they may indicate that URLs have changed or become obsolete since the last update of the site. To verify the currency of information on a site, researchers should check for several sites covering the same subject matter.

Accuracy

Determining accuracy involves further research to ensure that the claims or findings on a site are substantiated by other sources. If a site presents original research, the methods of the research and instruments used should be clearly explained, as well as potential limitations of the research. If authors make claims or conclusions, they should cite their

sources, and these sources should be tracked down to ensure their existence and authenticity. Websites should contain a list of works cited or footnotes on par with any print book or article. Since websites sometimes include fabricated resources, and erroneous or incomplete citations, sources should be verified using library tools such as indexes and catalogs. Lists of works cited with multiple errors reflect irresponsible research. If a website contains links, the links should be checked. Researchers should be wary of websites populated by broken links or links to defunct websites.

Quality

In general, sites that are poorly organized or sloppy should be approached with caution. Shoddy design may point to further weaknesses. Poor grammar and spelling errors are also red flags.

Bias

While bias is not always a negative attribute, Web searchers should be cognizant of bias as the search for information. The bias of a website can be partially discerned by the domain name (as discussed above under "Authorship"). Commercial websites may be motivated by the goal to market a product or service. Nonprofit organizations may promote a political agenda. While bias may be clearly stated in mission statements and "about" pages, many websites deliberately shroud their bias. Thorough research involves consulting additional sources to determine the history and activities of a particular organization. If a site contains links to other sites, those links should be checked to discern the character and activities of the other organizations listed. If a site is sponsored by other organizations, researchers should consider the relationship between the sponsors and the creators of the site.

Special Considerations for Evaluating Health Information on the Web

The American Medical Association (AMA) has published "Guidelines for Medical and Health Information Sites on the Internet" outlining evaluation criteria for websites publishing health information, whether for consumers or health professionals. While these guidelines are technically enforced only on sites sponsored by the AMA or affiliated organizations, they could be applied to all sites containing health information. Many of these guidelines mirror the previously outlined criteria for evaluating all websites, but there are certain factors that are heavily emphasized in the AMA guidelines, including the importance of peer review by experts in the field, the importance of clearly identifying sources of funding, an explanation of the relationship between individual researchers and the institutions sponsoring the research, the importance of clearly stating the purpose and intended audience of a site, and the need to address the stated audience in a consistent and effective tone. Seven criteria for assessing the quality of health information on the Internet have been developed by the Health Summit Working Group (Health Information Technology Institute 1999).

Information on health-related websites should be verified by checking sources such as journal articles, books, and other websites. These measures are needed as health information on the Web frequently includes unsubstantiated claims.

OVERVIEW OF ACCESSIBILITY ISSUES ON THE WEB

Disability studies research is unique in that many scholars in the field have disabilities that may impact their ability to effectively search the Web. While in many ways the Web "evens the playing field" by making a vast number of resources available electronically, inaccessible design frequently places barriers on Web searchers with disabilities.

Principles of Web accessibility have been developed by the World Wide Web Consortium's (W3C) Web Accessibility Initiative (WAI). The WAI establishes guidelines for creating accessible websites, browsers, and authoring tools to increase the ease of use of the Web for users with disabilities. Multiple scenarios outlining potential challenges to Web searchers with disabilities are summarized in a W3C working draft titled "How People with Disabilities Use the Web" (2001). Among other scenarios, the document emphasizes that many Web searchers with cognitive or visual disabilities use OCR (optical character recognition) software, which reads Web page text and transmits the information to a speech synthesizer and/or refreshable Braille display. Many users with visual disabilities use text-based Internet browsers instead of standard graphical browsers. The successful use of these tools requires that images on websites be accompanied by descriptive text and *ALT tags*. ALT tags are textual labels that appear on the computer screen when a mouse moves over an image. Since visually impaired

Web searchers often enlarge Web-based text using screen magnification programs, Web designers must create pages with nonfixed font sizes that can be altered as necessary. These are only a few of the issues facing Web searchers with disabilities. Other population groups with disabilities discussed in the guidelines include individuals with cognitive disabilities, hearing impairment, and mobility-related disabilities. Readers should consult the WAI website for the complete guidelines (http://www.w3.org/WAI/).

To support the goals of WAI, an online tool called Bobby™ helps website developers test the accessibility of their sites and adhere to accessibility guidelines. By entering a URL into the Bobby website, a Web developer can generate a report outlining which features of the site need to be adjusted to make it "Bobby compliant" and adhere to both W3C accessibility guidelines and guidelines established by the U.S. government's Section 508, a 1998 amendment to the Rehabilitation Act requiring that all federal agencies make their electronic and information technology accessible to people with disabilities. Complete information about these guidelines can be found on the Section 508 website (www.section508.gov).

CONCLUSION

While "one-stop shopping" in Google may be tempting, there is no single search engine leading to everything on the Web. Comprehensive and effective research in disability studies involves consulting multiple search tools, including but not limited to general search engines, subject-specialized search engines, directories, and indexes. In addition to using multiple search tools, Web searchers should experiment with multiple search strategies to maximize the effectiveness of their searching. As there are no standards of quality on the Web, researchers should apply multiple evaluation criteria to every website, verifying that research findings posted on sites are supported by other sources. Web accessibility is a crucial component to disability studies, as the Web has the potential to deliver equal content to all users but frequently presents barriers to people with disabilities by failing to adhere to standards of accessible design. Researchers can develop an awareness of accessibility issues on the Web by familiarizing themselves with the standards outlined by W3C's Web Accessibility Initiative and Section 508.

SENIOR EDITORIAL BOARD

INTERNATIONAL ADVISORY BOARD

LIST OF ENTRIES

READER'S GUIDE

The Reader's Guide is provided to help readers locate entries and primary sources by topical category. It classifies the A–Z entries (Volumes I–IV) and primary source documents (Volume V) into twenty-five categories: Accessibility, Arts, Biographies, Children and Infants, Deafness and Deaf Culture, Disability Studies, Economics and Employment, Education, Ethical Issues, Experience of Disability, Health and Medicine, Health Care, History of Disability, Information Technology, Language of Disability, Law and Social Policy, Models, Organizations, Politics, Rehabilitation, Rehabilitative Engineering and Assistive Technology, Religion, Science, Sports, and Therapies. Some entries and documents may appear in more than one category.

Page numbers for primary source documents and illustrations can be found in the Table of Contents and List of Illustrations for Volume V, which appear in the front matter of each volume, and in the index.

E

EARLY CHILDHOOD INTERVENTION

Early childhood intervention is defined by services for infants and young children to prevent or reduce disability and to promote their development and general well-being. It seeks to identify actual or potential risks for disability as soon as possible and initiate interventions to minimize limitations related to individual, social, and environmental factors. Early childhood intervention recognizes the central role of the family in the child's development and is based on the provision of individualized intervention for the child and family in the proximal environment. Interventions focus on reducing and/or removing physical, cognitive, emotional, social, and environmental barriers and promoting the child's growth, development, and health through stimulation and provision of support. Early childhood intervention builds on biomedical, behavioral, and social and educational research and requires the contributions of specialists from many disciplines. It is a complex and continually evolving field with broad, interdisciplinary involvement including psychologists, early childhood educators, social workers, pediatricians, nurses, child psychiatrists, physical and occupational therapists, speech and language pathologists, and professionals in public health and social policy.

Children with diagnosed conditions such as Down syndrome, autistic spectrum disorders, cerebral palsy, and communication disorders were initially the primary recipients of early childhood intervention. However, children with developmental delays and children with risk factors associated with low birth weight, disadvantaged environments, and neuromotor problems are increasingly likely to be served in early-intervention programs.

Early childhood intervention was established in the United States and in some countries in Europe in the 1970s. The interest for early childhood intervention is increasing around the world since it covers common issues that transcend national boundaries. Researchers, clinicians, parents, program developers, and policy makers from many countries contribute to the rapidly expanding knowledge base of early childhood intervention. The International Society for Early Intervention (ISEI) with members from 50 countries representing all continents, provides a forum for professionals to communicate about advances in the field of early intervention. In Europe, Eurlyaid (European Association on Early Intervention), a European working party of professionals and representatives of parent associations from more than 15 countries, is involved in promoting early intervention for children at risk or with developmental disabilities. The European Agency for Special Education is also involved in promoting early childhood intervention in Europe. There are national organizations working for early childhood intervention in many countries all around the world, for example, in Australia, India, Hong Kong, South Africa, and Russia.

The age of entry to the early childhood intervention services varies from country to country. In North

America, early childhood intervention covers the years from birth to three, whereas in Europe it covers the ages from birth to five or six. The form of early childhood intervention services provided varies as a function of the system of services existing in each country. In some countries, early childhood intervention is included in general health care and educational services for all children. In other countries, special programs for early childhood intervention are provided that may be center based, home based, hospital based, or a combination. Services may include identification, assessment, and the provision of direct intervention. Variability may be found in eligibility criteria and accessibility to early childhood intervention as well as the extent of involvement of parents in the intervention process.

The universal framework of early childhood intervention relies on recognition of the individuality of all children in terms of abilities and disabilities, and a comprehensive approach encompassing the child's health and well-being. It relies on the knowledge that children are born active and are ready to communicate and learn and that stimulating and responsive social and physical environments are essential for development. The growth of the field of early childhood intervention is influenced by the declarations of the United Nations and the World Health Organization (WHO). Key sources are the 1959 UN Declaration of Rights of the Child and the 1990 Convention of the Rights of the Child, where the responsibility of society to ensure children's health and development is underlined. Article 23 recognizes the importance of meeting needs of children with disability. WHO declarations serve as a premise for advocacy and legislative initiatives concerning health and disability. Parent associations have also to a great degree influenced the evolving field of early childhood intervention advocating the rights and needs of children with disability.

Early childhood intervention is influenced by theory and developmental science. Universal features include an ecological framework, a systems theory approach, a focus on the family and the proximal environment for intervention, individualization of services and supports, and a preventive perspective. An underlying assumption is that early intervention can prevent or reduce later manifestations of delay and disability. The ecological base and a family systems approach builds on the assumption that developmental problems must be addressed in the environmental context of the child. It focuses on interventions addressing the child, the family, and other proximal environments and intervention providers. A basic premise is that the unique and complex needs and resources of each child and family are met best by an interdisciplinary approach in collaboration with the family. A systems approach recognizes that the family and child are influenced by the world of work, the preschool, available services for health, and other major social systems. On the macro level, early childhood intervention is influenced by broader factors of laws, culture, attitudes, values, geography, and economy.

Developmental science has had a major influence on the philosophy and practices in early intervention. A fundamental assumption in child development literature is that the child is seen as active in constructing his or her world and that development occurs through the ongoing transactions over time between the child and his or her social and physical environment. Another foundation for early childhood intervention is the centrality of relations and of the environment in early development.

As research on early childhood intervention continues to evolve, a distinction has been made between first- and second-generation research. In first-generation research, focus has been on the child and methods to assess and intervene with the child's impairment and disability. In second-generation research, issues that are of value in the daily activities of children, families, other proximal environments, clinicians, and teachers are in focus broadening the scope of the discussion about assessment and intervention. Second-generation research addresses the questions about what intervention, for what child, under which circumstances, and with what desired outcomes?

The basic philosophy in early childhood intervention relies on a number of basic assumptions that define the essential elements in processes and outcomes of early childhood intervention. To reach the goal of preventing disabilities and promoting growth, development, and well-being of infants and young children, interventions must take individual differences into account. The focus for interventions is thus the child's health, development, and well-being in both assessment and intervention. To meet the goals of early childhood intervention, services must be designed that are personalized for the child and family as a unit and in their specific social and cultural context.

—Eva Björck-Åkesson and Mats Granlund

EASTER SEALS

Easter Seals has been helping individuals with disabilities and special needs, and their families, live better lives for more than 85 years. From child development centers to physical rehabilitation and job training for people with disabilities, Easter Seals offers a variety of services to help people with disabilities address life's challenges and achieve personal goals.

In 1907, Ohio businessman Edgar Allen lost his son in a streetcar accident. The lack of adequate medical services available to save his son prompted Allen to sell his business and begin a fund-raising campaign to build a hospital in his hometown of Elyria, Ohio. Through this new hospital, Allen was surprised to learn that children with disabilities were often hidden from public view. Inspired by this discovery, in 1919 Allen founded what became known as the National Society for Crippled Children, the first organization of its kind.

In the spring of 1934, the organization launched its first Easter "seals" campaign to raise money for its services. To show their support, donors placed the seals on envelopes and letters. Cleveland Plain Dealer cartoonist J. H. Donahey designed the first seal. Donahey based the design on a concept of simplicity because those served by the charity asked "simply for the right to live a normal life."

The lily—a symbol of spring—was officially incorporated as Easter Seals' logo in 1952 for its association with springtime, renewal, and new life, and it has appeared each year as part of a fund-raising campaign.

Public support for the Easter Seals' "seals" campaign triggered a nationwide expansion of the organization and a swell of grassroots efforts on behalf of people with disabilities. By 1967, the Easter Seals' seal was so well recognized that the organization formally adopted the name "Easter Seals."

Easter Seals assists more than 1 million children and adults with disabilities and their families annually through a nationwide network of more than 500 service sites. Each center provides high-quality, family-focused and innovative services tailored to meet the specific needs of the particular community it serves. In the United States, Easter Seals' services for children and adults with disabilities include medical rehabilitation, job training and employment, inclusive child care, adults and senior day care and in-home care, and camping and recreation programs.

Easter Seals also advocates for the passage of legislation to help people with disabilities achieve independence, including the Americans with Disabilities Act (ADA). At the core of the Easter Seals organization is a common passion for caring, shared by its 13,000 staff members and thousands of volunteers, and by those who support its mission.

EATING DISORDERS

Eating disorders (anorexia nervosa, bulimia nervosa, and binge eating disorder) have been identified by some clinicians as an emerging public health crisis. Rates of eating disorders are difficult to gauge because of underreporting and misdiagnosis, but the *DSM-IV-TR* (American Psychiatric Association 2001) estimates lifetime prevalence to be 0.5 percent for anorexia and 1–3 percent for bulimia, with data still being collected on the newly designated binge eating disorder. Over 90 percent of those affected by eating disorders are women. An estimated 20 percent of all college females actively struggle with either anorexia or bulimia.

Eating disorders have long been viewed as a "culture-bound syndrome," as they have been historically observed in white, upper-middle-class teenage girls in the United States. Eating disorders have often been interpreted as expressions of conflicted feminine identity in the wake of capitalist expansion and as the embodied representation of conflicting cultural discourses regarding individualism and dependency. Recent reports, however, note increasing rates of incidence in other ethnic groups, persons of diverse economic backgrounds, boys and men, and non-Western cultural contexts. This diversification of the "typical" profile, coupled with increases in reported cases, produces something of a conundrum. On the one hand, the appearance of eating disorders in such a wide range of people across the globe might seem to lend credence to studies suggesting a biological basis for the disorders. On the other hand, the apparent coincidence of these increases with the expanded reach of western cultural ideology suggests cultural factors as a precipitating factor.

Regardless of where one locates causation, the fact remains that individuals who suffer from eating disorders are significantly impaired in their abilities to care for themselves, to interact with others, and to pursue school or employment. Their bodies are often ravaged by the disorder, leaving their bones brittle and weak, their teeth fragile, their heart and other organs often permanently damaged. Given this, and the increasing numbers of people struggling with these illnesses, one might legitimately argue that eating disorders should be classified as a "disability," and their sufferers afforded all the rights and protections given to other disabled individuals.

But there is something perhaps unsettling about this, and it speaks to the precarious situating of eating disorders in the cultural and clinical landscape: Do eating disorders reflect individual pathology, or should they be understood as crystallizations of pathological cultural dynamics? Are eating disorders inevitable given the presence of certain causal factors, or do they reflect individual choices within a given social context? How one answers these questions has direct implications for where one places responsibility for these illnesses, and, consequently, how they are understood vis-à-vis other disabling conditions. Put another way, we might ask: Can and should we recognize a condition as a "disability" that in many ways—through its emphasis on self-control, efficiency, and personal achievement—makes manifest our most treasured social values?

In strict definitional terms, eating disorders do meet the criteria for "disability." In its biopsychosocial model of health and illness, the International Classification of Functioning, Disability, and Health (ICF) defines *disability* as an outcome of interactions between health conditions and contextual factors that involves dysfunctioning (given certain qualifiers) at one or more of the three levels of human functioning: body or body part, whole person, and whole person in context (World Health Organization 2001). Eating disorders in their active phases certainly impair an individual on each of these three levels in ways substantial enough to disrupt everyday life. The Americans with Disabilities Act of 1990 states that an individual is considered to have a disability if he or she has a physical or mental impairment that substantially limits one or more major life activities, has a record of such an impairment, or is regarded as having such an impairment. Again, eating disorders (viewed either from the perspective of mental illness or from the perspective of their physical consequences) would easily meet these criteria. But while conditions such as attention deficit hyperactivity disorder (ADHD), schizophrenia, major depression, and bipolar disorder are legally recognized as disabling conditions worthy of accommodation, eating disorders are not. What makes eating disorders different? The aim of this entry is not to argue either for or against classifying eating disorders as a disability, but rather to briefly outline some of the issues at stake when a disabling condition unfolds within a social context that explicitly values many of the features of that condition.

Few would argue that a person who has schizophrenia or bipolar disorder would (and should) qualify as "disabled" according to these criteria. But many eating-disordered individuals do not, at first glance, appear to be substantially limited in their ability to function in society (at least those with anorexia nervosa or bulimia nervosa). (There has also been increasing pressure in recent years to classify obesity as a disability. See LeBesco 2004 and Braziel and LeBesco 2001 for discussions of this and related issues.) One reason for this is that, as noted above, the heightened self-control, anxiety about not being good enough, and ambivalence about overconsumption characteristic of eating disorders, while perhaps pathological in their extreme expressions, are nevertheless "in sync" with our cultural ideology in a way that hearing voices or staying in bed for a week are not. And it is perhaps more difficult to view a condition as disabling if it appears (on the surface at least) to garner significant social and cultural capital for the person involved. Girls often *do* get more positive attention when they are thin; physical fitness and attractiveness *are* often linked to success in the business world (see, e.g., Bordo 1995; Wolf 2002). Indeed, the social perks that can accompany the attainment of the slim, fit ideal can easily transform eating-disordered individuals into objects of envy rather than of sympathy. This situation is complicated by the recent rise of "pro-anorexic" websites with names such as "Emaciate me," "Little Baby Nothing," "Ana By Choice," "Anorexic wit' Attitude," and "Beautifully Insane," which insist that being anorexic is a "life choice" and an avenue for empowerment. This would seem to lend credence to the position that people with eating disorders *choose* to be sick, and, by extension, could just as easily choose to be well.

But such a position obscures the everyday, soul-wrenching struggle many eating-disordered individuals endure as they work to pull themselves, inch by excruciating inch, out of the depths of their illness. In the throes of an eating disorder, one does not feel pretty or popular or successful or powerful. On the contrary, one feels hollowed out, hopeless, emotionally decimated. And the most debilitating aspects of the illness do not entirely go away with recovery. For most eating-disordered people, food and eating always remain wrought with anxiety, one's body is always to some degree the enemy, and the temptation to return to eating-disordered behaviors (horrible as they are) swells in the face of periods of stress (see Hornbacher 1999 for a particularly gripping personal account of these issues). The "disability" of eating disorders, then (should we choose to call it that), is perhaps more elusive and subtle than other forms of disability, such as blindness or cerebral palsy. It is more like a sustained vulnerability than a physical limitation in functioning. And unlike these other conditions, accommodations cannot be made for the eating-disordered person. On the contrary, recovery often proceeds *in spite of* social interventions (with its contradictory passions for super-sizing food portions, on the one hand, and fad diets, liposuction, and 24-hour gyms, on the other) rather than because of them.

What *can* be gained from exploring eating disorders as a form of disability, however, is an increased awareness of the lifelong, everyday struggle those in recovery must face as they navigate cultural expectations of control, success, and achievement through the attainment of the perfect body. This might also lead us to a critical revisiting of the notion of disability as a condition that prevents full participation in society. In some cases, it seems, this full participation itself can be implicated in both the causes and consequences of what often becomes a lifelong battle.

ECONOMIC ANALYSIS OF DISABILITY

Studies of the economic impact of disability have been conducted from the perspective of government and society at large. Government expenditures on behalf of persons with disabilities may total as much as $247 billion (in 1997 terms), with all but $4 billion due to medical care expenditures or disability transfer payments. The costs of disability from the perspective of society may be as much as $345 billion (in 1997 terms); even after taking into account the costs that would be expected among persons with disabilities in the absence of the disability, the costs may total as much as $217.3 billion (in 1997 terms), the equivalent of 2.6 percent of the gross domestic product (GDP) in the United States for that year.

METHODS OF COST OF DISABILITY STUDIES

Estimates of the economic impact of reduced health or functional status have been produced with regularity since the mid-1960s. Most have concerned the cost to society of the prevalent cases of individual medical conditions, but the methods have been adopted by those interested in estimating the impact of disability on the national economy. In these studies, analysts enumerate the resources consumed as a result of having a medical condition (or disability), encompassing the costs of procuring medical services (including assistive technology and personal assistance), labeled "direct costs," and those associated with reduced ability to participate in activities, labeled "indirect costs."

Indirect costs might include the wage losses incurred by those who would be expected to work in the absence of the disability or of their household members who reduced work to care for them. Indirect costs would also include the economic costs associated with reduced functioning in other spheres of activity, such as parenting, as well as the harder-to-measure costs associated with the psychological impact of not being able to function as well as one would like. A full accounting of the costs of disability, of course, might include some gains as well. On the tangible side, there is some evidence that persons with disabilities use fewer medical resources than expected because they learn to consume medical care more judiciously. Similarly, some persons with disabilities are actually able to find more remunerative work after the onset of their disabilities or are able to replace paid help in family roles such as child care because of their reduced work time. Finally, some report personal growth through the experience of having a disability and, thus, would not report psychological deficits, but the opposite.

There are two principal methods to assess the costs of illness or disability. The first, the human capital approach, was devised by Dorothy Rice and colleagues. The human capital approach provides estimates of the economic value of services or goods purchased to take care of oneself (principally medical care) as well as the economic value of losses to society when individuals function more poorly, principally, the wage losses of those who stop or reduce work effort and the equivalent in wages for those one would hire to replace other kinds of function, for example, the costs associated with paying someone else to do the tasks associated with being a homemaker.

In the other principal method, the willingness-to-pay approach, one accounts for the tangible and intangible impacts of lost function by asking respondents how much they would be willing to pay to forgo an illness or disability. As a practical matter, because the obstacles to implementing the willingness-to-pay approach are so numerous (including the fact that individuals have trouble completing the exercise of stating their willingness to pay, are far more willing to pay after the onset of illness or disability than before, and the amount they are willing to pay is proportional to income, suggesting that some lives are worth more than others), there are no cost-of-disability studies using this method.

Even among the studies using the human capital approach to estimate the cost of disability, most have enumerated the direct and indirect costs incurred by persons with disabilities, regardless of whether the disability status accounts for the costs, rather than estimating the actual economic impact of disability above and beyond what would be expected in the absence of the disability. (Table 3, below, provides summary estimates of the latter below.)

RESULTS OF PRIOR ANALYSES

Table 1 reviews the results of the principal studies of the economic impact of disability over the past several decades. The studies differ in their perspective (with some providing estimates of the costs to government; some to disability insurers, including those in government and the private sector; and some to society as a whole) and the range of costs enumerated (with some limited to medical care expenditures as well as those for disability-specific services such as rehabilitation, some to disability insurance benefits [called income transfers when provided by government], and others encompassing both). In addition, the studies differ in the populations studied—from all persons with disabilities to only those of working ages or only children. Moreover, the results of the studies using different perspectives cannot be compared. For example, studies of the costs of disability from the perspective of society would necessarily omit an enumeration of disability transfer payments to avoid double-counting the impact of lost wages.

The first comprehensive assessment of the economic impact of disability was completed by Berkowitz and Johnson in 1970 and concerned the magnitude of disability transfer payments by the federal government in 1967: $43 billion ($207 billion in 1997 dollars). Burkhauser and Haveman provided a thorough review of government and private disability expenditures in several years; Table 1 provides the estimates for the last year for which they have complete data, 1978. They reported that government and private disability expenditures totaled $82 billion in that year (or $202 billion in 1997 terms). Disability transfers, worker's compensation, and medical services comprised most of the total. Snook and Webster estimated the magnitude of disability transfer payments, by kind, for 1981. Social Security Disability Insurance payments totaled $17 billion, worker's compensation payments were $16 billion, while private disability payments amounted to $5 billion. In 1989, Berkowitz and Greene updated the earlier estimates for 1986, finding that disability transfers (including those from the private sector) were $87 billion (or $127 billion in 1997 terms). The real value is actually less than their earlier study due, in part, to differences in services and income transfers enumerated as well as errors in adjusting for inflation. In addition, medical care expenditures on behalf of persons with disabilities totaled $79 billion in 1986 ($116 billion in 1997 terms) while expenditures on disability-specific services amounted to $3 billion ($4 billion in 1997 terms). The total of government and private expenditures on behalf of persons with disabilities in 1986 of $169 billion amounted to 3.8 percent of the GDP for the United States in that year. More recently, Aarts and colleagues provided estimates of government disability expenditures. Although they provided the estimates in terms of the percentage of GDP, we have translated the figures into billions of dollars. In 1991, government disability expenditures totaled $45 billion, of which all but $3 billion was due to disability transfer payments.

Several analysts have calculated the magnitude of medical care expenditures for persons with disabilities in both the public and private sectors. In the first of these, Newacheck and McManus estimated that expenditures on behalf of children with disabilities totaled $2 billion in 1980, or $4 billion in 1997 terms.

Source: Author's analysis of 1997 Medical Expenditures Panel Survey.

Similarly, Rice and LaPlante estimated that medical care expenditures for persons with disabilities of all ages for the year 1980 totaled $63 billion, or $123 billion in 1997 terms. Trupin and colleagues calculated the magnitude of medical care expenditures for persons with disabilities for 1987, by source of payment. Of the total expenditures of $157 billion ($222 billion in 1997 terms), out-of-pocket expenditures were $29 billion, private insurance paid for $42 billion, public insurance paid for $80 billion, while other sources paid for $6 billion.

In 1989, Chirikos made the first comprehensive assessment of the costs of disability from the perspective of society using data from 1980. He reported that direct costs for medical care and disability services amounted to $91 billion in that year, indirect costs due to lost wages of persons with disabilities were $68 billion, while indirect costs of lost income among family members were $18 billion, for a total of $177 billion ($345 billion in 1997 terms). Using these figures, the cost of disability to society was the equivalent of 6.3 percent of GDP for 1980. Since the Chirikos study was published, no similarly comprehensive estimates of the costs of disability have been completed. However, the Institute of Medicine provided estimates of the indirect costs associated with disability for 1994 using two different data sources with and without adjustment for differences between persons with and without disabilities in demographic and health characteristics. The institute estimated that the indirect costs associated with disability ranged from $93 to 159 billion ($101 to $172 billion in 1997 terms). Thus, despite the passage of time since the Chirikos study, his estimate and that of the Institute of Medicine of the indirect costs associated with disability were of similar magnitude.

RESULTS OF NEW ANALYSES

The authors of this entry have used the Medical Expenditures Panel Survey (MEPS) to develop estimates of the economic impact of musculoskeletal conditions, the subset including various forms of arthritis, and respiratory conditions. The MEPS, jointly administered by the Agency for Healthcare Research and Quality and National Center for Health Statistics, is an annual survey of medical care utilization and attendant costs and functional status among the U.S. noninstitutionalized population. In these prior studies, we have estimated the direct and indirect costs incurred by persons with the aforementioned medical conditions regardless of whether the condition in question was responsible for those costs. In addition, we have used regression techniques to estimate the increment in direct and indirect costs associated with the specific condition being studied.

In the analyses reported here, we replicate the methods of the prior studies to provide estimates of the direct and indirect costs incurred by persons with disabilities as well as of the increment in such costs specifically associated with disability for 1997. For the analyses, we defined *disability* as the presence of a limitation in work, household, or school activities or a limitation in social or recreational activities or the presence of confusion or memory loss, difficulty making decisions, or the need to have one's activities supervised by someone else for one's safety due to cognitive impairment. All told, about 23.2 million persons (8.6 percent of the noninstitutionalized population) met one or more of these criteria for disability, of whom about 10.2 million were men and 13.0 million were women.

Table 2 shows the distribution of all direct and indirect costs incurred by persons with disabilities, by kind. Overall, direct and indirect costs for persons with disabilities averaged $19,620 per case, for a total of $297.6 billion (the equivalent of 3.6 percent of the GDP for 1997). Of the $19,620 average, $7,879 per case, or $182.6 billion (40 percent of all costs) was associated with direct costs and the remainder, $11,741 per case, or $115.0 billion, with indirect costs. Lost wages among persons who had stopped working altogether was by far the single largest component of costs ($8,489 per case, or 43 percent), while inpatient or ER costs and lost wages among those still employed represented 19 and 17 percent of total costs, respectively. To put the 3.6 percent of GDP figure in perspective, the economy is said to be in a recession when the overall economy contracts by 1 percent or more for two consecutive quarters. So the economic impact of the direct and indirect costs incurred by persons with disabilities would have an effect of a severe and ongoing recession.

The results of the analysis of the increment in direct and indirect costs associated with disability indicate that most of the costs incurred by persons with disabilities are the result of the disability itself rather than the other characteristics of persons with disabilities (Table 3). Accordingly, total costs associated with disability averaged $16,113 per case, or $217.3 billion (2.6 percent of GDP for 1997). However, the increment is disproportionately attributable to indirect costs as a result of lost wages. Whereas 40 percent of all costs incurred by persons with disabilities were for direct costs, only 18 percent of the increment associated with disability was due to direct costs. Prevention of work disability, one of the principal goals of the Americans with Disabilities Act, is essential to limiting the economic impact of disability.

Table 3 Direct and Indirect Costs Associated with Disability

	Mean ($)	*Sum (billions of $)*	*% of Total*
Direct Costs			
Total	2,953	68.4	18
Indirect Costs			
Total	13,160	148.9	82
Total	16,113	217.3	100

Source: Author's analysis of 1997 Medical Expenditures Panel Survey.

Note: Direct costs estimated for all persons age 18 and older; indirect costs for all persons ages 18–64.

Interestingly, the increment in the earnings gap is larger than the raw earnings gap. The implication is that persons with disabilities earn more than expected on the basis of their disability and their other characteristics; the results are inconsistent with the charge that persons with disabilities may not persevere at work because of the availability of disability benefits.

ECONOMIC AND SOCIAL DEVELOPMENT

Disability is linked to development in a manner that is neither obvious nor well established. For instance, increased disability may be the result of advances in health signaling broad-based welfare improvements, or societies may be in such economic or political disorder that continued poverty or war conflict leads to a rise in the prevalence of disability. At the same time, disability seems to impede development through the constraints it places on individuals’ productivities and earning capacities. These complications combined with a dearth of comparable data may explain why the link between disability and development has been the subject of very little research in both the disability and development literatures. More attention has been granted to the link between disability and poverty, widely accepted as a vicious circle. The relation between development and disability may be understood as a two-way street, where development affects disability and vice versa. Disability and development are intertwined, and we seek to understand both strands of the relationship. The major part of this review explores aspects of the relationship at a macro level, while touching on micro- and policy-level links as well.

This entry is organized as follows. I first clarify the concepts of development and disability. The entry then analyzes the two-way relation between development and disability. At the micro level, the entry explains the vicious circle between poverty and disability. Finally, I review disability policies of international development agencies such as the United Nations and the World Bank.

TWO CONCEPTS: DEVELOPMENT AND DISABILITY

We all have intuitive notions of *development* and *disability*. Yet these two concepts are complex and cannot be used without clarifying their definitions and measurements. Development typically refers to the structural transformation from a subsistence economy to an urban industrial economy, and to the sustained rise in income and productivity that follows. The transformation takes place in various aspects of the economy and society, including in the structure of consumption, production, investment, and trade and in demographic trends and economic institutions. While development is typically understood in its narrow economic sense, it also has human and political dimensions. Human development is the process of expanding the education, health, and other conditions of human life. In its political sense, development refers to the process that provides individuals with improved civil rights and with the opportunity to determine who should govern. It refers to entitlements and institutions one usually associates with democracies.

In this broad sense, development refers to the enhancement of individuals' capabilities and freedoms. This concept of development is far more difficult to measure than the conventional economic view of development captured in the per capita gross domestic product (GDP), growth, or industrialization measures. However, several measures have been developed to capture this broader approach of development including the Human Development Index of the United Nations Development Programme (UNDP). *Development* is thus a multifaceted term. We understand it as a broad concept with economic, human, and political dimensions when we attempt to understand its link to disability.

Disability has proved to be a very controversial and complex concept to define and measure, and analyzing its definitional problems is beyond the scope of this entry. In brief, different conceptual models have been created to define disability. For instance, the medical model considers disability as a problem of the individual that is directly caused by a disease, an injury, or other health conditions and requires medical care in the form of treatment and rehabilitation. An individual with an impairment is considered disabled (where *impairment* is the term used for an individual's condition) irrespective of whether the person experiences limitations in his or her life activities. The medical model is usually opposed to the social model. Overall, the social model sees disability purely as a social construct and a human rights issue. Disability is not the attribute of the individual; rather it is created by the social environment and requires social change. In the social model, disability is generally understood as the result of social oppression, and this oppression can start in the form of poverty and later on lead to disability.

Recently, S. Mitra used A. K. Sen's capability approach that was developed to analyze concepts of the standard of living, poverty, and development in order to define disability. Here, disability is understood as a deprivation of capabilities where capabilities refer to practical opportunities. Disability occurs when an individual with an impairment is deprived of practical opportunities. Such deprivation may result from the interaction between the resources available to the person, personal characteristics (e.g., impairment, age, gender), and the environment (physical, social, cultural, political, economic). Poverty is a factor that, while interacting with the individual's characteristics and environment, may lead to disability.

The development and disability concepts may overlap depending on the approach we adopt to define each concept. Development and disability do not intersect when they are understood in their narrow economic and medical senses, respectively. However, if development is defined as a broad-based process that enhances human capabilities, then it may well intersect with disability. If we place ourselves in the social model where disability is a human rights issue, or if we adopt the capability approach where disability may be considered as a capability deprivation for persons with impairments, then development and disability are entwined. Clearly, if being disabled means being deprived of capabilities, reducing disability can be conceived as an integral part of the development process. Development can be considered as a process that, among other things, curbs disability by enhancing human capabilities. Development and disability are then two intrinsically linked concepts.

In the remainder of this entry, we leave the complexities of the relation between the concepts of disability and development. We use the term *disability* as a two-facet concept that refers to both disability and impairment, and we understand *impairment* as a physiological, mental, or anatomical loss. Instead, we focus on the dynamic relation between disability and development, and between disability and poverty: How does development affect disability prevalence? How does disability affect the development process? How does disability relate to poverty?

DEVELOPMENT AND DISABILITY: A TWO-WAY RELATION

There are four fundamental questions relating to the relationship between development and disability: (1) How does development affect the prevalence of disability? (2) How does development affect the distribution of disability within the population? (3) How does development impact the major causes of disability? and (4) How does disability impact development itself?

The Impact of Development on Disability Prevalence

To attempt to address the first question, we introduce the notion of disability transition. Disability transition is a concept that is meant to capture the changing pattern of disability as a country develops. As there is a "population transition" apparent in reduced birth and death rates, one may wonder if there is a "disability transition" that accompanies development. There is no definite answer to this question, whether at the theoretical or empirical level. There are mainly three theories about the link between the effect of increased life expectancy and changing morbidity associated with development on disability prevalence. The first one, and probably the most widely accepted theory, is that development leads to increased disability prevalence. The basic rationale is that the demographic and medical changes associated with development, increased longevity and survival from disabling accidents and conditions, lead to increased disability prevalence. Second, in what is often called the compression of morbidity theory, it is argued that with medical improvements, the proportion of life lived with a disability decreases and the prevalence of disability also decreases. A third theory predicts a reduction in severe disabilities through enhanced medical intervention and a rise in mild disabilities.

Is there any empirical evidence of a disability transition? While we realize that country-level estimates are not comparable because different definitions and methods are used, available disability rates seem to show a higher disability prevalence in developed countries than in developing countries. On the basis of United Nations data, for developed countries, disability rates are in the 14 to 20 percent range, while they are generally below 5 percent in developing countries. However, one needs to be very cautious when analyzing this apparent correlation between disability and development. Many factors, in particular those related to perception and measurement, contribute to higher prevalence rates in developed countries.

There are several types of factors related to development that may have an increasing or a decreasing impact on disability prevalence. First, there are factors related to demographic and health changes associated with development. For instance, improved survival rates from conditions causing illnesses and impairments would lead to an increase in disability prevalence, whereas an increase in prevention care would generally be expected to reduce disability prevalence. Second, there are aspects in the environment that would be affected by development and would in turn affect disability prevalence. Wars and political unrest are surely not limited to developing countries, but it is in the developing world that the effects are widely borne by populations, in particular through disabling injuries. It is also in developing countries with mass poverty that there are impairments resulting from inadequate nutrition and hazardous modes of living. Such impairments resulting from political unrest or poverty would be expected to decrease with development.

Third, there are factors related to the way impairments and disabilities are perceived and reported. These include increased knowledge and awareness of impairments, increased diagnosis and screening, medicalization of problems, change in perceived standard of good health, and eligibility to social benefits based on disability. All these factors lead to an increase in perceived disability and would therefore explain a higher reported disability prevalence in developed countries compared to developing countries.

Finally, fundamental differences in measuring instruments also affect prevalence estimates across developed and developing countries. Developed countries typically use disability screens that assess activity limitations, whereas developing countries tend to use impairment screens. Activity limitation screens generally lead to higher rates of reported disability than impairment screens. Indeed, individuals are more likely to identify activity restrictions because they immediately connect with daily experience, whereas an impairment may be only vaguely familiar and its nomenclature may be unknown.

The first two types of factors mentioned above indicate that some factors associated with development changes per se (medical, demographic, environmental changes) are expected to have a negative impact on disability prevalence, others a positive one. In contrast, factors related to perception and measurement all seem to have a positive association with development. Altogether, these factors probably argue in favor of higher reported disability rates in developed countries compared to developing countries. This analysis is consistent with the much higher rates of disability prevalence that we find in country-level estimates for developed countries versus developing countries.

However, this analysis and these country estimates are not consistent with global estimates of disability prevalence. The United Nations estimates that 10 percent of the worldwide population have a disability and that two-thirds live in developing countries. In 1984, the UN secretary general reported that an average of 20 to 25 percent of the population of developing countries is disabled. This number is likely to have increased because of wars and other forms of violence, inadequate medical care, and natural and other disasters. The empirical evidence on the impact of development on disability is thus inconclusive: The lack of comparable data across countries prevents us from providing any clear and supportive evidence to any of the theories on a disability transition.

The World Health Organization (WHO) has recently released the International Classification of Functioning, Disability, and Health (ICF), which should provide a more unified and standard framework for the recording of disability in the context of development if it is implemented successfully. It is astonishing that disability data have been rarely collected in the human development literature. Since 1990, as part of the Human Development Reports, UNDP reports annually on the health access and profile of populations as part of its human development indicators and for the compilation of a human development index. Health profile indicators include, among others, incidence of malaria, HIV/AIDS, tuberculosis, cigarette consumption, and access to nurses and physicians; rarely has it included data on the numbers of persons with disabilities. One exception is the Human Development Report of 1999.

Despite these limitations due to the dearth of comparable data, we can make some general statements regarding the distribution of disability by age and causes across developed and developing countries. The distribution of disability causes across developing and developed nations is well-known. Disabilities resulting from land mines and wars, tuberculosis, malaria, anemia, HIV/AIDS, and diarrheal diseases are more prevalent in developing countries, while disabilities resulting from road accidents, heart disease, and pulmonary diseases are typical of developed countries. The distribution of disability by age is also well established. In developing as in developed countries, age-specific disability rates and the severity of disablement increase with age. However, because in developed countries the elderly represent a larger share of the total population than in developing countries, disability seems to be more concentrated in older age groups. In addition, in developing countries, the proportion of disabled children is higher than in developed countries.

The Impact of Disability on Development

We tackle the last question that we set out at the beginning of this section, what are the implications of disability for the process of development? This relationship is typically thought to be negative. A large disabled population means that there is a lower supply of productive labor, leading to a reduction in income and production. However, this question is somewhat more subtle than appears at first glance. There are many ways in which disability can influence economic and social outcomes and development in particular, ways that will vary given a country's resource endowments and its social, cultural, and institutional environment.

Simple economic arguments suggest that disability worsens social and economic outcomes and impedes development. Indeed, disability places constraints on individuals' productivities and earnings capacities. As such, there is an economic loss attributable to disability, and the extent of this loss has been assessed in some countries. For instance, a study by Cooper and Rice found productivity losses due to disability amounting to 3.5 percent of the gross national product (GNP) of the United States. Of course, this economic loss associated with disability is reduced in countries that have effective vocational rehabilitation programs in place that promote the labor force participation of persons with disabilities.

The economic and social implications of disability are also apparent in public expenditures and disability-related sectors of the economy. This is mainly the case though in developed counties, where disability has given rise to specific markets in the health care, rehabilitation, insurance and legal fields, and where government disability expenditures tend to be significant. For instance, estimates of public expenditures on disability-related programs stand at about 5 percent of GDP for the Netherlands and Sweden, and 1.5 percent for the United Kingdom. The net impact of disability on the overall economy depends on how the loss in productivity and potential earnings compares to disability-related expenditures in the private markets and the public sector. In developing countries, because government expenditures and markets related to disability are very limited, the main economic implication of disability seems to be the economic loss from reduced productivity and earnings. Thus, while disability seems to hold back development through the economic loss it brings about, the impact of disability on this process evolves and becomes more complex as a country develops and establishes public policies and private markets related to disability.

The economic loss resulting from disability points toward the importance of prevention and employment policies as part of the development agenda as well as toward the link between disability and poverty at the micro level.

DISABILITY AND POVERTY

Poverty is the most visible characteristic of underdevelopment. There is little controversy nowadays over the fact that the fundamental purpose of development is poverty eradication. Hence, the relation between poverty and disability is an important consideration. If the relation between disability and development is complex and ambiguous, what can be said about that between disability and poverty?

Poverty and disability have been linked through a "vicious circle" that has been described in several sources. For instance, it has been described as a two-way relationship with disability contributing to an increased risk of poverty and vice versa, resulting in persons with disabilities being part of the poorest of the poor.

From Disability to Poverty

The fact that disability may lead to poverty is common sense. Disability places constraints on an individual's earnings capacity and adds costs related to the disability in terms of health care for instance. The economic well-being and poverty status of persons with disabilities has received limited attention in both developed and developing countries.

The few studies on the economic well-being of persons with disabilities in the United States have assessed trends in incomes whether from work or public benefits for persons with disabilities. However, such studies do not take into account the costs that may be associated with a disability at an individual or a household level. There is a need to assess the costs of a disability in terms of both forgone earnings and direct costs at the individual and household levels to gain a better insight into the poverty status or risk of such individuals and households. Such costs include medical expenses, equipment, adaptations to housing, and means of transportation and personal care. One study by Erb and Harris-White found, based on a village-level survey in southern India, that the direct cost of a chronic illness or an impairment in terms of equipment and treatment averaged three months of a person's income. This does not include forgone earnings due to an inability to work, nor the opportunity costs borne by other members of the household. The costs to caregivers, particularly in terms of forgone work earnings, are increasingly recognized and have been evaluated in the United Kingdom. The cost of personal care on the household may be more important in developing countries than in developed countries since the former generally do not offer income maintenance programs and other funded entitlements as the latter do. In developing countries, families are typically considered as being responsible for persons with disabilities. The direct costs of disabilities and the forgone earnings they entail warrant more research in developing countries. Assessments of such costs would allow researchers to evaluate if the minimum standard of living encapsulated in the poverty threshold is sufficient to meet the needs of persons with disabilities and would aid the formulation of poverty reduction strategies for persons with disabilities. An obstacle to such research is the lack of sources of reliable data on both disability and poverty in developing countries.

From Poverty to Disability

Poverty itself can be the catalyst of a disability; this is particularly the case in developing countries where disability largely results from preventable impairments associated with communicable, maternal, and perinatal diseases and injuries. Poor individuals and families do not have enough resources to satisfy their basic needs, and their sanitation and shelter are inadequate. They may contract some diseases, which, with a lack of access to health care, make them become disabled. Malnutrition in its various forms is a cause of disability for adults and children. Malnourished mothers have low-birth-weight babies who are more at risk of debilitating diseases than healthy babies. Malnourished children are also more prone to impaired intellectual development. UNICEF notes that the incidence and severity of disability are the greatest in countries at earlier stages of development as a consequence of factors that are mainly related to poverty.

Poverty and disability are also linked through the general level of awareness and education of the poor. Parental awareness, access to information, and maternal education have been found to have a great preventive effect. In addition, poverty and disability are linked through the working environment of the poor given that poor people tend to work in more risky physical environments.

While this link from poverty to disability is usually addressed in the context of developing countries, it does not disappear with development. For instance, empirical evidence on the association of poverty and poor health or disability is clear in the United States. The link between poverty and disability is expected though to be more pronounced in developing countries with mass poverty.

Overall, it is obvious that poverty and disability are strongly correlated. Poverty may influence disability and disability may influence poverty. Understanding such relationships is essential for the design of poverty reduction strategies.

INTERNATIONAL DEVELOPMENT AGENCIES

Despite the strong but complex link between disability and development, international development agencies have paid marginal attention to disability. The emphasis has generally been on prevention of impairments and rehabilitation with additional initiatives in data collection efforts and rights-based initiatives. The United Nations has taken the leadership in providing assistance in the field of disability and development. Several UN agencies support or operate community-based programs providing rehabilitation or vocational training programs. In 1982, the United Nations adopted the World Programme of Action Concerning Disabled Persons as a global strategy to prevent disability, promote rehabilitation, and provide for the full participation of persons with disabilities. In 1993, the United Nations introduced the Standard Rules on the Equalization of Opportunities for Persons with Disabilities, which are not legally enforceable but do set an inclusive and antidiscriminatory standard that is used when national policies are developed. There is currently a campaign by disability organizations to have a UN convention on the rights of persons with disabilities.

The lack of comparable data on disability is an obstacle to research on development and disability as well as for international organizations to form disability policies and to evaluate policies aimed at tackling both disability and poverty. In 1993, the World Bank developed the disability adjusted life year (DALY) to provide comparable data on the burden of disease and disability. The DALY was strongly criticized on various grounds, including that disability is considered as a burden on society and that disability is equated to disease without recognizing the numerous factors that lead to disability including environmental ones. The WHO has taken several initiatives to develop comparable data sources, the latest being the development of the ICF. In the ICF, functioning refers to body functions and structures, activities, and participation, while disability includes impairments, activity limitations, and participation restrictions. The ICF is a model of disability that offers a concrete classification system of individuals, and it is thus expected to provide comparable data across countries if it is implemented successfully.

Thus, there is a very limited record of disability work in prominent development organizations. We are very far from having a disability paradigm in the development field as there has been a health or gender paradigm in the recent past. It is encouraging to note though that a new Office of the Advisor on Disability and Development was created in 2002 at the World Bank as a result of which the disability dimension of poverty reduction programs is starting to receive some attention and several data collection and gathering efforts in relation to development are under way.

CONCLUSION

It is evident that there is a strong link between disability and development. Despite this, disability remains a marginal area of interest in development research and practice. Certainly, efforts to improve the quality and comparability of disability statistics will help clarify some of the complex relationships we have pointed out in this entry and demonstrate the importance and relevance of disability issues in the context of development.

ECONOMIC AND SOCIAL DEVELOPMENT, INTERNATIONAL

"Disability" is a complex, global phenomenon. The number of persons with disabilities in the world is estimated to be 500 million. In most countries, at least 1 out of 10 persons has a disability with physical, mental, or sensory impairment (United Nations Enable 2004). What is disability? Though they are different, terms such as *functional impairment*, *disability*, and *handicap* often are used interchangeably. The World Health Organization (WHO) offered a comprehensive

International Classification of Functioning, Disability, and Health (ICF) as an operational standard (adopted by 191 member states of WHO) to facilitate policy development, economic analyses, and research uses involving disability (WHO 2002). ICF is complementary to WHO's International Classification of Diseases (ICD-10). ICF offers core classification on function, while ICD offers core classification of health condition and diagnosis. ICF is organized around body function and structure, individual activities and task participation, and environmental factors.

Countries gather data on disability and estimate prevalence rates. But due to differences in the concepts (or definitions) and methods used in collecting data on disability, prevalence rates are not comparable across countries. Differences in definition or method can lead to different prevalence rates even *within* a country. Inconsistency in definitions of disability can cause a problem in the administration of programs for persons with disabilities. For example, acknowledging this problem, Australia has been working toward national consistency in disability definition and data collection (Australian Institute of Health and Welfare 1997).

From a *traditional perspective,* many cultures associated disability with sin, shame, and feelings of guilt. Persons with disabilities were socially ostracized and excluded from participation in community activities. The presence of an impairment coupled with negative attitude and behavior of family and community led to rejection or isolation of children and adults. From a *medical perspective,* disability is regarded as a sickness or disease that can be cured through medical intervention. From a *humanitarian perspective,* disability is viewed as a function of the interaction between the individual with impairment and the environmental demands (cultural, social, architectural, and technological). From a *workforce perspective,* disability is viewed as a functional limitation preventing equal rights and full participation in an employment setting. Appropriate job accommodations may be used to increase the employability of persons with disabilities and create equal opportunities (Job Accommodation Network 2003).

Increasing numbers of persons with disabilities are linked to factors such as poverty, hunger, epidemics, violence, war, living conditions, illiteracy, health care, rural/urban geography, age shifts, accidents, natural disasters, environmental pollution, drug/alcohol abuse, and HIV/AIDS. The correlation between disability and poverty has been well established. In developing countries, 80 percent of persons with disabilities live in isolated rural areas and are extremely poor (Chaliand 2004). How a person responds to a disability depends on *intrinsic factors* such as the type/severity of impairments (e.g., diabetes, total blindness) and personal characteristics (e.g., gender, age, education, skills, interests) as well as *extrinsic factors* such as environmental variables (e.g., high unemployment area, dysfunctional family). Social, cultural, and economic disadvantages restrict access to health care, education, training, and employment. Progress in life expectancy and overall physical and mental fitness is related to contemporary social and cultural forces. Advancements in knowledge and practice in the areas of health care, technology, and management of economies have led to substantial improvement in physical fitness, mental health, and life expectancy.

Population and adult mortality rates for males and females for some of the developing and developed countries in different regions of the world are highlighted in Table 1. The WHO (2003) indicated that generally, the adult mortality rate for women in all of the countries (both developing and developed) is lower than the adult mortality rate for men. For example, in Zimbabwe, the adult mortality rate (AMR) for females (F) is 789 deaths per 100,000 in a year. For males (M), the AMR is 821. But the AMRs for men and women in developing countries are substantially higher compared to developed countries. For example, in Japan (Developed), the AMR (F) is 46, and in Cambodia (Developing) the AMR (F) is 298. The developing countries are, of course, at various levels of economic development. Much of their economic growth is linked to natural resources such as oil (e.g., Saudi Arabia, Libya), copper (e.g., Chile, Peru, Zaire, Zambia), and bauxite (e.g., Guinea, Guyana, Jamaica). Technologically developing nations of Asia, Africa, and Latin America generally are characterized as poor and with high rates of illiteracy, disease, and population growth. The technological and economic development promotes health, education, and quality of life of a nation and tends to reduce mortality rate.

Table 1 Population and Adult Mortality Rate (AMR) (Female and Male) in Developing and Developed Countries, by Region, 2002

High mortality rates are associated with various types of diseases and injuries. The three major categories used by WHO are (I) Communicable Diseases, (II) Non-Communicable Conditions, and (III) Injuries (World Health Organization 2003). Table 2 shows the rankings for these three categories within each of the

Note: VHAM = very high adult mortality; HAM = high adult mortality; LAM = low adult mortality. The three major categories (I, II, and III) are ranked based on the number of deaths that occurred in each category in 2002 in various regions of the world. Within each major category, the diseases or health conditions that caused mortality are ranked based on the number of deaths that occurred in each region (1 = highest rank, 6 = lowest rank).

six regions of the world (Africa, Americas, Eastern Mediterranean, Europe, Southeast Asia, and Western Pacific). For example, Communicable Diseases ranked highest (no. 1) in Africa, ahead of Non-Communicable Conditions (no. 2), and Injuries (no. 3). Within each major category, diseases or injuries are listed as subcategories. For instance, in Africa, HIV/AIDS was the highest-ranking communicable disease (no. 1), followed by malaria (no. 2), respiratory infections (no. 3), diarrheal diseases (no. 4), childhood diseases (no. 5), and perinatal conditions (no. 6). Ranks within the regions based on Table 2 show that Communicable Diseases rank highest in Africa and Eastern Mediterranean, whereas Non-Communicable Conditions rank highest in Americas, Europe, Southeast Asia, and Western Pacific. Furthermore, HIV/AIDS is the greatest contributor to mortality in Africa, but HIV/AIDS is the smallest contributor to mortality in the Eastern Mediterranean region.

Though diabetes does not rank high as a major cause of deaths, diabetes has been rapidly increasing and having a great impact on adults of working age around the world, especially in the developing countries. In 2000, there were 171 million people with diabetes worldwide, and by 2030 this figure is expected to more than double (366 million), and most of this increase will occur in developing countries such as India and China. And a global partnership spearheaded by WHO, Rotary International, the U.S. Centers for Disease Control and Prevention (CDC), and UNICEF supports the efforts of national governments to eradicate polio. The partnership includes private foundations, donor governments (developed countries), and humanitarian and nongovernmental organizations (NGOs).

The WHO promotes collaboration among health, education, social, and labor sectors to ensure that persons with disabilities receive all available services to assist them in achieving equal opportunities. WHO encourages the involvement of persons with disabilities as an essential feature of all program areas (health, education, social, labor). WHO holds that empowerment of persons with disabilities in community-based rehabilitation is necessary to achieve full social integration within their communities. Many developing countries have taken important steps during the past 10 years. Recognizing that inclusion and integration of persons with disabilities into their communities can be achieved only through political and social action, many developing countries have enacted legislation to guarantee the rights of persons with disabilities. For example, in 1991, Thailand passed its first governmental act, the Rehabilitation of Disabled Person Act, focusing on the rights of people with disabilities (Constantine 2000). Philippines has legislation known as the Magna Carta for Disabled Persons. In 1995, Philippines partnered with the Danish Society of Polio and Accident Victims, and initiated projects establishing Therapeutic Activity Centers serving 5,700 children with disabilities. In 1991, Bangladesh established (1) the National Forum of Organizations Working with Disabled and (2) the National Council for the Blind, both under the Ministry of Health (Economic and Social Commission of Asia and the Pacific [ESCAP] 2002).

In 1992, the ESCAP proclaimed a 10-year program known as the Asian and Pacific Decade of Disabled Persons 1993–2002 (ESCAP 2002). The program adopted an agenda for action to achieve the goals of full participation and equality for persons with disabilities. The ESCAP agenda called for a multisectoral approach reflecting the following 12 policy categories: national coordination, legislation, information, public awareness, accessibility and communication, education, training and employment, prevention of causes of disability, rehabilitation (community-based rehabilitation, and health/social development), assistive devices, self-help organizations, and regional cooperation. The program has produced initiatives of good practice in the ESCAP region by governmental and nongovernmental agencies (self-help organizations of persons with disabilities). For example:

- Bangladesh and Cambodia focused particularly on increasing public awareness of disability issues and outreach.
- Hong Kong, China demonstrated that legislation is effective with a built-in implementation and enforcement mechanism.
- Malaysia illustrated that general public awareness of disability issues must be accompanied by specific action to achieve necessary change.
- India stressed that determination and continued advocacy were necessary to achieve accessibility, and a project in India showed that a firm commitment to the education of all children was essential (increased enrollment of children with disabilities from 8 in 1981 to 31,000 in 2000).
- Thailand demonstrated (1) how appropriate and adequate training to rural people with disabilities (blindness) can help reduce poverty, and (2) how practical capacity building for training on productive small enterprise activities (e.g., mushroom production) could offer both improved food security and income generation for people with disabilities.
- Philippines and Bangladesh (using local organizations) underscored the importance of community-based effort as an integral part of rehabilitation as well as prevention of disability.
- Vietnam established importance of training on issues of policy, decision making, and mobilization of a self-help group.

Rehabilitation of individuals with disabilities facilitates their participation in the global marketplace. As formal and informal communication among countries increase, attitudes toward people with disabilities, government policies on disability, and rehabilitation programs are acquiring commonalities across counties. Targeted legislation, adequate service delivery programs, appropriate professional preparation, and continuing research and development will promote economic and social independence, leading to better quality of life for all citizens of the global community.

ECONOMIC DECISION MAKING BY THE DISABLED

Disabled people face many difficult decisions about how to best cope with their disabilities and plan for the future. In recent decades, policy makers have become increasingly interested in understanding how such decisions are affected by public policy. Until the 1960s, disability was primarily viewed as a clinical concept. As the federal disability rolls expanded rapidly during the 1960s and 1970s, researchers began to consider disability more broadly as a partly behavioral phenomenon influenced by economic, psychological, and social factors. A purely clinical view of disability was decidedly inconsistent with large observed variation in work patterns and public program participation among disabled people with the same observed medical conditions and sociodemographic backgrounds.

Often one of the most difficult decisions confronting a disabled person involves whether to remain employed in the current job, change occupations, or withdraw from the labor force altogether. The timing of changes in employment status depends on a variety of considerations including the type and severity of the medical condition, its prognosis, and the possibility of employer accommodations to improve access. Employment outcomes also depend on tastes for continued employment (which may be influenced by pain or difficulty in commuting), savings, income support from family members, other private sources of income, and the extent to which monetary and in-kind public transfers might substitute for forgone labor earnings.

Given sufficiently unattractive labor market prospects, a disabled person may decide to apply for disability benefits. The two dominant federal disability programs in the United States are Social Security Disability Insurance (SSDI) and Supplemental Security Income (SSI). Participation in SSDI is comparable to early participation in the Social Security retirement program. After a five-month waiting period, eligible beneficiaries receive monthly cash payments equal to the retirement benefits they would receive if they were 65. After two years, SSDI beneficiaries gain access to Medicare; the value of these medical benefits varies substantially across recipients depending on their specific health conditions and private health insurance status. SSI is a means-tested program targeted to low-income aged, disabled, or blind people. In contrast to SSDI, there is no waiting period or work history requirement. Beneficiaries have immediate access to medical care through Medicaid.

Much academic attention has focused on estimating how a disabled person's choice whether to continue work or apply for disability benefits depends on policy parameters (e.g., benefit levels, award standards, waiting periods) and personal characteristics (e.g., age, occupation, medical conditions). Economic theory assumes that people will make choices that maximize their expected well-being, given their constraints. Statistical models based on this assumption attempt to quantify a disabled person's expected level of well-being under various scenarios. The methods recognize that decisions are made in an environment of imperfect information, including uncertainty about the evolution of the work limitation, the path of potential wages, the quality of leisure time, and the government's decision about whether to approve a disability application. The methods also recognize that while some important personal characteristics can be observed in the data (e.g., age and years of schooling), others are unobservable to the researcher (e.g., motivation, the severity of a condition, and potential discrimination). Empirical estimates obtained from these models have been used to assess the degree of work disincentives associated with various policies and to forecast the extent to which policy changes would affect economic decision making. Researchers generally agree about the directions but not the magnitudes of these policy effects.

EDISON, THOMAS (1847–1931)

American inventor

Thomas Edison, the most prolific U.S. inventor, has appealed to the popular imagination since the late 1870s. Among the most enduring stories are those about Edison's lack of formal education. Generations of schoolchildren have learned these as object lessons in perseverance. In recent years, Edison's name has been used to encourage persons diagnosed with disabilities such as attention deficit hyperactivity disorder (ADHD) and dyslexia. Although there is no evidence that Edison, a prolific reader, was dyslexic, opinions are divided regarding ADHD. The affirmative case rests partly on his short school career, anecdotes about inattention and mischievousness, his restless creativity, and ability to work on several projects simultaneously. More likely is that economic hardship made it difficult for Edison's family to pay school fees; his mother, a former teacher, was manifestly capable and made use of the family's ample library. Edison's mind was distinctive and fecund, but there is no clear evidence of functional impairments, which an ADHD diagnosis requires. Rather, his combination of originality, energy, and learning through experience epitomizes the divergent thinking that psychologist Lucy Jo Palladino has termed "the Edison Trait."

Edison's hearing impairment was incontrovertible. Its origin is unclear; he seems to have recognized it as a youth and it grew progressively worse. When newspapers reported it in 1878 following his invention of the phonograph, Edison received many letters seeking advice and hearing aids, which he made some effort to develop. Even as normal conversation became more difficult, Edison remained sociable and enjoyed the theater, taking care to sit near the front. He had a lifetime love of poetry and music. In his 60s, he insisted on selecting artists and recordings for his phonograph business, to the company's detriment. He said that by biting into the wooden horn he could "hear better than anybody else" because the sound went directly to his inner ear, which had been "protected from the millions of noises that dim the hearing of ears that hear everything."

—Louis Carlat

> Paul D. Grossman (2001)

Support for students with a disability in higher education has both a long and a short history, an approach-avoidance relationship that both reflects and shapes the views of the larger social milieu. In the latter half of the nineteenth century, a national philosophy of educational egalitarianism began to influence colleges and universities in the United States. This movement was reflected in the Morrill Acts of 1862 and 1890, which created the land grant colleges, increasing both the diversity of the student body and the fields of study available.

During this same period, the Columbia Institution for the Deaf, Dumb and Blind was founded in Washington, D.C., by William Kendal. Kendal hired Edward Miner Gallaudet (the son of Thomas Hopkins Gallaudet, who founded the first school for deaf students in the United States) as the first superintendent. By 1864, Congress authorized the Columbia Institution to grant college degrees. The following year, the nine blind students at the institution were transferred to the Maryland Institution for the Blind, and the Columbia Institution for the Deaf and Dumb became the National Deaf-Mute College by an act of Congress.

In 1866, the National Deaf-Mute College conferred its first bachelor's degree, 21 years later the first women were admitted, and 28 years later the name of the college was changed to Gallaudet College. During Gallaudet College's first 30 years, numerous elementary, secondary, and vocational "schools for the deaf" or "schools for the blind" were established but did not lead to the spread of specialized institutions at the postsecondary level as it had for colleges founded to educate African Americans.

At the beginning of the twentieth century, the first dozen historically black colleges and universities had been established. Gallaudet would stand unique until 1965 when the Rochester Institute for the Deaf was established by Congress. This was not because individuals with disabilities were attending "mainstream" institutions in large numbers; they were as unique to postsecondary education as Gallaudet and would remain so for most of the century.

War, or more precisely returning veterans, became one of the driving forces in U.S. disability policy. Legislation supporting disabled veterans returning after World War I combined with early vocational rehabilitation programs aimed at injured workers began to increase participation in higher education. In 1943, the inclusion of assistance to disabled veterans in the Vocational Rehabilitation Act and the passage of the GI Bill in 1944 significantly increased this trend.

Similar to the latter half of the nineteenth century, the second half of the twentieth century oversaw a period of rapid expansion and democratization in education. In 1954, *Brown v. Board of Education* mandated desegregation of public education. In addition, college enrollments increased, the community college system was established, and open admissions programs were begun. By 1965, the Higher Education Act established grants for student support services aimed at fostering an institutional climate supportive of the success of low-income and first-generation college students. Eleven years later, the act would be expanded to include individuals with disabilities.

Beginning with the increasing presence of disabled veterans on campuses, services for students with disabilities began to emerge. By 1948, the University of Illinois at Urbana–Champaign had a formal program for students with disabilities. In a speech at the 25th anniversary of the program, Timothy Nugent, its founder, stated:

> The University of Illinois was the ideal place to bring about the total rehabilitation and integration of individuals with disabilities with its varied academic, social, cultural opportunities and challenges along with the resources and research capabilities to give credence to what we were doing. It was difficult and took time but it was well worth the pain and suffering. Very few of the young people today would tolerate or endure what many of my early students went through but they knew that they were building for the future. Of all of our facilities and programs the most effective was the development and participation in normalized competitive sports. To the individual participant, it helped overcome self-consciousness and develop self-confidence. There were many common denominators in our sports programs and those of the general population that all people could understand, appreciate, and respect. They began to recognize the normalcy of those with disabilities—their desires, skills, competitiveness, and emotions. They were athletes, and good ones too! (LaMere and Labanowich 1984)

The University of Illinois at Urbana–Champaign was typical of a few dozen programs that emerged as a result of the GI Bill. This university in particular provides a good example because of its better than average documentation over the years. With an emphasis on wheelchair users, programs applied the vocational rehabilitation model to higher education. Such programs offered adapted sports, housing, and transportation. The program at Illinois and the program helped to found the National Wheelchair Basketball Association, established a service fraternity for students with disabilities (Delta Sigma Omicron), introduced curb cuts on campus, and had lift equipped fixed-route buses by 1952. A transitional living program for students with severe disabilities needing assistance in the performance of daily living activities was established in 1959, and a study-abroad program for university students with disabilities was in place by 1965.

About that time, another model was developing in California. In 1962, Ed Roberts, who used a wheelchair by day and respirator by night, wanted to attend University of California, Berkeley. After a series of meetings between Roberts, his mother, and the administration, Ed Roberts was allowed to move on campus but in the campus' health facility, Cowell Hospital, not the residence hall. Word of this spread and by the end of the 1960s there were a dozen students on the third-floor Cowell Hospital.

In 1969, the students began moving from the hospital to apartments on the south edge of the Berkeley campus. In the spirit of the 1960s, the students organized. Calling themselves the Rolling Quads the organization gave voice to student concerns, negotiated with the college administration, and proposed the formal establishment of services for disabled students.

In 1970, the students were awarded a federal Department of Education grant of $80,000, and the Physically Disabled Students' Program was established. Its first director was John Hessler, one of the original students living in Cowell Hospital. By 1986, the program had grown to approximately 350 students; today it employs 30 staff members and serves more than 850 students.

By the early 1970s, there were isolated programs serving students with disabilities. Gallaudet and the Rochester Institute for the Deaf, established by Congress, stood at one end of the spectrum; a few dozen programs similar to the University of Illinois at Urbana–Champaign might be seen as a midpoint; and a handful of programs that were student driven along the lines of the program at Berkeley stood at the other end. Beyond these exceptions at most of the 3,000 or so accredited colleges in the United States there were no structured supports for individuals with disabilities, and if participation was encouraged it was based on individual circumstances and advocacy. This was about to change.

The disability rights movement was taking shape. When the Rehabilitation Act of 1973 was passed it included Section 504, and for the first time civil rights were legislated for people with disabilities in the United States. Section 504 prohibits programs receiving federal funds, which includes most colleges and universities, from discriminating against otherwise qualified "handicapped" individuals. It would take five years of lobbying and protesting before the American Coalition of Citizens with Disabilities (ACCD) won the release of regulations that would allow Section 504 to be implemented.

The full impact of Section 504 on higher education is not the focus of this entry, but it is important to note that the regulations for Section 504, subpart E, specifically covered postsecondary education and required that postsecondary education operate its programs (specifically identifying recruitment, admissions, academics, housing, research, financial aid, counseling, physical education, athletics, transportation, and employment assistance) in a nondiscriminatory fashion.

It is also important to note that Section 504 required institutions to make academic adjustment (modifications to policy procedure and practice) and provide auxiliary aids and services to students to provide equitable access to their programs. These adjustments and aids, commonly referred to as reasonable accommodations, must be provided unless they fundamentally alter the program or service in which the student participates. Balancing these competing equities, the individual right to participate and maintain the essential nature of programs became a part of the role and fabric of disability services in higher education.

In 1975, the Education for All Handicapped Children Act (P.L. 94-142) was passed and established the right of children with disabilities to a free and appropriate education in the public school systems. This increased the number of college students with disabilities prepared for colleges.

In 1976, the Higher Education Act was amended to include students with disabilities as one of the eligible populations for Student Support Services grants. This provided funding for the growth in disability service programs across the country. In March 1978, the Association on Handicapped Student Service Programs in Post Secondary Education was founded, which later became the Association on Higher Education and Disability (AHEAD).

The passage of the Americans with Disabilities Act (ADA) in 1990 did not substantially alter higher education's legal obligation because nearly all colleges and universities receive federal funds. From the early 1980s to the early 1990s, there was a growth in the enrollment of students with disabilities. A survey of first-time freshmen at four-year institutions indicated approximately 1.8 percent in 1980 reported a disability. In 2000, over 6 percent reported having a disability. The largest growth has been in the number of students with learning and psychological disabilities.

Shifting demographics has affected services. Today, disability services offices divide their work between two sets of tasks: accommodations and services. As accommodation decision makers, they review students' disability-related needs, relying heavily on documentation for students with learning and other "nonvisible" disabilities, and determine accommodations appropriate to the students' needs. Typically, they arrange for the conversion of print material into accessible formats, advise on facilities' access issues, provide proctoring for modified test conditions (extended time, reduce distractions), and provide adaptive equipment. In addition, they may provide awareness and training to faculty and staff, provide advising and counseling to students, and host support groups and student organizations.

EDUCATION, INTERNATIONAL

Education is universal and occurs wherever people interact and communicate with each other. Educational practice in all cultures and societies is a mirror reflecting the ways in which people relate to each other. While education may be a global occurrence, education systems are continuously shaped by local beliefs, customs, and history in diverse nations. The differing beliefs on educability remain deeply entrenched in the cultural values and attitudes of particular societies. Thus, the education of children with disabilities can best be understood if the precise historical and cultural contexts in which they are raised are well understood. Therefore, international perspectives on the education of persons with disabilities may focus on global issues, as the established universal values in education or on the diversity in education, fashioned by the prevailing principles and demands of various societies.

The manner in which societies exploit their distinct human resources is an acknowledgment and measure of the power of education. The education of persons with disabilities therefore provides a glimpse into the essential understanding of humanity as perceived by a particular culture. Schools are the vehicles that societies employ to advance their aims of education. The culture and philosophy of schools therefore reflects a view on education embedded in a particular historical and cultural context. The systems countries design, for educating their children with disabilities, characterizes their general outlook on the human character and spirit. Throughout history, children with disabilities have been regarded as nature's mistakes and cruelly neglected and often killed. Recently, better understanding of disabling conditions and more promising practices among practitioners have led to fruitful international exchanges and meaningful dialogue among professionals in this field.

Comparative special education attempts a description of similarities and differences in various systems and provisions engaged in the education of children and youths with disabilities. More recently, comparative approaches also examine trends in educational provision across the lifespan, including early education programs as well as adult education for persons with disabilities.

While comparative special education contrasts practices in various countries, international special education seeks to identify paradigms and models beyond the instructional practices in individual countries. More recently a global perspective as to the best methods for providing quality education for children with disabilities has developed alongside scientific enquiries into education in general. The international discourse on disability and education has been fashioned by the scientific community, on the one hand, and by international organizations, on the other.

Historically, educational services for people with disabilities developed from practices and traditions of the medical profession as well as the religious and charitable institutions. Today's international perspectives on education for persons with disabilities are more systems oriented and invite the education system to promote greater social cohesion, inclusive practices, and equitable access for all children and youths.

INTERNATIONAL PERSPECTIVES IN EDUCATION

International exchanges of views about good educational practices are often initiated by parents or professionals working with children with disabilities. Recommendations regarding the handling of complex and challenging situations as well as the most pragmatic methods for coping with everyday situations have cross-national legitimacy. Pioneer efforts are usually embraced by education systems once their intrinsic worth is established. Usually, such international exchanges tend to focus on specific issues such as the efficacy of "sensory training" or early intervention programs for children with specific disabilities. Other practices shared internationally are approaches to alternative and augmentative communication or ways in with children with cerebral palsy can be supported.

On the other hand, comparative special education does not concentrate on the individual successes of children, but rather on the achievements of the education system. These revolve around such issues as the types of provision in the various countries and their delivery systems. Comparative special education may entail simple descriptions of the manner in which states organize their education or present multidimensional facets of their pupils, resources, and attainments. The comparison of provision for children with disabilities in the various countries is not always straightforward because of the lack of precision in the definition of disability and limited information about the reasons for failure to join the regular schools.

A country's ability to integrate children with a hearing loss, for example, may be due to a wider definition of hearing impairment—leading to an overidentification, compared to procedures in other countries. Measures used for assessing the accomplishments of special education in various countries are the level of resource investment (attributes and qualifications of teachers, financial support, and the availability of auxiliary services), the quality of educational processes (assessment procedures, teaching practices, and team collaboration), and outcomes (academic performance, pupil and teacher satisfaction, personal well-being, and transition to work and other settings). The apparent differences between countries lead to cross-national collaboration, joint programs, and assistance to less developed countries. Some disadvantaged countries may have only insignificant provision; others may offer good facilities for the children of upper-class parents or those living in affluent urban districts, but have few services available to the poor in rural areas. Considerable sensitivity needs to be exercised in this exchange lest the superimposition of the donors' values on the recipient country undermines their trust and integrity of their own society.

An international discourse does not merely focus on educational practices in different countries, but is also concerned with theories and research results that underpin practices. Since the issues surrounding the education of persons with disabilities are so many-sided and complex, it is hardly surprising that a large variety of scientific workers (doctors, psychologists, sociologists, academics) and practitioners (teachers, therapists, social workers) are drawn to the study of disability. In its early years, the international dialogue centered on the educability of children with disabilities and methods to be applied to their education. The present discourse gives greater attention to societal and system transformations that may be necessary to ensure successful outcomes of education. Currently, there is a swing away from a medical model to a social model, which emphasizes the importance of social structures to support the independence and rights of people with disability. Presently, robust debates can be observed, particularly at international congresses when scientists and theoreticians freely exchange their respective views on burning issues of disability and education.

While academics base their position in accordance with their specific theoretical framework, international organizations pay more attention to changing practices according to their general mission. Recent emphasis on disability issues is also the result of a growing interest in human capital, lifelong learning, and understandably also in the education of persons with disabilities. Many major international governmental organizations initiating educational, economic, social, or cultural development are today concerned with issues about disabilities. Some of them have recently formed a common platform to discuss and coordinate their disparate endeavors with a view to reducing waste and overlap. The International Working Group on Disability and Development is one such initiative designed to coordinate the various internationally active organizations such as the Organization for Economic Cooperation and Development (OECD), the United Nations Educational, Scientific, and Cultural Organization (UNESCO), or the World Bank.

Nongovernmental organizations (NGOs) created by interest groups lobby strenuously to further their respective causes and make strong representation to governments. Several international NGOs unite national interest groups to further their objectives, such as Inclusion International and Rehabilitation International. The development and relevance of such international private bodies were facilitated by the United Nations when the organization conferred official status to international NGOs representing a relevant and substantial interest group.

DEVELOPMENT OF INTERNATIONALITY IN EDUCATION

Famous individuals have contributed to the theory and practice of educating children with disabilities across the centuries. In England, the writings of Charles Darwin may have influenced the view that only the fittest should survive. Indeed, Darwin's illustrious cousin Francis Galton, the geneticist, advocated the segregation and sterilization of children and adults with intellectual weaknesses. His contemptuous and callous description of even the mildly retarded as "polluters of the noble stock of humanity, too silly to take part in general society and easily amused with some trivial harmless occupation" relegated the disabled to institutions or asylums or placed in the care of hospitals or charitable organizations. Abroad in France and Italy, for example, a more optimistic view of the modifiability of human behavior was evidenced. The outstanding proponent of this view was enunciated by Jean Gaspard Itard, who rescued a "feral" so-called wild boy, Victor, found wandering in the forests of Aveyron in France. Itard designed and applied a systematic training program for the boy and made remarkable progress despite several vicissitudes. His disciples Edouard Séguin, Maria Montessori, and Alfred Binet continued his work by establishing classes for children with "mental retardation." Montessori, a doctor, recognized that the more effective "treatment" for such children was pedagogical, not medical. Today, most reformers accept the principle that through the promotion of education of persons with disabilities, critical insights into the makeup of a civilized society are discovered.

The philosophy underlying attempts to educate children with disabilities goes back several decades. It was, however, the influence of the English philosopher John Locke, who advanced the concept that knowledge was gained through the senses in his notable *Essay Concerning Human Understanding*, that aroused interest in the disabled. Jean-Jacques Rousseau emphasized that the "child's curiosity was the origin of learning" and that instruction should be based on its nature and not the demands of an artificial society. The climate of despair present in many countries of the nineteenth century was further improved by illustrious and legendary individuals and dedicated teachers such as Itard, Montessori, and Binet. They influenced educational practice for generations of children, by their practices and philosophy of teaching and interacting with children with disabilities. These individuals have in the past inspired parents and professionals and given them strong motivation to continue the quest for quality education. They are well-known internationally, having shaped our idea of education and changed restricted views people held on the educability of persons with disabilities. The story of Helen Keller and her devoted teacher Anne Sullivan has inspired countless parents, teachers, and professionals alike. However, it is necessary to avoid raising the hopes of parents and teachers when untested and bogus treatments and educational programs are advertised and marketed for parents and educationists. Rigor and scientific veracity are the watchwords to safeguard the welfare of this vulnerable group. The complex disorders of autism, cerebral palsy, hyperactivity, and other baffling conditions tend to be the targets of unfounded claims for effective treatment and cure.

Comparative special education began with contrasts between various state practices in dealing with persons with disabilities. In several countries, state institutions were founded in the late nineteenth and early twentieth centuries to care for the mentally ill or intellectually disabled. The regime in many cases was custodial, harsh, restrictive, and dismal. The isolation and lack of stimulation of the regime worsened the mental and emotional states of the "inmates" as they were referred to. These individuals were under the auspices of either health or social welfare departments/ministries. As a result of pressure exerted by professionals, parents, and other groups, the responsibility for such children was transferred to the ministry or department of education. Today, in all Western countries, the education of children with disabilities is the responsibility of education departments/ministries. However, in many developing countries the education of such children is still the under the authority of departments/ministries of social affairs or welfare.

It is of interest to learn that the earliest chair of special education in Europe was established at the University of Zurich in the 1920s and the first international conference on special education was held in Geneva in 1938. Since then, studies related to the education of children with disabilities have had contributions from general education, sociology, medicine, philosophy, and psychology. The international movement toward normalization occurring in the 1970s was led by Sweden and other Scandinavian countries. It spread to several Western countries making a deep impact on their education systems. For example in Italy, the antipsychiatry movement led by Franco Basaglia led to the rapid dismantling of special schools and the integration of most disabled children into the regular education system.

Today, there is a prevalent demand for increasing the number of children with disabilities to receive their schooling side by side with their nondisabled peers. This trend is now acknowledged and welcomed by the major education providers. It reflects a general world movement toward equity and educational opportunity for such a minority group. The growing conviction that all people have equal intrinsic value has permeated the thinking of those responsible for organizing and delivering educational services for children with disabilities.

In recent times, the recurring theme of "integration" has captured the attention of educationists, political activists, parents, and governments. This led to the promulgation of the Salamanca Statement and Framework for Action at the UNESCO conference in 1994, which invited all governments to embrace the philosophy of integration. More recently, the recurring theme of "inclusion" has captured the international attention of everyone working in the field. However, there is currently a major debate as to the efficacy of a particular form of social organization over another. The challenge facing the protagonists is to demonstrate that children with disabilities are meaningfully served in either the regular or special school system.

Critics of "segregated" (an unfair and pejorative term according to some) schooling claim that such placement denies children with disabilities the opportunities to access the full range of normal experiences and rich interactions available in the regular school. These strictures are strongly challenged, and it is argued that special education can and is offered in an array of integrated and special educational settings. In several countries, many segregated institutions for the education and well-being of children with disabilities were founded by parents or pioneers. These establishments often pioneered new and improved techniques and teaching methods for children who were deaf or visually impaired or had other disorders and maladies. With the spread of compulsory education, children with disabilities were now drawn into the sphere of the public education system and were in receipt of education as well as ancillary services. This might serve as a timely reminder that sensitivity toward local needs often serves the needs of children with disabilities preeminently.

Today, international scientific journals with interdisciplinary contributions help establish cross-national and international perspectives on issues affecting the education of children with disabilities. In addition, countries form alliances to tackle problems together. In Europe, for example, the education ministries of member countries have established a joint European Agency for Development of Special Needs Education. This agency serves as a platform for sharing and disseminating ideas and best practices in the member countries.

Today, many international organizations concerned with education still tend to ignore the specific circumstances of children with disabilities in their mainstream programs. For example, OECD's Programme for International Student Assessment (PISA) excludes children with functional disabilities from testing if the child's capacity to engage in a paper-and-pencil test on reading, mathematics, or science literacy is limited. Development projects of national and international donor organizations tend to focus on single issues, for example, health, women, children, or community-based rehabilitation. Recently, however, different organizations have met to discuss disability issues in depth and have tried to develop an integrated strategy to address complex issues of poverty or social exclusion. UNESCO's action plan on Education for All (EFA) was a response to the pressures exerted by various interest groups in including a specific flagship program on inclusive education.

SELECTED CASES

Tracing the developments of special education is a dynamic process, because changes are rapid and the literature on the subject has grown at an exponential level. This entry, however, deals with only the development in Western European countries. The advances in other countries as well as the developing nations is worthy of equal attention. Attitudes, values, and beliefs in all countries are undergoing dramatic transformations and the advent of preventive measures and early detection of disabling conditions as well as a renewed commitment on the part of society to remove the stigmas associated with disability have helped improve the circumstances of children and adults with disabilities. Countries vary in population and other demographic factors that can influence the practicalities of providing educational services.

Finland, for example, occupies the fifth-largest mass in Europe, but has a sparse population of about 5.2 million inhabitants and boasts a literacy rate of 100 percent—with one of the lowest rates of migration in Europe. In the past, children with disabilities were served by a variety of agencies and only recently has compulsory education for children with disabilities been guaranteed by law. Today, Finland is justly proud of making excellent educational provision for all categories of disability. The local communes and authorities are required to provide suitable education for pupils with disabilities. Recently, the movement for including all children with disabilities in the regular school has been adopted by the education and government authorities. There is a high level of cooperation between parents, teachers, and education agencies. Similarly, Norway has undergone considerable changes in the manner it offers education for pupils with special needs. In the past, the Norwegian authorities had a range of special schools as well as facilities that enabled children with milder disorders to be instructed in the regular school system. The country seeks to offer its services at the local level and has established a wide network of resources for teachers and pupils. These centers offer advice and short courses on a variety of topics related to the education of pupils with disabilities. Parents play a very significant role in planning and placement decisions affecting their children. Education for children with disabilities in the Nordic countries reflects the wish for good provision and equal treatment for everyone, a value embedded deeply in the framework of a Western democratic welfare state.

Education for children with disabilities in England and Wales began around 1870 when universal elementary education was first introduced in Britain. Children suffering from malnutrition or physical or intellectual disability were first identified in ordinary classes. Increasingly, children with poor sight, hearing, physical, and other ailments were recognized as different as teachers felt inadequate in instructing them. From 1895 onward, schools for "defective" children sprang up and a number of categories, mainly based on medical diagnoses, were employed to select children for placement in a variety of special schools. Many of these were run by religious or charitable organizations. In 1899, Alfred Eichholz, an inspector of special education, drew up key recommendations, which left their mark on the historic 1994 Education Act legislation. The next milestone for England was the publication of the Warnock report in 1978, drafted by a committee chaired by Baroness Warnock, the philosopher at Oxford University. In this report, the term *special needs education* was first introduced and soon gained acceptance worldwide. A decade later, the Education Reform Act was passed by Parliament. Meanwhile parents and professionals urged that the use of categories served the welfare of children poorly and argued that the education designed for nonhandicapped pupils should be available for children with disabilities. However, the Warnock Committee was anxious to point out that while supporting the concept and practice of "integration," they cautioned that integration must be accompanied by full resource support.

These short accounts illustrate diverse approaches to changes in educational practice in different countries. While countries can never copy practices in other countries, they may serve as inspiration and as a mirror to better identify potential problems and downfalls a system may be prone toward.

EDUCATION, PRIMARY AND SECONDARY

HISTORICAL OVERVIEW

Long before education systems became aware of issues surrounding disability, individuals responsible for providing health-oriented institutions became interested in the education of children and youths with disabilities. Nineteenth-century pioneers such as Jean Marc Gaspard Itard in France and Maria Montessori in Italy demonstrated through their work that education did make a difference to children with disabilities. Their work arose from an understanding that while the care offered by large institutions was essential for survival of their wards, education could make a significant difference to the lives of these children. The realization that children with disabilities could be educated was interrupted by the philosophies promoted by the eugenics movement before and during World War II. After the war, however, several professorships related to the education of children and youths with disabilities were established, thus heralding a new understanding that children with disabilities were not simply to be cared for but also educated. The charity perspective of saving the souls and possibly lives of persons with disabilities had yielded to the notion that education could make a difference to the children's development and quality of life.

In many cases, the parent's initiatives led to the establishment of institutions and services that competed with the existing institutions based either on charity or medical services. These private services often served groups that did not receive adequate or appropriate services offered by the state or existing organizations. This led to a very diverse range of services with a variety of methods, curricula, and equipment. These parent organizations played an important role nationally and internationally in persuading governments to improve their services and acknowledge that the needs of their children had to be taken seriously.

With the advent of social welfare states in Western countries, educational services for children gradually increased and a recognition grew that education was an entitlement rather than a charitable offering. Usually, departments of social welfare or social security assumed this responsibility and only later were these responsibilities transferred to education authorities. While in most Western countries education authorities assumed responsibility for children with disabilities, the services offered were not part of the general education system. A segregated educational service under the umbrella of regular education was organized based on the major functional problems or impairments of the child. Eligibility to the special education services was generally dependent on the severity of a particular disability.

In recent years, a progression from an eligibility-based to a rights-based approach became apparent not just by activists but also in legislation changes in some countries. This coincided with a move away from category-based services to an integrated provision in general education. International conventions and other international documents emphasized the rights of people with disabilities enshrined in such documents as the United Nations Standard Rules that urge nations to adequately address the educational needs of children with disabilities. It pays extra attention to the rights of girls, very young children, and children in impoverished families or communities. UNESCO's Dakar Action Plan describes the policy as "Education for All," which includes all children potentially excluded from participating in education, work, and social life. Whether these ideals can be translated into practice will become evident over the next decade.

COMPULSORY EDUCATION

In most countries, education is compulsory for all children at the primary and lower secondary levels (International Standard Classification of Education [ISCED] Levels 1 and 2). Many countries extend educational provision for children and youths with disabilities beyond compulsory schooling up to the age of 18 or even 21 years and offer special educational services for very young children. At the primary level of education, the focus is on basic reading, writing, and calculating skills as well as a general understanding of the world. The secondary level has a more discipline-oriented approach and may have an element for vocational and work skills preparation. Some students with disabilities follow a similar curriculum as their nondisabled peers and are given special assistance such as a sign language interpreter or information in Braille if needed. Others may follow a special curriculum that emphasizes the acquisition of life skills rather than academic skills.

The Organization for Economic Cooperation and Development (OECD) regularly compiles and publishes statistics and indicators in education. The OECD data on education reveal that depending on the country, the percentage of children in primary and lower secondary education who are identified as having a severe disability range from less than 1 percent to 5 percent of the school population. This variance is not primarily due to a difference in prevalence of disabilities, as more affluent countries tend to identify more children and youths as being "disabled" than poorer countries. The data reflect the manner in which countries allocate additional resources for the education of children. In some countries, the percentage of children receiving additional resources totals over one-third of the school population. This group includes not only children with disabilities but also children with learning or behavior difficulties as well as children and youths from disadvantaged backgrounds.

The diversity of student populations of today's schools has compelled education authorities to reconsider the traditional division between general and special education. With increasing numbers of children in need of special support, a reappraisal of the current policies is taking place in many countries with a view to ensuring effective and equitable uses of funds and resources.

Various countries and schools tend to offer diverse educational programs even to children with similar disabilities. These educational services could vary in terms of placement (i.e., integrated or segregated settings, day care or residential), function (preparation for an adult life in open society or a sheltered life in an institution), and content (regular or adapted curriculum, concentration on academic performance or life skills) as well as performance levels and range in intensity of support and training. A variety of professionals diagnosing the educational needs and the nature of therapy or special support may also be involved. These services may be school based or organized in centers that serve a particular region.

Education policies today are shifting from a content-oriented approach to a more standard-oriented one. The education authorities consider it more important to evaluate the competencies young people need to develop rather than insisting on the number of chemistry or geography lessons given. This coincides with a shift from judging education systems on input indicators to a general focus on outcomes. Thus, policy makers are more concerned with the abilities and achievements at the end of schooling rather than the amount of hours spent in school. This shift in perspectives has also led to a growing interest in the transition from school to work or employment. Young people seeking access to higher education, employment, and economic independence are perceived as important signs of the equity and effectiveness of compulsory education. The increased flexibility of school systems to respond to such changes could offer students with disabilities better opportunities for greater participation in education.

This development is reflected by the wide attention accorded to the OECD's Programme for International Student Assessment (PISA) in many countries. PISA claims to provide education systems better indication as to how well they have prepared their 15-year-old students for adult roles in their society and for lifelong learning. It measures the students' levels of reading literacy, mathematical literacy, and science literacy independent of a nation's curriculum or the specific contents of education in any given country. The results suggests that education systems with an integrative approach teaching all students together and focusing on their levels of competencies perform better than highly differentiated systems which direct students to different streams or programs.

CONCEPTUALIZING DISABILITY IN EDUCATION

The conceptualization of disability in education is reflected in the historical development of special educational services. Initially, an understanding as to what impact an impairment such as mental retardation or polio had on the development of a child was critical. Impairments were usually identified by a health professional in early life or following an injury or illness. Educational interventions were directed toward compensating or overcoming the impairment, generally focusing on children with sensory impairments and to a less extent, physical disabilities such as cerebral palsy. The emphasis of the compensatory approach was to ease or reverse the effects of a disability of the child. Functional approaches adopt a similar approach insofar as they also stress the disability or dysfunction of the child. While compensatory methods were more concerned with the overall development and well-being of children, functional approaches were mainly focused on learning in school. A functional approach to disability concentrates on a child's functioning in educational settings and relates mainly to behavior, learning, and interaction with others. Although problems with learning and behavior are often the result of complex interactions, functional like compensatory approaches focus on the diagnosis and intervention of the individual child. Many of the categories of disability currently employed in educational settings are based on the functional model.

The campaign launched by the disability advocates for equal rights and antidiscrimination legislation has had a considerable impact on accessibility, employment, and social security. But the rights-based approach to disability has had less of an impact on conceptualization of disabilities within primary and secondary education. The underlying premise that people with disabilities are a minority group implies that without barriers and discrimination, full participation in public life would be accomplished. This premise is not easily applicable to education. Accessibility to the full range of the curriculum is more complex. A right to be physically placed in a regular classroom does not necessarily ensure an equitable education. The minority model or rights-based approach may influence the overall policy to include all children within a single education system, but it has insignificant influence on the educational practice itself. Yet another concept of disability related to education is the social constructivist approach, which views disabilities not as a reality but rather a social phenomenon. It regards the school system or the social interactions occurring in schools as leading to the exclusion of children. Disability therefore is viewed as something that is created or constructed through the social processes inherent in the education system itself. The social constructivist model is helpful in understanding processes of diagnosis and disparities in the provision of services to children, but it has yet to establish its relevance to educational interventions and school practices.

It might help to view disability as a complex phenomenon with biological, psychological, and social aspects. Any conceptualization of disability in educational settings should take account of the fact that children are identified only if a mismatch between the expectations of the educator and the performance of the child becomes apparent. Attitudes and other factors in the environment need to be viewed as contributing to a disabling condition and therefore also as part of the intervention process. A multilevel approach that might lead to equitable access to the curriculum is of paramount importance.

EDUCATIONAL SERVICES

The primary concerns of educational systems center around the difficulties children and young people experience in accessing the curriculum as well as the issues of providing equitable education for all students. This has encouraged educational service providers to reappraise their policies toward education and learning.

Historically, in most countries, educational services for children with disabilities were developed separately from regular education system. Health professionals, parents or volunteers, and charitable organizations offered specialized services in special centers and schools. The groups catered to included those with mental retardation, blindness, deafness, and polio. These centers attracted workers who developed increased expertise in their respective disciplines, which led to greater improvements in services. Undoubtedly, such institutions provided opportunities for children unavailable in regular schools.

In the 1960s, a wider view of the term *disability* occurred, which resulted in the inclusion of children with behavior, learning, or social difficulties. As compulsory education extended to children with disabilities, services were organized under the umbrella of the education system. This resulted in a dual regular and special education system. In many countries, educational services still cater to specific categories of disabilities such as autism or dyslexia. They may also focus on associated aspects of disability categories such as communication, for example, through augmentative and alternative communication methods such as Bliss symbols or adapted computer technology.

A major shift in organizing educational services for children with disabilities was initiated in the late 1970s following the Warnock report. This resulted in the new conceptualization of special needs education. It assumed that while 2 percent of any given school population could be seen as disabled, about 20 percent constitute the larger group of children with special educational needs. Accordingly, special needs could be identified relative to communication, cognition and learning, behavior, emotional and social development, and sensory and/or physical functions. This change was confirmed internationally by the Salamanca Statement and Framework for Action on Special Needs Education, at the UNESCO's Conference held in Salamanca in 1994. Governments were urged to assume the responsibility for all children within the aegis of general education and abolish segregated settings. The integration of children into regular classrooms has been achieved to a greater or lesser extent in most Western countries, especially at the primary level of education. More recently, the trend has shifted from offering integrated services for individual children with special needs to the restructuring of education systems to better meet the needs of all children. This theoretical shift has been marked with the change of the term *integration* to *inclusion* or *inclusive education*. If and how this shift affects the everyday education of children with disabilities is yet to be seen.

In poorer countries where education is unavailable or not easily accessible for all, the issues are more basic. Children and youths with disabilities and especially girls and women with disabilities experience greater risk to being permanently excluded from learning and most aspects of adult life. Poverty is closely linked to disability and therefore increased exposure to social exclusion. UNESCO's initiative to ensure "Education for All" requires countries to increase the percentage of disadvantaged and disabled children and youth successfully participating in education. An effort is currently made by several international organizations to include issues of disability and education into their social development programs.

EDUCATION AND DISABILITY

EDUCATION AS A RIGHT OF ALL PERSONS

While public education is ideally a right of citizens in every society, universal access to schooling is only realized to varying degrees in countries around the world. In many countries, access to education is still denied or limited on the basis of gender, race, economic or social status, or disability. For individuals with disabilities, the right to education has been realized only in recent decades, a fact primarily true for individuals living in developed countries. As has been the case for girls and poor children in developing countries, most children with disabilities share the experience of being denied access to education. For these groups of children, education remains what it was in earlier times, a responsibility of the family. In societies where the families themselves are uneducated, the cycle of illiteracy and failure to realize individual potential is perpetuated.

Recognition of the right to education of all persons is relatively recent with international and national laws and legislation emerging only in the latter half of the twentieth century. At the international level, the first version of the UN Convention on the Rights of the Child was approved in 1959. Among the major principles in the convention is the right of the child to education. This right is inclusive of children with disabilities as defined in paragraph 23 of the convention. The right to education also is declared for children in the preschool years in another UN document published in 1993, the Standard Rules on the Equalization of Opportunities for Persons with Disabilities. In 1994, the Salamanca Statement and Framework for Action provided further elaboration of the right to education by defining special education for children with disabilities or learning difficulties. In this context, it was emphasized that the educational approach should be child centered and based on the principle of inclusion in which children with disabilities are served as much as possible in the same settings as their chronological age-peers. For young children with disabilities, goals for education in the preschool years should focus on fostering the child's development and readiness for school.

Collectively, the UN Convention on the Rights of the Child, rule 6 of the UN Standard Rules on the Equalization of Opportunities, and the Salamanca Statement provide a summary of universal standards for equalization of educational opportunity for children and youths. As such, they represent a declaration not only of the child's protection from discrimination, abuse, neglect, denial of access, and illiteracy but also of the right to care, support, and education. These documents make the rights of children explicit, representing practices pertaining to the education of children with disabilities. While the scope of these declarations is universal, a review of policy and practice on an international level indicates substantial variability in regard to access to education for children with disabilities. In most developed countries, some level of commitment has been made to ensure the right of children with disabilities to education. However, in many, if not most developing countries, children with disabilities are denied access to education with groups of other underserved children.

In regard to access to education for children and youths with disabilities, policies and practices in the United States have often served as a model for other countries. In that context, this entry will describe the history and contemporary status of education for persons with disabilities in the United States recognizing that the situation in other countries may differ to varying degrees. In the United States, policies endorsing education for students with disabilities began in the early 1970s, with federal legislation to support free and appropriate education for persons with disabilities taking the form of Section 504 of the Rehabilitation Act of 1973. The intent of the act was to eliminate barriers that exclude persons with disabilities from educational institutions and other agencies in receipt of federal funds. The general focus of the Rehabilitation Act of 1973 was followed by the legislation directed to access to education for children with disabilities in the Education for all Handicapped Children Act (EHA) (P.L. 94–142) in 1975. This was a landmark law guaranteeing the right of all children with disabilities to education, specified under a zero-reject principle in which no child could be denied schooling. Eligibility for special education was based on meeting the criteria for defined disability categories. A comprehensive evaluation served as the basis for the development of the individualized education program (IEP), which provided the means and the goals for educational achievement of the child. An important element of the EHA was recognition of the central role of family participation in the education of their children with disabilities.

In 1994, a report was prepared for congress about effectiveness of the implementation of P.L. 94–142. The report concluded that special educational needs of America's (then 8 million) children with disabilities were not being fully met. Specifically, three major findings reflected the lack of effectiveness:

1. Special education programs lacked full equality of opportunity.
2. One million children were excluded entirely from the public school system.
3. Disability was not identified in many children with the result that many children needing services were not served.

In response to these limitations of special education, the U.S. Congress passed a revision of the EHA, which was renamed the Individuals with Disabilities Education Act (IDEA) in 1990. IDEA was amended in 1997 and reauthorized again in 2004 as the Individuals with Disabilities Education Improvement Act reaffirming the underlying premise of a free and appropriate education with major guiding principles as follows:

- Free, appropriate public education (FAPE) for all children with disabilities
- Appropriate evaluation
- IEPs for each child with appropriate assessment techniques
- Least restrictive environment
- Parent/student participation in decision making with regard to child's education
- Procedural safeguards to protect rights of children with disabilities

Although each amendment of IDEA since its inception has included revisions, IDEA has continued to provide educators and parents with the tools necessary to promote quality educational experiences that will lead children toward a productive adult life. The intent of IDEA is remedial, requiring provisions of programs and services in addition to programs already provided to persons without disabilities. These provisions include education, technical assistance for families and children, assistive technology, parent and professional training, and an array of related services. The committee responsible for special education has the responsibilities and authority to determine what services and to what extent services are required for the child with a disability. Although the provision of services is decentralized giving authority to individual states, each state is required to establish performance goals and standards consistent with the goals and standards for all children established by that state. The federal government maintains ultimate oversight of each state and controls the funding to ensure states comply with the federal mandate.

A HISTORICAL PERSPECTIVE

1800–1850

Within a historical context, the provision of educational opportunities for children with disabilities in the early nineteenth century took the form of establishing special schools for children with sensory impairments. The first schools for children who were deaf and blind in the United States were established in 1817 and 1832, respectively. A similar pattern of establishing special schools for these two groups also was found in other countries. By the middle of the nineteenth century, children were taken out of almshouses and family settings to be sent to "specialized" schools developed specifically for children with auditory or vision impairments or mental retardation. Segregated settings excluded children with physical disabilities. While the goal of placement in these special schools was to assist the individual with a disability to become a productive citizen, the prevailing societal values and conditions resulted in the fact that these institutions often became custodial facilities with poor quality services.

1850–1900

While schools had been established for basic education of children and youths who were deaf, higher education did not become available until the National Deaf Mute College was established on February 16, 1857, as the first school for the advanced education of individuals who were the deaf and hard-of-hearing. Now known as Gallaudet University, it was named after Thomas Hopkins Gallaudet, a notable figure in the advancement of education for the deaf and hard-of-hearing. An interesting historical fact is that for more than a century, leadership of Gallaudet was provided by a hearing administrator. With the selection of a new university president who was not a deaf individual, students expressed outrage, finding it patronizing, marginalizing, and inappropriate in the context of such an essential part of the Deaf community. Subsequent to the students' strike, the university was forced to hire a deaf president who could represent and relate to the deaf individuals enrolled in the university. This action represented a significant cultural and educational advance on behalf of the Deaf community.

Services for individuals with disabilities in the first half of the twentieth century continued to be largely institutional in nature with segregated schools and institutions providing all services on site. An important change, however, was emerging by the middle of the century with the growth of parent groups. The National Association for Retarded Children (NARC) in Minneapolis comprised of middle- and upper-class families was the first and most powerful parent-driven, human-services lobby in the nation to emerge in the early 1950s. The continued growth of parent advocacy for services for their family member with disabilities resulted in a climate of policy and legislative changes. In 1963, Congress enacted new legislation to ensure funding for a comprehensive program of research on mental retardation through National Institute on Child Health & Human Development. The premise of the legislation was to reframe mental retardation as a condition requiring services to promote health and development rather than a psychiatric problem to be treated.

Complementing the changing perspective on mental retardation was recognition of the link between disadvantage and developmental outcomes of cognitive and adaptive disabilities. The solution was to prevent developmental disability by the provision of increased educational opportunities for disadvantaged children in the preschool years. This approach was formalized with the passage of the Economic Opportunity Act in 1964 and the Elementary and Secondary Education Act (ESEA), commonly known as Project Head Start, in 1965.

A key indicator of the changing climate for persons with disabilities in the late 1960s and early 1970s was the abandonment of the concept of institutionalization. The President's Committee on Mental Retardation advanced a federal policy based on the principle of normalization contributing to the deinstitutionalization movement of institutions such as the Willowbrook State School in 1972. Paralleling deinstitutionalization was the need to establish a spectrum of community-based services to permit persons with developmental disabilities to reside in the community. For adults, this range included the development of halfway homes and intermediate care facilities (ICFs/MRs) to care for individuals with mental retardation outside of the institution. For children and youths with disabilities, there was an expansion of educational services culminating in 1975 with the passage of the Education for All Handicapped Children Act (P.L. 94–142) endorsing the right to a free and appropriate public education. A central element of FAPE was the design of an IEP plan based on the child's unique characteristics and needs. With preparation for independent living recognized as a right for the student with disabilities (*Board of Hendrick Hudson Central School District v. Rowley* [1982]), the provision of educational and community experiences to optimize the transition to the age of 21 years was included in the IEP (Clark and Lillie 2000).

CONTEMPORARY EDUCATION

Special education means specifically designed instruction to meet the unique needs of a child with a disability at no cost to the parent including instruction conducted in the classroom, home, hospital or institution, and other settings.

Early Intervention

The system of early intervention (EI) is primarily parent driven with case coordination provided through the county agency. For children 0 to 3 years of age identified as having a disability, an infant family/child education plan is developed, similar to an IEP, to ensure that children have access to appropriate community, educational, and related services. It is mandated that emphasis be placed on the natural, least restrictive, environment for provision and service coordination. Parents have the right to choose home- or center-based services. Typically, families prefer home-based services for younger children. The parent is usually the "coordinator" of home services, which may include related services of speech, physical, occupational, special education, vision, and services for deaf and hard-of-hearing.

Local School Boards of Education

Each local school board has the responsibility to locate and identify all children with disabilities who reside in the district, whether they are of preschool or school age. A register must be maintained by the committee responsible for special education and revised annually. In addition, school boards must adapt a written policy to ensure that children with disabilities have the opportunity to participate in programs to which they are entitled.

Preschool Education

The local education agency (LEA) is responsible for the provision of services and procedural safeguards for eligible children 3 to 5 years of age. Procedural safeguards include notice, consent, and the right to an impartial hearing. An IEP is developed by the committee responsible for preschool education through the local school district. There is a continuum of service options for the least restrictive environment, and services need not be provided in conjunction with a program at a facility approved or licensed by a government agency. Least restrictive options include itinerant services, or related services at home; itinerant services in a day care placement; integrated, certified preschool with nondisabled peers; or segregated, approved preschool. The focus of instruction for children of preschool age is typically developmental with remedial treatment techniques supporting the transition to kindergarten. To be eligible for services, the child is given a general label of "preschooler with a disability." The more restrictive the environment the greater the intensity of services including one-to-one instructional support and a full array of related services including physical, occupational, and speech therapy; psychological counseling; audiological or other medical services; and transportation.

Elementary and Secondary Education

The LEA is responsible for the provision of services and procedural safeguards for children 5 to 18 years of age, and under certain circumstances until the child reaches 21 years of age. There are specific disability categories used to ensure eligibility for services under IDEA. These 13 categories are as follows: autism, deafblindness, deafness, emotional disturbance, hearing impairment, mental retardation, multiple disabilities, orthopedic impairment, speech or language impairment, traumatic brain injury, visual impairment, and other health impairment. There is a continuum of services for the least restrictive environment that includes full inclusion through a segregated, private setting.

The No Child Left Behind Act of 2001 (P.L. 107–110) aims to improve the performance of America's primary and secondary schools by increasing the standards of accountability for states, school districts, and schools, as well as providing parents more flexibility in choosing which schools their children will attend.

The state-mandated curriculum is typically modified to meet the child's individual needs as outlined in the IEP. Remedial techniques and adaptations to instructional material may be made based on cognitive, sensory, or physical impairments. All children, regardless of disability, are required to participate in mandatory state assessments or specifically designed alternative assessments. The state maintains ultimate oversight of the program implementation, and related services may be provided within the classroom setting or in a separate setting in a small group or individual format. Most related services are provided 1 to 5 times per week in half-hour units of time per session.

Parents are members of the committee responsible for special education program team, which is responsible for developing, reviewing, and revising the IEP. The committee members are required to meet on an annual basis to review progress, plan future goals, and make recommendations.

A functional curriculum may be implemented in conjunction with the mandated academic curriculum for students who require such educational training. Vocational skill development begins around the 10th grade, or when the child turns 15 years old. In some cases, as deemed appropriate by the committee responsible for special education, children with severe disabilities are eligible for school until the age of

21 years and also may be entitled to full-day, summer school (30 days) at no cost to the parent.

Vocational/Work

LEA/committee responsible for special education are required to develop transitional plans for children with disabilities at age 15 that address adult transition including employment and living options. It is expected that other state/federal agencies with responsibilities related to vocational education, rehabilitation, and work force development be contacted to be part of transition planning for the child. Parents maintain a key role in assisting the committee responsible for special education in ensuring their child is prepared for adult life. Community leaders and business managers also are important individuals that need to be closely linked to the LEA as most students with disabilities find employment in their hometown. The School-to-Work Opportunities Act (P.L. 103–239) was created to help states and local schools better prepare non-college-bound students for work. The provision of the law provides dollars for the state, local school district, and business partnerships to develop and implement a combination of vocational education and on-the-job training for work subsequent to graduation.

APPROACHES

Certified Special Schools

Certified special schools are schools regulated through the state, which are under the same state/federal mandates as the public school system. They are considered the most restrictive environment typically with self-contained classrooms and limited interaction with normal peers. Most children placed in these highly specialized, segregated settings are severely, multiply disabled with either medical or behavioral conditions that preclude them from attending public school. The curriculum must be responsive to the state standards, and all children must complete mandated assessments or state-approved alternative assessments to ensure progress and state compliance. Instruction is usually intense in terms of teacher/staff ratio and in some cases one-to-one instruction may be necessary to ensure educational benefit from the program. It is always preferred that a child be placed in state and as close to the parents' home as possible.

Special Classes

This option is available when a child cannot be taught within a regular class environment. Most children attending special classes and not being mainstreamed into the regular class present with moderate to severe disabilities that can be disruptive to others, or the child may be deemed incapable of participating in the curriculum in a regular classroom setting. The committee responsible for special education has the responsibility to determine the least restrictive environment and the ratio of teachers to students, which is generally lower than that of the regular class. Each child's placement should be reassessed on an annual basis. The curriculum implemented must be responsive to the state standards and all children must participate in the mandated state assessments to ensure progress in the learning environment.

Mainstreaming/Inclusion

Inclusion in the regular classroom setting with appropriate peers with special instruction and related services as needed is considered the least restrictive environment and most ideal for the majority of children with disabilities. Some children participate fully in the regular class with special instructional techniques/modifications to assist in the learning process, while others participate partially in a mainstreamed format. Special education teachers and/or related service providers assist regular education teachers in designing appropriate teaching techniques to assist a child in meeting IEP goals as designed by the committee responsible for special education. Each child's needs for continued services must be evaluated annually.

FUTURE DIRECTIONS

Access to education by persons with disabilities has a short history in the United States and industrialized countries and is only beginning to evolve in other, less developed countries in the world. The priority for the future is first and foremost to translate the right of all persons with disabilities to a free and appropriate education into practice (UNESCO 1994). In the developing world, this right means creating legislation guaranteeing access for young children to early childhood intervention and special education for school-age students. An essential priority in this translation is education of parents regarding the rights of their child with disabilities to education. Associated priorities are teacher training and the development of curricula relevant to the academic and cultural standards of the country. The recent experience of India provides an encouraging example of the realization of the right to education. With the enactment of the Persons with Disabilities Act, India is committed to the provision of individualized education for children with disabilities through initiatives in teacher training, collaboration among government ministries, changing examination requirements, and involvement of nongovernmental organizations in implementation efforts (Sharma and Deppler 2005).

With fundamental building blocks for access to education in place in the United States and other industrialized countries, emerging directions focus on improvement of the effectiveness of instructional approaches and enhancing transition and continuity beyond the public school experience. While the IEP has been central to the concept of effective instruction for students with disabilities, the need to meet eligibility requirements as the basis for developing the IEP endorses a remedial rather than preventive approach and introduces a time lag in the initiation of services. While a categorical basis for special education eligibility has been challenged for some time (Hobbs 1973; Triano 2000), only limited alternatives have been explored at the level of individual states and assignment to one of 13 categories continues to be intrinsic to IDEA requirements. A priority for improving instruction is to identify means to initiate interventions earlier in the child's academic experience. To this end, the criteria for eligibility may need to be rethought for greater flexibility or consideration given to presumptive eligibility for young children. A second priority for improving effectiveness of instruction is to address the challenge of teaching children with severe and/or multiple disabilities. The unique and complex learning needs of this population require innovation in the nature and form of instructional approaches.

The transition from public school to the post-academic environment of work and independent living has been a significant concern in the field. Issues to be addressed include not only more individualized tailoring of instruction but also improving linkages with the community and the settings of work that the student with disabilities will enter. Fundamental to the transition to adult life is the process of the youth acquiring the rights under the IDEA and Section 504. Clarke and Lillie (2000) have identified steps in this process for transition planning and defined recommended actions for the student, family, the schools, and the community. In keeping with IDEA 2004, all transition planning needs to be consolidated by age 16 and requires a summary of the student's academic and functional performance at the receipt of a diploma or age 21. Finally, in the context of rapid societal changes, individuals with disabilities, like other persons, need continuing access to education across the lifetime. Such access could include existing methodologies of job coaching and on-site training, but also expand with new technologies using the computer for simulation and direct skill building. Education provides opportunities to learn and grow, essential to the quality of life of every individual.

EDUCATIONAL ASSISTIVE TECHNOLOGY

Educational assistive technology (AT) can serve to both augment and replace function for students with disabilities at all levels of education. These functions can include reading, writing, speaking, walking, remembering, and other activities of daily living, but many barriers to acquisition of AT exist, including lack of funding. The Assistive Technology Act (AT Act) of 1998 provides a definition of AT: "Any item, piece of equipment, or product system, whether acquired commercially, off-the-shelf, modified or customized, that is used to increase, maintain, or improve functional capabilities of individuals with disabilities."

The law includes in the definition of AT, those services that are necessary to implement AT solutions: "Any service that directly assists in the selection, acquisition, or use of an AT device including: evaluation and assessment; purchasing, leasing, or acquisition; selecting, designing, customizing, repairing; and training and technical assistance."

Although AT has the potential to enhance function for students with disabilities, 50 percent of all AT is abandoned within six months. To some extent, this is explained by developmental progress or changes in health or functional status (e.g., a student outgrows the wheelchair). However, it also appears that the failure to include active participation by the individual and family, individualize the process of matching the AT to the individual, include provisions for training the individual in use of the AT, and include a plan for maintaining and servicing the AT contribute to the high rate of abandonment. Most school-based AT specialists recommend a student-rather than technology-centered ecological approach to the evaluation of AT needs for students with disabilities where the interaction between the individual and the educational environment is stressed. AT evaluations are also best conducted by an interdisciplinary team, which must include the student and family representative and may include the teacher, speech pathologist, occupational and/or physical therapist, school psychologist, or other specialists. If the student is of an age where transition from school to work and the community should be considered, then representatives of the adult service system, such as a rehabilitation counselor, job coach, or even potential employers should be included to ensure that the AT considered can bridge the transition from school to work and life in the community.

CATEGORIES OF AT

AT can be described in terms of the function it serves. It is important to note that many AT devices can serve in more than one category.

Aids for activities of daily living. Enhancing independence with activities of daily living reduces the need for human educational aids in school and increases the student's autonomy. Aids for daily living include devices to assist in eating, toileting, personal hygiene, and medical management, which may be useful for students with limitations in mobility, dexterity, endurance, cognition, and support, for example, daily medication requirements. Educators may also become involved in enhancing the independence of the student at home where bath lifts and home modifications may be useful.

Augmentative and alternative communication. Augmentative and alternative communications (AAC) include electronic and nonelectronic devices and strategies that enhance communication for students with severe communication impairment accompanied by limited or no speech. Included here are strategies such as alphabet and picture boards and other "light" tech devices that play a prerecorded digital message when a button is activated. In the mid-level of technology, AAC includes portable devices that can generate speech or text listened to or read by the communication partner as the student types. On the high end of technology solutions are very sophisticated devices that may or may not have dynamic displays that the user selects, depending on context, and that employ symbols or codes that can be sequenced to form communicative outputs. Commonly used communications/expressions, such as greetings, can be stored for ready access. These systems require an extensive assessment of the full range of skills and abilities and, to be successful, must consider issues such as the level of and acquisition of literacy, training availability, environmental access, and support.

Computer access. In this category are the devices that assist with gaining access to the computer. These include modified keyboards, using voice recognition software, or various switches including "sip and puff," to activate on screen keyboards or even the use of Morse or another coded system. Also included in this category of interfaces are alternative pointing devices to replace mouse function, which may be activated by other parts of the body such as the feet or head including the infrared pointing devices. Output may be made accessible through screen enlargement software that makes the screen easier to read for a student with low vision, text-to-speech software that reads text from the screen to the student, or hardware that allow students who are blind to read the screen from a refreshable Braille display. There are also a variety of software applications, including those built into some operating systems and office packages, that can increase accessibility for students when the user enables them.

Environmental control systems. Environmental control systems are primarily electronic and enable students with limited mobility to control various appliances (TV, radio); operate security systems; open doors; turn lights, heat, and air conditioning off and on; open doors; flush toilets; and other routine actions. For example, a student might have access to a remote control device mounted on a wheelchair that when activated opens the bathroom door.

Seating and positioning. Certain accommodations to a wheelchair, task chair, or other seating system can provide greater body stability, trunk-head support, and eye-hand coordination; reduce pressure on skin, spasticity, and pain; and enhance function.

Wheelchairs and mobility aids. Many students may require aided ambulation including canes, various crutches, and walkers. Others may be able to propel manual wheelchairs, which are less expensive, more durable, and easier to transport. Other individuals may require three-wheeled scooters, which can be easily stowed but cannot be used by students who do not have adequate leg function and trunk support. Electric-powered wheelchairs provide independence in mobility for the appropriate student. They can be configured to provide position changes to protect skin and to accommodate computers, cell phones, and other devices that may be powered from the chair battery. Power chairs require special consideration for initial training, transport, and a backup plan for repair, maintenance, and insurance.

Aids for hearing impairment. There have been significant advances in devices to aid hearing for students with significant hearing impairments including programmable digital hearing aids and cochlear implants (Some people in the Deaf community oppose cochlear implants contending that it is an invasive procedure that could be avoided if deafness were not viewed as a condition that should be cured.) There are a variety of systems available for use in the classroom or for one-to-one conversation. These systems can either interact with the digital hearing aid or transmit to a set of headphones or earpiece worn by the user and may include infrared and FM loop systems. Other AT includes alarms that generate flashes or vibration to alert the student who is deaf to an emergency. Text pagers can allow transmission of emergency messages to deaf or hard-of-hearing students and text telephones (available in portable models) also enhance communication.

Learning disabilities. If students with writing disabilities are vocally fluent, voice recognition software may be useful. For other students with writing disabilities, word prediction software may allow them to identify and select the appropriate word from a list of possible choices. When the writing disability is mild, built-in spelling and grammar checkers may be helpful. For some students with reading disabilities, a plethora of software is available that combine text-to-speech output with colored highlighting of the text as it is read and a variety of other study aids. Here, it is necessary that the text be available in an electronic form. For students with memory difficulties, or deficits in executive functioning, prompts delivered as text pages to pagers or cell phones, calendars with alarms in personal digital assistants, watches with timers, and other readily available tools can help to reduce demand on memory or what is referred to as cognitive load.

Internet. The Internet itself can serve as AT. For students with limited mobility, or who are in fragile health, there may be times when access to the classroom is difficult. Because many elements of instruction, particularly in postsecondary education, are routinely available on the World Wide Web (WWW), students may be able to achieve an economy of energy by accessing an actual classroom, libraries, vast array of resources, discussion sections, peer reviews, and other academic programming from their homes. Also, the Internet renders communication barriers irrelevant and creates transparent bridges to the world of education and peers. Students who are blind can easily communicate with students who are deaf when web-based instruction is fully accessible. The potential for students with severe disabilities and concomitant health restrictions to fully participate in daily education regardless of medical status is limitless—we need only fulfill the promise of the technologies that are available to a digital society.

CONCLUSION

Educational AT can significantly enhance the performance of students with disabilities at all levels by augmenting or replacing function. Matching the AT with the student by incorporating an ongoing assessment of the student's changing needs and adapting to the resources and psychoeducational and psychosocial demands of the context with reference to other kinds of physical accommodations and learning styles is critical to maximizing successful AT use.

▣ EDWARD THE CONFESSOR

(ca. 1005–1066)

English king

King Edward "the Confessor" was the penultimate king of the Anglo-Saxons (reigned 1042–1066), succeeded briefly by Harold, and then by the Norman, William the Conqueror. Edward's reign was distinguished by relative peace, concerns for succession of the childless king, and the early Normanization of the English church.

Edward's linkage with disability comes in two forms. The first, his reputed albinism, is dubiously supported by original sources. While later chroniclers of the twelfth and thirteenth centuries occasionally describe him as "white in his entire body," his only contemporary describer does not make such an observation. Even if he were an albino, the social consequences of such a pigmentary impairment would have been minimal in such an active and comparatively popular king.

Edward's more fixed association with disability is as the first of the European thaumaturgical kings. From Edward the Confessor through both the English and the French royalty came a tradition of the king's power to cure certain conditions by the touch of their hand—the royal touch. Cardinal among these was the "King's Evil," or scrofula/tuberculosis. King Edward, however, was also particularly well-known for healing blindness by touch.

King Edward was buried in Westminster Abbey and remains revered through accreted tradition as a "holy king." He was canonized in 1161 with a tradition of many healing miracles.

E-HEALTH CARE/ TELEMEDICINE

E-health is the use of emerging interactive telecommunications technologies such as the Internet, interactive TV, kiosks, personal digital assistants, CD-ROMs, and DVD-ROMs to facilitate health improvement and health care services. Use of these specialized technologies is considered to be a type of "online" intervention strategy. An online strategy involves the use of electronic technology usually in the form of a computer. Often a health care intervention uses a mixture of online and the more traditional offline approach as the methods for delivery of information directed either to the patient and increasingly to the health care consumer.

The *Internet* is a public, international network of linked, decentralized computers linked by fiber optics and other networks that allows users to communicate with each other no matter what the location or time. The Internet provides access 24 hours a day, seven days a week—24/7. The Internet is used to transmit electronic mail, find information, and engage in person-to-person exchange of text, graphic, audio, video, and other data. *Interactive TV* also known as polycom provides both audio and visual transfer of a variety of information between two or more individuals at two or more locations in real time. *Kiosk* is a free-standing device, usually a computer, that provides interactive information to the user. Most information is provided through a series of interactive prompts on a touch tone screen. Kiosks can also be used to collect data and information from users. *Personal digital assistants* (PDAs) also known as handhelds or palm pilots are personal organizers that store thousands of bits of data including phone numbers, addresses, notes, and customized software. PDAs exchange, or synchronize, information with a full-sized computer. *CD-ROM* also known as a compact disk is a device that stores a variety of nondigital data. Some CD-ROMs can be used repeatedly (read/write) while others can only be used once to store and retrieve data. *DVD-ROM* also known as a digital video disk is similar to a CD-ROM but stores data digitally.

Telemedicine, also known as telepresence medicine, is a field where telecommunications and medicine interact. Telemedicine can be viewed as a subset of E-health because it makes use of the wide variety of interactive technologies that comprise E-health and has the goal of health improvement, usually through clinical intervention.

Disabled individuals often lack some sensory ability (sight, hearing, touch, taste and smell) that prevents them from fully participating in society. E-health relies on environments that use a variety of technologies that can compensate for the lack of sensory ability. For example, technology can be applied to the movements of the hands, fingers, shoulders, or face so that communication can be established between the individual, the computer system, and the person's environment. These adaptations have the potential to permit access for the disabled to the information society due to the less constraining environment of cyberspace compared to that imposed by the physical world. Likewise, telemedicine as an E-health strategy has the potential to improve patient–health care provider interaction and patient outcome through the increased ability to communicate on clinical and educational issues.

E-health and telemedicine have grown out of the need for health care systems and providers to document and track the health process and procedures performed on their patients, including the need for such documentation for reimbursement purposes by third parties such as insurance companies. Initially, providers kept paper records on the history and status of their patients. In the United States, during the 1970s and 1980s, spiraling health care costs led to the need for a systematic review of the number and types of procedures ordered for patients. This was known as utilization review. Often organizations external to the health care organization were responsible for utilization review. These organizations were known as management services organizations and they developed electronic tracking systems. This was the beginning of the transition from a paper-based system to an electronic-based system, which is known today as E-health. As E-health technologies continued to be developed, the field of telemedicine emerged. The field of medicine became interested in the application of telecommunications to improve the delivery and quality of patient care. Telemedicine first began in 1959 when X-ray images were transmitted across telephone lines.

CURRENT STATUS

E-health and telemedicine are designed to provide for effective exchange of health information among individuals and organizations within the community, usually in community-wide collaboratives known as electronic networks. Most E-health applications involve virtual environment technology, which is a system of technologies that allow the subject to explore and interact with computer-animated graphics. Other terms for virtual environment include *cyberspace*, *telepresence*, *mirror world*, *artificial reality*, *augmented reality*, *wrap-around compuvision*, and *synthetic environment*. In theory all five senses are involved in responding to an environment created by machine. The infrastructure needed to create the virtual environment includes computer networks, hardware, software, people, and management/quality assurance capacity.

Telemedicine can be used for remote consultation between physicians or between physician and patient regardless of geographic distance. Examples of telemedicine include remote diagnosis and surgery in which a specialist gives advice and assistance to a non-specialist during actual procedures such as in a remote location or an inaccessible environment. Some specialized uses of telemedicine include the following.

Teletriage—a specialized type of teleconsultation applied to military scenarios in which a military physician receives online health advice from a remote medical expert.

Telesurgery and telediagnostics—the local and remote physicians share the same virtual space with the patient and the normal and pathologic anatomy can be projected to the consulting physician while examining the patient.

Telecollaboration—the interactive exchange of audiovisual information or conferencing in real time between two or more participants. Several forms of telecollaboration exist including the telephone call, voice conferencing, video conferencing, pictoral information exchange, and data and/or document conferencing.

A major advantage of telemedicine is that it provides for a rapid linkage to remote "experts" who can help with patient care in underserved areas. Telemedicine facilitates the reality of providing a remote specialty consult from virtually any location within minutes. This provides greater expertise to the care of any individual patient. In addition, telemedicine is used to enhance the education of providers and patients through use of Internet-based interactives. Education is facilitated through the creation of telecommunication-linked classes providing interactive information on care and prevention to places where such information and expertise is not currently available. For example, a number of international telemedicine efforts are currently taking place in Indonesia, Africa, Japan, Korea, China, Europe, and the United States. The Telehealth Africa project between African and European hospital centers is working to transmit health-related diagnostic images. A weekly teleconferencing link collaborative between an American hospital and a Budapest institution on issues related to diagnosis of pediatric movement disabilities is also taking place.

For the most part, E-health and telemedicine have been developed and studied as tools and strategies for use at the health care provider level to improve the quality and cost of care and to improve patient safety within the health care system. Viewed from this perspective, patients are the passive recipients of improved outcomes rather than active participants in the health care delivery process. Increasingly, however, consumers not only have become educated consumers due to the availability of E-health and telemedicine but also have become the primary intended audience for E-health-related information and technology. There are benefits and barriers to both provider and consumer use of E-health and telemedicine.

BENEFITS

Provider level. Beneficial impacts of computer-supported decision making on physician performance and patient outcomes have been documented. These include the use of computerized drug ordering systems for physicians that can reduce adverse drug events through decision support systems. Similarly, automated computerized reminders can increase orders for recommended prevention interventions such as yearly physicals, mammograms, and prostate examinations. In more extreme situations, E-health has been used by emergency medical personnel and first responders for consultation during natural disasters and in military battlefield situations. In rural and remote areas, this technology has been used by primary care providers to provide consultations and/or second opinions for patients through direct linkage to urban-based specialists. Increasingly, E-health is being used as a distance education strategy for primary and continuing education. International collaborative initiatives such as the Cochrane Collaboration, which produces a majority of the world's evidence-based medicine recommendations, have also benefited from advances in E-health and telemedicine by making information readily available to health care professionals and consumers.

Consumer level. Consumers have also benefited from advances in E-health. Pharmacy needs and prescriptions can now be ordered online and delivered directly to the buyer. Consumer-oriented health information is now a large market niche for a variety of medical and health-related organizations. A majority of hospitals and other acute care institutions host web pages that detail their expertise and services. For those with disabilities who reside in the community, a variety of E-health-based strategies exist. These include telerehabilitation systems for poststroke patients. These systems not only monitor vital signs of the patient (i.e., blood pressure, pulse, temperature) but also permit direct provider-patient communication through audio or video conferencing linkages to gauge home-based progress. Another consumer-oriented application is telelearning, which combines education with self-managed behavioral interventions designed to improve quality of life. Adaptations for consumers with disabilities who cannot use the standard computer are currently under development.

BARRIERS

Provider level. Barriers to wider use of E-health by health care providers include lack of financial incentives and reimbursement to support its use widely within and across organizations. As is true with adoption of any new innovation, the process is slow and has been characterized as a sequence that moves from innovator/risk takers, early adoptors, mainstream users, to latecomers. Incorporating a new technology will have effects on workflow with the initial start-up likely to slow established processes down due to the learning curve needed to implement the new technology, followed by a more streamlined and routinized system, which should increase efficiency and productivity.

Other barriers to E-health technology include cost (e.g., hardware/software purchases, maintenance/upgrades) and the current "lack of standards" concerning the format and content of E-health information, particularly private patient health-related information, which has legal and economic implications for providers with regard to liability and malpractice insurance.

Consumer level. One of the largest barriers to widespread consumer use of E-health is often referred to as the *digital divide*. The digital divide can be defined as a basic lack of knowledge about the availability and familiarity with technology in general. While access to electronic communications is steadily increasing both in the developed and developing worlds, these increases are not uniform and disparities in availability and skill level in using these technologies are growing wider. Issues such as cost, literacy level, cultural appropriateness, and compliance with standards for those with disabilities (i.e., Americans with Disabilities Act) continue to be barriers in the use of E-health. For patients and consumers, issues such as protection of privacy and confidentiality and informed consent should be considered. Finally, related to the disabled in particular is the need to determine the ease of use and ergonomic issues related to the use of E-health.

In response to many of the issues raised by the exponential growth in E-health, the Institute of Medicine (IOM) issued a report in 2001 titled "Crossing the Quality Chasm." The report recommended that an information infrastructure be built that will support the following: health care delivery, consumer health, quality measurement and improvement, public accountability, clinical and health services research, and clinical education. Implementation of the recommendations of the IOM report will provide greater assurance that high quality standards are in place that will help to improve the health of many communities, including those with disabilities, that can benefit from new technology such as E-health and telemedicine.

ELKIN, STANLEY (1930–1995)

American writer

One of America's most acclaimed twentieth-century writers, novelist Stanley Elkin lived and wrote with multiple sclerosis for 30 years. In 17 award-winning books, he developed a virtuoso prose style and a hilarious, provocative, humane "comedy of affliction" in

American life that reflected his adage: “The Book of Job is the only book.”

An early work, *The Franchiser*, published in 1976, employs paralysis as an ironic metaphor. Business visionary Ben Flesh hopes to “democratize” American wealth by spreading bright, identical franchises—Dunkin Donuts, KFC, Mister Softee—to the country’s underdeveloped corners. But “Flesh fails”—the entrepreneur is diagnosed with multiple sclerosis, his limbs grow dully indistinguishable (like franchises), and so MS turns Flesh into “Mister Softee”—a living parody of his plan to enrich America by homogenizing it.

In a 1993 novella, “Her Sense of Timing,” Elkin makes provocative dark comedy from the frustrations of dependent illness: A wheelchair-bound college professor’s wife leaves him suddenly, just before guests are to arrive for their annual faculty party. The plot pays ironic tribute to Elkin’s wife, who faithfully assisted him throughout his illness.

In *The Magic Kingdom*, from 1985, seven terminally ill children go on a last hurrah “dream holiday” to Disney World. The compelling, messy reality of sick children’s lives collides with the clean, efficient unreality of the Disney cartoon world. By turns hyperrealistic, fantastic, comic, and serious, the novel celebrates the shabby-but-wondrous condition of all embodied lives.

Elkin also wrote numerous Faulkner-styled essays about how art helps us prevail in the face of life’s—and the body’s—injustices: “As the old saying should go, as long as you’ve got your health you’ve got your naivete. I lost the one, I lost the other, and maybe that’s what led me toward revenge—a writer’s revenge, anyway, the revenge, I mean, of style.”

William Gass, novelist and critic, wrote that among Elkin’s achievements was “to disable disabilities by finding their use.”

EMERGING DISABILITIES

Our perspectives on disability are often framed by an implicit assumption that disability is an entity fixed in form and static in size. The term *emerging disabilities* was coined in the 1990s to focus attention on the changing nature of health risks in the United States and the possibility that these changes were affecting the composition of the disability population. Examples include the epidemic of drug-related gang violence, emergence of high-profile illnesses such as HIV infection, and growing awareness of the potential impact on disability of large-scale demographic transitions such as aging. The emerging disability concept can be seen as a working hypothesis about the impact of these trends on the size and character of the disability population.

Emerging disability is neither a discrete condition nor a group of diagnosable conditions. Rather, the term attempts to conceptually summarize different dynamics affecting the composition of the disability population: (1) changes in the economic or social environment that affect risk for disablement, (2) emergence of newly recognized conditions or sudden growth in the numbers of established disability conditions, and (3) changes in definitions that lead to the incorporation of conditions not traditionally thought of as part of the disability “universe.”

CHANGES ASSOCIATED WITH SHIFTING PATTERNS OF RISK

Understanding the impact of shifting cultural, demographic, or economic forces on disability populations is a major theme in emerging disability. The decade-long epidemic of firearm-related injury associated with gang violence and urban drug trafficking is a striking example of a disability shift embedded in the changing cultural circumstances of the 1980s. Data from spinal cord injury data systems reported violence-related injuries more than doubling from the 1970s to the early 1990s. Aging is an important example of change in disability populations caused by demographic forces since rates of severe disability are disproportionately represented among the elderly. With the anticipated rapid growth of the oldest population cohort—those age 85+ years—disability due to onset of later-life illnesses and impairments will become an increasingly important part of disability demographics. The shift in age distribution and its role as a risk factor for disability represents an unprecedented challenge to long-term care services, social welfare, and other health and support systems.

The role of economic forces is a central feature of emerging disability conceptions given the inextricable linkage of disability and poverty. Although the relationship is affected by age, education, and other demographic characteristics, two essential observations of disability and economic status are well established: first, that persons with disabilities are more likely to be economically marginalized, and second, that the poor are far more likely to be exposed to risks associated with disablement. The emerging disability framework considers this connection from the perspective of change, specifically, any changes in the structure of poverty. For example, the steady increase in income inequality since the 1960s signals a long-term change in the distribution of wealth in the United States—an expanding gap between rich and the poor, and greater concentration of poverty among families with young children. To the extent that impediments to childhood development are embedded in the conditions of poverty—lack of maternal and postnatal health care, malnutrition, and developmental deprivation, among other risks—emerging disability frames the trends in terms of the impact on the disability population.

CHANGES ASSOCIATED WITH NEW CONDITIONS/CHANGING ETIOLOGIES

A second form of change represented in the emerging disabilities concept is the recognition of new forms of impairments or unexpected increases in the incidence or prevalence of existing conditions. Examples of newly recognized conditions include chronic fatigue syndrome (CFS), multiple chemical sensitivity, and carpal tunnel syndrome. Conditions tend to be controversial because of an absence of standardized case definitions; consequently, estimates of the affected population tend to vary widely. Emerging disability also refers to familiar conditions or causes of disabilities that are undergoing a transformation in character or magnitude. Autism and attention deficit hyperactivity disorder (ADHD) are prototypical of the established condition becoming more prominent. Clinical service registries and school systems reported dramatic increases in the numbers of diagnosed children throughout the 1990s. However, the results of prevalence studies are contradictory and analysts fail to agree on whether the increases are real or merely an artifact of increased awareness and access to improved treatment options. Less contentious examples of increased prevalence among established conditions are spinal and brain cord injuries. With recent improvement in trauma care, survival rates for spinal cord and severe brain injury improved dramatically in recent decades. The form of injury is not new, but the increased likelihood of survival as well as the extension of lifespan because of improved posttrauma care creates new challenges for the systems of rehabilitation and support.

CHANGES ASSOCIATED WITH EXPANSION OF DISABILITY BOUNDARIES

A third emerging disability theme is the effect of conceptually broadening the disability universe by incorporating groups not traditionally served by the disability and rehabilitation field, such as persons with HIV infection, obesity, cancer, or other chronic illnesses. Expansion of the disability universe was first formalized in the 1990 Americans with Disabilities Act (ADA) in which *disability* was defined as a physical or mental impairment that substantially limits one or more major life activities, or as being regarded as having such an impairment. The qualifying phrase, "regarded as having an impairment," extended antidiscrimination provisions to those with conditions that did not directly affect performance, for example, the presence of disfigurement or obesity. Emerging disability extends the logic of expanded legal protections to encompass the potential role of traditional disability and rehabilitation service providers in addressing the needs of persons with conditions not typically associated with "disability" status. But expansion is problematic in that the linkage of label to disability is under increasing challenge in both our diagnostic theories and legal frameworks. In the new paradigms of disablement, disability is not an attribute of the person but rather a complex interaction of personal, environmental, political, and cultural considerations. The presence of impairment should not automatically be equated to disability status. Recent legal challenges seeking to restrict the scope of the ADA have also served to weaken the link between impairment and disability. In 1999, the U.S. Supreme Court ruled that impairments that can be corrected or do not substantially limit activities are not considered disabilities. Emerging disability is anchored in older, more medicalized paradigms of disability in its emphasis on reclassification of chronic conditions as disabilities and its focus on the causes and prevention of impairment. The effort to include these and similar groups of conditions highlight the ambiguities of defining a class of citizens as "disabled."

SUMMARY

Emerging disability is a conceptual amalgam of different dynamics affecting population change: changing demographics and etiologies, newly recognized impairments, and shifting boundaries for disability definition. Emerging disabilities is a useful conceptual tool for drawing attention to the dynamics of change in populations that may be the consequence of socioeconomic and cultural trends. It also serves to make more prominent public health concerns within the disability and rehabilitation fields by focusing on the epidemiology of impairment. The concept, however, has yet to gain widespread acceptance except as a broad and inconsistently applied umbrella term for unusual impairments. Perhaps a more fundamental challenge to the conceptual integrity of emerging disability comes from the new paradigms of disability that directly challenge disability definition based primarily on diagnostic categories. Contemporary disability definitions are increasingly nuanced. Until clear definitions and boundaries of impairment and disability are forthcoming (and there is debate whether that is achievable), the central utility of the emerging disability idea is to draw our attention to the reality of change and the fact that disability, however defined, is dynamic rather than static.

EMPLOYABILITY

Employability means the degree of possibility of finding or regaining employment. It can also denote an objective situation or a characteristic specific to an individual. In Europe, it was in the context of the great rise in unemployment at the end of the 1980s that the term took on its present meaning. This was accompanied by a shift in theoretical explanations of unemployment and in the measures taken to address it.

Until that time, employability had been a statistical concept, based on the average period of unemployment. It was an instrument to measure the workings of the labor market, which eliminated groups with objective characteristics such as age, sex, or qualifications. One could state from statistics, for example, that a given age cohort or that women, the disabled, or people with a certain level of education remained unemployed longer. For each of these categories, the chances of finding employment could be evaluated. Such tracking made it possible to better administer the flux of the unemployed, particularly by retraining them. This is employability in the "probabilistic" sense.

By the end of the 1980s, employability also denoted the medical and sociocultural obstacles encountered by job seekers. In other words, unemployment was no longer simply a question of vocational training; it was seen as linked, as cause or effect, to a desocialization, a destructuring of individuals. The solution to unemployment was sought in social qualifications, which could include such details as dressing correctly and arriving at work on time as well as having the necessary vocational credentials and references. From an objective, collective term, employability now designated an attribute of job seekers themselves, in fact, their only attribute, as the term "disabled" tends to do. Logically, then, attention to unemployment shifted toward attention to people, on whose behalf all sorts of social interventions, well beyond the vocational training of adults, had to be provided.

It was at this same turning point at the beginning of the 1990s that a new paradigm was introduced in Europe, along with a new term: the excluded. This term denotes the capability of maintaining oneself in the social fabric more than a capability for work. The job seeker is no longer simply one of the inactive; he or she becomes socially maladjusted, vocationally unfit, and, once again, one of the excluded.

Conceptual contours were becoming blurred from several perspectives. An individual's trajectory could move him or her from one status to another, according to which criteria were employed and to the interest of the stakeholders. Thus, we see the unemployed beginning to sign up for benefits previously reserved for disabled people or, inversely, disabled people finding, at least provisionally, greater satisfaction in being paid minimum wages that were primarily intended for job seekers. A second instance of blurred contours was on the level of interventions by social workers and counselors seeking to remedy unemployment.

Employability often becomes unemployability, as the lack becomes the focal point, thereby creating the category of the unemployable. The latter term is rather like a return to the old category of the able-bodied poor, that is, people who begged for lack of work but by virtue of their ablebodiedness were reproached, even condemned, as useless, lazy, or superfluous. But there is a growing confusion between the able-bodied without work and the disabled, whether the latter are themselves also without work or are prevented from working by their impairment. One confusion leads to another: Where does the distinction lie between the right to work and the duty to work? In countries with a welfare state, primarily in Europe, a distinction was established, on the one hand, between policies related to insurance, organized around the notion of salaried workers (social security), which covered the unemployed, and, on the other, policies of social assistance aimed at those who had difficulties in finding and retaining salaried work because of their individual characteristics(e.g., severely disabled people).

Even though things have never been so cut-and-dried—disabled workers are for the most part capable of work and there are many social assistance options available within the social security system—the fact remains that the expanded notion of employability, which includes notions of unemployable and of maladjusted, blurs employment policy. Indeed, new population groups that find themselves without work cannot be clearly identified as the able-bodied unemployed or as the disabled. The term employability leaves them between the two camps, sharing some of the characteristics of each. As a consequence, policy options drafted for their situation display neither a universalist vision, which would be that of integration policies focused on employment, nor an individualist vision, which would spring from social policy. It is into this interstice that the so-called insertion policies slip, producing a thick stratum of citizens who occupy a social substatus, always being inserted and disinserted.

In other words, the categories of employable and unemployable mask a variety of difficulties, for which there is now only a single remedy: minimal integration (some work, provisional and discontinuous, and some social networking effected by assistance and support measures). Such a minimum is self-perpetuating and creates a segment of the population whose stake is enduringly precarious.

▣ EMPLOYMENT

Employment and disability; these two areas appear to be antithetical. Employment portrays gainful productive activity, while disability depicts inability to work or be employed due to impairment or limitations. With or without disability, work is an important aspect of life, a major role in adulthood. Sigmund Freud saw work as one of the basic requirements of human existence, and Erik Erikson indicated that work brings people a sense of selfhood. Inability to work not only hampers one's development in the life cycle but also brings damage to an individual's self-identity and worthiness.

Vocational psychologists suggest that employment has six functions. It provides income for daily living necessities such as food, clothing, and shelter. It regulates daily activities, allows for social interaction with others, and is a major determinant of one's social status. For the most part, one's social standing is determined by the perceived prestige of one's occupation and accomplishment at work. It gives a person an identity and provides content and meaning to life. In sum, work determines a person's worth and place in society, and it influences one's psychological identity and sense of well-being. Employment, however, is not readily available to all people, especially to those who have disabilities. Environmental barriers, societal prejudice, and functional limitations caused by disabilities often exclude people with disabilities from the world of work.

In the United States, attention to the employment of people with disabilities was heightened after World War I, responding to the postwar employment challenges faced by veterans. Subsequent development of vocational rehabilitation legislation and the state-federal vocational rehabilitation program extended services to all citizens with disabilities. Recent legislation, such as the Americans with Disabilities Act (ADA), is intended to ensure equal opportunity and nondiscriminatory practice in employment for people with disabilities. Despite passage of such legislation, obtaining and maintaining employment for people with disabilities remains a big challenge.

Employment Statistics of Persons with Disabilities

Employment rates among persons with disabilities vary depending on the measure of disability that is used. In a 1996 U.S. Census Bureau survey, about 11 percent of working-age Americans reported a "work disability" defined as having a health condition that limits the kind of work they can do. Among those reporting a work disability, about 20 percent are employed in a given week, compared to 75 percent of those not reporting a work disability.

If one uses the ADA's broader definition of disability involving major life activity limitations and functional impairments, it is estimated that there are 54 million Americans with disabilities. Of these, 29.5 million are of working age constituting 20 percent of the total working-age population. Under this broader definition, approximately 50 percent are employed in a given month, compared to 80 percent of working-age people without disabilities. The figure is much lower among those with severe disabilities, of whom only 25 percent are employed in a given month. More recent data from the U.S. Census Bureau (2002) show that 22.3 percent of people with disabilities between age 16 and 74 were employed, of which only 14.4 percent worked full-time. As expected, 25- to 34-year-olds have the highest employment rate (36.9 percent); the next group is 35- to 44-year-olds (30.2 percent) followed by those ages 45 to 54 (28.8 percent) and 16 to 24 (28.5 percent). Employment rate decreases as the person's age increases after age 55. There are similar employment patterns between workers with disabilities and those without disabilities. In general, women with disabilities are less likely than men with disabilities to be employed, and employment rates are especially lower among people with disabilities who are African American, older than 45, or who have never been to college.

The above data clearly indicate that persons with disabilities have difficulties in obtaining and retaining employment. When asked whether they are willing to work, most persons with disabilities would indicate so, but in fact only about 25 percent do actually work and most are on a part-time basis. Thus, the question is not, and never has been, whether people with disabilities are interested in working, but rather what is prohibiting their participation in the work force and what corrective action is required.

Earnings of Persons with Disabilities

Workers with disabilities earn lower wages than do nondisabled workers. It is estimated that people with disabilities earn 10–25 percent less on average than do comparable people without disabilities. A recent survey on earnings of recipients of state-federal vocational rehabilitation services show that the average hourly wage was $7.33 per hour (median $6), which increased to $9.62 (median $7.65) per hour three years after exiting from the vocational rehabilitation system. The lower employment rates and earnings of people with disabilities contribute to lower economic well-being. Including all sources of income, the median personal income of working-age people with disabilities is only 60 percent that of people without disabilities, suggesting that the various sources of disability income do not come close to making up for the loss of earned income. More important, about 19 percent of all people with disabilities live in poverty households, twice the estimated rate for people without disabilities (8.9 percent). While employment provides the means for a better standard of living, the lower earnings of workers with disabilities causes them to be more likely to live in poverty than employed workers without disabilities. Health insurance coverage, though, is very similar between people with and without disabilities, since greater Medicaid and Medicare coverage among people with disabilities mostly makes up for the lower levels of employer-provided health insurance. It is evident that employment is critical to the economic well-being of people with disabilities. However, many people with disabilities continue to suffer financially due to higher unemployment rates.

Barriers to Employment

While many speculate that the disability itself would be the main barrier to employment, the literature in disability and employment suggests otherwise. In most studies, disability accounts for only a small amount of the variance in employment. Barriers due to accessibility and discrimination appear to be the main and surmountable hurdles for employment among persons with disabilities. In general, there are three major types of barriers: environmental, societal, and personal.

Environmental barriers. Buildings with stairs at entrances and doors that are too narrow are obvious examples of architectural barriers to persons with physical disabilities. These barriers can be viewed as arbitrary limitations on equal opportunity when a person with a disability is qualified for a job but cannot take the job due to inaccessibility. The building itself is, in effect, an agent of discrimination. Other environmental barriers include limited access to public transportation and communication. The federal government has passed legislation to create barrier-free environments for people with disabilities. Under Section 502 of the Rehabilitation Act of 1973, the Architectural and Transportation Barriers Compliance Board was established to enforce the accessibility standards. The subsequent passage of the ADA further enforces equal opportunity and accessibility to employment. The ADA has been called the "Emancipation Proclamation" for people with disabilities. It prohibits discrimination in employment, public accommodations, government services, and telecommunications. It requires employers to make reasonable accommodations in the work environment so that a qualified worker with a disability can be employed. Incentives have been proposed for removal of barriers to encourage both public and private companies to become more accessible. Businesses that incur expenses in removing barriers, as is required under the ADA, may receive up to a $35,000 deduction for expenditures to remove architectural and transportation barriers to people with disabilities.

Societal barriers. A hidden but pervasive barrier to employment of people with disabilities is prejudice and discrimination. Society has certain beliefs or stereotypes of people who are different. Commonly expressed stereotypes about people with disabilities include pity, dependence, incompetence, and character weakness. Just because most people have knowledge of a set of stereotypes does not imply that they agree with them. In fact, many persons can recall stereotypes about different racial groups but do not agree that the stereotypes are valid. People who are prejudiced, on the other hand, concur with these negative stereotypes and generate negative emotional reactions as a result. A behavioral reaction of prejudice is discrimination. Discrimination toward people with disabilities includes outright intentional exclusion or relegation to lesser services, jobs, or other opportunities.

Formation of stereotypes and subsequent prejudice toward people with disabilities are often caused by misinformation or misconception. Misconception about specific disabilities, including presumptions about the cause of disability, often affect hiring recommendations. These unfounded myths and false assumptions are deeply, often subconsciously, rooted in many of us. Some of the myths about people with disabilities include the following:

- Increased insurance costs due to workers' compensation and higher accident rates
- Limited dependability and poor attendance records
- Low productivity
- Need for special accommodations and work arrangements
- Lack of acceptance by coworkers

Many of these myths can be disputed by facts. For instance, workers' compensation insurance rates are based on the hazardous nature of the work itself, the previous accident rate of the company, and the amount of resulting compensation and medical costs charged to the insurance carrier. Research evidence shows that employees with disabilities in general do not have higher accident rates than employees without disabilities. Also a long history of research findings rejects the assumptions that workers with disabilities have more problems than workers without disabilities in regard to absenteeism, productivity, and ability to perform the job. In addition, most work site accommodations cost nothing or less than $500, not the thousands of dollars most people believe. Specifically, about 50 percent of the reasonable accommodations cost nothing, 30 percent cost less than $500, 10 percent cost between $500 and $2,000 and 10 percent cost in excess of $2,000.

Personal barriers. Research evidence indicates that there is a correlation with certain personal characteristics and employment opportunities. In general, those who are employed tend to be younger, male, Caucasians, have more education, have previous work experience, and a physical disability. To understand the extent to which disability affects employment, one has to consider the disability in relation to the individual's physical, psychological, and vocational functioning. Questionable physical capacity becomes a significant concern in the consideration of types of employment for which the individual is otherwise psychologically and vocationally suited. The literature suggests that it would be a mistake to ignore the fairly consistent limitations associated with particular disabling conditions in relation to employment choices. Obvious examples are people who have ambulatory difficulties need accessible facilities (e.g., barrier-free buildings), those who have cognitive process problems need to consider jobs with less complexity, and people with disabling conditions exacerbated by stress should be aware of the stress levels associated with the job.

Psychological functioning, a significant employability factor, can either restrict or enhance the chance of employment. Maladaptive adjustment to disability such as denial or oversensitivity to one's disability could reduce employability. There is research evidence that suggests self-stigma could be one of the psychological barriers that people with disability need to overcome to be gainfully employed. Living in a culture that endorses prejudices about disabilities (e.g., people with disabilities are incompetent to hold anything but substandard jobs), people with disabilities may apply the prejudice to themselves (I am disabled so I must be unable to hold a regular job), resulting from diminished self-esteem (I am less of a respected person because of my disability) and subsequently report lowered self-efficacy (why try to get a job; someone like me is incapable of doing regular work). Turning this negative psychological force into a positive power would be beneficial to persons with disabilities in terms of adjustment to disability and enhancement of self-efficacy and self-esteem. Current emphasis on empowerment of persons with disabilities is a positive strategy to assist people with disabilities to address self-stigma issues.

For an individual to be employable, one has to possess necessary vocational skills and demonstrate appropriate behaviors. Due to limited work opportunities and consequent work history, persons with disabilities may not possess these necessary work behaviors and skills. Work adjustment training, a service provided through the state-federal vocational rehabilitation system, is designed to teach people the behaviors needed to fulfill employment requirements. Work adjustment training covers three major areas: job responsibility, task production, and social-vocational competence with strategies to enhance physical capacities, psychomotor skills, appropriate dress and grooming abilities, interpersonal and communicative skills, orientation to work practices, work habits, response to supervision, and getting along with coworkers.

It is obvious that persons with disabilities possess certain limitations that handicap their employability. The extent of handicap does, however, depend in large part on the complex interaction of the individual, the disability, environment, society, and culture. Rehabilitation psychologists have extensively studied this complex phenomenon and offer the following observations to help explain the effects of disability on employment.

- It is more important to focus on the functional limitations resulting from a disability and the individual's psychological reactions to those limitations than on diagnosis such as schizophrenia, mental retardation, or learning disabilities.
- It is easier to predict the source of disability to a tangible functioning and behavior (such as spinal injury to ambulatory problems) than intangible behaviors (such as learning potential, employability).
- There is a weak association between disability and personality. That is, there is no such thing as a "blind" personality or a "spinal cord" personality. Stereotypes or overgeneralization of disability results in prejudice and discrimination toward people with disabilities.
- Psychological factors are only a part of the equation in determining how one responds to disability. The importance of social or sociological factors must not be underestimated and negative societal attitudes serve to mask the rehabilitation and vocational potential of persons with disabilities.
- Persons with disabilities have the abilities to perform successfully in a large variety of employment functions and have demonstrated dependability and good performance on jobs.
- Employers' attitudes in hiring persons with disabilities are mixed. Among employers there is a discrepancy between reported intention to hire and actual hiring of persons with disabilities.

Strategies and Practice to Secure Employment

To compete with nondisabled workers, workers with disabilities need to have adequate job-seeking skills and abilities to secure employment. While some individuals with disabilities have sufficient job-seeking skills, many do not have preparation in the area. Studies show that a high percentage of persons with disabilities do not look for jobs frequently enough, most are unaware of techniques for securing and following up on job leads, most of them could not explain skills to employers, some have poor personal appearance or inappropriate mannerisms, and nearly all could not explain their handicapping condition. Inadequate job-seeking skills often limit persons with disabilities to entry-level, secondary labor market positions, which are commonly the last hired and first fired. Only with sufficient job-seeking skills can they reenter the workforce on their own initiative.

Some job seekers with disabilities may be unclear as to how their abilities and interests can best meet the needs of employers or be unable to conduct an extensive job search. Rehabilitation service intervention, such as job placement service, is necessary in assisting individuals with disabilities to secure employment by acting as information intermediary or broker between buyers and sellers of labor.

Job-seeking skill training. The goal of the training is to prepare persons with disabilities in job-seeking skills so that they can seek and secure employment. Common activities in the training include the following:

- How to find job leads
- Preparing personal resumes
- Filling out applications
- Role-playing job interviews
- Understanding hiring practices
- How to disclose disabilities

The Job Club strategy developed by Nathan Azrin and his colleagues is an effective approach in job-seeking skill training. Based on behavior theory, the Job Club uses multiple proven techniques to increase the individual's job-seeking capabilities, such as the buddy system, family support, role models, intense role-play practice of job interview, and practice in completing job applications. Club members meet daily in a small group format and follow up on job leads they have obtained from family, friends, other Job Club members, the phone directory, and previous employers. Members have a standardized script to use in making phone calls to employers, after which they receive reinforcement and feedback from their counselors and other club members as they complete calls and job interviews. Studies have demonstrated the positive results of job-seeking skill training and the Job Club.

Job placement. People with severe disabilities may require direct placement intervention and support to secure and maintain employment. Acquisition of employment for these individuals often requires the help of rehabilitation professionals such as rehabilitation counselors or job placement specialists who can both sell employers on hiring them and supply the necessary on-the-job support. Strategies that match the person to job requirements are used frequently to place persons with disabilities. Job matching considers the person's skills, abilities, interests, and needs. To facilitate a good job match, job analysis often is performed by studying the job demands such as physical demands, mental demands, job-related stress factors, characteristics of work environment, and existing and potential hazards. Job tenure occurs when the job meets the needs of the person and the person meets the demands of the job.

Another approach to job placement is partnership with employers, also known as demand-side job development. As proposed by job development professionals, demand-side job development provides services directly to employers that make the workplace more user friendly for people with disabilities and assists employers in meeting their personnel needs by hiring persons with disabilities. The demand-side model extends marketing away from sales and into consulting. To make job placement successful, rehabilitation professionals must provide counseling and consulting assistance to both individuals with disabilities and employers. This would prepare employers to be better able to make accommodations and train employees in accepting diversity through increasing demand for applicants with disabilities. Rehabilitation professionals enhance persons with disabilities' employment outcomes by functioning as consultants to employers in providing services such as human resources planning and filling "hard to fill" positions. In addition, they provide postemployment counseling and consulting to employees with disabilities and their supervisors to improve work performance, maintain employment, and enhance career advancement. Several national chains and franchises have been involved in providing employment opportunities to persons with disabilities through this partnership approach.

Assistive technology and accommodation in the workplace. In addition to the job placement strategies described above, assistive technology is used in the workplace. Assistive technology is an effective means to replace or extend a person's capacities to cope with different types of vocational and daily living demands. Technology can contribute to employment and social integration of individuals with disabilities through enhanced mobility, manipulative capabilities, and communication. A specific use of assistive technology in the workplace is job accommodations. Reasonable accommodation is a logical adjustment to a job and/or the work environment that enables a qualified person with a disability to perform the duties of that position. Accommodations in the workplace could include making existing facilities used by employees readily accessible to and usable by individuals with disabilities, job restructuring, use of part-time or modified schedules, reassignment to vacant positions, and acquisition or modification of equipment or devices. Examples of physical access job accommodation can be putting the job on the first floor, near the employee parking lot, or near the bathroom. Resource accessibility accommodation for a person with hearing impairment can be providing a notetaker or sign language interpreter; for a person with visual impairment, accommodation can be providing a reader or notetaker. Adaptive equipment accommodation includes "low tech" and "high tech" assistive devices. Examples for the person with arthritis or carpal tunnel syndrome can be providing a special pen/pencil holder; for those who have orthopedic problems by providing desk or chair modifications, speaker, and earphone on telephones. Accommodations for persons with visual impairment can be by providing a talking calculator or talking computer.

Job modification for persons with disabilities is based on the principle that modifications are made only to the job performance while maintaining the same job duties. A modification for a salesperson with energy or ambulation problems may be to do more telephone sales with fewer field appointments. A parking lot attendant with orthopedic problems perhaps could use a chair for sitting instead of standing throughout the day.

The Job Accommodation Network (JAN; 1–800–526–7234) is a resource available for information on employer accommodations. Before contacting JAN for information, it is necessary to have specific medical restrictions regarding the worker with disabilities, job duties that are precluded as results of the restrictions, and general information about the industry in which the job is located.

Future Employment Trend and Its Impact on Persons with Disabilities

The U.S. Department of Labor (DOL) unveiled its 10-year long-term forecast in 1998. In its forecast for the 10 years from 1996 to 2006, total employment will grow by 1.3 percent per year through 2006. After the September 11, 2001, terrorist attacks and subsequent two foreign wars, the U.S. economy suffered from a high unemployment rate and huge federal deficits. One could question the accuracy of DOL's long-term forecast considering the aftermath of 9/11. Nevertheless, trends and characteristics of future work force and job markets identified in the long-term forecast remain relevant and can affect future employment opportunities for persons with disabilities. While manufacturing employment is forecasted to continue its modest decline, employment in service-producing industries is expected to grow 2.9 percent per year, with employment in personnel supply services expanding by 4.3 percent per year and employment in computer and data processing services increasing at 7.6 percent per year. In terms of supply and demand in the workforce, DOL predicts that the supply of workers will increase by 1.1 percent annually, short of the 1.3 percent annual increase of employment. In translating the percentages to numbers, it is forecasted that through 2006, employers will increase their payrolls by 18.6 million workers, while the labor force is expected to grow by 14.9 million workers, creating a shortfall of 3.7 million workers. In short, labor markets are expected to remain tight in the next few years. Research evidence suggests that lower unemployment rates benefit low-wage earners more than high-wage earners. In general, low-wage earners usually are individuals with low skills and they tend to benefit from greater employment opportunities and higher wages when unemployment rates are low. Similarly, people with disabilities benefit from low unemployment rates.

The DOL's long-term forecast shows a variation in growth rates among industries. The fastest growing employment sector is personnel supply services, including temporary employment agencies. The food and beverage industry is the second fastest growing sector. State and local governments, including education, is the third fastest growing sector. Computer and data processing, health practitioner, and retail trade services make up the fourth, fifth, and sixth fastest growing sectors, respectively. Variations in job growth predictions underscore a growing dichotomy in labor demand between high-skilled, high-wage jobs and low-skilled, low-wage jobs. The dichotomy becomes clearer when the top 10 fastest growing occupations are compared. The top 10 fastest growing occupations through 2006 as reported by DOL are (1) cashiers; (2) system analysts; (3) general manager and top executives; (4) registered nurses; (5) salespersons; (6) truck drivers; (7) home health aides; (8) teacher's aides and assistants; (9) nursing aides, orderlies, and attendants; and (10) receptionists and information clerks. Low- and modest-skilled occupations such as cashiers, salespersons, and aides and attendants are usually low-paying jobs as compared to high-skilled and high-wage occupations such as system analysts, managers and CEOs, and registered nurses. As suggested by the literature, people with disabilities, especially those with severe and multiple disabilities, will fill many of the low-skilled and low-wage occupations such as retail salespersons, waitpersons, hotel workers, janitors, cashiers, hospital attendants and orderlies, nurse's aides, and security guards due to limited training or education. In addition, high-paid employment requires technical and professional education beyond high school, and high school graduates face a much harsher employment outlook today than 20 years ago. Lack of career advancement opportunities for people with disabilities is an expressed concern of vocational rehabilitation workers. For persons with disabilities to compete in the future job market, they need post-high school education and specialized vocational training.

Economists point out that as technology develops, especially in the area of information technology, globalization becomes the norm of modern society. Development of a global economy causes changes to the U.S. work force. The traditional ways of performing work no longer hold true. Future workers will require greater use of communication technologies and computer skills. They will be expected to make choices and decisions on their own and have abilities to handle multiple tasks and skills, and work as part of a team. It is likely that the future employment opportunities will be temporary and part-time, rather than permanent and full-time employment. Flexible work hours and job sharing will become more common. While most people with disabilities benefit from these new employment structures, some may find these changes challenging. For instance, persons with a psychiatric disability may find flexible hours difficult to handle.

In sum, while some people with disabilities have made gains in employment, they still remain at a disadvantage in many facets of the labor market. A range of employment opportunities will continue; however, the best jobs go to persons who are literate, can adapt to change, and continue to learn new skills.

EMPLOYMENT, INTERNATIONAL

Employment is often considered to be work for which a person is paid. However, in many countries, work that provides sustenance does not also always provide a wage. Definitions of disability drawn from urban, industrialized settings that see disability primarily as an inability to work at a wage-paying job are problematic in the rural, nonindustrialized, and primarily agricultural economies found in developing countries. Nonwage work is an important source of sustenance for many people, both with and without impairments, in developing countries.

In developed countries, there is a large amount of research about people who have a "work disability"—that is, who have an impairment that limits the kind or amount of work they can do. However, that research—by definition—does not consider people who do not perceive themselves to have a work limitation, although they may actually have an impairment, and who are in fact working. Thus, results from this research do not apply to all workers with impairments. Although "objective" measures of disability are used as the basis for policies such as workers' compensation in the United States, they do not tell us about disability and work. For example, partial loss of a limb or a hearing impairment will qualify people for payments under workers' compensation, even if they can continue to work at their old jobs. One person with a severe impairment may be working, while another with a similar impairment may not—partially because of the types of training, skills, and job expectations they have.

When we put these two ideas together, we can see that there are four possible relationships between disability and work. These are shown in Table 1. These cells provide the organizing principle around which this entry is built.

Table 1

	Perceived impairment	
Type of work	*Work limiting*	*Not work limiting*
Wage	1	2
Nonwage	3	4

Cell 1: People who work in paid work and have an impairment that limits the kind or amount of work they can do.

This category of people has been extensively researched in the United States, Canada, and Western Europe, and the results tend to be fairly similar. People who are working despite having a work-limiting impairment, not surprisingly, earn less than workers without such an impairment, and they often feel that they are underemployed. In addition, they are more likely to be unemployed. (*Unemployed* means a person is actively looking for a job, but it does not refer to people who have given up looking or who have not yet started looking.) Because of this, one report on disability and employment in Canada states that "over 80% of disabled persons in Canada suffer from the 3 U's: unemployment, underemployment, and underutilization." In the United States, only about 30 percent of people of working age (ages 16–64) who have a work disability are even counted as being in the labor force (i.e., are either working or looking for work). In the United Kingdom, about one-third of disabled people of working age were at work in 1998.

In the United States in 1994–1995, men with nonsevere disabilities earned about 85 percent of the median salary of men without impairments; for women, the comparable percentage was about 82 percent. For persons with severe disabilities, the comparable percentages were 58 percent and 68 percent, respectively. (That women with and without impairments are more similar than men has been found in many different types of studies in the United States and is likely explained by the effects of occupational segregation by sex, which is strong and pervasive in the United States.)

Economic policies in many developed countries include support for segregated employment (Britain, Sweden, and the Netherlands) as well as incentives for employers to hire people with impairments. In addition, policies in all developed countries include some sort of social insurance system for workers with disabilities, which most have recently expanded to include nonworking people. Policies range from income assistance, as in the United States, to tax exemptions, as in Japan. These policies often offer disincentives to work, because the side benefits they offer, such as health insurance, cannot be duplicated in the lower-wage jobs that many people with impairments might be most likely to get. They are also sometimes seen by people with impairments as being given in exchange for exemption from benefits and obligations of citizenship.

Cell 2: People who work in paid work but do not have a perceived impairment that they perceive to limit the kind or amount of work they can do.

These people may have less severe impairments, or they may not, but in either case, they perceive their impairment as not limiting their work. Some research done on such people in the United States shows startlingly different results than does research related to people in Cell 1. For example, one study showed that workers with hearing or visual impairments earned higher wages than did workers of the same sex in the general population or with mobility or multiple impairments. These results showed that males had greater income than did females, while having an impairment, net of other differences, decreased income, and they showed that variables that have been strong predictors of incomes in many other studies are not consistently strong predictors of the wages of workers with impairments.

These results, which are so at odds with the preponderance of research results regarding people with work disabilities, support the notion that when the question is asked differently, the answers are also different. Thus, asking people who work *about* impairments they might have gives different results than asking people *if* they have a disability that limits their work. The latter group may be comprised of very different types of people, with very different types of jobs, than the former group. Workers with impairments are likely to be older (since the rate of impairment increases with age) and so more likely to have an established work history. As such, they are also more likely to be in a position to demand disability accommodations from their employer, since their expertise may have more value than the cost of the accommodations. Alternatively, some of these workers may be people who have earlier onset impairments but who overcame potentially disabling obstacles through the use of technology and or education. This is not to say that having an impairment has no effect on their work. Having an impairment *does* limit a person's occupational choices—although in the United States it is clear that gender is more limiting than is impairment.

This section has discussed research that comes from the United States only. But it is clear that similar research, which focuses on workers and only incidentally asks about impairments, needs to be done in other countries.

Cell 3: People who do not have a paid job and who have an impairment that limits the kind or amount of work they can do.

This situation may be more likely to occur in developing countries. However, in those countries, the percentage of people who actually hold wage-paying jobs is low and up to 80 percent of the population lives in rural areas. Unemployment rates as a proportion of people who *are in the work force* tend to be low. This is because people who cannot get wage-paying jobs do not spend huge amounts of time looking for work (nor do they spend that time drawing support payments such as unemployment, workers', or disability compensation, because most such countries do not provide such "social insurance").

Rather, people who cannot find wage work in developing countries have two choices: One is to work either in informal self-employment or informal paid employment, usually in cities; the other is to live in rural areas. Traditional examples of informal self-employment include selling cigarettes, souvenirs, toothbrushes, combs, toothpicks, or towels on the street. Begging, also an example, may entail walking around, sitting in a specific place, or visiting stores and asking for help. It could also include opening doors of cars in front of hotels or theaters, carrying baggage, or washing car windows, and requesting a small gratuity.

While people in Westernized countries tend to find the notion of begging or selling souvenirs to be morally or otherwise repugnant, the same reaction is not always true for people in other countries. For example, while the Hindu or Shinto religions may not explicitly view begging positively, helping beggars by giving money or food is seen as a charitable action which aids one's chances of a better life in the next world. (And, conversely, it is the duty of a disabled person to beg, to provide that opportunity for the person who is helping.) There is some indication that disabled people in developing countries are in fact beginning to object to the ways in which begging reinforces stereotypes and denies them the possibility of other types of employment.

Examples of informal paid employment could include working as a housekeeper, cook, gardener, or guard for a family. However, a person with an impairment may have difficulty finding work in this sector of the economy in developing countries. Such work is more likely either to involve physical labor (construction worker, gardener) or a certain level of education (housekeeper, ayah [nanny], or cook). This work is likely to be for people such as diplomats or employees of aid agencies who will need their employees to speak and possibly read some of their own language (often English, French, or Spanish). Since education is often not available to children with impairments in such countries, adults with early-onset impairments are quite unlikely to have these skills.

The picture of employment of persons with disabilities is quite different in rural villages in developing countries than in cities. In villages, people with impairments may be able to work within their family's farming or herding enterprises. While this will not provide a wage, it is likely to provide at least a minimum amount of food, clothing, and shelter. Physical, cognitive, or mental impairments *may* not prevent a person from fulfilling an economically productive role. (In fact, some scholars have suggested that industrialization had an important role in creating the notion of cognitive impairment.) For example, a person with a developmental impairment may be able to herd animals or carry water. Deafness might not prevent a person from working in fields or caring for animals. A blind person might be able to take care of children or grind spices. A person missing a leg might still be able to weave or stir porridge. (The diet in most African countries is based heavily on one type of starchy food. For example, in Zimbabwe, ground corn is made into *sadza*, while in Ghana, the staple food is *fufu*. Vegetables and/or meat and spices are cooked into sauces that can accompany these staple foods, which are often called porridge. Large parts of every day are spent in the preparation of staple foods as well as the accompanying foods.) In all of these examples, if nothing else, the person with a disability would be freeing another person to do other types of work.

There is a caveat to this discussion, however, related to gender role expectations. All societies have expectations about which sex does what type of work. Thus, if carrying water is expected to be done by women (which it frequently is), a deaf male either will not be expected to do that or he will be looked down upon (as being deviant) because he is doing "women's work." It is likely that many of the tasks that could be done by a person with a mobility impairment are usually done by females, since female gender roles tend to keep them closer to home than do male gender roles. This suggests that males in developing countries who have physical impairments may be at a greater disadvantage than are females.

In rural areas or small villages, it is likely that there is less difference between people with and without impairments than there is in developed countries. In developing countries, a larger proportion of the population exists at a subsistence level, whether or not they have impairments. People grow or produce much of what is needed for survival, and their village economy may not be based on cash but on informal exchange or reciprocity. They are most at a disadvantage in those parts of their society's economy that require cash, such as utilities (the provisions of gas, electricity, or telephone service), education, medical care, and transportation; in food, clothing, or housing, they may not be at a disadvantage if weather conditions are good for farming or herding. In such economies, people with impairments are frequently not worse off than people without impairments. They will not have cash, but they are likely to be supported by their families to the same extent that the families support themselves.

However, in developing countries, the impairment may interfere with noneconomic roles and thus may indirectly reduce economic status. Disability reduces the marriageability of women in many developing countries—and may even affect the marriageability of their siblings. This clearly affects their *economic status* in those societies, even though their *economic abilities* as such are not necessarily diminished.

Some of the initiatives that attempt to help people with impairments in developing countries focus on improving the possibilities for self-employment. These initiatives may include craft work done at home or sometimes in sheltered workshops. Zimbabwe had a very early example of this in the workshops set up by the Jairos Jiri organization.

Cell 4: People who do not have a paid job and who do not have an impairment that they perceive to limit the kind or amount of work they can do—although they do have an impairment.

People who have impairments that they do not define as work limiting in developed countries tend to be people for whom technology solves some problems posed by the impairment, who have enough education that they can find a job in an area in which the presence of a physical impairment is not in fact limiting, or who have a skill or talent that is so significant that it can overcome limitations posed by the impairment. Examples of these types of people include a person who has severe motor and speech impairments but who also has a computer that is programmed so that she can indicate words and the computer can "speak," a person who is deaf but who earns a Ph.D. and so can work as a college professor, and an opera singer who is blind but whose talent is recognized and nurtured despite her impairment.

One group of people quite likely to show up in this category in developed countries is women with impairments. Many women who believe that their impairments should not limit their work are, in fact, not working for wages. Rather, they are working as housewives. However, their work is not valued—it is not counted in economic statistics about national economies; it does not qualify them for pensions, disability support, or retirement income other than that derived from their husbands' work; and it does not qualify a woman for unemployment compensation if she should lose her "job" as a result of divorce.

In developing countries, however, people who have an impairment that they do not perceive to be work limiting and who do not have wage work are very similar to those people discussed with reference to Cell 3. They are people who are not part of the formal economy but who may be able to find many niches through which to support themselves. However, it is likely that this category of people is only beginning to exist in developing countries, since none of the developed country scenarios described above seems likely to occur in a developing country unless the person has a family with enormous wealth. Another reason why such scenarios are unlikely to occur in developing countries is that attitudes toward impairments are more negative and less accepting. Despite slogans such as "disability does not mean inability," which have appeared in several African countries, traditional cultures that equate disability with religious punishments still hold sway in many places. In addition, less developed countries are just beginning to adopt antidiscrimination legislation for people with impairments—even many developed countries are only beginning to make strides in this area. Thus, it would require an extremely unusual person in a developing country to have an impairment, not define it as work limiting, and be able to work.

This entry has shown that the relationships between employment and disability are not simple and are not universal. Rather, it has shown that more research needs to be done about these relationships in different types of economies.

EMPOWERMENT AND EMANCIPATION

Empowerment has become a key concept for disabled people and the disabled people's movement because of its associations with liberation and emancipation.

Disabled people's understandings of the idea highlight the essentially political nature of the concept and its focus on power and the redistribution of power. The idea of empowerment has also come to much wider prominence in recent years. This reflects broader interest in a concept that transcends conventional politics and ideology, addresses both the "personal" and the "political," and seeks to unite the two. Empowerment has become an important concept in public policy as well as personal living. It has become central in political, public, and social policy and educational, cultural, sexual, personal, and managerial discourses, as well as entering popular usage. This has been an international development. At the same time, there have also been growing concerns that the term has been reduced to jargon through overuse and lack of clarity.

The term *empowerment* can be used to refer to a process, a goal, or a combination of the two. While disabled people's definition of the term is closely connected with emancipation, this is not true of all interpretations placed upon it. There is little agreement about the definition of the term. Widespread concerns have been expressed about its meaning being diluted and distorted. But the contradictory and diverse meanings attached to empowerment say more about the complex origins of the idea than its practical or philosophical limitations. Inherent tensions in the concept are highlighted by its traditional dictionary definition, which is framed in terms of "licensing," "authorizing," or "giving power" to someone. The organization or individual "empowered" in this way is only an intermediary in the process, and the nature, extent, and goals of empowerment continue to be determined and circumscribed by the original powerholder.

Such a definition is far removed from the emancipatory interpretation of empowerment that has been placed on it by the disabled people's and other liberational and new social movements. It is helpful to remember that disabled people's discourse about empowerment is only one of a number of such discourses. In conventional terms, it is far from being the dominant one. The idea and practice of empowerment in relation to disability and disabled people can only be understood adequately in this broader context. The predominant discussions about empowerment in recent times have been consumerist and professional ones.

Many different strands can be identified in the development of the idea and usage of empowerment. There are self-help, liberational, professional, managerialist, and market models of empowerment. They are in complex relationship with each other. While there are overlaps between them, there are also important differences. Empowerment has become the site of key struggles over the nature and purpose of politics, policy, services, identity, and professional intervention. That is why its meanings are heavily contested and it is important to recognize its regulatory as well as liberatory potential.

The origins of modern discussions about empowerment are generally traced to the U.S. black civil rights movement of the 1950s and 1960s. They are also associated with theories and practices relating to feminist, (international) black liberation and radical politics of the 1960s and 1970s. Disabled people's discussions of empowerment are linked with these. Other key understandings of empowerment have subsequently developed, and disabled people's interest in empowerment needs to be considered in relation to these to avoid confusion. These approaches to empowerment—the popular, consumerist, and professional—all have had a bearing on the activities and debates of disabled people, but all have also been distinct from disabled people's own conceptualization of empowerment.

The most visible modern expression of the idea of empowerment is its adoption in popular culture. The word has now entered common usage. This is probably also the area where its use is most superficial. It has mainly been used to convey a sense of feeling good and powerful. It has increasingly been offered in this way in advertising, particularly to sell cosmetic, relaxation, and leisure products. Its lack of clear meaning has encouraged its being put to questionable uses. In the early 2000s, for example, an international pyramid selling scheme, called "Women Empowering Women," made headlines when many women lost their savings.

EMPOWERMENT, THE NEW RIGHT, AND PUBLIC PROVISION

Wider interest in the idea of empowerment toward the end of the twentieth century was associated with a political move to the right. This was characterized by a new enthusiasm for the private market in public policy and an increasing philosophical rejection of state intervention and provision. This shift in ideology extended to countries such as the United Kingdom, where there had been a strong tradition of large-scale state intervention and of collectivist state welfare.

The emergent political New Right highlighted the idea of empowerment. Its approach to empowerment was based on an individualistic consumerist model, which prioritized the market. The political New Right based its use of the term on its view of the state's capacity to meet individual needs as problematic and inferior to that of the market. It saw state services as inherently worse than market provision. Yet it also acknowledged that there might some policy areas where state services would continue to be needed, for example, for disadvantaged and impoverished groups. The New Right's understanding of empowerment was based on developing consumer rights, which would give citizens real and measurable powers over state services. "Customers" would have powers to make public services deliver the level and quality of services that the public felt were required. In this way, empowerment in public provision was offered as a parallel and complementary strategy to privatization. Arrangements for guarantees, regulation, and inspection were proposed to help ensure that "quality" standards were achieved. The political New Right conceived of empowerment in terms of equalizing the citizen's relationship with state provision. In the United Kingdom, for example, where this approach was particularly developed, it defined empowerment as increasing people's control over public services through "citizen's charters," "chartermarks," and government hotlines.

The political New Right's commitment to the market had long-term consequences for public services internationally, particularly health and welfare services. It gave direction to broader economic, social, and political pressures toward more consumerist and market-led approaches to public provision, particularly welfare provision. Traditional state welfare came in for criticism from both the political Left and Right for it paternalism, bureaucracy, centralization, inflexibility, and lack of responsiveness. A new welfare pluralist approach was pioneered in the United Kingdom with the advent of Thatcherism. This has had continuing effects on public service and welfare policies in Europe and beyond. It has been reinforced internationally by restrictions on public expenditure imposed by conventional approaches to and understandings of globalization. In the United Kingdom, this consumerist approach to policy was most coherently developed first in the field of social or "community care"—a key policy for disabled people.

Such community care reforms were explicitly concerned with changes in how and where disabled people and other service users received support, with an accent on them being able to live in their own homes and neighborhoods. However, they also actually heralded ideological changes that have had international significance. They entailed both a greater role for the market in the financing and supply of services and also the reframing of public provision to create "quasi-markets," where state and nonstate service providers operate in competition with each other. They highlighted a distinction between (public) purchasers and (private) providers. The rationale for this move was that the individual citizen/consumer would now have greater choice in health and welfare. This clearly had major ramifications for disabled people as a group historically denied choice and opportunities.

Empowerment became a core concept in such development. It was mainly understood in individual consumerist terms of the individual having voice, choice, and exit, that is to say, gaining opportunities to express their preferences, to choose from different services and service providers, and to go somewhere else if they don't like the service they receive. In practice, opportunities for choice and exit tend to be limited, particularly where people receive services on an involuntary basis, as is often the case for mental health service users, people with learning difficulties, and frail older people. Such arrangements have tended to be associated with charging, means testing, and with increasing restrictions on public expenditure, a tendency to increasingly restricted eligibility criteria. With an increasingly globalized sector of large multinational corporations as "care" suppliers and use of bulk contracts, it has also encouraged standardization of service, rather than customized provision.

Political interest in empowerment did not diminish with the waning of interest in the New Right. The realignment of left-of-center politics resulted in an increasing interest in reassessing relationships between state and market. One expression of this, which has had an international influence, extending to Europe, the United Kingdom, and United States, has been the development of ideas such as "the third way." Such remixes of market and state involvement have encouraged the development of ideas of empowerment that combine managerialist and consumerist elements.

THE PROFESSIONALIZATION OF EMPOWERMENT

Empowerment has become a key concept in public service professions particularly in health and social welfare. The concept has its longest history and has become most developed in social work and social care. The professional definition of empowerment sees professional intervention as the route to service users' empowerment. This is a strongly contested view. The concept of empowerment is now deeply ingrained in professional vocabulary, discussion, and practice. The most significant early developments in thinking about social work as empowerment came from the United States, highlighted by the writing of Barbara Solomon in the field of black empowerment. Professional interest in the concept has developed in European countries, such as the United Kingdom, in response to the new demands of the consumerist care market.

Empowerment has offered social care professions facing uncertainty and insecurity, new arguments for their own autonomy and consolidation, by emphasizing the prior need for their empowerment if they are to empower service users. Professionals, the argument goes, must be empowered if they are to empower service users. The concept of empowerment is also embraced enthusiastically as providing a new paradigm for practice, giving it fresh vitality, legitimacy, and credibility. Commentators such as Clare Evans and Mike Fisher argue that empowerment in social work and social care has largely been defined by professionals.

A liberatory and emancipatory rhetoric has been associated with such professional discourses on empowerment, as though the professional can play a key role in transformation for disabled people. Such workers are seen as having the potential to empower both individuals and groups. Some outside commentators, however, have also pointed to the regulatory as well as liberatory potential of such professional approaches to empowerment. Bearing in mind the social control role of professional social work, it is difficult to ignore this argument.

Professional approaches to empowerment have been particularly concerned with *personal* empowerment. Personal empowerment is concerned with people being able to develop new and different understandings of themselves and their world, so they are better equipped to respond to opportunities to take power. However, in professional welfare relationships, this can also mean working for change in people's attitudes and behavior consistent with the agendas, imperatives, and requirements of state agencies. Thus, empowerment becomes particularly concerned with people taking increased responsibility for managing their lives, relationships, and circumstances; to live in conformity with prevailing values and expectations; and to change in accordance with professionally set goals and norms. While this may be consistent with individual aspirations and self-determination, it cannot be assumed that the two are necessarily synonymous.

EMPOWERMENT AND DISABLED PEOPLE

Disability activists, however, have generally been suspicious of the idea that professionals can "empower" them. This is not least because such workers have historically been more often associated with structures, attitudes, and services that disabled people have seen as reinforcing their disempowerment. Disabled people have argued that professionals and service providers must learn to work in different ways and *stop* disempowering them. Many disabled people reject the idea that power can be "given" and see it as something that can only be *taken.* Two understandings of the role of professionals in relation to empowerment can thus be identified: first, the contested view that they can empower disabled people, and second, the idea that they can support disabled people to empower themselves, through the skills, resources, networks, and legitimacy that they can command. This latter view is consistent with the dominant view among disabled people that disabled people can only truly empower themselves.

Among disabled people, empowerment has tended to be understood through their understanding of *disempowerment.* The search for empowerment starts with the experience of disempowerment. This helps explain the significance that the idea of empowerment has among disabled people. They have wide experience of disempowerment through segregation, institutionalization, isolation, inferior educational opportunities, poverty, low income, and restrictions on opportunities and choice. For disability activists, empowerment means challenging their disempowerment, having more say in and control over their lives, being able to influence others and bring about change. The goal is greater autonomy and self-determination.

Empowerment is an inherently political concept and this is explicit in disabled people's understandings of the idea. These have focused on both personal and political empowerment. While professional interest in personal empowerment has tended to be concerned with encouraging change in individuals in conformity with state and service values and requirements, significantly different meanings have been placed on personal empowerment by disabled commentators. Here the aim is to alter disabled people's understandings of themselves and their situation as a basis for challenging and transforming both. Key elements toward achieving this are gaining new skills and knowledge and raising expectations, confidence, and self-esteem.

If the professional approach to personal empowerment is concerned with people accepting from outside the need to make change in themselves, disabled people's liberatory understanding of personal empowerment means having the chance to change your understandings of yourself and your situation.

A range of components are associated with empowerment. These include equal opportunities and access; access to advocacy and self-advocacy, to enable disabled people to speak and act for themselves; opportunities for personal development and to acquire new skills; participation, as fully as possible, in the range of activities in society available to nondisabled people and inclusion in the mainstream, rather than segregation in special institutions and services.

A key concept in achieving personal empowerment in the disabled people's and other liberatory and new social movements is consciousness-raising.

CONSCIOUSNESS-RAISING

Ideas of consciousness-raising are notably embodied in the writings and activities of Steve Biko in South Africa and Paulo Freire in South America. Freire has been described as the starting point for many liberationist and participatory approaches to empowerment, especially in the area of community work. Freire coined the term *conscientization*, the process by which oppressed people come to understand the causes of their oppression and to do something about it. Such approaches have been developed in many parts of the majority world by indigenous populations, communities, and their supporters.

There is a tension between these approaches to consciousness-raising and related professionalized, sometimes managerialist and top-down models adopted in community and international development. These tend to employ people without shared experience, often outsiders working for both government and nongovernmental organizations, who seek to involve and empower local disadvantaged groups and communities. They have raised concerns about the tyrannizing effects of supposedly participatory and empowering approaches to development. One initiative that has been associated with this approach has been the development of community-based rehabilitation (CBR) programs for disabled people in the majority world.

Raised consciousness involves an altered understanding of yourself (and others), based on a reinterpretation of your experience and identity. It entails a change in consciousness so that negative understandings of disability as an individualized, tragic (and blameworthy) medicalized condition are replaced by an awareness and understanding of disability as a social condition. Individuals are no longer the cause of "the problem." They are able to see what they have in common with other disabled people as well as how they are may be different from (as well as the same as) nondisabled people. They are able to see the social relations of their situation. They are able to question the legitimacy of their inferior treatment and status because they are disabled. They can resist external judgments that are discriminatory, as well as recognizing and questioning their own internalization of such judgments. Such altered understandings are liberating and provide a basis for taking collective action and seeking political change.

Consciousness-raising thus makes it possible to exert power. This connects closely with modern discussions about the meaning and nature of power. These have developed understandings of a view of power as relational, that is to say, based on the nature of relationships between people and organizations rather than a zero sum game where if one actor gains more power then it is because another loses it. In his influential discussion, Steven Lukes developed a "three dimensional" view of power that offered an analysis of why some people did not challenge their powerlessness, because of their inability to recognize or articulate their own interests. Thus, it is not enough for people to be offered power; they also have to be in a position to make use of it. This has traditionally been the situation of many disabled people, whose segregation and extreme powerlessness have frequently denied them the resources and opportunities to explore, reinterpret, and effectively challenge their disempowerment.

Three developments have supported and encouraged the self-empowerment of disabled people internationally: (1) the move to managerialist/consumerist models of public and social policy, (2) the development of the social model of disability, and (3) the development of new approaches to self-organization by disabled people.

CONSUMERIST/MANAGERIALIST MODELS OF PUBLIC AND SOCIAL POLICY

The managerialist/consumerist approaches to public policy and services that developed toward the end of the twentieth century brought with them very different understandings of empowerment and participation to those of the disabled people's movement. However, with their rhetoric of consumer choice and involvement, they provided a window of opportunity for the disabled people's movement and its related goals. The same was also true of the shift in public policy away from traditional institutionalization to the relocation and maintenance of disabled people in their own homes and neighborhoods. This provided opportunities for their integration, although it should also be remembered that it frequently created major problems through the failure to make adequate alternative provision. One particular consequence of this has been the imposition of additional restrictions on the rights of mental health service users who have been left without adequate or appropriate support in the community.

THE SOCIAL MODEL OF DISABILITY

The social model of disability provided a philosophical basis for raising the consciousness of disabled people. Traditionally in the West, disability has been understood in individualized terms as a problem of deficiency in the body, senses, or intellect. From the nineteenth century, this was overlaid with medical interpretations, which provided the dominant basis for both analyses and responses to disability. These were primarily based on a "treatment" model, which frequently equated disability with illness. This is still the dominant popular model of disability in the West.

The social model of disability developed by the disabled people's movement during the last quarter of the twentieth century drew a distinction between individual *impairment*—the (perceived) loss or deficiency of a limb or sense—and *disability*—the social response to such impairment. Disability was understood in terms of a negative social reaction, which manifested itself in prejudice and discrimination against disabled people and the operation of barriers to exclude them from mainstream life. While a dynamic discussion has developed among disabled people exploring the nature of disability and impairment and the relation between them, the social model remains the main model of interpretation developed by the disabled people's movement. It has provided the philosophical basis of the disabled people's movement. Efforts have also been made to extend its application to other groups, including people with learning difficulties and mental health service users/survivors. It has had a profound liberatory effect on many thousands of disabled people internationally. It has provided a coherent basis for consciousness-raising by offering disabled people an alternative way of understanding. It helps liberate them from a sense of blame, inferiority, personal responsibility, and pathology.

DISABLED PEOPLE'S SELF-ORGANIZATION

The social model of disability has also provided the philosophical basis for the self-organization of disabled people. The aims of disabled people's self-organization follow from the social model. They include seeking to increase the control they have over the support they require, overcoming discrimination that restricts their human and civil rights, and challenging the barriers that disable them in society. The effectiveness of its self-organization has been one of the distinct characteristics of the disabled people's movement. Traditionally in modern Western industrial societies, policies and services for disabled people have been developed and controlled by nondisabled people. They have also reflected their priorities and understandings of disability and disabled people. While the state has intervened systematically to make provision for disabled people since at least the establishment of the English Elizabethan poor law, charitable organizations have also played an important role in defining and providing for disabled people. This tradition has led disabled people to draw a distinction between organizations *for* and organizations *of* disabled people, which reflects their emphasis on and approach to self-organization. By *organizations for disabled people*, they mean those organizations operating in the field of disability that are controlled by nondisabled people. Disability policy and provision have predominantly been shaped by such organizations. The term *organizations of disabled people* has been used to signify those organizations that disabled people themselves control. Disabled people's self-organization has been based on the development of such independent organizations. The emerging organizations of disabled people met with strong opposition from traditional voluntary organizations for disabled people. There are now, however, a large and growing number of organizations of disabled people operating locally, nationally, and internationally. They are now found in North America, Europe, and the majority world.

The self-organization of disabled people has included both parliamentary and extra-parliamentary approaches to making change. There has been a concern with developing new ways of working that include people with impairments. This has extended to the development of new forms of direct action, as well as the development of disability culture, developing the body of disabled people's knowledge and providing user-led services through the development of centers for independent and inclusive living.

What also distinguishes the self-organization of disabled people is that it has tended to combine commitments to self-help and mutual aid with commitments to making broader social and political change. These twin aims help explain the centrality of the idea of empowerment within the disabled people's movement. This is because the idea of empowerment can be used to address issues of both personal and political change. In this way, it can provide a powerful conceptual framework for disabled people's aspirations for both.

Historically, there has often been a tendency to separate self-help and mutual aid from campaigning and political activity. Thus, the self-help tradition in empowerment has tended to be associated with (consensual) voluntary and charitable activity, rather than (conflict-based) political action. In contrast, disabled people's approach to self-organization has been based on an appreciation of the interrelation of the two activities. They have shared this approach with and learned from other new social movements, notably the women's, black people's, and gay men's, lesbians' and bisexuals' movements. The liberatory understanding of empowerment generally adopted by disability activists reunites the psychological and social elements of empowerment.

Disabled people's discourses have also highlighted both the individual and collective aspects of empowerment. Different commentators have placed different interpretations and emphases on the part each of these may play. Some, for example, have stressed the part that individuals' own reevaluation of themselves and their situation may play in leading them to become involved in collection action. In the mental health service user/psychiatric system survivor movement, for example, a particular emphasis has been placed on the part that support and self-help groups can play in encouraging people to get more actively involved with others.

A stronger strand, however, reflected in the writings of the British disability academic and activist Mike Oliver, sees empowerment as a collective process, whereby powerless people, by coming together with others, come to see and make more sense of their oppression and begin the process of challenging it, both within themselves and in the wider world. Self-organization becomes the means the means for both personal and political empowerment. Thus, the self-organization of disabled people has needed to address both. Just as there have been criticisms that the social model of disability has sometimes emphasized disability at the expense of addressing issues of impairment, so concerns have also been raised that disabled people's self-organization has sometimes inadequately addressed issues of personal empowerment because of the priority given to political change.

This has become a particular focus for discussion as efforts have increased to enable as wide a range of disabled people as possible to be included in the disabled people's movement. This includes, for example, people with learning difficulties, older disabled people, mental health service users, people who communicate differently, and people with chronic and life-limiting illnesses and conditions that are associated with impairment and disability. This has been linked with increasing pressures to address difference in terms of, for example, race, gender, sexuality, culture, and class. These developments have highlighted the need to support all disabled people to be able to exert power, acknowledging the particular personal and societal obstacles they may face.

The experience and activities of disabled people have highlighted that there are both individual and collective aspects to becoming empowered. Collective action can provide the basis for both personal and political empowerment. It provides an effective way of connecting the personal to the political, of making clear that the political is the personal and vice versa. Collective action among disabled people has also crucially been the basis for developing the philosophy, values, and goals of disabled people.

One large-scale initiative was taken in the United Kingdom (by an organization for disabled people) to support the self-empowerment of disabled people who were not involved in disabled people's organizations. This was based on a program of "empowerment training" developed and provided by experienced disabled trainers and offered to disabled people living in institutions as well as in their own homes. This was greatly valued by participants who reported the effects it had in raising their consciousness and understanding as disabled people. So far, however, it has not resulted in the organization involved changing its operation in line with service users' changed expectations and aspirations.

Research has been a major area of activity that disabled people have developed through self-organization. The disabled people's movement has equated much traditional research with broader structures of oppression and discrimination in society. The disability emancipatory research developed by disabled people highlights personal and political empowerment as key aims and has an explicit commitment to emancipation in its understanding of empowerment. Drawing on a social model of disability, it prioritizes a changed process of research production that aims to equalize relationships between researchers and research participants, as well as research primarily concerned with making change at both personal and social/political levels, rather than solely concerned with knowledge production. Such disability emancipatory research provides one of the bases for the development of disabled people's own discourse to challenge traditional, medicalized, individual understandings of disability.

END-OF-LIFE CARE

End-of-life care generally refers to palliative care, care that affords relief, but not cure, to dying patients with no reasonable possibility of cure. End-of-life care becomes an increasingly important issue as Americans more often see patients neither improving nor acutely dying, alive but with a dwindling capacity to recover from their injury or illness. Chronic diseases—such as heart disease, cancer, and diabetes—are the leading causes of death and disability in the United States. These diseases account for 7 of every 10 deaths and affect the quality of life of 90 million Americans. Prior to World War II, deaths from these diseases were quick and mostly at home. Since then, advanced medical technology has prolonged the life of people with these diseases when they cannot be cured. Moreover, technology continues to turn acute disease into chronic disease. For example, in the early 1980s, the median life expectancy for AIDS was often less than one year but now it follows a chronic disease trajectory. Those living with serious chronic illness at the end of life generally show three types of trajectory of function and symptoms. Cancer patients generally experience a short period of obvious decline at the end. Prior to that, most cancer patients do not suffer from serious loss of daily basic functions. On the other hand, those dying with chronic organ system failures suffer from long-term disability, with a periodic acute phase during which symptoms are severe and death seems imminent, and then go into temporary remission. The third type of chronic disease is typical of an elderly population—osteoarthritis, osteoporosis, failure to thrive, and dementia, to name a few—and is characterized by self-care deficits and a slowly dwindling course to death. Generally, non-cancer diseases are characterized by long-term disability and an unpredictable timing of death, making end-of-life care for people with these diseases more difficult.

Advanced medical technology also shifted the place of death from home settings to acute care settings in the 1950s. Many of those dying with serious chronic diseases tend to die in the hospital attached to life-sustaining machines. A 1995 study reported on death in intensive care units (ICUs) in hospitals across the country: 38 percent of patients who died spent at least 10 days in an ICU, and 50 percent of conscious patients in the ICU reported moderate to severe pain at least half the time. In response to futile care and unnecessary suffering at the end of life, the hospice movement began in the mid-1960s to provide pain and symptom management in the patient's home where the vast majority of people choose to die. The focus of care is not on curative treatment, but rather the palliation of pain and symptoms through interventions designed to promote comfort and function.

Recognizing the value of hospice care, the National Hospice Reimbursement Act of 1983 created the Medicare Hospice Benefit (MHB) under Medicare Part

A (hospital insurance) of the Social Security Act, which became a permanent benefit in 1986. In addition, states were allowed to develop their own coverage for hospice programs under Medicaid. Currently, 43 states and the District of Columbia offer a hospice benefit to all individuals who qualify for Medicaid. Many private health insurance plans also provide hospice care. Because the scope of services varies by states and insurance plans, contact must be made directly with individual states or private insurance plans for information on hospice care coverage. The following discussion focuses mainly on MHB because the services to be covered under Medicaid/private insurance are essentially those for MHB. Information on MHB is mostly from the hospice section of Social Security Act.

Eligibility for MHB is fairly straightforward: The patient's attending physician and the hospice medical director must certify in writing that the patient is likely to die within six months. On the part of the patient, the patient must, for the duration of an election of hospice care, waive all rights to Medicare A payments for the following services: (1) any Medicare services that are related to the treatment of the terminal condition for which hospice care was elected or a related condition; (2) hospice care provided by a hospice other than the hospice designated by the individual (unless provided under arrangements made by the designated hospice). Upon admission, a written plan of care must be established by the attending physician, the medical director, and the hospice interdisciplinary group prior to providing care and the care provided to an individual must be in accordance with the plan. The plan must include an assessment of the individual's needs and identification of the services including the management of discomfort and symptom relief. It must state in detail the scope and frequency of services needed to meet the patient's and family's needs. The hospice must have an interdisciplinary group that includes at least the following individuals: a physician, a registered nurse, a social worker, and a pastoral or other counselor. The hospice must designate a registered nurse to coordinate the implementation of the plan of care for each patient.

MHB also specifies the standards of care that must be routinely provided directly by hospice employees or contracted staff if necessary. Four types of core services include nursing services, medical social services, physician services, and counseling services. The nursing care and services are provided by or under the supervision of a registered nurse. Medical social services must be provided by a qualified social worker under the direction of a physician. In addition to palliation and management of terminal illness and related conditions, physician employees of the hospice must also meet the general medical needs of the patients to the extent that these needs are not met by the attending physician. Counseling services must be available to both the individual and the family. Counseling includes bereavement counseling for the family, provided after the patient's death (up to one year), as well as dietary, spiritual, and any other counseling services for the individual and family provided while the individual is enrolled in the hospice. In addition to the core services, physical therapy, occupational therapy, and speech-language pathology must be available. Home health aide and homemaker services must be available and adequate in frequency to meet the needs of the patients. Medical supplies and appliances including drugs and biologicals must be provided as needed for the palliation and management of the terminal illness and related conditions.

MHB pays hospices capitated per diem for almost all services needed in a day to treat the patient. The per diem rate varies depending on the level of care: routine home care, continuous care, inpatient respite care, and general inpatient care. The day is counted as routine home care with the rate of $118.08 (as of October 2003 and regionally adjusted) when patients, residing within the home (or nursing facility), under the supervision of the hospice program, receive fewer than eight hours of care per day. Routine home care accounted for 95.1 percent of patient days in hospice care in 2002. A continuous home care day is when continuous nursing care is needed for 24 hours and can be provided for up to five days. It is furnished only during times of crisis and only as necessary to avoid transfer to a hospital usually as death nears. Continuous care accounted for only 0.9 percent of patient days in hospice care in 2002 and its rate ($689.18) is the highest, six times higher than routine home care. The third level of care, inpatient respite care, allows hospice patients to receive care in approved facilities on a short-term basis (no more than five days at a time) as respite for their caregivers. Inpatient respite care accounted for 0.2 percent of patient days in hospice care in 2002. Finally, general inpatient care permits patients to be admitted into approved facilities for pain control or acute/chronic symptom management that cannot be achieved in other settings. This form of care can be provided in a hospital, a hospice with its own inpatient facility, or a skilled nursing facility. General inpatient care days accounted for 3.8 percent of patient days in hospice care in 2002. The current national Medicare rate for general inpatient care is $525.28 (adjusted for regional wage differences).

The number of Medicare beneficiaries choosing hospice services has grown substantially during the past decade—579,801 beneficiaries enrolled in 2001, more than five times the number that elected hospice in 1991 (108,413). Cancer patients account for more than half of Medicare hospice users, but the most dramatic growth in use is among persons with other terminal conditions, such as heart disease, lung disease, stroke, or Alzheimer's disease. From 1992 to 1998, hospice enrollment by beneficiaries with cancer increased 91 percent, while enrollment among beneficiaries with all other conditions increased 338 percent. By 1998, about 43 percent of Medicare beneficiaries electing hospice had non-cancer diagnoses, compared with about 24 percent in 1992. This growing share of hospice enrollees with non-cancer diagnoses reflects the continuing legislative efforts to adjust the organization and financing of care to match distinguishably different trajectories of chronic diseases. The way benefit periods were organized in the original 1983 hospice legislation was geared toward cancer patients. Patients were allowed to elect hospice care during one of the three benefit periods: two 90-day periods followed by one 30-day period with a limit of a maximum of 210 benefit days. Given the concerns about the complexity of making a prognosis of six months or less for non-cancer patients, Congress later repealed the 210-day limit and replaced it with four benefit periods. It added the fourth benefit period of unlimited duration. At that time, however, beneficiaries could have no more than four benefit periods. The current benefit period system was structured by the Balanced Budget Act of 1997 (BBA). The act established unlimited coverage by changing the four hospice benefit periods to two 90-day periods, followed by an unlimited number of 60-day periods. However, the law also increased the number of times of certification. Under this act, all patients are initially admitted for a 90-day benefit period. At regulated intervals (90 days after initial enrollment, 180 days after initial enrollment, and then every 60 days, indefinitely), a patient must be recertified by the hospice medical director. Once recertified at the required intervals, the patient can stay in hospice care with no limitation. When patients cannot be recertified and have to be discharged because of a change in prognosis due to an improved clinical status or stability over a period of time, the hospice program assists in establishing appropriate follow-up care. When physical status worsens again enough to get recertified, they can elect hospice care again. Most important, patients have the right to return to active disease-modifying treatment during any benefit period, thereby relinquishing the hospice benefit and returning to the usual model of care. Patients who select this option are not penalized for this decision, and are readily welcomed back should they elect additional hospice care. The act also allows patients to change the current hospice provider once during each benefit period.

MHB assumes full financial responsibility for all medications related to the primary hospice diagnosis, for durable medical equipment (e.g., hospital beds, commodes, wheelchairs), and for the participation of staff. A hospice patient pays no more than $5 for each prescription drug and other similar products for pain relief and symptom control. A patient pays only 5 percent of the Medicare payment amount for inpatient respite care, wherein the inpatient hospital deductible under Medicare A ($876 in 2004) is the annual limit for respite copayments. Even though they must waive their rights to all other inpatient hospital, skilled nursing facility, and home health services for the terminal illness, beneficiaries may still be treated for other medical problems under the regular Medicare program. Even though the hospice team includes a physician, patients can continue to use their personal physician. Medicare will help pay for covered services provided by a physician not affiliated with the hospice if the patient is covered by Medicare

Medical Insurance (Part B). Also, if the patient has Part B, he or she can use all appropriate Medicare Part A and Part B benefits for the treatment of health problems unrelated to the life-limiting illness.

Despite a rapid increase in use of hospice care, only one of five hospice-appropriate deaths occurs while in hospice care. Advocates for hospice care cite two barriers among others to access to hospice care. One barrier is related to the focus of hospice care on home-centered care. Medicare does not pay for room and board if a patient lives in a nursing home or a hospice residential facility. Another barrier related to the nature of home-centered hospice care occurs when elderly people do not have caregivers to manage care at home and cannot be safely cared for by hospice in the home. Although some states have passed laws to establish inpatient hospice facilities to house those having no primary caregiver at home, the patients without caregivers may be unable to afford hospice care when Medicare does not cover home and board cost in a inpatient hospice facility. Some states including New York cover the room and board cost through Medicaid for hospice beneficiaries with low income, but the assistance program tends to have a sunset provision, reflecting the financial concerns about increasing Medicaid cost among states.

Another barrier to access to hospice care is related to uncertainty involved in certification of survival of six months or less. Physicians are often confused about how Medicare interprets its terminal illness requirement: Intermediaries in reviewing hospice claims use different guidelines from those used by hospice providers to determine eligibility of beneficiaries for hospice benefits. Physicians often delay certifying patients for hospice care. Sometimes even when the patient's conditions and clinical prognosis do not change, they refuse to recertify patients who do not die within the first six months of the initial certification. It is often difficult for beneficiaries and their advocates to convince physicians that hospice certification may well remain appropriate, that the beneficiary need not have died within six months for the hospice certification to have been legitimate, and that recertification should not result in a fraud claim. The delayed certification has resulted in a decrease in length of stay in hospice care, despite the increase in the number of beneficiaries. Thirty percent of all hospice recipients died within one week and 63 percent died within one month in the year 2000. A government report revealed an increase in the share of MHB users with very short stays over the past years: Beneficiaries using hospice care for one week or less accounted for 28 percent of all users in 1998, compared with 21 percent in 1992. The Centers for Medicare and Medicaid Services, the financing agency for hospice care, formally acknowledged the difficulty in prognosis, reducing the fear of fraud scrutiny among physicians. On the part of hospice care providers, there have been continuing efforts to develop the guidelines for certification based on specific functions and symptoms characteristic of near death for non-cancer diseases.

There has been a call to assist patients who are reluctant to elect hospice care because they do not know anything about it. They need to have their questions answered by a physician who specializes in end-of-life issues or a hospice representative. In response to the call, the Medicare Prescription Drug, Improvement, and Modernization Act of 2003 provides provisions to permit physicians to refer terminally ill patients to a Medicare-certified hospice for consultation services that was not covered by Medicare. The provision applies on or after January 1, 2005. These consultation services include (1) assessing the beneficiary's need for pain and symptom management, including the individual's need for hospice care; (2) counseling the beneficiary with respect to end-of-life issues and care options; and (3) advising the beneficiary regarding advanced care planning.

Advanced care planning has been widely encouraged as a way of avoiding lingering deaths where the quality of life is poor and the patient cannot participate in decision making about continuing futile treatments to prolong life. Advance care planning, encouraged by a federal law, such as the Patient Self-Determination Act of 1991, generally involves two forms: living wills and durable power of attorney for health care. The former is a written document of wills that states the desire to not be kept alive by extraordinary or disproportionate medical interventions. Living wills become effective on the determination of terminal illness or imminent death, when the patient can no longer participate in decision making. Durable power of attorney for health care is to be distinguished from a living will in that it is a directive executed by a competent adult that appoints another individual to make medical treatment decisions on his or her behalf in the event that the person making the appointment loses decision-making capacity. The appointed surrogate is often referred to as the patient advocate, patient proxy, or patient representative. The laws governing the authority this individual does or does not have may vary from state to state and is dependent on the specific instructions of the document.

The Patient Self-Determination Act of 1991 requires health care organizations including hospice care providers (1) to inform patients of their right to complete an advance directive and (2) to document existing advance directives in patients' medical record. A significant increase in advance directives documentation in nursing home medical records was reported after the implementation of the act. Another study found that having a living will was associated with a lower probability of dying in a hospital for nursing home residents and people living in the community. However, many more studies cast doubt on the role of advance directives on definitive decisions to stop treatment in hospital: Only 47 percent of the physicians for the patients who preferred to avoid cardio-pulmonary resuscitation (CPR) knew that preference; 46 percent of do not resuscitate (DNR) orders were written late in the hospital stays—within two days of death. Studies reported a low level of physicians' compliance with patients' advance directives and a high level of reliance on their own clinical reasoning.

Hospice-appropriate deaths will increase. One of five Americans will be 65 or older by the year 2020. Advanced technology will increase the number of chronic diseases by turning acute disease to chronic disease. Advanced technology will prolong the life of those suffering from serious chronic diseases, probably increasing the difficulty in predicting the end of the life trajectory. Advanced technology will also prolong death, highlighting the need for physician and public education on advance care planning. Americans have generally made the choice to live as long as the quality of life is acceptable. As technology becomes more sophisticated, it is increasingly important for our aging population to indicate their wishes in advance about end-of-life care and what each person believes constitutes an acceptable quality of life. The quality of life standard, of course, differs from person to person. With life expectancy reaching well into the 90s in the foreseeable future, these decisions become critical in caring for our old-old, not only for their own personal dignity, but for the soaring health costs associated with life-prolonging technologies.

ENNS, HENRY (1943–2003)

Canadian (Ukrainian-born) activist

Henry Enns was a prominent leader in the disability rights and independent living movement in Canada, whose activities became international in scope through work with the United Nations and his leadership of the Disabled Peoples’ International organization. Enns was born in Ukraine and lived in Germany and Paraguay as a child, before settling in Manitoba, Canada, with his family. At the age of 15, Enns contracted rheumatoid arthritis, and gradually became increasingly interested in the issues facing people with physical disabilities. Throughout his adult life, Enns made notable contributions to the initiation and development of numerous disability rights organizations. In the early 1980s, Enns was a leader in the establishment and direction of some of the earliest independent living centers in both Ontario and Manitoba. From his base in Winnipeg, Enns became increasingly active in the 1980s and 1990s in the international disability rights movement. From 1990 to 1996, he served as executive director of Disabled Peoples’ International. At the time of his death, Enns was the executive director of the Canadian Centre on Disability Studies (1996–2002). He was the first non-U.S. citizen to receive the U.S. Presidential Service Award in 1992.

ENVIRONMENTAL CONTROL

Environmental control is a branch of assistive technology that includes the use of adaptive devices to manipulate objects and of electronic devices that enable an individual with a disability to control other electronic devices in a home, school, or work setting.

Devices that may be used to manipulate objects can range from low-tech reachers to high-tech robots. The low-tech devices are often available through mail-order catalogs or through durable medical equipment vendors. The low-tech environmental control equipment can take the form of individual devices that assist with the performing of a specific task. For instance, a wire-frame buttoner can assist with dressing.

For some activities, environmental control equipment can include a range of devices. For meal preparation and eating, environmental control devices can include adapted cutting boards, pot-handle holders, plates with built-up edges, and powered eating aids. For reading, devices can include angled bookholders and powered page-turners. The level of technology appropriate for an individual with a disability is dependent on the person’s abilities, goals, support systems, and environment, among other factors.

Environmental control units (ECUs), sometimes referred to as electronic aids to daily living, are devices that enable the user to control devices such as lights, fans, radios, televisions, and powered door openers. The ECU may require direct selection of the controls or offer a scanning feature that lets the user control the device with one or two switches.

ECUs communicate with the devices being controlled through one of four methods: house wiring, ultrasonic signals, infrared signals, or radio frequency signals. House wiring may be used to transmit signals to the electrical outlets in the environment. Devices being controlled must be plugged into a module that receives the ECU’s signals and converts this information to control power to the device.

An ECU may use ultrasonic signals to communicate with the devices being controlled. Again, devices need to be plugged into a module that receives the signals and uses them to determine if power is to be provided or not. Ultrasonic systems are useful when the ECU and devices being controlled are in the same room, as the signals do not go through walls.

An ECU's transmitter may use infrared signals, again going to receiver modules that use the signals to determine whether power is provided to the device, or to determine the level of some settings (e.g., volume). Systems using infrared signals need to be located in the same room, as the signals will not go through walls, and some difficulty may be encountered if the system is used in direct sunlight.

ECUs that use radio frequency (RF) signals have the advantage of controlling devices throughout a home or work environment, as the signals go through walls. The system may need to be set to avoid interference from other RF devices, or by inadvertent control from another ECU.

▣ EPIDEMIOLOGY

The term *epidemiology* is derived from the Greek roots *epi* meaning on or upon, *demos* meaning the common people, and *logy* meaning the study of. Epidemiology is defined as the study of disease in human populations, their causes, and means of prevention. The term *disease* in the definition refers to a broad array of health and medical problems including disability, injury, and death.

Epidemiology differs from clinical medicine in a number of ways. It studies groups of people, not just individuals. Epidemiology also studies both well people and people with disease to identify the crucial differences between those who are stricken and those who are spared. These differences are compared to identify the underlying causes or etiologies of disease. While the goal of clinical medicine is to diminish pain, restore function, and bring the patient back to full health, the main goal of epidemiology is to understand the causes of disease in order to prevent them from occurring.

Epidemiology addresses many areas of public health. For example, it studies the natural history and prognosis of disease. It is used to measure the extent and burden of disease within communities, states, and nations. Epidemiology is also frequently used to evaluate therapeutic and preventive health measures, such as determining the effectiveness and safety of health screening programs, new drugs, and vaccines. Public policy makers, government agencies, health insurance companies, hospitals, physicians, and others increasingly rely on epidemiology as the foundation for making sound decisions to protect the public's health.

The field of epidemiology is highly interdisciplinary. It relies heavily on the concepts, knowledge, and theories of such disciplines as biology, pathology, and physiology in the health and biomedical sciences, as well as the disciplines of anthropology, psychology, and sociology in the behavioral and social sciences. Epidemiology is also very closely tied to the discipline of statistics, particularly biostatistics.

HISTORICAL DEVELOPMENT

Epidemiology is a relatively new science that emerged in the nineteenth century. However, its historical development spans thousands of years and is best described as slow and unsteady. Over the centuries, many individuals have contributed to the establishment of the modern field of epidemiology.

The first important individual was the Greek physician Hippocrates (428–347 BCE), who is traditionally regarded as the father of Western clinical medicine. Hippocrates wrote the first epidemiologic texts *Epidemic I*, *Epidemic III*, and *On Airs, Waters, and Places*. In these works, he was the first person to attempt to explain the occurrence of disease on a rational rather than a supernatural basis. Since Hippocrates recognized disease as a mass phenomenon as well as one affecting individuals, he is recognized as the first epidemiologist.

Another figure of importance was the English statistician John Graunt (1620–1674). Graunt was the first person to analyze the *Bills of Mortality*, which recorded the weekly count of births and deaths in London. In 1662, Graunt published the results of his findings in *Natural and Political Observations Made upon the Bills of Mortality*. He found that male births consistently outnumbered female births, yet males no longer outnumbered females by the time they reached their childbearing ages because males experienced higher mortality rates. Graunt also constructed the first life table, a statistical table that uses death rates of a cohort of persons to determine the group's average life expectancy.

James Lind (1716–1794), a Scottish naval surgeon, also helped establish epidemiology. Lind studied the great sea plague scurvy. On long naval voyages, scurvy often killed two-thirds of a ship's crew. To prevent scurvy, Lind conducted the first planned controlled clinical trial, supplementing the diet of a small number of sailors with fresh citrus fruit and lemon juice (the experimental group). He then compared the incidence of scurvy among these men to that of other sailors on the same ship who ate the normal vitamin-poor naval diet (the control group). Finding that citrus fruit prevented the disease, Lind recommended dietary changes for all sailors, which ultimately resulted in the eradication of scurvy from the British navy. Hence, British sailors are still referred to as "limeys."

Edward Jenner (1749–1823), a British surgeon who practiced medicine in the small village of Berkeley in Gloucestershire, England, observed that milkmaids who developed cowpox (a mild disease) never contracted the severe and often disfiguring and deadly disease smallpox. Using matter drawn from the lesions of cowpox on the hand of a milkmaid, Jenner performed the first vaccination. In time, the practice of vaccinating for the prevention of smallpox became widespread. Today, smallpox is the only disease to ever be totally eradicated from nature. And vaccination is a widely used method to prevent the occurrence of many diseases.

William Farr (1807–1883), a British physician who worked as the first compiler of scientific abstracts at the Registrar General's Office in London, helped shape England's vital statistics system. His most important contribution to epidemiology was the establishment of a sophisticated system for classifying the causes of death. This enabled the comparison, for the first time, of mortality rates among different demographic and occupational groups. Farr's classification system still forms the basis of the International Classification of Disease and Related Health Problems (ICD) that is in use today.

Another great pioneer in the field of epidemiology was John Snow (1813–1858). Snow, a contemporary of William Farr, was a well-respected London physician who specialized in obstetric anesthesiology. One of his patients was Queen Victoria, whom he assisted in the delivery of two of her children. Snow became interested in the cause and spread of cholera epidemics that periodically occurred in London. In 1854, when a severe cholera epidemic once again struck the city, Snow undertook an investigation. At the time, most physicians attributed the disease to miasma or "bad air" formed from decaying organic matter. Snow, however, held the radical view at the time that cholera was caused by drinking fecal-contaminated water. Snow started his investigation by plotting the geographic location of all cholera deaths in London. When he found a large number of deaths (more than 500 in a 10-day period) clustered around a public water hand-pump on Broad Street in the Soho District of west London, he informed the local authorities, along with his hunch as to the cause. Although the authorities were skeptical, the next day they had the pump disabled by removing its handle. Immediately, new cases of cholera started to dwindle, and then disappear. However, because cholera deaths were already declining in the city, Snow was unable to attribute the end of the outbreak directly to the removal of the pump handle.

Snow doggedly continued his investigation of cholera and conducted what he called his "Great Experiment." To conduct the "experiment," Snow painstakingly documented the cholera deaths (nearly 1,400) among the subscribers of London's two independent private water companies. The Southwark and Vauxhall Company (which supplied more than 40,000 homes) drew its water from the sewage-polluted lower Thames River, while the Lambeth Company (which supplied more than 25,000 homes) obtained its water farther upriver. Snow conclusively showed that the number and rate of cholera deaths were much higher for residents in homes served by the Southwark and Vauxhall Company, which supplied the polluted water. Using meticulously gathered data and the power of statistics, Snow brought about the beginning of the end of cholera in Britain. Because of his study methods and insight, Dr. John Snow is generally regarded as the father of modern epidemiology.

BASIC CONCEPTS AND TOOLS

Epidemiology has two fundamental assumptions. First, disease does not occur at random. Second, disease has causal and preventive factors.

Epidemiologists often use models to explain the occurrence of disease. One commonly used model views disease in terms of susceptibility and exposure factors. Specifically, for individuals to develop a disease they must be both susceptible to the disease and be exposed to it. For example, for a person to develop measles (rubeola), a highly infectious viral disease that was once very common among children, they must be both exposed to a person who is shedding the measles virus (an active case), and they must also be susceptible to measles by lacking immunity to it. Immunity to measles may be derived from either previously having the disease or from being vaccinated against it.

Another commonly used model, the epidemiologic triad, views the occurrence of disease as the balance among host, agent, and environment factors. The host is the actual or potential recipient or victim of the disease. Hosts have characteristics that either predispose them to, or protect them from, disease. These characteristics may be biological (e.g., age, sex, and degree of immunity), behavioral (e.g., habits, culture, and lifestyle), or social (e.g., attitudes, norms, and values). The agent is a factor whose presence or absence is necessary for a particular disease to occur. Agents may be biological (e.g., bacteria, fungi, and viruses), chemical (e.g., gases and toxic agents), nutritional (e.g., carbohydrates, fats, and food additives), or physical (e.g., electricity and ionizing radiation). The environment includes all external factors, other than the host and agent, that influence health. The environment may be categorized as the social environment (e.g., economic, legal, and political), the physical environment (e.g., precipitation, temperature, and weather conditions), or the biological environment (animals and plants). To illustrate the epidemiologic triad, consider a case of lung cancer. The host is the person who developed lung cancer. He or she may have had the habit of smoking for many years. The agent is the smoke, tars, and toxic chemicals contained in the tobacco. Environment may have been the workplace where smoking on the job was permitted, and cigarettes or other tobacco products were readily available.

Epidemiologists classify the type of disease cases and frequency of disease occurrence within a population as being either endemic or epidemic. Endemic is defined as the usual occurrence of a disease within a population. In contrast, an epidemic is a sudden and great increase in the occurrence of a disease within a population. It may also be the first occurrence of an entirely new disease. A special type of epidemic is the pandemic, which is a rapidly emerging outbreak of a disease that affects a wide range of geographically distributed populations. Many pandemics are worldwide in scope. To illustrate the three, a small number of people may have the flu (influenza) in a large city throughout the year and these would be endemic cases of the disease. In contrast, the number of people having the flu in the same city may increase enormously in the fall and these would be epidemic cases. Last, if a new variety of flu emerges and people throughout the world get sick from it they would be pandemic cases. An example of a pandemic is the great influenza epidemic of 1918, which spread throughout the world killing an estimated 20–40 million people.

Epidemiologists study the morbidity and mortality caused by acute and chronic diseases. Morbidity is defined as the state of illness, symptoms, or impairments produced by a disease, while mortality is death caused by a particular disease. Acute diseases are those that strike and disappear quickly, within a month or so (e.g., chicken pox, colds, and the flu), while chronic diseases are those that are long term or lifelong diseases, many of which are incurable (e.g., cancer, diabetes, and HIV/AIDS).

One of the most important tools of epidemiology is the use of morbidity and mortality rates. Epidemiologists use rates so that disease cases and deaths can be compared to the unit size of population. A rate is a special type of proportion that includes a specification of time, and the numerator of the proportion is included in the denominator. Rates can be expressed in any form that is convenient (e.g., per 100, per 1,000, per 10,000, and per 100,000). Infant mortality rates, for example, are typically expressed per 1,000 live births, while cancer rates are expressed per 100,000 population.

The following example illustrates the important role rates play in making epidemiological comparisons. Assume City A has 10 cases of a disease while City B has 50 cases. Although in terms of absolute numbers City B has five times more cases of the disease than City A, the differences may be due to the underlying population size of the two cities. To compare the occurrence of disease in the cities on a unit population basis, rates must be calculated. If City A has a population of 10,000, and City B has a population of 50,000, the disease rates per 1,000 people would be the same for both cities. City A's disease rate is (10/10,000) × 1,000 = 1.0 case per 1,000 population, and City B's disease rate is (50/50,000) × 1,000 = 1.0 case per 1,000 population.

Rates may be crude, specific, or adjusted. Crude rates use the total number of disease cases and the entire population in their calculations. For example, the above rates for City A and City B are crude disease rates. Specific rates differentiate cases and populations into age, sex, race, or other subgroups. For example, if the rates for City A and City B were for disease cases who were 25–34 years of age/the population in each city who were 25–34 years of age, the rates would be age-specific disease rates. Specific rates can be very detailed; age-sex-race-specific disease rates can be calculated (e.g., the number of disease cases who are African American males ages 25–34 years old/the population who are African American males ages 25–34 years old). Adjusted or standardized rates allow for comparison of populations with different characteristics. To calculate adjusted rates statistically constructed summary rates are used to remove age, sex, or race differences in populations. For example, in the United States the population of Florida (a state where many people go to retire) is much older than the population in Alaska, so it would be inappropriate to compare the mortality rates of the two states without adjusting for the differences in their age structures.

Epidemiologists use two types of rates to measure the occurrence of disease: incidence rates and prevalence rates. The incidence rate measures the rapidity at which new cases of a disease are occurring in a population over a period of time. The incidence rate is an important measure for evaluating disease control programs (if any) and has implications for the future problems of medical care. Specifically, the incidence rate is defined as the number of newly reported disease cases in a defined period/the population at the midperiod × 100, 1,000, 10,000, or 100,000. Epidemiologists in health departments, for example, study the incidence rates of HIV/AIDS to see if the disease is spreading and whether AIDS prevention programs are working.

The prevalence rate measures the total number of existing cases of a disease in a population at a given point of time (or sometimes a period of time, or even over a lifetime). The prevalence rate is a useful indicator of the burden of a disease on the medical and social systems of a geographic region. It is useful only for diseases of long duration (months or years). Specifically, the point prevalence rate is defined as the number of known cases of a disease at a given point in time/population at that time × 100, 1,000, 10,000, or 100,000. Epidemiologists at the World Health Organization (WHO), for example, use prevalence rates to determine the medical, economic, and social burden of AIDS in developing countries.

There is a relationship between incidence and prevalence rates. Prevalence rates vary directly with both the incidence and duration of disease. If the incidence of a disease is low, but the duration of the disease is long, such as with chronic diseases, the prevalence will be large in relation to the incidence. Conversely, if the prevalence of a disease is low because of short duration (due to recovery, migration, or death), prevalence will be small in relation to incidence.

SOURCES OF EPIDEMIOLOGICAL DATA

Epidemiologists use primary and secondary data sources to calculate rates and conduct studies. Primary data is the original data collected for a specific purpose by or for an investigator. For example, an epidemiologist may collect primary data by interviewing people who became ill after eating at a restaurant to identify which specific foods they ate. Collecting primary data is expensive and time consuming, and it usually is undertaken only when secondary data are not available. Secondary data are data collected for another purpose by other individuals or organizations. Examples of secondary data commonly used by epidemiologist include birth and death certificates, population census records, hospital and clinic patient medical records, data from disease registries, insurance claim forms and billing records, public health department case reports, and surveys of individuals and households.

An important source of secondary data is the Centers for Disease Control and Prevention (CDC). The CDC, which is an agency of the U.S. Department of Health and Human Services, consists of 12 centers, institutes, and offices. The various centers collect a wide array of epidemiological data on such areas as birth defects and developmental disabilities, chronic diseases, infectious diseases, injuries, occupational safety and health, and sexually transmitted diseases. Within the CDC, the National Center for Health Statistics (NCHS) conducts, publishes, and widely disseminates the results of numerous health surveys of individuals and health care organizations. Examples of NCHS surveys include the National Health Interview Survey, the National Health and Nutrition Examination Survey, the National Hospital Discharge Survey, and the National Nursing Home Survey.

DESCRIPTIVE AND ANALYTICAL EPIDEMIOLOGY

The field of epidemiology can be divided into two broad categories: descriptive epidemiology and analytical epidemiology. Descriptive epidemiology characterizes the distribution of disease within a population. It describes the person, place, and time characteristics of disease occurrence. It specifically asks the questions: Who is getting the disease? Where is the disease occurring? When is the disease occurring?

A typical example of descriptive epidemiology is an investigation of a food-borne epidemic at a local restaurant. To determine the cause of the outbreak, epidemiologists would investigate how many customers of the restaurant and what proportion or rate of all customers got sick (i.e., determine an attack rate). They would determine the demographic characteristics of those who got sick (i.e., age, sex, and race). They would also determine when the customers were at the restaurant (i.e., time of day, day of the week), and what specific foods they ate (i.e., items on the breakfast, lunch, or dinner menu). The epidemiologists would also work closely with a public health laboratory to test the existing foodstuffs to determine, if possible, what particular pathogen caused the disease. After determining the cause of the outbreak, the epidemiologists would make recommendations and/or mandate changes (i.e., requiring colder refrigeration, more hand washing by employees, or perhaps using higher cooking temperatures for foods) to the restaurant's management to prevent other outbreaks from occurring in the future.

Analytical epidemiology, on the other hand, tests hypotheses to determine if statistical associations exist between suspected causal factors and disease occurrence. It also tests the effectiveness and safety of therapeutic and medical interventions. To accomplish these tasks, analytical epidemiology uses four major types of research study designs: cross-sectional studies, case-control studies, cohort studies, and controlled clinical trials. Each of these types of studies has strengths and weaknesses.

Cross-sectional studies examine the relationship between disease and other variables of interest as they exist in defined populations at one particular time. For example, a cross-sectional study investigating whether residential exposure to the radioactive gas radon increases the risk of lung cancer may examine the level of radon gas in lung cancer patients' homes. Cross-sectional studies have the advantage of being inexpensive and simple to conduct. However, their main disadvantage is that they only establish associations at most, not causality.

Case-control studies start with people with a particular disease (cases) and a suitable control group without the disease and then compares the exposure of the cases and controls to the factor that is believed to have caused the disease. These types of studies are most useful for ascertaining the cause of rare events, such as rare cancers. For example, to determine whether the use of cellular telephones causes head cancers a group of head cancer patients (cases) would be compared to a group of individuals without head cancers (controls). The two groups would then be compared with respect to the proportion that used cellular telephones and their level of exposure (i.e., how many minutes they talked over the telephone per day). Case-control studies have the advantages of being quick to conduct and inexpensive, and they require only a small number of cases and controls. However, their main disadvantage is that they rely on recall, which may be biased, or records to determine exposure status.

Cohort studies are observational studies in which a defined group of people (the cohort) is followed over time and outcomes are compared for individuals who were exposed or not exposed to a factor at different levels. Cohorts can be assembled in the present and followed into the future (a concurrent cohort study) or identified from past records (a historical cohort study). An example of a cohort study is the Framingham Heart Disease Epidemiology Study. The Framingham study is the longest ongoing epidemiological study in the United States. Starting in 1948 with an original cohort of 5,200 adult volunteers from Framingham, Massachusetts, the study has followed the volunteers and their offspring to identify the risk factors associated with developing heart disease (e.g., cholesterol levels, smoking, obesity, and diabetes). To date, the results from this landmark cohort study have been published in more than 1,000 scientific papers. The main advantage of cohort studies is they can establish the timing and directionality of events. However, their main disadvantages are that they require large sample sizes and a long follow-up time, and they are not suitable for investigating rare diseases.

Controlled clinical trials are studies that test therapeutic drugs or other health or medical interventions to assess their effectiveness and safety. Controlled clinical trials compare the outcomes of new drugs or interventions given to an experimental group compared to another group (control) that does not receive the same drugs or interventions. To minimize bias, individuals involved in clinical trials may be randomly assigned to the experimental and control groups. For example, to determine whether a new drug to treat breast cancer is more effective than another drug, breast cancer patients would be assigned randomly into either an experimental group that would receive the new drug, or the control group that would receive the other drug. The outcomes of the two groups (e.g., number of remissions, and increase in survival time) would then be compared. In the United States, and many other countries, all new therapeutic drugs are subject to rigorous controlled clinical trials before they can be provided to the public. The main advantage of controlled clinical trials is they provide unbiased results. However, their main disadvantage is that they are very expensive to conduct.

SUMMARY AND CONCLUSION

During the past several decades, the field of epidemiology has greatly expanded in size, scope, and influence. The number of epidemiologists has grown rapidly along with epidemiology programs in schools of public health and medicine. Today, epidemiologists investigate the outbreaks of acute diseases such as food-borne epidemics. They also investigate the outbreaks of new emerging diseases such as SARS, and reemerging older diseases such as tuberculosis. At the same time, epidemiologists study the underlying causes of many chronic diseases such as cancer, heart disease, and stroke. They also study the causes of psychiatric disorders, substance abuse, and social problems such as violence. Since the recent terrorist attacks in the United States, Europe, and Japan, many epidemiologists are involved in planning and implementing health surveillance programs to detect and prevent possible bioterrorism attacks. Epidemiologists are also just beginning to examine the determinants of health at the molecular and genetic levels. They are studying how individual genes influence the risk of developing chronic conditions such as Alzheimer's disease. And epidemiologists are beginning to develop new molecular markers to improve the measurement of individually specific exposure and susceptibility factors.

EPILEPSIES, TEMPORAL LOBE

Epilepsy arising in some discrete location in the cerebral cortices is termed partial, or localization-related, epilepsy and named for the region of cortex from which it comes. It is further classified according to whether it does or does not, *at the onset of a seizure,* give rise to convulsive phenomena—involuntary movements that are rhythmical or sustained. Temporal lobe epilepsies (TLEs) are the most frequently encountered nonconvulsive localization-related epilepsies, although the typical staring with loss of touch from surroundings may at times "secondarily generalize" and become convulsive. The classical temporal lobe seizure consists of nearly motionless staring ("deambulation") and loss of touch with surroundings without generalization of the seizure ("complex" partial).

They are often preceded by an even more focal phenomenon termed an *aura* by Galen, who recognized some aspects of this type of seizure more than 1,800 years ago. Auras include difficult-to-describe internal sensations of which a person is aware and remembers: an epigastric "rising" sensation, unpleasant aroma or taste, auditory or visual hallucinations, strong memories, "forced thinking," and psychic symptoms. The temporal lobe is an important link in systems for olfaction, memory, emotion, feeding, fear, aggression, and sexual matters. "Psychic" auras include strange "dreamy states," fear, déjà-vu and other strong seeming recollections, fear and other alterations of emotion (ranging from despair to exhilaration), time, and space. These prominent phenomena account for the application of "psychomotor" to these seizures. Over time, TLE may be associated with deterioration of memory, alteration of personality, psychiatric symptoms (e.g., depression, anxiety, obsessive diary keeping, hyper-religiosity, self-loathing), and behavior problems. It is of interest to consider that Dostoyevsky's TLE may account in part for the traits he assigned to characters in his novels.

The ensuing *complex* loss of interaction for which the person is *amnestic* represents a spread of seizure activity from the initial focus. This phase may be accompanied by perseverative *automatisms.* These are relatively subtle patterned motor activities carried out without any clear purpose such as lip-smacking, spitting, silly laughter, quizzical facial expressions with seeming attempts to speak, page-turning, posturing of limbs, rubbing some part of the body, or picking at the air or clothing with fingers. The typical duration is in minutes, although a temporal nonconvulsive seizure may go on for many hours. Once it is longer than 5–10 minutes, it is termed psychomotor (or partial complex) status epilepticus. The spell may then terminate with somewhat confused resumption of activities, sometimes with transient loss of speech. TLE may "secondarily generalize," especially in children or untreated adults, giving rise to a generalized convulsive seizure, followed by prolonged sleep.

Galen's prescient recognition that odd and complex behaviors could be epileptic was not pursued to any great extent until the nineteenth century. In France, Calmeil (1824) revived the clinical description and Bouchet and Cazauvieilh (1825) identified some features of the most common pathology of TLE observing with partial correctness that the change was the result rather than the causes of epilepsy. Tissot's (1865) enlargement and classification of auras provided a foundation for Englishman Hughlings Jackson to provide a conceptual framework for epilepsies on the basis of recurrent clusters of phenomena that could derive from particular parts or all of the brain, assigning psychomotor seizures ("uncinate fits") to the temporal lobes and explaining the evolution from aura through dreamy state to generalized convulsion to spread of the epileptic discharge.

This concept proved very important in the neuroscientific view of brain function and provided the foundation for syndromic classification of the epilepsies, which would in time bear importantly on diagnosis, treatment, and prognostication. The focal electroencephalogram (EEG) changes of temporal lobe epilepsy were not detected until the 1930s, based on the pioneering work of Berger of Germany. Additional sophisticated subsequent clinical and pathological investigations have described a family of discrete subtypes of TLE, their natural histories, and treatment. There are now more than 10 valuable drugs employed in the treatment of TLE, only 3 of which were in use before the 1970s. Despite new drugs, TLE has remained a difficult type of epilepsy to manage.

Mesial temporal lobe epilepsy (MTLE) has proven to be one of the most common human epileptic syndromes. It is a highly drug resistant form of epilepsy that arises in the evolutionarily ancient anterior inner portions of the temporal lobe, the amygdala and hippocampus—the region whose pathology Cazauvieilh misinterpreted in 1825. Ounsted in the 1960s set in motion intense study of the biology of this condition. Techniques for the study of slices taken from this brain region were developed, along with increasingly sophisticated physiological studies that have defined MTLE as a focal degenerative condition. Despite various hypotheses about the origins of MTLE, it is not yet known why these regions of the brain are vulnerable. Although we know that the worsening of this form of epilepsy is typically due to seizure-related degenerative epileptic "remodeling," we do not know how the remodeling brings about this effect. The poor response of so many cases to drugs has provided the most important fostering influence on epilepsy surgery, the origins of which date back to work in Germany (Förster) and Canada (Penfield and Jasper) more than 60 years ago. Falconer greatly advanced and popularized temporal lobectomy in the 1960s. At least 80 percent of appropriately managed MTLE patients become seizure free with little or no surgical morbidity and arrest of the epilepsy-associated degeneration of memory and psychosocial disturbances.

EEG video monitoring, computed tomography (CT), magnetic resonance imaging (MRI), and single-photon-emission-computed tomography (SPECT) imaging, psychometric testing, and other techniques have greatly refined disease definitions and surgical planning. Non-MTLE temporal lobe epilepsies have also been identified including (1) "lesional" TLE (e.g., due to tumors, dysplasia, scars, vascular malformations) and (2) comparatively rare "neocortical" TLE arising on the lateral surface of the temporal lobe and marked clinically in some instances by speech arrest, eye movements, and focal twitching that help to set it apart from MTLE or lesional TLE. "Dual pathology" epilepsies occur sharing features of these three TLEs. Benign transient childhood epilepsy arising in the temporocentral region has also been described. Presurgical studies, surgical pathology, and outcomes have permitted localization to be fairly reliably ascertained on the basis of clinical features, since particular manifestations may arise from particular locations and propagate along set "preferential pathways."

Experimental studies of TLEs have provided information and techniques that have greatly enriched understanding not only of the pathophysiology of epilepsy, headache, movement disorders, and other neurological and psychiatric diseases but also of the brain's normal development and physiology. A complex and elegant system of neurotransmitters, receptors, membranes with electrical charge, and chemical pores provides explanations of how the "thinking" neurons work and how they interact with other cells within the nervous system and outside of it and importantly for treatment, how and where things go wrong and how they might be fixed.

EPILEPSY

Epilepsy is the tendency to experience recurrent bouts of disturbed consciousness, sensation, or uncontrolled motor activities termed *convulsions*. It is the third most common primary, after migraine and depression, neurological condition. At least 1 in 25 people experience a seizure during their lifetime, while slightly less than 1 in 50 develop epilepsy (at least two seizures not explained by some controllable extrinsic influence). Since the beginning of time, it is likely that those with seizures and those witnessing them have struggled to deal with these strange and dramatic events that entail unpredictable loss of control, sometimes including bowel and bladder control, events that can engender shame and an anxious sense of vulnerability. Unmistakable descriptions of epileptic seizures in the ancient texts of China, India, and Babylonia ascribe them to "possession" by spirits—sometimes benevolent, other times demonic.

The ancient Graeco-Anatolian Hippocratic writings (ca. 400 BCE) coined the word *epilepsy* (επιλαμανειν or *epilamanein*) for a convulsive condition viewed as a disease rather than a possession or punishment—a potentially treatable disturbance of the equilibrium of the living organism. The view was not entirely enlightened. Seizures were associated with physical and mental imperfections with which Greek ideals were uncomfortable. In the second century CE, Galen recognized that there were disturbances of consciousness or behavior—nonconvulsive seizures—and that the onset of these or of convulsive seizures might be foretold by a strange sensation he termed *aura*.

Little further progress was made for 1,700 years, and indeed the stigmatizing view that seizures and associated physical or mental imperfections were somehow related to the concept of possession continued to be widely accepted until very recent times. In Christian doctrine arose the not uncontested view that the affliction of children with epilepsy and associated disabilities was judgment on the sins of parents, perhaps for having conceived a child on Sunday. It was recognized from ancient times, however, that epileptic swoons had afflicted such great men as Julius Caesar and possibly Alexander. Yet even here there remained uncertainty as to the boundary between madness and epilepsy, as well as a number of other neurological conditions. This, together with the absence of effective treatments, undoubtedly increased the degree to which epilepsy was feared and reviled. As of the end of the eighteenth century, better definitions began to be formulated and descriptions of transient and usually benign convulsions such as "teething fits" (probably febrile seizures) began to be described.

In the nineteenth century, French, English, and German neurologists and neuropathologists gradually compiled further descriptions of epileptic events. Based on this information and his own observations, the great English neurologist Hughlings Jackson formulated the concept that discrete brain lesions could give rise to particular epileptic manifestations; these, in turn, could predict the location of brain lesion. He also noted that the epileptic event could spread to contiguous areas. Jackson's colleague William Gowers explored the borderlands of epilepsy, enlarging the concept and defining some of its probable boundaries. Seizures and epilepsy came to be understood in the intellectual context that the nervous system was an organized collection of functional centers and interconnecting "wires" with, in part, an electrical function. The study of these relationships in individuals with epilepsy—ongoing to the present day—has made an enormous contribution to the study of the organization and function of the nervous system and to the diagnosis and management of epilepsy. Various treatments were developed, some very toxic, among which only bromides are now viewed as effective anticonvulsants. The agent had been chosen, however, in the effort to reduce prevalence of masturbation (viewed then and for the ensuing half century as a cause of epilepsy) in institutionalized patients. It improved epilepsy rather than the supposed etiology.

The twentieth century provided increasingly detailed clinical descriptions of epilepsies, their predisposing factors, and varied outcomes. Electroencephalography was added in the 1930s. Additional effective therapies were applied including treatments that remain valuable: phenobarbital (1909), the ketogenic diet (1924), and phenytoin (1937). A number of additional minor and some rather toxic anticonvulsants appeared in the next few decades. From the early twentieth century to the interwar period, patients with epilepsy faced a new challenge. Eugenicists hoping to improve the "gene pool" advocated and courts approved involuntary sterilization of some individuals with epilepsy, since the old and often incorrect notion that many were "feebleminded" persisted. More enlightened individuals opened epilepsy clinics devoted to the study and outpatient management of epileptic individuals, many of whom had found themselves in epilepsy "colonies."

Förster of Germany and Penfield and Jasper of Canada participated in the establishment of effective surgical techniques for management and even cure of epilepsy. In the 1960s, Dreifuss and others demonstrated the importance of long-term video/EEG monitoring of patients with epilepsy, data that they employed to systematically classify epilepsies into better refined syndromes as well as to explore related subjects such as conditions that look like epilepsy but are not (e.g., seizures, movement disorders) and the important topic of whether epilepsy is associated with violence. Additional "minor" medications, some of which carried serious potential side effects, were developed; since phenytoin, the past 30 years have been particularly fruitful, providing 10 new important and effective antiseizure medications. But surgery remains important, since some common categories of intractable epilepsies, such as temporal lobe epilepsy, are particularly suitable candidates for potential surgical cure.

By the 1970s, studies demonstrated that well-controlled seizures in children were often outgrown and that medications could be discontinued after several years of treatment. Long-term outcome studies defined with increasing precision these and other epileptic syndromes, some of which were inherited transient vulnerabilities, presenting at a particular age range and then resolving.

The development of imaging techniques, such as computed tomography (CT), magnetic resonance imaging (MRI), single-photon-emission-computed tomography (SPECT), and positron-emission tomography (PET) scanning, during the past 30 years elucidated structural causes of epilepsies, some requiring surgical management to be discerned. The development of many additional diagnostic interventions permitted other underlying conditions associated with epilepsy to be diagnosed and in many instances treated, thereby decreasing or eliminating the epilepsy that occurred secondarily.

Because of the development of experimental neurophysiology, particularly utilization of brain slices and sophisticated neurochemical and neurophysiological techniques, understanding of the pathophysiology of epilepsy has greatly advanced. A great deal is now known about the manner in which epilepsy may cause enlargement of an initial focus and unfavorably remodel an epileptic region of brain. It is as yet less certain how this process is initiated. It has also become clear that abnormalities in brain development underlie at least some epilepsies. Advances are also being made in defining the pathophysiology of heritable generalized and focal epilepsies, some of which resolve spontaneously. These studies, demonstrating overactivity and hypersynchrony of certain populations of neurons, have also revealed information of considerable importance concerning normal brain function and information pertinent to the understanding of nonepileptic conditions that also result from disturbances of specific neurotransmitters, membrane potentials, and ion channels. These studies help to explain the clinically observed relationships between epilepsy and sleep disturbances, movement disorders, migraine, and some psychiatric conditions.

Attention has been devoted to the understanding of relationships between seizures and conditions that may exacerbate them, such as sleep or lack of sleep, fever, menstrual flow, hyperventilation, and things that directly provoke what are termed *reflex* seizures—specific wavelengths and periodicity of repetitive flashing of lights or from such rare provocatives as certain tastes or even thoughts. Special attention has been devoted to epilepsy and pregnancy, from the vantage points of protection of fetuses from the effects of seizures or antiseizure medications and to the best management of epilepsy for the mother. These studies have discerned the importance of folate supplementation to prevent certain developmental deformities of the fetus that may occur if mother is being treated for epilepsy. Studies of great importance have been undertaken to understand and improve treatment of the sustained convulsive seizures, termed *status epilepticus*, a condition that may severely injure the brain or even prove fatal.

The evolving syndromic classification of epilepsies has permitted an increasing number of available therapies to be selected more intelligently and specifically. With such treatments, it has been proven to the satisfaction of all of the various state legislators that some restrictions on driving could be removed after treatment had achieved control for intervals of 6–12 months and that similar restoration of this important right could safely take place if individuals had remained seizure free for similar intervals after a resolved or adequately treated bout of epilepsy. Clinical experience also identified other important hazards for those with epilepsy, particularly the bathtub. Increasing knowledge of risks and natural history of the various forms of epilepsy together with the ability to tailor more effectively medical treatment to a specific syndrome rendered epilepsies increasingly predictable, alleviating fear and reducing the chance that individuals would experience embarrassment associated with public seizures. Public educational programs have also tried to foster greater understanding of epilepsy. Primary care physicians are educated concerning the recognition of unusual seizure types that require urgent treatment. These advances have greatly improved the lives of a very large number of individuals. Sadly, it is estimated that more than 80 percent of the 40 million people who currently have epilepsy throughout the world have access to few or none of these interventions.

The current approach to epilepsies entails excluding a wide variety of possible alternative diagnoses (including pseudoseizures) and then accurately characterizing the epilepsy syndrome. Electroencephalograms (EEGs) and other tests contribute to this otherwise clinical process. Epilepsies are categorized as to whether they are generalized (whole brain) or focal at onset and whether they are convulsive or nonconvulsive. Nonconvulsive or convulsive focal seizures are classified as to association with disturbance of consciousness (and therefore called *partial complex* or *psychomotor*). Convulsive elements include repetitive clonic movements or sustained tonic stiffening. Nonconvulsive elements of generalized seizures include typical and atypical absences, myoclonus, brief tonic activity, automatisms, and atonic (loss of tone) events. Atonic events may involve only part of the body or gradual incremental loss of tone or sudden and dramatic as in events termed *drop attacks*. Individual seizures may demonstrate evolution of one seizure type into another, most commonly to partial (simple or complex) to generalized convulsive. Some severe syndromes produce multiple seizure types.

Underlying identifiable causes are sought. A syndromic classification is then produced on the basis of the foregoing details and age. Provocative circumstances are identified and if possible alleviated, another anti-seizure medication is selected, and the dose systematically increased. If the drug proves ineffective or is not tolerated, it is replaced by another. In some instances combinations of drugs are employed. Perhaps 5 percent of all epilepsies are severe, intractable, often manifest several different types of seizures, and in some instances are associated with deterioration and even death, usually due to the underlying cause. Some of the most severe epilepsies have been reduced in prevalence because causative diseases have been eliminated or prevented by such things as dietary restriction. But for the majority of patients, epilepsies have minimal impact on their lives and those of their families. These and many patients who have temporarily troublesome epilepsy experience excellent control, resolution over time, or surgical cure of their epilepsies.

ESQUIROL, JEAN ETIENNE DOMINIQUE (1772–1840)

French physician

Jean Etienne Dominique Esquirol was a French alienist (a physician who studied "mental alienation," or insanity) who is best known for his attempts to facilitate a shift in early psychiatric practice from a taxonomy focus to a perspective favoring meticulous observation. A favorite student of Philippe Pinel, Esquirol succeeded his mentor at the Salpêtrière, continued to be an advocate of "moral treatment," and developed into an influential pioneer forwarding the idea that asylums were therapeutic mechanisms in themselves. Esquirol's vision of the institution as a place of recovery was based on the premise that isolation from an unhealthy environment was the first, and most crucial, step toward the restoration of "reason." While in many ways still a product of his era, Esquirol conversely attempted to move away from purgatives and bloodletting toward establishing individual relationships with patients; his "discussions" foreshadowed psychotherapeutic approaches in working with those with mental illness. Esquirol was a strong advocate for involving the state in the affairs of medicine—he was one of the originators of the 1838 French law that implemented a system of nationalized institutions. Quite famous in his day, Esquirol influenced a large number of students at the Salpêtrière with a series of lectures in psychiatry—possibly the first formal instruction in the youthful discipline. Looking back, perhaps his greatest accomplishment was his early endeavor at differentiating between insanity and mental retardation, which previously had been treated as one in the same.

ETHICS

Ethics is a branch of philosophy concerned typically with the systematic treatment of issues of right and wrong, good and bad, virtue and vice. The terms *ethics* and *morality* or *moral philosophy* are interchangeable in common parlance, although sometimes ethics is used for the specific moral codes of groups or professions and morality (*mores*) is used for the ethical beliefs or customs of a culture. Morals in that sense can be the object of empirical studies and sociological theories, whereas ethics is a matter of analysis and argument.

In its classical phase (roughly up to the twentieth century), ethicists devised normative ethical systems or first principles and tried to justify them, with the practical aim of giving guidance on how one should live. During the first half of the twentieth century, influenced by the "linguistic turn" in philosophy, ethicists focused on the meaning and use of basic moral concepts, as well as "metaethical" issues such as whether (and how) ethical claims can be justified rationally, and whether differences in moral views among individuals or cultures entail that that universal ethics is impossible. On the defensive, ethicists tried to stave off subjectivist, relativist, and skeptic attempts to undermine ethics itself.

Arguably, moral skepticism and relativism have now run their course as plausible challenges to ethical theory. It is more common these days to believe that morality is universal and objective simply because we regularly, without qualms, grade, evaluate, praise, and blame others and ourselves. More fundamentally, our lives are defined by ethical impulses that are both mundane and universal: We feel gratitude to those who benefit us, sympathy with those in pain, and our sense of justice is offended when the guilty prosper or the innocent suffer. Building on this commonsense foundation, the most recent generation of ethicists have found the confidence to return to normative ethics and traditional questions of the good and the right, although seeing the need to respect cultural and other differences of moral opinion and to be wary of the effect of class, power, gender, racial, or ableist presumptions in mainstream ethical intuitions.

Since ethics concerns the values and actions of all human beings, ethics is relevant to the lives of people with disabilities. Like everyone else, people with disabilities, and their perceptions of themselves and the social world, are in part shaped by the moral climate in which they live. They use and rely on the basic concepts of ethics and have and express ethical impulses and judgments. This said, there are many particular ethical debates in which disability and the experience of people with disabilities are especially relevant, and some in which they play an important and salient role. Some of these specific issues are found at the interface of ethics, biology, and medicine, and of ethics, politics, and justice; in the field of bioethics and political philosophy. Increasingly, ethicists in and outside of these specialized areas have broadened or modified their analyses to include disability, or, as important, have reconsidered or challenged preconceived notions about disability that are found in classical or modern ethical writings.

The following three areas of ethical debate are examples of the kinds of linkages that have already been explored between disability and ethical concepts and theories, which should give the reader an idea both of what is already in the ethics literature and what the future holds for research at the interface of ethics and disability.

THE GOOD LIFE AND THE QUALITY OF LIFE

What makes a life worth living? What does it mean for a human life to go well? What is the "good life"? Given their antiquity and perseverance, these are arguably the central questions of ethics. A similar question (or perhaps the same question with a different spin) concerns the meaning of life, in the sense of what it is that makes life meaningful (and therefore valuable or good). Finally, and more recently, questions about the good life have been recast as questions about the value of life, about what constitutes human well-being. Arguably, the more ancient question about the good life focuses on the best way to live (or what kind of life one should lead in order to lead a good life), whereas the more recent value-of-life question widens the possible domain of evaluation to include, for example, the value that a person's life may have for other people, for the state, or for some other entity.

Traditionally, there are two general approaches to the good-life question: One can either posit an intrinsic value to human life itself, or else one can try to identify features of a person's life, or the living of it, that are components of the good life or are instrumental to bringing about something else that is, on its own, constitutive of a good life. The first approach offers little scope for expansion or explication: If life is intrinsically valuable, then the value of any particular life is unaffected by what happens in that life. That is, human life has intrinsic value, but there are no gradations or variation in that value. This has the important consequence that every human life has equal value. Most philosophers, however, take the opposing approach and argue that, even if life itself has some intrinsic value, lives are not equally and optimally good, since there is variation in the value, or as it is often put, the quality, of one's life.

The question then becomes, what are the components of life that affect its value or quality? On this question, philosophers from at least Aristotle (384–322 BCE) have had much to say. Aristotle himself surveyed the possibilities (fame, fortune, love and friendship, beauty, health, honor) and insisted that all these were good things, without which a life would not be good, but that in the end, the "good life" itself is what all of these good things help a person achieve, namely, a life of eudemonia—a sort of complete spiritual and intellectual happiness or satisfaction. Other philosophers have assessed the value of life in terms of more mundane, ubiquitous, and achievable experience. Jeremy Bentham (1748–1832) argued that in the end, the goodness or badness of a life was entirely a function of the extent of pleasure or pain that is experienced. Indeed, if one took into account the degree, extent, duration, and probability of the pleasures and pains experienced in a life, one could calculate the value of a life, thereby comparing the good-life outcomes of different kinds of lives a person might lead, or of the lives of different people.

As is well-known, Bentham and his more sophisticated follower, J. S. Mill (1806–1873), went on to develop a complex moral and political philosophy called utilitarianism, based on this relatively simple premise. In the century and a half since Mill wrote, utilitarianism has undergone a variety of refinements and revisions, to appeal to those with conceptions of goodness that go beyond pleasure, pain, satisfaction, and happiness, and to avoid such disturbing implications as the imperative to sacrifice an innocent person to appease a lynch mob or provide organs to several other people. What all these variations share is the evaluation of actions by their (expected) consequences, however defined; the broader approach is now referred to as "consequentialism," with act-utilitarianism—the appraisal of individual actions by the net utility they yield—merely one historically significant and conceptually simple variant.

Consequentialism retains the two features of utilitarianism that may have the most troubling implications for people with disabilities: the aggregation of the good found in the lives of separate individuals to make an overall outcome assessment—which tends to treat those individuals as mere sources or receptacles of goodness—and the commitment to maximizing whatever counts as good—which in effect places a higher value on those who directly or indirectly contribute more good to the total. Although some philosophers have attacked the aggregative and maximizing features of consequentialism head-on, others have tended to focus on the criteria for assessing outcomes as good or bad. We will touch on the former concern (which is dealt with at greater length in the "Justice" and "Health Resource Rationing" entries), but our focus here is on the latter: the relevance of impairment in assessing how well a life has gone or is likely to go.

Contemporary followers of Aristotle, such as Martha Nussbaum, reject pain and pleasure as a metric of well-being and tend to assess outcomes across people by their conformity to a pattern, such as equality, rather than by their aggregated magnitude. They argue that although there may be many kinds of life that qualify as valuable, still there are essential human "functional capabilities" (mobility, pleasure, happiness, cognition, play, health) without which the good life is unachievable. Because this approach relies on a conception of core or essential human goods, it is often called "essentialist." Whether one adopts Bentham's experiential approach or Aristotelian essentialism, the very endeavor to assess individual well-being, let alone to aggregate the results, is problematic for people with disabilities.

Since impairments are limitations of one capacity to perform actions, tasks, or social roles, and since they often cause pain, discomfort, or distress, is it inevitable on any definition of "good life" that the lives of people with disabilities are of less value? Are any of the "normal" or "standard" functional capacities of human beings essential to well-being, or are they only contingently related? Does severity of impairment matter? Is there a lower threshold of functional capacity below which a life lacks value, whatever else may be happening in the person's life? Are limitations in cognition or the senses more a threat to living a good life than limitations in mobility or strength; is a life of physical pain worse than a life of emotional distress? Does it make any sense to compare impairments in this manner, or to rank them with respect to their impact on the quality of a person's life? These are just some of the kinds of questions that arise when impairment is brought into the domain of moral value in the analysis of the value or quality of a human life.

It is true that classical and modern philosophers have often assumed without argument or discussion that all impairments substantially reduce quality of life. Similar assumptions of inherent inferiority have been made on racial, gender, and cultural or religious grounds. Still, the case of impairment may be different. Even if we rely on the modern conception of disability as an interaction between features of an individual's body or mind and the physical, social, and attitudinal environment, and insist that it is a person's environment, as well as or instead of his or her physical and mental differences, that account for the disability, still impairments have a reality that should not be ignored or glossed over. We may be confident that the lower quality of life of women is entirely the product of sexism, but it would be intellectually dishonest to insist either that chronic pain or severe depression has no effect on the value of a life or, worse yet, that the negative value of pain and depression is somehow "socially constructed."

There are very practical, indeed, life-or-death consequences of this realm of ethical debate for people with disabilities. If a fetus has a low quality of life because of congenital or acquired impairments, should that be a reason to abort it? Should we insist on prenatal screening to make sure that the children that are born are not disadvantaged from the beginning by a low quality of life? When there is a scarcity of medical resources, should it matter that one potential recipient is also disabled and so would not have as good an outcome as another recipient who is able-bodied? Should we make it easier for people with severe disabilities to kill themselves, or be euthanized, than it is for other people?

In light of these possible implications, some disability scholars have argued that the notions of "quality of life," the "good life," and "well-being" are dangerous nonsense. Some have insisted that what makes life valuable is entirely a matter for the individual—with or without a disability—to decide (so-called experts will inevitably judge lives with disabilities to be worse than individuals with those disabilities think they are). Such radical responses, however, create their own ethical issues. Eliminating the notions of the good life and quality of life from our ethical lexicon would eliminate important ethical dialogue: Surely we want to insist that it is ethically better to live free, to have our basic needs met, and to enjoy equal opportunities. We need to agree on what makes a life go well, what improves the quality of our lives, in order to better the lives of people and reduce what we all perceive as great, undeserved inequalities. What improves or devalues a life, moreover, is not merely subjective opinion: Not even saints or sages are infallible about what makes their lives go well. We may not want to leave it to "experts" to decide on the components of human well-being, but that does not mean that every individual must be the ultimate arbiter of his or her own good; it may be a matter for deliberation and consensus.

Perhaps a standard distinction in ethics may help here. Ethicists say that an experience, action, or state that is a candidate for a good and valuable thing is either intrinsically or instrumentally valuable. Something is intrinsically valuable if that experience, action, or state is valuable itself; instrumentally valuable if it tends to produce or cause something else that is intrinsically good. Now since impairments limit the activities we perform, we can ask whether common activities such as walking, reading, talking, and seeing are intrinsically or merely instrumentally valuable. If some or all of these activities were intrinsically valuable, then a life in which they cannot be adequately performed would lack an important source of value. Alternatively, though, we can maintain that these activities—indeed almost any activity—are merely means to the production of something ultimately valuable (perhaps the experience such as pleasure, satisfaction, or happiness). In that case, not being able to walk or speak need not limit the value of one's life as long as one can achieve the same ultimate end in other ways (e.g., by using a wheelchair or a communication device). In this manner, one could argue that impairments need not have an adverse effect on quality of life, as long as people with disabilities are given the resources they need to pursue alternative means.

This is an interesting moral argument, but it still needs more work. Some impairments do appear to involve the loss of something intrinsically valuable and irreplaceable. If one cannot see a painting, would having it described (say, by the artist herself) ever count as an equivalent means to the end of aesthetic enjoyment? Could we say that listening to a piece of music could produce the same kind and degree of aesthetic enjoyment as seeing the painting? Does this make any sense? Alternatively, could we argue that there are many different collections of activities that people do, each of which is intrinsically valuable (or else of sufficient instrumental value to produce the same degree and kind of intrinsic value) even though no two are identical? While one person cannot see and another has diminished intellectual capacity, with appropriate resources, training, or other facilitation, both their lives could be lived with equal value accruing from very different experiences. Certainly, these are interesting questions that might bring a more realistic understanding of the effect of impairments on well-being. But more work needs to be done to make them concrete and plausible. The onus of doing such work should not, however, rest exclusively on disability scholars. Arguably, the burden of developing a full account of human flourishing should fall on those who, in the absence of such an account, proclaim the lives of people with disabilities to be lacking in the requisites of well-being.

AUTONOMY, COMPETENCE, AND MENTAL DISABILITY

Some impairments affect mobility, others affect perception, fine hand motion, or communication. Still other impairments—those we call "mental impairments"—affect our abilities to make judgments, to reason, or to cope with the stresses of living. When mental illness or brain injury leaves individuals with very serious mental impairments, we may be tempted to say that these individuals lack the capacity to make decisions about themselves or others—a capacity often called "competence"—and others should make those decisions instead. Overriding the right of individuals to make decisions about themselves is a big step, and in many jurisdictions, the law put limits and restrictions on this form of paternalism.

The ethical significance of paternalism links to one of the central notions in the history of ethics: autonomy. Autonomy, or self-governance, was for Immanuel Kant (1724–1804) the foundation of ethics itself. Attempting to meet the challenge posed by David Hume (1711–1776) and others who claimed that reason played no role in ethics, Kant argued in effect that one cannot rationally act immorally, since to act within the bounds of reasons is, roughly, to treat others as you would have them treat you, or more formally, to act in accordance with a rule that you would will that everyone follow—that is, to act in accordance with what you could will as a universal law. Acting immorally, therefore, would in effect to irrationally demand that others act in the same immoral manner toward you. This so-called categorical imperative presumed that moral agents have the capacity to will to do things (indeed, Kant believed that the only truly good thing in the world was a good will). That meant that for Kant, ethics was rationally grounded in the human capacity to will actions, that is, to be autonomous moral agents.

The Kantian tradition is very strong in ethics, and is a source, among other things, of traditional liberal values, in particular, respect for the individual, for individual freedom, and finally, the recognition of individual moral rights (which, logically, apply only to moral agents). The ethical significance of autonomy, moreover, is reflected in the very foundations of our law: The fact, for example, that you can be convicted of a crime only if you have a "guilty mind" (mens rea) is another version of Kant's insistence that only agents with free will are autonomous and so morally responsible for their actions.

This Kantian view on the rational will as the source of human dignity is in one respect highly congenial to disability rights. It regards impairments of physical function, however severe, as contingent and morally insignificant features of the individual, and it opposes any attempt to value human lives on the basis of their productivity or utility. The Kantian injunction that people have worth, not a price, is often invoked to reject the whole project of allocating scarce resources on the basis of physical functioning. Yet at the same time, the Kantian premium on rationality leaves the moral status of individuals with cognitive impairments insecure.

The Kantian tradition underwrites the law of competence and mental illness, which in turn has consequences for disability. A person with a severe mental impairment may, if incompetent, lose his or her status as a moral agent, as a person with autonomy. Mental impairment can undermine what, in this ethical tradition, is absolutely fundamental to moral personhood. This creates a fundamental asymmetry between mental and physical disability. And Kant was well aware of this. He wrote that even if a person is severely physically impaired ("by a special disfavour of destiny or by the niggardly endowment of stepmotherly nature"), and can perform no actions, good or bad, the person will still be a moral agent as long as he or she has the mental capacity to will, that is, to intend to act.

The Kantian liberal ethical tradition is very influential, and a distinction between the physical and the mental is central to it. For those judged to have the mental capacity for practical reason and autonomy, it has been a source of important safeguards. For those who appear to lack that capacity, however, by virtue of mental impairment, it has been used to justify paternalism, as well as a wide range of social and professional practices involving the restraint, forced treatment, and other limitation of freedom. At the same time, the lack of ethical parity between mental and physical disability is hardly unique to Kantian morality. It is evident across modern society, and indeed, is sometimes played out within the disability rights movement itself.

DISABILITY AND THE LANGUAGE OF RIGHTS

The language of rights (human, civil, legal) has dominated the disability movement of the past couple of decades. The political fight for equality and antidiscrimination has been described as a battle for basic human rights. Although we often use the term freely and without much thought, morally speaking rights are vague entities. Probably because of the influence of the "natural rights" movement that dominated seventeenth-century political thought, we tend to speak of rights as if we were describing entitlements people have, rather than, more accurately, asserting a moral proposition about what entitlements people ought to have (but may not have in fact). The temptation, at least in the West, to find rights everywhere ("I have a right to smoke!") suggests that the concept is useful to us precisely because it is empty and vague. But this much seems to be logically required of a right: If it is true that a person has a right to something, then (a) there must be someone (institution or other social arrangement) who (b) has a moral duty to provide it. There is, moreover, an important logical limit to this duty, traditionally expressed by the Kantian maxim that "ought implies can"—namely, that one only has a duty to do something that one can actually do.

These simple, logical features of the concept lead directly to the vagueness of rights language. The United Nations Universal Declaration of Human Rights (1948) declares in Article 3 that "everyone has the right to life, liberty and security of person." But what does this right mean in concrete terms? How many resources can I demand if I truly need them to keep alive? And who has the duty to provide these to me? More troubling still, since everyone has the right to life, and since life-saving resources will always be finite, if not downright scarce, how do we determine whose right to life trumps someone else's when there are not enough resources to go around? And who has the duty to resolve this horrendous practical dilemma?

Given these and other worries, some ethicists have suggested that rights language is mostly rhetorical and not intended to have practical implications. Moral rights should be clearly distinguished from legal rights, which actually can get the job done. Even when they are abstractly expressed, legal rights are embedded within social practices and institutions whose job it is to interpret rights in specific circumstances and for specific individuals, and to transform the rhetoric of rights into precisely operationalized directives to the state or its agents. A legal right, in practical terms, is merely an entitlement to bring a legal action, to cite facts, and to make arguments before a tribunal that is both obliged to adjudicate one's claim and empowered to do something about it.

Some philosophers, most notably Karl Marx, have argued that moral and legal rights are individualistic, indeed egoistic, and so socially destructive. All our moral concern is focused on the demands of particular individuals, at the expense of the general good. In the liberal tradition, however, this is more or less what makes rights so attractive. The individual in a social setting needs rights to protect him or her from the egoistic demands of other individuals, the tyrannies of the majority, or the encroachments on freedom perpetuated by the state itself in its pursuit of what it sees as the common good.

The prospect that rights could protect individuals, or minority groups, against the majority was what attracted the disability movement to rights discourse. In the United States, especially, disability was characterized as mark of a minority subject to historic treatment of discrimination, stigma, and denial of opportunities. As a political strategy, characterizing people with disabilities as an oppressed minority—or more recently, as a social and cultural group—was a success. It is not as clear, however, whether this is the best strategy for the long term. There is the obvious difficulty of creating a "discrete and insular minority" (Americans with Disabilities Act of 1990) out of individuals whose impairments are highly diverse and whose experiences cannot be easily generalized. In addition, physical or mental functional limitations are highly dynamic, unlike race or gender, and, more important, are features of the human condition that everyone will experience over the course of his or her lifetime. The minority rights model that accepts the adversarial relationship and seeks to empower the weaker side conflicts with another, arguably more plausible, model of disability that sees it as a universal feature of humanity and that treats people with disabilities as having precisely the same human rights as everyone else.

It is unlikely that the politics of disability will soon abandon the language of rights. It is important, therefore, to be aware of the limitations of this language as an ethical discourse.

EUGENICS

A term coined in 1883 by the British scientist of heredity, Sir Francis Galton, *eugenics* was a movement devoted to "race improvement." Fueled by late-nineteenth and early-twentieth-century scientific advances in the identification and measurement of "defective mentality" (Mendelian genetics, human pedigree charts, intelligence testing), the eugenics movement sought to link social ills such as crime, prostitution, poverty, juvenile delinquency, and promiscuity to people with cognitive disabilities. To diminish instances of social "vice" and the prevalence of mental "defects," eugenicists extolled a wide range of restrictive social policies including marriage laws prohibiting unions of those diagnosed as feebleminded, epileptic, and insane; an expansion of lifelong incarceration in institutions for the feebleminded; laws that legalized state-sponsored sterilization programs; immigration restrictions on people with disabilities; widespread intelligence testing in public schools aimed at identifying feeblemindedness at the earliest possible age; and segregation of "backward" students in special or ungraded classrooms.

The eugenics invention of the category "feeblemindedness" moved from a general classification of "inferior" intellect to a tiered model of "defective" types: *idiots* referred to individuals with a mental age of two years or less, *imbeciles* represented those with an arrested mentality of three to seven years, and *morons* referred to those attaining a mental age of no more than 12 years of age. There were also classifications of varying degrees of backwardness for people occupying the intellectual cusp between "normal" and "feebleminded." Whereas the European construction of feeblemindedness tended to emphasize intellectual capacity, the U.S. definition recognized physical and sensory disabilities as visible bodily expressions of a feeblemindedness residing within.

Eugenics can be broken down into four specific historical stages: the early-nineteenth-century transition from familial and community responsibility for people with cognitive disabilities to a social and state problem, post–Civil War rhetoric that characterized feeblemindedness as a social burden to be alleviated through custodial institutional care, the promulgation during the first two decades of the twentieth century of an extreme version of feeblemindedness as a menace to society, and the post-1920 psychiatry-based mental hygiene movement that began to supplant eugenics with an emphasis on adaptation and adjustment through services that perpetuated segregation and that could be based in the institution or the community.

As an ideological practice cloaked in the empiricism of scientific research, eugenics was widely practiced in Europe, the United States, and Canada. Culminating in the systematic murder of more than 260,000 disabled people by the Nazis between 1939 and 1945, the eugenics movement gave birth to the contemporary forms of nearly every social and therapeutic discipline that attempts to treat and manage disabled people today: physical therapy, occupational therapy, social work, genetics, genetic counseling, special education, and community and applied psychology.

Beyond Europe and North America, eugenics also achieved global influence by exporting its practices to countries as varied as Africa, Mexico, India, Australia, Japan, Russia, and Israel. In many of these countries, eugenics was implemented with respect to distinct national and cultural contexts; for instance, Bolshevik eugenicists used family pedigree charts to demonstrate the degeneracy of czarist lines, Israel imported eugenics models to bolster arguments for a more robust Jewish citizenry, colonial Africa used eugenics as a rationale to solidify arguments about African inferiority and violent tribal practices such as female circumcision, and Japan sequestered its sensory feebleminded (deaf and blind) populations on islands.

▣ EUGENICS: GERMANY

The theory of evolution developed by Charles Darwin and published in his book *The Origin of Species by Means of Natural Selection* (1859) can been seen as a starting point for eugenic thinking in Germany. Already during the 1860s, Ernst Haeckel (1834–1908), a German zoologist, spread Darwin's theory, although in a reduced form. Haeckel saw the concepts of adaptation to the environment, heredity, and struggle for life as essential elements of humankind's history. In public, Haeckel defended his position in numerous disputes and scripts. Mostly, representatives of confessional theories were against him, since Darwin's evolution theory stood in strict opposition to the biblical creation narrative. Haeckel's lectures "Natürliche Schöpfungsgeschichte" ("Natural History of Creation" 1868), written in a clear diction easily understood, had an overwhelming success. The book was published in 12 editions and translated in 25 languages.

With Haeckel as its pioneer, about the turn of the past century eugenics gained more significance in Germany. At 1900, a deep economic crisis combined with a distinctive retrogression of births took place. This situation inspired a fundamental criticism of civilization. It said that the birth decline happened only in the upper classes whereas the lower classes increased in large numbers. As a consequence, a successive degeneration of the German people was feared. One of the first German eugenics representative was Wilhelm Schallmeyer (1857–1919), who advocated for the degeneration theory in his book *Über die drohende körperliche Entartung des Kulturmenschen* (*About the Threatening Physical Degeneration of the Cultural Human Being*, 1891). Schallmeyer argued that under the influence of culture the quality of humankind was deteriorating. To stop this development, he demanded that hereditary biological registration, the population's instruction about hereditary processes, and barriers to marriage be employed. Besides Schallmeyer, the physician Alfred Ploetz (1860–1940) was important for the German eugenics movement. It was Ploetz who coined the term *Rassenhygiene* (racial hygiene) in 1895. This German term was used as a synonym for eugenics until the end of the Third Reich in 1945. In contrast to other countries, German eugenics allied itself under the term racial hygiene with the nationalist and anti-Semitic ideology of "race anthropology." This connection created the conditions for the specific German way of eugenics.

Ploetz, who originally sympathized with the social democrats, turned toward eugenics because he thought that with the "human race" existing in Germany at that time socialism could not be put into practice. He aimed at "racial welfare" by installing measures that should foster the procreation of many "high quality" descendants and simultaneously the weeding out of the so-called inferior parts of the population. Ploetz thought that the "Aryan race" was the best race in terms of culture. As members of the Aryan race he counted all peoples except "Negros." To him, Jews belonged to the Aryan race as well. In other words, Ploetz's position originally was not anti-Semitic.

Until the end of World War I (1914–1918), eugenic/racial hygiene was debated only by an academic minority. After the war, when the great numbers of casualties caused by the war battles became apparent, during inflation and the crisis of the welfare state, gradually eugenic ideas gained more and more influence within the political establishment of the Weimar Republic (1918–1933). In 1920, the Prussian Ministry of Welfare set up a committee for racial hygiene. In 1927, the German social democrats and the Catholic Centrum Party initiated the "Kaiser Wilhelm Society," whose institutes were to pursue scientific research. The Kaiser-Wilhelm-Institut für Anthropologie, menschliche Erblehre und Eugenik (Kaiser-Wilhelm Institute for Anthropology, Human Genetics and Eugenics) had the task to develop the scientific base for eugenic measures. The model for the Kaiser-Wilhelm Institute had been the Rockefeller Institute of Medicinal Research. Over the years, the German institutes gained such a good reputation among American science managers that they got funding until the United States entered World War II as a combatant in 1941. During the Weimar Republic, it seemed that German eugenics was just one part of the international eugenics movement. The Kaiser-Wilhelm Institute for eugenics was led by Hermann Muckermann (1877–1962), a Catholic priest having good connections with the Catholic Centrum Party. Muckermann had been developing his eugenic approach since 1917. At first, he pleaded for positive eugenic measures only. However, during his work at the Kaiser-Wilhelm Institute his position got radicalized; in 1929 he called for compulsory sterilization.

In general, during the Weimar Republic moderate eugenic positions were more influential than radical ones. A dispute between the social democrat Oda Olberg and Wilhelm Schallmeyer throws light on the socialist eugenic approach. Olberg shared Schallmeyer's opinion about the dangers of the population's degeneration, but she contradicted him in the causal analysis. For her, Schallmeyer was one-sided in primarily emphasizing genetic causes. Instead, Olberg saw the degeneration caused by the pauperization of the working class. Therefore, she pleaded for the improvement of the living conditions of the poor. Consequently, she saw a compatibility between eugenics and socialism whose common starting point was the orientation toward a strong state.

Besides the socialists, the middle-class women's liberation movement had also been open for eugenic positions since the beginning of the twentieth century. In 1905, Helene Stöcker (1869–1943) established the feminist Bund für Mutterschutz (League for the Protection of Motherhood). Stöcker stood up for a "new ethics" in sexuality and family planning. She pleaded for free sexuality in equal partnerships between men and women, but she argued against licentiousness and digression. Rather, the sexual partners were meant to use their liberty for a greater eugenic responsibility for their offspring. Of course, racial improvement was meant to be the result. In opposition to the mainstream racial hygiene approach, Helene Stöcker's position was individualistic. For example, she was against compulsory measures such as birth control and emphasized the human right to free decision. However, only "healthy" persons were meant to use this right. Patients with incurable and hereditary diseases were refused procreation. Concerning these people, Stöcker pleaded for restraint and compulsion. The women's liberation movement of which Helene Stöcker was a main spokeswoman accepted the degeneration thesis but saw their reasons in bad social and economic living conditions. In that respect, they joined the German socialists.

Before 1933, many parallels between the German eugenics and international approaches existed. A draft for a sterilization law, which was worked out by the Prussian ministry administration in 1932 was very similar to the laws that had been discussed or put into force in other countries. In this draft, sterilization was to be undertaken under the condition of the patient's agreement. Before 1933, even the German Society for Racial Hygiene was against compulsory sterilization without the patient's consent. However, it did not primarily have in mind the respect for the individual's right to physical integrity; instead it argued that too little about the hereditary traits of certain diseases was yet known. On the ground of the still insignificant hereditary knowledge the passing of compulsory legal measures was not seen as enforceable, especially in a democracy. With respect to the issue of compulsion, important differences between German eugenicists and their international colleagues did exist. Germans tended to be more radical in their positions. Owing to a weakly developed democratic culture in their country, they believed in state authority more than others. This belief was one factor why German eugenicists were susceptible to national socialism. Shortly after the Third Reich was established, they came to an agreement with the national socialist state. The state promised them to extend and promote genetic research; in turn, the eugenicists helped to legitimize racist policies and ideologies. During the 1930s, the registration of the supposedly racial and hereditary inferiors took place, and one result was the mass murdering of disabled people from 1939 onward.

After World War II (1939–1945), eugenics had a bad reputation all over the world. It especially lost its credit when as a consequence of the Nuremberg trials against Nazi leaders it got publicly known that in the concentration camps and hospitals scientific experiments with humans had taken place. But the end of the Third Reich did not mean the end of eugenic thinking. Instead, the scientific discipline got a new name and was called "human genetics." Many German eugenicists stayed in the background for some years but continued to dream of genetic enhancement, especially after James Watson and Francis Crick discovered the structure of the hereditary substance in 1953. During the 1950s and until the beginning of the 1960s, German eugenics/human genetics was internationally isolated. Nevertheless, despite history, former Nazi eugenicists managed to get appointments for the first professorial chairs in human genetics at German universities. For example, Otmar von Verschuer (1896–1969), who had been director of the Kaiser-Wilhelm Institute for eugenics during the Third Reich, got a professorship in human genetics at the University of Münster/Westphalia.

At the end of the 1960s, prenatal diagnostics was started in Germany. Since then, the second scientists' generation after the war gradually managed to acquire an international reputation again. When the first steps were taken to establish prenatal diagnostics in Germany, a eugenic argument was used. It was claimed that disabled children meant a burden both for their families as well as society in general. Cost-benefit analyses were undertaken to prove the efficiency of prenatal selection, called "primary prevention" in postwar Germany. The so-called new eugenics at present installed not only in Germany but all over the world certainly differs from the old conception as it is oriented toward individual autonomy and self-responsibility. In contrast to the early eugenics, which aimed at a population's enhancement, today's human genetics appeals to the needs of the individual. In Germany, disabled people have been among the first who criticized individualistic eugenic approaches and disclosed the connections between human genetics, national socialist racial hygiene, and eugenics.

EUROPEAN COMMISSION POLICY

The European Union is founded on the principles of liberty, democracy, respect for human rights, fundamental freedoms, and the rule of law. The right of individuals to equality before the law and to protection from discrimination is a fundamental right that is essential to the proper functioning of democratic societies. Equal treatment and nondiscrimination are fundamental to the principles for the achievement of the European Union's objectives of promoting economic and social progress and a high level of employment by increasing economic and social cohesion.

The European Union has long been involved in the promotion of equality on the grounds of gender and nationality. It has also consistently shown its commitment to eliminating other forms of discrimination through a variety of instruments—joint declarations, resolutions, directives, and action programs. The 1989 Community Charter of the Fundamental Social Rights of Workers recognized the importance of combating every form of discrimination in order to ensure equal treatment for all.

With regard to disability, the European Union has supported and implemented actions in favor of people with disabilities, principally in the form of European Social Fund interventions that finance training and support the integration of people with disabilities into the workplace. These measures were complemented in the early 1980s by a series of action programs (best known as the Helios Programmes) aimed at facilitating the exchange of information between member states and nongovernmental organizations (NGOs) with a view to identifying good practices, integrating people with disabilities into society. The action programs made an important contribution to raising awareness on the issues affecting people with disabilities and widening the agenda beyond simple financial assistance.

In addition to funding and awareness-raising measures, the EU Council of Ministers adopted nonbinding instruments—recommendations and resolutions—laying down principles concerning the integration of people with disabilities into mainstream employment or education. In particular, the Council Recommendation on the Employment of Disabled People calls on member states to "eliminate negative discrimination by reviewing laws, regulations and administrative provisions to ensure that they are not contrary to the principle of fair opportunity for disabled people."

A further step was taken when the European Commission issued in 1996 a communication on equality of opportunities for disabled people. This communication set out a new European disability strategy. The new policy framework attempted to move the agenda away from a so-called welfare type approach to disability issues and toward eliminating the barriers that prevent the realization of equal opportunity, full participation, and respect for difference. It provided details on discriminatory practices experienced by people with disabilities, held that these practices violated deemed various universal human rights, and affirmed that "the core right at stake is that of equality." This communication was subsequently endorsed by the Council of Ministers representing the member states. For the first time, there was a clear and shared commitment by the European Union and its member states to promote equal opportunities, to eliminate discrimination, and to recognize the rights of people with disabilities.

The new emphasis, often called the "rights-based approach," was no longer about conferring special treatment or measures on people with disabilities but was rather about ensuring that people with disabilities are given equal treatment and equal rights. Although the communication marked an important step toward the recognition of the rights of people with disabilities, the European Community's involvement was limited to encouraging the member states to fulfill the commitments they had made at the European level.

Despite this progress, the European institutions were often criticized for not going further and in particular for lacking a specific legal base to take action against discrimination on the grounds of disabilities.

This changed in Amsterdam, in June 1997, when the heads of state and government agreed to strengthen Europe's capacity to act in this area by introducing Article 13 of the treaty establishing the European Community, which gives the European Community specific powers to take action to combat discrimination based on sex, racial, or ethnic origin; religion or belief; disability; age; or sexual orientation. The inclusion in the treaty of a general nondiscrimination article covering, among other areas, disability has greatly improved the situation for persons with disabilities. Article 13 opened the way for the commission to propose legally binding measures to combat discrimination on the grounds, specifically, of disability.

The disability strategy that the European Community has developed since the mid-1990s finds its clearest expressions in Article 13. This groundbreaking provision endorses the shift from thinking about people with disabilities as passive recipients of charity to viewing them as active claimants of the right to be treated equally. The European Commission moved swiftly to implement the new treaty provisions. After a consultation period, in November 1999 two draft directives and an action program were adopted by the European Commission. The whole package was unanimously adopted in a record time by the council the following year.

The first directive, 2000/43/EC, prohibits discrimination on the grounds of racial and ethnic origin and prohibits discrimination in the fields of employment, education, social protection (including social security and health care), social advantages, and access to goods and services (including housing). The second directive, 2000/78/EC, prohibits discrimination in employment and occupation on the grounds of religion and belief, disability, age, and sexual orientation. Both directives prohibit discrimination in employment and occupation, defined as access to employment, self-employment and occupation, vocational guidance and training, employment and working conditions including dismissal and pay, and membership of organizations.

The directives prohibit any discrimination, direct or indirect, on all grounds mentioned. With regard to disability, the Equal Treatment in Employment Directive (2000/78/EC) requires major changes to existing rules in certain member states. Employers—public and private—will be obliged to accommodate the needs of people with disabilities to ensure that they have an equal opportunity to compete in the labor market. Failure to provide a reasonable accommodation in the workplace can constitute discrimination. In practical terms, such accommodation includes measures to adapt the workplace to people with disabilities, for example, adapting premises, equipment, and patterns of working time to facilitate their access to employment. The directive expands the concept of discrimination with respect to disability in that employers must not only refrain from discriminating but also take steps to accommodate people with disabilities in the workplace to ensure that they are treated equally.

The "reasonable accommodation" requirement in essence should ensure that there is a level playing field for people with disabilities in the employment sphere. The directive, and the obligations contained therein, challenges the equation according to which disability equates unfitness or incapacity. Indeed, it applies only to individuals who are competent, capable, and available to perform the essential functions of the post concerned without prejudice to the obligation to provide reasonable accommodation for people with disabilities. The concept of reasonable accommodation is the keystone of fighting discrimination on the grounds of disability. Reasonable accommodation is not a positive action left to the discretion of public or private operators but an obligation whose failure can constitute unfair discrimination.

The reasonable accommodation obligation necessitates a balancing act between the needs of the employer to conduct a profitable business and the aspirations of people with disabilities to enjoy equal employment opportunities. The obligation therefore does not apply to employers in all circumstances. The directive provides that an employer can deny a reasonable accommodation if it would impose a "disproportionate burden." The directive gives in that respect some guidance as to how to measure and assert the disproportionate burden: "to determine whether the measures in question give rise to a disproportionate burden, account should be taken in particular of the financial and other costs entailed, the scale and financial resources of the organisation or undertaking and the possibility of obtaining public funding or any other assistance."

The directive provides for positive action in that it acknowledges that the prohibition of discrimination should not be without prejudice to the maintenance or adoption of measures intended to prevent or compensate for disadvantages suffered by a group of persons of a particular religion or belief, disability, age, or sexual orientation.

The paradigm shift that has taken place at the European level—transforming needs of people with disabilities into rights—has spread across the international community. The debate around the need to develop a United Nations thematic convention on the rights of people with disabilities has clearly demonstrated the shortfalls of the existing international human rights instruments in relation to people with disabilities. The European Commission has signaled in a communication its full support toward the development of such a convention that would secure unequivocal protection for the fundamental human rights and freedoms of people with disabilities and acknowledge their legitimate membership in the international human rights system.

EUROPEAN DISABILITY FORUM

The European Disability Forum (EDF) was created in 1996 by its member organizations to defend issues of common concern to all disability groups and to be an independent and strong voice for disabled citizens in dialogue with the European Union (EU) and other European authorities. Its mission is to promote equal opportunities for disabled people and to protect their human rights.

EDF has 127 member organizations reflecting a broad geographic base and a wide range of concerns across the disability movement. Its membership currently includes 21 National Disability Councils: one from each of the EU member states, plus Iceland and Norway, Czech Republic, Estonia, Malta, and Slovenia. These national federations are independent organizations of disabled people, including all major impairment groups in each country; 96 organizations representing the various disability groups and interests in Europe and specialized by type of impairment or sector of activity, such as the European Blind Union and the European Union of the Deaf.

EDF's motto and basis for work is "nothing about disabled people without disabled people," as promoted by the Madrid Declaration. Therefore, its scope of work is very large, covering all EU areas of competence that can have an impact on people with disabilities' lives (e.g., employment, information society, social inclusion, transports, media, telecommunications).

One of EDF's most important campaigns was the European Year of People with Disabilities 2003, a proposal presented to the European Commission in 1999. The European Year marked the history of the European disability movement, providing the necessary impetus to advance the disability agenda in all EU member states and accession countries. The future challenge for EDF remains the adoption of a new disability-specific directive that will protect disabled people from discrimination in all fields of life, such as education, transports, information, and leisure. Ensuring that disabled people are able to benefit from the same rights and obligations as other citizens in the European Union will continue to be EDF's main goal; legal instruments to combat discrimination will remain the basis of its work.

EUTHANASIA

Both in conception and in practice, within and beyond disability communities, euthanasia provokes impassioned contentiousness. The word itself is derived from the Greek for "dying in a good way." How people of different persuasions react to the idea itself encapsulates the debate about practices variously labeled as "euthanasia."

To many people, such a notion is an oxymoron, for it is inconceivable to them that dying can ever be good. Many people therefore conclude that policies permitting euthanasia must be deceptively corrupt. The way that the practice is named is seen as a disingenuous attempt to pass off as instrumentally desirable an outcome that is intrinsically bad and that therefore should be avoided at all costs.

Many other people take a contrary view. To them, euthanasia is a commendable idea for making the best of a bad event that otherwise would be even worse. According to this very different understanding, death inevitably comes to all persons, but whether death occurs peacefully or is reached only through great suffering sometimes lies within our power to decide. In such cases, proponents of euthanasia argue, society owes its citizens at least the option of having a peaceful experience at the end of life instead of an anguished one.

In its broadest sense, euthanasia comprises any action intended to hasten death for the purpose of dispensing a merciful benefit. There are two different kinds of supposed beneficiaries. Euthanasia is said to benefit individuals by offering them death to relieve their suffering. Euthanasia also is said to benefit whoever is burdened by or otherwise disadvantageously implicated in the lives of the aforementioned sufferers. Thus, euthanasia divides populations into two classes of people: those who are supposed to benefit from their own quick deaths and those who are supposed to benefit from others' quick deaths.

Among the theoretically benevolent, but malignant in practice, ideas that have been applied to people with disabilities, euthanasia is one of the most prominent. Indeed, societal permission to commit acts of killing that might be labeled as, or lead to, euthanasia, and the frequency of such acts commonly are cited as evidence of societal disregard of the value of disabled people's lives. For example, although we commonly think of ourselves as mandated to provide nourishment to dependents, our sense of being obligated to do so seems to weaken to the extent that the dependent appears irremediably impaired. As a result, certain societies have condoned withholding nourishment from babies with certain congenital anomalies, people with profound traumatic brain injuries who are in the prime of life, and elderly people with dementia. The reasons for not nourishing them have been that their quality of life is inescapably inferior to individuals without impairments and that it is wrong to condemn them to the prolonged suffering occasioned by their deficits. This practice thus is fueled by societal presumptions that such people necessarily are very unhappy, absent sufficient research or other evidence that its empirical foundation is true.

SUFFERING WORSE THAN DEATH

The degree of suffering that qualifies as serious enough to call for hastening death is as controversial as every other aspect of euthanasia. We sometimes euthanize discarded pets simply because there is no one willing to care for them. Occasions of human suffering that people have thought grave enough to make death preferable include intractable or unceasing pain, hopeless illness, loss of control of bodily function, loss of dignity or autonomy, or becoming dependent or burdensome on others.

Culture and context affect whether or not persisting in any of these conditions is felt to be worse than dying. Of course, both cultural values and personal experience affect assessments of the badness of death. Islam, for instance, proclaims the sanctity of life and also holds that enduring unavoidable pain will be to an individual's credit in the hereafter, the real and enduring life. To take another example, Christian doctrine also usually is committed to the sanctity of life, and the doctrines of some versions of Christianity oppose any end-of-life intervention that reduces an individual's competency to repent in preparation for imminent death. To take a third and contrary example, Japanese Buddhism (but not other Buddhist sects) traditionally does not advance similar claims about sanctity of life and under certain circumstances tolerates or advises ritualized suicide, abortion, and euthanasia. And as a fourth example, Jehovah's Witnesses do not count life as of preeminent value; they forgo certain medical interventions prohibited by their scriptural doctrine even if the outcome of rejecting treatment will be death.

Personal experience also divides opinion on this subject. As a group, people with chronic impairments or long-standing disabilities are more likely than nondisabled people to consider pain, illness, and dependence as components of ordinary life rather than as reasons to hasten death. To many people with disabilities, therefore, the usual arguments about benevolently hastening death are impositions made from the perspective of the nondisabled majority. Those who hold this opinion presumably prefer to endure all unfortunate future alterations of their current state of life. Maintaining the security to continue living even if existence seems unbearable appears to them to be the best strategy for safeguarding that life itself.

There are many other people with disabilities, however, who are less disposed to relinquish control over their own fates. They want to command decision making about their own medical treatment and to retain authority over the degree of pain and suffering they must endure. For many, such self-determination or autonomy is central to achieving value in their lives. Consequently, to be forbidden to do so by a possibly overprotected state is of overriding repugnance to them. Maintaining the liberty to end life should existence become unbearable appears to them the best strategy for safeguarding the value of that life.

DEFINING EUTHANASIA

Voluntary, Nonvoluntary, Involuntary Death

Variables affect whether or not an act of hastening death genuinely is euthanasia. One variable has to do with whether the person whose death is at issue seeks such acceleration; if so, the expression *voluntary* euthanasia is used. *Nonvoluntary* and *involuntary* euthanasia are the other types, and in theory these are distinguishable. In the latter, the euthanized individual is competent to consent but does not, while in the former no capacity to consent exists.

Passive and Active Killing

A second variable has to do with whether death is accelerated by intervening or by failing to intervene. *Passive* euthanasia is the term applied to failing to provide, or withdrawing, necessary life support, so that a patient dies. *Active* euthanasia is the term applied to intervening by administering lethal medication or applying some other technique that ends life.

A related controversy concerning the boundaries of euthanasia regards the condition of the individuals who die. Some think that to hasten death on grounds of benevolence always is to euthanize, regardless of whether the patient's life already is slipping away. Others hold that euthanasia applies only where individuals would have lived but for being subjected to a fatal intervention.

Private, Professional, and Public Agency

The third significant variable involves the identity of death's agent. Whether or not a terminal intervention is called "euthanasia" may be affected by whether the means of death is self-administered, administered by a health care professional in the course of treatment, or administered by an individual who is not qualified to or charged with giving medical care. There is disagreement about who has the status to euthanize. From one perspective, parents who end the lives of their own disabled children should be described as having euthanized them. Another perspective, however, reserves agency in euthanasia for medical personnel, or for the state. The ground for being concerned with this distinction is the action of a parent in regard to a child who is disabled is morally different, in important ways, from the action of a medical professional or government agent in regard to a population that is disabled. For some people, however, this distinction is morally negligible.

DIVERSITY OF TERMINOLOGY

No Agreement

There is no agreement as to whether these variables should be addressed so as to broaden or narrow the kinds of cases that are counted as true instances of euthanasia. In some venues—for example, in the Netherlands—only voluntary self-executed and assisted deaths are termed euthanasia. There are other venues, such as the United States, where voluntarily assisted deaths usually are not called "euthanasia" and voluntary self-executed deaths never are. In the Netherlands, nonvoluntary deaths brought about for compassionate purposes are labeled as resulting from "life-terminating acts without explicit request," but in the United States some such nonvoluntary deaths may be the clearest examples of euthanasia.

In the Netherlands, both euthanasia (using the Dutch terminology, which entails voluntariness) and compassionate nonvoluntary life-termination have been deemed to be patients' rights. Physicians who facilitate their patients' exercise of these rights by dispensing euthanasia usually are shielded from punishment. In contrast, in the United States only voluntary passive dying is the right of the patient, made so because competent individuals are permitted to refuse treatment and thereby to reject life-supporting medical interventions. Voluntary active interventions to hasten death are called either mercy killings or assisted suicide, depending on whether the terminal intervention is executed by another party or is self-executed. All these open the U.S. agent or enabler of the death to prosecution, except that in the state of Oregon a patient within six months of death who is legally competent may obtain and self-administer a lethal prescription without triggering punishment for the physician.

Physician-Assisted Suicide as Euthanasia

Contention abounds about whether assisting disabled individuals who seek to self-execute their own deaths is nothing more than a camouflaged version of euthanasia. Physician-assisted suicide (PAS) is where the patient prefers self-administering the means to death over prolonged suffering from illness or injury, but also where procuring the means of death requires assistance from a physician. Some people believe that permitting physicians to facilitate disabled people's suicides is equivalent to killing them because, even when self-executed, such deaths are not really autonomous and therefore are not purely voluntary. They are prompted, it is said, by the disabled person's internalizing society's disparagement of disability. Other people believe it is simply a permissible implementation of people's exercise of the liberty to self-determine the time and manner of their deaths and that disabled people as a class are no more incompetent to enjoy such freedom than other people. Claims to such liberty are based on people's broader right to control when they will be subjected to medical intervention, a kind of freedom much cherished by many people with disabilities.

In the United States, physician assistance to a competent individual who self-determines to die and self-executes the activities needed to do so is suicide, not euthanasia, although opponents marshal the standard objections to euthanasia to combat permissiveness in regard to physician-assisted suicide. In the Netherlands, however, physician assistance in suicide is a form of euthanasia, with no moral difference drawn between a physician's providing a patient with a lethal prescription to be self-administered and administering a lethal dose to the patient. In opposition to U.S. practice, an equity argument with reference to people whose disability prevents them from self-administering is mounted in the Netherlands. This consistency of respect argument contends that physicians ought to accommodate patients who choose lethal drugs but whose conditions prevent self-administering them, as readily as they do nondisabled, as well as manually proficient disabled, individuals.

This argument is extended to people who are not able to give or refuse consent, fueling charges that physician-assisted suicide initiates a slippery slope that catapults a society into widespread practice of euthanasia. The thrust of the argument is that physicians ought to treat patients whose conditions prevent their making or communicating a wish to end their lives as benevolently as they do nondisabled and disabled individuals who are competent to consent to medical treatment. Therefore, in the Netherlands, physicians may end the lives of individuals who have not requested a hastened death but who, in the view of the physician, are or will suffer similarly to competent people who ask not to live. Ending the lives of neonates who almost certainly will not survive, or are dependent on intensive care and have a grim prognosis, or are not dependent on intensive care but are predicted to have a poor quality of life with sustained suffering, such as with severe spina bifida, is an accepted medical practice under the hospital policy known as the “Groningen Protocol.”

Withdrawing Life Support as Euthanasia

At the other end of the spectrum lies the hastening of death passively by refusing or withdrawing measures required to continue a patient’s life. Some people think of such actions as killing and therefore characterize them as euthanasia, whereas for others these are decisions to refrain from futile (and arrogant) prolonging of the natural conclusion of a life. For example, in nations under shari'a (Islamic religious law), to withhold nutrition from patients is to euthanize them and is unlawful, while in the United States to do so for a patient at the end of life, and with the patient’s or surrogate decision maker’s consent, is not euthanasia at all.

Further dispute occurs over what kinds of interventions are artificial. Some hold that providing nutrition is natural because we do so for humans too young to feed themselves but that mechanically effecting respiration is not so. Others contend that all medical intervention is artificial, while still others believe that our better natures categorically call for taking all measures to fend off death.

Such profound differences of view about the propriety of providing patients with perpetual life support explain the different treatment afforded Karen Quinlan and Terri Schiavo, who both were young women with brain damage resulting in a persistent vegetative state (PVS). Believing that she was being kept alive on a respirator in defiance of what nature decreed, Quinlan’s parents sued for the right to have her ventilation equipment removed. When doing so revealed she could breathe on her own, however, they maintained her nutrition and hydration using medical means because, they contended, parents have a natural duty to nourish their child. In contrast, Schiavo’s husband, who possessed the legal power to represent her wishes, rejected tube-feeding as being so artificial a route to nourishment as to occasion intolerable suffering. But Schiavo’s parents, joined by many disability advocates, contended that the overriding value lay in Terri’s continuing to live.

LOOKING BACK AT EUTHANASIA

Given such disparities of usage, not to mention profound differences in fundamental conceptualizations, beliefs, and values, it is impossible to say to what extent euthanasia is legally prohibited worldwide, and it is equally impossible to discover how widely it is either openly or surreptitiously practiced. There are, nevertheless, clear historical instances of programs and practices that euthanized people because they were physically or mentally anomalous and thereby were deemed to be disabled and unfit. The most often cited and clearest example is the Nazi program initiated in late 1939 that authorized certain physicians to put to an involuntary “merciful” death people who had been diagnosed with incurable illnesses or who could not conceal their impairments but who were far from dying of natural causes.

This euthanasia program was preceded, in 1933, by the Law for the Prevention of Progeny with Hereditary Diseases, among which were counted schizophrenia, bipolar disorder, epilepsy, Huntington’s disease, intellectual retardation, blindness, deafness, physical deformity, and alcoholism. Health care professionals were required to report anyone at risk of developing, or transmitting to progeny, these conditions. Almost 400,000 were sterilized. In 1935, the Marital Health Act forbade marriage between “healthy” people and carriers of “diseased” heredity. The latter were put on trial and then sterilized. The warrant was that citizens should be healthy to be productive and contribute to the social and economic well-being of the nation. Beginning in the previous century, Germans had enjoyed state-funded health and disability insurance, so keeping the population healthy also meant keeping down public spending.

The 1939 euthanasia program focused on the systematic killing of institutionalized individuals without their families’ knowledge. Some disabled people living in the community also were targeted, however. Questionnaires disguised as census documents were distributed to physicians and then used to find victims. Those euthanized (initially children and later adults) were mainly individuals with developmental disabilities, psychiatric illnesses, neurological impairments, genetic anomalies, and progressive diseases. As one

German clergyman of the period wrote: "Recently the inmates of old-age homes have also been included. The basis for this practice seems to be that in an efficient nation there should be no room for weak and frail people" (Letter from Dr. Wurm 1940). Opposition, especially from the clergy, led to the program's suspension in late 1941, but a year later it was reinstituted. Instead of transporting "unfit" individuals to be gassed, the unfit, who now included geriatric patients and bombing victims, died from withdrawal of nourishment or lethal injection at treatment clinics or residential institutions. An estimated 250,000 Germans with disabilities were killed by the euthanasia program.

There is no moral ambiguity about the case of the Nazi euthanasia program. Disabled people were exterminated against their interest and without their consent, under the guise of helping them, but actually to relieve and thereby benefit nondisabled people. Such moral clarity is not characteristic, however, of most contemporary cases in which permission for a merciful death is pursued through legal or legislative processes.

CONTEMPORARY CASES

There is a question about whether a sufficiently troublesome resemblance exists between the paradigmatically morally reprehensible Nazi euthanasia practice and instances in which disabled individuals ask courts to permit their obtaining assistance in ending their lives. In the United States, Larry McAfee, a respirator-dependent quadriplegic, successfully sought to shield the individual who manufactured a device permitting him to turn off his breathing support. Elizabeth Bouvia, whose cerebral palsy and arthritis led her to want to cease eating, obtained a court order to prevent nutrition's being forced on her. In Canada, Sue Rodriguez unsuccessfully petitioned to enable a physician to provide a device permitting her to self-administer a lethal dose when she believed her motor neuron disease (MND) had reached an intolerable stage. In the United Kingdom, 19-year-old "A. K.," a MND patient, won the right to have his ventilator removed when he became "locked in" and no longer able to communicate even by blinking. Another MND patient, Diane Pretty, was unable to acquire a legal shield against her husband's being prosecuted should he help her to kill herself.

In these cases, disabled plaintiffs, exercising autonomy, voluntarily sought death, sometimes by refusing life-supporting treatment, sometimes by obtaining physical assistance to execute a lethal act, sometimes by arranging to self-executing the lethal act. Thus, these cases seem to lie very far from the paradigmatic Nazi euthanasia program, where disabled people met death involuntarily and through active interventions by the hands of others. In all these cases, nevertheless, there were disability advocacy groups that opposed the disabled plaintiff's plan. These groups warned against a slide down a slippery slope toward the same societal presumptions that energized the Nazi euthanasia program.

First, they argued, only if prompted by presuming the worthlessness of disabled people's lives could courts find for the plaintiffs in these cases. But it is precisely such a view of the dispensability of this class of citizens that inspired the Nazi program. Furthermore, equal protection would be violated if courts found for these plaintiffs, given that starving or suffocating nondisabled people never is condoned.

Second, courts that create such law in particular cases endanger all the disabled. Law and public policy arguably have an expressivist function: Beyond their letter, they also can send messages of approbation or disapproval, respect or contempt. Excepting disabled people from prohibitions against killing thus may send powerfully broad messages about their inferiority.

Furthermore, these messages may depress disabled people's estimation of themselves, to the extent that some disability advocates report experiencing depression so profound as to have brought them to the brink of terminating their lives. In a society they know very well will reject them, newly disabled people are especially vulnerable to losing hope of having a satisfactory future life. Families or other caregivers who fear being burdened might intentionally or inadvertently induce their disabled dependents to relieve them if an easy death could be found without difficulty. Disabled people or their loved ones also may think of death as a cost-effective alternative to expensive care that prolongs their lives without improving the quality.

Related to this point are concerns about euthanasia's attractiveness as an instrument of cost control. Some disabled people believe that health care economics recommends using legal routes of causing death to remove patients and so reduce expense. It is unclear, however, whether eliminating the patients who are most readily removable this way serves the profit motive because at least some such patients—for instance, tube-fed geriatric patients—can be profit centers for custodial facilities. Nevertheless, a system to protect vulnerable patients from being sacrificed due to the cost of their care is unlikely to be effective because of the privacy that cloaks physician-patient interactions. It would be difficult to be confident that the patient's consent was voluntary and informed.

Third, the state is obligated to protect weak and vulnerable dependent people, such as the disabled commonly are. In the case of Diane Pretty, for example, the U.K. House of Lords ruled against a disabled woman seeking the right to kill herself on the grounds of the overriding public interest in protecting the weak and vulnerable. One lord remarked that it was impracticable for the law to attempt to distinguish between self-determining and vulnerable disabled people who are assisted in suicide. The U.S. Supreme Court has held that prohibiting assisting disabled people to end their own lives protects the poor, the elderly, disabled persons, the terminally ill, and persons in other vulnerable groups from indifference, prejudice, and psychological and financial pressure to end their lives and prevents a possible slide toward voluntary and perhaps even involuntary euthanasia.

LOOKING FORWARD: FEAR OF A SLIPPERY SLOPE

Two circumstances might prompt a slide toward a program of involuntary euthanasia such as the Nazis practiced. First, given the nature of physicians' access to patients, it might be difficult to prevent physicians from coercing patients into agreeing, or else fabricating patients' agreement, to end their lives. Second, given the nature of patients' reasons for ending their lives, it would be difficult to defend a prohibition against nonvoluntary euthanasia. Arguments for permitting competent disabled people to determine if they want to continue to live could be extrapolated to noncompetent people with similar illnesses or impairments. If a competent person finds living with a particular disability unendurable, courts might presume that incompetent people with similar disabilities would come to the same decision if they could.

Euthanasia policy therefore pits the interests of individual disabled citizens who prize self-determination against disabled people considered as a vulnerable group. A subset of the group of disabled people is especially dependent on strong paternalistic protections. Paternalistic policies, however, threaten opportunities for exercising choice by eliminating seemingly risky options for the group they are supposed to protect. There thus is a question about whether society is obligated to bar fully competent disabled individuals from an end they choose simply because of their membership in the disability classification. A related discussion addresses whether such self-sufficient disabled people are especially obligated to forego self-determination and under no circumstance seek to hasten death in order to safeguard their more vulnerable disabled peers.

POLICY IN THE NETHERLANDS

The developing freedom of ill and disabled people in the Netherlands to voluntarily end their lives increases the urgency of resolving these uncertainties. Until 1973, euthanasia courted prosecution and conviction in the Netherlands. In that year, a physician who had shortened her mother's agonized dying was put on trial but not punished. Courts then set guidelines for permissible medical intervention to hasten death: The patient must be suffering from a terminal illness, and the patient must request an immediate death.

Policy in the Netherlands has been influenced by the standard of community practice, by which is meant the prevailing consensus among physicians about the proper medical intervention once a diagnosis and/or prognosis is made. In 1984, the Dutch Royal Society of Medicine issued "rules of careful conduct" for euthanasia. Physicians had to inform the patient of the prognosis, consult the family (with the patient's permission), consult at least one other physician, keep written records, and obtain the consent of parents or guardian if the patient is a child. The boundaries set by these rules quickly proved elastic, however. In the following year, a court dropped the "terminal illness" requirement. A physician was not punished for assisting a young woman who did not wish to experience the struggle of living with nonremitting multiple sclerosis to end her life, even though her condition was not terminal.

The Dutch courts and the Royal Dutch Medical Association (KNMG) subsequently established new guidelines for physicians: (1) voluntariness—patients' request must be freely made, well-considered, and persistent; (2) unbearable suffering—patients' suffering cannot be relieved by any other means; and (3) consultation—attending physicians should consult with a colleague. If these guidelines are followed physicians will not be prosecuted. The KNMG chose a narrow definition: Officially, euthanasia is the ending of the life of one person with the help of another but at the first person's request.

Thus, in the Netherlands euthanasia is by definition always voluntary. But there is no punishment for ending the lives of babies with Down syndrome or spina bifida or adults in a persistent vegetative state. In fact, during the past decade, about half of the physician-assisted deaths in the Netherlands would be identified as nonvoluntary or involuntary euthanasia in most other legal systems.

This last observation recalls the danger of creating a slippery slope. Some people conclude that permitting Dutch physicians to perform voluntary euthanasia encourages them to perform nonvoluntary and involuntary euthanasia. Others say that that the data about these nonvoluntary and involuntary deaths merely document the results of a community practice that has long prevailed but only recently been revealed. There is no possibility of resolving this dispute scientifically, however, because the data are drawn from physicians' interpretive reports of their own and their patients' intentions. The Dutch experience therefore does not establish, but neither does it disprove, the inevitability of society's sliding from permitting a disabled person to freely choose to hasten death toward prescribing the deaths of entire disabled populations.

CONCLUSION

Current conflicts and confusions about what should be called euthanasia preclude a global approach to identifying the principles most beneficial to disabled people in regard to policies permitting or prohibiting the hastening of death. This state of affairs makes it difficult to develop evidence about how likely various medical practices and community standards are to evolve into a euthanasia program that mirrors the Nazis' purpose of purging disabled people from the population. Yet such careful study is crucial if we are to create safeguards for the disabled that do not cross the line into paternalism and violate their freedom of self-control.

EVALUATION IN EUROPE

See Disability Assessment/Evaluation, Europe

EVIDENCE-BASED MEDICINE

Evidence-based medicine (EBM) is a shorthand term for an approach to patient care in which decisions about the management of the individual patient are made by the clinician using his or her personal experience and expertise combined with use of the best-quality and most up-to-date scientific evidence. Summarized in this way, it may be thought that there is nothing about EBM to distinguish it from the main traditions that have dominated the science of health care provision for the past 200 or 300 years. While the degree of real originality of EBM is still disputed, it is beyond dispute that in the 1990s a powerful and cogent force swept through medicine, driven by articulate and forceful advocates for EBM, drawing largely on principles based in clinical epidemiology.

The enormous appeal of EBM stems from the very worrying and growing evidence that health services involve enormous and inexplicable variations between clinicians in the management of the same health problem. These variations are seldom explained by differences in either variations in patient characteristics or health care resources. Moreover, medical textbooks, far from instilling standard high-quality practice, have been shown to be major sources of error, producing misleading recommendations out of step with best available scientific research. For example, clear evidence from research about the benefits of intravenous thrombolytic therapy in acute myocardial infarction was available for many years before it appeared in any medical textbooks.

At the heart of EBM is the use of best possible evidence in diagnostic and treatment decisions where *best* is defined by a clear hierarchy of quality-of-study designs providing evidence. The most reliable evidence is generated by properly randomized, controlled trials (RCTs). Below such study designs are well-designed cohort or case-control analytic studies. Less reliable evidence can be obtained from multiple time series with or without the intervention. Least reliable of all, and therefore at the bottom of the hierarchy, is evidence in the form of the opinions of respected authorities, based on clinical experience, descriptive studies, and case reports, or reports of expert committees. Much debate has been provoked by the assertion by proponents of EBM that the RCT represents a gold standard method with all alternatives to varying degrees inferior. However, it is difficult to contest their basic argument that well-designed randomized controlled trials generally are least prone to biased estimates of treatment effects. In other words, if patients are properly randomized, estimates of benefits of an experimental intervention are less likely to be biased by, for example, differences in the pretreatment health status of patient groups or various other selection effects.

Increasingly, EBM emphasizes the central role of systematic reviews rather than individual trials. Where appropriate, systematic reviews of evidence result in a meta-analysis to produce an estimate of the net effect of an intervention across studies. Systematic reviews have their own sources of potential error and bias. For example, publication bias is one risk: Trials with a positive result are more likely to be published than trials showing no effect. As a result, the systematic review often needs to search the unpublished literature. Similarly, individual trials may not all be of similar quality in terms of how well they address risks of bias. A meta-analysis of the net benefits of an intervention across trials may need to omit or downplay the significance of poorer-quality trials.

One of the key developments in EBM was the foundation of the Cochrane Collaboration in 1993. Named after a British epidemiologist, Archie Cochrane, the Cochrane Collaboration is an international nonprofit and independent organization dedicated to making up-to-date, accurate information about the effects of health care readily available worldwide, particularly via its database of systematic reviews (the Cochrane Library).

EBM emphasizes five essential steps in the optimal clinical practice. First, the clinician identifies a clear clinical question arising out of the management of an individual patient, a question leading to a need for information. In the second step, he or she will identify the best source of evidence to address the need. Third, the evidence will then be critically appraised for its validity and applicability to the problem at hand. Fourth, the evidence will be combined with clinical experience and the patient's own preferences and values to determine an intervention. At the last step, the outcomes of the intervention in the patient are subsequently evaluated.

EBM began as a movement to improve individual patient care. Its principles are, however, just as relevant to many other aspects of health care. What are the optimal ways of delivering health care? What are the most effective ways of improving health professionals' practice? What are the most cost-effective methods of promoting healthy lifestyles of populations? It is commonly argued that all such questions are more effectively addressed by synthesis and meta-analysis of best available evidence. Some of the greatest returns from investment may arise from relatively simple interventions in resource-poor populations: hygiene-oriented interventions such as hand washing, nutritional supplements for children, and antibiotic prophylaxis for HIV. The need for randomized controlled trials and evidence-based practice in such global health challenges is enormous.

The initial impetus for EBM came from academic medicine, understandably advocating the application of applied health research to clinical practice. Strikingly, the financial, managerial, and ideological support for EBM of governments and other funders and providers has been of enormous importance in sustaining the movement. This support arises in general terms because of the attractive prospect of services being developed that are more appropriate and cost-effective for the population served. In more specific terms, EBM generates detailed guidelines and explicit protocols for the delivery of services, developments that in principle make it far easier to monitor and steer the performance of health professionals than was the case when professional decisions were essentially a "black box beyond scrutiny." The provision of unbiased information about effectiveness of interventions also has an obvious appeal to patient groups otherwise dependent on commercial or other biased sources of information and advice. EBM would seem an advantageous development for all stakeholders in health care.

Three major issues currently confront EBM: (1) technical and scientific issues regarding the foundations of EBM in RCTs, (2) political critiques, and (3) practical and organizational challenges of implementation. The initial momentum of EBM in some ways resembled the fervor of a religious movement; the current phase of development requires confrontation with many complex realities of health care.

The first complexity is the widely expressed argument that RCTs cannot provide a sufficient knowledge base for all problems in the delivery of health care. There are some important questions in health care that will never be resolved by RCTs for practical reasons. This may occur when adverse events to be avoided are so infrequent that trials would require impossibly large sample sizes or where the health outcomes are so far in the future that there would be major practical problems of maintaining a trial. A quite different problem is that many questions will not be addressed because of ethical concerns about conducting a RCT to address such questions, for example, in the field of critical care. There may also be political objections to the use of RCTs. For example, methods of funding and organizing primary care in the United Kingdom have repeatedly been introduced without a firm evidence base, their introduction being determined rather by political preferences and intuitions about change.

There is also a continuing and lively debate about whether RCTs have to be the gold standard in proving an evidence base for practice. Several studies have compared the results emerging from meta-analyses of RCTs with those obtained from observational studies such as cohort designs. The conclusion is often that although observational studies are more frequently prone to methodological failures to address bias, well-designed observational studies produce similar results to those obtained from RCTs.

Another important technical problem is the relevance of results from clinical trials and systematic reviews to decisions about individual patients. The research evidence is usually about the average effect of an intervention across all types of patients. The extent to which this average effect is applicable to patients with any given features of disease severity or comorbidity may be unclear, because the evidence from trials does not have sufficient power to analyze trends in subgroups. Where it has been possible to examine evidence in subgroups, for example, in drug and surgical treatments of stroke, it has become apparent that benefits do differ significantly according to patients' baseline characteristics. A related and more general criticism of evidence from RCTs is that trials tend to be performed on a rather narrow range of patients, for example, often patients with more favorable overall health status, so that generalization to more "typical" patients is difficult.

Although the scientific limits of RCTs are increasingly being identified and recognized, these limitations do not fundamentally flaw the basic principles of EBM. They may mean that trials and related studies will need to be increasingly large and complex to address information needs that arise in caring for individual patients.

A second challenge stems from political critiques. One powerful analysis of EBM argues that the movement represents a fundamental (and undesirable) erosion of professional autonomy of health professionals, especially medicine. Some observers argue that the reduction of clinical decisions to explicit guidelines and protocols results in the practice of "cookbook" medicine with all important decisions taken at much higher levels in the overall management of health care organizations. In turn, these higher-level priorities will be largely driven by business models of efficiency and cost control rather than the interests of patients. Such critiques view EBM as one of a number of managerially led developments that lead to the deprofessionalization of medicine, motivated either by the profit motives of business or government concerns to control costs of the welfare state. It is also argued that the significant investments by organizations such as the U.K. National Health Service (NHS) in bodies such as the Centre for Disseminations and Review and National Institute for Clinical Excellence (key bodies assessing the evidence base for health care interventions in the NHS) are the outcome of a conflict for power and resources won by statisticians, accountants, and economists over traditionally powerful groups such as the medical profession.

The political critique forces us to reflect on the broader significance of EBM and usefully draws attention to potentially harmful threats to responsible and professional clinical practice if reduced to mechanical implementation of guidelines. On the one hand, however, the scale, scope, and reality of such threats are probably exaggerated. Moreover, the political critique underplays the extent to which the overall goals of EBM are welcomed by practicing clinicians and overlooks the extent of collaboration of clinicians with statistical and other nonclinical disciplines in developing the scientific underpinnings of EBM.

The third and ultimately the most important issue surrounding EBM is whether it is an approach to medicine that is feasible to implement in practice. Studies from around the world, including Australia, Canada, New Zealand, and the United Kingdom, suggest that only a minority of clinicians report using evidence-based information sources such as the Cochrane Library. One survey found that only 4 percent of a sample of U.K. general practitioners had ever used the Cochrane database of systematic reviews to help in clinical decisions. Studies have identified a range of reasons for the relative lack of uptake. Many clinicians remain unaware of what constitute high-quality forms of evidence, still relying on traditional reviews and textbooks. Clinicians are often unaware of how to access systematic reviews. In some cases, their offices may simply lack appropriate Internet connections.

In general terms, research evidence suggests that although clinicians do express concerns about the threat to autonomy posed by what seems like guideline-governed medicine, they nevertheless welcome the emergence of EBM. There remain concerns about the importance of intuition, context, and judgment as important factors in the practice of medicine that are devalued by some versions of EBM. The view is also expressed that EBM may jeopardize the role of the doctor as therapist (the so-called placebo effect) regardless of specific interventions that he or she may use.

The biggest single barrier to uptake, however, is lack of time due to heavy workloads. Clinicians feel that it is unrealistic in clinical practice to seek out and appraise relevant scientific evidence to resolve clinical uncertainties. For this reason, the EBM movement has moved on from its original pure conception. Now it is argued that while some clinicians may be "doers" of EBM, in the sense of following all of the steps from problem identification through evidence searching and synthesizing to action and evaluation, they are likely to be outnumbered by two other important categories of clinician. First. there is the "user" of EBM who does make use of secondary reviews already made readily available. Probably even more important in the future is the "unconscious user." This clinician will work in an environment in which EBM-based cues, prompts, and advice will be made available in the course of routine practice without being actively sought by the clinician. To take an example, clinicians may receive specific relevant advice on an automated basis when they enter a prescription into an electronic system. There is very encouraging evidence that such automated prompts induce more appropriate use of prescribed drugs by the doctor.

EBM is now entering a more mature phase where the complexities of what constitutes good evidence are accepted and the difficulties of applying evidence to individual practice are acknowledged and addressed. Constant advances in information technology encourage optimism that feasible applications of EBM will emerge. One outstanding issue is relatively unexplored. Clinicians often identify patients' own views, preferences, and requests within the consultation as a further barrier to EBM, especially when they are in apparent conflict with best evidence. Ways of achieving the active inclusion of the patients' values in the EBM will represent the larger challenge to the evolution of this exciting paradigm.

—Ray Fitzpatrick

EVOLUTIONARY THEORY

The first half of the twentieth century was consistently characterized as an age where the eradication of disability was within Western science's grasp. Beliefs about the potential for eradicating disability need to be understood with respect to developments in evolutionary theory and the process by which "defective" human bodies were produced in the wake of Charles Darwin's revolutionary notions of natural selection. Briefly, Darwin's theory of species adaptation and diversification rested on three key principles that have great value for disability studies:

1. Most variation is for the good of the species.
2. Adaptation is random and gradual in nature.
3. Fortuitous variations are unpredictable given that shifting environments alone determine organismic viability.

As an important aside, Darwin disapproved of any human intervention efforts to control the process and direction of species variation.

Few theories have had a greater impact and been so misread as Charles Darwin's revolutionary analysis of the origins of the species. Rather than a divine presence overseeing and orchestrating the invention of nature and the organisms that comprise it, Darwin's evolutionary model premised that all organisms evolved from a shared origin and that differentiation is the product of adaptation over time produced by interactions with environmental forces. Previous theories of species development hinged on a belief in a mechanism of internal determinism that guided species toward increasing perfection. Darwin overturned these notions by positing that species development occurs through a haphazard process (termed *natural selection*) where some organismic characteristics prove accidentally fortuitous to certain environmental conditions. Thus, one of the major innovations of Darwinian theory rested on a debunking of an ideology of progress in species "advance" that undergirded Enlightenment thought.

What we often refer to as disabilities today are central to evolutionary theory. Such conditions have been represented as either a failure of adaptation (organismic regression to a prior primitive state) or as a site of potential species innovation. The intellectual history of evolutionary theory is multiple and vexed with respect to the meaning of mutation (those forms of organismic and species differentiation marked as "severe" or most atypical). Following Darwin's philosophical break with the formalist tradition (planned internal design toward perfection), as represented by debates between Geoffrey, Cuvier, Agassiz, and Owen and particularly in theories of gradualism developed by Darwin's primary mentor, geologist Charles Lyell, Darwinian theory's three central themes have been amended and/or extended but not toppled in the sense that the kernel of natural selection remains intact. The solidity of this theoretical foundation is surprising in spite of those who have made relentless challenges to all three key Darwinian domains.

Those who attacked Darwin's theories from the mid-nineteenth century onward included eugenicists such as Galton; the mutationists such as de Vries and Goldschmidt; the catastrophism of Kelvin and Malthus; the "hardening" of Darwinian thought that occurred during the modern synthesis (1937–1963) in the work of Simpson, Dobzhansky, and Mayr; the rise of modern genetic theories that try to locate adaptation exclusively at the molecular level; and finally, the contemporary macroevolutionary theories of Gould and others. The primary argument that has served as a catalyst for evolutionary theory is between those who argue for the excesses of mutancy as superfluous, and thus largely undesirable, deviancy and those who believe that organismic/species creativity originates at the "extremes" of special variation. This structuring dichotomy is the focus of the remainder of this entry as that which is most critical to ongoing evolutionary debates for disability research.

The saltationists argued against the validity of Darwinian natural selection based on limitations ("structural constraints") inherent in the germ plasm or organisms. Following the lead of Sir Francis Galton, eugenicists theorized that species differentiation occurs according to the laws of regression toward the mean where atypical features—both desirable ("genius") and undesirable ("idiocy")—tend to give way to the overreplication of traits considered average or typical across a species. Unlike Adolphe Quetelet, the Belgian statistician who viewed average characteristics as most desirable, Galton's fascination was exercised in favor of extreme points of deviation from the mean. By dismissing the critical principle of Darwinian gradualism as too slow and inefficient to adequately explain species development, the saltationists advocated directed breeding practices. Unlike Darwin, who argued for an Adam Smith-like laissez-faire attitude toward adaptation, saltationists-turned-eugenicists encouraged the practical application of Mendelian principles to state oversight of human reproduction. Eugenics promoted the adoption of public policies that would better ensure the transfer of "desirable" characteristics (i.e., intelligence, eye color, and other features primarily associated with Caucasian peoples), and discourage the passage of "undesirable" traits (i.e., feeblemindedness, epilepsy, blindness, deafness, congenital impairments, alcoholism, and ethnicity). In other words, saltationist theories encouraged direct intervention in the process of species evolution to artificially cultivate some traits at the expense of others in a nation's germ plasm.

Another aspect of the saltationist debate with Darwinism was the more promising development of mutation theory by the Dutch botanist Hugo de Vries in 1909. Like Galton, de Vries poured his energy and theoretical development into the interpretation of genetic "extremes" (those rarefied cases that comprised the right and left tails of the bell curve). Yet, whereas Galton viewed "deviation" as largely irrelevant to organismic adaptation in nature and across epochs, de Vries's "mutation theory" championed "deviancy" as the locale of species "creativity." As a mutationist who also paradoxically embraced Darwinian principles of natural selection, de Vries argued that the production of "giant" and "dwarf" forms of the *Oenothera* plant signaled the origin of a new variation in an otherwise doomed organismic homogeneity. Consequently, de Vries merged the two extant theories of evolutionism—Darwin's non-directed selectionism with Galton's saltational "facet-flipping" (the sudden appearance of a new organismic form)—in the articulation of one of the first DNA-like arguments of organismic invention. Mutation theory's penchant for rapid and dramatic change in the matter of a generation provided one of the first successful efforts to overturn Kelvin's arguments that the planet was too young to accommodate Darwinian investments in the single species hypothesis. In other words, genetic mutations (many of which are classified as today's congenital impairments) serve as catalysts for species differentiation over time.

DeVries's celebration of mutational principles continue to resonate not only in the much maligned formulation by Goldschmidt in 1940 of "hopeful monsters"—"a completely new anatomical construction" that emerges in "one step from such a change"—but also in more contemporary theories such as Gould and Eldridge's most original contribution to macroevolutionary theory called "punctuated equilibrium." While Darwin located adaptation exclusively at the organismic level, Galton moved down the evolutionary scale to the level of germ plasm, and de Vries's mutation theory manifested its most significant impact at the species level, punctuated equilibrium formalizes its theory of adaptation at the cladistic level (evolutionary branching at the level of multiple lineages). This theory is distinct from that of most contemporary geneticists who (like the saltationists before them) argue that the molecular scale determines outcomes at all levels above: organisms, species, clades. As a field that relies on narrative methodologies that include history and interpretations of the fossil record, macroevolutionary theory seeks to analyze the crucial dimension of adaptation as an expression of interactionism between species-individuals and environments. In doing so, evolutionary theory places itself in direct competition with genetic determinist models where the transfer of molecular materials across generations can presumably account for the majority of manifestations of species differentiation.

At stake in these arguments for current disability-based research is the overreliance on molecular analyses as deterministic of human forms perceived as "unacceptable" at the social level. In displacing a social process into the organic, one effectively seals off the complexity of social influences upon an object of study. By locating a gene (or now perhaps a protein) as the origin of "deviancy," geneticists perpetuate the fallacy of the early saltationists who believed that organisms were internally directed in a deterministic fashion. As a direct disciplinary descendant, contemporary genetics threatens to reproduce the value system that powered eugenical practices at the beginning of the twentieth century, namely, by misrecognizing the organism (rather than the messy interactional space that exists between individuals and society) as the appropriate arena of intervention. This is a critical site where social model approaches to disability can contribute to the growing theoretical base of evolutionary thought.

As with the field of ethics, the meaning of disability functions as the unacknowledged Other in evolutionary theory. The discourse provides significant materials to fuel further disability research efforts to transform impairment from a presumed inferiority into a system of adaptive responses that continue to guide the origins of the species.

—David T. Mitchell

EXERCISE AND PHYSICAL ACTIVITY

During the past 50 years, many scientific studies have examined the relationship between physical activity, exercise, and health. The results of these studies have demonstrated that physical activity and exercise have a significant and positive effect on health promotion, disease prevention, treatment of chronic illnesses, and rehabilitation of people with disabilities. At the same time, lack of physical activity or a sedentary lifestyle has been identified as an important risk factor for chronic diseases. Thus, governments and public health agencies have developed policies including recommendations to promote and maintain an active lifestyle. Furthermore, many professional organizations have included exercise as an integral part of various clinical therapeutic and rehabilitative protocols.

Physical activity can be defined as any activity that involves the neuromuscular system and results in energy expenditure. Physical activity can be classified into various categories including occupational, recreational, or sports-related based on the objectives of the activity and the environment in which it takes place. All categories of physical activity have been associated with positive health outcomes in a large number of studies conducted since the 1950s. Exercise, on the other hand, is a subset of physical activity that is planned, repetitive, and structured to improve the physical and psychological health of a person. Exercise can be classified based on the nature of the muscle action involved (static [when there is no joint movement] vs. dynamic), the physiological adaptations induced (aerobic, strengthening, flexibility, or stretching), or the clinical objective of the exercise program.

Many disabling conditions are associated with reductions in health-related fitness. A practical classification of exercise is based on the nature of the specific component of health-related fitness that the exercise program is targeting. The health-related components of fitness include flexibility, muscle strength, muscle endurance, cardiovascular endurance or aerobic capacity, and body composition (percentage body fat or lean body mass). In this context, the type of exercise chosen must be specific for the physiological or functional capacity that needs to be developed. Thus, when the objective is to increase muscle strength, a specific exercise prescription for strength (or resistance) training such as weightlifting is indicated. If the clinical need is to develop flexibility, then a stretching exercise program is recommended. For cardiovascular endurance, and to increase aerobic capacity, exercise programs that activate large muscle groups such as walking, swimming, cross-country skiing, dancing, and many other similar activities are more effective in obtaining the goal. Finally, both strengthening exercises as well as aerobic activities influence body composition in a positive way by reducing body fat and maintaining or increasing lean body mass.

It should be clear that the goals have to be defined first and that the exercise recommendations must be specific for the chosen goals. The process of setting goals, one of the central tenets in the practice of clinical rehabilitation, is guided by the nature of the disease or injury and the physiological or functional losses associated with it. For example, when an injury to the knee joint results in joint swelling and pain that requires immobilization in a brace to protect tissues from further injury, the range of motion of the joint may be reduced and muscle atrophy can develop. In this situation, a program of flexibility exercises is indicated to treat the joint loss of motion and a strengthening exercise is designed to prevent or restore the loss of muscle mass and strength. Joint contractures and muscle atrophy are examples of impairments that, if not treated, could lead to a permanent disability.

Exercise and physical activity have been shown to be effective in the primary prevention of several chronic diseases that are common causes of death and disability in many countries. For example, epidemiological studies show that physically active men and women have a lower incidence of coronary heart disease, stroke, hypertension, diabetes, obesity, breast cancer, colon cancer, and depression. The evidence is so strong that many professional organizations and public health officials have included exercise as an important component of their health promotion strategies and the World Health Organization has endorsed an international "physical activity day" to promote the benefits of physical activity.

Although primary prevention is important, exercise can also be used for secondary prevention after the disease has evolved to a clinically detectable condition. Patients who have already developed these diseases can benefit from exercise programs because the regular participation in such programs induces adaptations in almost every organ/system of the human body. Some of the physiological and metabolic adaptations to exercise that help in the treatment of these diseases are a reduction in body weight and fat, an increase in lean body mass, lowering of blood pressure at rest and during exercise, enhancement of cardiac function, improvement in peripheral circulation, proliferation of small blood vessels or capillaries, increase in HDL (or good) cholesterol, reduction in LDL (or bad) cholesterol, improved sensitivity to insulin, and increased tolerance for physical stressors.

Finally, patients in rehabilitation programs, for example, stroke survivors, patients recovering from heart surgery or myocardial infarction, patients with pulmonary disease, amputees, and many others can also benefit from exercise programs. In a rehabilitation setting, where disability is prevalent, exercise can be used to normalize the basic pathophysiology of the disease (e.g., carbohydrate metabolism in diabetics), limit impairment (e.g., by increasing motor control in the hemiplegic arm), and correct functional losses (e.g., with gait training in amputees). In other words, physical activity and exercise have been shown to be effective interventions at different points of the pathway to disability. Without offering a cure for a permanent impairment or an incurable chronic disease, exercise can enhance the functional capacity and quality of life of the person with a disability.

It should be noted that although the physiological adaptations to exercise training have received more attention, exercise has also been shown to have important psychological and mental benefits. People involved in regular exercise programs report lower levels of anxiety, reduced depression scores, higher levels of self-esteem, improved well-being, enhanced cognition, and higher tolerance to pain. More research is needed in this area but the scientific evidence in this respect is convincing.

When recommending exercise as an intervention to minimize tissue damage, limit impairment, enhance function, or reduce disability, it is important to be specific. Thus, an exercise program must de defined in terms of the type of exercise and its frequency (sessions per day or week), duration (number of minutes per session, number of sets and repetitions), and intensity (usually expressed relative to the maximal capacities of the person). Although general guidelines exist, more research is needed to define the optimal combination of these elements for different patient populations and for persons with different types of disabilities. Furthermore, many recommendations have been developed for healthy subjects without disabilities and it is not clear that the results of those studies can be extrapolated to all.

The type of exercise is defined by the goal (as mentioned above) and the other three elements (frequency, duration, intensity) are specific for each type of exercise. The selection of the type of exercise is also influenced by the nature of the disability, the personal preference of the individual, and the existing resources in the community to support the choice. In other words, if swimming is ideal, does the person have access to a swimming pool? Another important consideration is the equipment that may be needed to perform the exercise. A wide variety of options are commercially available and both home- and gym-based options can be considered. Considerable research has been done in this area to develop adapted equipment for the exerciser and the practice of sports modalities for people with disabilities. For example, persons with permanent disabilities such as amputations and spinal cord injuries can use special skis for downhill skiing and wheelchairs to play basketball and compete in track sports.

Exercise programs have to become part of the daily and weekly routines of the individual. If not practiced regularly, the benefits of exercise will be lost, usually over the course of several weeks or a few months. In general, flexibility exercises are practiced daily, strengthening exercises 3 or 4 times a week, and aerobic exercises almost all days of the week. Although each person may have to develop an individualized program, specific recommendations regarding duration and intensity have been published in many forms and are available for specific types of exercise.

In summary, physical activity and exercise can be effective in the prevention, treatment, and rehabilitation of disability. There are no reasons for persons with disabilities to avoid exercise.

EXHIBITION

The term *exhibition* is a very general way of describing public presentations of a wide variety of subjects, including art, goods, services, athleticism, and performance. In the context of nineteenth-century popular entertainments in the Western world, "exhibitions" were colossal, grand-scale displays of industry and commerce held in various metropolises on grounds constructed specifically for that purpose. The largest of these were known also as "International Expositions" or "World's Fairs," sponsored by leading citizens and supported with vast government grants. Generally speaking, these events resembled small, rapidly erected cities of massive, architecturally ornate buildings showcasing the greatest recent advances in scientific development. Inside the buildings, visitors could bear witness to the agricultural, commercial, cultural, and technological marvels of the day.

The exhibitions were also known for attracting entrepreneurial vendors, showmen, and cheap service providers who erected ramshackle restaurants, hotels, saloons, amusement booths, and fly-by-night dime museums in hasty conglomerations that attached themselves to the larger, more "official" fairgrounds. These side-exhibitions were known as "shantyvilles" and "dinkeytowns," and they provided a profitable environment for less respectable forms of entertainment. In this *demimonde,* certain persons with disabilities, unusual appearances, or special skills could profitably present themselves as freaks to an audience whose appetite for wondrous entertainment was already whetted.

The first such exhibition in the world was held in London in 1851 and had been so successful and profitable that it spawned American revivals as early as 1853, when an attempt was made to create a New York City World's Fair. This attempt proved abortive, however, despite the fact that the entrepreneur Phineas Taylor (P. T.) Barnum had been invited to the board of directors. In his memoirs, Barnum blames the failure of the event on the refusal of the other prudish, middle-class directors to incorporate popular entertainments (which included freaks as well as musical and dramatic presentations) into the program. Paris would hold World's Fairs in 1867, 1878, 1889, 1900, and 1937.

The next great American exhibition was the Philadelphia "Centennial Exhibition" of 1876, which commemorated the century since the signing of the Declaration of Independence. It operated under no prudish restrictions, and during the six months of its operation it hosted some 10 million visitors (one-fifth of the total population of the United States at the time). The shanteyville it spawned was a mile long and featured some of the most widely known freak performers who appeared as "traveling foreign curiosities." These included the "Wild Australian Children," the "Aztec Children," the "Man-Eating Feejees," and the very famous "Wild Men of Borneo." Freaks who appeared in the context of exhibitions cultivated a performance style that conventional freak performers of the dime museum or the carnival midway adopted with less frequency. This style was distinct in two ways: It was "exhibitive" rather than "performative," and it was "exoticized" rather than "aggrandized."

The freaks of the exhibitions focused less heavily on "performance" than traditional freaks, who habitually included presentations of virtuoso skill in, for instance, acting, acrobatics, contortion, comedy, recitation, impersonation, mental acumen, singing, playing of musical instruments, or craftwork. Exhibition freaks relied less heavily on performance and more strongly on merely appearing in an exoticized manner. This mode of performance required the freak to be understood as an exemplar of a foreign culture. Indeed, the exhibition of disabled persons in such fairs was often wholly conflated with the exhibition of "perfectly ordinary" members of exotic tribes. The exhibits usually wore ostensibly authentic costumes and conducted ostensibly authentic activities in ostensibly authentic backgrounds. It was often the case that the entirety of an exhibit was invented, the elements of the presentation bearing no real relationship whatsoever to actual foreign persons, artifacts, or settings. The great manager George Middleton related an incident where he had employed his roustabout Bill Jackson, an African American from New Jersey, to pretend to be a "Zulu Warrior." Jackson, dressed in a lionskin with a great shield and assegai and a bone in his hair, suffered acute embarrassment when a lady in the audience recognized him and called out his name. The Wild Men of Borneo, in addition, turned out to be brothers of Scandinavian descent from Ohio.

Audiences of the time would not have drawn great distinctions between the presentation of exotic, nonwhite persons and freaks; in the context of the exhibition, both were presented as "scientific" exhibits to "educate and uplift" the public and were associated very much with middle-class Yankee values of courage, thrift, common sense, piety, and patriotism.

EXPERIENCE

Our aim is to situate the primary experience of the disabled person that wakens to a relation with the lived body, temporality, spatiality, lived speech and in relationship to "others." For to contemplate the experience of disability is to bracket the thing itself. It is to be concerned with phenomenology rather than ontology. In the discourse of disability studies, it is to be concerned with disability over impairment, and with social construction, politics, and self-image over biology. The experience of disability is properly fundamental to disability.

Phenomenology aims at description of the patterns of lived experience. It is a philosophical approach that incorporates the mathematical-scientific point of view while providing access to a primary realm of human experience that remains irreducible. Such experience cannot be understood as merely "subjective" or

---

psychological. Phenomenology cuts across the objective-subjective dimensions by which many view reality, and we maintain that a phenomenological perspective can bring important insights to disability that have eluded more traditionally "objective" social sciences.

The lived body maps out our temporal-spatial world through our movements and actions. The lived body is our own, one that experiences directly. It is not merely the residue of the anatomical body and conditions our being situated in a world with others. As Sugarman suggests, "near" and "far," "up" and "down" register as irreducible categories of corporeal existence. For the disabled person, these "directions" may present and raise questions that do not readily occur to others.

The experience of human temporality is measured by meaning and concern before it is calibrated by counting and calculation. This lived time is qualitative, heterogeneous, discontinuous, and purposive. Mathematical time is quantitative, homogeneous, and continuous. The reduction of lived time to mathematical time reduces the human subject to an object.

Recent discoveries, particularly by the French philosopher Emmanuel Levinas, show an irreducible exteriority that demonstrates an "otherness" prior to the distinction between social construct and biological condition. The relation between the other and the self has foundational implications for an ethic of disability. It is in the act of recovering from the encounter with the other that the self recognizes both his or her own subjectivity. This is the locus of responsibility of one for the other.

A philosophical deficit arises from our currently diminishing sense of primary experience. Able-bodied people are in a corresponding position to relearn perceptual experience from disabled people. As examples, the discontinuous character of lived time is punctuated for the disabled person. Waiting for the other person can become a commonplace personal and social experience for a disabled person. This kind of waiting is, or course, found in the everyday experience of the able-bodied as well. Indeed, often the disabled person inhabits the time of the other, perhaps experienced by the disabled person as waiting, anticipation, rejection, in any event, as disruption. For that matter, the disabled person often inhabits the space of the other and does so not as an intruder, but as captive. Even attempts to make space his or her own may be interpreted as confinement (i.e., the phrase "confined to a wheelchair"). The disabled person may simultaneously be apart from and mesh with the space and time of the other. This engagement of the disabled body with space and time, although not unique to disability, is particularly revealed in the experience of disability. With the accelerating pace of the workplace, the impatience fostered by an ever-increasing desire for instantaneous access to information, and an impatience with delayed gratification, the phenomenon of waiting and the virtue of patience are a diminishing part of postmodern industrial life. Indeed, expectations for maturation have left less time for children to act like children. It is possible to imagine social worlds where a disability is not disclosed as dysfunctional, deviant, or pathological. In such worlds, people would have different conceptions of disability and work that would make different demands on persons, whether disabled or not. If the structure of the work world is not necessary but contingent, then the significant message in an advanced technological society may be one of social artifact rather than social necessity. But frequently we regard the world of work as a natural order and try to adjust the disabled person to that world by education, medicine, counseling, placement, advising on the job, and so forth.

While everyone can potentially benefit from advances in information technology, the premature reduction of understanding to mere information benefits no one. Academic lectures now imitate the sound bites of televised news with the result that education itself may proceed in ways less than desirable. In fact, as Roth suggests, the disabled person paradoxically may have more to gain from the revolutions in computer technology than others. The necessity to modify or adapt computer equipment for disabled people returns us to the domain of the lived body and the primary experience of the senses. Using the ball of the foot to control a mouse refers the engineer back to the capacities of a foot that is guided by conscious intention. Intentional movement, understanding, attention, and waiting are all inescapable aspects of irreducible human experience.

Loneliness is a dominant category of contemporary postmodern experience that, as David Reisman showed in the 1950s, can be experienced in a crowd. However, being alone is quite different from loneliness. The impediments for disabled people, and here we include the ill, the sick, the aged, and the young as well, can bring about life-threatening circumstances as well as the desire for human companionship. The nature of such solitude depends on whether it is forced or optional, momentous or trivial, and contingent or noncontingent. Here we see the emerging of a foundation for an ethics where the disabled person performs the role of teacher rather than student. All infants need care, supervision, and nurture. There is an asymmetry involved in the obligation of the parent to the child. Consciousness emerges for the parent as a continuing responsibility for the child. In most cultures, the reciprocal obligation of a child to care for a parent does not bring with it either the same obligations or legal sanctions. This would suggest that there is a concession that is made to the irreversibility of aging. The awareness that our time and the time of the other are different for each of us may be more likely to be known in advance by those who are disabled. This sense that the other approaches us from without—exteriority—forces a doubling of consciousness where we experience ourselves as a body-subject. The first experience is one of positionality or proximity and therefore of a subjectivity.

The disabled person may experience lived time and space with a greater degree of discontinuity born of dependency than many an able-bodied counterpart. In this sense, the life of the disabled person is more likely to be folded into the urgencies, priorities, and concerns of the able-bodied. This creates a surplus suffering over and above physical impairment. Psychological consequences, the experience of depression in particular, may accompany such temporal marginalizing. However, what remains to be explored is the precise relation between pain and suffering, the self and other. It is a commonly held opinion that suffering can exist without physical pain. Such suffering may be understood as psychological, emotional, or spiritual. However, from a radically empirical point of view, it would appear that where there is suffering, it is experienced in a corporeal sense first as pain. Pain may be temporary, even fleeting, like stubbing one's toe or an insect bite. Furthermore, pain can be experienced without a consciousness of an expectation with respect to the source of the pain as being unfair or unjust. Suffering, however, requires pain experienced for a sufficient duration to be memorable. At the same time, suffering arises in relation to expectation and therefore in relation to the expectations of others as well. The element of surplus suffering for the impaired person is unnecessary and therefore, in the language of Levinas, useless suffering. Useless suffering refers to the arrogance that would rationalize the sufferings of the other, our friend or our neighbor.

If we wish to reflect on our own suffering and endow it with some deeper purpose or insert it within some eschatological scheme, we are perfectly free to do so. This rationalizing in the first person superimposes a kind of theodicy that, when applied to others, shows ethical obtuseness. The surplus suffering of others can be decreased and ameliorated. This is done by placing the other before ourselves. Levinas argues that "the only absolute value is the human possibility of giving the other priority over oneself." This, according to Levinas, is the responsibility that founds consciousness in relation to experience. Ethics, according to Levinas, begins with justifying our spontaneity in the presence of the other. What is assumed here is that the other approaches us with immanent demands that we are not free from obliging. There would seem no end to such responsibility. How then would the market place, the workplace, cohesive social groups, function?

It is the third party, the neighbor, who may be present or absent, near or far, a close family member or a stranger, who limits our responsibility so that the order of justice can be installed. In this way, there can be justice for us as well for others and neighbors. By responding to the other, we assume our responsibility as a body-subject. This temporal distance between ourselves and the other is lived in first instance as a responsibility for our passivity. This extreme vulnerability registers in the sensibility through which perception informs understanding.

In this entry, we adhere to what William James called a radical empiricism that brackets issues of essence, ontology, biology or, for that matter, any of the other issues that may or may not be hidden behind the naked fact of our experience. Yet the experience of social beings is different from that of monads. The population of the experiential world by self and others and its animation by the multitude of relationships among these is not only part of that from which issues the experience of impairment but also, more important, that from which issues the rich complexities of the social experience of disability.

It is only a beginning to note that disability is overwhelmingly social, that is, given by the interactions of the self and others. Of course, others are of enormous variety and complexity. It is in the spirit of suggesting such complexity that we offer a rough-and-ready taxonomy of the other. Others can be divided into friends and strangers. The experience of disability is likely to be different for a friend or a stranger, as is the experience of this experience by the disabled self. Sometimes an other moves from being a stranger to being a friend, and the experience of disability may change accordingly. Another distinction about others, whose primacy we shall not comment, is that between master and slave. This sheds its dialectical relationship and is reified in the writing of Nietzsche through Foucault into the postmodernists. Here it is power that constructs knowledge including, of course, knowledge of disability.

There has been much talk about the medical model of disability. However, in the experience of disability, medicine is reabsorbed from its position of dominance as indeed it has been trumped by other vectors of social power. Gliedman and Roth point out that it has become ever clearer that the medical model is only a special case of the social pathology model. It appears then that power constructs our social world, some even say our non-social world. Hence the question of power is important to our experience and disability and it will be necessary to speak truth to power even if that involves questioning the primacy of power itself. Such indeed has been the trajectory of modern phenomenology.

Another distinction of others can be made between the professional and layperson. Often the professional invents and deploys a power that may be predicated on illusion. Other professionals may share the illusion, and laypeople may share it as well and be humbled before it. When the layperson is disabled, such dynamics become part of his or her experience. However, people of privilege know full well that professionals work *for* them. This has become evident in modern American culture with the displacement of the professional by the entrepreneur. For example, Bill Gates did not finish college, and he hires professionals. This is only part of an ancient tradition.

There are countless other distinctions that can be made between others such as distinctions in gender, age, proximity, class, or ethnicity. All or any can change the experience of the disabled self. For example, whether the other is erotic or neutered and whether the other considers the disabled self, for after all selves are others to others, as erotic or neutered can profoundly effect their relation in being that is contingent on relationships with others.

Thus, the human world is composed of complex aggregations of others. Indeed, the experience of others can make of them bigots actively hostile to people with disabilities. Far more typically, however, they do not know. Such ignorance may issue from their limited experience with disabled people. Often ignorance, or misinformation, echoes through the world of the other through complex mechanisms of culture that include language, practice, education, the media, advertising, or the law. In good measure, the liberation of people with disabilities involves changing such mechanisms. At times, disabled people have been unduly rancorous insisting on notions like temporarily able-bodied. Such nomenclature is often the reflection of the experience of the disabled person. How then are we to adjudicate the truth of experience?

An examination of the experience of disability recognizes the rich complexity of the location of the disabled person in the social and political world. Of course, society is never a monolith; rather it is a collection of ever-shifting people and groups. Often the relationship between these collectivities and people can be subdivided into a sort of taxonomy such as sketched above. Sometimes this taxonomy would seem to express relations of power constructing local and less local meanings to disability. Sometimes these meanings overextend themselves, forcing their experience on people with disabilities and on others. One example is the medical model of disability, perhaps questionable itself, certainly questionable when used outside of medicine. Understanding the experience of disability can be magnified through the reciprocal experience of self and other. Indeed, it is not only the disabled person who must be concerned with the other, it is everyone, including others. A coherent explanation of the self, disabled and otherwise, is contingent on an examination of the other that transcends even the other as a source of much experience to the self.

Society, social agencies, social actors, and social scientists are governed by a rhetoric that implies a disabled person ought to adjust to the reality of disability and to the physical and social world. The disabled person who does not adjust is presumed to flirt with deviance and stigma. But there is another way to regard adjustment. Reckon that it might not be the disabled person who should adjust, but rather the social and physical world. The social world is composed of others. These others have certain ways they do things, beliefs and values they hold, and certain goals they desire. "Adjustment" expresses a relationship between a person and the environment. This relationship can expand or contract by changes in the person or environment or both.

Usually, we dwell on changes in the person. But corresponding possibilities of change elsewhere in the social structure exist, and we shall refer to them by the word *inversion*. Such terms as *work*, *education*, *productivity*, and *poverty* also express relationships between a person and the environment and are subject to inversion. If we are to understand and legitimate the experience of the disabled person, these terms must be explored with inversion in mind. The social structure is generally assumed to be natural and unchangeable. This is unjust both to society and the disabled person. Indeed, inversion involves not the adjustment of the disabled person to society but more frequently the adjustment of society to the disabled person—the complex reciprocities of adjustment reflecting back and forth through the mirrors of inversion.

Political and social reality is predicated on our experience. It is in the multitudinous reflections and refractions of countless others that a politics of experience is generated. Without the experience of disability, a politics of disability is arduous if not impossible. Stripped of experience, disability collapses into mere biology, bureaucratic case, or object of oppression. With experience the disabled body is activated and must be reckoned with. Of course, the sorts of politics that the experiencing disabled body can engage with are manifold ranging from exercising our bill of rights to voting, from communicating to organizing, from direct action to subtle pressure, from being constructed to constructive, from power to powerlessness, from freedom to servitude.

Perhaps special education, vocational rehabilitation, and other disability-dependent practices and professions exist to further the goals of professionals and an increasingly complex professional bureaucracy. It is possible that a system ostensibly serving a patient, person, or client primarily serves itself. Such inversion is a theoretical possibility and not a necessary fact. A society that discriminates does not know it erects barriers to disabled people and engages in unnecessary repression. This is particularly evident where society has generated a high degree of freedom from nature through technological mastery. The social and political construction of the disabled world by the able-bodied tends to disenfranchise and stigmatize persons with disabling conditions.

Embodiment, the lived body, discloses what a disability is. Disability is a difference in body orientation as well as appearance and anatomy. Or, to be more precise, disability is experienced as difference in the world inhabited by the lived body. It is, then, not only the body—which in most respects may be the same as a nondisabled body—but the way in which that body is informed by life, intentionality, will, intelligence, and other bodies that is decisive. A person with a disability is experienced as a person with a lived body that is different from the lived body of an able-bodied person. Body is a more interesting and fruitful notion than behavior, the sterile response to a stimulus. It is a more direct, tangible notion than that of action—we all are bodies, know what they are, and what they mean.

Sometimes the disabled person may resent being taken for a body, insisting rather that the real person lies within. Phenomenology suggests that the disabled person may be mistaken in this view. The proper relationship of the self to the body is not one of habitation, cohabitation, or possession, but is much stronger, approaching identity. Rather than "I am in my body," or “I own my body,” or “I and my body go through the world together,” it is more accurate to say, “I am my body.” From the phenomenological explorations of the lived body by Merleau-Ponty, Ricoeur, Sartre, Straus, Levinas, and others, we have learned that the phenomenon of embodiment holds the central place in understanding the meeting place between the “subjective” and “objective” poles of human experience, products of the division of “mind” and “body,” a dualism set in motion by Descartes.

The brain is part of our body. It is an organ of exquisite complexity whose very existence is prima facie evidence of the importance of bodies. Should one give brains attributes like consciousness and the ability to encounter the world with the rest of the body, much of our senses an extension of the brain, the requisite connection of the brain and the rest of the body become self-evident. The experience of our brains is a thorny issue, important nonetheless given the primacy of our brains and our brain’s connection to experience itself. At times, our brains function differently, and mental illness, cognitive irregularity, and even the nature of experience itself change. Our brains are connected to our motor functions, senses, memories, and most of the rest that makes us who we are. If multifaceted, our experience of our brains is important. Sometimes we refer to this experience as “mind” (Minsky).

Often it is not our brains we experience, but rather the actions that issue from them and our bodies. Thus, much of our experience with mental illness is the experience of our actions that mental illness causes and the responses that they elicit from others. We all have the experience of being conscious beings, conscious among other things of our actions. An account of the experience of disability must be one of our actions and brains both—or together. Many impairments derive from the human brain or the difficulties it may have in connecting with other parts of the body. Such impairments may include those of the senses, motor system, cognition, mood, and more. Often our experience of a disability includes our experience of impairment. Often our experience of the impairment is an experience of our brain as revealed to us by other parts of our body, the brain having no sensory neurology to reveal experience. With impairments most commonly attributed to the brain such as emotional, psychological, mood, thought, speech, and reading and writing, experience becomes of supreme importance, for it is our experience of these that brings them to our consciousness and our actions, which may occasion responses by others that refract them into disabilities.

The experience of disability by the disability-experiencing self and by the disability-experiencing other and society rubs up against the non-human world. The relationship between the human and non-human world has transmuted into one where people have or expect to have dominance over most of the non-human world. For example, architecture, systems of transportation, education, and production are part of the human environment, and the disabled person’s experience of them, perhaps hostile, perhaps inviting, is less experience of implacable nature than it is of human artifact. Usually, what human beings make could have been made otherwise. That it is not, and further that it is not even thought of being otherwise, suggests that the non-human environment is often constructed after the needs of some and not of all or even most. It is not surprising, then, that disabled people’s experience of the non-human environment may be painful. It also follows that such awkwardness may in fact be in the face of actions of some people, usually those described as having power. A disabled person’s experience of the human environment may be painful as well. Human organizations, bureaucracy, or culture may be experienced as painful by a disabled person. These are often in the service of those in power. Usually, people with disabilities are poor in power and therefore experience power as domination and oppression, rather than as empowerment and freedom.

When the disabled person desires to be accepted for what he or she truly is, rather than as a mere disabled body, that individual really protests against the obscure and tormenting construction of the disabled body by the able-bodied other. Such protest is in order; but if social oppression is internalized into a bifurcation of the disabled person and the body, insult is compounded.

The key to understanding the phenomenon of embodiment is intentionality. Only a dead body can be reduced to an anatomical object devoid of consciousness and subjectivity. From a purely naturalist or objectivist standpoint, a stillborn child may prove every bit as important to pathological examination as a child born living. The newborn infant moves with precognition to its mother's breast. There is, however, a significant difference between the intentionality of oriented movement and its accomplishment. Here the human experience of disability can be measured by the distance between the intention to grasp, stand, walk, or speak and the ability to do so. Subjectivity is given as embodiment. "Here" and "there," "up" and "down," "before" and "after" are inexplicable abstractions without reference to a world mapped out by an oriented body-subject. Embodiment conditions all spatial and temporal relations. It is embodiment that by engendering perspective compels us to have "experiences." Attempts to devalue human experience run up against the limiting condition of embodiment. Embodiment renders subjectivity universal, and thereby opens up the lifeworld for indefinite exploration.

In a posthumous retrospective, Merleau-Ponty summarized his own discoveries on the meaning of embodiment while pointing out new directions. For contemporary psychology and psychopathology, the body is no longer merely an object in the world under the purview of a separated spirit. "On the side of the subject, it is our *point of view on the world,* the place where the spirit takes on a certain physical and historical situation" (Merleau-Ponty 1964:5). Merleau-Ponty, Straus, and others have already explored cases of disoriented subjectivity arising from differing corporeality to shed light on the phenomenon of embodiment in general. More simply put, phenomenology has buttressed its case by making reference to disability.

The lived body is more, however, than a medium through which self-transparent thought would express itself without interference from its embodiment, and, therefore, its situated history. As Merleau-Ponty (1964:6) states, "The perceiving subject is not this absolute thinker; rather, it functions according to a natal pact between our body and the world, between ourselves and our body." The inner world, or human subjectivity, is rendered possible and knowable by the concrete experience of human embodiment. Disability, viewed from the perspective of functionality alone, is a limiting condition binding childhood to old age. It is discovered in childhood as the "I cannot yet" and in infirmity of age as "I can no longer." In an emerging world of potentially embodied technology, the nature of disability is arguably changing. Yet with existing technology able-bodied assembly-line workers are not unlike disabled people in contemporary society. By expressing knowledge as power, function, or utility innovations in technology can extend the reach of the able-bodied population as well as the disabled, and thereby close the unnecessary, socially constructed distance between the two groups.

To design programs and policies without understanding the experience of disabled persons does violence to their integrity and engenders their understanding of the world in terms of powerlessness, anger, and discrimination. The surplus suffering experienced by the disabled population is largely socially constructed and begs each of us to return to the sources of intimacy and human relations. The face-to-face encounter is preserved in the body's mutability. So, too, is the empathy and love for the one who is other, strange, different, and so rendered by virtue of his or her embodiment.

The precariousness of the able-body is a counterpart to its soundness, for neither the able-body nor the disabled body is dead. Both experience the dynamic of change and the body's incarnation of the will to self-assertion. Both have pasts, presents, and futures. Both are more alike than otherwise. There is, after all, a substantial measure of truth in the conception of the able-bodied person as a temporarily able-bodied person. If this truth is burdensome it is because it is so close to the able-bodied person and the able-bodied person has a stake in an able-bodied existence. To the extent that "negative attitudes" of the able-bodied population toward the disabled may be predicated on fear, it is not taken lightly. What appears as a fear of the unknown is more accurately fear of the known. And what is known although denied as real, its density making it unavoidable (or to be avoided at all costs), is that time and change are unavoidable and, therefore, disability is universal in its implications.

We are at a crossroads where disabled people inform us of the answer to our humanity: "Every incarnate subject is like an open notebook in which we do not yet know will be written." The meaning of humanity is open for both disabled persons and others. The latter should ground their encounters with disabled persons by keeping in mind how their own life-worlds were and are influenced by a complex social structure as well as by the possibilities of inversion. And finally—but not so since there is no finality here—the other must recognize his or her own subjectivity given as embodiment and the different subjectivities and experiences of different disabled people with different embodiments. He or she should never presume to know "what will be written," much less to write it. Assistance in the writing—by skill, teaching, counsel, wisdom, and by helping change the social order–is proper and honorable.

A decent society is measured by the way that people hold themselves responsible for the well-being of one another. The realization of social justice recognizes the asymmetrical relation between the other and the self. The experience of disability, or at least, to use Kant's term, "the possible experience," demonstrates the universal reach of ethical responsibility of one for the other. The social responsibility of one generation for another is enhanced with the recognition of the experience of finitude that disability brings. It also marks the achievement of a certain humanity when the framework of meaningful life and work is extended through refining the ethical obligations that elevate the social contract upon which societies are based. In this sense we are able to ground a policy of non-indifference towards the other as the starting point for further investigation into the experience of disability by inseparably linking it to the domain of ethics by which we measure the human within the order of things. Such an ethics begins with the other rather than the self and breaks with the dominant model of cultural and political imperialism that has dominated Western thinking since Hobbes. The idea of the one for the other is found not in the "State of Nature" as Rousseau thought; rather it begins with the capacity that we have to respond to and for the other.

It is the other who renders explanation philosophically intelligible. Explanation begins by turning towards a *someone* to whom such explanatory discourse can be made meaningful. In this way, to reason is to justify. Prior to discourse itself is the phenomenon of the expression that poses a question, asks something of us, and assigns to us a responsibility for responding. This experience of the expression coming from the other assigns us the possibility of recognizing subjectivity as our own, and therefore being inseparably bound up with an awareness of justice that we are called upon to perfect. This consciousness of the experience of a disability common to all serves as the prelude to any education.

EXPERIENCE OF DISABILITY: BRAZIL

Brazil is one of the few countries to include an entire section on disability in its census (2000). Results showed that 14.5 percent of the population, roughly 24 million people, reported having some form of disability. The poorest region, the northeast, reported the highest percentage of people with disabilities (16.8 percent) while the richest region, the southeast, reported the lowest percentage (13.1 percent).

HISTORY

In the first half of the twentieth century, people with disabilities in Brazil had no voice and no representation. They were either living in isolation with their families, or they were institutionalized. They were primarily studied, diagnosed, and "treated" by professionals such as medical doctors, psychiatrists, psychologists, and educators. In the years prior to World War II, Brazilian professionals viewed disability in three ways: a biomedical puzzle (to be solved using modern technology), an educational challenge, and a social problem. The professionals were divided as to whether disability, particularly intellectual disability, was primarily a biomedical or educational issue. As early as the mid-1800s, there were institutions for different types of disabilities—psychiatric hospitals, such Psychiatric Hospital Pedro II in Rio de Janeiro, and schools for the blind and deaf, such as the Imperial School for Blind Children, now called the National Benjamin Constant Institute, and the National Institute for the Education of the Deaf.

Much scholarly attention was focused on the physical and mental disabilities and illnesses of people living in rural poverty, especially those of African or mixed descent. However, due to Lamarkian-influenced eugenics theories, Brazilian professionals believed that improved health and social welfare would improve the genetic inheritance of these groups. Thus, the focus was not on institutionalization or sterilization of "pathological" populations, as was practiced in the United States and Europe, but rather efforts were primarily focused on improving public health and social welfare. However, laws were passed mandating prenuptual examinations that were specifically designed to deny marriage to people who were deaf or had intellectual disabilities.

Prior to the 1930s, educational programs for children with intellectual disabilities were located in psychiatric hospitals, and children who were blind and deaf were sent away to residential schools. In 1932, however, educator Helena Antipoff founded the first Pestalozzi Society—a community-based school for children with intellectual disabilities. In 1954, influenced by the Arc (formerly called National Association for Retarded Children/Citizens) movement in the United States, parents of children with intellectual disabilities opened the first APAE chapter (Associação de Pais e Amigos de Pessoas Excepcionais [Association of Parents and Friends of the Exceptional]). By the end of the twentieth century, there were 146 Pestalozzi Societies and more than 1,700 APAE chapters throughout Brazil. Many public and private schools currently strive to include children with disabilities, but issues such as proper teacher training and accessibility make inclusion a challenge.

Independent Living Movement in Brazil

After World War II, Brazilians with physical disabilities organized around sports and recreation clubs. There was no existing national public policy on disability. People with different types of disabilities did not have a unified group identity, nor were they represented as a group through the constitution or legislation. What opportunities and rights existed for people with disabilities were the result of isolated initiatives, mainly led by professionals and parents.

In the late 1970s, however, Brazil began to prepare for the International Year of Disabled Persons in 1981. By the early 1980s, there were hundreds of local organizations representing different disability groups. These groups began to work together, for the first time adopting a cross-disability perspective. People began to connect to the international disability rights movements and organized disabled people's councils in most Brazilian states and major cities. For the first time, there were people with different types of disabilities working together and representing themselves.

The experience of self-representation led to further initiatives in both advocacy and service provision.

The first center for independent living (CIL) in Brazil was founded in Rio de Janeiro, Brazil (CVI-RIO) in December of 1988. CVI-RIO was spearheaded by a group of activists with disabilities from the grassroots Brazilian disability rights movement. They differentiated themselves from preexisting advocacy organizations by offering services such as peer counseling, employment placement, and skills training. CVI-RIO established a new organizational model by adapting the philosophy and the services from the CILs in the "first world" to the Brazilian context. As the independent living (IL) philosophy spread throughout Brazil, the demand for personal services for people with disabilities quickly generated more than twenty new centers around the country, each adapted to meet specific needs of the communities in which they are located. In 1999, the National Council of ILCs (independent living centers) was established to ensure that organizations using the term *independent living* in their title adhered to the philosophies of the movement and provided services as well as advocacy.

Priorities of the Brazilian ILC include peer support, personal assistance, personal autonomy, information and assistance about civil rights, accessibility, technical assistance in development and counseling, ILCs led and staffed by people with disabilities, training for leadership, and professional training programs where none are offered by local or national organizations.

In 1992 and 1995, CVI-RIO organized, in partnership with other groups, two international conferences on disability issues called DefRio. Hundreds of participants from more than two dozen countries attended. During DefRio 95, participants drafted a document titled "Goals of the ILM." This document delineated the basis for the independent living movement (ILM) in Brazil, whose goals and objectives were applicable to current and future ILCs. Since financial support is not provided by the government, the ILCs struggle for sustainability through a variety of means, including grant writing, producing adaptive equipment, and acting as an employment placement service for people with disabilities. The employment placement services benefit from federal laws instituting a quota system that generates job-contract opportunities between companies and organizations of people with disabilities.

DISABILITY IN CULTURE AND POLITICS

Brazil has progressive policies toward disability. The Brazilian Constitution includes sections on the rights of people with disabilities and laws have been passed with regard to accessibility, education, and employment. The laws are enforced by the Office of the Public Defender on local, state, and national levels. Discrimination is penalized with prison and fines. This office, called Ministério Público, also promotes public awareness campaigns on legislation and civil rights of disabled people, among other minorities. They reach out, for instance, to big companies and pressure them to comply with employment regulations. As a result of the laws and partnerships to enforce them, individuals with disabilities are participating in the society in record numbers and the cultural impact is in proportion to this increased visibility.

On the national level, people with disabilities are elected to office in large enough numbers for there to be an association of national members of Congress with disabilities. Within the Secretary of Human Rights of the Ministry of Justice, there is a National Council on Disabilities and CORDE, the main Disability Office for the Inclusion of People with Disabilities. This office is responsible for the development of policies on social inclusion, protection of rights, and promotion of citizenship for people with disabilities.

Brazil is a Catholic country with a paternalistic structure of family relationships. In contrast to a cultural model where "independence" is achieved when adolescents or young adults leave their parents' home, Brazilian children often do not leave home until they get married, and may even return if the marriage ends in divorce. This homecoming is not necessarily dependence, but rather a form of interdependence reinforced by economic necessity. People with disabilities may not have the possibility to attain this type of "independence" and may rely completely on family to fill all their needs, while those without disabilities may have more opportunities to maintain autonomous spaces for themselves through their work, friendships, and romantic relationships. Although there is still a persistent lack of visibility and equal opportunities for people with disabilities to fully participate in society, there is more potential for IL than ever before in Brazilian history, due to Brazil's social development process as a whole and the progress made by the disability sector, specifically.

Through the disability rights movement and the support of the new laws and enforcing mechanisms, disability groups are taking important roles, both as advocates and service providers, to move the disability agenda forward. The IL concept is now beginning to be understood and spread all over the country: autonomy, empowerment, and self-determination as keys to a new human rights approach to inclusion and full participation.

EXPERIENCE OF DISABILITY: CHINA

There are 60 million disabled people in China (includes sensory, physical, intellectual, and mental health impairments). Discrimination and disadvantage are daily experiences. Long-standing negative attitudes combine with structural barriers, making it harder for disabled people to attain personhood through work and marriage. In a country ambitious for economic and scientific progress, disabled people have to show they are not a liability.

Inevitably, given the scale of underdevelopment in many parts of China and the size of the population, there is limited state provision and heavy reliance on self and family. A series of laws and initiatives, led by the China Disabled Persons' Federation, have increased visibility and awareness and have affected hundreds of thousands of people, but the quality and availability of medical and support services vary widely, are heavily concentrated in large cities, and are accessed only by those with money and good social networks. There is growing demand from some city-resident parents of disabled children and educated disabled adults for services and opportunities; this has potential for positive change if helped to develop. Prospects are bleaker in parts of rural China where poverty is entrenched and disabled people fare worse.

ATTITUDES

Attitudes are changing, especially among urban élites, but there is extensive evidence of discrimination in all aspects of life. Confucian legacies of bodily difference as nonnormal persist, deepened by the construction of the active and productive body during the socialist Mao years, and the emphasis on economic growth and mobility since the 1980s. The language of disability is inscribed with notions of sickness, deficit, and worthlessness. Positive attempts to promote neutral terminology have yet to trickle down through China's social strata. Pejorative words are widely used, but less so face-to-face than in the past. Pity and disdain increase with the severity of impairment. Particular stigma attaches to intellectual impairment and mental illness, especially in urban areas where education and employment are markers of personal status and ability. People with congenital impairments (seen as evidence of wrongdoing or neglect in pregnancy, bringing particular shame on the mother) are treated more negatively than people with impairments acquired through illness, accident, or military service.

DISABLED CHILDREN

Since the economic reforms of the 1980s, families with disabled children have faced increased socioeconomic vulnerability and pressures. Former sources of (limited) support from work units or collectives have been eroded, particularly the practice of providing employment in the parents' work unit upon adulthood. The one-child policy and increased opportunities to make money for those with ability (*nengli*) have intensified parental hopes for their children, making diagnosis of childhood disability even more devastating.

Having a disabled child is seen as a major misfortune for the household as well as the child, whose own prospects for making a decent living, having a family life, and supporting parents in old age will generally be diminished. For the household, it signifies reduced productive labor, including from family members required to provide care; damaged social standing and perhaps damaged marriage prospects for nondisabled siblings; and increased costs of seeking medical treatment. Family and societal expectations to seek a cure are very high. The search begins locally, can last for years, and takes families far from their homes, with rural families traveling to the cities to get the best help they can afford. Parents take on additional jobs, sell their assets, and incur debts. Both Chinese and Western medicine are used, doctor-swapping is expected, and diagnoses of incurability may go ignored for years. Advertisements promising cures for deafness or paralysis add to the pressures, but a cure is seen as the best guarantee of averting the poverty that, as the saying goes, is bound to follow disability (*fengcan biqiong*).

Abandonment is illegal but still occurs for girls (nondisabled and disabled) and for disabled boys, despite permission to have a second child if the first child is disabled (the government also operates relaxed rules for domestic and foreign adoption of disabled children). The practice of keeping a disabled child hidden at home has reduced with increased educational opportunities (since 1994, schooling has been compulsory for disabled children). Notwithstanding, many parents are highly protective and may restrict the extent of interaction that their children, including adult children, have in the local community for fear of abuse or being taken advantage of. In urban and some rural areas, children with mild physical impairments access mainstream schools; children with visual or intellectual impairments and deaf children attend segregated schools or classes (Alison Callaway has done an insightful study of Chinese deaf children, their families, and education). In poorer areas, school is a luxury for parents, who may struggle to pay the fees, although some families prioritize education for their disabled child.

ADULT PERSONHOOD

Work and marriage are the central markers of personhood in China. How far disabled people attain these is often shaped by gender, impairment, and location.

Opportunities for mainstream employment are limited. Even the tiny number of high-achieving disabled graduates has encountered serious difficulties in getting a job, due to negative employer attitudes in a highly competitive labor market. Most state and private employers prefer to pay a fine than comply with the quota system of 1.6 percent disabled employees. There is evidence from welfare and commercial enterprises of disabled people on the payroll who have been paid to stay at home, often against the wishes of disabled people who want to work. Around 1 million disabled people work in social welfare enterprises (sheltered employment provided in factories or local workstations). However, a qualitative study by Pearson, Wong, and Pierini on the employment experiences of young adults with learning disabilities suggests that welfare enterprises are struggling despite tax relief (in Guangzhou Province a drop from 3,113 welfare enterprises in 1995 to 394 in 1999) and that low-waged, low-status work and phantom employment frustrate young people's ambitions to work and contribute to the family income, and thereby attain adult status.

In cities, more disabled people are becoming self-employed, perhaps assisted by vocational training, tax relief, and/or permission to buy a three-wheeled welfare-motorbike that can carry a passenger or goods. Often disabled people work in basic-level and stereotyped jobs (visually impaired masseurs or piano tuners, appliance repair, tailors, data entry, packing, cleaning). In poor rural areas, prospects are bleak for disabled adults whose impairment reduces their ability to do physical work or join the so-called floating population of 100 million migrant men and women who leave the countryside to find work in the cities and Special Economic Zones.

Economic self-reliance increases marriage prospects but is no guarantee. A complex hierarchy of attributes comes into play: gender, type and severity of impairment, whether impairment is congenital or acquired, residence (rural/urban), education, family status, and background. While Chinese men are more likely to be never married than Chinese women, the incidence of never-married disabled men is dramatically higher than among disabled women. Matthew Kohrman's analysis of the experiences of middle-aged men with a wobbly gait (mostly polio survivors) attributes this to the smaller gap perceived to exist between the female disabled body and dominant constructions of female personhood (at home, bringing up children), compared to that between the male disabled body and constructions of manhood (out of the house, mobile, active).

Hierarchies of normalcy intersect with gender, location, and education to shape what makes an appropriate match. For example, an urban disabled woman might be expected to marry a nondisabled man but he would probably be from the countryside with lower education. Deafness and intellectual impairment may be less stigmatizing in rural than urban areas, and for women than men, reflecting the different ways in which livings are earned and social status acquired. The process of marriage exclusion can be protracted and painful, particularly for disabled men. For disabled women, finding a (nondisabled) spouse may be easier but little is known about the quality of their marriages and incidence of domestic violence.

IMAGES AND IDENTITY

The China Disabled Persons' Federation has endeavored to improve public images of disabled people, showcasing entrepreneurs, athletes, and artists who have contributed to China's economy and international standing. There has been a proliferation of manuals, magazines, research, and creative writing, including by disabled people (Shi Tiesheng is one of China's most popular writers), and also films such as *Beautiful Mama* (1999) starring internationally acclaimed Gong Li as a divorced mother putting her deaf son through mainstream school. All challenge negative attitudes of disabled people as worthless (*canfei*). They also put ordinary disabled people under intense pressure to demonstrate their worth and aspire to be better than so-called healthy or normal people.

There are signs of shared identity among some strata of disabled people. Kohrman has written about identity and brotherhood among urban men with physical impairments; there is an emerging Deaf cultural community; there is increasing collective action among parents of disabled children, ready to set up support groups and services where permitted. The extent to which disabled people and families identify with the China Disabled Persons' Federation and the term *canji* (disabled) is likely to reflect what the individual can expect to gain. Parents may delay registering their child as disabled in case this restricts access to mainstream school. In contrast, growing numbers of disabled men register to get help with starting a business or a license to drive a three-wheeled welfare-motorbike. Some commentators are pessimistic about the scope for civil society and a grassroots disability movement in the People's Republic of China. Certainly, this is unlikely across much of China where basic needs preoccupy families and local governments, and where strong legacies of negative attitudes act against individuals and families acting to draw attention to themselves. But among urban élites, as domestic and international networks expand and as more disabled children finish school and college, supported by family and friends, there is cause for cautious optimism.

EXPERIENCE OF DISABILITY: COLOMBIA

Colombia is a country in South America, in the northwestern part of the continent, south of Panama. The capital and largest city of Colombia is Bogotá, with a population of about 7,000,000. In 2001, the total population of Colombia was reported at about 43,000,000, with 73 percent of the population living in urban areas. The majority of the country's population is young; 54 percent of the total (18 million people) under 18 years of age. Life expectancy at birth for the overall population is 72 years. It is estimated that about 95 percent of the population is Roman Catholic. Religion has played a critical role in how disability is perceived. Some view disability a punishment from God. Others see it as a challenge imposed by God to prove one's faith and courage. Children with disabilities are often hidden from public view, in part because of family members' shame, guilt, and lack of education about disabilities. This entry covers incidence of disability, current disability laws and policies, living conditions for people with disabilities, and current efforts to address disability concerns.

INCIDENCE OF DISABILITY

The 2003–2006 Plan Nacional de Atención a las Personas Con Discapacidad (National Plan of Attention to Persons with Disabilities) estimated that 18 percent of the general population has some type of disability. However, the government recognized the difficulty in having an accurate estimate due to the lack of adequate methods to conduct a census in rural areas and families displaced by violence and insurgency. It is also difficult to assess the characteristics of the homeless population. Moreover, there is a tendency for families experiencing shame not to report the presence of a family member with a disability. It is estimated that of those identified with a disability, 68 percent have sensory, physical, and/or cognitive impairment; the majority experience blindness, deafness, paralysis, and/or loss of limbs. It is estimated that 12 percent of people with disabilities are under 14 years old and 27.6 percent are over 60, and that over 60 percent of people with disabilities are males. Disability in the infant population is mostly due to prenatal, congenital, or infectious conditions. Young male adults also experience a high rate of disability, mostly associated with injuries, accidents, and the current violence and guerrilla war.

CURRENT LAWS AND POLICIES

In 1991, Colombia promulgated and passed into law a new constitution, which was intended to recognize and protect the rights of people with disabilities. The adoption of the new constitution provided a national policy in which people with disabilities had opportunities for social participation in the areas of education, communication, health, well-being, work, transportation, information, sociocultural development, and recreation and sports. Specific policies that were enacted included entitlement programs to assure benefits to eligible disabled individuals and discretionary grant-in-aid programs. In addition, supplementary financial assistance was approved to support specified activities for people with disabilities, and incentives (appropriations bills, tax legislation, and loans) are provided for covered entities to comply with the existing regulations regarding the rights of people with disabilities. Examples of these regulations include access to local and nationwide television channels, as well as access to sport activities through the Paralympic Federation. Much of the new constitution of 1991 focused on general rights and social and recreational programs with little or no emphasis in the areas of education, housing, employment, public accommodations, and transportation.

In 1997, the government passed the General Act for People with Disabilities also known as the Disability Act: Law for Opportunity, which includes five titles covering basic rights, education and rehabilitation, social welfare, accessibility, and transportation and communication. The implementation of these national policies is coordinated by the Ministry of Health and the year 2000 budget allocation was US$3.6 million. Yet many people with disabilities are not aware of the law, the national plan, or of their benefits. As of 2001, Colombia had 37 disability-related legal policies. The majority of these regulations are national civil rights statutes that provide people with disabilities with human rights and liberties, such as the protection against discrimination based on one's disability. Despite the existence of these laws, the government provides limited spending on programs that protect the rights of people with disabilities, and the lack of enforcement of disability rights is a major concern.

DAILY LIVING CONDITIONS

In the areas of daily living, people with disabilities face a number of barriers and challenges. People with disabilities are often marginalized in employment, education, and housing. Colombia has faced an economic crisis and guerrilla violence since the 1950s. These problems have led to an overall unemployment rate close to 25 percent as of 2003, the highest in its history. As a result, many young adults and families with small children sell goods on the streets. With such conditions, people with disabilities are not a priority when it comes to job placement, and as a result, 80 percent are unemployed. It is not unusual for individuals with physical disabilities to become street vendors.

In the area of education, access to free elementary education is available and much effort has been devoted to eliminating illiteracy. However, children with disabilities are often rejected by public and private schools resulting in a high rate of illiteracy. Forty percent of people with disabilities are illiterate. These rejections result from lack of accommodations, lack of accessibility, and lack of trained teachers to assist children with disabilities. Upper-class families with children with disabilities often send their children to expensive private segregated schools for children with special needs. A limited number of public educational centers are available for children with disabilities, and such centers often face funding problems.

Housing is an area in which people with disabilities face many challenges. In Colombia, public and private funds to remodel and accommodate homes to meet the needs of people with disabilities are not available. Most people with physical disabilities depend on family members to move around and to have their needs met.

In terms of welfare benefits, the only disabled people in Colombia who receive a pension are either military personnel who become disabled while on duty or insured workers who become disabled while on the job. No other individuals with disabilities receive pensions, social security, or health care coverage. There is no welfare system to assist them.

Accessibility around Colombian cities and small towns can also be challenging because many are more than 400 years old. Small rural villages and towns are not wheelchair accessible, since streets are often made of dirt, stones, or gravel. Furthermore, only people with disabilities who come from wealthy families have access to technology (e.g., adapted computers to communicate) and equipment (e.g., power wheelchairs) that they import, mostly from the United States.

Some efforts have been made to increase accessibility and mobility in the large urban areas such as

Bogotá. For instance, the new public transportation system, Trans Millennium, involves a system of rail buses that provides fully accessible transportation for people with physical disabilities including ramps and wide accessible entrances. This system is one of the first accessible transportation systems in Latin America. In large urban areas, most streets have curb cuts and most modern buildings have elevators.

CURRENT EFFORTS

Another component of the 2003–2006 National Plan of Attention to Persons with Disabilities has been to develop community awareness efforts throughout the country. These awareness efforts include marathons with the participation of the general population to raise money for educational programs for children with special needs, Special Olympics, new organizations such as ASCOPAR (Colombian Association for the Development of People with Disabilities), and media awareness campaigns to stop the use of negative language and characterization of people with disabilities. Some programs have gained national recognition such as Foundation Teletón, the Foundation for the Development of People with Disabilities, which sponsors rehabilitation and recreational programs for people with disabilities. DAVIDA (Give Life) was created by a mother of a child with a disability and provides comprehensive services for children with disabilities at one center.

Despite current laws and efforts to protect the rights of people with disabilities in Colombia, much remains to be done to further the implementation and enforcement of existing laws and policies.

EXPERIENCE OF DISABILITY: COSTA RICA

As many other countries, Costa Rica has been influenced by the traditional, medical, and rehabilitation models that led societies to consider a disability as a “problem” and the person with disability as the cause of that problem. Those models reinforced the view of people with disabilities as dependent, ill, incompetent, limited, or even subnormal. The concept of being “normal” is a fallacy that still persists in the imagination of those who are not aware that being different is in fact being “normal.” The purpose of this entry is to share with the reader a descriptive analysis of the experience of living with a disability in Costa Rica.

During the past decade, the experience of disability in Costa Rica has been changing, an ongoing but slow process. Quantitative as well as qualitative changes have had an important impact on the public and private services offered by various sectors of the Costa Rican society such as education, health, employment, culture and recreational activities as well as the accessibility to information and communication. Considering living conditions from a human rights development perspective and the increasing participation of disabled people and their families’ organizations have contributed to these changes.

The social and economical context in which the majority of people with disability live in Costa Rica, in many cases conditions of extreme poverty, has influenced the quality of life of disabled people and is still limiting their access to services particularly in their own communities and in rural areas of the country. Furthermore, these economic limitations have definitely interfered with the efforts being made in terms of legislation and the promotion of human rights and opportunities. Despite all the actions taken to change attitudes and awareness about the needs of disabled people, experiencing disability in Costa Rica is closely related to and cannot be separated from economic and social development.

> After a half century of economic performance that was well above average for the region, Costa Rica has begun to experience a significant slowdown. The worsening economic situation is reflected in a stagnant poverty rate, which has remained constant at 21% over the last eight years, and an increasingly large gap in the distribution of income between rich and poor. (National Institute of Statistics and Census 1998)

According to the Ombudsman Office, the population with disabilities is among the most excluded sectors of Costa Rican society. Two surveys provide data about the general population and the percentage of disabled people. The Multipurpose Household Survey, conducted in 1998, reported that the population of the country totaled 3,340,909, of whom 261,371 persons, approximately 8 percent, had a disability. The National Census included for the first time information about disabled persons, and it reported that the total population was 3,810,179 and persons with a disability were approximately 5 percent of the general population. The difference in percentages was interpreted as methodological, since there are factors such as how disability is understood by the interviewers and who provides the information.

Based on the country’s economic conditions, there is no doubt that the social model, as it applies to disability experience in Costa Rica, inevitably leads us to concentrate on the priorities established by the government regarding social policies, the provision of additional funds to provide accessible services, and the inclusion of specific indicators related to disability experience as an effective measure to monitor the national development with regard to disabled people’s lives.

One of the turning points, during the past decade, was the approval of the Law 7600 in May 1996, called Equal Opportunities for People with Disabilities in Costa Rica. Before the existence of that law, there were already various projects presented by members of the General Legislative Assembly and the Costa Rican Parliament, and there was already a long list of demands presented by disabled people and their families at the Ombudsman Office, most of them related to lack of access to buildings, services, and educational accommodations.

The law was also inspired by the United Nations Standard Rules on the Equalization of Opportunities for Disabled People, published in 1993 by the United Nations and prepared by a group of experts who were people with disabilities themselves. The General Legislative Assembly in Costa Rica ratified this document. Even though the Costa Rican National Constitution guarantees the same rights to all Costa Rican citizens, it became obvious that these rights with regard to disabled citizens were not guaranteed on an equal basis with others.

Disability experience in Costa Rica has been definitely transformed in many areas as a result of the mandates of this generic law. There is no question about the fact that people with disabilities and their families in Costa Rica started to use this legal instrument as a strategy to empower themselves and to become aware of their rights as well as understanding the role of the state in accomplishing its responsibilities.

Education has been historically a priority for the Costa Rican government, and a significant part of the national budget is invested in education in general. Traditionally, as in many other countries disabled students have received their education in special schools. The first special school in San José was opened in 1940, and many young disabled people ended their education process in vocational training programs offered in sheltered workshops, some of them administered by nongovernmental organizations.

Even though access to educational programs was mainly offered in special settings, an increasing number of disabled students are attending regular primary and secondary schools as well as regular schools at the higher education level. According to the implementation of the law, support services have to be provided at all levels and modes of education, from early stimulation programs up to higher education. Support services include access to the curriculum as well as curriculum accommodations.

Experiencing disability in the Costa Rican educational context is still a continuous and great challenge for the national educational system, public and private. At present, one of the main educational barriers for young students and adults with disabilities seeking to finish their studies is the lack of professional resources, mainly educators who are trained specifically to teach students at the secondary or adult level. In a special report from the Ministry of Public Education, presented to the National Council of Rehabilitation and Special Education (CNREE), the national institution responsible for monitoring institutional progress in the field of disability, it was stated that "the model of teaching students with disability-related educational needs has shifted towards a new model that aims at providing schooling opportunities in less restricted environments" (Ministry of Public Education 2002). Presently, the diversity of programs in education include special schools, integrated classes in regular schools, and support services specialized in different disabilities. Teachers working in these services work together with the regular teachers so that the education program responds to the special educational needs of the students based on the regular curriculum.

The Statistical Department of the Ministry of Public Education indicated, based on growth rates in 2000–2001, that there were approximately 79,600 students with educational needs related to different disabilities attending regular classes in 2002. The majority of students with disabilities have access to regular education classrooms, but some are receiving their education in special classes located in regular schools or special schools. It was reported in 2002, by the Department of Special Education of the Ministry of Public Education, "Students with special educational needs comprise about 10.13% of the total number of students. Thus, out of a student population of 937,154, there are approximately 95,000 students with disabilities" (Ministry of Public Education 2002).

The transitional stage from education to work remains a challenge for professional training as well as for some nongovernmental organizations administrating sheltered workshops with a very low budget and little technical support. Systematic efforts have been made recently to provide access to technical education for young people to increase their competence at applying to jobs. For example, the National Institute for Learning (INA), which offers educational opportunities for all people in many regions of the country, has been putting into practice a variety of measures such as providing curriculum accommodations for people with intellectual disabilities who traditionally have been segregated from such programs.

Higher education for students with disabilities is mainly offered by public universities. Most disabled students are concentrated in public universities. Some private universities have started to introduce services for disabled students. There are four public universities that have been working together in a special committee to share experiences on accommodations and to prevent discrimination acts against students. Support services offered by these universities to students include sign language interpreters in classrooms, Braille printing, tutoring, text recording, note taking, and access to computers by training students on the use of text reading software, which is taught by a blind student. Deaf instructors offer courses on Costa Rican Sign Language (LESCO), and the national association monitors the quality of education for the deaf. It should be highlighted that during the past few years more disabled students have enrolled in various graduate programs, such as linguistics, law, project evaluation, and interdisciplinary disability studies.

Access to employment it is still a challenging experience for people with different disabilities, mainly for people with intellectual disabilities. Even though Law 7600 refers to specific measures to be taken by the Ministry of Labor, it has been very difficult to put them into practice. The ministry's national director of employment acts as a facilitator to contact potential employees, but this process seems to be very slow. It was reported by the Ombudsman Office (1999) that "only 15 disabled workers were hired." This office also promotes self-employment and the development of small businesses; however, people with disabilities often cannot meet loan requirements and therefore their opportunities are limited. The National Council on Rehabilitation and Special Education offers loans through a rotating fund so that people with disabilities can initiate their own businesses.

Recently, some positive actions have started to promote access to employment. A special unit was established to facilitate accessible conditions as an incentive to public institutions and the private sector so that they hire disabled employees. Some organizations of disabled people have estimated that the unemployment rate among this population is approximately 65 percent. This situation means that many disabled people and their families live in a constant struggle to survive and have limited participation in society.

Health services in Costa Rica are available through a public health system; a public institution, the Costa Rican Social Security Fund, also covers rehabilitation services. These are mainly offered by the National Rehabilitation Center (CENARE), a hospital located in San José, the capital of Costa Rica, and the National Psychiatric Hospital, which provides temporary and permanent services to people with mental disabilities.

General health services are available in regional hospitals and clinical settings, and recently there has been a new development, Comprehensive Health Care Units, called EBAIS, which have been located in urban as well as rural areas of the country and cover smaller communities. Some of these units are training their personnel to support disabled people in their communities.

Though there is a large coverage and access of people with disabilities to the general health system, rehabilitation services are not available at the community level and not all the infrastructure is accessible. Another important limitation of the system is the limited provision for technical aids and assistance devices, which according to Law 7600 should meet the requirements of disabled persons. In some cases, wheelchairs are provided by private organizations as part of a social welfare program, reinforcing the traditional view of disability and not as part of the obligations of the state or as a human right.

Other areas covered by the law include access to housing, buildings, transportation, information, communication, and recreational activities. The inclusion of accessibility as part of public life is a slow process. According to the law, new buildings have to be designed to meet accessibility requirements in order to obtain the construction permission given by the government. The concept of universal design is not yet incorporated into construction planning, and professionals working in this field are starting to be trained with regard to accessibility guidelines.

In some cases, accessibility is considered during the process of designing but is not well implemented or supervised by the government. Since San José and other regions of the country had not been planned to be accessible, it is still very common to find partially accessible places, where there are ramps to access the first floor but no elevators or accessible bathrooms. There is an increasing effort from the private sector to build accessible hotels and to offer accessible facilities in restaurants and shopping areas. A project provides guidelines to National Parks to have pathways and signals accessible for visitors.

Public transportation is starting to become accessible. The National Council on Rehabilitation and Special Education has negotiated with private enterprises and the Ministry of Public and Transport to start accessible services with a percentage of their units and routes and continue increasing these services until all buses are accessible. According to Law 7600, 10 percent of the taxis must be accessible. Many drivers who are interested in this kind of service have already obtained registered plates but are unable to obtain vehicles to operate because of their high cost. There is still much to be accomplished in terms of public transportation. Drivers should become aware of the needs of all people including persons with different disabilities and be trained on how to properly provide this kind of service.

As a general consideration, it becomes obvious that experiencing a disability in Costa Rica is relative to the living conditions and opportunities of all Costa Rican citizens. All the social and economical policies that affect the majority of people in this country have an impact on the quality of life of disabled persons. Nevertheless, the results during the past decade show systematic progress toward improving the living conditions of disabled people in Costa Rica and the continuing efforts toward including their particular needs, such as access to education, health, work, housing, transport, and recreation, as part of the national development planning. A crucial factor to accelerating this process is the pressure and participation of an organized movement of disabled people as a way of vindicating their human rights. Universities have an essential role in promoting access and supporting disabled students but also should educate all professionals with regard to their attitudes, knowledge, and skills necessary to develop an accessible society.

EXPERIENCE OF DISABILITY: INDIA

The history of experiences of disabled people in India has never been recorded systematically. It would be unwise to generalize disability experiences because they are contextualized in a culture and region that is very diverse in a country the size of India. There is a dearth of historical investigation and resources. What little is available is archived in the interpretation of folk tales, mythology, special education, social welfare policy, and the Hindu and Islamic religious texts and other scriptures. An analytical study of these sources exhibits the following characteristics. First, in urban settings where it is being recognized that disability is an issue of development and rights, there has been a remarkable change in attitude toward disabled people. This change has come in the past 10 years, partially due to globalization and the self-help movement of disabled people. Second, Indian scholars tend to interpret disability experience in the context of mythology and other historical sources, viewing it as a result of as extreme neglect, past sins, or evil epitomized in the crooked body. Third, in the precolonial period the attitude of religious charity existed and care and welfare of disabled people were the responsibility of families, the state, and religious institutions. Fourth, archival evidence suggests that disabled people did not enjoy an equal status and were denied the opportunity of education and development. Attention to their education started with the emergence of Christian missionaries in the colonial period. Fifth, the level of acceptance, discrimination, and stigma varies with the type of disability, its onset, family's educational background, and also the region.

References to disability can be found in the two prominent mythological epics, *Ramayana* and *Mahabharata,* which form the basis of societal responses to disability and help in exploring the meaning of disability in India. A study of disabled characters in these texts demonstrates, on one hand, acceptance of disabled people in positions of power (although marginally); on the other hand, these images go a long way in perpetuating the idea of equating disability with evil, weakness, and inflicted as a form of punishment. In *Ramayana,* Manthra—Queen Kaikeyi's (consort of King Dasaratha) favorite maid—though hunchbacked, enjoyed an exalted status. However, she is held responsible for the exile of Lord Ram—heir to the throne after King Dasaratha—by her machinations. Another episode is that of Shurpanakha, the she-demon. She was Ravana's (the chief antagonist) sister who had eyes on Rama and wanted him for her husband. On sensing that Rama was not interested in her, she pounced on his wife Seeta, upon which his younger brother Lakshmana cut off her nose and ears and thus defaced her.

In *Mahabharata,* King Dhritrashtra of Hastinapur is blind. But he is a weak ruler and his status is used as a rubber stamp by his sons called *Kauravas.* The episode of Bhagwad Geeta (holy text of Hindus) in this epic sets the code of conduct for rulers to follow in their treatment of the disabled. It prescribes that people with visible disabilities such as being blind, crippled, or otherwise deformed, and especially the war veterans and their dependents, should be treated with sympathy and care. Bhagwad Geeta also establishes the rules for practicing charity and lays down the theory of good and bad karma (deed)—that disability is a result of moral sins committed in former life. It further prescribes the forms of charity—*artha* (money), *vidya* (education), and *abhaya* (courage). There is evidence that charity of *artha* was practiced generously but other forms of charity, that is, of education and courage, were rarely followed. It can be said that although disability was a social construct, it was not seen as such. It was perceived more as an economic problem and therefore remedies were provided in the form of charity. In this way, disability was intricately associated with poverty. The solution was seen more in terms of handing out doles rather than empowering them with education and other skills. The dictates of Manu—the ancient Hindu lawgiver—in his work Manusmriti, written between 200 BC and AD 2 and translated into English from Sanskrit in the colonial period, exhibit a dichotomy. On one hand, he lays out that those who are afflicted should be given food, clothing, and shelter, and be exempt from paying taxes; on the other hand, he refuses to give them the right to social equality since he deprives them from inheriting property and occupying any position in the decision making. In the rules for householder, he prescribes that he should "wed a female free from bodily defects." He treats physically and mentally disabled people, women, people of low caste, and aged at par with insects and dogs.

Thus, in ancient India, disability was believed to be a consequence of actions done in past or present life. This was corroborated even by the medical works such as *Charaka Samhita* (an authoritative book on the Indian system of medicine). The folk tales and ballads of Bengal, on the other hand, also hold mothers responsible for producing disabled babies. There is no evidence of the neglect of disabled people by the families, caste, and rulers; however, there definitely are images of blind beggars in folk tales and ballads. They also give evidence of blind people as talented musicians, singers, and poets. This has gone a long way in keeping the visually disabled out of the purview of other vocations. Even in independent India, the government jobs reserved for the blind in several states have been those of music teachers.

The position of disabled people improved in the reign of Maurya Dynasty between 322 and 299 BC. During this period, Buddhism and Jainism emerged as a powerful influence. They emphasized the virtues of nonviolence, charity, truth, purity, selfless service, and compassion to the disabled. For the first time, vocational rehabilitation for the disabled was looked at in ancient India. Kautilya, the prime minister of Chandragupta Maurya, wrote a manual for administrators and politicians called *Arthshastra,* where he called on them to employ dwarfs, the hunchbacked, and otherwise deformed people as political spies as well as secret agents in the royal palaces. In the reign of Ashoka, medical rehabilitation also started.

In medieval India, between the thirteenth and eighteenth centuries, the Mughal rulers continued with the practices set by their Hindu predecessors. They strictly adhered to the five *rukans* (duties) enshrined in the holy Qur'an, one of them being *zakat* (charity). As Mani describes,

> The forms that this charity took were: alms to the poor and the infirm: construction of mosques, rest-houses, erection of ponds, hospitals and orphanages. The Mughals had a special department with a head (sadr) to supervise charities and endowments. During the reign of Emperor Akbar, the benefits of such charitable institutions were extended to include even the non-Muslims.

The period of India's colonization by the British is seen by scholars as the beginning of the era of institutionalization of disabled. Prior to this there was no concept of educating and institutionalizing them and family was still the primary caregiver. It was seen more as an infringement and an attempt to break the traditional systems. They promoted a culture of custody rather than care. Special education institutions for the hearing and visually disabled were established in 1880s in Mumbai and Amritsar, respectively, by Roman Catholic missionaries. If, on one hand, the advent of colonial rule in India resulted in the creation of segregating environment for the disabled, on the other hand, it also helped in the formulation of welfare policy, which included disability. The first census of disabled people also commenced in this period—a practice that was discarded in the postcolonial period and restarted in 2001 after a lot of agitation.

The modern disability movement in India began in the early 1990s. The responses to disability by the government and society prior to this were more in terms of catering to the medical, rehabilitation, and welfare needs of disabled people. Disability groups had started organizing themselves and groups of visually disabled took the lead. They were successful in getting reservations for themselves in education and government employment, tax concessions, and travel concessions. Other disability groups also started demanding similar benefits and entitlements. Their demands were accepted, but they were more a piecemeal measure. They were not entitled to any benefits as a matter of right. Cross-disability groups started joining hands in the early 1990s to demand for a comprehensive disability rights legislation and protection of rights. After a prolonged struggle, the Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act was finally passed by the Indian Parliament in 1995. The enforcement of this act has brought some change in the experiences of and responses to various categories of disabled people in India, especially in the urban areas. According to a Cross-Cultural Applicability Study conducted in Bangalore, Chennai, and Delhi—three metropolitan cities of India with high rates of literacy—mental disability, HIV/AIDS, and substance abuse remain the most stigmatizing, and mobility impairment and blindness are the least stigmatizing. Provision of accommodations for the disabled in the physical environment—for example, by construction of ramps—is at a very basic stage. Awareness among the general public, judiciary, government, and disabled themselves regarding their rights is gradually increasing. Employment and accessibility are the crucial issues that are being raised today. Little attention has been paid to the issues of disabled women. Overall, though, Indians still see support to disabled as a matter of charity and an act of kindness rather than a development and human rights issue. In the absence of any substantial archival material, it is difficult to map the experiences of disabled people in India. However, it could indicate the areas of future research.

EXPERIENCE OF DISABILITY: IRELAND

PREVALENCE OF DISABILITY

Over the past 20 years, there have been repeated criticisms about the lack of reliable data on disability in Ireland. Since the late 1990s, the Irish Health Research Board (HRB) has undertaken the measurement of the numbers of people with intellectual disability and those with physical and sensory disability in Ireland. In 1995, the HRB began compiling the National Database of individuals with intellectual disability in the country. The HRB is also currently compiling the Physical and Sensory Disability Database, which will be used for planning developments and prioritizing service needs. A recent report shows that there were 26,668 people registered on the National Intellectual Disability Database in 2001, representing a prevalence rate of 7.35 per 1,000 of the population. The report noted that the total number with more severe levels of intellectual disability has grown by 31 percent since 1974 when the first census of this population was conducted. This increase is attributed to the general population increase over the period, improved standards of care, and an increase in the lifespan of people with intellectual disability.

The report also shows an increase in longevity in those with intellectual disability with those ages 55 years and older, who now represent 11.3 percent of all those with intellectual disability in Ireland. However, a most significant change is the large increase in those with disability currently in the ages 34–54 group. This cohort has now grown from 19 percent of the overall population of those with intellectual disability in 1974 to 32 percent of the overall population in 2000. The impact of this aging population of people with intellectual disability has major implications for service planning and provision. It is likely that data compiled on numbers of people with physical disabilities will show similar patterns of increased life expectancy.

NONGOVERNMENTAL ORGANIZATIONS IN SERVICE PROVISION

A unique aspect of the provision of services to disabled people and their families in Ireland is the major role played by voluntary (nongovernmental) organizations in the development of services for those with disability and their families. The growth of such organizations is often derived from the work of individuals, concerned groups, and religious orders trying to address gaps in state service provision. Other disability services have evolved from other medical services founded to respond to specific medical situations such as the tuberculosis epidemic of the 1940s and a serious outbreak of poliomyelitis in the late 1950s. Some voluntary organizations address the specific needs and issues of a single condition such as cystic fibrosis, muscular dystrophy, or multiple sclerosis. Fewer, larger organizations encompass a wider range of disabilities in their brief such as the Irish Wheelchair Organization for adults with a variety of physical conditions that impact on their mobility. Services for those with intellectual disability are also largely provided by voluntary organizations and are provided primarily on a geographic basis to individuals and their families.

Traditionally, Irish voluntary organizations have played both a pioneering and a reactionary role in the development of services for people with disabilities. They have also played a key role as pressure groups, trying to keep the issues of a particular condition or the situation of people with a range of disabilities on the political agenda. In the absence of state provision, they have played a major part in creating and providing a wide range of health and personal social services such as physiotherapy, occupational therapy, speech therapy, social work, family support, and respite care. Voluntary organizations rely on a combination of state funding and resources raised from fund-raising. Over time, state funding has become an increasingly significant factor in service provision, and the laissez-faire arrangements for such funding have been replaced by contractual agreements between the statutory payers and the voluntary providers in which the respective obligations of accountability and transparency are defined.

ACCOMMODATION

In Ireland, many of those with disability were traditionally cared for in residential facilities, but from the 1980s, Ireland has followed international trends in deinstitutionalization and community-based care. However, the ideal of care in the community in which those with disability can live a full, inclusive life, nurtured by those around them, has never been fully achieved and many disabled adults live long-term in the family home. The provision of home-based support services is underdeveloped and, as a result, parents still approach old age without the reassurance of alternate services when they can no longer take care of their child. From the viewpoint of disabled adults, scarcity of alternative accommodation can limit life choices and some may only leave home on foot of a crisis, primarily the illness or death of a parent. While respite provision and some supported independent living accommodation have been provided, they are inadequate to meet current needs.

EDUCATION

Education for people with disability in Ireland is provided in a mixture of mainstream and special schools. Over the past decade, the number of disabled children in mainstream education has increased while the numbers attending special schools has remained constant. In 1990, two landmark legal challenges were instigated that highlighted a lack of any education for children with severe and profound disability. The first of these, the *O'Donoghue* case (1994), resulted in many children with severe and profound intellectual disability being granted the right of a formal education for the first time. In the second (*Sinnott v. Minister for Education* [2001]), the Supreme Court held that the state's constitutional obligation to provide for free primary education ceased at the age of 18. Both of these cases attracted much public attention and pressurized the government into reviewing its education provision to disabled pupils. Many of these reviews have been integrated into aspects of the Education Act (1998) and the Education for Persons with Disabilities Bill (2003). The Education Act requires schools to provide education to students that is appropriate to their abilities and needs. It specifies that a school must use its available resources to ensure that the educational needs of all students, including those with disability or with other special needs, are identified and provided for. However, the level of actual provision leaves a gap between aspirations and reality and the paternalistic approach to the educational provision for people with disabilities has been attributed to the continuing dominance of the psychomedical model.

EMPLOYMENT

Since 1977, the Irish public sector has had a 3 percent quota program for people with disabilities, which has never been fully realized. This quota does not apply to the private sector where efforts to secure jobs for those with disability have concentrated on facilitating and encouraging employers to take them on voluntarily.

The Irish Employment Equality Act (1998) is based on the principle that all individuals are entitled to equal treatment in training and employment opportunities regardless of gender, marital status, family status, sexual orientation, religious, age, disability, race, or membership of the traveling community. The 2002 annual report for the Irish Equality Authority (Irish Equality Authority 2003) noted that that the number of employment equality claims brought by disabled people discriminated against by the public/semi-state sectors at the point of access to employment has been striking. The report notes that the effectiveness of the Employment Equality Act to deter such discriminatory behavior is hampered by the low fines that employers found in breach of the act can be asked to pay. Put simply, employers in public or semi-state organizations may prefer to pay the maximum fine of €12,700 ($12,000) at 2002 rates, rather than incur the expense of taking on a suitably qualified disabled person as an employee.

A more hopeful initiative in the area of employment and disability has been the development of supported employment programs for those with disability. These have been effective in the integration of people with disabilities into the open labor market. They are built on the principle of person-centered planning and have helped to place people with disabilities into jobs to which they are suited and that offer them personal fulfillment.

IRISH DISABILITY POLICY AND LEGISLATION

The *Report of the Commission on the Status of People with Disabilities: A Strategy for Equality* noted that people with disabilities were the neglected citizens of Ireland, many of them suffering intolerable conditions because of outdated social and economic policies and unthinking public attitudes. The report itself represented an important development as 60 percent of the membership of the Commission on the Status of People with Disabilities consisted of people with a variety of different disabilities, and carers. The result was a document that highlighted the multitude of problems facing those with a disability in Irish society, and it presents a number of policy measures to address them based on the fundamental concept of rights.

Recent European directives on employment and social inclusion have resulted in the development of new Irish equality legislation that encompasses people with disability. In addition, the period from 1998 onward has seen an unprecedented focus on the need for specific legislation on service development for people with disability. This was first addressed in the Disability Bill (2001) published on December 20, 2001. Many hoped that this new legislation would offer Irish disabled people and their families a rights-based piece of legislation on a par with the Americans with Disabilities Act. However, the bill was met with a storm of protest over the government's perceived failure to underpin the rights-based approach in the bill that had been advocated in the *Report of the Commission on the Status of People with Disabilities* (1996). Particular criticism was leveled at Section 47 of the bill, which purported to deny people with disabilities the right of appeal through the courts to seek improved services or judicial redress. A number of powerful advocacy groups organized a high-level publicity information campaign. This campaign, along with a growing sense of unease about the bill from the public in general, put pressure on the government to withdraw the bill on the evening of a mass meeting in Dublin in February 2002. An extensive consultation process with interested groups was then initiated in preparation for the redrafting of the bill. The redrafting of a new Disability Bill has suffered from continuing delays. However, any new legislation is unlikely to be full rights-based and may well be limited by that frequently used qualification that services are to be provided "where finance allows." This follows the tradition in Ireland of providing services for people with disabilities on a discretionary rather than mandatory basis.

EXPERIENCE OF DISABILITY: JAPAN

Experiences of disability (*shogai* in Japanese) in Japan are as unique as those in other countries. Disability movements and disability studies in Japan have developed with the strong impact of Aoi Shiba, a group that raised fundamental and radical questions about disability and society. Disability movements in Japan are vocal and work closely with other Asian and Pacific as well as international movements.

RADICAL QUESTIONS ABOUT DISABILITY AND SOCIETY

A Murder in Yokohama in 1970

In one way, disability studies as well as modern disability movements in Japan were born when members of Aoi Shiba (*aoi shiba* literally means green grass), a group of people with cerebral palsy, made their views publicly heard in 1970. It was another murder. A mother killed her two-year-old daughter who had cerebral palsy. These killings of disabled people by their parents had been happening every year. When the murder was reported, the community was sympathetic to the mother. This was a usual response. Neighbors and members of the local family organization asked the court for leniency. More than 700 neighbors signed a petition expressing sympathy to the mother. The family organization protested the city government saying that since there were no institutions or support, there was no other choice but to kill disabled children whose right to life was denied by the society. This was to be just another murder of a disabled person and another typical response from the community.

But then, something unusual happened. Adults with cerebral palsy who were members of Aoi Shiba protested against these sympathetic views publicly for the first time. One leader of Aoi Shiba in Kanagawa Prefecture wrote in August 1970 that "in today's production-oriented society, people with cerebral palsy tend to be marginalized and their rights are denied. Even their life is not taken seriously" (Yamakita 1970:1).

Platform for Action

Then in October 1970, in the newsletter of Kanagawa Aoi Shiba, the four-point platform for action titled "We Act Like This" was announced as follows (author's translation):

- *We identify ourselves as people with cerebral palsy (CP).*

  We recognize our position as "an existence which should not exist," in the modern society. We believe that this recognition should be the starting point of our whole movement, and we act on this belief.

- *We assert ourselves aggressively.*

  When we identify ourselves as people with CP, we have a will to protect ourselves. We believe that a strong self-assertion is the only way to achieve self-protection, and we act on this belief.

- *We deny love and justice.*

  We condemn egoism held by love and justice. We believe that mutual understanding, accompanying the human observation, which arises from the denial of love and justice, means the true well-being, and we act on this belief.

- *We do not choose the way of problem solving.*

  We have learnt from our personal experiences that easy solutions to problems lead to dangerous compromises. We believe that an endless confrontation is the only course of action possible for us, and we act on this belief.

The following fifth point was added in 1975.

- *We deny able-bodied civilization.*

  We recognize that modern civilization has managed to sustain itself only by excluding us, people with CP. We believe that creation of our own culture through our movement and daily life leads to the condemnation of modern civilization, and we act on this belief.

Activities of Aoi Shiba

Throughout the 1970s, Aoi Shiba campaigned successfully against the revision of the Eugenics Protection Law of 1948, which was proposed to legalize abortion based on fetal impairments, protested against the mandatory segregated education, worked successfully against the national census on disability, moved against amniocentesis for the identification of fetal impairments at prefectural hospitals, and took to the street to stop inaccessible buses.

In addition to these visible actions, they claimed that "shogai was an indispensable part of their identity." Aoi Shiba also made an effort to create its own culture, as mentioned in the fifth point of the platform. Though they did not fully succeed in this project, they have at least managed to bring the "cultural revolution" permanently into the disability agenda.

Ideas and claims of Aoi Shiba have left a strong and lasting impact on disability activism and disability thinking, leading to the advancement of the independent living movement in Japan as well as to the later formation of *shogaigaku* (disability studies).

Aoi Shiba's fundamental objection to the production-oriented society led to the critical review of the U.S. Americans with Disabilities Act of 1990 (ADA), which had much impact in Japan. Though the majority welcomed this landmark antidiscrimination legislation across the Pacific, some did not agree with the overall emphasis of ADA on integration into the market.

Also, Aoi Shiba's criticisms against women's claim of right to self-determination over abortion in general sparked the initially bitter debate in the early 1970s and later led to some collaboration between the disability movement and the women's movement. Prenatal screening in Japan is not as widespread as in other industrialized countries, partly because of the disability movement, which was informed by Aoi Shiba.

NATIONAL, REGIONAL, AND INTERNATIONAL DEVELOPMENTS

Japanese movements, which included Aoi Shiba, joined the regional and international movements in the establishment of Disabled Peoples' International (DPI) in 1981, which was the International Year of Disabled Persons, organized by the United Nations. When the UN Decade of Disabled Persons came to an end in 1992, disability movements in Japan initiated the Asian and Pacific Decade of Disabled Persons from 1993 to 2002, declared by the Economic and Social Commission for Asia and the Pacific (ESCAP) to maintain the momentum created by the UN Decade nationally and regionally. The success of the Asian and Pacific Decade, owing largely to the efforts of regional and national nongovernmental disability organizations, promoted similar regional efforts in other regions, such as Africa and Europe.

International and regional work also served as a catalyst for the formation of a unified national organization, Japan Disability Forum (JDF), in October 2004. JDF, a loose umbrella organization, includes major organizations of disabled people and their allies and serves as the national representative organization. JDF, for instance, has regular dialogues with the government. JDF focuses on the following four major areas: (a) UN Convention on the Rights of Disabled People, (b) promotion of Asia and Pacific Disability Forum, (c) national disability plan, and (d) prohibition of discrimination against disabled people and the establishment of rights legislation. These are the priority areas for the movements in Japan.

DISABILITY STUDIES

In 1995, the intellectual impact of the deaf culture movement was keenly felt in Japan with the "Declaration of the Deaf Culture," by Harumi Kimura and Yasuhiro Ichida. By its emphasis on an independent culture as well as the denial of impairment and disability, this manifesto led to rethinking of impairment and disability not only in the context of the deaf/Deaf field but in the disability field in general.

Against this background, in 1999, "Invitation to Disability Studies," coedited by Jun Ishikawa and Osamu Nagase was published. This initiative resulted in the establishment of the Japan Society for Disability Studies in October 2003 at the University of Tokyo. Ishikawa, a blind professor at the University of Shizuoka, was elected the first president.

Disability studies in Japan, with its emphasis on disability as a form of discrimination as well as a meaningful way of living, has roots in Japan at least as far back as Aoi Shiba in the 1970s and today has a critical mass of people, disabled and nondisabled, who are committed to its development.

EXPERIENCE OF DISABILITY: THE NETHERLANDS

Many terms and definitions in the area of disability, disablement, handicap, and invalidity exist. They vary depending on the aim, time in history, context, country, and the person who is using the terms and definitions, and it is important to explain the terms and definitions used. Because the World Health Assembly of the World Health Organization endorsed in 2001 the International Classification of Functioning, Disability, and Health (ICF) for international use and urged member states to use the ICF in research, surveillance, and reporting, in this entry we use the ICF terminology and definitions. The description of the situation of persons with disability in the Netherlands in 2002 is derived from the *Report on the Disabled* 2002. This report is published every two years at the request of the Ministry of Health, Welfare and Sport. Many persons with and without activity limitations (physical activity limitations or mental impairments) have been questioned on their situation in different population surveys.

TERMS AND DEFINITIONS

The ICF provides a framework and a standard language for the description of health and health-related states from different perspectives: the perspective of the body (body functions and structures) and the perspective of the individual and society (activities and participation). *Functioning* is the umbrella term encompassing body functions, structures, activities, and participation. *Disability* is the umbrella term for impairments, activity limitations, and participation restrictions. The ICF lists also environmental factors that interact with all of them as facilitators or barriers.

The ICF is to be seen as a supplement to the International Statistical Classification of Diseases and Related Health Problems (ICD-10), which includes morbidity and mortality causes and diagnoses. ICF and ICD are the core classifications of the Family of International Classifications of the World Health Organization (WHO-FIC).

In Figure 1 the relations between the components of the ICF in relation to the ICD domain are reflected. Table 1 shows the key terms and definitions derived from the ICF.

In the next paragraphs, we describe the disability situation in the Netherlands by using ICF terms. The information source is mainly dealing with disability in terms of participation (restrictions) by persons with activity limitations (physical activity limitations or mental impairments) and does not include the level of body function and structure (impairments) as such. It means that we present a short paragraph on the number of persons with activity limitations, a more extensive paragraph on participation (restrictions) in major life areas, and a paragraph on the use of existing services as facilitators by persons with activity limitations.

PERSONS WITH ACTIVITY LIMITATIONS

There are currently around 500,000 people living independently in the Netherlands with severe physical activity limitations, and around 1 million persons with moderate physical activity limitations, that is, people who have severe or moderate difficulty in carrying out day-to-day tasks relating to personal care, mobility, or household activities because of a health condition. In addition, there are around 9,000 people under the age of 65 living in residential facilities and 150,000 persons age 65 and older living in residential facilities because of severe or moderate physical activity limitations. There are more than 100,000 persons with mental impairments, roughly half of whom live in supported housing.

These people, excluding persons age 65 and older living in residential facilities, form the target group for Dutch government policy on disability. The core objective of this policy is to offer effective, high-quality support that is directed toward enabling the

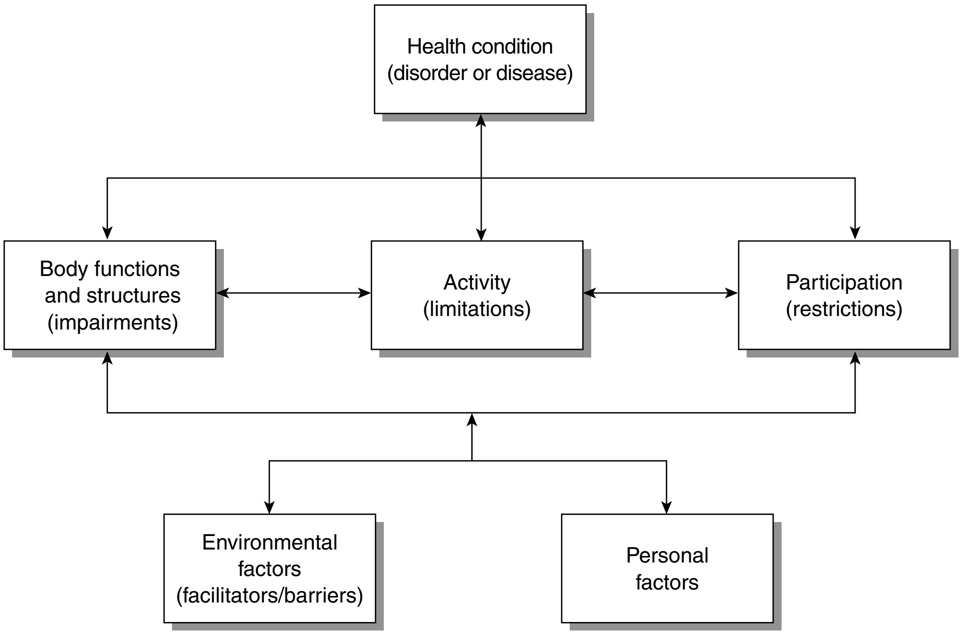

Figure 1 *Interactions between the Components of ICF*

persons with impairments and activity limitations to play a full part in society.

The next paragraphs describe the extent to which people with activity limitations (including those with physical activity limitations and with mental impairments) in the Netherlands participate in society in a wide range of major life areas (education, employment, economic life, recreation, and leisure) and how they make use of available facilitators (care and housing). The question of whether this participation and use is adequate is, however, difficult to answer, since there is no norm against which the participation of people with activity limitations can be measured. In the absence of such a norm, the social position of persons with activity limitations is consistently compared with that of people without activity limitations. Implicitly, this presupposes that both parts of the population ought to participate equally.

Participation in Major Life Areas

Education

Only a fragmentary picture is available of the school careers of people with physical activity limitations. Nothing is known about their participation in mainstream education, and they can only be partially identified from the records of the main special provisions (peripatetic support and special education). What is apparent is that pupils with moderate or severe activity limitations generally leave school with a lower level of achievement. This offers an important explanation for the relatively low participation of people with physical activity limitations in the labor market.

The amount of peripatetic support used in mainstream education has tripled since the early 1990s, and in special schools has increased by 40 percent. This growth is striking, since it is unlikely that the number of young people with activity limitations has risen so much faster over the period than the total number of young people (8 percent increase). The reasons for this growth in the take-up of provisions is not known. It may be that there was some underuse in the past, but it may also be that children with relatively slight activity limitations have begun making more use of these relatively "heavyweight" provisions.

It is also unclear to what extent people with mental impairments participate in mainstream education, though a clear trend can be seen whereby people with Down syndrome are increasingly participating in mainstream education: Today almost half of them

Table 1 ICF Key Terms and Definitions

Term	Definition
Body functions/impairments	Body functions are the physiological functions of body systems (including psychological functions). Impairments are problems in body function or structure such as a significant deviation or loss.
Body structures/impairments	Body structures are anatomical parts of the body such as organs, limbs, and their components. Impairments are problems in body function or structure such as a significant deviation or loss.
Activity/activity limitations	Activity is the execution of a task or action by an individual. Activity limitations are difficulties an individual may have in executing activities.
Participation/participation restrictions	Participation is involvement in a life situation. Participation restrictions are problems an individual may experience in involvement in life situations.
Environmental factors/facilitators/barriers	Environmental factors make up the physical, social, and attitudinal environment in which people live and conduct their lives. Environmental factors may be a facilitator or a barrier.
Personal factors	Personal factors are the particular background of an individual's life and living, and comprise features of the individual that are not part of a health condition or health states, such as: gender, race, age, fitness, lifestyle, habits, coping styles, social background, education, profession, past and current experience, overall behaviour pattern, character style, individual psychological assets, and other characteristics, all or any of which may play a role in disability in any level.
Functioning/disability	Functioning is the umbrella term encompassing body functions, structures, activities, and participation. Disability is the umbrella term for impairments, activity limitations, and participation restrictions.

Table 2 Disability in the Netherlands in 2002: Number of Persons with Activity Limitations (physical activity limitations and mental impairments)

Number of Persons	*abs 1,000*	*%*
Persons with		
severe physical activity limitations living independently	512	3.5
moderate physical activity limitations living independently	980	6.6
Persons aged below 65 living in residential facilities	9	0.06
Persons aged 65 or older living in residential facilities	150	1.0
Persons with mental impairments	103	0.7
Total persons with activity limitations	1,754	11.8

attend mainstream schools, at least for a few years. Strikingly, there has been an enormous increase in the size of the education sector for children with severe mental impairments, which has grown by 70 percent in the space of 10 years. There are no indications that the total number of children with mental impairments has grown so strongly.

One out of 10 persons with a physical activity limitation has at some time given up a course or been prevented from following a course because of their activity limitation. Almost all of them cite physical problems (pain, fatigue, absence due to illness or therapy) as the reason. They feel that adapted facilities (enlarged computer screens, adapted furniture) and the ability to follow lessons at their own pace are important conditions for their participation in education courses.

Employment

Physical activity limitations form a major obstacle to people's participation in the labor market. This is apparent from the fact that only 38 percent of people with activity limitations perform paid work, compared with 61 percent of the general population ages 15–64 years. The participation rate is even lower where people with activity limitations also have a low education level, are older, or are female.

A large body of new legislation and regulations has been implemented in the Netherlands in the past 10 years aimed at tightening up the rules on incapacity for work and encouraging more people with activity limitations to find employment. The results of these legislative changes have been disappointing: The proportion of persons with activity limitations performing paid work is still small and the number of people helped into jobs is only a fraction of the number who find employment by their own efforts.

People requiring more protection and support than the mainstream labor market can offer can seek admission to sheltered employment or day centers. Around the turn of the century, approximately 30,000 people with mental impairments were in sheltered employment and some 15,000 people were visiting a day facility for adults. Research among the users of these facilities suggests that the vast majority have a positive view of them, though around 10 percent of the parents/carers of the employees feel that the pressure of work in sheltered employment placements is too high, while roughly a third of the persons themselves would rather be carrying out activities other than those they are performing at present.

Economic Life

On average, 18- to 64-year-olds with severe physical activity limitations have a gross personal annual income that is more than €3,000 lower than that of those without physical activity limitations (€21,600 and €24,800 per annum, respectively). These income differentials occur largely because people with activity limitations participate in the labor market less frequently than people without activity limitations. At the household level, too, households in which (at least) one member has severe physical activity limitations have a lower income than households where no members have activity limitations (the difference is just under €2,000 per annum). People with mental impairments almost all have to live with a very low income.

Roughly 80 percent of people with physical activity limitations incur health-related expenses each year (e.g., for dentistry, nonprescription medicines, or their own contribution to home adaptations). These expenses average €750 per year, though can vary widely; for example, around 10 percent of persons with activity limitations spend more than €1,360 per year. It is not known what costs are incurred by people without activity limitations, and it is therefore not always possible to say that having an activity limitation necessarily leads to extra expenses.

Of people with physical activity limitations, 23 percent experience social deprivation. This means that financial reasons prevent them from doing or having a number of things that are necessary to function socially in the community (such as going out or inviting people for a meal).

Recreation and Leisure

People with an activity limitation participate in sports less often and also less frequently visit cultural or recreational amenities than people without activity limitations. The more serious the activity limitations, the greater the difference compared with people without activity limitations. The majority of people with an activity limitation see their own health status as the most important obstacle to leisure activities. They also cite the poor accessibility of buildings and problems with transport. People with severe physical activity limitations in particular are often unable to use public transport and are then forced to rely on adapted transport. Currently, around 860,000 transport provisions have been granted, almost half of which concern collective transport facilities. Local authorities are increasingly opting for collective transport; however, the fact that lots of people use these facilities does not mean that they are satisfied with them. The main complaints are that the transport often does not run on time and it is difficult to meet the requirement of asking for transport an hour before wishing to make a journey. This makes adapted transport relatively inflexible.

Roughly half of all adults with a mental impairment engage in leisure activities via an association or club. By far, the majority of these are associations that are used mainly by people with mental impairments. Around a third to 40 percent of people with mental impairments express a need to go out more. The main obstacle preventing them from doing so is lack of a suitable social network. Many are dependent on their family or carers from their residential facility, and as a result, the majority of people with mental impairments do not appear to be very socially integrated.

Use of Available Facilitators

Take-up of Care

In 1999, around 9 percent of households were receiving informal help with household tasks or personal care, while 8 percent were using private care facilities. Approximately 7 percent were receiving help from the home care services with household tasks or personal care. This figure is somewhat higher than in 1991 (5 percent). The increase is related to the fact that the number of people with disabilities has increased as the population ages. The average number of hours of care per client has, however, declined; approximately 40 percent of home care institutions ration the amount of care afforded to each client in order to be able to provide care to as many people as possible. These people receive an average of almost three hours per week less care than that for which they have an indication. More than a quarter of clients themselves feel that they receive too little care.

One of the biggest problems in the care sector is the waiting lists. In March 2001, there were around 30,000 people on the waiting list for home care services. Roughly 40 percent of them do, however, receive “bridging care” (i.e., another product or fewer hours than indicated).

Housing and Care

The vast majority of people with physical activity limitations live independently. The accessibility of their home is an important condition for their being able to do so. And yet 60 percent of those who have difficulty climbing stairs live in a home with a staircase (either indoors or in order to reach the front door). Only a small number (6 percent) have a stairlift.

A minority of people with moderate or severe physical activity limitations live in adapted housing, though the number of people with adapted homes increased by around 40 percent between 1995 and 1999. In many cases, these adaptations are carried out using grants pursuant to the Services for the Disabled Act (WVG): Each year 70,000 (in 1996) to 100,000 (in 1999) adaptations are approved the under the act.

Around 60 percent of the 80,000 adults with mental impairments live in supported housing units (total capacity: 17,500 places) or in a general institution for people with mental impairments (35,000 places). The capacity of these latter institutions increased by more than 30 percent between 1980 and 2000, and that of the supported housing units doubled over the same period. Those living independently or with their parents generally have less severe mental impairments, fewer physical limitations, and fewer behavioral problems than those living in institutions. In the Netherlands, as in other countries, the aim is to enable more people with mental impairments to live independently, with support where necessary.

CONCLUSIONS

An enormous amount of government policy has been implemented in recent years aimed at improving the living situation of people with activity limitations (including those with mental impairments) and increasing their participation in the community. These efforts have met with only partial success. To some extent, this is because the legislation brought in is still too new to expect its implementation to have had any impact yet. Where legislation has been in place for longer, as is the case with the WVG, for example, the picture is very mixed. Thanks to this act, a great many people with activity limitations have access to home adaptations, which enable them to continue living independently for longer. However, users are less positive in their views about the WVG provisions in the area of transport; whereas in the past people with activity limitations often received benefits for which they could pay for whatever form of transport they themselves chose, they are now often forced to rely on collective transport, which is characterized by a lack of flexibility.

The information presented in this entry reveals that the Netherlands is still not sufficiently accessible to people with activity limitations and so creates participation restrictions for them. This applies across a whole range of fields: education, the labor market, public buildings, people's own homes, public transport, care provision, voluntary work, and associational and club life. Although the government does pursue policy designed to improve this accessibility, the measures often have a nonobligatory character.

A minority of people with activity limitations in the Netherlands live in poverty, partly because of a lack of income from employment. Increasing the labor market participation of people with activity limitations ought therefore to be one of the central planks of government disability policy. As well as employment placement services, training and improving the school achievements of younger people with activity limitations are among the ways of achieving this.

Adults with mental impairments increasingly live independently in average neighborhoods. However, the expectation that this will enable them to play a greater part in the community is not being fulfilled; in practice this integration encounters numerous problems. For example, people living independently are found to play virtually no part in general social activities. People with mental impairments often lack a network of people with whom they can undertake activities; many of them remain dependent on their family or carers from a residential facility for this.

Living in an institution often causes people to become dependent on others and to have little autonomy. On the other hand, life in an institution does often result in an integral provision of diverse amenities, both residential and with respect to filling residents' days. This cohesion is lacking when people live independently.

Choosing between a residential facility and living independently is still too much a matter of choosing the lesser of two evils: In the former case people with mental impairments have too little autonomy, while in the second they are in danger in the present situation of losing quality of life.

EXPERIENCE OF DISABILITY: NEW ZEALAND

New Zealand is one of the most recently settled major land masses. Polynesian settlers arrived around AD 500–1300. The first European expedition to New Zealand was led by Abel Tasman in 1642. The name New Zealand comes from the initial Dutch settlers. Around the 1760s, Captain Cook started surveying the islands, which opened the way for trade and whaling expeditions. This led to the colonization of the islands predominantly by European settlers.

In 1840, a treaty (Treaty of Waitangi) was signed between Maori chiefs of New Zealand and a representative from Queen Victoria. This treaty promised complete chieftainship over resources. Today, the exact meaning of the treaty is being debated and it remains a source of resentment for both Maori and Pakeha (Europeans).

New Zealand became an independent dominion in 1907 and gained full independence from the United Kingdom in 1931. New Zealand is still a constitutional monarchy in the Commonwealth, although there is a growing movement to establish New Zealand as a republic. This change would also include shifting governmental representation from a governor-general appointed by the queen (on advice of the government in power) and a prime minister to a president.

New Zealand has two main islands (North and South Island) and a number of smaller islands. The total land mass area is 268,680 square kilometers, meaning that it is smaller than Japan or the United Kingdom and just slightly larger than the state of Colorado. New Zealand extends to 1,600 km through its main north-northeast axis.

Its closest neighbor is Australia, more than 2,000 km away to the west, with Antarctica to the south and Fiji, Samoa, and Tonga to the north. Due to New Zealand's isolation from other countries and the number of uninhabited islands that come under its jurisdiction, its economic zone is the world's fifth largest, totaling 4.2 million square kilometers.

Colonial life in New Zealand was tough with accidents more likely to cause death due to shock or loss of blood; nowadays people who experience an accident are more than likely to survive due to the advanced medicines and treatment available. However, in the 1800s a death of the breadwinner (usually a man) resulted in the family being destitute. Diseases such as whooping cough, measles, diphtheria, and poliomyelitis were also major causes of death or impairment. Alcohol also caused a fair amount of physical and psychological damage. Between 1863 and 1865, there were 42 admissions into an asylum in Dunedin and it was thought by the medical superintendent at the time that half of the admissions were the result of alcohol (450 out of 909).

One of the first pieces of legislation passed, the Lunatics Ordinance Act 1846, dealt with the issue of insanity and gave the right to detain or arrest those people who were deemed likely to cause danger to the general public. The first asylum was built in a suburb of Wellington and opened in 1854 with places for 10 people. This was followed in short time by a number of asylums throughout the country. Staff members at these facilities were appointed because of their ability to handle a large number of people rather than any skill in the area of working with or caring for people. In fact out of all the asylums opened only Auckland appointed a person with a medical background.

An early piece of legislation specifically affecting disabled people was the 1882 Imbecile Passengers' Act. The act required a bond from a ship's captain who brought into New Zealand anyone who was deemed to be a lunatic or someone who would become a burden by requiring charitable aid. The 1899 Immigration Act prohibited any immigrant that was seen to be an idiot or suffering from a disease to enter the country. Neither of these pieces of legislation was stringently enforced. The first piece of education legislation was passed in 1877 and introduced free and compulsory education; however, there was no acknowledgment of special education. The act did state that a temporary or permanent infirmity was grounds for exemption from attending school. Mother Aubert founded the Sisters of Compassion, which took in disabled children with spina bifida, Down syndrome, and a variety of other impairments. However, most of the institutional care provided in the late nineteenth and twentieth centuries was for people with mental illness.

Around the same time, the first institute for deaf and dumb people was established in Sumner near Christchurch in 1880. Instructions for deaf students were conducted orally because there was a ban placed on the use of sign language. It was not until 1979 that the ban was repealed.

While plans for the first asylum for blind people were made in 1874, the building was delayed due to the low numbers of people eligible for housing; at that time it was thought there were only about 12 people in the Auckland area with significant visual impairments. It was not until 1889–1891 that a school to teach blind children was established in Parnell. At that time, Parnell was an outlying suburb of Auckland and a difficult journey. The town was in the heart of the market gardening area, and funds were provided by a bequest from a strawberry grower who left $12,000 in 1905 (the sum is equivalent to $200,000 today). The building of the school started later that same year, was finished in 1907, and officially opened two years later. In present day, the Royal New Zealand Foundation of the Blind is in the heart of the city and a major landmark in the Parnell area. Individuals are housed in any of the original buildings.

At the start of the twentieth century in New Zealand, there was a feeling that the affairs of the country were historically linked to the United Kingdom. As a result, New Zealand eugenicists based many of their arguments on data and information received from England. In 1903, W. Chapple published *The Fertility of the Unfit*, in which he proposed that the increase in crime, destitute people, and insanity was the result of society being born of defective stock. The book was well received not only by the public but also by the chief justice of the time (Sir Robert Stout), who thought the work was excellent and helped to have the book published in the United Kingdom. According to Chapple, "the unfit" were those who, because of mental and physical disabilities, were unable to support themselves. This classification included criminals, paupers, and those who were defined as idiot, imbecile, lunatic, or alcoholic. When the New Zealand Society formed in the early twentieth century, it sought to directly replicate the London Eugenics Education Society. It was widely believed that New Zealanders were stronger and fitter than people from other countries; however, this perception was challenged when 57 percent of conscripts for World War I were rejected from serving.

A question in the census of New Zealand was framed to ask about infirmity in the household, in other words, to identify those people who were unable to work due to injury or illness. The question was withdrawn after the 1916 census, which identified 206 people as deaf and dumb, 566 as blind, 3,741 as lunatic, and another 777 as feebleminded. The reason for the question being dropped was a growing reluctance on the part of the population to acknowledge such impairments. The question was brought back into the census in 1996 and revealed that 20 percent of the population had some form of impairment. The elder population—those over age 60—had the greatest percentage of people with impairments.

In 1907, the Education Amendment Act was passed, which mandated the education of "defective" or epileptic children from the ages of 6 to 21. The minimum age for disabled adults in education today still stands at 21.

World War I resulted in New Zealand having a large number of returned servicemen in need of support due to the nature of their wounds. The government offered monetary compensation to these returned servicemen, and it was expected that the pension received would replace what the soldiers could have earned. The government offered no services to people, just monetary compensation. One of the returned servicemen was Clutha Mackenzie, who lost his sight at Gallipoli. Prior to enlisting, Clutha was on the board of the Auckland Institute for the Blind and it was through his lobbying that the government passed the Pensions Amendment Act in 1924, which introduced pensions only to blind people over age 21. It was not until a number of years later (1936) that pensions were offered to other impairment groups.

Also as a result of World War I, new procedures and organizations introduced in orthopedics and plastic surgery to returned servicemen were now offered to people with congenital disabilities. The war also had the effect of raising public awareness of people with mental illness—particularly in the form of neuroses—and this led to a halfway house and an outpatient's clinic being established. Finally, there was a need for more masseurs to treat wounded soldiers and this increase eventually resulted in the establishment of a Registration Act in 1920.

In 1925, a Royal Commission into the health of New Zealanders believed that the country was losing its colonial and pioneering energy. One of the committees of the commission, the Inquiry into Mental Defectives and Sexual Offenders committee, was the most openly eugenicist-minded committee in the Royal Commission. This committee also linked mental defectives and sexual offenders for the first time. Three years later, in 1928, the Mental Defectives Amendment Act was passed, and this led to the setup of the Eugenics Board, which was charged with compiling a register of people who were deemed to be mentally defective.

Templeton Farm was established in 1929 for the institutional care of people who were diagnosed as either imbecilic or feebleminded but without "psychotic complications." A number of people with physical impairments ended up in Templeton on the advice of doctors to their parents. These medical personnel during the early and middle part of the twentieth century advocated for the placement of children with disabilities in institutions.

In the early 1930s, New Zealand experienced another polio epidemic, which led to Alexander Gillies, a noted orthopedic surgeon, establishing the New Zealand Crippled Children Society (now known as NZCCS) in 1935. The organization was charged with helping the crippled child and in no way to usurp the local authorities or government obligations to those defined as "defective." The society sought to work in a supportive and cooperative way. During its formation, Lord Nuffield, who was visiting from the United Kingdom, donated £50,000 towards it establishment. Along similar lines, the Wilsons (one of the founders of the major morning newspaper, *The Herald*) donated a family home to assist in the rehabilitation of children under the age of 21 who were recovering from either illness or an operation.

World War II again added many veterans to the number of disabled people in New Zealand, and it was estimated in 1946 that 23,000 (or approximately 11 percent) of the returned servicemen and servicewomen were paid some form of pension. Again there were spin-offs with new technologies developed to treat wounded soldiers and these would again be used to treat the general public. Also occupational therapy became a professional career option for people who wanted to work with disabled people.

The 1940s brought two distinguished visitors to New Zealand; in 1947 Helen Keller visited on behalf of the Royal New Zealand Foundation for the Blind, and in 1948 Earl Carlson, a specialist in the treatment of people with cerebral palsy, recommended a facility be built for their care. This facility was duly completed in 1951 at Rotorua. In recognition of his influence, a school was named after Carlson in the Auckland area.

The postwar years brought about a view that people with disabilities deserved to have the same rights as other members of society. Through the Depression and war years New Zealand sought safeguards to prevent a repeat of eugenics in order to establish a fairer society so that the cause of the wars would not be in vain. In earlier years, an attempt was made to form an organization that represented the parents of children with intellectual disability called the After Care Association. While it did meet some of the needs of family members, parental voices still went unheard. In 1949, another attempt to bring about the first parent-driven association for children with intellectual disability was attempted. A group of 22 parents met on October 25, followed less than a month later by the establishment of the Intellectually Handicapped Children's Parents Association. The major focus of the group was to be a voice and support for those parents connected with people with an intellectual disability.

The 1950s saw the establishment of other specific-impairment groups, including the New Zealand Epilepsy Association and Hoehepa Homes (based on the Rudolph Steiner principles). Also in the 1950s, the first vaccinations of children against poliomyelitis took place. The Asthma Association was formed in 1962. The 1960s saw a settling-down period of single-impairment groups as efforts began to work with children, young adults, adults, and family members of people with impairments. A residential facility for blind children was established in the Auckland suburb of Manurewa and eventually children from this school were integrated with the local area schools.

The 1970s saw the introduction of three key pieces of legislation that would have long-term effects on the disabled community. In 1972, the Labour government passed the no-fault Accident Compensation Commission Act. This act gave people monetary compensation when they were a victim of an accident—no matter who was at fault. This monetary amount was based on the level of impairment suffered; the greater the level of impairment, the more compensation. This compensation was given only to people who gained their impairment from an accident after the introduction of the act in 1972. It did not and still does not apply to people who have the same level of impairment due to birth or illness.

In 1975, the Disabled Persons Community Welfare Act (DPCWA) was passed. The act gave assistance to disabled people, parents, and guardians, as well as voluntary associations. The act defined a *disabled person* as someone who has or suffers from any physical or mental disablement to a degree that the person is seriously limited in the extent to which he or she can participate in activities of everyday life. The DPCWA also introduced a program to give parents or guardians a chance to take up to four weeks of respite leave and have someone either come in and care for their child or send the child away to be cared for at either an organization or other type of facility.

The final act that had an impact on New Zealand's disability population was the passing of the Human Rights Act of 1977. This act made it illegal to discriminate on the grounds of gender, marital status, or religious or ethnic belief. Disability, however, was not included as a recognized grounds for discrimination.

The International Year of Disabled Persons was in 1981, and this saw a plethora of disabled people and organizations promoting disability issues. A telethon was held to celebrate the year, and it raised more than $6 million (New Zealand at that time had a population of just over 3 million people). In 1982, the Disabled Person's Assembly was formed to represent the voice of disabled persons. Its charter stipulated that the national executive committee had to have a majority of disabled people on the board.

CONCLUSION

New Zealand has grown from a small isolated island with strong ties to the United Kingdom. As has been shown, key events along the way have shaped the country's response to disabled people. What lies ahead for disabled populations will be more challenges as the community fights to establish an identity as disabled people rather than a group needing "welfare."

In fighting for this identity, what may happen is an explosion of smaller impairment groups as happened in the 1950s. This will lead to government departments having to contract to a large number of impairment groups rather than the "big four": CCS (provider of support and services to people with physical disabilities), IHC (provider of services to people with intellectual disabilities and their families), the Blind Foundation, and the Deaf Association. The first task will be to include disability as a group against whom discrimination is outlawed.

—Russell Vickery

EXPERIENCE OF DISABILITY: SERBIA

Serbia is located in the central part of the Balkan Peninsula, on the most important route linking Europe and Asia, occupying an area of 88,361 square kilometers. Serbia is in the West European time zone (one hour ahead of Greenwich time).

The ethnic population of the Republic of Serbia is heterogeneous, a result of the country's turbulent past. The majority of the population of Serbia are Serbs, but another 37 ethnicities also live on its territory. All citizens have equal rights and responsibilities and enjoy full ethnic equality. The Constitution of the Republic of Serbia guarantees rights to minorities, in accordance with the highest international standards. The last 2002 census puts the population of Serbia (excluding Kosovo-Metohija) at 7,498,001, which is 92.3 percent of the population of the State Union of Serbia-Montenegro. The main religion of Serbia is Christian Orthodox.

GEOGRAPHIC INFLUENCES

This overview of rights for people with disabilities begins from a geographic perspective. This perspective is important because Serbia has shared similar experiences of disability with neighboring countries of Southeast Europe such as Croatia, Bosnia and Herzegovina, Serbia and Montenegro (Yugoslavia), Macedonia, Albania, Hungary, Bulgaria, Romania, and Moldova. All countries in this region had communist regimes in the past and poverty was widespread. These demographic factors significantly influenced the position of people with disabilities in the region.

As a research area of social importance, the topic of disability is poorly investigated. Internet resources are rare. This situation represents a problem for developing research on Serbia and people with disabilities, but at the same time, it also represents a challenge and an opportunity to make recommendations for future research.

Documents authored by the organization Disability Right Advocates (DRA; 2001) have proven both invisible and neglected. Yet one can find insights on the situation of people with disabilities in Central Europe spread throughout such reports. A summary of these analyses will occupy the bulk of this entry. Such documents present a starting point for research in this part of the world. Their analyses reflect global issues of disability oppression and deal with key perspectives and issues of importance for people with disabilities. They also present a special focus on the education of people with disabilities. The DRA report starts by describing the situation of people with disabilities in Central Europe:

> Indeed, although many of the nations of Central Europe stand poised to assume their places as essential political and economic partners with Western Europe, many are like third world countries in their treatment of people with disabilities. Thus, throughout Central Europe, very few people with disabilities have the opportunity to lead a full and independent life. As a group, disabled people are segregated and immobilized by pervasive architectural barriers. They are also poor, without necessary assistance or assistive devices, discriminated against, and lack sufficient information or governmental support to improve their situation. They suffer from massive unemployment and social, political, and economic exclusion. . . . Throughout the region, treatment of people with disabilities is also still dominated by the medical model and outmoded concepts of charity, pity and non-productivity.

One of the important facts about this part of the world is that people with disabilities are largely hidden from public view. Factors that contribute to this situation are widely held myths and prejudices that saturate the culture about disability as tragedy. These beliefs together with inadequate family supports for people with disabilities—families that often lack knowledge about disabilities and that are trapped in similar debasing ideas—form some of the core problems facing disabled people in these countries. The DRA (2001) explains this detrimental situation in the following manner: “In the past, disabled people were hidden by their family members and there is still considerable stigma attached to having a disabled child. . . . One result is the frequent institutionalization of the severely physically disabled, as well as developmentally disabled children and adults.” Furthermore, it is said that “the medical model for disabled people is still the dominant paradigm. The communist concept of the ideal citizen—a healthy manual worker—reinforced this negative image and labeled disabled people as misfits.”

The report also identifies prevalent myths about people with disabilities—myths that define common approaches toward this group. The first myth is that persons with disability cannot lead a productive life. This belief is identified as the “helplessness myth” and promotes ideas of extreme dependency as well as overall incapacity to contribute to society. The second myth, known as the “charity myth,” claims that philanthropy rather than organized institutional structures should deal with the “problem” of disabled people. The third myth (recognized in first contacts with policy makers in Serbia and other countries of the region) is the “costs myth.” According to this approach, disability costs too much and these countries cannot afford to spend their beleaguered budgets on the repair of disability issues.

The Association of Students with Disabilities of Serbia and Montenegro (ADS; 2004a) gives additional statements with regard to regional characteristics. These statements are mostly built from the valuable experiences of people with disabilities in the region, and therefore they have not yet attained the status of formal research insights:

Lack of political activities—It is very rare that one finds persons with disability as members of any national or local governments.

Architectural barriers—In most countries of the region, architectural barriers represent an impediment for people with disabilities. Lately, some regulations of accessibility for wheelchair users have been coming into use. Accessibility regulations for blind and other visually impaired people as well as people with hearing problems are extremely rare. Ineffective laws are the main reason for such situations, because such policies provide only mild sanctions at best against institutions that do not respect general accessibility regulations.

Inaccessibility of means of transportation—In the countries of Southeast Europe, regionally accessible public transportation usually does not exist. In big cities and capitals of the region, there are special means of transport for people with disabilities but these are often limited.

Employment—In Serbia and Montenegro, young people with disabilities are most frequently only fictively employed in a company and retire after only six months to two years, with the aim to gain a right to pensions. A pension thus acquired is very low and people with disabilities are once again dependent on the government and their families. When a vacancy exists, employers will invariably employ able-bodied workers in almost 100 percent of the cases. Such practices continue regardless of the qualifications that applicants with disability might have. An additional problem exists because few data on qualified young people with disabilities have been published. Companies willing to offer employment are, as a rule, inaccessible to persons with disabilities (due to a failure to implement accessible construction regulations). There is no legal obligation or stimulation by the government for solving this problem. This description is for the most part applicable to all countries in the region.

Personal assistant programs—A personal assistant initiative has been introduced in Hungary. The program is organized and carried out by a nongovernmental organization (NGO) motivated by a cooperative arrangement with the government. One of the ways this problem might be addressed in the region is civil service as an alternative to military service, and a number of organizations and individuals support this initiative. Currently, military service in the region is compulsory so that the introduction of a civil service requirement has yet to be adopted by most countries in the region.

Because Serbia is a small country, its politics have been greatly influenced through intersecting histories with neighboring countries. Consequently, the development of disability rights in Serbia could be studied from a regional perspective.

HISTORICAL PERSPECTIVE

What was the situation of disability rights in Serbia through history? Few written documents are available for study and thus analyses of disability in Serbian history are rare.

In a recent World Bank document titled *Poverty Reduction Strategy Paper for Serbia* (2004), a general history of Serbian social protection services is presented. It draws links between poverty and people with disabilities while also challenging the common practice of institutionalizing people with disabilities throughout Serbian history.

A first Serbian law for the protection of human rights for poor people was implemented in the thirteenth century by Saint Sava.

> In close cooperation with the civil authorities, the church was in charge of the creation of "honorable homes" for: the elderly, the poor, children deprived of parental care, foreigners etc. These homes had their administrative and managerial staff, as well as real estate and other assets that were bestowed upon them. The operation of these charitable institutions was closely monitored by the overseers, who were in charge of advocating for the poor, comforting the mourners, defending the abused etc. Among the vulnerable were also those with physical disabilities: the blind, deaf, mute, lame, etc. (World Bank 2004)

In the fourteenth century another piece of legislation was introduced:

> It is characteristic of the Law of Saint Sava that, apart from the material aspects of poverty, equal attention was paid to the legal protection and equality of all before the courts, regardless of their material status. This principle of universal legal equity was also included in the Law book of Tsar Dusan from the 14th century, which states: "Every washerwoman must be as free as the priest"; "a poor soul, who cannot represent herself at court, may send a representative to speak in her name." (World Bank 2004)

Such laws suggest an uneven history of the treatment of disabled people in the region. They also present possibilities for the existence of more humane efforts than recent history may present.

Yugoslavia after World War II

The filmmaker and disability rights activist Victor Pineda, in his research, *Disabled Yugoslavia—Integration and Disability in Serbia and Montenegro* (2003), tries to illustrate the situation of human rights and people with disabilities in Yugoslavia from 1940 to 1990. In addition, Pineda also examines the situation of disabled people in the second half of the twentieth-century incarnation of Yugoslavia as Serbia and Montenegro during the past decade. Pineda is fully aware that research and data on people with disabilities in Serbia and Montenegro are nearly nonexistent. Reports like his contribute to a better understanding of the situation of people with disabilities in this area.

From the 1960s to the 1980s, Yugoslavia was lauded for being a socially advanced nonaligned nation, providing respected national health and educational institutions for all members and ethnicities in its society. Today, a very different reality prevails due to the existence of more than 1 million disabled citizens, refugees, and casualties of the recent wars. Twenty years after this progressive period, disabled people in Serbia and Montenegro are left with shattered pieces of a spent past, and hardly a glimmer of hope for a brighter tomorrow.

Disability has been primarily treated in Yugoslavia, as well as in other communist countries, as a welfare "problem." Persons with disability needed, it was widely thought, the protection of the state, as they were unable to lead productive lives. Similarly, Pineda's (2003) report starts with an overview of the situation of people with disabilities in Yugoslavia between 1960 and 1980:

> Throughout the Federal Republic of Yugoslavia (FRY), associations of disabled people are impairment specific and their approach is based largely on a medical/charity approach. As in other communist or socialist countries, the disabled person is under the protection or care of a specialized state agency. This view is still very embedded in the health and social services and it continues to influence the way in which services are delivered today.

In contrast, Pineda provides access to the unique and rare citations of Yugoslav's longtime premier, Josip Broz Tito, speaking about people with disabilities in 1948, during a debate on the budget in Federal Assembly:

> Since 1945, 13,133 disabled ex-servicemen have completed different courses, schools or learnt various trades in their servicemen's centers while 29 thousand disabled ex-servicemen have found employment through their organization. The disabled ex-servicemen have undertaken the production of various prosthetic appliances and are today covering all their needs.

Furthermore, Pineda describes the financial support for people with disabilities through an analysis of "invalid relief benefits." (*Invalid* is the term used for persons with disability. It is interesting to note that disability terminology in Yugoslavia has remained largely unchanged with time. Lately, some more politicized disability organizations suggest changing such antiquated terminology.) From there, Pineda goes on to discuss Tito's views of government support for people with disabilities:

> Tito committed 74% of the total expenditures for social welfare to "invalid relief benefits." This included free medical examination and medicine in all health institutions, and entitled 13,000 disabled ex-servicemen (between 1945–1948) to visit and undergo treatment at different spas and seaside treatment centers. These centers were very popular and thousands of sick and injured people from each of the six republics in the federation would be allowed universal and free treatment and usage, regardless of religion or ethnicity.

However, significant financial government support ended by the end of the 1980s. It was at this time that the situation for people with disabilities started to dramatically change for the worse. The contemporary wars that have decimated Yugoslavia started in 1991. Later, Serbia and Montenegro (formerly part of Yugoslavia) faced enormous poverty and increasing numbers of refugees. For instance, poverty increased from 6 to 40 percent.

In its publication *Disability and Poverty in Literature* (2002), the World Bank addresses the health care situation in Yugoslavia after 1990. It states that Yugoslavia enjoyed relatively well-developed systems for health care, health insurance, social services, and education before 1990. Yet, due to the conflicts in Yugoslavia after 1990, such advanced programs have experienced radically decreasing resources. As a result, many conditions that would normally be treated regularly ended in chronic impairments for lack of treatment.

LEGAL PERSPECTIVES

The legal analysis of this section concerns disability issues in Serbia from reports by experts Damjan Tatic and Branka Pecanac, both persons with disabilities. *The Right of Disabled Persons to Higher Education* (Tatic 2000) gives an in-depth analysis of Serbian legislation pointing out that the Constitution of FRY (Federal Republic of Yugoslavia) prescribes special protection of disabled persons in accordance with legal provisions. Tatic lists all the international documents and acts for equal opportunities and human rights for people with disabilities, which Serbia has adopted: the Universal Declaration of Human Rights and the Covenant on Economic, Social and Cultural Rights, UN Convention on Rights of Children, and UN Standard Rules for Equalization of Opportunities Provided to Disabled Persons. According to the report, “Under the auspices of United Nations, two crucial acts for regulation of legal status of disabled persons had been adopted at the beginning of the last decade of the 20th century: UN Convention on Rights of Children and UN Standard Rules for Equalization of Opportunities Provided to Disabled Persons.”

Comments on the Draft of the Law against Discrimination of Persons with Disability (Pecanac 2004) explains that

> discrimination against persons with disability is a long term problem in our country, a problem in the face of which both professional public and community prefer to keep their eyes closed. The Draft of the Law against discrimination of persons with disability is a preliminary legal text treating this matter in full. The law is based on principles of sanctioning discrimination, respect of human rights and involvement in all spheres of social life on the bases of equality and also in all decision making processes about the rights and duties of persons with disability.

Pecanac recognized in the law one paragraph that is discriminatory: “organizing special forms of education for children and students with sensory and motor invalidity who cannot follow curricular activities in the usual way, as well as directing someone to special forms of education if this direction is based on categorization statement, is not to be considered discrimination.” Such a provision for segregation speaks to an unchanged perspective on people with disabilities after many years of legislation in Serbia. Pecanac reminds us about this continuing praxis in special schools and the ongoing segregation of children and youths with disabilities (this entry will address these issues in more detail later). She continues with an analysis of the recent introduction of a few government bodies that oversee issues of human and civil rights for people with disabilities, and again detects discrimination in the formulation of these bodies.

EDUCATION

One of the main topics of this overview is education because this creates a foundation for the movement of people with disabilities in any country.

DRA, in its report *Invisible and Neglected* (2001), includes a description of the educational system in Central Europe, including higher education for students with disabilities:

> In education for children and young adults with disabilities, Central Europe lags far behind most Western European countries. Not only are educational levels lower for people with disabilities but there is minimal, if any, educational integration. Virtually all of the universities and graduate schools, as well as research institutes, are not accessible to wheelchairs users or people with mobility limitations.

As in the Pecanac report, Pineda (2003) also includes a brief commentary on education systems for people with disabilities in Serbia and Montenegro.

> Public education at all levels is necessary to dispel the deeply rooted prejudice against children with

Table 1 Number of Students in Special Schools in Serbia, for the School Year 2000–2001

	Total number of students	*Boys*	*%*	*Girls*	*%*
Primary	7,560	4,488	59.37	3,072	40.63
Secondary	1,269	806	63.51	463	36.49
	8,829	5,294	59.96	3,535	40.04

> disabilities. Currently special schools exist for the blind, and deaf, these schools have existed for over 120 years. The newer special education schools were combined with medical treatment and rehabilitative centers in remote areas.

Likewise, the World Bank report *Poverty Reduction Strategy Paper for Serbia* (2004) includes an overview of the educational system for people with disabilities in Serbia. This document was made in cooperation with the Serbian Ministry of Social Affairs. One can notice outdated terminology such as "children with special needs" and a focus on special schools throughout the discussion:

> Children with special needs requiring long-term assistance due to irreversible disability account for approximately 7%-10% of the total student body. The majority of children with special needs are usually not covered by rehabilitation programmes until their enrolment to primary education,
>
> Pre-school education is organized in three forms:
>
> 1. Special pre-school groups in special schools;
> 2. Special development groups in regular pre-school institutions;
> 3. Pre-school education undertaken together with other children in the same pre-school group, without a special programme.
>
> Only 1% of pre-school children with special needs are covered by early childhood education and other preparatory programmes, whereas 22% of pre-school children in the general population are included in this form of education.
>
> The current education system for children with special needs is organised in three basic forms:
>
> 1. Special schools for children with mental, physical and sensory disorders and children with behavioral disorders (some 15% of children with special needs are enrolled in special schools);
> 2. Special classes in regular schools;
> 3. Classes in regular schools where children with special needs of all categories are educated together with other children, without special support.
>
> There are 85 special schools in Serbia, of which 5 are in the territory of Kosovo. Excluding Kosovo, the capacity of these institutions is 8,829 students. 61 schools are for mentally challenged children. In terms of organization and space, primary and secondary schools are normally located together. In 8 students' residences serving schools for children with visual and hearing disabilities, accommodation is provided for 480 students. The available data show that special schools do not fulfill their basic functions. They isolate children with special needs and do not prepare children for inclusion in regular life.

The document recognizes key problems in special education for children with disabilities including segregation and low-level education. The issue of low-level education is directly addressed in a later chapter of the report:

> The network of special schools and special classes in mainstream schools is not evenly distributed across the regions of Serbia. These schools are located in major cities so that rural children and children from small towns are separated from their families and placed in boarding facilities which are most often located with special schools.
>
> There are several problems related to the education of children with special needs:
>
> 1. There is no unified data concerning persons with special needs;
> 2. Only 30% of children with special needs who have completed primary school continue their education, in comparison to 79% of the total population.

Yet the editors of this document conclude in a positive way: "More efficient and greater inclusion of children with special needs in the education system, particularly in inclusive education, is necessary."

The ADS, mentioned earlier, is a nongovernment, nonpartisan, nonprofit organization, based in Belgrade, Serbia. The organization specifically addresses improvement of the position of young people and students with disability and their inclusion in society. ADS is an active organization, both locally and in the Southeast Europe region. ADS organized many successful and internationally recognized projects, such as international conferences, Southeast European Youth Network, media campaigns, counseling centers, summer schools, scholarship programs, youth employment services, legal regulations, and special transportation projects.

The ADS document *Higher Education for People with Disabilities in Serbia and Montenegro* (2004a) reviews the situation and position of students with disabilities by students with disabilities of Serbia. The report begins with a depiction of the legacy of former communist era regimes with regard to social engineering goals:

> The former government and communist regime of Serbia and Montenegro strived to establish a "perfect society" during the last decade of their governing. In such a society there was no room for people with disabilities.

The document further explains several steps that were taken to establish a so-called perfect society: considering disability as a medical category, existence and insistence on special schools, inadequacy of existing laws and regulations, and the dominance of charity media approaches.

Description of the "promotion" of special schools is especially interesting:

> The education process of children with disabilities mostly starts with diagnosing a disability. The physician suggests a special school in which a child with disability should commence her/his education (such as schools for visually impaired children).

Detailed description of programs and perspectives in special schools is stated: Curriculums of special schools are shortened, children with mental and physical disabilities are together in the classrooms, curriculums are adjusted to pupils with the highest degree of disability, children are segregated, and special schools have increasingly become boarding schools.

From here the document goes on to introduce a description of the higher education system for students with disabilities:

> Young people with disabilities find it extremely difficult to continue education at institutions for higher education. This further contributes to their isolation, and their choice of employment is limited to jobs they were trained for at special schools.

The text goes on to discuss obstacles for students with disabilities to obtain higher education, such as inaccessible buildings and programs, lack of accessible transportation, lack of personal assistance support programs, and lack of recognition of some types of disabilities in the country in general (such as some types of learning disabilities).

Apart from technical barriers, other more important and harder to reach objectives include the following:

- Laws and other legal regulations are not dealing with students with disabilities, or if they are, then they do not use the social model approach.
- Academic community and relevant institutions (including ministries of education, rectors' offices, students without disabilities, professors, university administrators and staff) do not have enough interest in and sensitivity to the rights and problems of students with disabilities.
- Students with disabilities are not sufficiently empowered and skilled to pursue their rights.

Report on Project: Promotion of Higher Education in Southeast Europe, by ADS (2004b), represents the first descriptive research on inclusive higher education in Serbia by disabled people. This document is not in the form of a research or scientific document, but rather a collection of observations and recommendations for improvement of human rights of young people and students with disabilities. It represents a unique, insider view on the topic of education for persons with disabilities and, in this way, provides an important and previously unavailable resource on the research of higher education for students with disabilities in Serbia.

The first part of the report deals with the overview of the situation in Serbia and with the accomplishment of results from the project:

> Students with disability in Serbia seldom take part in activities relating to changing their status in society. One of the basic characteristics of stigmatized groups, such as the group of young persons with disability, is that individuals that form it are isolated from society and withdrawn, with reduced social relations. They rarely have the opportunity to develop their social and intellectual abilities and skills.

In the second part of the report, one can find results of two surveys carried out in May and June of 2004, with students with disabilities at the University of Belgrade and the University of Nis.

The document also places a special emphasis on cases of privilege and discrimination by professors and colleagues as well as attitudes and needs of the interviewees regarding support and solutions. Adaptation of teaching styles is also addressed:

> Results demonstrate that in the situations when the teaching staff is prepared to make adaptations to fit the needs of students with disability, they mostly do it through flexible approach. Even when it comes to professors who are open to specificities of students with disabilities, there is still no idea about introducing learning/teaching aids and other means that would make studying easier for this population.

The second part of the survey emphasizes students with disabilities' motivation to pursue higher education. Finally, the last part of the report focuses on the analysis of legislation and policy related to the position of students with disabilities in Serbia, followed by proposals for policy change.

This document represents a first attempt to investigate the situation of students with disabilities in Serbia. At the same time, it is part of regional Southeast Europe initiatives for inclusive education for youths with disabilities. Additional research is absolutely needed as a follow-up to these insights.

DISABILITY MOVEMENT

After World War II, the first associations and groups of people with disabilities were established. Across the board, they were uniformly founded and organized according to types of medical diagnoses. These organizations were, and continue to be, largely funded by the federal government. Weak mutual cooperation between these organizations exists.

For years, these kinds of organizations worked to create an image of people with disabilities as persons in need of compassion and assistance. From the beginning of the period of crisis in 1990, and along with destabilization of the region and warfare, activities carried out by these associations basically consisted of delivering humanitarian aid and organizing charity events. As new, younger generations have taken up leading positions in some of these associations, they have endeavored to foster new attitudes and new ways for the associations to function. However, because such kinds of leadership shifts enact changes only at a slow rate, much has not changed in terms of the emphasis on charity.

In the past decade, a number of national government organizations have been founded with the intent to alter this situation. They mainly work with cross-disability principles in mind. The organizations have helped to introduce a new approach to disability problems by emphasizing a social model of disability with the stated purpose being the full integration of disabled persons into society.

In closing, Victor Pineda offers further perspective concerning the disability rights movement in Serbia:

> The nascent disability rights movement in Yugoslavia has already initiated small and successful changes and is shaping policy and public perception in line with the social model. This analysis recognizes that the circumstances of people with disabilities and prejudice they face are socially created phenomena and have little to do with the impairments of people with disabilities. This model sees the problem not as residing in the person with a disability, but as resulting from the structures, practices, and attitudes that prevent the individual from exercising his capabilities. . . . Overall there are over 40 active disability related organizations in Serbia and Montenegro, the great majority of these are primarily organized along single disability lines, and many are quite small, having an active membership of 25 or less. Two of the most active and organized voices in Serbia are the Association of Students with Disabilities, and the Center for Independent Living in Belgrade. These

> groups are claiming access and inclusion in an environment full of cultural, social and physical exclusion. In the new Democratic Serbia these proponents have passed laws, initiated media campaigns, and have been introducing a broader understanding of disability.

A new regional disability initiative, a project named Share SEE (Self-Help & Advocacy for Rights and Equal Opportunities South East Europe; http://www.share-see.org), could have outcomes not only for the Serbian disability movement but also for the whole region in general. The project promotes self-representation of people with disabilities, promotes cross-disability approaches, and advocates for changes in disability legislation in countries of the region.

Many positive signals are being transmitted that cooperation between cross-disability and social model organizations and the new government in Serbia is likely, particularly with the Ministry for Labor, Employment and Social Policy. Will this cooperation build foundations for changes in law, the inclusion of people with disabilities in civic events, and the establishment of equal opportunities for services that allow for inclusion to occur? The future for Serbian people with disabilities remains open to the possibilities for a new era of integration and access for all, but it remains to be seen how the country will ultimately respond.

CONCLUSION

Serbia, as well as other countries of the region, is in a state of transition. Laws are changing, the political situation is not stable, and minorities are at the end of legislators' priorities. This overview of the situation of people with disabilities in Serbia (and in the region of Southeast Europe) claims that future research is needed.

EXPERIENCE OF DISABILITY: SLOVAK REPUBLIC

The Slovak Republic/Slovakia is among the "newest" nations in Europe. The former Czechoslovakia gained independence from the Soviet Union in 1989 in a nonviolent process termed "the Velvet Revolution," and the Czech and Slovak Republics subsequently separated into two independent countries in 1993 in a nonviolent political process referred to as "the Velvet Divorce." Since gaining this two-phase independence, the Slovak Republic has faced much greater economic struggle and political instability than the Czech Republic, though in 2004 both countries made a major advancement toward "rejoining Europe" when they were granted entry into the European Union.

The Slovak Republic is a small, land-locked nation of fewer than 6 million people, bordered by Austria, the Czech Republic, Poland, Ukraine, and Hungary. With the exception of Austria, all of Slovakia's neighbors are also formerly communist nations that are undergoing transition to forms of democratic governance and free-market economies at varying speeds. Slovakia possesses a beautiful and largely rural landscape of heavily forested alpine regions, rustic villages, ski and trekking resorts, and farming regions. The capital city of Bratislava was largely overrun by communist era architecture, resulting in drab city blocks with the occasional enclave of preserved historic buildings. Architectural barriers to accessibility, however, are endemic, existing throughout urban and rural regions, pervading government, private, educational, and residential structures and public transportation systems.

As in many developed Western countries and other postcommunist countries in Central and Eastern Europe, the Slovak Republic population is aging, the birth rate is declining, the nature of illness is changing, and the pressure on limited public resources is rising (Kovic 2000). Health services are poorly equipped to address disability and chronic illness, as the health care infrastructure is largely based on a biomedical, acute care model (Holland 2003). While the current political climate is encouraging a greater percentage of the gross domestic product (GDP) to be dedicated to health care (Kovic 2000), there remains an emphasis on biomedical technology over community-based services, independent living, or prevention. Indeed, health care reform in the Slovak Republic has been referred to as "a case study in social policy immobility" (Lawson and Nemec 1998). Further complicating matters is a residual health care "gray market" system in which consumers pay out-of-pocket fees to health care professionals for clinical care. This gray market system not only serves to neutralize well-intended policy changes at the national level, but it also disadvantages those citizens who do not have significant private resources. Individuals and families with disabilities are disproportionately among these disadvantaged citizens, compounding health access difficulties.

Largely in response to the biomedical and custodial nature of services for people with disabilities, as well as some instances of severe human rights violations (Mental Disability Advocacy Center [MDAC] 2003), a large number of highly innovative and resourceful grassroots nongovernmental organizations (NGOs) have emerged to address the human rights, quality-of-life, and independent living priorities of citizens with disabilities in Slovakia. These grassroots NGOs have worked to fill existing gaps in community-based and independent living services by functioning outside of the confines of the sluggish, institutional, state-sponsored medical infrastructure. Many of the disability NGOs in Slovakia, often founded and led by citizens or families with disabilities, are actively promoting the independent living model and are challenging a long history of institutionalization of disabled people (Holland 2003). They pursue this mission, however, with extremely limited resources and with varying degrees of support for civil society organizations from a highly diverse and, at times, chaotic multiparty parliament.

Many of the disability NGOs in Slovakia are, like the broader national context, undergoing change and transition, and struggling with issues of identity. While some of the grassroots disability groups focus almost exclusively on service provision addressing complex activities of daily living, others have pursued a much more politicized human rights mission, challenging specific national policies and promoting political candidates who understand and support disability issues. This diversity among the disability organizations will ultimately constitute a strength, but at this stage of civil society development, the dramatic differences in missions among the groups can at times appear like lost opportunities for coordination.

The survival and strength of the disability NGOs in Slovakia, as well as in other transitioning countries in Central and Eastern Europe, will be critical for the independent living movement. The highly biomedically oriented, institutionalized, and custodial approach to disability, as reflected by the health care infrastructure, will likely change slowly. The remarkably resourceful grassroots disability NGOs in Slovakia, however, bear tremendous hope for disabled citizens there. It will be these disability NGOs that eventually direct necessary policy changes at the national level, while continuing their grassroots efforts to promote independent living in their communities.

EXPERIENCE OF DISABILITY: SUB-SAHARAN AFRICA

Disability as a category of discourse is foreign to sub-Saharan African thought. Disability is fundamentally a Western category that should be understood as a result of historical developments between people and society, in particular between people and states. In developing an idea about the experience of disability in African societies, one tries to approximate African ideas and practices that have had impacts on their existence, the individual and social lives, the development of disability services and practices during colonial times, and postcolonial developments.

How do people experience disability in Africa? Are there particular cultural practices and beliefs that inform this experience? These are important, but perhaps a more fundamental question is: Do people experience "disability"? What is the history of this experience? This entry first explores the nature of the category of disability in Africa and then looks into specific realities of disability in Africa.

DISABILITY IN AFRICAN THOUGHT

It can be said that disability as a conglomerate concept that defines people with different physical, sensory, mental, or emotional deficiencies does not exist in sub-Saharan Africa. Words referring to the concept of handicap or disability simply do not exist in African languages. This finding refers to the complicated history in Western thought that gave rise to the emergence, growth, and historical transformations of disability as a category of thought. The globalization of this thought is both part of a history of industrialization and the creation of modern society, as well as of colonization. While disability identifies "lack of," "deficiency," African thought refers more positively to a striving toward "wholeness." Indeed, "whole" and "health" have the same meaning in certain African languages, such as Swahili. While a category of disability does not exist as a repository in African languages, it should be stated that concrete translations for physical disability (lame, crippled, blind, deaf) do exist. But there are equally specific categories of deviation from the ordinary that are part of the African experience. Most notably, extra-ordinary children are identified by their assumed supernatural power. Among the Songye of Congo and many other African peoples, the birth of particular children signifies something out of the ordinary. Twins, children who are believed to hold up the rain, children born with particular characteristics (with a hand on the cheek, born with feet first, with the umbilical cord, with teeth) are given specific names and respect, and they are surrounded with ritual behavior.

In the postcolonial era, which is characterized by a decline of the state order, some children are identified with supernatural powers. With the absence of a generalized category, such as disability or handicap, it should not be assumed that there has been no historical development in the development of terminology in African languages. Yet it can be determined that some terms not only have a large time depth but also that their meanings and connotations varied over time and regionally. A contemporary example of terminology development can be found in Swahili. Here, the term *kipofu* (blind) became rejected because of its placement in the class of nouns associated with "smallness." A replacement was devised through the term *msiona* (pl. *wasiona*), which literally means "the person(s) who does not see."

During the colonial period, some institutional settings, such as schools, medical centers, and vocational services, were developed. In many instances, they were merely copies of developments in the colonial center and initiatives of the colonizing country. In a few cases, there have also been initiatives during the colonial period by Africans themselves. For some, these initiatives were the result of study in the colonial center. For others, these initiatives were spurred by influences both in and out of the country. Inside some countries, the idea of self-help for Africans became prominent. The most remarkable of the latter are perhaps the initiatives of Jairos Jiri in southern Rhodesia, now Zimbabwe, because of its African initiative, aided by colonial and later international help, and its large national network of institutional development. For a long time, during the colonial period and beyond, Jairos Jiri furthered opportunities for disabled people through rehabilitation and vocational training programs.

But in general, it should be stated that disability was not an important priority during the colonial period. The postcolonial period was characterized by some attention to the plight of veterans from the liberation wars. More significant though is the growing influence of the United Nations, which culminated in the International Year of Disabled Persons in 1981. For some African countries, the international year meant the organization of a national survey as its most important activity. For the first time, disabled people were to be counted in the African context. In the following years, specialized agencies in the United Nations each developed programs in education, health, employment, and agriculture designed to affect the disability problem in Africa on both national and regional levels. In an effort to develop a concept of disability appropriate for developing countries, the World Health Organization took the lead when it launched the concept of community-based rehabilitation (CBR). Its impact was very important on the conceptualization of practices and services that were developed by other UN agencies and the work of nongovernmental organizations (NGOs). The impact in some countries was considerable, but in others it was rather limited. In many cases, these efforts were considered as generated from the outside, as postcolonial, "development," activities. In the context of the Organization of African Unity (OAU), a multilateral organization was created for the purpose of guiding the development of disability services and policy in Africa, namely, the African Rehabilitation Institute. It influence has, however, remained limited.

During the middle 1980s, self-help was being reinvented, but in the different context of global and postcolonial realities. On the global scene, human and civil rights became translated into a disability consciousness and liberation movement. It was geared against institutional development and rather toward the formation of membership organizations, although service development became also part of the agenda. The distinction between "organizations of" and "organizations for" disabled people became relevant. The development of this movement in Africa was an interesting mix between political realties, most notably the resistance to the apartheid system in South Africa, the political alignment of the so-called frontline states, and the continued global influence of UN organizations and international NGOs. Again, Zimbabwe, partly because of its lead in the frontline states movement, also showed great leadership in the development of disability-oriented membership organizations, such as the Southern African Federation of the Disabled (SAFOD). Such leadership also expanded and translated into enhanced leadership at the national scene through the representation of disabled people by disabled parliamentarians, on a more global scale, such as within the leadership of Disabled Peoples' International, and in the development of new regional initiatives, such as the African Decade of Persons with Disabilities.

The remainder of this entry explores some pertinent cultural themes relevant to the understanding of disability in African contexts.

WHY DISABLED?

Moral or religious model thinking aims at achieving an insight into the essence of phenomena. It attempts to develop links between individual, social, and religious behavior and the occurrence of disability. Traditional knowledge systems, such as taboos, sorcery and witchcraft, and knowledge of God are instruments in grounding the very reason for not being whole, for being disabled.

These systems take away the attention from the individual into the natural, social, and religious realms in which disability is embedded. It would be correct to say that African knowledge of disability is "embedded" in its seeking for links between the occurrence of disability and several world orders. Examples are the natural order (e.g., through the observance of practices related to food and those related to contact, such as sexual and gaze taboos), the social order (as this is regulated by links between social behavior and misfortune, e.g., through sorcery and witchcraft systems of belief, and marriage regulations), and the cosmological order, in which a distant, bifacial (i.e., both good and bad) God is central.

An embedded concept of disability appears to be more powerful in addressing questions of the nature of our lives, less geared to the practical solutions. Such a concept seeks for solutions to be found outside of the disabled individual, for example, in the correction of behavior or in the taking out of evil forces. In contemporary African societies, the proliferation of religious sects supports the retaining and transformation of an embedded knowledge.

INFANTICIDE AND AFRICAN BROTHERHOOD

The killing of disabled children at birth is a practice that has been both described and denounced by colonial administrators in Africa. Such practice was seen as incompatible with the development of modern society and therefore forbidden by law. Little attention, however, went into the analysis of ritual practices and belief systems that surrounded such killing. It can be said that the occurrence of a deformed child at birth was seen as a disturbance of the order that required the intervention of an authority beyond the head of a household. In certain cases, and perhaps already under the influence of colonial practices, a fine was charged because of causing such disturbance. It is important that a higher authority (not the father) be charged with conducting the killing and observing certain rules. These rules included that such a child could not be buried because it would pollute the earth. An exception is the burial in a termite mound, because its earth is already infertile. More common was the practice of throwing such a child in the river, in accordance with the belief that people not merely die but return to a place before they are once again born. The spirit of the child was to be respected, for example, by placing a small white chicken (a symbol of purification) around the neck or ankle of the child. The person charged with the killing further would have to send the child back and admonish God to send perfect children instead. Returning from the river, this person could never look back. Such practices put into better perspective the nature of the killing and would make it difficult to maintain the colonial argument that these were cases of murder.

In some West African cultures, the killing of disabled children is mediated by beliefs that surround "children of the snake." These beliefs stress the wrong-headed impression that people can have of each other: "While one may see a child, it could be a different creature." These beliefs emphasize the permeability of borders and the possibility of transformation between different creatures. It is possible to test whether a child is of the snake by practicing ritual behavior that enables one to see whether such a child will transform itself. In some cases, it legitimates abandoning a child as a test of seeing whether it belongs to the snake.

Diametrically opposed to such practices of restoring order, the notion of African brotherhood or solidarity is a theme that emphasizes tolerance and mutual help, also toward people who are deemed to be unfortunate. The basis of brotherhood is the clan or totem. The theme has been expanded in political discourse, such as in the Kenyan concept of *harambee*. In the modern context, however, notions of brotherhood have sometimes been criticized as working opposed to capital accumulation and economic development in general. It also appears that institutional development, such as in the case of the Jairos Jiri association, became reasons to forego African brotherhood. Moreover, colonial influence created the disabled beggar who, situated in the colonial city, is entitled to its spot in the street and request alms. The disabled beggar is equally supported in countries influenced by Islam, where almsgiving is a central pillar.

AFRICAN PROVERBS

In Bantu-speaking Africa, a major theme dominates the moral imperative toward disabled people, as it is communicated in proverbs. In the first part, these proverbs admonish "Not to laugh at disabled people." The admonishment can be found in many, if not all, Bantu languages, that is, spoken by sub-Saharan African people. It is a very direct statement, without much variation. The second part of the proverb has many variations, but the message is very similar: It is unsure what will happen to your own life. This is expressed by referring to God as creator, of both good and bad things that can happen. It can also be expressed by referring to certain possibilities of things to happen, thereby referring to some trade-off between different choices: If this does not happen, then something else could still happen.

These proverbs communicate that one has no control over one's destiny and that laughing at disabled people would be the worst way of challenging that destiny, worse than, for example, laughing at poor people. These proverbs relate to an existential insecurity, essentially not knowing what the future will bring, and cultivating that knowledge.

LOCAL AND GLOBAL DIMENSIONS OF DISABILITY

In contemporary Africa, disability can be associated with contagious diseases, emerging industrialization, and traffic accidents; civil war and genocide; and terrorism. For these local conditions, there have been numerous responses, from within and outside Africa. In the aftermath of colonial initiatives, local NGOs have developed services, followed by the input of international NGOs, and from the UN specialized agencies. First, some of these services were driven by charitable and medical services, and development took place in the context of "centers for physically handicapped people." Since 1976, CBR was formalized by the World Health Organization as the more appropriate strategy for meeting the needs of rehabilitation, compared to institution-based rehabilitation. The other specialized agencies, such as UNESCO and the International Labor Organization, followed with compatible strategies in the areas of education and employment. Integrated education and income-generating projects were launched. Throughout the 1980s, many initiatives in Africa were geared toward the integration of persons with disabilities in all sectors of society. An emerging disability movement that became especially prominent in southern Africa crossed these service-oriented approaches. Influenced by international meetings, disability leaders such as Joshua Malinga became prominent in the disability movement, both in their own country and at the international level. The organizations that characterized this emerging disability movement were characterized by their membership, not services. Eventually, by the end of the 1990s, attempts were made to find a meeting place between service provision and the disability movement.

EXPERIENCE OF DISABILITY: TAIWAN

PRESENT SITUATION

Dignity has always been a major concern for disabled people in Taiwan. Most of them feel that they have been ignored and dishonored in every aspect of their lives, including the right to receive an education, to get a job, to have easy access to public places, and most of all, to live an independent life. In Taiwan, it was not until June 2, 1980, that the entire 26-article text of the Physically and Mentally Disabled Citizens Protection Law was promulgated, which was then completely modified to 65 articles in 1997. This law was passed to protect "the legal rights, interests, and livelihood of the disabled, secure their opportunity to participate in the social life fairly, consolidate the government and private resources, [and] plan and implement all measures of assistance and welfare." The law guarantees legal rights for the disabled and has significantly improved their welfare. The disabled persons referred to in the law are

> the people whose functions of participating in the society and engaging in the production activities are restricted or cannot be brought into full play due to physical or mental factors and who, after the process of examination and determination, are regarded as suffering one of [the] malfunctions which are in conformity with the grades regulated by the central competent authorities in charge of health and have received the handicap manuals.

The Ministry of Interior, Department (Bureau) of Social Affairs in the provincial government and the local governments are supposed to be in charge of all related affairs, such as welfare, nursery, services at home, medical treatment and rehabilitation, special education, vocational training, and employment services.

CULTURAL CONSTRUCT OF THE DISABLED IDENTITY

Before promulgation of the Physically and Mentally Disabled Citizens Protection Law, the disabled in Taiwan had gone through a very difficult period of time, and the disabled and their parents had to rely on themselves to take care of almost everything. The law helps solve many problems encountered by the individuals and their families. However, despite its well-intentioned plan and design, it still has limitations when put into practice, because the people who execute the regulations do not really care for the needs of the disabled. Indeed, given its 5,000-year cultural legacy, Chinese society is slow to react and care for the rights of underprivileged people. This negligence has its own history in Taiwan and speaks a lot about the human values that Chinese culture has nourished. With its long history, the Chinese should have more cultural assets that epitomize human values. However, when speaking of the rights and dignity of the disabled, Chinese society seems to head the other way.

To study and locate the source of the identity and stigmatization of the disabled in Chinese culture and to reveal old myths about disabilities, be they attitudinal, representational, or empirical, one may begin with a comprehensive understanding of the feudalist ideology, which is deeply embedded in Chinese culture. Given this ideology, the Chinese people are inculcated to respect only the privileged, the wealthy, and the powerful, and they look down on the underprivileged, who are often considered worthless and useless. Accordingly, disease is considered a taboo, a moral deficit, or a personal blemish, so the names of contagious or stigmatized diseases such as polio, cancer, and AIDS are not supposed to be mentioned directly. When a member in a family gets such a disease, the whole family will be discriminated against and considered morally inferior. In this situation, people might suspect that the family has done something evil or that their predecessors might have not accumulated enough merits to raise sound and healthy descendents.

Moreover, the Chinese people value family highly, and parents are responsible for continuing the strong lineage of a family. Children are supposed to honor their parents, so they will not be accused of disrespecting them. Thus, a family's value depends on its good genes or blood. Children are often considered extended egos of the parents, so a good and prosperous child can honor his or her parents by continuing the strong lineage of the family. Given this concept, a disabled child is therefore considered shameful and a burden to a family, as well as being a symbol of bad blood. The child is unwelcome because he or she cannot get married easily and is therefore unable to continue the lineage of the family. Raising children, earning enough income, maintaining a decent family, and showing filial piety all become impossible for a disabled child. Unfortunately, his inability to fulfill the family obligations marks him as less of a human.

Presently, Chinese and Taiwanese societies have changed greatly in terms of their treatment to the disabled, but most people still retain the same prejudices about them. These misconceptions make it harder for the disabled to find work. To help the disabled get minimum-wage jobs, the Taiwanese government deliberately offers them the job of selling lottery tickets. The government's intention is good, but the job system is still based on the biased understanding that the disabled cannot earn a decent living by their abilities and have to rely on the public's sympathy to buy lottery tickets. Sadly enough, misery and poverty seem to be the necessary outcome of a disabling condition.

GREATNESS PERSONIFIED

Given all the disadvantages, however, a disabled person can be redeemed by academic or worldly achievements, because the Chinese people, on the basis of either a feudal concept or Confucianism, think highly of scholars, officials, and successful people. If a disabled person overcomes his limitations by achieving something valued and recognized by Chinese society, such as scholarship, he or she will be treated differently and thus gain respect. Liu Hsia, for instance, is one of them. Liu contracted rheumatoid arthritis at the age of 12 and was confined to a wheelchair. She once jokingly called herself a "walking quadriplegic fossil" since she had been suffering from the disease for almost five decades. Her disease hindered her from receiving any formal school education, but she managed to study on her own and went on to establish herself as an acclaimed author under the pen name Hsing lin tsi, with a body of work of more than 30 books of essays, novels, autobiographies, and audio books. Most of her articles are inspirational, and she won the National Literature and Art Award in 1982. Liu's writing also earned her a commendation as one of Taiwan's 10 most outstanding women in 1980, and she used the award's NT$200,000 (US$5,700) in prize money to establish the Eden Social Welfare Foundation to take care of people who have disabilities. Many people adore her and are deeply inspired by her strong sense of humor and inspirational attitude toward life. For instance, Reverend Maurice Alwyn Sween III, an American missionary who has been residing in Taiwan for the past 15 years, once said that Liu often inspired him with fresh ideas. "Reading her articles helped me calm down, think deeply and remain clear minded toward the challenges in my life," said Sween. Indeed, she had a unique perspective, which encouraged people to hope and to never give up. In 2000, she was appointed as a presidential adviser. In 2003, Liu passed away at the age of 61 as the result of an accidental but fatal assault from her Indonesian maid.

In Taiwan, there are still many outstanding disabled people whose lives can always be a source of inspiration. In addition to Liu, Wu Shu-chen is another exceptional figure who has drawn attention to the human rights and dignity of the disabled. She is the first lady of President Chen Shui-bian. In 1985, while accompanying her husband to thank voters for their support, she was seriously injured after being run over by a truck. Her life was spared after multiple operations, but she has ever since been a wheelchair user. Despite her physical impairment, she was later elected as a legislator. Wu's experience in overcoming her trials further enhances her standing as not only a spokesperson for Taiwan's battle to win international recognition but also a role model for the disabled.

In addition to these extraordinary figures, most of the disabled people in Taiwan are still struggling to earn their due respect. At any rate, the disabled people's awareness is emerging gradually and significantly in Taiwan, and they are now able to fight against the able-bodied public's ideological projections and feudalist investments, which have accorded a common set of stigmatizing social values to disability and determined the treatment and positioning of the disabled people in society. With their arduous efforts, they hope that one day they can rewrite the history of the disabled in Taiwan and redefine the meaning of disability.

EXPLANATORY LEGITIMACY THEORY

Explanatory legitimacy theory builds on historical and current diversity analyses and debates. Within this framework, disability is defined as a contextually embedded, dynamic grand category of human diversity. Thus, who belongs and what responses are afforded to category members are based on differential, changing, and sometimes conflicting judgments about the value of explanations for diverse human phenomena. This approach to defining disability differs from previous schemes in which disability was determined by the presence of a medical condition that caused permanent limitations in one's daily function. For example, consider three individuals who use a three-wheeled cycle. The first is a child learning to ride a bike. The second is a woman who, because of balance challenges, uses a tricycle. The third is a man who delivers groceries in an urban neighborhood. Each individual engages in cycling activity using a tricycle but the explanation differs. According to explanatory legitimacy, none, one, two, or all may fit the category of disability or not and may engender different responses. Let us see how.

BACKGROUND AND THEORETICAL FOUNDATION

Looking back in history to civilizations that predated the emergence of industrialization, medical knowledge, and technological sophistication, the grand category of disability did not exist. Rather, the identification of, worth of, and community response to those who acted and appeared in ways that were considered to be atypical were inferred on the basis of context-embedded value judgments about attributed explanations for why individuals did not fit within conceptualizations of typical. And while definitions and responses have changed over time, contextually embedded values still form the basis for defining and analyzing disability. Thus, the influence of multiple factors (including but not limited to natural, chronological, spiritual, and intellectual trends) on value judgments is the key to understanding categorization, the legitimacy of individuals and groups who fit within a category, and the responses that are deemed legitimate for members.

In the twentieth and twenty-first centuries, three contextual factors—(a) economic productivity; (b) medical knowledge, technology, and professional authority; and (c) diversity—have had significant roles in definitions of what is typical, how phenomena that fall outside of the typical are explained, and the differential and complex determination of these explanations as legitimate disability status and response.

These factors have intersected to produce two overarching and hotly debated views of disability in the current literature: medical-diagnostic and constructed. Medical-diagnostic definitions locate disability within humans and define it as an anomalous medical condition of long-term or permanent duration. Thus, within this conceptualization, the domain of disability definition and response remains within the medical community. In opposition, however, to what was perceived as a pejorative, the constructed school of disability emerged. Within this broad theoretical category, disability is defined as a set of limitations imposed on individuals (with or even without diagnosed medical conditions) from external factors such as social, cultural, and other environmental influences. Both categories of thinking provide a forum for rich debate and intellectual dialogue. However, as the discourse expands and is applied to increasingly more fields of study and application, analysis of what disability is and is not calls for theoretical specificity that can address the complexity of disability within the larger context of human diversity.

THREE ELEMENTS OF EXPLANATORY LEGITIMACY

Explanatory legitimacy theory makes the distinctions among descriptive, explanatory, and the axiological or the legitimacy dimensions of the categorization of human diversity and identifies the relationships among these elements. Thus, similar to legitimacy-based analyses of other areas of human diversity, disability, defined and analyzed through the lens of explanatory legitimacy, is composed of the three interactive elements: description, explanation, and legitimacy.

Description

Description encompasses the full range of human activity (what people do and do not do and how they do what they do), appearance, and experience. Of particular importance to description is the statistical concept of the "norm." Developed by Belgian statistician Adolphe Quetelet in the late 1800s, "the normal man" was both *physically and morally normal.* Based on probability, the concept of normal translates into the most frequently occurring phenomena. Extremes are the "abnormal" and minimally occurring. Thus, common and frequent phenomena formed the basis for what we consider as normal and are the foundation of many theories and practices today regarding the acceptable limits of human description. Observation therefore turned to prescription and anyone exhibiting difference in activity, appearance, and/or experience was considered abnormal.

Because understanding and naming of what is normal are value based, use of terms such as *normal* does not provide the conceptual clarity sufficient for distinguishing description from axiology. Thus, in applying explanatory legitimacy to disability, the terms *typical* and *atypical* are used. They refer to magnitude rather than desirables.

Thus, description is conceptualized as two intersecting dimensions (typical/atypical and observable/reportable). Typical involves activity, appearance, and experience as most frequently occurring and expected in a specified context. Atypical refers to activity, appearance, and experience outside of what is considered to be typical.

Observable phenomena are activities and appearance that fall under the rubric of those that can be sensed and agreed on. Reportable phenomena are experiences that can be known through inference only.

Explanation

The second element of explanatory legitimacy is explanation. Applied to disability, explanation is the set of reasons for atypical doing, appearance, and experience. For example, what are described immediately above as the medical-diagnostic and constructed approaches are in our definitional taxonomy, explanations of doing, appearance, and experience across the lifespan. What is important to highlight with regard to the link between description and explanation is that explanation is always an inference. Because of the interpretative nature of explanation, this definitional element lends itself to debate and differential value judgment.

Legitimacy

The third and most important definitional element of explanatory legitimacy is legitimacy, which we suggest is composed of two subelements: judgment and response. Judgment refers to value assessments of competing groups on whether or not what one does throughout life (and thus what one does not do), how one looks, and the degree to which one's experiences fit within what is typical and are valid and acceptable explanations that are consistent with an all-too-often unspoken value set. Responses are the actions (both negative and positive) that are deemed appropriate by those rendering the value judgments. We have selected the term *legitimacy* to explicate the primacy of judgment about acceptability and worth in shaping differential definitions of disability and in determining individual, community, social group, and policy responses to those who fit within diverse disability classifications.

APPLICATION

Consider the following two examples.

Example 1

On the first day of their physics class, John and Jane both bring tape recorders for note taking. Dr. Joseph asks John and Jane to turn off the tape recorders, letting them both know that she does not allow students to tape her lectures. After class, John talks with Dr. Joseph indicating that he uses the tape recorder as an assistive device for a learning disability as recommended by disabled student services. Jane, however, tapes the lectures because she lives over an hour from the university and has a new infant who distracts her from reading at home. By taping lectures she is able to study in the car. In both cases, the observable atypical activity is tape recording a lecture when all other students are taking notes. John has a medical-diagnostic explanation and Jane has a social explanation for the atypical activity. For Dr. Joseph, only John's explanation legitimates him as a disability category member worthy of special response.

Example 2

Two women present in the emergency room with broken noses and bruises (description). Because Sue was injured in a fall after tripping on the shoes that her husband left on the floor (explanation), she is not considered to be a victim (illegitimacy as a victim). Heidi, who was assaulted by her partner (explanation), qualifies for legitimate victim status and is afforded the services and supports of the domestic violence system (legitimacy response). Knowing that Sue has very poor balance (explanation), her husband left the shoes on the floor purposively with intent to harm. On the basis of disability membership (disability legitimacy determination), Sue is tacitly and perhaps unintentionally denied credibility as a victim (victim illegitimacy determination) and thus is not met with access responses to services that may prevent further injury or even death (illegitimacy response).

Explanatory legitimacy is a theoretical framework that not only addresses a full range of analytic complexity but also provides guidance for related social action. Both examples highlight the link between explanatory legitimacy theory, universal ideology, and the action steps that derive there from. If responses to both students had been considered in terms of need rather than disability category membership, it is likely that Dr. Joseph would have expanded tape-recorded note taking as an option for all students. To the contrary, if the victim identification protocol had been universal in scope and focused on harm rather than inferred explanations for harm, disability membership would not have been met with exclusion.

In summary, explanatory legitimacy theory builds on a rich history of intellectual examination and debate. As a pluralistic theoretical framework, it locates disability within multiple discourses and provides theoretical clarity to pave the way for informed social action.

F

FACILITATED COMMUNICATION

Facilitated communication training (FCT) is a strategy for teaching individuals with severe communication impairments to use communication aids with their hands.

> In facilitated communication training a communication partner (facilitator) helps the communication aid user overcome physical problems and develop functional movement patterns. The immediate aim in facilitated communication training is to allow the aid user to make choices and to communicate in a way that has been impossible previously. Practice using a communication aid such as a picture board, speech synthesizer, or keyboard in a functional manner is encouraged, to increase the user's physical skills and self-confidence and reduce dependency. As the student's skills and confidence increase the amount of facilitation is reduced. The ultimate goal is for students to be able to use the communication aid(s) of their choice independently.
>
> Facilitated communication training is a teaching strategy of particular relevance to individuals with severe speech impairments who can walk but have had difficulty acquiring handwriting and manual signing skills. Many such people are diagnosed as intellectually impaired and/or autistic. Through facilitated communication training numbers of these people have achieved functional communication, often revealing unexpected understanding and academic potential. (Crossley 1994)

Practices very much like facilitated communication had emerged from time to time around the world with particular people (e.g., Oppenheim 1973), but its development as a technique of general application dates from its rediscovery in Australia in 1975 by Rosemary Crossley and Anne McDonald and its adoption in the United States by Douglas Biklen. Crossley and Biklen also suggested that the high proportion of people previously regarded as intellectually impaired who had been enabled to communicate through facilitation cast considerable doubt on traditional views on the nature of the condition.

From the outset, FCT was surrounded by controversy. Many people continued to assert that the communications said to be coming from the person with communication impairment were in fact simply unconscious projections by the facilitator. An extensive bibliography deals with the conflicting studies on the validation of these communications. Two books of essays dealing with the controversy are Shane (1994) and Biklen and Cardinal (1997). Arguments became particularly pointed in the 1990s when many allegations of sexual abuse were made though facilitated communication. The method was condemned by the American Psychological Association in 1994 as a "controversial and unproved communicative procedure" and was described by one critic as "an unacceptable challenge to professional belief systems" (Shane 1993). Evidence of clients successfully achieving communication was condemned as anecdotal.

The debate continues, but differing epistemologies and presuppositions make it unlikely that any professional consensus will emerge. FCT continues to be used by a number of people around the world, assisted by the emerging evidence of increasing numbers of facilitated communication users who have graduated to independence. In the section on facilitated communication in the 1998 edition of their widely used textbook on augmentative and alternative communication, for example, Beukelman and Mirenda describe one long-term user:

> Sharisa Kochmeister is a person with autism who at one time had a measured IQ score somewhere between 10 and 15. . . . She does not speak. When she first began using facilitated communication (FC) several years ago to type on a keyboard, she required an FC facilitator to hold her hand or arm as she hunted for letters on a keyboard. No one thought she could read, write, or spell. She can now type independently (i.e., with no physical support) on a computer or type-writer.
>
> Sharisa joins a small group of people around the world who began communicating through FC and are now able to type either independently or with minimal, hand-on-shoulder support. There can be no doubt that, for them, FC "worked," in that it opened the door to communication for the first time. . . . We include FC here because of Sharisa . . . and others who now communicate fluently and independently, thanks to FC. For them, the controversy has ended. (p. 327)

FAIR HOUSING ACT AMENDMENTS OF 1988 (UNITED STATES)

Although not as well known as the Americans with Disabilities Act (ADA), the 1988 Fair Housing Amendments to the Civil Rights Act of 1968 (Fair Housing Act) guarantee civil rights of people with disabilities in the residential setting. The amendments extended coverage of the fair housing laws to people with disabilities and established accessible design and construction standards for all new multifamily housing built for first occupancy on or after March 13, 1991.

The Fair Housing Act, U.S. federal law that includes provisions for making all newly constructed multifamily housing accessible to a limited degree, covers the sale, rental, and financing of dwellings and other housing-related transactions. It prohibits discrimination based on color, national origin, religion, sex, familial status, and disability. Civil rights organizations are active in advocacy to promote the goals of the act and ensure its compliance. This includes monitoring and documenting cases of discrimination as well as legal action to obtain compliance.

By mandating adaptability (such that features of buildings that are not initially accessible can be made fully accessible with little effort and expense) and minimum accessibility in all new multifamily projects, this law was a major step toward achieving universal design in housing in the United States. But the amendments also ensured that residents with disabilities have a right to make accommodations to multifamily dwellings. Prior to the enactment of the law, the owners of buildings could prevent a tenant from adding a grab bar, widening a doorway, installing a ramp, or lowering cabinets, even if the tenant was willing to pay for the renovations. Not only did the amendments provide the legal means by which they could make modifications that they needed for accessibility, but they also require landlords to allow tenants to make changes to public parts of facilities, such as installing an automatic door opener at the entrance to a building or a ramp on the site. However, landlords can require the tenant not only to pay for the modifications but also to restore the areas modified back to their original condition when the tenant leaves.

Perhaps the most important feature of the Fair Housing Act amendments is the requirement that all new construction of multifamily buildings comply, unless covered by specific exceptions. *Multifamily* is defined as any building that has more than three dwelling units (although not including row houses). The act applies to housing finance both privately and publicly. Prior to the enactment of the act, only a few states had laws that required accessibility to dwelling units constructed with private funding. All dwelling units covered by the act must be accessible. Prior to the enactment of the act, accessible housing was generally provided by a small percentage of designated units. Thus, for new construction, the Fair Housing Act amendments introduced universal access to the multifamily housing industry.

To ensure compliance with the provisions of the act in new construction, the U.S. Department of Housing and Urban Development issued the Fair Housing Act Accessibility Guidelines (FHAAG). There are seven requirements in the guidelines:

1. An accessible building entrance on an accessible route
2. Accessible and usable public and common-use areas
3. Usable doors
4. An accessible route into and through the dwelling unit
5. Environmental controls in accessible locations
6. Reinforced walls for grab bars
7. Usable kitchens and bathrooms

Each of the seven requirements has specific technical design criteria that provide a basic level of accessibility. It is important to note that, as minimum design criteria, the FHAAG does not serve all the needs of people with severe disabilities, particularly inside the dwelling unit. The guidelines are also not as comprehensive and detailed as the ADA Accessibility Guidelines, but the latter do not have requirements specifically for dwelling units.

There are three important exceptions to Requirement 1. First, only the first-floor units in buildings that do not have elevators in housing built on steeply sloping sites are covered by the act. Second, there are exceptions for sites where accessibility is impractical due to the topography of the site (steep slopes). Third, another set of exceptions is allowed for unusual site characteristics such as location on a flood plain or coastal high-hazard area where building codes require floor levels of living areas to be a certain distance above grade.

Requirement 2 basically treats the shared areas of multifamily buildings and facilities like public buildings. This includes laundries, playgrounds, swimming pools, mailrooms, and other shared spaces. The FHAAG specifies the scope of accessibility to these spaces and references the ICC/ANSI A117.1 Standard, the model standard used to define minimum accessibility in the United States (American National Standards Institute 1998), for technical criteria. Only one entry to the dwelling unit is required to be accessible. And only one accessible path of travel is required. So, for example, a first-floor dwelling unit may have an accessible entrance to the front of the unit, but there may be stairs leading to a rear door.

Requirements 3 and 4 ensure that the circulation spaces inside the dwelling unit are accessible. The requirements do not preclude lowered or raised areas of rooms, but they do require that all rooms be on an accessible path. A major difference between other accessibility provisions in the United States and the FHAAG is that doors inside dwelling units are not required to have latch side clearances. This restricts usability for people who have limited reaching ability or large wheelchairs.

Requirements 5, 6, and 7 require a basic level of accessibility to the fixtures and equipment in the dwelling unit. This includes electrical switches and outlets, appliances, and plumbing fixtures. There are detailed requirements for access to bathrooms, ensuring privacy and independence. However, the requirements for the kitchen do not include knee clearances and lowered cabinets and counters. Bathroom requirements are also less generous than those required by the ADA, especially due to the lack of latch side requirements at doors and shorter grab bar allowances at toilets. Finally, the FHAAG does not require grab bars to be installed in any unit.

The guidelines produce dwelling units that are accessible at a basic level. The authors of the act and the regulations that support it consciously traded off the extent of accessibility required to obtain political support to cover a wider number of dwelling units. The guidelines, however, do incorporate features that allow the units to be easily adapted to an individual's specific needs. For example, Requirement 6 specifies that reinforcing must be installed in the walls of bathrooms to allow grab bars to be installed easily in the future, should they be needed by the current resident of a dwelling or some future resident. Furthermore, although the FHAAG does not specifically require it, there is an incentive for vanities to be removable or adaptable to allow the provision of knee space under a sink in the kitchen or bath. Both these measures save money by reducing expensive modification costs, and they provide added value to the design of the home.

The FHAAG does not substitute for other accessibility requirements in housing. For example, other federal accessibility laws still require 5 percent of dwelling units in federally financed housing projects to comply with the more stringent requirements of ICC/ANSI A117.1.

Housing designed to the guidelines is attractive to a wide variety of people, including people with chronic pain, temporary disabilities, visitors with a disability, and older people. Incorporating adaptability into the design also reduces the cost of making expensive modifications to accommodate an individual with a disability. This type of change is not limited to a new tenant moving in. Older people often need modifications to their dwellings to maintain independence. Disability can also occur to otherwise "healthy" people as a result of accident or disease.

Compliance with the Fair Housing Law, like the ADA, is a complaint-driven process. Initially, there was no local method of implementation in regulations. This situation is changing as the United States moves toward more uniformity in building codes. The 1999 version of the ICC/ANSI A117.1 Standard incorporated optional requirements for design of dwelling units that are essentially the same as the FHAAG. These requirements are now referenced in model construction codes that are adopted by the states and, increasingly, are being incorporated in state accessibility codes as they adopt the new model codes. In states that had more stringent requirements for housing, there is a concern that these modifications will reduce the level of accessibility provided.

While the guidelines are generally easy to implement, in comparison with the far more extensive ADA Accessibility Guidelines, information about the Fair Housing Law and its impact on new construction has not been nearly as easy to obtain as information about the ADA requirements. In fact, there is evidence that architects and builders are not very knowledgeable about the Fair Housing requirements. Builders, who prefer to construct the same design as much as possible, have made few changes in their designs to address compliance. The result has been the beginning of a wave of litigation by the U.S. Department of Justice to raise the profile of the law and ensure that the building industry understands that it must comply. Several cases have been either settled or are in the process of litigation. Settlements can include requirements to renovate common facilities, renovate units already constructed, provide opportunities for owners of condominiums to renovate their apartments if desired, and provide funding for other home modifications in the community if renovating the noncomplying units is infeasible.

FAMILY

In a rapidly changing world, there is no longer an easy answer to the question "Who is the family?" Yet it is a profoundly important question for people with disabilities and their families. Governments around the world are committed to policies that support citizens with disabilities and their families, often under the banner of community care. But we know that most care in the community is care by the family, and that families "who care" save governments billions of dollars. Support and care between family members are the product of many forces—love, duty, obligation, reciprocity, altruism, custom—but it is a vital form of support that is primarily unpaid. As far as is known, it is also the norm in all societies. Who, then, is the family that takes on these responsibilities? How do families organize support of disabled relatives? How is this experienced? And what should families expect from governments to assist them in their endeavors?

WHO IS THE FAMILY?

Governments come and go but, taking a traditional view, the family as an institution is supposed to be a constant, even a stabilizing influence on society. In countries where major economic, political, and social changes have taken place, the family as an institution has endured but family structures, family forms, and the boundaries of families are being reshaped (Silva and Smart 1999). In many postindustrial societies, people are marrying later, having fewer children, and becoming parents later in life. Women are realizing improved educational opportunities, control over their fertility, and greater participation in paid employment. Changing demographics such as these will continue to affect the supply of people within families who are theoretically available to undertake caregiving responsibilities, but government policies can foster or restrain conditions that make this possible.

More significant than banner statistics about the family is the growing consensus that diverse patterns of family life exist. Perhaps the most major change in the concept of the family is that it can be represented in terms of the subjective meanings of intimate connections as well as formal, objective blood or marriage ties. This means that it is subjective experiences that can create ties between people living in separate households for part or all of the time, as well as people who choose to belong as a family.

What a family is can be closely linked to what it does, including, for example, support of disabled relatives, child care, sharing of resources and skills, and the meeting of demands and responsibilities. Within this context of changing definitions of *family*, there is little evidence to suggest an abandonment of commitment or obligation, much as those with more conservative views might argue. Newer family forms generate their own rules and norms to regulate exchanges and responsibilities so as to address the same commitments as other, more traditional, families. Though some of these arrangements are recognizable—families of choice, parenting across households, parenting by people with disabilities, single-parent families, and stepfamilies—many do not yet have names. Gene therapy and sperm donorship are making sure of that. Hence, there exists not solely one kind of family capable of producing moral, autonomous, caring citizens or of supporting in a sensitive manner family members with disabilities.

Values and beliefs that are culturally rooted, and long established, have a powerful influence in the setting of hierarchies of responsibility within families. Who ends up caring for whom therefore is likely to be a direct or indirect product of this. This may also affect who is defined as being part of the family and how help-seeking is negotiated. Currently, little is known about relationships between disabled people and their families from different ethnic and racial groups, especially outside of North America. Constructs of "the family" in developing countries, and how they organize their affairs, are likely to provide important lessons about effective ways of supporting disabled relatives, and how disabled people in turn can make valued contributions within the family and the community.

It is self-evident that "the family" is more than the sum of those individuals who live in the same home. Steady improvements in health and survival together with social and geographic mobility lead inevitably to the dispersal of families, though not necessarily to their fragmentation. More recent technologies such as the Internet, e-mail, and cell phones are means by which physical barriers to communication between family members can easily be accommodated, and responses to demands and crises dealt with. Indeed, these technologies represent one way in which care and support "from a distance" can be brought into play. By definition, they cannot replace requirements for more hands-on support and care where direct contact, intimacy, or constancy is necessary. This illustrates one of the fundamental divisions in how families fulfill their caregiving responsibilities toward those with disabilities or high support needs, that is, by accommodating responsibilities toward "caring for" persons while maintaining a commitment to "care about" them.

FAMILIES SUPPORTING DISABLED RELATIVES

Many ways of describing how families "do their caregiving" have been discussed in the literature. One of the more enduring approaches is to distinguish "caring for" from "caring about" responsibilities. Early social policy research tended to focus on caring-for responsibilities depicted largely in terms of highly personal care (e.g., helping someone with bathing, toileting, dressing) or homemaking (e.g., assisting with laundry, ironing, gardening). These activities can be regarded as task-based or *instrumental* in character, and clearly important as such. This is sometimes referred to as direct work. At the same time, families express how they care about their disabled children and relatives in other ways. These are rather less tangible, but no less important, and include things such as planning and anticipating, negotiating, problem solving, and case managing, all of which can be regarded as kinds of indirect care. With both direct and indirect care (caring for and caring about), there is typically an integral affective or emotional dimension reflecting the strength of ties that bind family members together.

Such ways of mapping how families express their support and care of children and relatives with disabilities dominate in the literature. They typically show that mothers are responsible for most direct care, with male partners playing a more secondary or even discretionary role. Indeed, it is the mothers who continue to occupy the role of what might be termed *primary caregivers*. In these regards, their commitments parallel those of mothers of nondisabled children. There is further evidence to suggest that when caregiving needs are most intensive or prolonged it is mothers who will be on the front line. At lower levels of caregiving intensity, contributions from male partners are more apparent. Gender divisions are not quite so clear-cut in relation to indirect care, not least because responsibilities do not fall so readily into the hands of any one person.

In relation to disabled children, grandparent support has been tacit but only recently formally studied in a systematic way. Maternal grandparents have been found to provide more support than paternal grandparents, grandmothers typically provide more support than grandfathers, and grandparents living closer to the family of the child with a disability seem to provide more support than those living farther away. Current research is exploring whether such support truly complements parent support and how it ameliorates or contributes to parental stress and adaptation. Support from siblings of the child with disabilities can similarly complement that of parents and may be particularly important at times when parents are under pressure. The impacts of such obligations on younger siblings, especially those of school age, require special attention given the formative stage of their own development.

Support and care within families are generally presumed to be positive in their effects, but this is not always so. The intent is one thing; the experience may be another. This makes it imperative to draw distinctions between motivations for caregiving, delivery of care, and the actual experience and outcomes of that care from the perspectives both of family members and disabled people in the family. Through careful and ethically sensitive research, representations of the views and experiences of disabled children about aspects of personal and family life are now emerging that will shed further light on supportive arrangements within families.

Family caregiving has also been studied with reference to its intended purposes with a focus on motivations and outcomes rather than tasks. Such research highlights caregiving that is anticipatory, preventive, and protective as well as supervisory and instrumental. Indeed, there is evidence to suggest that family caregivers tend to think more readily along these lines. This has the advantage of sensitizing those with responsibilities for supporting families to the goals to which families aspire, to what families achieve, or to what frustrates them along the way. It therefore shifts the focus from a purely process-based orientation to one that embraces both processes and outcomes.

A linked conceptualization sees disability and its consequences for families constructed from four dimensions: onset, course, outcome, and incapacity. The *onset* of a disability may be immediate or gradual, expected or unexpected, with the particular circumstances creating challenges and demands for families. The *course* of a disability may be progressive, constant, or relapsing/episodic. The character of the course therefore affects the ability to predict when and how supports need to be put in place. The *outcome* of a condition relates primarily to the expectation of death or shortened life expectancy, which may lead to the tendency to overprotection by families. *Incapacity* is the final dimension, characterized in five areas: cognitive, sensory, mobility, energy, and stigma. Different types of incapacity are seen as requiring differing responses from individuals and families, mediated in turn by values, expectations, and available coping resources. The four dimensions within this model are united by what has been called a "meta-characteristic," namely, predictability. Evidence suggests that families find it more difficult to deal with things when conditions remain less predictable. To some degree, this can be overcome by having access to good information about the onset, course, outcomes, and incapacities likely to be encountered.

These are examples of medical model thinking that views the person's disability as *the* challenge to be addressed or overcome. They do not fully explain oppressive forces that people with disabilities and their families face on a day-to-day basis. On the other hand, the social model redefines disability as the product of how the institutions of civil society exclude, disadvantage, or oppress people, rather than viewing impairment as a personal tragedy with the individual as victim. It addresses the lived experiences of people with disabilities and their families. Potentially, then, the social model has the capacity to see the interests of disabled people and their families as being united in a struggle to overcome the environmental roots of disadvantages that bar people from participating in community life on an equal footing with others. A critique of the social model is that impairment per se cannot and should not be marginalized on the grounds that it does in fact play an important part in their everyday experiences as disabled people.

EXPERIENCES OF FAMILY CARE

After many years of research about how families experience disability, most of the accounts are from the primary caregivers—principally, mothers of disabled children, spouses or partners of disabled adults, or children of older people with disabilities. Multiple accounts from different family members within studies are still rare, so controlled comparisons of the roles, reciprocities, experiences, and outcomes of supporting disabled relatives remain a priority for prospective research.

Family caregiving of children and relatives with disabilities is frequently portrayed as a stressful experience. Images of burdened or even burned-out family members who need respite from their caregiving roles continue to dominate the professional and academic literature. These perspectives depict family carers as being physically and emotionally stressed, with limitations placed on fulfilling social relationships, employment prospects, and quality of life. This view is based on a deficit model, which presumes that supporting someone with a disability must be burdensome or unduly challenging and that burden and challenge lead inevitably to negative experiences within the family. Nevertheless, there is a lot of evidence showing that perception of potential stressors and how these are appraised in relation to available personal coping resources are important keys to understanding how family members adapt to the pileup of demands they face.

Recent studies of parents with children with intellectual disabilities show that mothers tend to be more stressed than fathers by the behavior problems of the child, possibly because they are more involved in everyday direct caregiving, but that fathers can be more troubled by external factors such as other people's responses to or acceptance of the child. Many mediating factors have been identified in explaining such gender differences, but there is a general acknowledgment of the need for much further carefully designed research here.

Stereotypes are sometimes used to maintain an underlying pathological view of families. For example, it is still common within professional discourses to hear families being talked about as if they were responsible for the difficulties faced by their disabled relative. This is perhaps most prevalent in connection with parents of disabled children where the language of overprotection is commonly used. Similarly, the stress and burden families are presumed to face are sometimes linked to the idea that families are rather passive, unresourceful, and lacking in agency. Alternatively, in other accounts of family caregiving there is a tendency to view families as having agendas and needs that stand in opposition to those for whom they care, this perhaps being more common where disabled family members have reached adulthood with distinctive rights and claims of their own. Then there are families who are depicted as being frozen in time as a result of wanting to remember earlier times before they were engulfed by caregiving demands.

This type of imagery identifies caregiving, most of it undertaken by women, as a part of their oppression or marginalization, the proposed solutions to which appear to be a return to forms of residential or collective group home living by disabled people. This position has been criticized by disabled feminists for assuming that disability equates with dependency, and for also overlooking the voice and subjective experience of disabled people themselves, and what they contribute to collective well-being within the family and beyond.

More recently, there has been growing recognition of the wider complexities of family caregiving, including a fuller appreciation of its associated transformations and rewards. This, in turn, has been leading to a more positive view of how families accomplish their caregiving and of the capacity of families to learn, adapt, and overcome. In families with children and adults with intellectual disabilities, for example, there is undeniable evidence showing how the coping repertoires of families expand through experience. This evidence also shows how mastery increases though the growth of self-confidence and skills. As family members ascribe meaningfulness to their caregiving, the role and position of caregiving are often reevaluated in a positive way. Strengthened ties between the caregiver and the cared-for person are commonly reported arising from a fuller acknowledgment of the layers of reciprocities that bind people together. Love, coupled with the moralities of duty and obligation, is important here.

There is also experience suggesting that rewards and satisfactions accrue from overcoming everyday challenges. These can emerge from dealing successfully with matters that might seem mundane to third parties—helping to lift someone more efficiently, receiving a smile of acknowledgment from someone with a severe cognitive impairment—but they can also occur when families make breakthroughs, especially when their caregiving efforts give rise to a reevaluation of prognoses by doctors, as has happened quite frequently in families with disabled children.

Hence, despite what might at first appear to be multiple limitations in their daily lives as a result of caregiving, many families share hopeful visions and experiences, or what some have called profound personal growth, because of this experience. This "embrace of paradox" as it has been called is a perspective that acknowledges the frustrations, the sometimes dashed hopes, and the emotional troughs of caregiving experiences, but it also suggests the existence of a capacity to bounce back as a result of something more resilient that makes families what they are.

Identifying all the factors that appear to make some families, or some family members, more resilient than others when facing similar challenges remains an important topic for continuing research. Different theoretical starting points are assumed: some searching for personal qualities that make some individuals more resilient than others, while there is an alternative view that resilience should be viewed as a family-level construct. A number of different starting points have been suggested for further investigation here.

First, there is the theme of identifying capacity rather than incapacity within families. Families are often reminded by outsiders of their deficits rather than their competencies and expertise. Like disabled people, families are often reminded of their dependency status by formal organizations that continually check their eligibility for health or social care services. Newer service models are placing an emphasis on devolved systems of funding and decision making, including the introduction of direct-payment systems.

Second, there is growing evidence of the importance of the search for meaningfulness as a key to understanding successful coping and management. Families can be presented with many unexpected demands or find themselves doing their caregiving under nonnormative circumstances, for example, continuing to look after a disabled child for years beyond what they had predicted. Hence, they typically reframe the meaning of what they are doing, often by adapting their values and beliefs as they proceed. Such evidence can be found within the accounts of many older family caregivers.

Third, the ability of families to maintain a sense of control in difficult situations is a recurrent theme. Problems arise when matters that need control are beyond the direction of the family. This can implicate services as a prime culprit, for services that are designed to support families are often not available, are not synchronized with family routines and structures, are insensitive to family norms and rules, or else fail to involve families as partners when important decisions have to be made. These remain serious challenges for services in many countries.

Fourth, resilient family members need to be able to reaffirm their own sense of identity not only as caregivers but also as persons with important duties and obligations to themselves and to others. These families balance competing claims on their time and energy, giving rise to successful "boundary maintenance" or "border crossing" between their different identities. The role of culture and ethnicity in cementing, if not underpinning, the resilient qualities of families is not clear. Indeed, features of the "holding environment," that is, the social and cultural context in which families do their caregiving, are still being mapped. It is important to understand not only how these environments mold the dispositions and values that family members bring to their caregiving but also how the social networks to which they give rise shape the giving and receiving of care.

An important dimension of the family caregiving experience is the life course of the family. For family members, the life course sets the context for considering tensions around the uncertainties about future caregiving scenarios, maintaining a sense of control of environmental demands, and keeping a balance between the use of private and public time.

Particular tensions arise when individuals have to spend too much of their private time in caregiving when in fact they would prefer to use their time in other ways, private or public. The classic example is the conflict many families of working age face in balancing caregiving demands with employment. These opposing demands are less likely to clash if families can realize tax breaks, welfare payments, flexible working conditions, and job satisfaction, and disabled people can access inclusive education, suitable employment opportunities, or, as necessary, day care. Difficulties can arise for families when they become aware of growing discontinuities between the biological and psychological development of the disabled person. This is perhaps more typical when the disabled person has a cognitive impairment. It is often a signal that caregiving will have to take place "out of time," that is, beyond the point at which other families would normally end their caregiving. This perception of being out of sync with the rest of society represents another conflict for families, here between private time and social time.

While this is happening, families and disabled people have to manage their time and their activities within the calendars set by services and other institutions of society. With increasing plurality in the supply of services, for example, people with disabilities and their families are likely to encounter many transition points as they move between health, education, social care, employment, housing, and independent sector services during the course of their lives. Each transition is potentially very stressful since it usually heralds fresh ambiguities and a requirement to adapt to new service philosophies along with their accompanying rules and obligations.

Over the life course, families then are faced with an array of time demands generated by different personal and public calendars. How families manage such competing demands relates to their resilience and capacity, the "family-centeredness" of services, and the degree of continuity and predictability over the life course. How far this is possible given the destandardization and increasing individualization of the life course in postmodern societies remains to be seen.

ROLE RELATIONSHIPS WITH SERVICES

Families supporting either children or adults with disabilities have been described as having an ambiguous role relationship with services designed to help them. This ambivalence seems to be tied to the stereotypes of families described earlier that introduced family members as potential competitors for health and social care services, as well as allies of the disabled people they support. Four tacit models for understanding this ambivalence have been put forward: viewed by services as "resources," families would be maintained in their role as caregivers; viewed as "co-workers," they would attract greater recognition of their role from services; viewed as "co-clients," their needs are likely to be difficult to disentangle from those of their disabled relative; and finally, in the case of the "superseded" family caregiver, services would aim to replace or substitute them.

These are not fixed categories, and it is likely that over the life course family carers may well move between these roles as circumstances change, reflecting the accumulation of expertise, a preparedness to continue caregiving, and the emergence of the family caregiver's own needs. The implications of perceiving family caregivers in these contrasting ways are quite profound, for each category is associated with different sets of assumptions about what carers bring to their caregiving as well as what they might expect by way of support from services.

Service systems tend to view families largely as resources, and by various means seek to maintain them in their caregiving roles. This commitment seems to predominate over other functions, for example, those tied to enabling families to enhance caregiving enrichment, or supporting efforts by families to abrogate caregiving responsibilities without feelings of guilt when demands become too onerous. The agendas of services and families can therefore be dissimilar in significant respects.

For many years, there has been talk of professionals and services working in partnership with families, but often the rhetoric has not been matched by funding to plug gaps in family support services, by addressing imbalances in power relations, or by providing incentives for families to engage service systems in a more positive way. More recent policy initiatives in a number of countries are at last beginning to tackle these issues. System change at a number of levels is occurring to help make partnership work with families a reality. This change has entailed the following:

- A reorientation of professional activity from individualized casework to family systems approaches where reciprocities and individual autonomy within the family are respected
- A shift from the professional as expert to the family and disabled person as expert and potential case manager
- Adoption of a competency (or *salutogenic*) view of the family rather than a pathological view of the family
- An approach to assessment of family support needs that is committed to enabling families and disabled people to articulate their dreams and strengths
- Recognition that the solution to people's needs and problems is likely to be found by tapping the natural resources of the family and community with services acting as enabler, rather than by a reliance on services as the solution to everything
- Decision making that adopts a "non-zero-sum" approach, that is, where, as a result of consultation, there is the prospect of multiplying support, expertise, and knowledge that benefits all parties
- Delegation of decision-making responsibility and control of resources to people with disabilities and

families where this is feasible and, where not, to the point closest to them as possible
- A long-term view so that families can realize the kind of transitions that will occur over the lifespan and can plan for these
- New organizational forms that are more responsive, organic, and network driven rather than formal and bureaucratic
- Autobiographies and narratives based on the lives of people with disabilities and their families that act as testimonies to the values and principles to be respected in how they should be supported

FAMILY, INTERNATIONAL

Internationally, the great majority of families caring for a disabled member live in the developing world. Life is hard for everyone, but these families often have a poorer quality of life due to the persisting stigma of disability in most cultures and the extra care demands that are placed particularly on the women of the family.

In the past two decades, three strategies have been effective in supporting these families: parent associations, home-based support, and income generation. Nonetheless, the obstacles to providing a better quality of life are formidable and their removal is dependent on a much larger agenda of political and economic advancement within and across nation-states. The primary lesson from the twentieth century is that it can be done. The challenge for this century is to make this a reality for most families with a disabled member.

WOMEN'S WORK

In all societies of the world, the task of child rearing and child caring falls mainly on women, usually mothers but also grandmothers and daughters. Mothers fulfill four main roles in relation to the disabled child or dependent adult: survival, intellectual development, socialization, and emotional support. (For convenience, the term *mother* is used throughout this entry.)

For many families in developing countries, their immediate need for survival is for food, clean water, sanitation, and basic health services. Unlike rich countries, the major causes of disability in these countries are childhood illnesses such as measles and cerebral malaria. Mothers have to keep the family fed and healthy.

Mothers and siblings promote intellectual development through the one-to-one attention in tasks such as feeding and dressing or through family games and activities. Often it is mothers who seek out nursery and school placements and assist with homework. With the disabled child, it is mothers who attend clinic appointments and who are expected to carry out recommended therapies at home.

In many cultures, it falls to mothers to socialize the child into the wider community, by bringing the child to family and community events such as religious ceremonies and celebrations and also by encouraging friendships with peers and relatives. Implicit in this is an inculcation of moral values and conduct.

Emotional support, in the form of close, sensitive, and loving relationships between mothers and children, will do much to foster their self-confidence and self-esteem, providing the child with a much needed sense of security and safety.

Mothers have to fulfill these roles alongside the other demands placed on them: working in farms or factories, coping with household chores, caring for aging parents, and being a wife. Most mothers manage all these roles despite the famines, wars, and poverty that beset many lives. A child with a disability may be the least of their worries and can even be a solace amid their woes.

The fact that most mothers and families cope is not to imply that it is natural or easy. The sacrifices are many, not least in terms of self-fulfillment and the poorer physical and mental health of these mothers, which has been evidenced in many different countries.

Yet despite attempts at finding other ways of bringing up a disabled child, the best alternative for families who are unable to care for a disabled member is undoubtedly to find another family. In Western countries, fostering and adoption rather than placement in children's homes and residential schools—no matter how well these institutions are staffed and resourced—has become a much sought after alternative. Professional workers are limited in their expertise and influence in the lives of children. Their essential role is to support families in their child-rearing and child-caring responsibilities. In the case of persons with disabilities, this may extend far into their adult years.

Yet research suggests that support from professionals is secondary to the support mothers receive from their partners and extended families. A disturbing trend internationally is the rise in the number of single parents caring for a disabled family member and the breakdown of extended family networks.

Support from neighbors and friends is more forthcoming too when the disabled person is accepted socially within the community. Particular emphasis is now placed on creating inclusive schools that are prepared to enroll all children, no matter their impairments.

PARENT ASSOCIATIONS

The perceived shame and disgrace of having a child with a disability are often keenly felt by families. Common explanations for the disability revolve around old superstitions and punishments for misdeeds, usually by the mother. Parents, individually and collectively, have been to the fore in challenging these beliefs. The pioneering parents tended to be better educated, articulate, affluent, and well connected in society. And although motivated to get the best for their child, they argued for a better deal for similarly affected families. Invariably, they came together with others to share experiences and to join forces in making their views known, and so parent associations were born. Although varying in size and sophistication, these associations commonly fulfill four main functions: providing parents with solidarity, information, advocacy, and services.

Solidarity

The heartache that comes from feeling alone with a problem can be assuaged by meeting others who have been through or are going through similar experiences. Membership can also boost parental self-confidence and help to create a sense of pride in having a child with a disability. This appears to be best fostered at a local level; hence, national associations work hard to instigate and sustain a network of branches throughout the country. Likewise, solidarity can also be nurtured internationally through worldwide organizations such as Inclusion International, which claims links with 20,000 associations of families and self-advocates.

Information

Parents bemoan the lack of information available to them even when they have access to a range of professionals. They need information that is tailored to their needs and concerns and presented in readily accessible ways. Parent associations often produce newsletters for their members; most organize meetings, conferences, and training events with invited speakers; some have telephone helplines; and other employ "parent advisers" or development workers to provide information and training for their members. The Internet is becoming a major information resource for parents in more affluent countries.

Advocacy

National associations play a vital role in speaking up for the rights of people with disabilities. They often organize events to profile issues of concern and to gain media interest. Delegations from the association may also meet government officials to press their case. Likewise, national association may support individual members as they confront local discrimination, such as school enrollment. Parent members can be trained to act as advocates and trainers of others.

The advocacy role is more effective if alliances are made with other organizations that share a common interest, most notably organizations of people with disabilities. In many countries, there is now some form of national disability council or forum that brings together all the disability organizations with a primary goal of advising and lobbying government.

Services

Parent associations through co-operative endeavors can offer services to their members. For example, parents may take turns in staffing a day care center so that other mothers can have time for other duties. Many associations have opened resource centers for their members where they can meet visiting specialists, obtain information, borrow toys and equipment, and attend income-generating activities. In more affluent countries, parent associations have started special schools, training workshops, and residential homes. These service initiatives are open to criticism, mainly on the grounds that it absolves communities and governments from investing in service provision and perpetuates a charitable ethos rather than a rights-based approach.

HOME-BASED SUPPORT

In Western countries, one of the success stories of modern disability services has been the advent of home-visiting programs in which a trained worker regularly visits the family to advise on ways of promoting the child's development. With experience, their role has widened considerably, often providing emotional support to mothers, giving advice on other family matters as well as acting as an advocate for the family. Among the best-known programs are those based on a model originating in the United States in Portage, Wisconsin, but now used in many other countries.

Around the same time, the World Health Organization started to promote the concept of community-based rehabilitation (CBR) as a means of helping people with disabilities in the developing world. Here too, a trained worker, who may be paid or unpaid, visits the person with a disability at home to show the families what they can do to help their disabled member and to offer the family support and encouragement. Although the evidence remains equivocal as to the impact such home-based programs have on the development of the person with disabilities, there is widespread agreement that they are valued highly by families. James Gallagher attributed this to "a new spirit of optimism and encouragement within the family," replacing the despair and feelings of hopelessness that usually flow from disability.

Home visitors are not a new concept. The extended family or "tribe" has often provided an adviser or confidante to new mothers with whom they can discuss their concerns. The home-visiting concept builds on this tradition by introducing the family to a person who has particular expertise or interest in the disability. However, cultures vary in their tolerance of an outsider becoming involved in family issues, and services must be sensitive to this when recruiting staff to act as home visitors.

Recruiting Home Visitors

Home visitors can be recruited from at least three different sources, and around the world, projects invariably use some combination of these. First, existing personnel are redeployed to act as home visitors. Teachers, therapists, and health workers have adopted this new style of working rather than solely seeing people in hospital clinics or disability centers.

Second, home visitors are paid employees who have been recruited and trained specifically for this role. Although the original idea was to recruit people from the community, in later years an increasing number of people with disabilities or parents of children with disabilities have successfully been employed as home visitors. This strategy not only gives much needed employment opportunities, but these individuals come with personal insights and motivation that can make them more effective and acceptable to families.

Volunteer workers form a third option. Some community services use family members as their primary workers, whereas other community programs have successfully recruited teachers and health workers, among others, to act as voluntary supporters for families. This is best exemplified in Brian O'Toole's work in Guyana.

However, the qualities that home visitors bring to the job, rather than the background from which they come, ultimately appear to contribute more to their effectiveness. In particular, it is important that home visitors do the following:

> *Empathize with the culture of the family.* Families are then more accepting and trusting of them.
>
> *Respond practically to the family's needs.* Parents should experience some immediate benefits from having a home visitor.
>
> *Try to involve all family members.* Grandparents, siblings, and cousins can all be recruited to assist with the child who has a disability.
>
> *Empower families to be decision makers.* They should share information and expertise freely with families so that they are empowered to make decisions and solve their problems.

Although the options for finding effective home visitors are available in most communities around the world, a great deal of effort needs to be expended on recruiting suitable persons because of the inevitable turnover that occurs with poorly paid or volunteer workers.

This approach of providing personal supports to families and people with disabilities is now widely accepted in developed countries as a means of giving carers extra help at home or short breaks from caring as well as enabling people with disabilities to live independently in what has become known as *supported living.*

RESPONDING TO POVERTY

All over the world, disabled people are more prevalent among poorer families. In more affluent countries, state pensions and social payments help to offset some of the consequences for families of having a disabled member, but this is not so in developing countries. Indeed, many of the so-called developing countries are in fact becoming poorer as they are beset with trade barriers, famine, civil wars, and diseases such as AIDS.

Malnutrition among mothers and infants is endemic in many developing countries. The economies of developing countries will never be able to sustain the levels of health care needed by persons with biological impairments. Infant mortality and increased morbidity will long continue to be featured in third world statistics.

The growth of industrialization and the drift to the cities has split families as fathers have sought employment away from the rural areas. Moreover, people with disabilities are more likely to be discriminated against by employers, or they risk exploitation with poor wages and substandard working conditions.

In many developing countries but especially in Africa, AIDS is taking a heavy toll on families, leaving many children orphaned and in the care of aging grandparents and relatives. Among these are teenagers and adults with disabilities who will require lifelong care but have no one to provide it. The full impact of this tragedy has yet to be felt and may never be fully known.

The option of moving away from the family home into other forms of care situations is an option for few people with disabilities in the developing world. Nursing homes, shared housing, or supported tenancies may be available but only for a few and for those families that can afford it. As medical advances have an impact on developing nations, increased longevity will surely result. Yet there are few provisions for the care of adults with disabilities who outlive their carers.

This depressing analysis had led some to question the wisdom of focusing intervention efforts solely on people with disabilities and family supports while ignoring the wider social context in which the recipients live. Rather, the solution they espouse is to empower communities to manage and direct their own development and in so doing to help all their members. This is new and radical thinking and for which Western style disability specialists have little experience.

Income Generation

Foremost is the need to instigate and sustain income generation initiatives for families and persons with disabilities because any member of the family who is not productive is then a drain on family resources. At a minimum, children with disabilities need to become self-reliant in their personal care and be able to undertake jobs around the home such as water fetching so that the family workload is shared and others are freed to earn an income.

It is better still if the young people can play a part in income generation perhaps by assisting on the family farm or business or by holding down a job with local employers. The latter option is becoming more of a reality in developed countries with the advent of supported employment programs in which a support worker trains the person with a disability on the job and remains available to offer support and guidance to employers and co-workers should problems arise. It is possible that similar programs could operate in developing countries, especially in urban areas and as industrialization advances.

Likewise, co-operatives have been established for disabled people or for mothers in which they generate the goods and services that will find a ready market in local communities, for example, the production of school uniforms and leather goods, basketry, and raising chickens.

Revolving loan and micro-credit programs have been used to provide the necessary capital to individuals and communities. The payments on the loans are used to help fund others to start similar schemes.

Community Development

Three basic tenets must underpin these and similar initiatives. First, change has to come from within families and communities. If imposed from outside these systems, it is unlikely to be sustained or to flourish.

Second, the leaders who will instigate and nurture new developments are already present in every community, but they need to be equipped with the skills and knowledge needed to function as effective leaders and given a vision of how things could improve for their community.

Third, development has to start with the present reality within communities and be shaped according to their needs; hence, there is no one universal "treatment" or approach that can be immediately applied across a nation.

Finally, these approaches will become fully successful only when society's attitude to disability is transformed from primarily a medical problem to a social issue, from a specialist concern to a community focus, and from a charitable ethos to an issue of human rights. This is starting to happen through government policies stimulated by the United Nations Standard Rules, but the transformation has to grow also at the grassroots level, and that is the bigger challenge.

Throughout human history, families have nurtured, supported, and loved their weaker members. This still remains the most cost-effective means of responding to the needs of disabled persons the world over.

FAMILY: LAW AND POLICY

The historical norm for individuals with disabilities was isolation and segregation from the rest of society. Due to the work of disability advocates, however, attitudes toward people with disabilities started changing from one of exclusion to one of integration. In the 1970s, the United Nations passed declarations that argued that people with disabilities have the right to full participation and nondiscrimination in their communities. By the end of the twentieth century, many nations created laws that protect individuals with disabilities by making discrimination illegal and protecting their right to full participation and integration in society.

This entry focuses on the relationship between the law and families that have children with disabilities. Two topics are pertinent. First is how the law can serve as a tool for families to protect their children's right to "live in the world" with the same rights and benefits as nondisabled children. What follows is a brief overview of nondiscriminatory laws, educational laws, and entitlement services that provide support and legal protection for families and their children with disabilities. After examining how the law protects a disabled child's right to integration and nondiscrimination, the second topic addressed is the controversial issue of whether a disabled infant has any right to live at all. In particular, the issue takes the form of a question of whether the law provides a right for parents to refuse necessary life-sustaining medical treatment and intervention.

NONDISCRIMINATION AND INCLUSION

Antidiscrimination legislation is a powerful tool for parents to prevent their child from social exclusion and isolation as a result of her or his disability. The earliest and most comprehensive antidiscrimination legislation emerged in the United States through Section 504 of the Rehabilitation Act (29 U.S.C. § 794) and the Americans with Disabilities Act (ADA) (42 U.S.C. § 12101–12213), which prohibit discrimination on the basis of disability. The statutes forbid discrimination based on invidious affirmative animus, and discrimination based on thoughtlessness, apathy, and stereotypes about disabled persons. The U.S. Congress found that individuals with disabilities are a "discrete and insular minority" who face restrictions and limitations "resulting from stereotypic assumptions not truly indicative of the individual ability of such individuals to participate in, and contribute to, society" (42 U.S.C.A. § 12101(a)(7)). By prohibiting discrimination on the basis of disability, these two statutes were designed to ensure that disabled individuals have the same access to education, employment, goods, and services as the nondisabled.

Section 504 became law in 1973, and it was the first major nationwide antidiscriminatory legislation designed to protect disabled Americans. The purpose of Section 504 was to "firmly establish the right of . . . [disabled] Americans to dignity and self-respect as equal and contributing members of society, and to end the virtual isolation of millions of children and adults from society" (118 Cong. Rec. 32,310 (1972) (statement of Sen. Williams)). Section 504, however, was not the panacea to eliminate societal discrimination against disabled persons because its scope was limited to prohibiting discrimination by the U.S. government or any program or activity that receives federal financial assistance.

The ADA, which became effective on July 26, 1990, expanded Section 504's mandate to eliminate discrimination by prohibiting discrimination in employment, housing, public accommodations, education, and public services. It requires that

> no individual shall be discriminated against on the basis of disability in the full and equal enjoyment of the goods, services, facilities, privileges, advantages, or accommodations of any place of public accommodation by any person who owns, leases, (or leases to), or operates a place of public accommodation. (42 U.S.C. § 12182(a))

The ADA's purpose is "to provide a clear and comprehensive national mandate for the elimination of discrimination against individuals with disabilities" (42 U.S.C. § 12101(b)(1)).

The ADA and Section 504 provide a framework that is designed to differentiate discriminatory from nondiscriminatory behavior toward individuals with disabilities. This legislation requires places of work, education, or transportation to make "reasonable accommodations" for individuals with disabilities that enable them to enjoy the same opportunities as the nondisabled. Reasonable accommodation essentially means that business and places that provide public services must make modifications in their programs and services that would provide disabled individuals the same benefits and privileges as the nondisabled. Failure to make a reasonable accommodation constitutes discrimination unless there is no way to accommodate the difference or it is an "undue hardship" to provide such accommodation. An undue hardship means that providing reasonable accommodations would require extreme difficulty or expense, which has to be proven on a case-by-case basis.

Similar antidiscrimination legislation emerged in other countries throughout the 1990s. Specifically, Australia's Disability Discrimination Act, New Zealand's Human Rights Act, the United Kingdom's Disability Discrimination Act, Israel's Disabled Persons Act, Canada's Human Rights Act, and India's Disabled Person's Act all prohibit discrimination against disabilities. In addition to nondiscriminatory legislation, there are other critically important legal tools for families to guarantee their disabled child's ability for full participation and integration in society, especially the Individuals with Disabilities Education Act (IDEA), which is designed to protect disabled children's right to education.

Education

In 1975, the IDEA was enacted to meet the educational needs of children with disabilities (20 U.S.C. §§ 1400–1485). The U.S. Congress found that more than 1 million children with disabilities were being excluded from public education, and 50 percent of all children with disabilities were not receiving appropriate education (42 U.S.C. § 1400(c)(2)). The purpose of the IDEA is to

> ensure that all children with disabilities have available . . . a free appropriate public education which emphasizes special education and related services designed to meet their unique needs and prepare them for employment and independent living, to assure that the rights of children with disabilities and their parents or guardians are protected, to assist States and localities to provide for the education of all children with disabilities, and to assess and assure the effectiveness of efforts to educate children with disabilities. (42 U.S.C. § 1400(d)(1)–(3))

Protecting and improving disabled children's educational experience is necessary to "ensure equality of opportunity, full participation, independent living, and economic self-sufficiency for individuals with disabilities" (id.).

The purpose of the IDEA is to provide disabled children with an individualized education. Specifically, each disabled child must be educated in the least restrictive environment (LRE) appropriate to her or his needs. This means that a disabled child may be removed from the regular educational settings only when "the nature or severity of the disability is such that education in regular classes with the use of supplementary aids and services cannot be achieved satisfactorily" (34 C.F.R. § 300.550(b)(2)). Thus, the LRE then creates a presumption of integrating disabled children in their school environment.

The cornerstone of the IDEA is an individualized education program (IEP), which is a joint document between the disabled child's parents or guardians and school authorities. The IEP describes the child's abilities and needs and prescribes services to meet the individual needs of the child. An IEP must be formalized in a written program that contains information about the child's current level of educational performance, annual educational goals, specific services that the child will receive, and details concerning the extent of the child's involvement with regular educational programs.

In addition to protective laws for children with disabilities, many nations also have entitlement programs that provide services to families and their children with disabilities, which will be addressed next.

Entitlement Programs

The United States, as do many other countries, provides entitlement programs for families with disabilities. Entitlement programs can cover a wide range of different services from subsistence income, educational grants, and training for disabled individuals or their families. In the United States, for example, families that have disabled children may qualify (based on income and resources) for Supplemental Security Income, which entitles families to monetary assistance, and Medicaid health care coverage for their disabled child. Moreover, federal grants provide training for disabled individuals and their families. For example, under IDEA, grants provide support and information centers for parents of children with disabilities.

In the next section, this entry moves from discussing antidiscrimination protection and social support to examining whether parents have the right to refuse necessary life-sustaining medical treatment for their newborn.

DISABLED NEWBORNS

In the early 1980s, families, lawyers, bioethicists, and the courts were involved in a legal and moral battle over whether the parents of disabled children had the right to refuse medical treatment for their children. The legal question was whether parents or medical authorities could choose to let a disabled infant die rather than provide the child with necessary medical treatment or nourishment essential to sustain life. The following is a brief overview of this dispute, explaining how U.S. courts and the federal government tried to resolve this controversial issue.

In 1982, the debate started when the parents in a Bloomington, Indiana, family wanted to let their baby, who had Down syndrome and an esophageal blockage, die rather than receive lifesaving medical treatment after their doctor told them what their child's life would be like with his disabilities. The parents' decision, however, was challenged in the now famous *In re Infant Doe* case (commonly known as the Baby Doe case). The child's parents and doctors argued against corrective surgery because they believed a child with Down syndrome would have diminished quality of life—in essence, it would be better for the child to die than live with his specific disabilities. The court held that that the parents had a right to withhold treatment and ordered the hospital to comply with the parents' decision. A few days later, Baby Doe died from starvation.

Advocates of letting parents have the right to refuse medical treatment for disabled children had several rationales, which, generally, focused on sparing a life that they believed would suffer an exceptionally low quality of life. Adrienne Asch (2001) summarized the reasons for withholding treatment in the following:

> Rationales for withholding treatment focused on the physical suffering and pain of the potential treatments as well as the impairments themselves; the conviction that technology was being used to sustain children who would have short, painful, and miserable lives regardless of what was done for them; the anguish for parents who had to watch a child die slowly after enduring fruitless medical procedures; disappointment for parents who would not have the healthy child they expected and desired and might instead have to raise one who would always have disabling conditions; and believe that the millions of dollars spent for such treatments were better spent in other ways. (Pp. 303–304)

Disability rights advocates who opposed allowing parents to let disabled children die rejected arguments that disabled children have a low quality of life. A 1989 study by the U.S. Commission on Civil Rights supported disability rights advocates' arguments when it found that a majority of disabled Americans do not see themselves as having a poor quality of life and would not choose death over life (pp. 32–33). Disability advocates argued that disabled individuals had the right to receive treatment, and refusal constituted unlawful discrimination.

In response to *In re Infant Doe* and similar cases, the U.S. Department of Health and Human Services (DHHS) created a rule maintaining it unlawful for any federally funded hospital to withhold medical treatment from disabled infants. Hospitals and doctors challenged the DHHS decision in U.S. federal court. The issue of whether the federal government could require hospitals to treat disabled children despite the wishes of parents and medical providers finally made it to the U.S. Supreme Court in *Bowen v. American Hospital Association.* In 1986, the Supreme Court held that denying treatment to disabled infants did not constitute legally protected discrimination under Section 504 of the Rehabilitation Act. The Court argued that the hospital and physicians do not make treatment decisions for disabled newborns. Instead, hospitals and doctors implement the decision of the parents. If the parents do not want treatment for their child, then the hospital is not discriminating against the child. In essence, the Court held that for a hospital or doctor to discriminate against a disabled child, parents of the disabled infant would have to want medical treatment but the hospital and doctors would have to refuse treatment because the child is disabled.

Although the *Bowen* decision held that federally funded hospitals and doctors do not discriminate against disabled children when they refuse medical treatment in accordance with the parents' decisions, the U.S. Congress enacted the Child Abuse Amendments of 1984, which called for the medical treatment of newborns with disabilities unless the child would die even with medical intervention (42 U.S.C. §§ 5101–5106, 5111–5113, 5116 [1990]). Specifically, the amendment only allows medical treatment to be withheld if it would be "futile" or "merely prolong dying" (id.). The only remedy for violations under the statute, however, is loss of federal funds, which limits the statute's effectiveness.

Currently, the vast majority of disabled infants receive necessary medical support and care. Asch (2001) states that as of the year 2000, most newborns with Down syndrome and spina bifida and infants born with premature and low birth weight in the United States receive medical intervention (p. 305). Thus, she argues that the Child Abuse Amendments, presidential commission writings, and disability advocates "have all combined to ensure that most babies who can benefit from medical interventions do receive them" (p. 305).

CONCLUSION

The challenges in the legal relationships of families that have children with disabilities are ongoing. Antidiscrimination laws, educational laws, and entitlement services provide important tools for families to protect their disabled child's right to full participation in society. U.S. Supreme Court decisions, such as *Bowen v. American Hospital Association,* show how U.S. courts and the federal government have tried to resolve the controversial issue of whether parents have a legal right to withhold necessary life-sustaining medical treatment from their disabled newborns.

FEEBLEMINDEDNESS

By the early 1900s, *feebleminded* was widely used by eugenic social reformers and mental health professionals in England and the United States as an umbrella term referring to all degrees and types of "congenital defect." Upon its inception, this term attempted to replace earlier, more offensive categories such as moral and intellectual idiocy, but by uniting discrete social, medical, behavioral, and economic stigma under one name, the category provided dangerous interpretive flexibility. By 1915, the American Association for the Study of the Feeble-Minded defined the category broadly to include any person deemed "incapable of performing his duties as a member of society in the position of life to which he is born." Similarly, in England, the Royal Commission on the Care and Control of the Feebleminded defined a feebleminded person as incapable of competing on equal terms or of managing his or her affairs with "ordinary prudence."

Such wide-ranging classifications allowed eugenicists to conflate myriad social problems such as poverty, growing immigrant and nonwhite populations, unemployment, and criminality with purported medical and scientific diagnoses of cognitive impairment. In effect, influential eugenicists reductively explained complex cultural issues as part of a crisis brought on by a menacing and ever-expanding army of "subnormal" classes. As examples, Walter Fernald applied feeblemindedness to groups as diverse as the blind or cognitively impaired to those with poor social conduct. Harry Laughlin, an active proponent of sterilization and eradication policies, built on Henry Goddard's model to define "social inadequates" as those who failed chronically in maintaining themselves as "useful" citizens. Laughlin's inadequate classification brought together the criminal, poor, vagrant, physically and cognitively impaired, chronically ill, and visually and hearing impaired with the leprous, tuberculous, syphilitic, orphaned, and alcoholic. In this way, the process of diagnosing feeblemindedness became a simple project of locating disability, disease, moral impropriety, or economic dependency, and using these traits as evidence of mental deviance.

In an effort to further refine taxonomies of feeblemindedness, eugenicists designated specific subcategories such as the *idiot*, *imbecile*, and *moron* to reflect the range from lower to higher grades of mental defect. The introduction, maturation, and proliferation of mental testing during this period allowed eugenicists to attach particular mental ages to these categories. By 1920, these designations were solidified: Idiocy indicated a mental age up to two years; imbecility from three to seven years; and the moron category referred to those graded from 7 to 12 years. Goddard invented the term *moron* to designate those individuals most difficult to identify as mentally deficient because of their seeming normalcy. Many eugenicists considered such "borderline" individuals the greatest threat to social progress and reform.

The process of naming, labeling, and classifying individuals is inevitably a process of differentiation, and in the case of identifying feeblemindedness, it also provided eugenicists with a troubling rationale for treating people with coercion, disrespect, and profound inhumanity. Using ungrounded hereditarian arguments and misplaced medical diagnostics, anyone designated within these categories of subnormality became particularly vulnerable to state-sanctioned segregation, institutional confinement, and enforced sterilization. Once someone was *diagnosed* as feebleminded, this person was rhetorically constructed as a social menace or economic burden and represented by eugenicists as part of an urgent problem in need of eradication.

FEMINISM

Feminism can be defined as a movement to achieve equality between men and women and to end male domination of society. It has its origins in the late eighteenth century when Enlightenment ideals of equality and individual freedom supported an emerging campaign to extend education, professional employment, and the vote to women. "Second wave" feminism, which dates from the late 1960s (by which time women's suffrage was well established in most industrialized countries), has sought to broaden the focus of attention to include women's position within the private sphere of domestic and family life. Fundamental to its approach is the distinction between *sex,* which is regarded as a biological characteristic rooted in nature, and *gender,* which is viewed as a social characteristic deriving from the meanings given to sexual differences by society. It is these socially assigned meanings that are seen as at the heart of women's subordinate position in society, and it is the transformation of society in relation to these meanings that is seen as liberating women from oppression and exploitation.

Feminism (or the women's movement) has much in common with the disability movement in terms of both its analytical position and its political activism. It has therefore been a source of some frustration to those who have links with both movements—most notably, disabled women and mothers of disabled children—that stronger alliances have not been forged between them. Indeed, it appears that neither movement has paid serious attention to the concerns of the other. Feminism, while increasingly recognizing difference and diversity among women, has largely overlooked disability with the result that it has at times argued in ways that have been detrimental to disabled women. The disability movement, traditionally dominated by men, has largely neglected gender and adopted an agenda predominantly concerned with participation in the public sphere. It has been left primarily to disabled women feminists, marginalized by both movements, to challenge their analyses and to work toward a more inclusive model that recognizes a common cause among all oppressed groups.

A number of very different strands have developed within feminism over the past 40 years, and while none has incorporated a disability perspective, proponents of many have offered their own analyses of disability. Liberal feminists, for example, have focused on inequality of rights and opportunities and have emphasized the need for legislation and education to challenge stereotypes and open up opportunities to all disadvantaged groups including women and disabled people. The latter group includes disabled women who are regarded as bearing a "double disadvantage." Marxist and socialist feminists have focused on women's class position within capitalism and their subordinate position within the family. They argue that equality of opportunity is not enough and call for a transformation of society to challenge the structures that create and perpetuate sexism, disability, and other forms of oppression. Radical feminists explain women's subordinate position in society as the product of patriarchy, a mode of social organization in which men have dominance and control over women, and advocate radical changes ranging from separate communities for men and women to androgeny. Radical feminism is also associated with standpoint epistemology, which recognizes women as having a particular position from which to speak. A similar standpoint positioning has been proposed with regard to disability, which would include the body of knowledge built up by disabled women and a recognition of the interdependence of disabled women's experiences, consciousness, and actions.

Feminists within the disability movement have also tried to take forward the analysis of disability by extending the social model of disability to incorporate impairment. The social model of disability views disability as a problem within society rather than within individuals with impairments. Drawing on the feminist principle that "the personal is political," feminists within the disability movement argue that by focusing exclusively on disabling barriers in the external environment, the social model of disability denies an important aspect of their experience. They stress the need for an analysis that encompasses all aspects of disability, including the experience of impairments and the problems to which they give rise that cannot be solved by social manipulation. These developments are highly contentious within the disability movement where an emphasis on impairments and the *differences* between disabled people is seen as potentially divisive and threatening to the movement as a whole.

While feminist analyses of disability have largely been welcomed by disabled women (and men), disabled women themselves rarely feature in mainstream feminist analyses. As a result, disabled women have argued that much of feminist analysis is of little relevance to, or even in conflict with, their interests and concerns *as women.* This is perhaps best illustrated in relation to two issues of central concern to women: reproductive rights and care in the community. With regard to the first, disabled women feminists point out that mainstream feminism has done much to liberate able-bodied women from the constraints of their roles as wives and mothers but has largely overlooked the way in which disabled women have been denied the possibility of ever fulfilling these roles. Within mainstream feminism, reproductive rights have been seen largely in terms of access to methods of birth control that enable women to make choices about and within motherhood. For disabled women, however, reproductive rights mean something quite different: in the context of discriminatory assumptions about the legitimacy of their desire for children and about their capacity to bear and raise them, reproductive rights mean acknowledgment of their right to have children should they wish to and provision of practical help to enable them to bring them up. Perhaps most contentious of all aspects of reproductive rights has been that of abortion. Feminists have traditionally argued for a woman's absolute right to choose to terminate a pregnancy when the fetus has an "abnormality" and have welcomed antenatal screening as a means through which women can gain further control over their own reproduction. Disabled women, by contrast, have been critical of prenatal screening and selective abortion, arguing that they devalue people with disabilities and that they are potentially a new form of eugenics.

Another key point of debate between mainstream feminism and disabled women has been in relation to community care. Those in the disability movement have welcomed the move away from residential care to care in the community for people with disabilities as a major advance toward greater social inclusion. Mainstream feminists, however, have challenged the development of community care, arguing that it depends largely on women's unpaid labor in the home. By increasing this burden, community care policies further exploit women and perpetuate their dependent role within the family. Disabled women feminists have criticized this analysis, pointing out that it is made exclusively from the point of view of the caregiver and casts the recipient of care as passive and dependent. It also fails to recognize that most recipients of care are themselves women and many have caring responsibilities of their own. It is because they have failed to integrate a disability perspective into their analysis, disabled women feminists argue, that their nondisabled sisters have argued in support of institutional forms of care, which disabled people oppose. It also explains their failure to recognize that the family could be the site of oppression for disabled people as well as women and to join with disabled people in seeking alternative ways of supporting them so they do not have to depend on unpaid care by their family. Feminist philosophers of the ethics of care offer an alternative to both these analyses, challenging the stress each places on autonomy and individualistic independence as aspirational ideals and emphasizing instead the values of caring solidarity and interdependence.

With the turn of the twenty-first century, both feminism and the disability movement have faced new challenges from the growing influence of postmodernism. Postmodernism has the potential to undermine both movements through challenging the principle of universal rights based on citizenship entitlements and through denying that either "women" or "disabled people" constitute a unitary or stable subject on which to base political actions. Despite this, postmodern feminism has developed as an influential strand within feminism, criticizing both the "grand narrative" of feminism and the extreme relativism of postmodernism. Ironically, perhaps, the emphasis that postmodern feminism places on the deconstruction of accepted categories (such as disabled), multiple identities, and the politics of difference may provide fertile ground for a more insightful—though local, contested, and provisional—understanding of disability issues than that provided by previous strands of feminist thinking.

FERAL CHILDREN

Before the seventeenth century, outside of myth and legend, only scattered and fragmented stories of feral or wild children appear in European history. Suddenly, during the 1600s, several accounts emerge; there are descriptions of a wolf boy in Germany and children abducted by bears in Poland; and, in 1644, the first story appears in English of John of Liège, a boy lost by his parents in the woods who took on animal-like behaviors to survive on his own for years. Early descriptions of such children detailed their nonhuman qualities: running on all fours, foraging and hunting for food, exceptional hearing, and absence of language. As several such children were rescued from the wild and brought back into human society, their continued animalistic behavior coupled with a seeming inability to master language fascinated philosophers, who began to wonder if such children actually belonged to a different species than the human family.

This question was taken up with great seriousness in the eighteenth and nineteenth centuries as science attempted to name, classify, and understand the intricacies of the natural world and human development. The most widely known feral child of the early eighteenth century was a boy found in Hanover in 1724. Peter the Wild Boy—as the famous Dr. Arbuthnot named him—became a fascination of the English royalty, living for the next few years both with King George I and the Prince of Wales. Like earlier children found in the wilderness, however, Peter's unbreakable silence and unique ability to survive much as an animal would compelled scientists to address this animal-human divide. Within a decade of Peter's discovery, Carl Linnæus, the hugely influential natural historian, actually included feral man, *homo ferens,* as one of six distinct human species. Notably, *ferens* is the only classification listing individuals—rather than whole races—as examples.

In the 1792 translation of Linnæus's *Natural Systems* into English, however, a note was added that such children were probably "idiots" who had been abandoned or had strayed from their families. It was this conflation of feral nature and disability that was taken up by Jean Marc Gaspard Itard in his project of civilizing one of the most famous cases in Europe, Victor of Aveyron, a wild boy caught in 1800 in the forests near Lacaune. Philippe Pinel, the foremost physician in France, dismissed Victor as an "idiot," but to Itard, the boy was a living artifact—an atavistic body on which to test Rousseau's notions of original perfection against a belief in language as the only means through which human identity could be forged. After several years of training, however, Victor was still unable to use language, a failure that further solidified an understanding of feral children as mentally "infantile" and "inferior."

In many ways, the systematic education, training, and confinement of cognitively disabled people in the nineteenth and early twentieth centuries drew on the legacy of "civilizing" projects taken up by teachers of feral children. Building on the techniques of Itard, for example, Eduoard Séguin promoted repetitious physical and mental training processes for "feeble-minded" children—training systems that were further developed by eugenicists in Europe and the United States. During the twentieth century, as psychologists endeavored to distinguish between behaviorism and biological nature, wild children—a designation including children in isolation as well as those who survived among animals—again seemed to provide a key to the puzzle. A pervasive assumption that such children are abandoned or confined by their parents because of apparent cognitive impairments remained entrenched until the later decades of the century.

Presently, most psychologists attribute the inability of such children to master language to their unique histories of survival outside of human society—as a behavioral mechanism specifically adapted to their environment and circumstances rather than a biological inability. Fascination with wild children, however, remains, and the fates of such children become deeply tied to the doctors, teachers, and caregivers, who, through measurement, diagnosis, training, and compassion, inevitably attempt to resocialize these children and return them to the fold of human interaction.

FERNALD, WALTER (1859–1924)

American institution administrator

From the time of his appointment in 1887 to his death in 1924, Walter Fernald served as superintendent of what was then known as the Massachusetts School for the Feeble-Minded (now known as the Fernald Center). In this role as head of the first public asylum in America specifically created to house intellectually disabled people (started by Samuel Gridley Howe in 1848), Fernald became one of the most prominent institutional professionals in the United States, associated with a strong advocacy of institutional care of people with intellectual disabilities. He served two terms as president of the main professional organization in the area of intellectual disability (now called the American Association on Mental Retardation). For many years, Fernald wrote in aggressive terms about the "burden of the feeble-minded" on the rest of society, and he was an active proponent of involuntary sterilization just as eugenics laws were being passed by state legislatures throughout the country.

Unlike most of his colleagues, Fernald moderated some of his more extreme views by the end of his life. He became a supporter of community placement for many of those he previously characterized as part of a "parasitic, predatory class," eventually developing one of the country's largest "parole" systems for moving institutional residents back into smaller, community-based residences.

FETAL ALCOHOL SYNDROME

Fetal alcohol syndrome (FAS) comprises a recognizable pattern of birth defects attributable to the adverse effects of maternal alcohol abuse during pregnancy. The condition was initially described independently by Paul Lemoine in France in 1967, and Kenneth Jones and David Smith in the United States in 1973. The observations of these investigators, later confirmed through animal model and human epidemiological research, constituted the first recognition that alcohol is a teratogen (a substance causing birth defects).

The full-blown disorder encompasses prenatal growth deficiency (persistent after birth), neurodevelopmental deficits, microcephaly (small head size), and a specific facial appearance, including small eye openings and an underdeveloped midface. Cardiac, renal, and skeletal anomalies may also be observed. Subsequently, a spectrum of disability was delineated accompanying prenatal alcohol exposure. Most accurately termed fetal alcohol spectrum disorders (FASD), the gamut of disability ranges from full FAS to neurodevelopmental deficits absent the other features of the syndrome. FASD is the most common environmentally induced cause of mental retardation in the world. Although the prevalence in the United States is generally quoted as 0.5–2.0 cases per thousand births, in some children in the Western Cape province of South Africa rates as high as 48 per thousand have been documented.

FIBROMYALGIA

Fibromyalgia is a medical syndrome (constellation of symptoms) that is characterized by chronic widespread pain of at least six months' duration. In 1990, the American College of Rheumatology proposed criteria for diagnosis:

- Pain in the axial skeleton (pain in the region of the cervical or thoracic spine, anterior chest, or lower back)
- Pain above and below the waist
- Pain upon palpation in at least 11 or 18 paired tender points throughout the body. (Palpation is performed over the tender points with just enough pressure to just blanch the fingertip of the examining physician.)

SYMPTOMS

The most common symptoms that people with fibromyalgia experience are widespread pain, fatigue, sleep disturbance, and myalgias (muscle aches). There are several other syndromes that are commonly associated with fibromyalgia. These include migraine headaches, irritable bowel syndrome, interstitial cystitis (pain of the bladder region), depression, anxiety, and temporomandibular dysfunction (pain in the region of the jaw).

PHYSICAL EXAMINATION

The treating physician should perform a thorough general medical and neurological examination, which is generally normal. In addition, a complete examination of the musculoskeletal system should be done to evaluate for local overuse pain problems such as bursitis (inflammation of the bursa or fluid sac between bone and muscle), tendinitis, radiculopathy ("pinched nerve" or sciatica), and myofascial trigger points (areas of "muscle knots").

The examining physician should palpate the 18 paired tender points with approximately 4kg of pressure. This is just enough pressure to blanch the fingernail of the examiner. The patient will experience pain at these locations.

TREATMENT

Initial treatment includes patient education, pharmacologic treatment (medications), gentle exercise, and relaxation training. Pharmacologic management aims to normalize sleep patterns and diminish pain. Low doses of sedating antidepressants at bedtime (e.g., 10–25 milligrams of amitriptyline) can be helpful for sleep and pain. In addition, small doses of more stimulating antidepressants (e.g., fluoxetine) can be given in the morning to reduce pain and fatigue. The combination works better than either medication taken alone.

Pain may be relieved with simple analgesics such as acetominophen or ibuprofen. Tramadol is the next-line agent. Opioids (e.g., morphine) are rarely necessary. Adjunctive nonpharmacologic pain control methods include acupuncture, massage, and biofeedback.

REHABILITATION

Physical therapy is used to educate the patient on a stretching, gentle strengthening, and cardiovascular (aerobic) fitness program. This can improve fitness and function and decrease pain. Occupational therapy is incorporated to review ergonomics (efficient ways of performing tasks) of daily household and worksite activities. Task simplification, pacing, and maximization of function are emphasized.

Mental health professionals can be helpful in the rehabilitative phase to educate the patients in a mind-body stress reduction program. This provides the patient with positive coping strategies for living with chronic pain. Associated depression and anxiety may require evaluation and treatment by a psychiatrist.

FUNCTIONAL LIMITATIONS AND DISABILITY

Patients may be limited by both pain and fatigue. Patients also report cognitive dysfunction with difficulty in concentration, organization, and motivation. This has been termed "fibro fog." Approximately 25 percent of patients with fibromyalgia report themselves as disabled and are collecting some form of disability payments. Individuals are more likely to become disabled if they report higher pain scores, work at a job that requires heavy physical labor, have poor coping strategies and feel helpless, or are involved in litigation.

FILM

The portrayal of disability on film shares traits with that of literature and drama. Disability in film has been disproportionately underrepresented at the same time that it has been excessively displayed. For the most part, disabled characters onscreen are minor figures, whose less-than-perfect bodies serve as a foil for the protagonist. In this way, characters portrayed as disabled perform the dual purpose of signifying a "lack" or character flaw to which more primary characters (and presumed-to-be-able-bodied audience members) might succumb, while at the same time disabled characters reestablish the wholesomeness and integrity of those key characters (and supposedly normative audience members).

In such films, disability figures as metaphorical emphasis for any moral impact in the films that directors wish to impart. Some notable examples include the unconscious character of Alicia (Leonor Watling) in Spanish filmmaker Pedro Almodóvar's *Hable con Ella* (*Talk to Her* [2001]) whose coma enables her nurse and suitor, Benigno (Javier Cámara), to sexually violate her body, or the title character of the independent U.S. film *Pumpkin* (2002), a young man (Hank Harris) with developmental and physical disabilities who comes to represent the undesirable "other" to sorority girl Carolyn (Christina Ricci). The mainstream Hollywood movie *At First Sight* (1998) features a blind character, Virgil (Val Kilmer), who struggles to adjust once he has *regained* his lost vision. This film ironically presents its character as doubly "challenged": first as a character who must relearn how to negotiate his changed environment and second as a living metaphor for the ills of the world that other characters "choose" not to see.

Alternatively, Dogme 95 (a Danish-based collective of film directors) member Lars von Trier's film *The Idiots* (1998) depicts characters who embody the physically normative, yet who perform as if they have cognitive disabilities in order to disrupt and disturb their conventional world. Independent Canadian filmmakers Shawna Dempsey and Lorri Millan, in their short video *The Headless Woman* (1998), display the circus freak not only as metaphoric of the contemporary status of women and especially lesbians but also to reveal the haven that the sideshow world has traditionally offered to people whose bodies and bodily desires did not always fit into societal ideals of "the norm." A small number of mainstream films embrace disabled characters as central to the plot, but that plot usually depends on a narrative of triumph, wherein the protagonist must "overcome" a physical impairment to fit into the normative nondisabled world. In such narratives, the protagonist strives for a victory of personal achievement and attitude, rather than one of making the world more disability-accessible or disability-centered. Examples include Susie Hendrix (Audrey Hepburn) in *Wait Until Dark* (1967), a character who has gone blind and must summon her limited resources to battle the crooks who threaten her, and Alice Culhane (Mary McDonnell) in *Passion Fish* (1992), whose accident has left her a wheelchair user and has also deprived her of her job as television soap opera star.

DISABILITY STUDIES FILM SCHOLARSHIP

Film scholarship on disability representation has followed the stages named by critics David Mitchell and Sharon Snyder in *Narrative Prosthesis: Disability and the Dependencies of Discourse.* Tom Shakespeare, Paul Longmore, and Paul Darke helped to initiate the field with articulations of what Mitchell and Snyder call the "negative imagery" school of disability film criticism. Martin Norden's *The Cinema of Isolation: A History of Physical Disability in the Movies* clarifies such disability critique in its categorization of such disability stereotypes. Norden's categories include the "Civilian Superstar," the "Comic Misadventurer," the "Elderly Dupe," the "High-Tech Guru," the "Noble Warrior," the "Obsessive Avenger," "Saintly Sage," the "Sweet Innocent," the "Techno Marvel," and the "Tragic Victim." He emphasizes the placement of these stereotypes in a number of films, especially those not predominantly focusing on disability.

The first collection of essays to explore the "fusion" of disability and film studies, 2001's *Screening Disability: Essays on Cinema and Disability,* edited by Anthony Enns and Christopher R. Smit, moves to what Mitchell and Snyder call the "social realist" school in an attempt to contextualize and confront the negative images that dominate cinematic representation. Mitchell and Snyder's own work in *Narrative Prosthesis* participates in a stage of disability criticism they have labeled "transgressive reappropriation," which demonstrates how disability representation can work against dominant modes of understanding power and can undermine typical portrayals of social dynamics. For example, in Atom Egoyan's *The Sweet Hereafter* (1997), the character of Nicole (Sarah Polley) openly plays on the effects of her disability to emphasize her newfound power over her sexually abusive father—rather than showcasing her recently acquired disability as an outward sign of a shameful secret. More recently, the Korean film *Oasis* (2002) depicts the "severely" disabled central character Gong-ju (Moon So-ri) forging an intimate link with a male character, Jong-du (Seol Kyeong-gu), who has sexually assaulted her. The characters' outcast status allows them a transgressive space in which to call into question societal assumptions about their personal lives.

SILENT ERA FILMS

With Charlie Chaplin's *His New Profession* (1915) and Tod Browning's *The Unknown* (1927) as perhaps the most prominent and famous examples, the silent era of film introduced a number of disability themes and patterns that continue to this day. For example, *Stella Maris* (1918) features Mary Pickford as a disabled avenger. Though this pattern continues throughout film history, it is important to note that the female avenger is less common than the male. D. W. Griffith's last successful film, *Orphans of the Storm* (1921), portrays a blind sister Louise (Dorothy Gish) dependent on her sighted sister Henrietta (Lillian Gish). The two sisters set out for Paris to seek a cure for Louise's condition and are both kidnapped in the process. King Vidor's *The Big Parade* (1925) introduces a visual standard for the portrayal of veterans who acquire disabilities in battle. *The Hunchback of Notre Dame* (1923) began a long tradition of adapting the novel for the screen and also marked Lon Chaney as a key actor in early disability roles, particularly in the horror genre.

HORROR FILMS

For many filmmakers and viewers, the image of disability and the horror genre are closely intertwined. In Hollywood, movies such as *Darkman I, II, and III* (1990, 1994, and 1996), the various versions of *Frankenstein* (1931, 1970, 1973, 1984, and 1992, among others), *Night of the Living Dead* (1931, 1994), *Terror in the Wax Museum* (1973), and the first of many *Halloween* films (beginning in 1978) exploit viewers' unease about screened versions of crippled, disfigured, or mentally disabled characters. Filmgoers' long association of disabled characters with evil (or at least as living within the realm of evil) reaches from the silent film era's *Hunchback of Notre Dame* (1919), *The Shock* (1923), and *Phantom of the Opera* (1925) to the new millennium's *X-Men* I and II (2000 and 2003), and *Hannibal* (2001). An influential film for directors, actors, and disability activists, the early "talkie" *Freaks* (1932) blasted into cinemas by presenting actual disabled actors as their disabled character counterparts. Both praised and reviled, *Freaks* director Tod Browning reinvented the horror genre at the same time that the ending of his film reinforces a horror-disability correlation.

A subcategory of the horror genre is the science fiction film, many of which began to surface in the late 1930s and return with significant consequences in the late 1980s and early 1990s. Set in a time markedly different from the present, sci-fi narratives invariably propose "alternative" bodily categories as abundant examples of the "norm" gone deviant. Some examples include the Mariner (Kevin Costner) in *Waterworld* (1995), where the proliferation of ocean miraculously encourages evolutionary changes onto the body, such as the main character's gills and webbed feet. Less "neutral" bodily transformations include the clichéd chemical and biological mutants that sci-fi films continue to offer. Examples range from *The Island of Dr. Moreau* (1933) to the tedious genetic-experiment-gone-amok of Ang Lee's *Hulk* (2003). In David Cronenberg's film *Dead Ringers* (1988), twin gynecologists Beverly and Elliot Mantle (both played by Jeremy Irons) liken themselves to the famous conjoined twins Chang and Eng. The twins indulge in sexual exploration while studying the genetically "mutant" body of medical patient Claire Niveau (Geneviève Bujold) at the same time as their attempts to claim individual lives descend into a medical nightmare.

WAR AND WAR VETERAN FILMS

Beginning with Thomas Edison's newsreels featuring war coverage (first projected in 1897), war veterans and characters who have been affected and impaired by war have played a large role in film history. Such documentary spots soon gave way to narrative features, beginning with *The Empty Sleeve* (also released as *Memories of Bygone Days* [1909]). This film participates in a long-standing tradition wherein disabled war veterans gain social value only when they can display triumph in a homecoming celebration of their geographically distant nationalist triumphs. U.S. war films made during or immediately following prominent international conflicts tend to valorize the positive symbolic potential of brave wounds. This pattern has resulted in waves of patriotic World War I films such as *For Valour* (1914), *I'm Glad My Boy Grew Up to Be a Soldier* (1915), and *Womanhood: The Glory of Nation* (1917). U.S. patriotism continued in post–World War II films such as *Thirty Seconds over Tokyo* (1944), *The Enchanted Cottage* (1944), and *Since You Went Away* (1944).

In part because of the large role played by television representation, making the horrors of war immediately available in American living rooms, the Korean, Vietnam, and Iraq (1991) conflicts have yielded many filmic depictions of veteran postwar experiences. Examples include *Coming Home* (1978), *Deer Hunter* (1978), and *Courage under Fire* (1996). A main concern for largely male disabled veterans featured prominently in such films is the type of sexual life they will be able to pursue, and, as a result, their subsequent (masculine) virility comes into question, a patent example being *Born on the Fourth of July* (1989).

Films made following major conflicts are more likely to question the cost of war, with *The Big Parade* (1925) providing an early example. After the glow of World War II conquest began to fade, U.S. filmmakers initiated film plots that questioned the ease of readjustment to ableist home environments. Prominent examples include *The Best Years of Our Lives* (1946), *The Men* (1950), and *Bright Victory* (1952). A film about life subsequent to World War II that contrasts such patriotism is Akira Kurosawa's *Hachigatsu no Kyoshikyoku* (*Rhapsody in August* [1990]), which depicts a character who survived the Nagasaki bombings. She retells (and relives) those days to her grandchildren, for whom the war is simply a long-ago ghost story.

CHILDREN'S FILMS

An often overlooked medium, films directed at children present an especially high number of disabled (or "afflicted") characters. Whether child audiences actually demand physically distinct characters, or whether filmmakers simply find such characters a convenient route through which to navigate the film's narrative and moral conclusions, a plethora of films reproduce disability stereotypes in the visual depictions of secondary characters. Even in a film such as *Toy Story* (1995) that offers a fantastical depiction of childhood imagination, the unavoidable "real world" invades owing to the minor character of the boy next door who destroys the toy-characters and then reconstructs them as "mutant" beings.

As is true of their literary counterparts, disabled characters appear on children's screen as either diabolical (e.g., Captain Hook in *Peter Pan* [most recently 2003] and *Hook* [1991] or Governor John Ratcliffe in *Pocahontas* [1995]) or delightfully benevolent and determined (e.g., the tin man in *The Wizard of Oz* [first made in 1939] or the beast in *Beauty and the Beast* [1946, 1991]). Quite often in children's movies, characters are represented as *both.* For example, in the *Harry Potter* (2001–2005) films, Harry has been injured and scarred for life, which is admirable, yet his nasty cousin, Dudley, is obese and constantly gorging himself. As well, a character such as the grinch (in *The Grinch* [2002]) is visually obvious as the villain, yet the very visual "difference" that sets such a character apart as evil indicates to the audience that such a character can be morally redeemed.

Children's movies also frequently feature the disability as a plot device that enables the action. For example, in *Mulan* (1998), the main character (voice-over by Ming-Na Wen) not only hides her gender in order to go to war to fight for her people, she also steals her father's papers in order to fake his identity. Had she not done this, the film implies, his disability injury from the previous war would have led to his likely death in battle.

CONCLUSION

Too frequently, written narratives and narrative films (especially but not exclusively dominant Hollywood productions) portray disabled characters as either pathetic victims (some examples include Blanche Hudson [Joan Crawford] in *Whatever Happened to Baby Jane?* [1962] and Tiny Tim in *Christmas Carol* [adapted for the screen several times between 1938 and now]), courageous heroes (Christy Brown [Daniel Day-Lewis] in *My Left Foot* [1989]), avenging villains (Quasimodo [Lon Chaney initiated the film role] in

Hunchback of Notre Dame [repeatedly adapted for film between 1923 and 2002]), or minor metaphorical glosses to a more important ableist central narrative (e.g., Warren Jensen Matthews [W. Earl Brown] and Tucker [Lee Evans] in *There's Something About Mary* [1998] and Ronny [Nicholas Cage] in *Moonstruck* [1987]). However, the history of cinematic depiction of disability both in Hollywood and elsewhere differs from that of literature and other representational arts in part because of techniques such as lighting, framing, and editing that control the gaze of the film audience. In addition, the film industry and its domination by Hollywood renders film a unique example of visually imposed normativity. Disability roles can be the focus of a movie (e.g., Sam, played by Sean Penn in *I Am Sam* [2002] or Helen Keller, played by Patty Duke in *The Miracle Worker* [1962]) or can be tangential to the main plot (e.g., a character who happens to be deaf, such as the brother character, David [played by David Bower], in *Four Weddings and a Funeral* [1994]).

Frequently, filmmakers use disability to portray a character as essentially evil, the character's disability serving as bodily signifier to inherently "flawed" human characteristic (e.g., Elijah Price [Samuel L. Jackson] in *Unbreakable* [2000] or Arliss Loveless [Kenneth Branagh] in *Wild, Wild West* [1999]). As Robert Bogdan (1988) says about the depiction of such characters (quoting his young son) in *Freak Show: Presenting Human Oddities for Amusement and Profit,* "If they look bad, then they are bad" (p. 6). Almost as frequently, filmmakers portray the opposite; rather than presenting villains whose disabilities display their essential evil, many films depict "ordinary heroes" whose disabilities—in and of themselves—transform them into noble and dignified "better than average" characters (e.g., Ben Affleck's blind and therefore extremely physically adept do-gooder lawyer, Matt Murdoch, in *Daredevil* [2003] or the tormented yet dignified John Merrick [John Hurt] in *The Elephant Man* [1980]).

Recently, independent and documentary films have begun to explore a more rounded or complex representation of disability onscreen. *What's Eating Gilbert Grape?* (1994), although still predominantly focused on main character Gilbert (Johnny Depp), depicts his brother (Leonardo DiCaprio), who has a developmental disability, and their extremely overweight and reclusive mother (Darlene Cates) as major players in the film's narrative. The documentary narrative *When Billy Broke His Head . . . And Other Tales of Wonder* (1994) humorously adopts a road-trip format while portraying Billy Golfus's attempts to rejoin the workforce with a brain injury; as well, David Mitchell and Sharon Snyder's short film *Vital Signs* (1995) situates disability as a provocative site of culture and performance. The two documentaries *Forbidden Maternity* (2002) and *Face to Face: The Schappell Twins* (1996) portray "Othered" lives from the point of view of the subjects'—rather than the expected viewers'—point of view. More and more, such films work to undermine clichéd presentations of disabled characters at the same time as they achieve grounds for further filmic narrative explorations.

FINANCIAL COSTS OF DISABILITY

Examining financial costs of disabilities from a number of different perspectives having to do with actual and opportunity costs, presented by the disability, is the focus of this entry. Analysis of who pays the costs for the treatment of the disability must also be understood. This entry also looks at factors involved when a decision is made to no longer pay the financial costs associated with disability and the impact on the society in which the person with a disability lives. Consideration of the factors involved in conceptualizing the extent and impact of the financial costs of disabilities is a useful exercise in promoting an understanding of the impact of disabilities on the individual and society.

Understanding the financial costs of disability requires examination of actual and indirect costs. This is a complex task, since the term *disability* means different things in different cultures and countries, and sometimes means different things within a culture and country.

DISABILITY DEFINED

In the United States, for example, the term *disability* is defined in a variety of ways in different pieces of federal legislation. Disability, as defined in the Ticket to Work and Work Incentives Improvement Act (TWIIA), relates to functional limitations that determine a person's eligibility for national vocational rehabilitation services (TWIIA 2001). Under the Americans with Disabilities Act (ADA), a disability implies real or perceived impairment, which may result in some discriminatory activity (ADA 2001). Disability under the Social Security Act means the inability to engage in substantial gainful activity because of a medically diagnosable impairment (Social Security Act 2001).

Similar legal and cultural discrepancies exist in the way the term *disability* is defined or treated within and among other cultures. The dialogue about disability centers around the concept that an individual has a disability when he or she has diminished physical, mental, or emotional capacity(ies) when compared with the population in which he or she lives. For example, the World Health Organization (WHO) defines disability as the functional limitation(s) secondary to a mental, physical, or emotional impairment (WHO 1980). Although cultural norms vary, the standardized approach to defining this diminished functional capacity would be a standard deviation or more below the mean of that culture on that functional limitation. In many cases, cutoff points are defined by formalized testing to justify qualification for programming or services.

From a societal perspective, existence of diminished capacities associated with disabilities threatens the decision-making abilities of those who have them. Therefore, persons with disabilities, whether they are children, adolescents, or adults, (often) have a diminished capacity to make binding decisions in regard to their lives (financial or otherwise), which is consistent with their non-disability-related state of life.

ACTUAL COST

Because people with disabilities, by definition, have a limitation in physical, mental, or neurological capacity, an accommodation to that diminished capacity needs to be made. For example, the societal burden of accommodating and treating mental illness was estimated to be more than $170 billion in the United States alone in 1990 (Rupp, Gause, and Regier 1998). In the U.S. Social Security system, total maintenance support income for consumers with disabilities (both Supplemental Security Income [SSI] and Social Security Disability Insurance [SSDI]) is estimated at $7.3 billion of the $70 billion Social Security Administration budget, or roughly 10 percent of the U.S. taxpayers' contribution to the Social Security system (Garske, Williams, and Schiro-Geist 1999).

Substituting, replacing, or adding to the usual and customary way things are done in order to accommodate a person with a disability also has cost. Often, the real cost of accommodation is not monetary. Rather, the cost is in the thinking and planning process associated with creation of an appropriate appliance, therapy, or program that makes the accommodation functional. Application of the thought process can often be done with little cost. In returning a person with a disability to work, 90 percent of the accommodations required end up costing $500 or less (Geist and Calzaretta

1982). This cost can be borne by the employer or the potential employee or by some external benefactor such as the state/federal system of vocational rehabilitation in the United States.

Medical costs and therapeutic interventions are also borne by the person with a disability, his or her family, or society. In countries without national health care, this can become an overwhelming burden on the family system. To respond to this burden, persons with disabilities are often emancipated from their family situation to allow the shift in therapeutic intervention from the individual/family to societal responsibility.

In the United States, for example, the SSDI program evolved to an income maintenance program from the original concept of holding benefits consistent from the point of disability to the usual retirement age of 65+. SSI evolved in the 1970s as a general welfare program for adults. Benefits from this program have since been extended to include children with disabilities who have not contributed to the pension system to earn the benefits of this insurance-based system. The amount of maintenance provided for SSI recipients is subject to the generosity of the U.S. Congress.

In other countries, reliance on government support rarely guarantees an amount consistent with even a substandard level of gainful support. The expectation exists that some other part of society, usually the family, will help support the person with a disability who is not working. In some countries, persons with disabilities are considered “lucky” to have any kind of regular income maintenance, and the income maintenance payment itself becomes a disincentive to competitive employment.

Examination of disability cost extends beyond medical services. Persons with disabilities in many cultures and countries receive special vocational support and administrative services (Schiro-Geist 1992). Service delivery systems vary from centralized or decentralized depending on the size and structure of the country. The costs also vary greatly depending on the availability of other benefits such as free or low-cost educational services, attendant care, housing, and administrative costs. Analysis of international costs of nonmedical expenditures is hampered by inconsistent availability of data.

In addition to the more obvious physical disabilities, mental disabilities financially tax society. Individuals with mental disorders make up the largest single disability group in the United States. Services for this group absorb one-quarter of all federal disability funding. Provision of direct services for this population accounts for more than $69 billion in annual costs in the United States. Indirect costs such as social disruption and loss of productivity were estimated to account for an additional $78.5 billion annually. These direct and indirect costs include income maintenance, disability-related costs such as case management, rehabilitation service costs, and work-related cost containment. Although advances in treatment for mental health problems are being made, the amount spent on mental health research is disproportionately low when compared to other research in the life sciences (Rupp et al. 1998).

In Western countries, which will soon see the full effect of the aging baby boomer generation, the fear of disability-related costs looms large. There is limited discussion about the reality that this increased cost to society will also result in increased production of goods and services consistent with the increased need of the majority aging population.

When totaling the cost of disability, one should attend to the profit accrued by components of disability-based industries. The population of persons with disabilities requires a variety of drugs, appliances, therapies, and support to function. Producing these products and services is done at a profit. Vendors of products as well as service providers live and run their businesses based on the needs of people with disabilities, borne by themselves, their families, and society. This often overlooked contribution to the gross national product, created by the disabled community, is one to be reckoned within any national economy. Many people with disabilities report only limited income for fear of losing their maintenance payment. They contribute to the national economy of a country with the goods and services produced through their “shadow economy” of work products and services rendered but not reported and taxed. Economists can only estimate the value of this disability shadow economy related to disability for a country and assume it to be a major contribution. Removal of the costs and benefits connected with people who have disabilities would undoubtedly affect the productivity of the country.

OPPORTUNITY COST

In addition to the actual costs accrued for goods, services, and income maintenance, there are costs to the person with a disability, his or her family, and society. These include lost opportunity, time, status, and often diminished return on benefits. People with disabilities are prohibited from doing things that they want to do and families and society assume the responsibility to provide for (whether or not they want to) the functional limitations created by disabling conditions.

The perception exists that people with disabilities are a negative financial influence on society or weigh society down. This creates stigmatizing values. These values lead to the conclusion that the person with a disability creates a huge financial drain on society because things have to be done for them or to them and these costs would otherwise not accrue to society as a whole. This misperception may come from the lower socioeconomic position of many people with disabilities. If people with unlimited financial resources have someone do their laundry, clean their house, do their shopping, and even dress them, there is less stigmatization. The wealthy person commands respect in spite of being dependent on a host of people to maintain his or her status. When a person with a disability of lower means requires or uses the same services, however, that person is seen as a burden on society even if the person is paying for the services.

TERMINATION OF PAYMENT OF COST

Society, to contain the ever rising and inflating costs, often puts caps on direct and indirect costs. In countries with national health care policies, there are age limitations on treatment offered to persons with potentially terminal disabilities. Medicare, the major insurer for retired persons in the United States, has caps on the amount of payments made for a variety of medical problems. Some states in the United States are moving toward limitations on all but palliative care for persons over age 80. Persons with private insurance or unlimited personal resources can continue to access treatment and services that are limited in the public domain. This highlights the inequity of disability support for persons based on their socioeconomic status.

SUMMARY

Just as the term *disability* varies in definition across and within countries, so does an estimate of the financial cost of the disability vary depending on the perspective of the analyst. The costs of the disability can be seen as a negative drain on a society, especially if the society or culture views disability in a negative way. However, the financial costs connected to disability can also be perceived as a positive influence from the perspective of the disability industry as an active economy within the larger gross economy of a country.

FLEURY, VICTOR (1800–1856)

French author and school administrator

Victor Fleury was born in France and moved to St. Petersburg in 1817. He began as a teacher of the deaf and then became director of St. Petersburg School for the Deaf (1838–1856). He authored the book *Deaf-mutes* (1835), which described methods of instruction and analyzed sign language of the deaf.

—*Anna Komarova*

FOLK BELIEF

Folk beliefs are often cautionary tales that locate misfortune, accidents, and unexpected events in human causes, and people who seem different from others appear most frequently as these causes. Fairy tales and folklore recount the adventures of human beings with creatures who seem less or more than human: witches, nature spirits, fools, trolls, dead ancestors, speaking and singing animals, shape-shifters, zombies, ogres, giants, and dwarfs. Superstition holds that people with the evil eye harm with a glance, that hunchbacks bring good luck, and that diseased or deformed children are changelings substituted for a human child. Some figures of folk belief, of course, are neither less nor more than human. They are simply human beings who present some form of mental or physical disability. The creatures of folk belief include the seeing and hearing impaired; twins; people with achondroplasia, epilepsy, birthmarks, or birth defects; and those simply deemed more ugly than others by social convention.

Folk belief represents disability as a curse or punishment, a symbol of sin and disgrace in the family, or a sign of impending disaster, and people with disabilities are said to have malignant influence over other people or to possess magical powers. The world of folk belief is a world of human difference often explained to the detriment of disabled people.

The reliance of folk belief on disability is at once obvious and little discussed. Gods, cultural heroes, magical beings, and their adversaries bear marks of bodily and mental impairment that echo or exaggerate common disabilities. Divinities are routinely portrayed in folklore as possessing a surplus or deficit of organs. In Hindu folklore, gods have six faces; in China, three faces; in Jewish lore, five faces. Hindu and Chinese legends tell of gods with many eyes, while Tonga folk belief describes a god with eight mouths. In India, Tahiti, Hawaii, and Russia, divinities possess many heads, but they are legless or armless in Borneo. Irish and Greek legends describe one-legged and lame gods. A cultural hero of the Maori has different-colored eyes, while Irish legend pictures a hero with seven pupils in each eye. Oedipus has a clubfoot in Greek myth, and Balor of Ireland possesses an evil third eye. When gods or cultural heroes do not have a disability, they may pretend to have one for the purpose of humble disguise. In England and Ireland, fairies have unusually long ears or hair, or they might possess hairy bodies, a long tail, half a thumb, or red eyes. Changelings are recognized by large teeth, a thick neck or skull, and congenital disorders. Ogres are blind in Iceland and one-eyed in Ireland, while other minor villains of folklore present a broad variety of disabilities and bodily differences, including being one-eyed in Jewish, Irish, and Chinese superstition; toothless in India; and left-handed among the Inuit.

The most common superstitions attribute to ordinary people exceptional powers based on unusual characteristics. The evil eye, for example, is a folk superstition evident in nearly every world culture, both archaic and modern. It expresses the belief that certain people may pass illness, do harm, or cause accidents with a look. Those accused of possessing the evil eye are often disabled or distinguished physically or mentally in obvious ways. Eye disabilities such as lesions, corneal scars, and strabismus increase the chance of being accused of possessing the evil eye, as do squinting or red eyes. Eye color may also affect the possibility of being accused. In regions where an eye color is rare—for example, green eyes in the Middle East—that color is inevitably associated with the evil eye. The idea that an evil or envious eye that disapproves of wealth or beauty causes accidents, injuries, and disabilities is seen as the products of malignant wishes or curses. Moreover, the evil eye superstition explains that certain illnesses and deformities may be passed from person to person through the medium of the eyes. The cleft palate takes its common name, harelip, not only from its resemblance to the lips of the hare but also from the belief that a pregnant mother may pass the feature to her child if she sees the animal. Folk belief explains common birth defects as impressions passed to child from mother when she looks too intensely at her surroundings.

Many other folk beliefs are based on congenital disabilities, appearances deemed ugly, cognitive disabilities, or physical and mental characteristics uncommon to a given population. Scholars argue that people with epilepsy or catatonia provide the model for the belief in zombies in Haiti. A host of exaggerated beliefs surround the seeing impaired, often representing them as possessing magical or malignant influence. On the one hand, the blind are routinely said to possess second sight or clairvoyance, as in the case of the blind prophet Tiresias of Greek mythology. Folk beliefs also suppose the blind to be more impartial judges than other people because appearances do not deceive them. On the other hand, blindness symbolizes evil, sinfulness, ignorance, avarice, or self-delusion. Leviticus 21:18 forbids the blind from entering the temple, and Jewish legend calls Satan “the blind one.” Superstition holds that the evil eye produces blindness or that the blind may transmit their impairment if they accidentally look into the eyes of a sighted person.

In general, the appearance of disability foretells evil or impending disaster. Dwarfs are universally credited with malignant powers. Their lack of growth represents ignorance in Hindu myth, and they are often described by other folk traditions as jealous or miserly hoarders. Animals offered for sacrifice in Greek and Jewish belief must be unblemished, and the lame, blemished, or disfigured are often forbidden from appearing in places of worship. The birth of monsters signals the end of the world in Jewish mythology. In soothsaying, the birth of a child without nostrils portends that a country will enter a period of affliction, while the birth of a child without fingers prophesizes mass infertility. However, the presence of disability may also herald favorable times. Rubbing the back of a hunchback is thought to promise good fortune. Touching cripples or giving them alms ensures good luck.

Folk beliefs throughout the world characterize disability or deformity as a punishment for sinful or improper behavior. Blindness is characterized as God’s will or a punishment for promiscuity or immorality. In folk belief, people are often struck speechless as a punishment for misbehavior. In Ireland and Iceland, paralysis is a frequent punishment. Curses produce leprosy in India, loss of an eye in Ireland, and the head to drop off in the United States. They lead to stillbirths in India and sick children in Canada. In Ireland and the United States, monstrous births are a punishment for pride, while in China and Greece incest causes misshapen children. Folklore also attributes the forms of animals to misbehavior: The flounder was punished with a crooked mouth for discourteous speech; the crab has eyes in the back of its head and the hare a cleft lip as punishment for speaking rudely or out of turn.

Folk humor reserves a special place for disabled people. Folklore makes fun on many occasions of misunderstandings caused by deafness. It also recounts numerous stories about the blind leading the blind to ridiculous effect or about duping blind people for a good joke. The fool is a universal figure in the disability humor of folklore. Taking advantage of fools, duping them into injuring themselves, or laughing at their stupidity are recurring motifs in world mythology, showing that folk belief is preoccupied with mental as well as physical disability. Other human characteristics ridiculed by folk humor include long noses, stuttering and speech impediments, ugliness, lameness, fatness, and small stature. Folk belief provides a convincing catalogue of the human propensity to mock unusual people or to make them the butt of a joke.

People with disabilities would seem to have little in common with the creations of folk belief and superstition. The fantastic worlds of folklore are populated by mythological gods, witches, monsters, magical heroes, and supernatural villains such as the possessor of the evil eye. But the worlds of folk belief and human difference collide when the need to account for misfortune and accidents places blame on people who do not seem to fit the norms of appearance and ability dictated by society. It is a small step from the human diversity of disability to the supernatural differences of folklore, mythology, and superstition.

FOLLY LITERATURE

See Literature, Folly

FOOLS

The origin of fools is uncertain. During the Middle Ages and Renaissance, fools played various roles. They were merrymakers at court, had their own "fool-societies," and particularly played their roles during the time of carnival. At the end of the Middle Ages and in the beginning of Renaissance, literature often used foolishness as a metaphor to describe the radical changes taking place in religion, economy, politics, and culture.

In late medieval times, particularly at court, fools were separated into natural and artificial fools. To the latter, merrymakers and jesters such as the German Kunz von der Rosen, the Italian Gonnellas, or the French Brusquet belonged. They were expected to act in foolish ways to make people laugh. To fulfill this aim, they performed comic and obscene productions and mimicry. Artificial fools were laughed at and laughed with. In contrast, natural fools were only laughed at. They were objects of mockery, adoration, and, in later times, pity. From the perspective of disability studies, natural fools are the more interesting topic.

Until the Enlightenment, natural folly was understood as a mental difference that was congenital. It was perceived neither as a mental disease nor as a changeable condition of human being. Instead, mentally challenged people were interpreted as a category in their own right. According to the Dominican friar and theologian Thomas Aquinas (1225/27–1274), natural folly was not a sin but a natural disposition. Natural fools belonged to the "marvelous" human beings, as the fourteenth-century encyclopedist Konrad von Megenberg (1309–1374) put it in his *Buch der Natur* (*Book of Nature*).

Marvelous human beings were divided into two different groups: marvelous people and monstrous individuals. Marvelous people were thought to live at the "end of the world." It was assumed that they were different from the European type of mankind and formed their own cultures with their own rules and customs. Monstrous individuals, showing selective physical or mental deviations, were also regarded as marvels. These individuals were seen as divine beings whose purpose was to warn mankind about forthcoming evil events.

Within this categorization, natural fools did not belong to the group of marvelous people but to the one of monstrous individuals. Courts kept natural fools and made them live in special conditions. They were treated like children and often exposed to physical violence. They could be laughed at and were allowed to say nearly anything. They did not own property nor did they get any wages, as was the case with their artificial counterparts.

Written evidence about natural fools is rare. Few records only reveal nicknames or first names. Some bills are preserved, but they simply state the cost of clothes or, in some cases, the salary for the fool's waiter. In general, natural fools had to be looked after, since they were not held responsible for any damage they did. According to various laws such as the German *Sachsenspiegel*, fools and mentally ill people could not be judged. Any cost of damage caused by them had to be paid by their guardian (*Sachsenspiegel*, III, 3: "ouer rechten doren unde sinnelose lüde en scal men oc nicht richten. wenne se auer scadet ere uormünde scal dat geldene").

Outside the courts, people designated as natural fools lived with their families at home or sometimes in special institutions. In Germany, these institutions were named *Narrenhäuser* (fools' homes) or *Torenkisten* (fools' boxes). In these asylums, fools were locked away together with the mentally ill, drunkards, or men who visited whorehouses. These inhabitants were supposed to be dangerous to themselves or society and were therefore put away in special institutions. For admittance, a medical diagnosis was not required; therapy was not offered, either. If families could not afford to look after their temporarily or permanently mentally impaired members, they brought them to the *Narrenhaus* (fools' home). Fools from foreign towns were also kept in these asylums, but only for a short time before being sent home again. Towns even used ships to get rid of foreign fools. However, there never were any "ships of fools" aimlessly traveling around the country as the French philosopher Michel Foucault falsely described it in his book *Madness and Civilization*.

During the sixteenth century, natural fools were increasingly kept as "marvels of nature." In various courts, marvelous and miraculous objects such as precious stones, ostrich eggs, whale bones, and peculiar plants were collected. Even humans belonged to these "cabinets of curiosity." As marvelous objects they were not only thought to have material value but magic forces, too. Like the religious relics, which often were the basis of these collections, the objects represented their aristocratic possessor's power and uniqueness. At court, physically different people, such as dwarfs, giants, or people with dark or hirsute skin, were kept as living attractions. Natural fools were collected as well because of their different mental abilities. In contrast to the fifteenth century, they were no longer exclusively laughed at, but also adored, like the "folyshe Duke at Lancaster." He was the first natural fool taken by Henry VII (1457–1509) on his formal progress to Sittingbourne in 1492. Other natural fools also accompanied English kings on their formal progresses. This tradition was practiced until James I (1566–1625). The illustrated Triumph progress of the Holy Roman emperor and German king Maximilian I (1459–1519) at which artificial fools as well as natural fools were shown can serve as a further example of the fools' increasing value at the beginning of the sixteenth century. The emperor outlined his Triumph himself: He included not only pictures about his life and genealogy but also about his fools.

Natural fools were also used as presents. A natural fool named Sexton was given to Henry VIII (1491–1547) by Cardinal Wolsey in exchange for a ring. The fool was described as "for a nobleman's pleasure he is worth a thousand pounds." Details about his life are preserved because, like other fools, he was counted as part of the King's Privy Chamber. According to Cavendish's "Life and Death of Cardinal Wolsey," the fool himself did not want to be separated from his former possessor, Cardinal Wolsey. "Six tall yeomen" were needed "to conduct and convey the fool to the court."

During the sixteenth century, it was even discussed whether mocking natural fools should be prohibited. Paracelsus (1493/94–1541) among others believed that divine messages embodied by the fools could not be read if they were vexed. Fools such as the German Claus Narr were expected to show insight and prophecy. Natural fools belonging to the so-called monstrous individuals were seen as prodigies. Their behavior was interpreted as containing divine messages. However, in contrast to physically different "monstrous" individuals, it was said that the divine signs made by natural fools could not be seen from the outside. It is told that once Claus Narr divided a precious coat. His action was interpreted as a warning to the Saxon sovereigns not to divide their country. During the sixteenth century, insight and prophecy were no contradictions to mental diversity.

At the end of the eighteenth century, the exclusion of mentally impaired people from society—analyzed by Foucault in his book *Madness and Civilization*—also had an impact on natural fools. The Enlightenment saw natural folly declared a treatable mental sickness and the focus of medicine and pedagogy. Natural folly became an object of different scientific approaches and lost its marvelous characteristics.

FOUCAULT, MICHEL

(1926–1984)

French philosopher

Michel Foucault’s work is immense, exploring extremely diverse fields, and it is read and commented on throughout the entire world. Here, only a few aspects that concern the sphere of disability will be reviewed. *The History of Madness in the Classical Age* (1961) inaugurated his major inquiries into the production of truths and bodies of knowledge but revealed less about the institutionalization of “disorders” (poverty, infirmity, madness, social marginality) than about the new relationship between reason and unreason, the creator of a radical madness and of the mad without remission. It would take a century and a half after the founding of the General Hospital by Louis XIV (1656) for madness to be considered curable (Philippe Pinel), and unreason came to be viewed as one more manifestation of the human mind. For all those concerned with the archaeology of madness and its treatments, Foucault’s book remains obligatory reading and an academic *rite de passage.* In 1974–1975, Foucault (1999) devoted his classes at the Collège de France to the “abnormal” (*les anormaux*): the monster, the incorrigible, and the onanist. As concerns monstrosity, his views are consistent with those of Georges Canguilhem, but for Foucault, it is essential to show that social categories no longer function, while disability, even when upsetting the natural order, still has its place in law. Yet it may be confused with monstrosity and so be exiled from the common social space.

FRAILTY

The term *frail elderly* is accepted in the medical community to refer to a physically weak older person who is susceptible to disease. Geriatricians are trying to develop a working definition of frailty so that it relates to measurable physical attributes and functionality. Although debates continue about whether it is possible to diagnose “frailty,” the term serves to differentiate those older individuals who require specific care from those who appear to function without assistance and without impediment to their regular daily activities (as defined by the medical establishment). Although literary gerontologists such as Kathleen Woodward and Margaret Morganroth Gullette have argued that the elderly are mistakenly interpreted as always already weak and in decline from their youthful vibrant selves, the need within medical parlance for a distinguishing adjective indicates that “elderly” itself does not denote frailty. That is, it suggests that a robust late life is possible.

Given the diagnostic tests recently developed by Thomas M. Gill, however, the addition of the adjective *frail* also implies that physical disability in late life is a marker of weakness. Gill’s tests consist of asking patients to stand up from a chair without the assistance of one’s arms and to walk a measured distance at a normative pace. Of course, people with disabilities of all ages may score as frail under these tests when they do not really match the criteria geriatricians seek to measure. The attempt to measure frailty through physical function does not capture the impact of normal daily activities as desired by the geriatric community. Furthermore, while *frail elderly* is wielded selectively within the medical and gerontological communities, laypeople often assume *frail* and *old* to be interchangeable. The broader usage of the term and implications of frailty, such as referring to an older woman as a “little old lady,” support the findings of age scholars in the humanities and social sciences. As demonstrated in the well-known usage “Frailty, thy name is woman,” *frail* connotes delicacy, unreliability, and moral corruptibility capturing the ways in which people with “extraordinary” bodies are interpreted as socially suspect on a number of fronts. Although it has been interpreted as meaning physical fragility in contemporary contexts, frailty in this sense refers to the tendency of women to be unfaithful in love. The ascription of frailty to older people who essentially fail to remain young, then, fits into a long-standing context of depicting people with physical disabilities and nonnormative physical functionality as though they are immoral.

FRANCE

See Advocacy Movements: France

FREAK SHOW

The term *freak* appears to be descended from the Old English word *frician,* to dance. *Freking*, for the medievals, was a form of cavorting, sudden movement, or capricious behavior. During the craze for scientific classification of the eighteenth century, as naturalists attempted to find specific categories for all life forms, organisms that failed to match a perceived species average were often referred to as *lusus naturae,* "cavorts" or "freaks of nature." In the early nineteenth century, certain naturalists toured Europe and America with examples of exotic or unique animals, charging admission to view their "cabinets of curiosities." Humans with bodies that were perceived to deviate significantly from an understood norm were often grouped with these *lusus naturae* shows, and so developed a variety of different performance genres that became collectively known as the freak show.

"Freak show" was a very general category that could refer to nontheatrical exhibits such as fetuses in jars ("pickled punks") or exotic or deformed animals as well as exhibitions of human "curiosities." In this context, *freak* was considered a relatively odious way of referring to humans, in performance or not, and was rarely used by professional performers or promoters until close to the end of the nineteenth century, after the death of Phineas Taylor (P. T.) Barnum (Barnum was never once known to use the term himself; see below). Favored alternatives were "raree show," "pit show," "kid show," and "ten-in-one."

Freak performers were present in America as early as 1738, but these freaks were not highly professionalized, and they appeared more often in the context of scientific lectures than theatrical performance, possibly as a means of evading colonial anti-theater laws. During the middle part of the nineteenth century, freaks gained great legitimacy, respectability, and profitability by performing their acts within the context of a new form of American entertainment known as the Dime Museum.

In 1835, Joice Heth, ostensibly a 161-year-old African American woman who had been the nurse of George Washington himself, was exhibited in the hall of a hotel in Bridgeport, Connecticut. She was a tremendous success, partially because of her flamboyant promotion, partially because her tales of Washington's youth were, reportedly, told with such integrity and intimacy that a controversy over her true identity was kept alive for decades. The controversy was resolved when an autopsy revealed she was merely 80, but Heth's fame only increased after her death. Skillful protestations of innocence on the part of her manager, P. T. Barnum, resulted in widespread publicity and interest.

Following his success with Heth, Barnum became a promoter of theatricals and the emerging variety entertainments. In 1841, Barnum purchased Scudder's American Museum on the corner of Broadway and Ann Street in downtown New York City; this moment is considered to be the beginning of the "Golden Age" of the freaks, which would persist until the 1940s. Among the human curiosities at the museum were the notorious and controversial Broadway actor Hervey Leach (also known as Hervio Nano), Mlle. Fanny (who turned out to be a perfectly normal orangutan), Native American and Chinese "families," giants such as Jane Campbell ("The largest Mountain of Human Flesh ever seen in the form of a woman"), a 220-pound four-year-old known as the Mammoth Infant, giantess Shakespearean actress and "sentimental soloist" Anna Swan, giant Captain Martin Bates, Isaac Sprague the "Living Skeleton," R. O. Wickware the "Living Phantom," a variety of dwarves, the famous "Albino Family," African Americans with vitiligo, the armless wonder S.K.G. Nellis, a cadre of sexually ambiguous persons such as bearded ladies and hermaphrodites, clairvoyants, "Lightning Calculators," and many, many others. Without question, the greatest of all the American Museum's stars was Charles Stratton, better known as General Tom Thumb. The General appeared not in the traditional "pit show" or "cabinet of curiosities" format but was celebrated around the world as a talented actor of highly theatrical, expensively produced melodramas, and appeared in performances before American presidents and industrial barons as well as the royal sovereigns of Europe and Asia.

By 1860, the human freak, appearing in the museum, on the legitimate stage, or in carnival sideshows (so named because they required a separate fee for entry from the main circus or carnival midway), had become one of the chief attractions for American audiences. A major moment in this period was the "Revolt of the Freaks" in 1898, when a collection of the 40 or so most famous freaks in the world staged a labor strike while on tour in London, demanding that the management of Barnum and Bailey's remove the term *freak* from promotional materials for their shows. A nationwide campaign to produce a new name was instigated, and the term *prodigies* was adopted by the "Council of Freaks." The intensity of this controversy reflected and magnified the popularity of freak shows, even though the whole event was probably nothing more than a publicity stunt.

In the middle of the twentieth century, the freak show began to suffer a major decline in popularity. Many factors combined to this decline; certainly the emergence of the medical model of disability, which replaced the freak show's narrative of wonder with one of pathology, made freak shows seem to be celebrations of disease, but advances in mechanical ride technology (rides were cheaper to run and more profitable than freak shows) and the rise of cinema and television were probably even more significant to ending the Golden Age of the freaks.

The use of the term *freak* did not diminish as freak shows became less prevalent in the latter part of the twentieth century, although its connotation suffered a sea change. The most common use of *freak* in modern American English refers to anything that appears in contrast to expectations, as in "a freak hailstorm," "a freak allergic reaction," or a person whose behavior is bizarre or unconventional, as in "an acid freak," or obsessive, as in "a computer freak." In the 1960s, the pejorative was appropriated by those who sought to celebrate an intentional rejection of conventional, conformist ideals by "Lettin' Your Freak Flag Fly." *Freak* entered American slang in the late 1970s with an undoubtedly positive spin: "Le Freak, C'est Chic," sang disco group Chic on a 1978 Atlantic Records hit to describe a joyful dance, while Rick James's "Superfreak" described a desirable woman in his 1981 funk album *Street Songs.* Nevertheless, *freak* continued to be applied pejoratively to disabled persons.

Freak show performance has a complicated relationship to disability; not all freaks were persons with disabilities, and activists of the disability rights movement have tended to avoid *freak* as a term of hatefulness. Eli Clare, activist and author of *Exile and Pride,* wrote: “Unlike *queer* and *crip,* [*freak*] has not been widely embraced in my communities. For me *freak* has a hurtful, scary edge; it takes *queer* and *cripple* one step too far; it doesn’t feel good or liberating.”

Two of the twentieth century’s most well-known professional carnival personalities, Priscilla the Monkey-Girl and Half-Girl Jeannie Tomaini, reported that they had “problems” with being referred to as *freaks.* The tension between freaks and disability rights came to a head in 1984, when disability rights activist Barbara Baskin successfully lobbied the New York State Fair to remove Sutton’s Incredible Wonders of the World Sideshow, featuring the beloved performer Otis Jordan (a limbless man who performed as the “Frog Boy”) from the midway.

More recently, however, activists have argued that the “Geek Love” mentality (referring to the title of the 1989 freak show novel by Katherine Dunn) is generating a desire even among “norms” to “freakify” themselves with piercings and tattoos. To the Geek Love advocates, the freak show signifies a celebration of human difference, which includes a politically motivated rejection of normality and conformity. Geek Love has, in fact, come to connote “disability pride” among certain disability activists.

In the twenty-first century, the freak show persists in America as part of the avant-garde underground circus movement. One chief practitioner is the highly regarded director and circus performer Jennifer Miller. Coney Island’s “Sideshow by the Sea” maintains the classic ten-in-one freak show approach and includes many forms of bizarre entertainment. Freak show imagery and history are also increasingly used in avant-garde performance, visual art, cinema, and music, notably including the 2004 HBO television series *Carnivàle* and the popular *Jim Rose’s Circus Sideshow.*

FREUD, SIGMUND
(1856–1939)

Austrian neurologist and psychoanalyst

Born in 1856 in a caul, an event that he believed guaranteed his future fame, Sigmund Freud invented psychoanalysis and established the direction of modern psychology. *The Interpretation of Dreams* (1900) elaborates his theories that the mind has both conscious and unconscious dimensions, that dreams seek the fulfillment of wishes, and that human beings are socialized under the pressure of an Oedipal triangle that places in conflict the desires of father, mother, and child. Freud devised the psychoanalytic session in which patients reveal the first thoughts that enter their mind as a mechanism for unlocking the unconscious basis of their mental problems. Freud’s most enduring influence on the study of disability was to develop the theory of psychosomatic illness in which a psychopathological flaw is given corporeal form as a symptom, thereby establishing the notion that people succumb to disease or disability because they feel guilty about past actions or repressed desires. In 1914, he further connected mental and physical states with the concept of narcissism, a pathology of self-love, whose theory also explains that bodily injuries prevent neurosis but make one susceptible to more serious narcissistic disorders such as megalomania or paranoia. Freud’s last theories divide the mind into the ego, id, and superego where the demands of the social world struggle with those of libido and conscience to determine the mental and physical health of the individual. Freud’s death in 1939 was physician-assisted by a dose of morphine to relieve suffering caused by cancer of the mouth.

FULLER, MARGARET (1810–1850)

American journalist

Margaret Fuller was an American journalist and Transcendentalist writer. Fuller's experience with disability was both personal and familial. She had chronic severe migraines of which her friend, Ralph Waldo Emerson, said, "She read and wrote in bed, and believed that she could understand anything better when she was ill. Pain acted like a girdle, to give tension to her powers." Her youngest brother, James Lloyd Fuller (b. 1826), had mental disabilities that seemed to combine elements of intellectual disability and mental illness—at the time he was called slow, lunatic, eccentric. When she left home for her writing career, she maintained a strong interest and responsibility for Lloyd's well-being, arranging jobs, clothing, and housing for him or sharing her own rooms with him during some periods. Margaret Fuller took a professional interest in disability as well. She wrote about the salutory effects of community living, with a romantic view of caregiving and resignation to one's fate as a moral opportunity and moral example to others. She wrote glowing reports from France about advances in education for people with developmental disabilities, and she described the Bloomingdale Asylum for the Insane in articles (1845–1846) for the *New York Daily Tribune.*

FUNCTIONAL ASSESSMENT

A gerontologist in Philadelphia, M. Powell Lawton, wrote in 1971 the first definition of *functional assessment*. He said that functional assessment was any systematic attempt to objectively measure the level at which a person is functioning in a variety of domains. Functional assessment, as a scientific endeavor, was slow to develop in rehabilitation. In fact, during the 1970s, most clinicians regarded functional assessment as an effort to measure the unmeasurable.

Substantial progress has been made in the past 30 years and functional assessment, in combination with outcomes analysis, is now considered one of the "basic sciences" of rehabilitation. Measurement of function is essential to the goals of rehabilitation, particularly medical rehabilitation. These goals are to monitor, support, and facilitate human performance and behavior, while considering environmental, structural, physiological, or psychological limitations. Functional assessment is a method for describing a person's abilities and limitations.

The essence of functional assessment is the measurement of a person's use of skills included in performing tasks necessary to daily living, leisure activities, vocational pursuits, social interactions, and other required behaviors. Information obtained from functional assessment is used to help formulate judgments as to how well essential skills are being used and to gauge the degree to which tasks are accomplished and social role expectations are met. Performance-based functional assessments take into account the social and physical contexts of the person. Measurement of functional abilities and outcomes must relate to real-life situations and settings.

Commonly, the emphases of rehabilitation programs include improving the functional status of individuals through a system of interdisciplinary interventions. Outcomes are determined by periodic reassessment of changes over time. The purposes of measurement are to make explicit the effectiveness, the efficiency, and the cost-effectiveness of the interventions. In this manner, outcomes of professional interventions of health care, rehabilitation, education, or psychological and social counseling may be described and monitored. Once outcomes become measurable, they become manageable.

The term *evidence-based practices* fits nicely with the idea of functional assessment and outcomes analysis as a basic science of rehabilitation. A scientific approach to assessing function and rehabilitation outcomes enhances national and international communications through use of a common language.

MEASURING FUNCTION AND ANALYZING OUTCOMES

Functional assessment and outcomes analysis require measurement. Measurement begins with understanding what is to be measured. This understanding must be grounded in theory and must be connected to a comprehensive model for identifying and then meeting the needs of the person being assessed. Each tool used in measurement must be designed and tested with respect to its purpose, practicality, construction, standardization, reliability, validity, responsiveness to change, feasibility for use, and meaningfulness in the clinical setting.

There are many difficulties in applying measurement principles to function and outcomes because the concepts to be evaluated relate to whole-person perceptions, attitudes, knowledge, or behaviors and are more often intangible (so-called latent traits) rather than tangible. For example, physical performance measured in terms of muscle strength, endurance, velocity of contraction, oxygen uptake, or even timed ambulation is much more tangible than measuring the ease or difficulty that a person as a whole experiences in tasks of daily living. Another example is the long-standing difficulty in measuring pain. Pain is a factor that often limits a person's ability to complete daily living activities, social interactions, and role participation.

Person variables are latent traits because they are hidden in the person; we can only infer them from observation of behaviors. These are just a sample because the person may generate a universe of behaviors, not simply mechanistic responses to external stimuli. One can infer that a person is "independent in daily life" by observing that he or she eats, dresses, or moves autonomously, but many other behaviors, if produced and observed or reported, might convey the same kind of information. This implies (a) discontinuity in the source data (we can only count discrete observations along a continuum); (b) nonlinearity of the counts (different behaviors do not represent the same amount of autonomy, despite being counted as "one more"); (c) more numerous behaviors replicate (and thus make more reliable) the observation that the variable is there, but do not necessarily reveal "more" of the variable; and (d) inhomogeneity of the error surrounding the observation (too easy or too difficult tasks for a given person provide very reproducible outcomes, whereas tasks "on target," despite being more informative, may end up in "pass" or "fail"). Thus, despite integer numbers, counts of observations represent a potentially poor surrogate of the intended measure. Recent developments of psychometrics, led by Rasch analysis (after the name of the Danish mathematician Georg Rasch), are at last shedding light on this fundamental challenge to functional assessment.

One technique for developing measures of tangible and intangible phenomena is through use of the Rasch mathematical model. Easily used software programs are now available to assist in the measurement process using the Rasch model. Rasch is described later, in the section titled "Uses of Functional Assessment."

Distinctions must be made between performance-based functional assessment, taking the social and physical contexts into account, and the conceptually simpler, more objective evaluation and measurement of functional capacity. Functional capacity assesses the person's performance under controlled circumstances, similar to judging optimal performance in laboratory conditions. These results may not reflect how the person performs in daily living activities in the "real world." Testing muscle strength and timed walking distance, as described above, are measures of functional capacity rather than of daily living activities.

There are many models for conceptualizing the attributes to be measured. Most emanate from the work of psychologist Abraham Maslow (1954), who evolved a hierarchy of needs to achieve self-actualization in order to live a fulfilling life. He understood that life's work was to systematically overcome barriers. At the base of Maslow's hierarchy lie needs for physical survival, and at progressively higher levels are satisfaction of needs for security, social interaction, and self-esteem. One derivation considers that the concepts to be measured are challenges to quality of daily living. In this model, the goal of fulfillment is achieved through balancing one's choices, options, and expectations (functional opportunities) with one's physical, cognitive, and emotional constraints (functional demands/barriers).

When opportunities and demands are not directly measurable in quantitative terms, then the underlying factors that either support or form barriers to health and functioning are often chosen for measurement. For example, functional opportunities that are supported by good health may be described and measured by assessing physical status, mental/emotional status, social interactions, role participation, and general well-being. On the other hand, functional demands/barriers may be described and measured by assessing pathophysiology, impairment, functional limitations, disability, and societal limitations (see definitions below).

As another example, motivation is felt to be an important underlying determinant of how well a person may cope with adversity, for instance, a chronic disease or disability. While not directly measurable, inferences may be made by measuring variables related to motivation, such as self-esteem, mood, or by analyzing the steps one follows in solving a problem or in developing a plan of action.

The World Health Organization (WHO; 1980) originally proposed a series of definitions that have had a profound impact on the assessment of functional status and outcomes in rehabilitation. The original WHO framework was modified in a National Institutes of Health, National Center for Medical Rehabilitation Research report published in 1993. This report included the following definitions that are widely used within rehabilitation:

> *Pathophysiology* is any interruption of, or interference with, normal physiological and developmental processes or structures.
>
> *Impairment* is any loss or abnormality at the organ or organ system level of the body.
>
> *Functional limitation* is any restriction or lack of ability to perform an action in the manner or within a range consistent with the purpose of an organ or organ system.
>
> *Disability* is any limitation in performing tasks, activities, and roles to levels expected with physical and social contexts.
>
> *Societal limitation* is any restriction attributable to social policy or barriers (structural or attitudinal) that limits fulfillment of roles or denies access to services and opportunities associated with full participation in society.

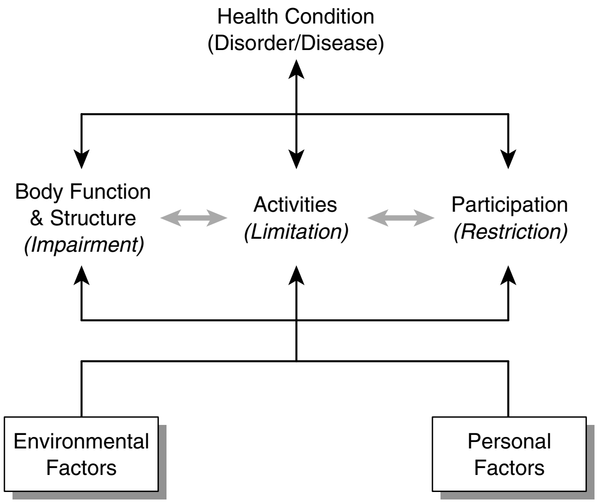

Figure 1 Interaction of Concepts
Source: World Health Organization (2001).

Recently, the WHO (2001) proposed a revised model referred to as the International Classification of Functioning, Disability, and Health. The components of this model are presented in Figure 1.

The dynamic evolution of disablement models illustrates that measurement of functional abilities and rehabilitation outcomes is an ongoing challenge in which researchers and clinicians attempt to disentangle complex nonlinear interactions that occur in real life, across many different variables. Yet measurement of each variable, itself, must be linear, that is, proportional to the quantity it is claimed to represent. Rehabilitation outcomes are multiple rather than singular. Assessment of "quality of life" requires use of measures that cover several aspects of functioning concurrently, yet cooperating in defining a unitary construct. This means that using a large number of instruments is not necessarily better than using a few well-chosen ones. As well, one must be vigilant that instruments are measuring accurately and succinctly. Johnston, Keith, and Hinderer (1992) have identified interdisciplinary standards and guidelines to foster improvement in development of functional assessment scales in rehabilitation. These standards and guidelines were compiled to counter the tendency to measure the "whole person" based on evaluation of severity of focal impairment alone.

The guidelines cover validity, reliability, clinical application, and program evaluation/quality improvement.

Validity includes three forms (content, predictive, and construct) and is the paramount criterion for choice and use of an instrument. Validity is regarded as the extent to which a test measures what it is intended to measure. Commonly, a "gold standard" is sought against which newer measures may be compared.

Reliability is the extent to which the data contain relevant information with a high signal-to-noise ratio versus irrelevant static and confusion, that is, sufficiently free of either random or systemic error. Repeatability indicates reliability. Agreement is the most stringent form of repeatability in which results of testing match across raters, time, or subjects. Agreement, however, may come also from the same bias affecting multiple observations (e.g., across raters or times). Internal consistency is another, perhaps even more stringent, form of reliability, demonstrating that all items are evaluating the same general construct. The more coherent the items are, the more they will be free from individual changes, independent from the shared construct, and thus, the scores will tend to be repeatable.

Clinical application means that users need to understand the scientific basis for the inferences they make from their clinical assessments and the boundaries of this knowledge.

Program evaluation/quality improvement involve application of measures to groups for purposes of ongoing review to systematically resolve identified problems and pursue opportunities to improve care and services, to accomplish accreditation, and to use evidence to support policy making. Wide variations in responses of individuals may reflect an instrument or measurement process that is not accurate or stable. Outcomes not only are dependent on the effectiveness of treatment but also depend on patterns of input, process, and conditions surrounding the treatment intervention. Good outcomes are the culmination of the combined effects of structure and process. Case-mix adjustments must be made to account for variations in severity or qualitative differences in the individuals being measured.

USES OF FUNCTIONAL ASSESSMENT

Using data from the Uniform Data System for Medical Rehabilitation, Margaret Stineman, associate professor, Rehabilitation Medicine, University of Pennsylvania, and colleagues (Stineman 1998; Stineman et al. 1994; Stineman et al. 1997) developed the FIM-FRG system to classify patients at the time of admission to inpatient rehabilitation. The FIM-FRG system was designed to facilitate prediction of length of stay and level of function that can be achieved during rehabilitation, and to compare outcomes between patients, having made case-mix adjustments. The classification system uses type of impairment, severity of disability using the FIMTM instrument (*Guide to the Uniform Data System* 1996) motor and cognitive measures, and for some groups, age. The IRF-PAI (Inpatient Rehabilitation Facility-Patient Assessment Instrument), developed for the U.S. Centers for Medicare and Medicaid Services (www.cms.hhs.gov) to use for prospective payment to rehabilitation hospitals, incorporates the FIMTM instrument, and has been used in the United States since January 2002.

In contrast to continuous linear measures (such as those for length and weight), item-response scales are most commonly used for functional assessment and outcome analysis. Scales are typically discontinuous-ordinal. The raw scores they provide are neither linear nor equal-interval, thus they should not be used in parametric statistical analyses. Interval measurement derived from raw scores through Rasch-based (Wright and Linacre 1989) transformation improves functional status analysis by providing unidimensionality and additivity. Unidimensionality means that items cooperate with each other as they progress in difficulty across a common range of performance, with each item adding a level of difficulty for the subjects. Unidimensionality also means that the abilities of the subjects can be located along the continuum defined by the items, according to common standard units. Additivity means that adding one more unit always increases the pool by the same amount, whatever the overall level of the measure.

Together, these two concepts of item difficulty and person ability being measured on the same linear metric are referred to as conjoint additivity. Conjoint additivity is achieved only if the measure is independent of the particular sample being tested, and of the particular set of items adopted. Therefore, Rasch-transformed measures, complying with the requirement of conjoint additivity, permit statistical validity and generalizability in comparing individuals on the basis of results using an aggregate rating and in comparing changes in ratings over time. The Rasch measurement model offers opportunities for comparing standardized expected values both for aggregate ratings and item responses when persons have problems that are relevant to the latent trait being measured.

Measures of function and outcome analysis are classified according to questions that they are intended to answer: (1) discriminative, (2) evaluative, or (3) predictive. The first task in using a measure is to identify levels of severity from low to high. The second task is to identify whether the value of the measure changes with changing severity. The third is to predict another parameter that is either concurrent, such as the cost of the treatment program or the value of a variable in the future, such as the likelihood of recovery.

A challenge that remains for the medical rehabilitation field to solve is the predictable relationship between the "dose" of rehabilitative services and the "response" of the person. In fact, depending on the problem and the treatment, rehabilitation outcomes may follow teaching-learning paradigms (e.g., in therapeutic exercises), in the same way that chemical dose-response dynamics (e.g., in chemical treatments for pain or spasticity) do.

When functional assessment is performed by observation of activities, it is very important to assure accuracy or intrarater and interrater reliability. This may be accomplished through several methods that include (1) testing competence of the assessors with an examination, (2) testing the results of the assessments with standard statistical studies of variance, and (3) Rasch modeling of the data testing for separability of persons and items and the fit of item responses to expected rating patterns. Assessors who are performing ratings through observation or interview need to receive training and then be tested to ensure their knowledge of the criteria for rating.

CONCLUSION

Feedback of the results of functional assessment and outcome analysis is extremely important (1) for clinicians to know whether they are "on track" and (2) for administrators to perform program planning and program evaluation and to make policy decisions responsibly. Accrediting bodies require functional assessment and outcome analysis as evidence of quality assurance. Accreditation agencies are also increasingly sensitive to feedback from the consumers of rehabilitation services. In the effort to measure quality of daily living, it has become important to use patient-centered questionnaires that gather the person's perspective, rather than attempt to infer this perspective from objective testing of body functions. The patient-centered approach to functional assessment and the evaluation of rehabilitation outcomes is consistent with the goals of medical rehabilitation and reflected in the motto "As we function, so shall we live!"

FUNCTIONAL MEASUREMENT

Functional measurement is a general term that describes the processes by which we collect information to evaluate disability and determine the need for vocational or rehabilitation services. On the surface, functional measurement may simply represent the act of determining a meaningful quantity of something. The term *functional* means purposeful or useful. Measurement refers to the process of determining a quantity or amount. However, the term takes on a special meaning in the context of disability and refers more specifically to the process of quantifying an individual's performance of particular tasks and activities in the context of specified social and physical environments. A preponderance of functional measurement is focused on the completion of tasks and activities that relate to work (specifically, to a particular job) or to caring for oneself. Thus, key tasks and environments that are most often the focus of functional measurement are *activities of daily living* (e.g., eating, dressing) completed in the home and specific job functions completed in the workplace. Another, though less emphasized, area of functional measurement involves getting around and using the community at large.

The reason for conducting functional measurements is to obtain a reliable and valid representation of how well an individual performs particular tasks or activities under certain circumstances. This task is complex, because people have a dynamic and personal relationship with the environments in which they inhabit. Therefore, the circumstances of any given performance involves many factors, including personal capabilities (knowledge, skills, abilities, and attitudes), the particular demands of the task that needs to be performed, and the setting in which the performance takes place. In practice, individual performance can be influenced by improving the person's capabilities (through accommodation or some other rehabilitation strategy), by altering the task to reduce or eliminate unnecessary demands, or by modifying the setting to remove environmental barriers. Rehabilitation and vocational specialists engaged in improving client performance and reducing disability use all of these strategies. Furthermore, the range of options is made known only through functional measurements that take into account the individual's capacities, the specific tasks to be performed, and the specific settings in which they take place.

HISTORICAL FOUNDATION

The concept of functional measurement has evolved over the past century as views toward compensation for injury and rehabilitation have become more sophisticated. In the first third of the twentieth century, disability was primarily considered a "defect with a cash value." Honored workers in the national economy (such as those in the military or civil service) were compensated for injuries that occurred on the job. At that time, assessment was limited to determination of impairment. The resulting compensation was rather crude involving a set cash payment for different types of impairments. For example, the loss of vision in one eye resulted in a different payment than did the loss of function in an arm.

Society continues to compensate workers for their injuries, although the method of calculating benefits has changed substantially. During the middle third of the twentieth century, we also began teaching injured workers to use and adapt residual capacities to work and reach their maximum vocational potential. This happened for a variety of reasons. However, the primary reason was the growing population now living with impairment due in part to the large numbers of casualties resulting from both World Wars and to increasing numbers of car accidents. Advances in medical science and technology resulted in people surviving injuries that previously resulted in death. The remarkable change in rehabilitation during this period was the acceptance of the holistic philosophy in rehabilitation. This philosophy held that the mind and body accomplish tasks in an integrated way. By implication, one cannot obtain a clear picture of the capacity to perform tasks or activities by measuring the functioning of body structures alone. Instead, the focus of assessment shifted to the "whole" person completing tasks and activities associated with daily living. According to Kessler (1970), the effective dynamic action of mind, body structure, and body function work as a single unit to complete tasks and achieve goals. During this period, there was a proliferation of functional assessment instruments that focused on the accomplishment of key activities of daily living, such as eating, dressing, and bathing.

The latter third of the twentieth century saw profound changes in rehabilitation. Advances in rehabilitation medicine led to improvements in the ability to remediate and improve patient capacity following injury or disease. However, just as important was the recognition that disability is "a form of inability or limitation in performing roles and tasks expected of an individual within a social environment" (Nagi 1977). In effect, Nagi defined disability as a distinct concept, one that is different from impairment. *Disability* is a socially derived term that refers to an individual's performance of tasks and activities related to achievement of social roles. The term *disability* was further formalized with the introduction of the World Health Organization's International Classification of Impairments, Disabilities, and Handicaps in 1980 and further refined in its International Classification of Functioning, Disability, and Health in 2001. As researchers and clinicians set about the task of "measuring" disability, the concept of functional measurement began to take shape.

PURPOSES OF FUNCTIONAL MEASUREMENT

There are two principal purposes for conducting functional measurements. One purpose is to facilitate reintegration back into one's living environment following injury, disease, or disorder. Rehabilitation or vocational specialists gather information about their client's home and work environments to discover ways to improve the individual's ability to complete important daily tasks. In this case, functional measurement refers to the collection of information to reflect the dynamic characteristics of the individual, including personal activities, capacities, environmental conditions, and needs. Together, this information is used strategically to plan for the individual's reintegration back into familiar work and living environments. Rehabilitation strategies can range from new surgery or therapy that is needed to improve the individual's personal capacity to remodeling the home to accommodate incapacity due to permanent impairment. Vocational strategies can range from retraining the individual to do a current or previous job to remodeling a previous work environment or training for a new vocational goal. All of these actions have the effect of reducing disability.

Analogous to this purpose is the concept of habilitation that concerns the integration, as opposed to reintegration, of an individual into increasingly demanding adult living situations or environments. Habilitation most often relates to the education of children and youths with disabilities. The goal is to reduce the potentially disabling effects of the increasing demands associated with adult living tasks and environmental settings through education. Functional measures provide a means for understanding educational needs.

The second purpose for conducting functional measurements is to facilitate decisions about access to relief under various laws. Functional measures provide critical information to the decision of whether a claimant meets the legal definition of disability, thereby making him or her eligible for benefits under the particular law. While the definitions are somewhat different under each law, they all require some functional measure of a claimant's ability to meet the demands of age-appropriate daily living requirements. For example, disability under the Social Security Administration (SSA) is narrowly defined and reserved only for individuals who cannot perform substantial gainful activity (i.e., SSA's term for work) now or in the foreseeable future. A determination of work disability, as it is sometimes called, leads to an award of monetary and health benefits to claimants who are disabled under the law. Given that the consequences of the decision for the individual and for society are costly, it is not surprising that disability determination under Social Security is a formal and often lengthy process involving careful assessment of a claimant's capacity for engaging in previous work or any work available in the national economy. If the impairment is severe and interferes with the completion of previous work requirements or the work requirements of any job found in the national economy, then the claimant is judged unable to engage in substantial gainful activity and is awarded benefits.

In all cases where a legal determination of disability is required, the decision is reached through a formal process of data collection and analysis. Functional measures are only a part of that process. For example, while the definition of disability is markedly different under the laws governing education and Social Security, both processes require that measures of impairment be collected before actual functional measures are collected. This makes sense, given that impairment is a prerequisite to disability.

Disability is sometimes "presumed" based on an assessment of impairment alone. In these cases, the impairment is considered so severe that it is not necessary to assess the environmental consequences of the impairment. In effect, it is already known. For example, individuals with Down syndrome who have a measured intelligence quotient in the low 50s are presumed to be disabled. This decision is based on accumulated knowledge that such persons will now (and in the future) face serious barriers to gaining control over their environment and will not be able to take on expected social roles. These individuals will largely require supervision in the conduct of daily living tasks and activities requiring higher levels of language, problem solving, and judgment.

MEASURES OF IMPAIRMENT

Functional measurement can be contrasted with measurement of impairment. Measurement of impairment is focused on a determination of the extent to which the body's structure or function deviates from that which is considered normal. In the International Classification of Functioning, Disability, and Health, examples of body structures include the nervous system (such as the brain and spinal cord), the eye, voice mechanisms (such as the nose, mouth, pharynx, and larynx), and structures related to movement (such as the head and neck, upper extremities, and lower extremities). Examples of body functions include mental functions (such as general functions of consciousness and intellect as well as specific functions such as memory and attention), sensory functions (such as taste and smell), and neuromuscular and movement-related functions (such as mobility and stability of joints and muscle power).

We may measure handgrip strength or range of motion associated with the shoulder, elbow, or wrists to determine the extent to which hand or arm function is impaired. The extent to which these measures deviate from normal measures, given age and sex, determines the existence of impairment.

Measurements for mental capacity or emotional development can be treated in a similar fashion. An individual's performance on a test of intelligence (IQ test) provides the information needed to determine the extent of mental impairment. Thus, measures such as the Stanford-Binet scale or Wechsler Adult Intelligence Scale (WAIS) yield information on the intellectual performance of an individual compared to "normal" intellectual performance. For many years, low IQ test performance was all that was necessary to "presume" disability for purposes of disability under SSA. However, these days IQ test performance is only part of the SSA disability determination process involving mental impairment. In recognition of the many skills and abilities that apply to successful work performance in one's environment, functional measures are now also required to supplement IQ testing in the determination of disability.

Functional measurement can also be contrasted with functional capacity evaluation (FCE). FCEs move a step closer to measures of a person's ability to perform daily tasks and activities. Even so, the measures remain focused on the individual as opposed to the relationship between the individual and the environment. FCEs assess individual performance on meaningful tasks, as does functional measurement. The purpose is to generalize to functional abilities that result from normal physical or mental development. Thus, FCEs require individuals to perform tasks that are specifically designed to measure limitations in physical ability (pushing/pulling, carrying, reaching, seeing, and hearing), neurobehavioral performance (walking, balance, and stamina), cognitive ability (oral or written language, memory, and problem solving), and interpersonal interaction (teamwork and responsibility). Performance on these "functional" abilities is then used to predict ability to engage in a previous job and meet daily living expectations. It is obvious that FCE is complementary to both measurement of impairment and to functional measurement. However, functional measurement is focused on the performance of actual job functions whereas measurement of impairment is focused on the extent of damage to a body structure or function, and FCE is focused on the effect of impairment on particular uses of the impaired body structure or function.

FUNCTIONAL MEASUREMENT METHODS

Functional measurement employs one or more methods of data collection. There are generally three types of methods for obtaining functional measures: (1) self-report methods, (2) structured performance rating methods, and (3) behavioral observations and situational assessment methods. Each method has its own unique use and characteristics.

Self-Report Methods

Self-report methods include checklists, rating scales, and inventories. The common characteristic among these types of instruments is that the data collection procedure involves obtaining the information directly from the individual who is the target of the assessment. They report on their own functioning. The individual affected is often considered to be the best source for information about his or her ability to function in familiar environments. Thus, self-reports are an efficient and direct way of obtaining reliable information. In addition, they can cover a wide range of topics and content. However, they are also subject to problems of validity since they are easily influenced by the desires of reporters who wish to appear more or less disabled, depending on the circumstances and the reinforcers apparent in consequences tied to the assessment. For these reasons, self-reports form only a small part of eligibility decisions associated with legal disability determination.

Self-report methods are used mainly in health care settings and in national surveys. In the health care setting, self-reports are often supplemented with clinical evaluations and judgments. For these reasons, their potential invalidity—due to "wishful" reporting—is less of an issue. Self-report is also the primary method for obtaining information in national surveys, since this method is the most efficient and cost-effective way of finding out about an individual's situation.

In some cases, another person, called a proxy, completes the self-report because the targeted individual may not be capable of reporting his or her own behavior due to weakness or fatigue or mental incompetence, for example. Proxy reports are most useful when the questions do not address personal feelings, opinions, or hypothetical situations. These types of questions lead to results that differ from the target individual's.

Structured Performance Ratings

Structured performance ratings include checklists, rating scales, and inventories completed by a trained evaluator. The notion behind structured performance ratings is that a trained evaluator provides objective evidence of performance. Typically, such persons include a physician, therapist, nurse, vocational assessor, or other service provider. The sources of information about the target individual might include observations, interviews, case histories, and tests. However, this implies that structured performance ratings are retrospective rating scales that provide judgments about performance observed in the past. While still subjective, structured performance ratings offer a more objective method for assessing target individual performance since the trained evaluator would have less incentive to skew the ratings.

The major limitation of structured performance ratings is the common context for making ratings. Evaluators may have insufficient information to arrive at a valid rating. This result could be due to ambiguous questions or bias. One way developers of such instruments confront this problem is to accept input only from evaluators who meet specified criteria—such as knowing the targeted individual for a certain period of time, or having observed the targeted individual in specific settings.

Behavioral Observations and Situational Assessments

Behavioral observations and situational assessments include observations of target individuals performing in natural or artificial environments. Behavioral observations typically focus on performance in natural settings, such as the individual's home, community, or workplace. Situational assessments are observations of performance in artificially constructed (situations) environments. Both methods provide a rich source of information about target individual performance. However, they are also time-consuming and costly. Their major limitation is the breadth with which one can generalize performance to a broader range of environments in which the target individual may find himself or herself. Another issue is that the episodic nature of some impairments does not lend well to these types of methods unless repeated trials can cover the length of time or period needed to obtain a complete picture of performance.

G

GAIT ANALYSIS

Twenty years ago, Gordon Rose, a pioneer in the field, suggested that the term *gait assessment* should be applied to the whole process of evaluating a patient's gait and that the term *gait analysis* be reserved for the high-tech component of gait evaluation. In the diagnostic triad of history, physical examination, and laboratory tests, gait analysis is a laboratory test. Historically, while Eadweard Muybridge (1830–1904) famously used sequential photographs to display gait in several species, gait laboratories were developed to support research into the biomechanics of human movement. The difficulty of the process limited the amount of data that could be processed and the sophistication of the models used to interpret the results. In the past few decades, gait analysis technology has improved significantly, resulting in a potential for wider clinical application. The development of powerful and inexpensive microcomputers has reduced the time and labor costs of gait analysis. Coincidentally, commercial vendors have developed standard packaged gait analysis systems that integrate the basic technologies required for gait analysis, motion capture, ground reaction force measurement, and muscle activity monitoring. Gait laboratories have developed a consistent set of parameters for describing gait and gait pathology.

At present, the most common clinical use of gait analysis is the assessment of spastic gait in patients with partial paralysis from an upper motor neuron pathology. Gait analysis allows one to understand the dynamic implications of a specific impairment, such as spasticity or weakness in a particular muscle group. Gait analysis helps the clinician determine those impairments and functional limitations that likely contribute to a walking disability. Probably no two sets of quantitative gait data from two individuals are the same, no matter how visually similar the individuals' gait disabilities appear. Logically, the optimal treatment for a given individual will be the one that addresses the impairments and functional limitations most contributory to that person's gait disability.

By defining causative impairments and functional limitations, gait analysis can focus and optimize rehabilitation treatment, including the prescription of specific exercises, electromyographic biofeedback, functional electrical stimulation, orthotics, and nerve or intramuscular blocks. In patients with upper motor neuron pathology, traditional static evaluations are not effective in measuring either functional muscle strength or spasticity. By identifying which muscle groups need strengthening (or electrical stimulation, or bracing) and which need relaxation (or stretching, or intramuscular neurolysis, or tendon lengthening), gait analysis can lead to optimal, methodical, and directed treatment.

Undoubtedly, gait analysis technology will continue to improve with developments in computer vision, artificial intelligence, computational methods, and computer power. In addition, models used to interpret gait analysis data will be refined and standardized. Ultimately, a clinician will likely be able to input kinetics measured with current gait analysis technology into a computerized robotic model that will produce a kinematic gait pattern, or mathematical description of the person's entire gait, that is similar to the individual's actual kinematic pattern. Changing the kinetic inputs in the robotic model could simulate rehabilitation, such as strengthening a particular muscle. The resulting modeled kinematics would help predict the kinematic changes to be expected if the patient were to undergo the treatment.

GALEN (129–CA. 199/216)

Greek physician and philosopher

Galen was a physician from Asia Minor who practiced on both gladiators and rulers, serving as physician to four emperors. He was also a philosopher and author who wrote more than 350 works in Greek on subjects ranging from anatomy to deontology, from philosophy to poetry, from pathology to therapy. He was a vigorous advocate of the tradition of Hippocrates but was equally eager to display his own innovative knowledge and investigations. In particular, Galen enhanced the concept of the four humors as a system of explanation for diseases.

At once arrogant and brilliant, Galen, through his texts and ideas, had a profound influence on elite Western medicine until the nineteenth century, although observations by anatomists and physiologists starting in the sixteenth century (e.g., those of Andreas Vesalius [1514–1564]) began to undercut the power of his ideas.

Galen's descriptions of disabling conditions ranged from fractures and paralyses to visual impairments and epilepsy, while his therapeutic interventions embraced dietary changes, fractured limb reductions, and bloodletting. He helped differentiate the trachea and the larynx, thus allowing speech disorders to be pathologized. Galen publicly demonstrated the function of the recurrent laryngeal nerve, which innervates the voice box. He cut the nerve in a squealing pig and thereby "removed" its voice, thus demonstrating both a refined physiological sensitivity and the use of impairment as a marker of physiological dysfunction. Galen's influence on disability, by way of medicine, is at once distant and profound.

GALLAUDET UNIVERSITY

See Gallaudet, Edward Miner

GALLAUDET, EDWARD MINER (1837–1917)

American educator

Edward Miner Gallaudet, an influential nineteenth-century educator, was the founder of the world's first institution of higher education for deaf people. During his 46-year tenure as the head of the National Deaf-Mutes College (today known as Gallaudet University), Gallaudet was internationally renowned as the originator and chief proponent of the so-called combined method of educating deaf children, a method that stressed a combination of spoken-language training and the use of sign language in the classroom. A native user of American Sign Language (his mother was deaf), Gallaudet maintained lifelong connections with the American Deaf community largely through “his boys,” the Deaf male graduates of the college.

The youngest son of Thomas Hopkins Gallaudet, cofounder of American Deaf education, Gallaudet was born in Hartford, Connecticut, on February 5, 1837. After a stint as a teacher at the American School for the Deaf from 1855 to 1857, he was invited to establish a school for deaf children in the District of Columbia. The Columbian Institution for the Instruction of the Deaf, Dumb, and Blind was established on February 16, 1857, its college division charter signed by Abraham Lincoln on April 8, 1864. Gallaudet died in Hartford, Connecticut, on September 26, 1917, in the centennial year of the founding of American Deaf education.

GALLAUDET, THOMAS HOPKINS (1787–1851)

American educator

Thomas Hopkins Gallaudet was the cofounder of American Deaf education in 1817. A noted orator and evangelical Christian, Gallaudet used his considerable rhetorical skills to garner support from influential citizens and financial assistance from state legislatures for the then outlandish notion of educating Deaf people. Gallaudet held a lifelong interest in education and social reform, campaigning in areas as disparate as the common school movement, work with the mentally ill, and the abolition of slavery.

Gallaudet, born on December 10, 1787, became interested in the education of Deaf people after meeting Alice Cogswell, the Deaf daughter of a neighbor. With funding from Cogswell’s father and other prominent Connecticut citizens, Gallaudet traveled to Europe in 1815 to learn how to teach Deaf children. Dissatisfied by what he saw in British schools for Deaf people, Gallaudet was invited to visit a school in Paris. There, he received training from Deaf teachers Jean Massieu and Laurent Clerc. The latter accompanied Gallaudet back to Hartford in 1816 and helped him establish the first permanent school for the deaf in the United States in 1817, now known as the American School for the Deaf. Gallaudet served as the institution’s principal until 1830. Gallaudet and his wife, Sofia Fowler, a former pupil, had eight children, the eldest and youngest of whom continued their parents’ work with Deaf people. Gallaudet died on September 10, 1851.

GALSWORTHY, JOHN E. (1867–1933)

English novelist and dramatist

Educated at Harrow and at New College, Oxford, and recipient of the 1932 Nobel Prize in literature, John Galsworthy is best remembered for his series of novels tracing the history of the upper-middle-class Forsyte family from the 1880s to the 1920s. Appointed to Britain's War Propaganda Bureau (WPB) in 1914, Galsworthy refused to encourage public hate of Germany, instead emphasizing support of men wounded and disabled in the conflict. To this end, he worked with the Red Cross in France at the Benevole Hospital for disabled soldiers, offered his family house as a convalescent home for recovering British soldiers, and chaired the executive committee of Kitchener House, a club for wounded sailors and soldiers. Galsworthy also published successful appeals on behalf of the Star and Garter Home for Disabled Sailors and Soldiers, contributed material to the *American Journal of Care for Cripples,* among many other publications, and wrote the foreword to the proceedings of the second Inter-Allied Conference on the After-Care of Disabled Men (1918). Additionally, he served as editor of *Recalled to Life,* later *Reveille,* a Ministry of Pensions journal designed to inform the general public of the welfare of disabled sailors and soldiers. Galsworthy resigned as editor following ministry disenchantment with the public indignation sparked by the publication. Galsworthy's collections *A Sheaf* (1916) and *Another Sheaf* (1917) contain articles he wrote specifically for the WPB.

GALTON, FRANCIS (1822–1911)

English inventor, scientist, geographer, meteorologist, eugenicist

Francis Galton, inventor, scientist, explorer, and developer of eugenics, was born near Birmingham, England, on February 16, 1822. He entered medical school at King's College, London, in 1839 but subsequently left, in part owing to the urgings of his second cousin, Charles Darwin. Galton then entered Trinity College, Cambridge, to finish his medical degree; he graduated in 1844.

Inspired by Darwin's *Origin of Species,* Galton believed humankind could improve its physical and mental health through selective breeding, which he termed *eugenics.* Galton spent much of his later life conducting research on the physical and mental characteristics of Londoners in his anthropometric laboratory. He conducted studies on eminent men, twins, and adopted children to demonstrate the heritability of mental characteristics. Galton developed the idea for intelligence tests and the statistical methods of correlation and regression, which were used to verify the strength of heritable relationships.

Galton's eugenics ideas inspired many countries, including the United States, France, Sweden, and Germany to adopt racial hygiene movements, immigration restrictions, and forced sterilization laws. These activities resulted in the castration, vasectomy, salpingectomy (the tying of the fallopian tubes), and deaths of numerous individuals from diverse racial and ethnic backgrounds who suffered from physical and mental disabilities.

GASTROINTESTINAL DISABILITIES

The gut is vital to the process of digestion and the processing of food into metabolic substrates necessary for energy, growth, and survival. In the medical model, functional failure results in disabilities ranging from mild to severe and may even be life threatening. In general, the gut comprises an entrance orifice, the mouth, and a lengthy hollow tube, the intestine; the mouth allows food to be masticated by the teeth and passed on for digestion and absorption in the intestine. The intestine includes first the esophagus (transit tube into the stomach) then the stomach (which secretes acid to kill ingested bacteria and also an enzyme, pepsin, to activate digestion), duodenum, and small bowel (jejunum and ileum), and finally the colon (cecum, right, left, and sigmoid) and rectum, which terminates at the anus for the elimination of feces. Most digestive products are absorbed into the portal venous system and thence metabolized by the liver, from where they enter the general circulation. Fats are absorbed in a similar fashion but conveyed via lymphatics and the thoracic duct directly into the circulation, bypassing the liver. The entire gut is supplied with blood by the celiac, superior, and inferior mesenteric arteries, which in turn give rise to the gastric, hepatic, and pancreatic vessels. Interference with either the arterial supply or venous drainage results in pain, bleeding, ischemia, and even bowel death. Medical evaluation of the gut is by endoscopy (upper or lower), barium studies, computerized axial tomography (CAT scan), and/or angiography; surgical evaluation is undertaken either by open operation (laparotomy) or closed visualization (laparoscopy)

Infection of the stomach with *H. Pylori* (bacteria) results in gastritis and peptic ulceration, although this can also be produced by excess acid production or agents such as alcohol and aspirin. Inflammation of the esophagus (esophagitis is caused by acid reflux) results in substantial pain and even difficulty in swallowing. Inflammation and ulcers of the esophagus, stomach, or duodenum may all result in bleeding, perforation, or stricture, with results ranging from discomfort to incapacitation and even death. The esophagus may also perforate after vomiting or during the medical procedure endoscopy. Inflammation of the small bowel (Crohn's disease) and colon (ulcerative colitis) is generically referred to as *inflammatory bowel disease;* its sequelae include bleeding, ulceration, and perforation, with symptoms ranging from pain and diarrhea to death. The cecum has a congenital diverticulum (the appendix) that often becomes infected (appendicitis) and requires surgical removal. The sigmoid colon with age develops other diverticuli that may become inflamed, bleed, or perforate, requiring either antibiotics or surgical therapy for treatment. The anus is commonly the site of dilated venous channels (hemorrhoids) that are problematic in terms of pain, prolapse, and bleeding. They may be removed by banding or surgical resection.

Cancers of the hollow viscera usually cause bleeding and block the lumen, resulting in obstruction and death if surgery is not undertaken to relieve the problem. They are most common in the colon, stomach, and esophagus but are rare in the small bowel. Surgical resection alone may not be adequate, as the tumors may spread either locally, to the liver, or elsewhere.

The accessory digestive organs, the pancreas and liver, drain their secretions (pancreatic juice and bile, respectively) into the duodenum via ducts, thus providing digestive enzymes and bile salts to facilitate absorption of carbohydrates, fats, and amino acids in the small bowel. The pancreas, in addition, secretes a hormone, insulin, into the blood from the islets of Langerhans that is necessary for glucose homeostasis. In certain conditions (chronic pancreatitis and islet cell dysfunction) lack of insulin secretion results in diabetes mellitus. Acute pancreatitis is usually due to alcohol or gallstones and causes an often uncontrollable inflammation of the pancreas that may result in death. Tumors of the pancreas are very malignant, present late, and even if removed usually lead to early death, although tumors of the endocrine pancreas are in general far more benign. The liver is susceptible to damage by viruses (hepatitis) and by alcohol and may become cirrhotic (fibrosed) leading to malfunction, jaundice (a yellow coloration of the skin and eyes), and the accumulation of fluid in the abdominal cavity (ascites). Bile is stored in the gallbladder before secretion during digestion, and gallstones often form, causing inflammation (cholycystitis) or even blockage of the bile duct and jaundice. Tumors of the liver are generally highly malignant and despite surgery are usually incurable.

In general, the organs of the gastrointestinal system are crucial to vital functions. Impairment of those functions leads to a variety of disabilities, as noted above, and their consequent handicaps under World Health Organization definitions. While many therapies exist, an enormous amount of work remains to be done through the collaboration of researchers, clinicians, and people with these impairments to improve their quality of life.

GENDER

Globally, persons with disabilities have historically experienced stigmatization and discrimination that continues to the present day. Evidence suggests that society views and stigmatizes persons with disabilities as second-class citizens, thus placing this group at risk for isolation beyond what may be caused by the disability itself. Among the many social divisions ascribed to individuals in a society is that of gender. It has been suggested that gender may play a role in the disenfranchisement that persons with disabilities experience in everyday life. Men with disabilities are often thought to be less masculine and weaker than nondisabled men. Likewise, disabled women are viewed as being less feminine and weaker than nondisabled women. It is important to view the role of gender in disability from both of these dichotomies (disabled/nondisabled and men/women) because evidence suggests that women with disabilities are at increased risk for poor health and social outcomes that go beyond placing them in "double jeopardy" as a result of sexism and disability bias.

Gender is often regarded as synonymous with sex differentiation, which posits that biologically and physiologically there are only two sexes, male and female. According to the World Health Organization, *sex* refers to the biological and physiological characteristics of male and female animals: genitalia, reproductive organs, chromosomal complement, and hormonal environment. However, transsexual individuals and those born with congenital anomalies such as ambiguous sex organs suggest that categorization of individuals by sex is not clearly differentiated. A broader interpretation of gender suggests that it is a culturally bound interpretation of biological differences. Again according to the World Health Organization, *gender* refers to the socially constructed roles, rights, responsibilities, possibilities, and limitations that, in a given society, are assigned to men and women. In sum, *gender* refers to what it means to be considered "masculine" and "feminine" in a given time and place. In this context, *gender* refers to a set of societal norms, roles, and behaviors that can be ascribed to individuals. For example, men are viewed as being more powerful than women and as exhibiting masculine traits, such as dominance and competitiveness, whereas women are viewed as exhibiting feminine traits, such as passiveness and nurturing. However, persons who are gay or lesbian, bisexual or transsexual provide evidence to suggest that the norms, roles, and behaviors associated with a particular gender cannot be universally applied. It is useful to consider both sex and gender concepts when addressing health and disability as a practice generally referred to as *gender awareness* or *consciousness.*

DISABILITY FRAMEWORK

Several conceptual frameworks related to the disabling process exist. Two of the most widely used disability taxonomies, those developed by Nagi (1969) and Wood (1975), suggest that there is both an individual role performance component and a social role performance component in the disabling process. In both the Nagi and Wood taxonomies, the "impairment" stage involves abnormality or loss of structure or function at the anatomical, physiological, mental, or emotional level of the individual. Such change requires medical intervention. As end points in the disabling process, Nagi views disability as limitation in the performance of socially defined roles within the larger societal environment. Similarly, Wood suggests that a handicap is a disadvantage that limits or prevents a normal role from being fulfilled. These taxonomies' "disability" and "handicap" stages both involve the notion of performance in a sociocultural context.

These distinctions are important because they parallel the two major sets of understandings of how persons with disabilities are viewed and stigmatized by society. When viewed as deviating from the "normal-bodied" norm, persons with disabilities become medicalized. When viewed as deviating from the "able-bodied" norm, persons with disabilities become second-class members of society.

In the social model of disability, disability is viewed as the discrimination against persons with disabilities that result from mainstream society's orientation toward "able-bodiedness." In this view, disability is a socially constructed phenomenon and those with disabilities find themselves socially oppressed. This is in contrast to more individually derived models in which those with disabilities must learn to cope and accept their status as having the individual and personal burden of disabilities that society views negatively.

The social model argues that two primary components reinforce the notion of disability as a societal negative: medicalization of disability and socioeconomic discrimination. Medicalization of disability can be seen as the ways in which the medical profession claims control of defining disability. Socioeconomic discrimination takes a variety of forms, including discrimination in employment and the strong relationship between poverty and disability. Ample evidence suggests that persons with disabilities worldwide experience multiple disparities in terms of social, economic, and health status compared with those who are not disabled. Specifically, these disparities are exhibited as greater rates of isolation and mental health impairments, higher rates of poverty and unemployment, and increased risk for premature mortality and morbidity.

THE GLOBAL BURDEN OF DISABILITY

According to the 1990 Global Burden of Disease project, a worldwide collaboration of researchers sponsored by WHO and the World Bank and based at the Harvard School of Public Health, several patterns may be seen in the global burden of disability:

- Disability plays a major role in influencing the overall health status of a population.
- The leading causes of death are substantially different from the leading causes of disability.
- Worldwide, almost half (49.4 percent) of all disability due to disease or injury occurs in the young adult age group (15–44 years), one-fifth (18.3 percent) occurs in the early childhood age group (0–4 years), and less than one-tenth (9.3 percent) of the disability burden is due to the incidence of disease or injury.
- The burden of psychiatric conditions has been underestimated.
- Of the 10 leading causes of disability (measured as years lived with a disability) 5 are psychiatric conditions: unipolar major depression, alcohol use, bipolar disorder, schizophrenia, and obsessive-compulsive disorder.
- There are differences by gender with regard to the leading causes of disability due to disease and injury.

Table 1 illustrates how the prevalence of disability differs by gender. The primary indicator used to analyze the burden of disease and injury by cause is years lived with disability (YLD). The 10 leading causes of

SOURCE: Adapted from Murray and Lopez (1996).

worldwide YLD account for nearly four-tenths (39.9 percent) of all YLD. As noted above, of these 10 causes, 5 are related to neuropsychiatric conditions (unipolar major depression, alcohol use, bipolar disorder, schizophrenia, and obsessive-compulsive disorder). Unipolar major depression accounts for 11 percent of all YLD worldwide. The other leading causes of YLD include anemia, falls, osteoarthritis, and chronic obstructive pulmonary disease (COPD).

When comparisons are made across gender, differences are also noted in YLD rank ordering and cause. For men, alcohol use (rank 2) and road traffic accidents (rank 9) are among the 10 leading causes of YLD worldwide. For women, anemia (rank 2) and chlamydia (rank 8) are leading causes of YLD globally. There are also differences in the rank ordering of the 10 leading causes of YLD by gender.

WOMEN AND DISABILITY

Most of the literature on gender and disability does not differentiate between women and men. Rather, the focus is on those with disability compared with those without disability. This is due, in part, to the societal stigma attached to those with disability as being "abnormal." This deviance from the norm has been the focus of most work in disability studies, and gender concerns have not been well investigated. Other barriers include social issues such as the feminization of poverty, abuse, violence, and sexual and reproductive rights. However, in recent years research examining the impact of gender on persons with disabilities has pointed to a relative decrease in status of women with disabilities compared with men with disabilities. Some examples:

- Disabled women are poorer than disabled men and are often heads of households.
- Disabled women have lower incomes than disabled men.
- Disabled women are at greater risk of sexual abuse than are nondisabled women.
- Women with disabilities are viewed as "asexual."
- Women with disabilities receive less education than do either nondisabled women or men with disabilities.
- Most disabled students are educated in segregation from students of the opposite sex.
- Women with disabilities have less access to "rehabilitation" services than do men with disabilities.
- There are differences between men with disabilities and women with disabilities in the rates and degrees of disability following heart attacks and strokes.

An estimated 300 million women and girls are disabled worldwide. A majority of these live in resource-poor or developing countries. Given that disability is a dynamic process, changes in gender differences among persons with disabilities can and will occur with increasing worldwide focus on women's rights. As a consequence, cultural taboos may lessen and more information will likely emerge about the disabilities resulting from such practices as female genital mutilation and domestic violence.

Although men and women with disabilities share many similarities, the literature suggests that women with disabilities are at a double disadvantage. This is manifested in a variety of ways, including disabled women's lower levels of participation in societal activities and lower levels of self-concept. In addition, the sociocultural aspects of being a disabled woman take the form of a variety of stigmas, including sexism and ableism.

Societal Participation

Compared with men with disabilities, women with disabilities are more likely to be isolated from general societal participation, including social relationships, education, and employment. This could be due to the general stigma society places on persons with disabilities. With regard to social relationships, compared with disabled and nondisabled men and nondisabled women, women with disabilities are more likely to remain single and, of those who marry, more likely to be divorced or separated. Similarly, women with disabilities are less likely to have children and to have significant relationships. These factors may result in forms of social isolation that may contribute to poorer general health among women with disabilities. Isolation may also be increased by the general lack of mobility due to disability.

With regard to education, women with disabilities are less likely to graduate from high school or to attend college for some period of time. In addition to the amount of education, differences may also exist in the content of the education received by women with disabilities. Comparison of employment rates between women with disabilities and other groups indicates that disabled women have lower rates of labor force participation, lower rates of full-time employment, and lower wage earnings.

Self-Concept

Women with disabilities generally have lower self-concepts than do men with disabilities. In particular, such women often feel the oppression of being disabled, the feeling that they cannot and should not engage in certain activities, and this is reflected in lower self-images and low levels of self-esteem. Such a poor self-concept may come from the woman's family members, who may place guilt on the disabled member as causing inconvenience or, conversely, may have an overprotective attitude toward the disabled woman.

Sociocultural Aspects

The sociocultural aspects of being a woman with a disability include stigma and discrimination. *Sexism* refers to the devalued status of women in comparison with men in society generally. Women are seen as childlike, passive, and dependent. Women with disabilities are often perceived as not being able to fulfill the variety of roles society places on women in general, such as mother, wife, and sexual partner. Likewise, society often views these women as not being physically attractive and thus as being relatively passive, nonsociable, uninteresting, and unintelligent. Needless to say, women of color who have disabilities can experience a third layer of bias. Clearly, women with disabilities bear a disproportionate share of stigma and discrimination from both internal (self) and external (society) perspectives.

The current global approach to addressing disability includes efforts not only to reduce the incidence and prevalence of disability but also to address the personal, economic, and social consequences of disability and thereby improve the quality of life for disabled individuals, their families, and society. Whatever specific strategies are developed in the future to address the issues related to disability worldwide, the process will be much enhanced by attention to the multiple influences that gender has on persons with disabilities.

GENDER, INTERNATIONAL

THE MEANING OF GENDER

> Gender is the structure of social relations that centres on the reproductive arena, and the sets of practices (governed by this structure) that bring reproductive distinctions between bodies into social processes. (Connell 2002:10)

Why do we need to understand about gender in disability studies? What is the relationship between gender and disability? How are men's and women's experiences of disability similar or different? Indeed, are gender and disability such different concepts given that women have been seen as deformed men and disability is often associated with femininity? In order to address these questions, we must examine the meaning of gender.

Gender is closely connected to sex, although there are different ideas about how sex is usually understood as relating to the biological and physiological body. The term *gender* is often understood to refer to the cultural interpretation of sexed bodies, embedded in the whole apparatus of a society's roles and norms. Thus, a sex/gender binary is set up parallel to that of nature/culture. Gender, as a relationship between sexes in societies, is usually seen as operating hierarchically, with men being more powerful and dominant, and women being less powerful and weaker. These power relations produce stereotypes of masculinity and femininity—traits and behavior that are expected of men and women (see further below). Role expectations of women as nurturers, men as breadwinners, and so on define approved ways to perform gender.

While the simple binary has been persuasive, insofar as there are two sexes involved in biological reproduction, we now know that there are more than two sexes—including transsexuals and people with congenitally ambiguous sex organs—and many ways of performing gender. Far from being a simple dichotomy, gender turns out to be a complicated and evolving realm of meaning making among people with sexed bodies. Gay, lesbian, and transgender individuals suggest the fluidity of these performances and their capacity to change over time and across societies.

Many of these questions go to the heart of understanding disability. The simple binaries have become complicated as we have learned more about the social construction of bodies and the biological influences on human behavior. Nature and culture, sex and gender, have their reflections (although not mirror images) in the distinctions between impairment and disability. The term *impairment* has been used to describe functional limitations accruing to an individual as a consequence of embodied differences, whereas *disability* has been used to refer to a system of social relations that limit an individual in the course of daily life. This simple binary, while heuristically useful, masks the interpenetration of the social and the biological. Gendered analysis of disability has been particularly valuable in demonstrating the web of social and biological factors that disable people, not just women. Gendered analyses address the processes through which both femininity and masculinity are constituted and the implications of these processes for people with impairments, thereby moving beyond the particular focus of feminism on the experiences of women.

THE GENDERED EXPERIENCE OF DISABILITY

Disabled people have often been represented as *without gender,* as *asexual* creatures, as freaks of nature, monstrous, the "Other" to the social norm. In this way it may be assumed that for disabled people gender has little bearing. Yet the image of disability may be intensified by gender—for women a sense of intensified passivity and helplessness, for men a corrupted masculinity generated by enforced dependence. Moreover, these images have real consequences in terms of education, employment, living arrangements, and personal relationships, victimization and abuse that then in turn reinforce the images in the public sphere. The gendered experience of disability reveals sustained patterns of difference between men and women. For people with disabilities gendering is conditional. Age of onset combined with the type of impairment leads to gender expectations.

Gendered studies of disability in Western industrialized nations reveal the following patterns of public and private dimensions. In the public arena:

- More women than men are classified as disabled, particularly as aging populations mean that larger proportions of the elderly are women with impairments.
- Disabled people are much more likely than nondisabled to live in poverty, and disabled women are likely to be poorer than disabled men, especially in developing countries, where women are often heads of households.
- Younger disabled women achieve lower educational outcomes than do men.
- Disabled women are less likely to be in the paid workforce than either men with disabilities or nondisabled women, and in general have lower incomes from employment.
- Women are less likely than men to have access to rehabilitation and to employment outcomes when they do receive rehabilitation.
- The age distribution for disabled women is different from that for disabled men (older versus younger).
- The types of impairments are different for women and men, with women more likely to experience degenerative conditions and men more likely to experience injury-related events.
- Disabled women are more likely than disabled men to experience public spaces as intimidating and dangerous.

In the private and familial arena, disabled women compare with disabled men in the following ways:

- Disabled women are more likely to be living on their own or in their parental families.
- Disabled women are more likely to be divorced and less likely to marry.
- Disabled women are more likely to face medical interventions to control their fertility.
- Disabled women are more likely to experience sexual violence in relationships and in institutions.

- Disabled women experience more extreme social categorization, being more likely to be seen either as hypersexual and uncontrollable or as desexualized and inert.

Moreover, in the developing world, gender patterns in relation to disability indicate the following:

- Poverty hits women and girls harder due to patriarchal property ownership structures.
- Aid is less likely to reach women and girls who are less able to compete in situations of scarcity.
- Disabled women are more vulnerable to domestic violence.
- Disabled girls are likely to find their access to education even more limited than that experienced by girls in general.
- Women disabled by war have few resources with which to survive.
- Disabled women who are sexually abused are likely to have few if any social supports or options.
- Disabled women are less likely to be accepted as refugees by industrially advanced countries (e.g., Australia prohibits the immigration of people with disabilities).

Gender has been widely used within the humanities and social sciences as both a means to categorize differences and an analytic concept to explain differences. In both the humanities and the social sciences, feminist disability studies have emerged partly as a result of attempts to explain gendered experience of disability and partly as a challenge to contemporary feminist theory on gender that fails to take account of disability, such as the work of Judith Butler.

THE PSYCHE AND GENDER

Disability has been used as a powerful metaphor in psychology, particularly as a means to assign to women the status of incomplete or deformed men. In addition, gender stereotypes have been used to characterize disabled people, particularly men, who have been presented as feminized and lacking masculine traits. These approaches have confused the conceptual difference between disability and gender.

Gendered analyses of disability have tried to move beyond these metaphors, to create a disciplined account of the impact on the gendered psyche of disabling social relations. Here four elements are presented: the development of the "normal" individual, the impact of disabling events, support for the survival of the disabled psyche, and strategies for normalization and social role valorization.

Psychological models of individual development are increasingly taking account of gender formation. As the psyche takes form, it develops a sense of self through interaction with others, one result of which is the defining of relations through the lens of gender. This process of identity formation contains a deeply embedded set of responses geared to the hierarchies of value in the able-bodied world. The identities that coalesce are thus both gendered and embodied, affected by the hormonal changes of growth and the social influences of role expectations, peer groups, family, and the wider society. For people with impairments, the reading of them from significant others and the wider society combines with the gendered nature of relations to differentiate them from the "normal" world. For instance, disabled girls may have their desires to be mothers supported by their gender role expectations but simultaneously denied by their disability status.

For people without impairments who experience disabling events later in life, their suddenly changed status creates major conflicts in their expectations and self-images that are reinforced by public perceptions of them as disabled. For instance, women may no longer be able to mother and thus may have their children taken from them in custody battles. Or men may have their masculinity denied and thus face struggles to sustain an affirmed identity. Whatever the situation, in such cases gender is centrally implicated.

Psychologists and social workers can provide support to people with impairments who are seeking to survive their disabilities. Approaches include adjustment and adaptation as key mechanisms of "coping" used in such support; these are themselves gender saturated. Assumptions of appropriate behavior, suitable outcomes, and role allocation reflect professional stereotypes and models, and are often dominated by medical model assumptions about the gendered body.

There is ample evidence that women with disabilities experience major psychosocial problems that remain largely neglected, including depression, stress, lowered self-esteem, and social isolation. Evidence also suggests that disabled women tend to be directed toward home-based activities, whereas disabled men are likely to be supported into more public and outward-looking opportunities.

People often recognize that disability can undermine masculinity, so many therapies assert traditional masculine identities—for example, encouraging disabled men to play wheelchair rugby. On those occasions when identity assertion occurs for women, it is likely to be about hyperfeminine self-presentation, such as makeup and grooming sessions.

With deinstitutionalization, there has been a growing emphasis on the social education of people with intellectual and developmental disabilities to support their living in the community. The primary orientation, *social role valorization* (SRV), uses a training approach to modify the behavior of people with impairments and thus reduce the disabling impact on them of social stereotypes. SRV adopts a "conservatism corollary" in its individual program plans, seeking to minimize the dissonance created for "normal" people by the presence in their midst of people with significant impairments and high support needs. This means, unfortunately, that training seeks to impose more traditional gender roles, and disabled people are drawn to perform these roles in order to reduce their visibility as stigmatized others.

While much of the professional practice concerned with the link between gender and disability occurs together within psychologically inflected professions, there is a wider social science involvement in the analysis of these questions.

CULTURE AND MEANING

Stereotypes are artifacts of culture that can be understood only through an exploration of their relations to each other in the cultural system. Gender stereotypes interact with disability stereotypes to constitute a deep matrix of gendered disability in every culture, developed within specific historical contexts and affecting those contexts over time. While language is the most analyzed site for the examination of both gender and disability, they interact in many other cultural locations as well—such as in cinema, television, fiction, clothing, body language, and gesture. Thus, cultures sustain the social relations of gendered disability in constant reiterations of stereotypes and expectations.

Put simply, disabled men are expected to behave and express their being differently than disabled women in all cultures, although the manner of these expressions is culturally specific. It is likely, however, that the hierarchies of power—usually male over female, able-bodied over disabled—will set the cultural parameters. In most cultures, too, the subordinate groups are not passive, but have developed strategies of resistance and self-affirmation.

Ironically, the interaction of stereotypes can generate resistance that consists of an embracing of stereotypes—for example, disabled women may be perceived as inappropriate mothers and only have status as receivers of care by others, so their resistance may consist of asserting a desire for a traditional female caregiver role in relation to their own children. Disabled men who are not able to behave in stereotypically competitive masculine ways may adopt a variety of strategies to cope with the stigma they experience from others, such as redefining masculinity as financial autonomy rather than physical prowess, building physical strength in areas of physical capacity (the "supercrip" phenomenon), or creating alternative masculine identities that stress personhood rather than gender roles.

Disabled men and women narrate their experiences in significantly gendered terms, with both the content and styles reflecting the ways in which gender expectations are modulated by disability status. Illness narratives are mobilized to make sense of the experiences, which are in each case centered on the impact on sexual identity, sexual relationships, and gender opportunities. Riessman-Kohler (2003), who has examined masculinity and multiple sclerosis, points to the breakdown of traditional marriage relationships when partners cannot cope with the disease state. She reflects on the importance of moving beyond the analytic binary of male/female sexual identities. She also reveals the analytic binary of able-bodied/disabled, which she argues can force descriptions of experiences into either/or categories rather than allow sensitivity to a complex range of responses and attitudes. When some men find themselves unable to perform masculine roles (including employment) and resent their decreasing capacity to be independent, self-sufficient, and self-determining, they explore their sexuality and widen their definition of gender identity to include more feminine and bisexual components.

THE SOCIAL REALM

Sociological accounts of gender and disability stress the systemic nature of the social order and its reinforcement of powerful social institutions and their capacity to enact and impose definitions and allocate resources. For disability the most central institutions remain those associated with the medical profession, rehabilitation, and social support. Many other institutions also reproduce patterns of gendered discrimination—such as education, employment, and transport. One of the most potent patterns of discrimination is found in the area of access to and use of public space.

Both gender and disability have traditionally been seen as products of biology. Gender as a result of biology has been thought to determine all manner of social behaviors on the part of men and women. In a similar way, disability as biology has been seen as determining disabled people's choices and behaviors. In the 1970s, feminists attempted to differentiate gender from sex (the social from the biological) to counter the argument that women are naturally inferior and weak. So, too, disability theorists have attempted to separate disability from impairment (the social from the biological).

But it is no longer adequate to separate the social from the biological in this dichotomous way. The social relations of gender and the social relations of disability are now viewed as much more complex and nuanced. The social model of disability has demonstrated that wider power relations (e.g., class relations in capitalist societies) significantly affect the pattern of disability disadvantage, making disability survival into a lottery critically affected by individuals' income and other material resources. Because the model draws on political economy, it emphasizes political and economic processes that generate disabling environments.

For instance, scholars who have analyzed the medical establishment's uses of individualizing and victim-focused ideologies and technologies have argued that disability is devalued because disabled individuals have little economic worth. Rehabilitation is thus geared to prospective productivity. But this ignores the differences between men and women in their economic situations. In order to understand the differential outcomes for men and women, a gendered model that incorporates patriarchal structures into class structures is absolutely crucial.

Lorber (2000) has shown that while social action around disability issues has benefited both women and men, women with disabilities are less likely than men with disabilities to be economically self-supporting or to have spouses to care for them. These patterns, together with conventional norms of femininity, have hindered disabled women's quest for independence. Women thus confront major obstacles not only in relation to overcoming disabling environments, but also in achieving outcomes equal to those of men who are similarly disabled.

GENE THERAPY

Gene therapy is the treatment or prevention of disease through the alteration (through addition or deletion) of genetic material in human cells, tissues, or organs. The term *gene therapy* is also used to describe the manipulation of genetic information already within the cells for the same purpose. However, at present most of the available technology relates to the addition of new genetic information, and many researchers prefer to use the term *gene transfer* rather than *gene therapy* to reflect the fact that the purpose of this work is not always therapeutic. Throughout this entry, however, the term *gene therapy* is used in reference to processes aimed at both the treatment and the prevention of disease.

There are two types of gene therapy: somatic and germ line. Somatic gene therapy modifies any cells except reproductive cells (i.e., sperm and ova). The aim of this modification is to treat or prevent disease in the individual. Many such treatments are temporary, as the genetic material is not permanently integrated into the cell. Germ line gene therapy modifies reproductive or "germ" cells. This includes modification of sperm or ova and altering the DNA in a fertilized egg. The aim of this treatment is to affect the individual who will develop from the reproductive cells or embryo, together with that individual's descendants. However, germ line modifications may also be carried out as part of the therapy for an existing subject, the modification of the germ cells being an inevitable part of the genetic modification overall.

Various possible approaches to gene therapy have been identified. Where a faulty gene exists, a normal gene could be introduced. Alternatively, the faulty gene could be repaired. Another possibility would be to introduce a gene to "switch off" the faulty gene. Gene therapy has also been seen as a way to treat disease rather than to correct inherited disorders. For example, genes that generate specific toxins could be introduced into diseased cells (such as cancer cells) to kill them. It might be possible to engineer resistance to both cancer and HIV/AIDS through gene therapy. If so, such modifications would be both therapeutic and enhancing, since humans are not naturally resistant to cancer or to AIDS. If such modifications affect the germ line, they would also constitute permanent enhancements.

Gene therapy first entered clinical trials (i.e., trials in humans) in the early 1990s. As of January 2004, according to the *Journal of Gene Medicine* clinical trial database, 636 gene therapy clinical trials had either been completed or were ongoing or pending. These trials involve 3,496 patients, the majority of whom are in the United States. The majority have been or are being directed at the treatment of cancer (63 percent) as well as genetic conditions (12 percent) and vascular conditions (8 percent).

ISSUES

Gene therapy raises several social, ethical, and legal issues, including those discussed below.

Playing God

Some objections to gene therapy are based on the view that humans should not "play God" and interfere in the natural order. In response, it may be argued that we already seek to frustrate the course of nature through medicine, whether by using treatments such as antibiotics or preventive measures such as vaccination. If we accept these practices, we cannot consider it wrong to interfere with nature. Viruses, bacteria, and genetic mutations are perfectly natural, after all.

Writing from a theological standpoint, Ronald Cole-Turner (1993) has argued that genetic engineering may be justified where it is consistent with the purposes of God as creator.

Safety

Some critics are particularly concerned about the safety of germ line gene therapy, because any harm caused by this treatment could be passed to successive generations. However, given that any benefits will also be passed on indefinitely, if the probability of the magnitude of possible harms can be brought to an acceptable level, germ line therapy would be both hugely beneficial and highly cost-effective. Concerns about safety (together with other ethical concerns) have been reflected in public policy. In the United Kingdom, the Gene Therapy Advisory Council, which scrutinizes proposals for gene therapy research, will not yet consider proposals for germ line gene therapy research. Similarly, the Recombinant DNA Advisory Committee, which scrutinizes research proposals seeking federal funding in the United States, has stated that it "will not at present entertain proposals for germ line alterations."

Although the successful use of somatic gene therapy has been reported, trials have also shown associated risks. In 1999, a U.S. teenager, Jesse Gelsinger, died after taking part in a trial. In 2000, a group of French researchers announced that they had successfully used gene therapy to treat two infants suffering from severe combined immune deficiency (X-SCID). The researchers treated 11 patients, 2 of whom are reported to have developed a leukemia-like illness. This highlights one of the difficulties foreseen in relation to somatic gene therapy. Vectors may be used to transport correctly functioning genes into the patient's cells. These vectors, which are often viruses, are inserted either through placement into cells that have been taken out of the patient's body *(ex vivo)* or through placement directly into the body *(in vivo).* However, this process may cause mutations that can lead to diseases such as leukemia. Although the viruses are "disabled" so that they cannot replicate, the patient may suffer an immune response, as was the likely cause of Jesse Gelsinger's death. Concern has also been expressed that there is a risk that even the use of somatic gene therapy may affect germ cells. Nevertheless, where gene therapy could be lifesaving or remove oppressively burdensome conditions, and where the alternative is death or severe disability, many would argue that it is ethically justified in spite of such risks, for the risks are to be borne by the subject who would suffer the risks of denial of therapy.

The Introduction of Eugenics?

In addition to safety, another concern has been whether the use of gene therapy is a form of eugenics. Although one can scarcely use the word *eugenics* without invoking events that took place in Europe during the twentieth century, the concept is nonetheless profoundly ambiguous, admitting of both benign and malign interpretations.

Adopting the definition of the adjective *eugenic* as "pertaining or adapted to the production of fine offspring," John Harris (1993:178) has argued that gene therapy is eugenic, but that this in itself is not morally significant. We can consider a scenario in which a woman has had five of her eggs fertilized in vitro and, following usual medical practice, then has two or three implanted. If preimplantation screening reveals that two of the embryos possess disabilities, would it be right to implant these two embryos rather than the others? If we consider it would be wrong to implant the "disabled" embryos, this suggests that disability is something we do not desire and have good reason to reject. It suggests that disability can be identified as "a physical or mental condition we have a strong rational preference not to be in" and a condition that is "harmed" (Harris 1993:180). This approach avoids the task of defining disability by reference to a "normal" human being. Furthermore, it provides an explanation of disability that can be applied to the "potentially self-conscious" (Harris 1993:181) such as embryos and also the temporarily unconscious. It is not based on the subjective viewpoint of the individual or of the future individual concerned.

Thus, according to this approach, gene therapy is eugenic, but it is the treatment parents should adopt when it will avoid disability for their child (on the assumption that the procedure is safe). However, although parents may harm their child by not preventing avoidable disability, this approach does not state that parents should be compelled to adopt such treatment. Furthermore, to argue that parents should seek to avoid harming their children is not to discriminate against the disabled.

Some observers, such as Solveig Magnus Reindal (2000), have challenged this view of disability. Reindal refers to the distinction between impairment and disability, noting that the fact that an individual has an impairment does not necessarily mean he or she is disabled. Reindal propounds a "social model" of disability, which does not deny the fact that impairments exist but asserts that whether or not impairment leads to disablement depends on numerous other factors, such as the individual's view of the situation, social norms, and societal attitudes. Reindal is critical of "medical models" of disability such as that espoused by Harris. By focusing solely on impairment, Reindal argues, those who are unimpaired are led to make judgments about whether an impaired life is worth living. With reference to gene therapy, she holds that if a medical model is used in debate, those who are disabled will view such discussions as "eugenics in disguise." Such "biological determinist understandings" were, she argues, the foundation of sterilization laws passed in the 1930s. In Bill Albert's (2003) view, gene therapy not only legitimates the medical model of disability but also raises hope that research will lead to new treatments, which is followed by disappointment when these do not materialize.

Enhancement

Debate has also focused on whether gene therapy should be used to enhance individuals. Some enhancements might mirror the effects of other medical interventions currently in use. For example, if it were possible to use gene therapy to generate antibodies to infections such as HIV, this would be an enhancement similar to that provided by vaccination against diseases such as tetanus.

Eventually it may become possible to enhance, or at least alter, attributes other than health, such as height, behavior, and intelligence. However, it is acknowledged that many traits, even if found to have a genetic basis, are likely to be determined by complex interactions among perhaps many genes together with environmental factors. Gene therapy aimed at modifying such traits, even if it were to become possible, lies many years away. However, debate has focused on where the boundary should be drawn between acceptable and unacceptable enhancement, if indeed such a boundary can be defined. Even if it were generally agreed that an appropriate boundary would lie between "disease" and "disorder," there would remain the issue of how these terms are to be defined.

Individual Choice

Some observers have argued that if it were possible to do so, individuals should be permitted to use gene therapy for enhancements. For example, Jonathan Glover (1984) considers that it would be acceptable for individuals to improve their intellectual functioning even if theirs is currently in the "normal" range. In contrast, LeRoy Walters and Julie Gage Palmer (1997) consider it acceptable to use genetic enhancements to enable functioning within the "normal" range, but see further enhancement as more problematic, particularly given issues surrounding resource allocation (see below).

Parental Choice

Further issues arise in relation to the extent to which parents should be entitled to make enhancement choices on behalf of their children or future children. Walters and Palmer consider the issue of parents choosing intellectual enhancement for their children and express concern that this might present opportunities for a new form of child abuse. However, they accept that it might be appropriate for parents to seek some intellectual enhancement for their children; they note also that boundaries might need to be set to limit parental discretion in this area.

John Robertson (1996) considers this issue from the viewpoint of the principle of procreative liberty. He asserts that as reproductive decisions are so important, society has a sound moral basis for ensuring that these decisions are respected. In particular, he highlights the role of the law in this area. In relation to the selection or control of the characteristics of future offspring, he considers that two questions will need to be addressed. First is the question of whether the characteristic is central to the decision to procreate; only if it is should the law uphold procreative liberty. Second, the extent of any harms that would flow from a policy allowing selection must be considered. In the context of the nontherapeutic enhancement of traits such as intelligence, Robertson argues that even if such decisions do not fall within procreative liberty, they might be argued to fall within the parental right to rear the child after birth. As he points out, the law already enables parents to influence their children's development after birth by sending them to tutors, orthodontists, and so on.

A final issue relates to whether parents should be entitled to choose treatments for their children that will affect future generations. An argument frequently made in this regard is that if the technology were to exist to make the alteration in the first place, the technology needed to reverse the process would also likely be available.

Justice

Resource Allocation

It is widely acknowledged that gene therapy technology will initially be very costly. Given that treatments cannot be provided to all those who might want to receive them, this raises long-standing debates concerning issues of justice and political theory. A libertarian approach, as espoused by Robert Nozick (1974), would suggest that access to such treatments should be based on free-market principles. In other words, those who can afford them should be entitled to them (although Nozick does foresee the need for some restrictions). Alternatively, if justice is viewed in terms of equality for all individuals, then access to treatment should be available to all on an equal basis. However, although there is no agreement as to how this principle should be applied in practice, it is clear that it would be unethical to deny therapies to some unless and until they can be provided for all. The development and availability of new and effective therapies cannot wait on agreement as to just principles of distribution.

Benefit

Additional questions relating to justice arise even if we resolve the problems associated with the allocation of treatment. Once such treatments have been allocated, classes of people may develop who are in stronger positions than others in certain respects. For example, individuals who have received therapy to slow down the aging process may be more attractive as employees, given their longer life expectancy.

Changing Humanity

Francis Fukuyama (2002) asserts that developments in biotechnology, such as gene therapy, have the potential to alter human nature and so lead us into a "posthuman" era. He therefore urges the establishment of regulation to ensure that we are not driven by technological progress to abandon values we might wish to protect. In contrast, Gregory Stock (2003) sees the potential to re-create ourselves as an expression of our humanity and argues that this process should be subject to minimal regulation.

Gene therapy is a new technology, and as yet it is unclear to what extent the expectations surrounding it will be fulfilled. It raises many of the same issues that are already under discussion in the larger health care arena, such as how limited resources should be allocated. It also raises specific issues linked to the possibility of affecting future generations and the consequences that might result.

GENETIC COUNSELING

Genetic counseling is a process of communication in which a specially trained professional, often but not always a doctor or nurse, meets with an individual, couple, or family to provide information about a genetic condition that has affected the individual, couple, or family or may do so in the future.

The 1940s saw the establishment of genetic counseling clinics in both the United States and Great Britain. Initially, the purposes of these clinics were to aid in the delivery of eugenics policies and to control population growth among specific ethnic groups. The purpose of the clinical practice of genetic counseling has now changed considerably, and such counseling is available in most developed countries. The focus of modern genetic counseling is to provide people with balanced information and nondirective support so that they can make informed decisions regarding issues related to genetics. The expansion of genetic knowledge and improvement of diagnostic techniques has led to an expansion in the profession since the late 1990s, and professional courses in genetic counseling are taught worldwide.

WHO RECEIVES GENETIC COUNSELING AND WHY?

Genetic counseling should be an integral part of genetic testing at the points of the life cycle discussed below.

During Pregnancy Planning

Couples who are planning pregnancies often seek the assistance of genetic counselors when one or both of the partners themselves, one or more of their existing children, or other family members are already affected by genetic conditions. Members of ethnic communities in which recessive genetic conditions are particularly prevalent also frequently seek genetic counseling during pregnancy planning. The genetic counselor gathers relevant information from the counselees to assess their risk of passing on a particular condition to the next generation. DNA testing (e.g., from a blood sample) is often required for a clear diagnosis.

During Pregnancy

In developed countries, it is now routine for pregnant women, especially those over 35 years old, to be offered some form of genetic testing. Noninvasive screening tests such as ultrasound or serum screening, conducted between 10 and 20 weeks of pregnancy, can provide information about whether the fetus is developing normally or is at increased risk (greater than 1 in 250) of being affected by a chromosomal condition (e.g., Down syndrome) or neural tube defect (e.g., spina bifida). Usually, these tests allow counselors to provide risk estimates, not conclusive results. Diagnostic tests such as amniocentesis or chorionic villus sampling (CVS) are performed after a positive screen result to obtain accurate results for chromosomal conditions such as Down syndrome. However, these tests also carry some risk of miscarriage (approximately 1 percent). Population pregnancy screening can identify only a limited number of common genetic conditions; most genetic conditions are rare and difficult to detect.

If a diagnostic test reveals a positive result (i.e., that the fetus is affected by a genetic condition), the woman must decide whether to terminate the pregnancy or continue with it and give birth to a disabled child. At this point, it is essential that the woman receives unbiased and accurate information about the relevant condition and feels supported in making the right decision for her.

Most women who undergo screening or testing in pregnancy will receive genetic counseling in some form, possibly from a midwife, general practice physician, or obstetrician rather than an individual who specializes in genetic counseling. Such counseling may be cursory and directive, sometimes even eugenic. Both before and after testing, a woman should have access to the services of a trained genetic counselor to ensure that she can make genuinely informed decisions and be confident that she has made the right ones, as terminating a wanted pregnancy can be as distressing as giving birth to a disabled child. Because the screening procedures used today are often noninvasive, and because many times full information on her options is not readily available, a woman may end up drifting into a situation in which she is forced to make a difficult choice about termination, whereas if she had been fully informed up front, she may have declined to embark on the "antenatal testing conveyer belt."

Childhood

Most babies in the developed world undergo genetic screening within the first 72 hours of life, through blood taken from a heel prick (Guthrie test). The blood is screened for a number of genetic conditions for which early detection and intervention can offer increased chances of effective management; these may include cystic fibrosis and phenylketonuria as well as rarer metabolic conditions. Although hospitals seek parental consent prior to taking an infant's blood, no formal genetic counseling is provided unless it is requested or a positive result is found. Frequently new mothers are unaware that the tests are being done, or, if they are aware, give very little consideration to what such tests could disclose.

Families and individuals who are directly affected by genetic conditions may also seek genetic counseling. They may want to gain more information about particular conditions and why those conditions affect them, to explore the specific ways in which genetic conditions affect them, to seek advice about managing their conditions, and/or to meet others who are similarly affected. Many genetic counselors specialize in certain groups of genetic conditions, such as bone dysplasias and metabolic conditions. Such counselors tend to be very familiar with the day-to-day effects of living with particular genetic conditions and can help individuals to find appropriate support groups.

Adulthood

One of the largest growth areas in genetic testing is that of predictive testing—that is, testing aimed at determining whether a person is at risk of developing a late-onset genetic condition (e.g., Huntington's disease, some forms of cancer) or has a genetic predisposition to a common disease (e.g., heart disease). Before individuals begin the predictive testing process, genetic counseling is advisable. Discovering that one is going to develop an incurable late-onset disease such as Huntington's can be highly traumatic. Individuals in affected families may not wish to know their status if there is nothing they can do to avoid their fate. Even when preventive action is possible—for example, mastectomy to minimize the risk of breast cancer—this knowledge itself can be traumatic. Also, some recommended preventive actions may be hard for individuals to comply with (e.g., behavioral or dietary changes). There is evidence that many individuals have difficulty understanding risk percentages: Without the benefit of counseling, some may underestimate their risk; alternatively, some individuals who receive diagnoses of genetic conditions may believe they are facing an unavoidable fate even though preventive action may be effective.

WHAT HAPPENS IN A GENETICS COUNSELING SESSION?

A typical genetics counseling session starts with the professional's ascertaining what it is that the counselee (usually called the *proband*) expects or wants to get out of the session. The professional spends a large proportion of the initial session taking the proband's pedigree, or recording the proband's family tree.

A pedigree usually includes the names, birth dates, ages, and causes of death and brief medical histories of the proband's family members over three or more generations. The pedigree may assist the counselor in calculating the likelihood of the proband's being affected by a genetic condition or passing it on to future generations. A geneticist may also physically examine the proband during the first session. Once all of the relevant information has been collected, the proband, counselors, and anyone else who may be present (e.g., family members, partners, other medical professionals) discuss the implications. This is the time when the proband asks questions and receives explanations from the counselor. Often, a clear diagnosis cannot be given based on the pedigree and a physical examination. In such a case, the counselee may be sent for follow-up diagnostic testing (e.g., blood tests, X-rays, MRI). Following a genetic counseling session, the counselor usually sends the counselee a letter documenting what was discussed during the session, giving details of the relevant genetic condition, and providing information about available support services and how to follow up the session.

WHAT ARE THE ISSUES FROM A DISABILITY PERSPECTIVE?

Many within the disability rights movement view the medical advances being made in genetics as a "return to the eugenic past"; they find the concept of genetic counseling confronting, inappropriate, and part of an eradication process. Societal investment in diagnostic technology and screening programs sends a message that disability is a major problem that should be prevented at all costs. The language of "risk," "abnormality," "burden," and "medical tragedy" is prejudicial to disabled people and ignores the high quality of life that many disabled people achieve. From this perspective, genetic counselors are implementers of eugenic policies, despite their professional rhetoric of supporting individual choice.

For individuals who are affected by genetic conditions, the process of genetic counseling can be a confronting experience. The aim of genetic counseling sessions for disabled persons should be exactly the same as for individuals without disabilities. But disabled persons who choose not to have children with the same conditions as theirs may feel that they are somehow "validating" society's view or belief that their own lives are not valuable or worth living. Deciding whether or not to take the risk of passing on a genetic condition can be challenging to a disabled person's sense of self, raising problematic emotions. A good genetic counselor should be able to provide such a client with accurate, balanced, and understandable information; help the counselee to explore his or her feelings about possible outcomes; and, most important, support the counselee through whatever choice he or she makes.

Since the 1990s, genetic counselors' stated aspiration to provide nondirective counseling has been debated, and some observers have questioned whether nondirective counseling is achievable. They argue that the language in which counselors present risks and the information they provide about disability are bound to influence counselees' decision making. In practice, counselees often look to genetic counselors for direction, asking, in essence, "What would you do in this situation?" Genetic counselors have to be able to support those they counsel whatever they decide; thus counselors need to have a heightened awareness of their own prejudices and moral stands on issues surrounding genetics and, more specifically, disability.

GENETICS

The science of genetics has an increasingly powerful influence on contemporary ideas about the causes of disability and how impairment might be cured or—perhaps more controversially—prevented. It is important to be clear from the outset that "genetics" is no longer restricted to the ways in which characteristics, including impairments and chronic disease, are inherited. With the development of sophisticated molecular techniques, geneticists today are equally interested in uncovering the genetic bases for all the biological processes that keep organisms going and that, if disrupted, can contribute to disease or disability. This entry gives a brief outline of some key genetic concepts and goes on to discuss the relationship between genes and disease, the contribution of the Human Genome Project to genetic knowledge, recent developments in genetic medicine, and some issues in genetics that are of particular relevance to disability.

SOME KEY GENETIC CONCEPTS

As the study of the transmission of characteristics between generations, genetics has existed for more than 100 years. The early history of the discipline was dominated by attempts to understand *patterns* of inheritance while at the same time trying to identify the *mechanism* through which characteristics are transmitted. It was not until the 1940s that the chemical deoxyribonucleic acid (DNA) was conclusively shown to play a key role in heredity, and not until 1953 that a plausible three-dimensional structure for the DNA molecule was proposed. As Francis Crick and James Watson noted in the paper publishing this result, the structure of DNA also gave clues to genetic mechanisms. Over the next few decades, enormous effort was devoted to unraveling the fundamentals of gene action.

According to the simplest model of gene action (and it should be noted that even among biologists there is disagreement over the details and scope of models of gene action), genes give rise to proteins in a series of steps. The DNA sequence of a gene specifies ("codes for") the production of a related type of molecule, messenger RNA, which in turn specifies the sequence of constituent amino acids in a protein. Proteins play a number of diverse and crucial roles in the development and maintenance of an organism, forming structural components (e.g., the constituents of muscle), enzymes that regulate biochemical pathways, and components of the hormonal signaling systems of the body.

Although we often speak casually of a "gene for" a disease, as in the "cystic fibrosis gene" or the "Huntington's disease gene," this is a shorthand that can be misleading. Genes are not *there* to cause disorders; rather, disorders arise when changes (or mutations) in genes alter the production of proteins required by the organism. So the "cystic fibrosis gene" encodes a protein that transports ions across cell membranes. It is mutant forms of this protein that do not perform their transport function adequately and result in the condition called cystic fibrosis. Similarly, the commonest form of hereditary hearing impairment in European and American populations results from mutations in the cx26 gene, the unmutated form of which specifies the production of a gap junction protein, connexin 26.

GENETIC DISORDERS

Single-gene, or *monogenic,* disorders are caused by mutations in the DNA sequence of just one gene. More than 6,000 monogenic disorders have been identified, and these affect approximately 1 in 200 live births. They include some of the best known and most studied genetic disorders, such as cystic fibrosis (CF), sickle-cell anemia, achondroplasia, and Huntington's disease (HD).

Monogenic disorders may show *dominant*, *recessive,* or *sex-linked* inheritance. People who inherit only one copy of a mutated gene are described as *heterozygous* for that gene, whereas those with two copies are *homozygous.* Where a condition is dominantly inherited (e.g., achondroplasia, HD), a person need inherit only one copy of the mutated gene in order for the condition to be apparent (that is, for the *genotype,* or genetic constitution, to be expressed in the *phenotype*). For recessive disorders, inheritance of two copies—that is, one from each parent—is necessary; a heterozygote will usually be phenotypically normal but be a carrier, and so can still transmit the mutated gene to his or her children. Probably the best known example of a recessive genetic disease is CF. In sex-linked disorders, the abnormal gene is on one or other of the so-called sex chromosomes, and this often means the condition occurs only in males. Sex-linked conditions include fragile X syndrome and Duchenne muscular dystrophy.

Geneticists and genetic counselors often show what seems to be a disproportionate interest in vanishingly rare monogenic disorders. This is because these disorders are relatively easy to diagnose and usually have straightforward inheritance patterns, so the inheritance may have been well characterized by classical genetics even before the relevant gene was identified. Nevertheless, it is now thought that most conditions of medical interest are *polygenic,* with numerous genes making greater or lesser contributions to the phenotype, alongside environmental factors such as diet and exposure to pollutants. Tracking the inheritance patterns of these disorders is difficult unless the gene loci have already been identified. Examples of conditions for which some of the genes involved have been tentatively identified include breast cancer, heart disease, asthma, and diabetes.

Mitochondrial disorders are much rarer genetic conditions caused by mutations in the DNA carried by mitochondria, small organelles that are found in cells and that carry their own tiny pieces of DNA.

In addition to genetic conditions there are *chromosome disorders*. These are larger-scale abnormalities in which entire chromosomes may be lost or duplicated, or show major structural changes (such as translocations). Probably the best known chromosomal disorder is trisomy 21, or Down syndrome, in which the affected person's cells contain three copies of chromosome 21 instead of the usual two.

THE HUMAN GENOME PROJECT

The Human Genome Project (HGP), an international effort to specify the 3 billion base pairs that make up the DNA sequence of the entire human genome, produced its first draft in June 2000. A key rationale for the massive investment of money and effort in the HGP is that the more we know about gene sequences, the more we will understand—and be able to prevent—disease and disability. Even at this early stage, the genome sequence has thrown up some interesting observations. For instance, only about 5 percent of the entire genome seems to contain sequences that actually do code for proteins, while the function of the remaining 95 percent remains unknown.

Nevertheless, it has rapidly become clear that the expanding knowledge of human genomic sequences will, at first, do no more than enable us to diagnose more genetic variations. The number of loci being linked to disorders is growing day by day, and this straightforward increase in diagnostic ability is coming onstream well before the genome sequence has provided much in the way of greater understanding of the complex developmental pathways that lead from gene to phenotype. Any possible therapeutic interventions lie even further in the future.

GENOTYPE, GENE ACTION, AND PHENOTYPE

Genetics' understanding of the route from gene to living organism is still very limited. The earliest and simplest model (the Central Dogma) held that DNA makes RNA makes protein, makes a particular phenotype. Thus, a given DNA sequence straightforwardly determines the final appearance of a characteristic. Mounting experimental evidence has shown that, although broadly correct, this model is inadequate. For example, it is clear that the molecular structure of genes is more complex than was once thought. There may be ambiguity about which DNA sequence elements in reality form a gene, multiple proteins can be produced from a single gene, and the protein product can be regulated in unexpected ways. Furthermore, molecular biologists now realize that genes in a genome interact with each other, and with the nongenetic aspects of the whole organism, such that facile extrapolation from experimental setup to the living individual may be misleading. And finally, the environmental context may also interact with the genetic constitution to produce the resulting phenotype in ways that are not predictable.

Equally, since any given protein can be implicated in a host of physiological functions, many genes are *pleiotropic*—mutations in them will have numerous phenotypic effects. This is why many genetic disorders are classed as syndromes identified by characteristic constellations of signs and symptoms. For example, genes such as cx26 have been identified where mutation leads to hearing impairment, but there are also many genetic disorders that *include* hearing impairment among other features. Whether we consider the relevant genes to be primarily to do with hearing impairment or primarily associated with one of the other characteristics will depend more on our point of view than on the biology of the gene.

What all this means is that genetic determinism, the idea that the characteristics of individuals (and, in the extreme, their whole lives) are determined exclusively by their genes, must be abandoned. At the clinical level, it means that even for well-characterized genetic lesions it is rarely possible to predict exactly what the phenotypic consequences will be for each individual. In terms of disability, it means that the story is not as simple as "reading off" an impairment from a gene sequence, let alone understanding how that impairment will be experienced as disability. It is salutary to remember this when evaluating claims that the sequencing of the human genome will *by itself* increase our understanding of disability and illness.

GENETIC VARIATION

Perhaps the most provocative observation of the HGP is the sheer amount of variation between different people's genomes (known as *genetic polymorphism*). Each individual's genome differs slightly from everybody else's, and moreover everybody's genome carries a number of polymorphisms that have no phenotypic consequence, either because the change for some reason does not affect the production of a gene product or because the mutation is recessive and is compensated for by the normal copy inherited from the other parent.

According to standard evolutionary theory, this high degree of genetic variation is necessary to provide the raw material for adaptation to changes in selective environmental pressures. Any group of organisms, however currently well adapted they are to their habitat, needs to contain a reservoir of phenotypic diversity so that if things change (the environment gets hotter or wetter, food becomes scarcer, a new predator comes along), some individuals will find themselves flourishing better under the new conditions. Randomly generated genetic variation helps provide this diversity. Some of the variation will be extreme, producing phenotypes that would be regarded as impairment or disabling under any circumstances; examples here might be osteogenesis imperfecta (brittle bone syndrome) and Gaucher's disease. But even in some cases of apparently harmful mutations, there may be hidden advantages. Although both sickle-cell anemia and CF are disadvantageous, often painful, and life-shortening diseases for homozygotes, there is evidence that sickle-cell heterozygotes (carriers of one copy of the mutant gene) have greater resistance than noncarriers to malaria, and CF carriers have similar improved resistance to cholera.

GENETIC CAUSES OF DISABILITY

A focus on genetics tends to obscure the fact that a relatively small proportion of impairment is directly attributable to genetic causes. It is notoriously difficult to estimate the number of disabled people in any given population because of international differences in definitions of disability and in the methods used to collect the data, and these factors also make it impossible to compare the causes of disability across countries. However, the U.K. 1991 census gives a figure of 12.2 percent for the proportion of people with disabilities (Office of Population Censuses and Surveys 1993). Of this total, perhaps 10 percent may be directly attributable to monogenic disorders. Another, unknown but still probably rather small, percentage will be disabled by polygenic conditions such as heart disease or diabetes and its complications. But it remains the case that *most* disability is caused by events that occur after birth: aging, illness, and trauma, including war.

The fact that we can identify the inheritance pattern or can do a genetic test tells us something about the strength of the genetic contribution to a condition, but it may not tell us very much about the most significant causes of that condition in real life or its severity or prevalence. Prenatal testing for Down syndrome has been widely available for many years in Europe and the United States, not because Down syndrome is the most devastating of all genetic disorders but because trisomy 21 is easy to detect by ultrasound and on a chromosome spread. Conversely, major depression, which according to many surveys is the condition with the most disabling global impact, has not been unequivocally linked to any gene loci and will probably turn out to have a multifactorial etiology. This is an important point, because it is tempting to assume that genetic knowledge is focused on (the most) severe or significant conditions, or that the existence of a genetic test reflects how severe the condition is, and this is not always true.

GENETIC MEDICINE

Until recently, genetic medicine was restricted to using classical genetic methods to study the transmission of familial disease and providing genetic counseling to affected individuals. The new genetics has not only made genetic diagnosis much more targeted and accurate, as more and more gene loci are identified, but has also opened up a range of novel interventions. Some of these are already part of clinical practice, whereas others are more or less likely to arrive in the foreseeable future. All have practical and ethical implications for the conceptualization of disability.

Prenatal screening has become standard antenatal practice in most parts of the developed world. To date, prenatal screening has relied on ultrasound scanning of the developing fetus, which detects only a few gross abnormalities, and examination of the fetal karyotype for chromosome disorders following amniocentesis or chorionic villus sampling. Again, as gene loci are identified it will become possible to test fetal genetic material specifically for genetic variations. And as with earlier forms of screening, if the test result is positive—that is, if an anomaly is detected—the question the parents then face is whether to terminate the pregnancy or not. Given that many more conditions will be diagnosable by genetic testing than by ultrasound or karyotyping, the number of affected pregnancies is predicted to increase. (Figures for the United Kingdom in 2000 indicate that about 1,760 of the total 175,542 legal terminations were performed solely because of fetal abnormality; Office for National Statistics 2001, Table 10.)

Preimplantation genetic diagnosis (PGD) is a technique that combines in vitro fertilization (IVF) with genetic diagnosis. After "test-tube" embryos are produced through IVF, they can be tested for the presence of disease-associated genes before a decision is made regarding whether or not to transfer them to the future mother's uterus to continue the pregnancy.

Both kinds of prenatal diagnosis are loaded with the same questions about what detecting the presence of a gene locus actually means for the life of the person who carries it (or will carry it if the pregnancy is continued to term or the embryo implanted). The ambiguities of the relationship between genotype and phenotype outlined above have to be borne in mind here. Other ethical questions are raised by carrier testing—where the embryo or fetus is heterozygous for a genetically recessive condition that, because it is recessive, will not directly harm the baby itself.

Genetic testing can also be done *postnatally,* in newborn babies, during childhood, or at any stage of adult life. The aim of this testing may be to *confirm a diagnosis* made on clinical grounds, perhaps to distinguish two similar disorders from each other, which may be necessary to provide the appropriate treatment or give the right prognosis. In other cases, postnatal genetic testing may be *presymptomatic.* Presymptomatic genetic testing may be offered for disorders that develop later in life, the best known example probably being Huntington's disease. HD is a late-onset autosomal dominant condition in which symptoms of neurological degeneration generally first appear when the individual is aged 40 or older. The gene responsible for HD produces an aberrant version of the protein huntingtin. Until it was identified, people who knew they were at risk of the disease could only wait to see if they developed symptoms. In 1983 the gene was located, and in 1993 it was cloned. Since then it has been possible for at-risk individuals to determine their genetic status—if they want to.

Moving beyond diagnosis, the identification of genes strongly associated with particular characteristics opens up the possibility of *gene therapy.* This involves removing an impairment by replacing a variant gene that plays a significant role in the development of the condition with a normally functioning gene. Numerous disorders are potentially treatable by gene therapy, including classic single-gene diseases such as CF and muscular dystrophy, but also more complex conditions such as diabetes, cancer, and AIDS. Although the idea behind it is straightforward, technically gene therapy is highly complicated. Among the problems that have to be overcome are delivering the gene to enough cells to be useful, to the right type of cell to correct the defect (e.g., into the epithelial lining of the respiratory tract to treat CF). The exogenous gene must be expressed as the right protein at the right time (which demands a good understanding of these processes) and must not interfere with the normal functioning of any other gene or cause a new clinical problem. Clinical trials of gene therapy began in the early 1990s and were successful in treating some rare blood disorders, but by the early years of the twenty-first century no form of gene therapy is in routine clinical use, and there is skepticism about whether the technical barriers will ever be overcome successfully enough to make it a practical clinical intervention.

A more realistic use of genetic information is *pharmacogenomics.* The idea here is to understand the genetics behind the physiological responses to medication. When people take a drug, most respond as expected, but a minority prove to be more sensitive or less sensitive, fail to respond at all, or show unusual or dangerous side effects. This variation can make treatment dangerous, time-consuming, and expensive; identifying which class of antihypertension drug a patient will respond best to, for example, is generally a matter of trial and error over weeks or months. Much, although not all, of the variation in individual response to drugs can be traced back to genetic differences, and the idea behind pharmacogenomics is to use genome data to identify which genetic compositions make people best or least suited to treatment with particular pharmaceuticals.

GENETICS, ETHICS, AND DISABILITY

Genetics is a discipline that has grown up in close association with medicine and with developmental biology, both of which make it conceptually relevant to thinking about disability. Moreover, advances in genetic medicine provide a range of new or foreseeable interventions in disability. Hence it can be argued that the ethics of genetics and disability are especially pertinent to each other. Over the years, writers in disability studies, disability activists, bioethicists, and others have raised concerns about all of the genetic medical technologies outlined above. Although the practical implications have received most attention so far, the impact of genetic thinking on disability ethics—and the impact of a disability perspective on genetic ethics—may have more subtle but equally far-reaching effects.

Prenatal genetic screening and PGD both raise the specter of what is frequently referred to as “eugenics,” although many scholars are not convinced that contemporary genetic selection is directly comparable with the well-characterized eugenics movement of the twentieth century. The disability critique suggests that selection against fetuses or embryos on the grounds that they have detectable impairments is based on unexamined prejudices about living with genetic disorders. These prejudices are encouraged by societal unwillingness to accommodate to disability and by a model of disability that sees it as a biomedical (and currently genetic) issue. The expressivist argument claims that selecting against fetuses and embryos with genetic disorders sends out a negative message to disabled people, and to society as a whole, about the value of disabled lives. Similar arguments might be made about any form of therapy, in that removing an impairment could be interpreted as a message that the person is more acceptable without the impairment than with it. But therapy does not involve the same existential life-or-death moral choices that are clearly part of prenatal genetic screening or PGD. Postnatal genetic testing may exacerbate the existing marginalization of disabled and chronically ill people, generating a new underclass of people and families with genetically detectable disorders who may be discriminated against in health or life insurance, employment, education, or other areas—even when they are presymptomatic. Pharmacogenomics has been criticized for threatening the same on a grander scale in which whole groups of people are marginalized because their genetic constitutions make them less attractive to pharmaceutical companies interested in developing drugs targeted at the profitable majority.

Lurking behind the regulation of the practice of genetic medicine, however, are wider ethical issues that extend beyond the topic of disability as such. Trying to set limits to prenatal screening or to gene therapy means taking a closer look at some fundamental but often unexamined community beliefs about the goodness of choosing the kind of people we want to have, the value of choice in general, and whether human diversity has any moral or metaphysical meaning. This set of questions in turn links to a discussion of the contemporary significance of human genetic data: how genetics' scientific authority confirms sequence data as the most fundamental description of an organism and whether the current dominance of genetics is impoverishing our repertoire of culturally available models of what it is to be a human being. The ethical dimension of genetics will necessarily focus on the proximate, practical applications, but it will become increasingly necessary to consider the broader moral background as well.

WHAT DOES GENETICS HAVE TO SAY ABOUT DISABILITY?

There is no doubt that genes make a contribution to many illnesses and disabilities, but the level of that contribution, and exactly how gene action interacts with environmental and social factors, is likely to be different for every condition. For some, the genetic influence is overwhelmingly strong, and here genetics can offer an understanding of pathology and, potentially, therapy. For others, genetic knowledge will never do more than offer a partial insight into the etiology, and nongenetic interventions (changing working conditions, for example) are likely to remain the most effective.

The disability rights movement has often been skeptical of or hostile toward genetics. The major concrete objection is that genetic diagnostic technologies will be abused for eugenic ends. But genetic science has also been condemned as just another way of locating the source of disability in an individual's deviation from the (genetic) norm, simply acting to reinforce the undesirable methodological and political individualism of the medical model of disability.

Genetics certainly has the potential to do this, alongside an equally worrying potential to divert attention and resources away from any nongenetic etiologies or to encourage the misclassification of all forms of genetic variation as pathological. Arguably, these potential misuses are not inevitable. They will depend on the social and economic climates in which genetic knowledge is put to use. It is just as conceivable that the information about human genomes generated by the HGP can radically and positively destabilize some entrenched assumptions about norms, normality, and deviation. As described earlier, the HGP provides material evidence of the huge degree of interindividual genetic variation, with many apparently "normal" people identified as the unwitting bearers of highly atypical genetic sequences. The implication of this is that in genetic terms, any line running from normality to defect, or normal to abnormal, is a continuum along which the cutoff points are determined by the needs of human groups rather than by biology. Extreme variations would impair or disable under any circumstances, but for others the point along the continuum where "variation" becomes "impairment" is dependent on environmental, cultural, and social factors. So, for example, many people with genetic short stature claim that they are chiefly disabled by society's inability to accommodate to their size. As another example, the effect of a genetic variation that reduces reading ability (there is evidence for a genetic component in dyslexia) is unlikely to have been experienced as problematic in preliterate societies. By this interpretation, genetics supports the radical consensus within disability studies that disability cannot be theorized as a fixed, stable dichotomous category. The model in which there are two groups of people, one with "the" normal genome and the other made up of people with deviations from that genetic norm, is no longer tenable, and it is genetic knowledge that makes its abandonment necessary.

GENETICS AND DISABILITIES: SOCIAL AND ETHICAL DILEMMAS

The scientific community has made enormous strides in the knowledge of genetics since the landmark discovery of the double-helical structure of DNA more than 50 years ago. While the promises of genomic medicine are manifold, the coming decades of genetics and biotechnological developments will undoubtedly raise social and ethical concerns that may undermine the human rights of people with disabilities.

Inclusion International, a nongovernmental organization representing agencies from more than 115 countries and promoting the inclusion of persons with intellectual disabilities, has articulated the fear that genetic data, although anticipated to do much good, may also lead to discrimination. Also, this organization argues that developments in genetics could be used in ways that restrict rather than enhance the rights and choices of people with disabilities and their families.

This entry examines the social, ethical, and policy implications arising from developments in genetics against the backdrop of four core ethical principles that are emphasized in much of the discussion about disability and human rights. These principles are as follows: justice (every person has the right to have access to services and to develop to his or her full potential), nondiscrimination (every person has the right to be respected for who he or she is, and to live as an equal citizen), diversity (every person has the right not to be judged on the basis of notions of perfection and normality), and autonomy (every person has the right to make his or her own decisions and to participate in decisions that will have an impact on his or her life). In light of the social and ethical issues raised by genetics and biotechnology, this entry presents a selection of ethical norms emanating from such international and regional bodies as the United Nations Educational, Scientific and Cultural Organization (UNESCO), the World Health Organization (WHO), the Council of Europe, as well as other documents from nongovernmental organizations.

The suspicion that people with disabilities and their representatives entertain toward genetic technology can be explained by the discrimination they have historically faced. This anxiety is notably exacerbated by past eugenic abuses in which it was deemed appropriate and desirable to sterilize those considered unacceptably different. Moreover, during the 1920s and 1930s, two Canadian provinces implemented laws that allowed for the sterilization of mentally disabled persons; these laws, which led to the undue restriction of the rights of people with disabilities, were not repealed until the late 1970s.

DEFINITION OF DISABILITY

Over time, approaches to disability have evolved. Initially, disability was considered within an individual framework. This focus on the individual was promoted by what is commonly known as the medical or rehabilitation model of disability. The next generation of approaches focused on society—that is, on the social, economic, policy, and legal conditions that lead to disability. This paradigm shifted the emphasis to culture and environmental factors. More recently, the model adopted has been based on human rights, which is a powerful framework from which to defend and protect persons with disabilities from genetic discrimination.

For the purposes of this entry, a broad-based definition of disability is adopted, a definition that encompasses the WHO 2001 International Classification of Functioning, Disability, and Health. This definition views the etiology of health conditions as neutral and reflects the interactive relationship between health conditions and the contextual factors of the environment and the individuals.

ETHICAL PRINCIPLES AND INTERNATIONAL POLICIES

Overall, human genetics concerns figure prominently in statements issued by international and regional health- and culture-related organizations. Some of the policy documents of such organizations specifically mention disability. Furthermore, in response to advances in human genetics and biotechnology, a number of governmental and nongovernmental organizations at the international and regional levels have taken an interest in addressing genetics within a human rights framework. A broad consensus of remarkable consistency is emerging. It addresses four ethical principles: justice, nondiscrimination, diversity, and autonomy.

A starting point for the discussion about ethical principles is the 1948 Universal Declaration of Human Rights, which promotes and affirms the fundamental rights to life, liberty, and security (Article 3); to medical care and social services (Article 25[1]); and to the benefit from scientific progress and its uses (Article 27[1]). The WHO, notably in its 2001 International Classification of Functioning, Disability, and Health, focuses on social and environmental barriers and on the rights to which people with disabilities are entitled. Nevertheless, developments in genetics raise particular new concerns that need to be addressed. The landmark 1997 UNESCO Universal Declaration on the Human Genome and Human Rights frames the actual application of the new scientific developments raised by genetics. A core principle of the UNESCO declaration is respect for human dignity; the declaration promotes a perspective based on the basic rights to justice, nondiscrimination, diversity, and autonomy. As a policy statement it provides the first signs that genetics will be applied in ways that maintain human rights. Even though most of the documents under review here do not expressly address disability, they can be interpreted as implicitly applying to disabled individuals, as most of them address the "new" genetics, either tacitly or explicitly.

Justice

The principle of justice implies the obligation to distribute benefits and risks equally. Genetics and biotechnology may harm people with disabilities by classifying and possibly devaluing people who are different and treating them as deviations from the norm. In the extreme, some believe that preventing the birth of a disabled child following preimplantation genetic diagnosis (PGD) or prenatal testing is a rejection of people affected by the specific genetic disorders tested for. However, others argue that it is not rejection of the individual per se but of the disorder. There are other ways, not limited to persons with disabilities, in which genetics and biotechnology can breach the principle of justice. For example, physicians' lack of awareness of the need for genetic referral and consumer lack of knowledge of genetic services might also lead to inequality of availability and accessibility to genetic services and care for all citizens.

Justice and International Policies

Internationally, many guidelines, although not specifically addressing persons with disabilities, consider that all humans, regardless of differences, are entitled to access to medical and genetic developments. Foremost in this area, UNESCO's 1997 Universal Declaration on the Human Genome and Human Rights specifically addresses the principle of justice in Article 12(a), stating that advances in biology, genetics, and medicine concerning the human genome shall be made available to all, with due regard to the dignity and human rights of each individual. Article 12(b) of the declaration recommends that research (including applications in biology, genetics, and medicine) concerning the human genome shall seek to offer relief from suffering and improve the health of individuals and humankind as a whole. In other words, equitable access to care, services, treatments, and research findings in the field of genetics is a fundamental human right of individuals and, where applicable, of groups of people.

The Council of Europe and the council's Steering Committee in Bioethics, concerned with genetic developments, have issued policy statements of general relevance to persons with disabilities. The council's 2003 working document Application of Genetics for Health Purposes recommends equitable access to preventive, diagnostic, and therapeutic genetic services (Article 10). Also, its 1997 Convention on Human Rights and Biomedicine holds that screening must be made available to all (Article 3). The binding force of the convention depends on its being signed and ratified by the council's member states. Furthermore, each ratifying member country may adapt these obligations with regard to its own health needs and resources.

In the case of gene therapy, in 1994 the Group of Advisors on the Ethical Implications of Biotechnology of the European Commission (GAEIBE) voiced concern regarding equity. It recommended that within the European Union appropriate measures should be taken to ensure equal access to gene therapy. With regard to prenatal diagnosis (PND), the GAEIBE (1996) agrees that all genetic services that are available for the entire population should be equally available for persons with disabilities. The GAEIBE specifically mentions that prenatal diagnosis should not discriminate against people with disabilities or those who do not terminate a pregnancy. This organization expresses two concerns regarding the application of genetic tests to persons with disabilities: First, people who test positive for genetic mutations have a variable likelihood of developing the disorder in question; and second, it is difficult to define the severity of disorders. In view of these concerns, the GAEIBE concludes that it is inappropriate to generate a list of disorders that qualify for prenatal genetic diagnosis.

Finally, Inclusion International (2003) stresses that genetic research must not lead to the reduction or suppression of opportunities for health and social services, education, employment, leisure, or citizenship responsibilities for people with disabilities.

Nondiscrimination

Issues related to genetic discrimination by insurers, employers, and educators are of major concern to many persons with disabilities. There is some evidence, admittedly anecdotal, that genetic information is being used or could be used to deny access to life or health insurance and employment. Advances in genetics may have major financial implications for people seeking health insurance, especially in countries that do not have universal health care funding. Moreover, in such countries employers may use genetic information to maximize their economic benefits by denying jobs to people with particular genetic profiles. This serious concern merely aggravates the already widespread discrimination that people with disabilities face. If genetic testing is increasingly successful in predicting genetic susceptibility, even those with "future" disabilities may suffer in the present.

The issue of discrimination is not limited to employers and insurers. Some individuals might be denied fertility treatment or adoption rights in light of past mental illnesses. There is also a fear that genetic information will lead to stigmatization and have a negative impact on disabled people's rights to accept or refuse medical treatment and to reproduce according to their own wishes.

PGD and genetic screening raise similar concerns of discrimination. Whereas testing for very rare monogenic conditions such as Tay-Sachs disease and Huntington's disease is generally accepted, testing for less "severe" diseases is more controversial, especially if the results may determine whether a fetus will be aborted or not. In some situations, and in order to increase their chances, couples with disabilities may request PGD to select embryos without hereditary conditions such as deafness, achondroplasia, or intellectual disabilities; such couples may also wish to have children who have the same disabilities they do.

"Wrongful life" lawsuits are seen as inherently discriminatory toward persons with disabilities. The Perruche case, which urged France to modify its health law policy, is an example of the concern. The case concerned a boy who was born deaf and severely disabled due to the rubella his mother contracted while pregnant. The boy claimed damages from doctors who, because of laboratory negligence, did not diagnose the mother's rubella. Even though medical negligence was proven, this ruling offended people with disabilities who felt the decision implied that disabled people were not worthy of life. The Perruche lawsuit is just one of a number of similar suits that have suggested that disabilities are injuries worthy of compensation.

Issues concerning discrimination are likely to intensify and become more widespread, particularly if research succeeds in linking genes to behavior, intelligence, and personality traits. The topics of the genetics of mental disorders and behavioral genetics are sensitive, controversial, and complex, and research in these areas may rekindle the old debate between nature and nurture and serve as a basis for discrimination and stigmatization, as suggested by the Nuffield Council on Bioethics (2002).

Nondiscrimination and International Policies

Overall, there are strong indications that key international organizations, through their policies and guidelines, promote the principle of nondiscrimination based on genetic information. Generally, these organizations' statements avoid singling out persons with disabilities; rather, they promote collective human rights irrespective of race, ethnicity, gender, or physical or mental characteristics.

Mention should be made of two influential United Nations documents specific to genetics. The UNESCO Universal Declaration on the Human Genome and Human Rights states that people should not be excluded because of certain genetic characteristics and that no one should be subjected to discrimination based on genetic characteristics. In the International Declaration on Human Genetic Data, the United Nations proposes that genetic data should not be used for discriminatory purposes or in any way that will stigmatize a group. The declaration also states that there should be no unauthorized disclosure of genetic data to third parties (e.g., insurers, employers, and educational institutions).

The World Health Organization explicitly recommends adopting language that is sensitive and nonpejorative; terms such as *mentally retarded* and *defective fetus* are absolutely unacceptable. At the regional level, the Council of Europe prohibits any form of discrimination on grounds of genetic heritage in its Convention on Human Rights and Biomedicine.

The Council for International Organizations of Medical Sciences has developed ethical guidelines for biomedical research in which the organization recognizes behavioral genetics as a very sensitive area and recommends that behavioral geneticists publish their research findings in a manner that is respectful of the interests of all concerned.

Finally, although an emphasis on nondiscrimination toward all individuals and populations is a core ethical principle, and seen as a collective right, many organizations still explicitly recognize a need for the special protection of persons with disabilities. For instance, the European Parliament highlights disability in its Charter of Fundamental Rights. Under the terms of Article 21.1, any discrimination based on any ground such as genetic features and disability shall be prohibited.

Diversity

Respecting diversity entails valuing and accepting a wide variety of human characteristics, including disabilities ranging from the relatively mild (such as ectodactyly, or partial fusion of fingers or toes) to the very severe (such as Huntington's disease). Many observers fear that genomics will menace human diversity. Some persons with disabilities feel their rights are threatened by genetic advances such as PGD and prenatal testing and screening. Disabled Peoples' International (DPI) and a number of nongovernmental organizations within the disability community have voiced concerns that these reproductive technologies challenge the principle that all individuals have equal value and deserve respect.

In medical circles, the word *serious* is often used to differentiate disorders. Studies suggest that among professionals, interpretations differ concerning the “seriousness” of various conditions, including cleft lip/palate, hereditary deafness, diabetes, Huntington’s disease, cystic fibrosis, sickle-cell anemia, Down syndrome, and bipolar disorder. Such divergent interpretations raise difficult ethical questions because individuals, families, and medical professionals may perceive the seriousness of particular genetic conditions very differently.

Currently, PGD is offered when there is a high risk of a “serious” genetic disorder. Further developments in genetics may change what is considered a serious disorder and what is perceived as falling within the range of normal. DPI has noted that the field of genetics is threatening to undermine the rights of persons with disabilities because only a few genetic conditions are so severe as to make living unbearable. The organization points out that the views of people living with disabilities have not been heard.

Finally, there is also a concern that developments in genetics will allow policy makers to increasingly treat disability as a medical problem and conceivably overlook policies that advance the integration of people with disabilities into society by adapting the environment to the needs of these individuals. Over the past 20 years, the social model of disability, which emphasizes the role society plays in the experience of disability, has achieved legitimacy. However, with developments in genetics and biotechnology, the disability community fears a rekindling of the medical/biological model of disability, which places genetic factors at the forefront and overlooks environmental, social, political, and economic factors.

Diversity and International Policies

UNESCO’s Universal Declaration on the Human Genome and Human Rights asserts every individual’s right to dignity and human rights regardless of genetic characteristics (Article 2). Similarly, in its Proposed International Guidelines on Ethical Issues in Medical Genetics and Genetic Services, the WHO recognizes the need to respect human diversity and minority groups.

In a similar vein, the GAEIBE maintains that in light of the current controversies raised by germ line therapy and the actual state of the art, germ line therapy on humans is not currently considered ethical.

Regarding the complex interplay among several societal factors, the WHO’s International Classification of Functioning, Disability, and Health serves as a focal point for addressing the importance of the interactions among physical, social, economic, environmental, and genetic factors.

Autonomy

The right of persons with disabilities to participate in decisions affecting their lives is central to the principle of autonomy. However, in addressing the needs of persons with disabilities, two problems emerge: First, it is often presumed that persons with intellectual/mental disabilities lack the capacity to make their own decisions, and second, there is a tendency to make choices for competent disabled adults and their families because they are often seen as vulnerable and thus in need of protection, their choices are not perceived as appropriate, or the public sometimes has low expectations of them.

A distinction is generally made between care and research. Research requires more stringent conditions in terms of justification, disclosure, and consent. Research should be undertaken with and personal health services administered to human beings only as long as the persons involved are given exhaustive background information that will enable them to make informed decisions about whether or not to participate in research or clinical care (e.g., on the risks and benefits of participation, alternatives to the testing, treatability of the disorder). Some individuals may interpret the simple offering of prenatal screening or genetic testing as a suggestion that such screening or testing is necessary, desirable, and in their “best interest.” Also, it has been argued that if parents refuse prenatal tests they may later be made to feel guilty or blamed if their child is born with a disability.

Another important ethical issue is the need to involve the public and to provide forums in which the community can participate in identifying needs, setting priorities, and making decisions involving health services and medical research. Persons with disabilities feel they have a great deal to offer in this respect because they are most affected by and aware of the issues associated with their conditions. The phrase “Nothing about us without us,” originated in the early 1990s by disability rights activists, is today a widely recognized motto for people with disabilities who want to take a full and active role in their care as well as at all levels of decision making in matters concerning their lives.

Autonomy and International Policies

Two core issues concerning autonomy are addressed by international policies: The first is consent, a principle at the foundation of any ethical research and health service; the second is the right to participate and be involved in policy decisions that have an impact on services and research.

UNESCO’s Universal Declaration on the Human Genome and Human Rights recognizes the importance of informed consent, stating that in all cases, the prior, free, and informed consent of research participants shall be obtained. Obtaining meaningful informed consent from people with disabilities who are participating in genetic research raises challenges. There is an ongoing debate about the adequacy of the safeguards currently in place to protect disabled participants. The UNESCO declaration tries to strike a balance between the need to protect individual rights and the need to ensure freedom of research, primarily in relation to genetic information. Article 5(a) of the declaration states that research, treatment, and diagnosis should be made only following an assessment of the potential risks and benefits of performing these research activities and should adhere to a national standard.

As a health service, genetic testing of incapacitated adults also raises special concerns. The UNESCO declaration requires that the testing of an incapacitated adult be done only on the basis of that person’s best interest. Article 5 of the declaration states that if, according to the law, a person does not have the capacity to consent, research affecting his or her genome may be carried out only for his or her direct benefit, subject to the authorization and protective conditions prescribed by law. The Council of Europe’s Steering Committee in Bioethics recommends that testing should be permitted on an incompetent person only if certain safeguards and the following conditions are met:

- The purpose of the test is to allow the family member or members to obtain important preventive, diagnostic, or therapeutic health benefit, or to allow them to make an informed choice with respect to procreation.
- The implementation of such test is essential to obtain the benefit envisaged.
- The importance of the benefit foreseen has been independently assessed.
- The risks and burden of the intervention, and risks to private life that may arise from the collection, processing, or communication of the results of the test, are minimal for the person who is to undertake the test.
- The person undergoing the test does not object.
- The authorization of the person’s representative, or an authority or a person or body provided for by law, has been given.
- If the person tested has expressed the wish not to be informed of the result of the test, this wish shall be observed.

During the prenatal period, the GAEIBE recommends that no prenatal genetic testing be imposed by law, by public health services, or by any other institution or person. Tests should be done only at the request of the woman or couple after they have been fully informed through genetic counseling.

Regarding population-based genetic screening, Inclusion International stresses the importance of every individual’s having the choice to opt into or out of genetic (population) screening. This organization also suggests that a disabled person should not be pressured either tacitly or explicitly to undergo genetic testing and that the disabled person and his or her parents or other personal caregivers should be allowed to refuse to receive any test results.

Recognizing the need for public participation, internationally, agencies such as the WHO, UNESCO, and their advocates are vocal about the importance of providing people with the means to play a greater role in policy development with regard to genetic research. Responding to this need, the WHO (1997), in a report on ethical issues in medical genetics, stresses the necessity for close cooperation between medical professionals and patients' organizations. In a research context, a similar participatory approach is promoted by the Human Genome Organization's Ethics Committee (1996), which recommends that consultation should precede the recruitment of participants and should continue throughout the research.

In addition, recognizing the double discrimination experienced by women with disabilities, Rehabilitation International (1997) demands that the concerns and input of disabled women and girls be heard clearly in all debates and policies concerning genetic engineering, bioethics, prosthetic design, and human engineering, with regard notably to cochlear implants, abortion on grounds of disability, assisted suicide, and other eugenic practices.

SUMMARY

While the promises of genomic medicine are manifold, the coming decades of advances in genetics and biotechnological developments will undoubtedly raise social and ethical concerns with regard to the human rights of people with disabilities. The rights of disabled people that may be violated include the right of each individual to develop according to his or her potential, the right to equality and respect for each individual, the right to be valued in positive terms and not solely based on notions of perfection and normality, and the right of each individual to make his or her own life choices and to have a voice in discussions that shape and define genetics policies.

UNESCO's Universal Declaration on the Human Genome and Human Rights remains a pivotal document because it lays down general principles and provides a framework for addressing a complementary approach between human rights and medical sciences. The World Health Organization, the Council of Europe, and consumer organizations such as Inclusion International and Disabled Peoples' International also play major roles in translating genetic innovations into the health service and public health fields. Current policies have adopted an all-encompassing approach, focusing on the general recognition, respect, and protection of the rights to which all people, whether disabled or nondisabled, are entitled.

GENNARO, ALDO (?–1987)

Chilean-Australian theater and dance director

> *Institutions suppress individual creativity; creativity is our tool to keep growing.*
>
> —Aldo Gennaro (in the film *Stepping Out*, 1980)

Aldo Gennaro was born in Chile, where as a young man he became an Augustinian priest in his quest for "spiritual energy." One manifestation of Gennaro's subsequent attainment of this energy came after he migrated to Sydney, Australia, when as a dancer and director, he worked with young people with Down syndrome from the Lorna Hodgkinson Sunshine Home on a dance theater project. The project emerged from the activity therapy center that Gennaro had established at the home. He saw the body as "an instrument of communication" and developed a "language of gestures" with the group that enhanced the young people's ability to communicate through dance.

In the first piece developed by the dance group, one of the performers took the role of the Clown. This offended some observers, who felt that the young man was somehow being mocked. But he himself insisted: "Yes, I can be a clown. There is nothing to be ashamed of to be a clown, not because I am Downs Syndrome, and when I go in the street people look at me funny . . . . I can be a clown. I can laugh from inside and invite you to laugh with us."

During the preparation of the group's major dance piece, which was eventually performed at the Sydney Opera House, Gennaro developed a special relationship with the group. In an interview given shortly before his death of an AIDS-related illness in 1987, he described this as "the first time I experienced real love in my life, unconditional love." The dance piece made an enormous impact. One critic described it as a "marvelous, colourful, creative, vibrant performance." The piece reached a far wider audience when Chris Noonan (who later directed *Babe*) made a documentary film about the group's dance project. The film, *Stepping Out,* was released in 1980; it was shown throughout the world and won 14 major awards.

GENOCIDE

This entry describes the disability-genocide nexus. Conceptions of genocide are distinguished, and practices that may accompany genocide and historical examples are described. Little has been written about the disability-genocide nexus, except for the Nazi example, although more is written about disability-related topics that can accompany genocide, such as eugenics, euthanasia, and famine. Genocide has legal, political, anthropological, and moral aspects, and this entry seeks to capture all of these.

The relationship between genocide and disability depends on how disability is defined. Weapons tipped with depleted uranium and posttraumatic stress disorder in Kosovo and spirit injuries in Rwanda have major individual and social consequences that may or may not be classified as disabilities.

Two approaches to identifying genocide are described below. The order is not hierarchical; thus the legal definitions mentioned first resulted from popular debate, which is mentioned second.

EVOLVING ATTEMPTS TO PREVENT AND PUNISH THE PRACTICE OF GENOCIDE

I. Limited Conceptions

The term *genocide* has multiple definitions. As with *disability,* definitions are not neutral; rather, they serve to spotlight or obscure particular practices. Each definition calls attention to particular aspects of what is done in a genocide and to whom it is done. Depending on one's definition, there may either be many instances of genocide or very few.

The word *genocide* first appeared in Polish lawyer Raphael Lemkin's 1944 book *Axis Rule in Occupied Europe.* Lemkin combined the Greek *genos* (race, tribe) with the Latin *cide* (killing). He was describing Nazi Germany's practices, but also sought the adoption of legal restrictions so that genocide would not recur. After that book's publication, Lemkin discussed genocide in a 1946 article in the *American Scholar,* in a 1947 article in the *American Journal of International Law,* and elsewhere. Lemkin's definition for the term was simple: "the destruction of a nation or ethnic group." Lemkin identified political, social, cultural, economic, biological, physical, religious, and moral dimensions of genocide. These included practices such as "racial discrimination in feeding" and "endangering of health," both often sources of disablement and death. In Lemkin's definition, "destruction" was not equivalent to "killing." Instead, it could mean measures such as prevention of births, endangering of health, and discrimination in feeding.

Earlier, in 1933, in an essay titled "Acts Constituting a General (Transnational) Danger Considered as Offences against the Law of Nations," which extended a report presented to the Fifth Conference for the Unification of Penal Law in Madrid, Lemkin proposed a multilateral convention making the extermination of human groups an international crime. The crime Lemkin identified in 1933, "Acts of Barbarity," would be a subject of a later convention under another name, genocide.

In the wake of the Nazi genocide, the United Nations adopted first a declaration and then a convention on genocide. Article 2 of the 1948 UN Convention on the Prevention and Punishment of the Crime of Genocide describes both against whom genocide might be directed and acts constituting genocide: "Genocide means any of the following acts committed with intent to destroy, in whole or in part, a national, ethnical, racial or religious group." The convention goes on to specify a set of acts that can constitute genocide: "(a) Killing members of the group; (b) Causing serious bodily or mental harm to members of the group; (c) Deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part; (d) Imposing measures intended to prevent births within the group; (e) Forcibly transferring children of the group to another group."

People with disabilities (PWDs) do not literally qualify as "the group." The disability community, however, is especially vulnerable to practices such as forced resettlement, famine, and diversion of resources that may be part of genocides. Prosecution of violators of rights of PWDs, specifically, has been for war crimes or crimes against humanity, but not genocide. People prosecuted for genocide under the UN convention have been violators of PWDs' rights, but the evidence has been anecdotal rather than gathered by prosecutors who were focused on the disability-genocide nexus.

Cases brought under the UN convention have run into procedural difficulties. Even with a limited conception, governments have been reluctant to cede the identification of genocide to international institutions. Article 9 of the convention provides for the resolution of disputes by the International Court of Justice in the Hague. However, many parties to the convention, including the United States, conditioned their ratifications by taking exception to this article.

Language identical to that in the UN convention is used to define genocide in Article 6 of the Rome Statute of the International Criminal Court (ICC). The ICC became a reality in 2002, and more than 90 countries, from Afghanistan to Zambia (but not the United States), are parties.

The Rome Statute contains provisions for the prosecution of many crimes against PWDs. Before destruction reaches the level of "genocide," there may be matters receiving the ICC's attention. Article 7, on "crimes against humanity," includes many offenses that have given rise to genocide (with great consequences for PWDs), among them deportation in paragraph 7(1)(d) and enforced sterilization in 7(1)(g). Similarly, Article 8, on "war crimes," includes enforced sterilization, unlawful deportation, biological experiments (as a form of torture or inhumane treatment), intentional starvation, and medical or scientific experiments. Some instances qualify as war crimes and could be the basis of prosecutions. But other instances would not; for instance, mutilation or experiments on occupied populations might be "justified by the medical, dental or hospital treatment of the person concerned."

Under Article 30 of the Rome Statute, prosecution requires that the material elements of a crime were committed "with intent and knowledge." That a defendant "must have known" or "should have known" is not sufficient. So the elimination of groups cannot be prosecuted as genocide unless it was intended.

The prohibition of genocide is fundamental in international law, and even where states have not consented to prohibition by written treaty, they are bound to obey the prohibition as a peremptory norm of international law (*jus cogens;* literally, constraining law). Leaders and scholars therefore often attempt to distinguish mass killings (sometimes permitted as self-defense or humanitarian intervention) from genocide (always prohibited).

II. Conceptions Challenging the Limits

Jus cogens has changed over time, so the public struggle over concepts such as genocide may eventually be reflected in law. Raising narrow definitional arguments is a strategy of genocide deniers, countered by advocates who insist that genocide be confronted.

In the 1948 UN Genocide Convention, limit to four types of groups was chosen over interpretations that might have added linguistic, political, or economic groups. "Political and other groups" were mentioned in a 1946 draft resolution, one that came from the drafting committee of the United Nations General Assembly's Sixth Committee, but later were excluded. Like the ICC, the International Criminal Tribunal on Rwanda (ICTR) used the fourfold enumeration, but it held that "all 'stable' groups, constituted in a permanent fashion and membership of which is determined by birth," should be included. By these criteria, some groups of PWDs would be included, but others would not.

Anthropological Conceptions

Alexander Hinton (2002) and others have followed the ICTR's example in calling for a broad definition of genocide, even suggesting that disabled people might be a "stable group." They contend that the essence of genocidal practices is "otherness," based on race or ethnicity in some contexts, but based on sexual orientation, gender, disability, political, or economic status in others. Genocidal circumstances may make group membership less stable, for instance, because of many people becoming newly disabled.

Other Conceptions

Cultures, advocacy organizations, and countries have sometimes adopted less exclusive conceptions of genocide. The use of cochlear implants has been described as "cultural genocide" directed at Deaf culture. Many opponents of forced institutionalization and involuntary practices of psychiatric drugging describe the practices as "genocidal." Philosopher Jean-Paul Sartre persuaded the nongovernmental Bertrand Russell Tribunal that the Vietnam War was "genocidal." The Spanish statute under which former Chilean dictator Augusto Pinochet was indicted included "political groups." French and Belgian approaches to defining genocide also include nonexhaustive lists of groups.

Users of broader conceptions of genocide apply the term to bring public focus to humanitarian issues faced in the present and future, not just the past. Users of narrower conceptions contend that this dilutes attention to important instances of genocide that must not be repeated.

PAST AND PRESENT PRACTICES REFLECTING THE DISABILITY-GENOCIDE NEXUS

Once "genocide" entered public discussion, it was applied to many practices and cases, some of which are described below. The disability-genocide nexus is seldom mentioned by observers, usually because they ignore it rather than because it does not exist.

Practices That Illustrate the Nexus

Many past and present practices reflect the disability-genocide nexus. If not part of genocide, they may constitute crimes against humanity or war crimes under the Rome Statute. Often, however, they have been accepted practices not just by prosecuted genociders, but by the prosecutors.

Eugenics was an important part of the Nazi genocide, but it was explicitly practiced in the United States and is advocated by many policy makers today. Thinking about eugenics intensified in the nineteenth century. In 1883, Francis Galton, a cousin of Charles Darwin, defined eugenics as "the science of improving the stock." That intention was invoked in efforts common in the twentieth century, including bans on marriage, sterilization, and rationing of scarce resources.

Advocates of euthanasia sometimes make eugenic arguments. PWDs are especially likely to be targeted as "worthy of death" as they were during the Nazi genocide.

Weaponry used to perpetrate and respond to genocide will mean that many people will become PWDs. Elaborate new weapons may help genociders, but they are not necessary to it. New and old forms of weaponry will kill many PWDs but will also make PWDs of other formerly nondisabled people. In Rwanda the machete killed many people but made amputees of others. Land mines are used both by perpetrators of genocide and by counterforces. Depleted uranium on modern weapons and posttraumatic stress disorder are two more reflections on the disability-genocide nexus.

Food is a common weapon in genocides, sometimes the primary weapon. Deprivation of food kills many people; it may also mean disability. For some people who are already disabled, the struggle for food, either where genocide is being practiced or in refugee camps, may mean death. Malnutrition's consequences for learning are great, even where the ultimate message is one of human resilience.

Historical Examples

The case most written about by far is the Nazi Holocaust. The Holocaust included practices of eugenics and euthanasia—labeled "child's play" compared to what followed by historian Daniel Goldhagen. Henry Friedlander (1995), Hugh Gallagher (1990), and others present a compelling contrary view that the actions against PWDs were central to the Nazi genocide. The techniques later used in the death camps were perfected in killings of disabled people.

A German law enacted on July 14, 1933, allegedly to prevent "hereditarily sick offspring" was the basis for sterilizations, initially voluntary, later mandatory. Many disabled people were killed in T-4, a project named for the street of its location, Tiergartenstrasse, that began in 1939 and ended in 1941. Others were "selected" at concentration camps as unlikely to be useful for arduous forced labor. The 14F13 program operated during most of World War II, and occupying forces found that killings of disabled people continued throughout the war.

Imprecise criteria resulted in hundreds of thousands of killings (about 250,000 PWDs). "Mental patients" describes some victims, but certainly not all; some had epilepsy, others were blind or deaf, and still others were killed for offenses such as bed-wetting.

Although each genocide has unique aspects, each can be compared and contrasted with others. The following 10 propositions explore the disability-genocide nexus. Each is more applicable to some genocides than others. (Earlier iterations of this list appear in Blaser 2001, 2002.)

1. PWDs may be selected as direct targets by a genocidal regime.
2. The earliest effects of genocide are likely to be felt by PWDs.
3. Genocidal movements' or regimes' perspectives on medicine may have disproportionate effects on PWDs.
4. Genocidal movements' or regimes' diversion of resources to carry out genocide may have disproportionate effects on PWDs.
5. Genocidal movements' or regimes' minimizing of contacts with other governments and nongovernmental organizations may have disproportionate effects on PWDs.
6. PWDs are disproportionately affected by genocide (in comparison with the nondisabled population).
7. Genociders may increase numbers of PWDs in the furtherance of genocide.
8. International organizations and intermediate national organizations may assist PWDs.
9. The "survivor syndrome" that is a result of genocide reflects the continuing relevance of disability.
10. Regimes following genocidal regimes are unlikely to deal successfully with issues affecting PWDs.

Cambodia in the late 1970s provides illustrative comparisons. The prosthetic devices used by many PWDs were identified as indicating ties to the West and therefore as bases for killing. Observers noted that people found near hospitals were targets for killing, all the easier if they were mobility impaired. Medical supplies were scarce, and temporary disabilities became permanent ones. In some cases, death resulted. Aid from humanitarian organizations was suspect, to the detriment of PWDs.

As in the Cambodian genocide, in 1994 Rwanda, ideology took precedence over human needs. In Rwanda it was a vaguely defined ideology of "Hutu power," where the more numerous Hutu destroyed many of the Tutsi minority. Early targets included institutions such as schools and hospitals that housed disabled people. Some people who survived lost limbs from machete attacks. Wing and Johnson (2002) suggest that genocide survivors are disproportionately women, many of them disabled. They also note the importance of including "disability" in the equality clause of Rwanda's postgenocide constitution.

Genocides were common in the twentieth century, and the term also applies to prior and later practices. The conquest of indigenous peoples and their lands, the status of Armenians in Turkey, the status of Kosovar Albanians in 1979, and the widespread use of sanctions are cases in which the consequences of "genocide" were felt disproportionately by PWDs. Contemporary practices of forced institutionalization and euthanasia include characteristics of past acts widely acknowledged as genocidal.

GEOGRAPHY AND DISABILITY

In its most common understanding, geography can be defined as the science of the earth's physical features, resources, climate, and population. From a broader perspective, geography is also the study of landscapes. Landscapes include spaces that can be classified as either environmental (natural) or human (built). Each type of space has important implications for persons with disabilities. Space plays a critical role in the lived experience of persons with disabilities because space is directly tied to accessibility and mobility. Therefore, space can be used to enable or disable persons with disabilities. Landscapes can have real (objective) or perceived (subjective) barriers for persons with disabilities. Thus, for persons with disabilities who may already experience social segregation, the presence of physical barriers due to space may further contribute to marginalization and lack of full integration into the community. These circumstances contribute to health disparity and inequity present in society worldwide.

Space is considered to be a social phenomenon that is influenced by the interactions of people, organizations, and systems in a historical process. As new landscapes are produced, those with power in that particular social structure are able to decide who will be advantaged and who will be disadvantaged. Therefore, the ability of persons with disabilities to participate in or influence decision makers has profound implications for how space will be built or altered to have a positive impact on people with disabilities.

Space is produced both naturally and socially. *Natural space* refers to geographic features such as mountains, rivers, oceans, and deserts. The ability of persons with disabilities to negotiate natural space is an important topic. It is often the case that the natural environment may pose obstacles for persons with disabilities; for example, those who are blind or physically disabled may have difficulty mountain climbing or skiing. In recent times, human guides and specially designed equipment have become available that permit disabled persons access to and mobility within natural environments. Similarly, innovations and alternations to the natural environment from engineering, architecture, and urban planning have increased access to and mobility in the natural environment. Physical change to the natural environment through human intervention is often referred to as the *built* environment.

A second way to view geography and its implications for disability is as social space. *Social space* is defined as nature that has been transformed through human practice. Human social space can be thought of as being physically produced (e.g., construction of a school)—the built environment—and socially produced (e.g., interaction between students and teachers in a classroom). In this sense, social space is viewed as the interaction of both a process (educational interaction) and an outcome (a building). It is important to note that environmental or natural space also plays a role in the creation of human social space (e.g., the construction of cities and towns near a river). Likewise, human creation of "built" space may also alter natural space so as to create a new environmental space that is oppressive to some groups such as those with disabilities (e.g., the lack of wheelchair-accessible street curbs in a city). When geography is viewed as a social phenomenon, several policy implications arise.

POLICY IMPLICATIONS

Employment

The experience of physically disabled persons is socialized in different times and in different places. Historically it has been shown that in capitalist-oriented Western societies, landscapes have been built that have a tendency to desocialize or marginalize persons with disabilities. This phenomenon has been characterized as the production of landscapes of exclusion. One example of this exclusion is the creation of sheltered workshops worldwide. Sheltered workshops often exclude disabled persons from mainstream employment opportunities and the work is often low paying and conducted under harsh conditions. In this regard, sheltered workshops have been viewed as places of exploitation and marginalization. Progressive social policies that view sheltered workshops as a source of production within the larger economy are needed, such as those in Germany, where federal policy mandates the employment of a certain proportion of disabled people in the country's large firms. Because research shows that poverty due to "work" disability is associated with geography, it is important for policy makers to consider the economic implications of the geography of disability.

Community Integration

Historically in Western societies, the disabled have often been isolated and institutionalized in hospitals, asylums, and other forms of sheltered housing. With the movement toward deinstitutionalization in the mid-1970s in the United States, persons with disabilities were transitioned to community-based forms of social care. This change in landscape, brought about by social policy, has implications for geography and disability. Most notable have been studies of community and neighborhood resistance to relocation of persons with mental and physical disabilities into their areas. This resistance has been termed "not in my backyard," or NIMBYism. Social policy directed at the deinstitutionalized has often resulted in poverty and social isolation, including increases in the numbers of homeless.

Incorporating a broader understanding of geography that includes not only attention to natural and built landscapes but also social spaces will help to create places that are more inclusive of persons with disabilities.

GEORGENS, JAN DANIEL (1823–1886)

German educator

Jan Daniel Georgens, a typical "restless worker," was born on June 12, 1823, in Bad Dürkheim, Germany.

He visited a teacher seminar and quickly became interested in the *Volksschule* (elementary school), which he regarded as the central educational institution for the nation. Beginning in 1844, he worked as a teacher in various locations. In 1848, the year of the failed German revolution, he founded a girls' grammar school in Worms, and two years later, the first south German nursery school in Baden-Baden. He had close contact with Friedrich Fröbel (1782–1852), the founder of *Kindergarten* (German nursery schools). In 1852, Georgens went to Vienna, where he accepted a private tutoring position for four years.

In 1856, Georgens developed a plan to erect the Institution for Special Education in Vienna. Together with the author Jeanne Marie von Gayette (1817–1895)—his future second wife—and the pedagogue Heinrich Deinhardt (1821–1880), whom he most likely met in Weimar while visiting the German *Idiotenanstalten* (institutions for the feebleminded), Georgens was able to open the private Heilpflege- und Erziehungsanstalt Levana (Remedial and Educational Institution Levana) a year later in Vienna. The institution focused its efforts on children of the noble and middle classes but also had a few openings for needy children. "Normal" children as well as the "infirm" and "degenerate" were accepted. Levana was conceived as a pedagogical model institution. It had a department for infant care and general and occupational training facilities as well as a Gesunden- und Krankenabteilung (Healthy and Ill Division) for up to 30 children. In 1857, the institution was relocated to the Liesing castle near Vienna. Due to low demand, the institution had to abandon the castle in 1859 and occupy a smaller building near Vienna. The ultimate end of the entire enterprise came during the mid-1860s. Numerous factors—including personal conflicts, lack of organizational experience, unprofessional business practices, and lack of governmental and private support—contributed to the failure of this reform-pedagogical experiment.

One permanent outcome of these years was an extensive two-volume publication that covered the theoretical foundations of special education as a scientific discipline. The dual-authored publication, which was titled *Die Heilpaedagogik. Mit besonderer Berücksichtigung der Idiotie und der Idiotenanstalten* (*Pedagogy of Special Education: With Special Consideration of Idiocy and Institutions for the Feebleminded*), was published in 1861 and 1863 in Leipzig. After that period, Georgens and his wife lived in Switzerland, Nuremberg, and Berlin. Georgens involved himself in other educational projects and worked professionally and politically with the Allgemeinen Deutschen Lehrerversammlung (Public German Teachers' Association). At the same time, he devoted himself more extensively to literary activities. He died on November 9, 1886, in Bad Doberan on the Baltic Sea.

GERMAN TRAINING SCHOOLS (*HILFSSCHULEN*)

The concept of the training school emerged during the last third of the nineteenth century in Germany. It was designed for the so-called feebleminded, who were excluded from the elementary school system. The foundations of the concept cannot be detached from industrialization, because of its nature as a practical training school (*Erziehungsschule*). The training school was intended not as a model of "normal" education, but rather as one of occupational training for a predominantly proletariat clientele.

Karl Ferdinand Klein (1814–1868)—a teacher for deaf-mutes—and Heinrich Ernst Stötzner (1832–1910) are considered the founding fathers of the training school. In a memorandum written in 1864, Stötzner called for the establishment of this new school system:

> In all of the large cities, people ought to create schools for less capable children, with the goal of taking individuals—who would on the whole otherwise become burdens of the state—and training them, by appropriate personnel and through relevant instruction methods, in order to create useful and productive members of society (quoted in Klink 1966:55).

The main argument of the founders of the training school was that elementary schools must be relieved of the strain associated with educating less gifted children. Having no elaborate diagnostic instruments at their disposal, the school's administrators maintained that a person should be considered "feebleminded" if he or she remained unsuccessful in the elementary school for two years. The so-established categorization of "feeblemindedness" was then certified by additional doctors who served as consultants and fixed within the personal learning curves of individual students. The concept of feeblemindedness—which was borrowed from psychopathology—served to legitimate a new pedagogical institution and profession.

Through the establishment of the Verband der Hilfsschullehrer Deutschlands (Association of German Training Schools' Teachers) in 1898, the training school gained enormous attention: In 1893, there were 110 special classes in 32 cities in Germany, with a total of approximately 2,300 students. By 1911, the number of classes had increased to 1,544, with approximately 33,000 students.

In spite of further expansion in following years, the training school system first experienced formal recognition during the period of German fascism through the Allgemeine Anordnung für die Hilfsschulen (General Order for Training Schools) in 1938. Even opponents of the National Socialist state protected the position of the training school by claiming that the productivity of their clientele would be useful for the armament industry and again that the training schools relieved strain on the elementary school system. In addition, the training schools saw themselves as holding tanks with respect to the sterilization law and participated in the selection of the "uneducable" (*Nicht-Bildungsfähige*), who fell victim to the so-called Euthanasia program between 1939 and 1945.

After 1945, a restoration of the previous training school system emerged in West and East Germany. In the Federal Republic of Germany the newly founded (as of 1949) Verband Deutscher Hilfsschulen (Association of German Training Schools) published a 1954 memorandum that appealed to the Deutsche Städtetag (German Congress of Municipal and Local Authorities) to proceed with haste to reconstruct and extend the Special School System *(Sonderschulwesen).* This memorandum stimulated the *Gutachten zur Ordnung des Sonderschulwesens* (*Report of the Rules of the Special School System*) of 1960, published by the Kultusministerkonferenz (Commission of the School Ministers of West German Federal States). This report explained that, in addition to the training school, other types of special schools (e.g., for children with sensory, speech, and physical disabilities; the sick; and those with behavior problems) were also elements of the German education system. At the beginning of the 1960s, the Special School for the Cognitively Disabled was added. Likewise in the 1960s, the classical training school successfully renamed itself Sonderschule für Lernbehinderte (Special School for the Learning Disabled).

Modern critics of the Special School for the Learning Disabled in Germany focused on the high overrepresentation of socially and economically underprivileged students in this type of school, such as children with immigrant backgrounds. Another area of criticism was that the relatively low achievement level was not, on average, being raised through small classes and individualized instruction methods. In this respect, the Special School for the Learning Disabled proves to be a significant component of the selective German educational system.

ARNOLD GESELL

(1880–1961)

American physician and psychologist

Arnold Gesell is best known for pioneering work in child development and as the founder of the Yale Child Development Clinic. Gesell was born and raised in Wisconsin, completing a Ph.D. in psychology at Clark University in 1906 and an M.D. at Yale in 1915.

When Gesell started his investigations into child development, he was most interested in the child with disabilities. Like Edouard Séguin and others before him, Gesell was fascinated by the pathological as it reflected on the normal, particularly in the form of a feral child discovered in the early twentieth century. Nevertheless, most of his work was concerned with describing the "normal child." A number of his publications caught the eye of James Angell, then president of Yale University, who orchestrated Gesell's move to New Haven. The Child Development Clinic, institutionally, began in the Yale Psychology Department but later moved to the Medical School and the Department of Pediatrics. Gesell received funding from the General Education Board of the Rockefeller Foundation as well as the help of Abraham Flexner. Eventually, Gesell and his work split, with the Child Development Clinic remaining at the Yale University Medical School (to this day) and another group creating the private Gesell Institute in New Haven. At times, these two institutions vie for the mantle of successor to Gesell's work.

Gesell was one of the first child developmentalists to use quantitative measures as tools for assessment throughout the continuum of childhood. He also extensively employed film and photographs to illustrate his arguments. He created orderly sequences of developmental stages to explain maturation of the child, resulting in the Gesell Development Schedules, which describe a child's motor, language, adaptive, and social responses to a variety of stimuli and produce a "developmental quotient" (DQ) suggesting a child's proximity to a "normal" child of the same age.

Into the central decades of the twentieth century, Gesell assumed a position as doyen of child development in the public mind. The author of many books, Gesell popularized his ideas of normal development through a series of lay guides. Middle-class mothers in particular found his work appealing, bringing his books with them when they visited their children's pediatricians. He helped standardize issues around developmental expectations in the minds of the public as well as in the minds of pediatricians, psychologists, and educators. Into the second half of the century, his ideas were overshadowed by more "environmental" developmentalists such as Jean Piaget.

GILMAN, CHARLOTTE PERKINS

(1860–1935)

American writer and feminist theorist

Charlotte Perkins Gilman's childhood was spent in poverty after her father essentially abandoned the family. Her own first marriage was an unhappy one and ended in divorce. These early experiences were instrumental in forming Gilman's theoretical approach to feminism—expressed most fully in her 1898 classic work *Women and Economics,* which stripped away romantic notions about the family and called for society to view domestic duties as social responsibilities.

Gilman's personal experience with what she described as long-standing melancholia—what today would be called major depression—led her to write the short story "The Yellow Wallpaper," which has endured as a feminist and disability classic and has been the subject of wide critical commentary. Gilman herself had been advised by a leading medical specialist to "live as domestic a life . . . as possible" and "never to touch pen, brush, or pencil again." She reported that following this advice brought her "so near the borderline of utter mental ruin that I could see over" (Gilman 1913). In "The Yellow Wallpaper" she transmutes these experiences into powerful and disturbing fiction.

In addition to writing other fictional and theoretical works, Gilman also lectured widely and was one of the founders of the Women's Peace Party.

GLOBAL INEQUITIES

Numerous historical, economic, political, and cultural factors and forces have contributed to significant inequalities in the lives of disabled persons worldwide. These include inaccessible or uneven geographies; underdevelopment; globalization; the strengthening of state structures and surveillance mechanisms; the imposition of Western-style rehabilitation models; warfare; a burgeoning refugee population; indigenous values, categories, and practices; and cultural representations that circulate through art, film, literature, the media, and theater. These factors and forces are refracted through the lenses of race, class, gender, and sexual orientation, creating multiple and intersecting marginality and invisibility for some. Nonetheless, an emerging and expanding global disability rights movement is currently seeking recognition from national and international bodies, demanding that disability rights be recognized as human rights.

Approximately 80 percent of all disabled people live in the majority world (third world). James Charlton (1998) argues that the imbalance between the minority world (first world) and the majority world needs to be placed in the context of world-systems theory. This theory purports that wealth inequities between these spheres emerged as formerly colonized countries were forced to remold their economies to meet the demands of the West. Leaving these countries resource poor has produced disability by generating inadequate food supplies, unsanitary living conditions, and unsafe working conditions. It has also stripped these countries of the assets necessary to guarantee disabled citizens integration and self-determination, contributing to underdevelopment and a sense of internalized oppression for some disabled people. This pattern of underdevelopment has been exacerbated by globalization processes that support unfair trade policies propelled by profit-seeking capitalists promoting a world open-market economy. The pattern is also bolstered by structural adjustment policies devised by the World Bank that require debtor nations to repay loans at the cost of undercutting basic safety nets, health care, education, and employment opportunities and training. These policies further disenfranchise already disenfranchised disabled populations. Additionally, these policy restrictions and stipulations perpetuate paternalistic models of development, silencing majority world voices that the minority world needs to hear.

Benedicte Ingstad and Susan Reynolds Whyte (1995) have published an edited collection that examines disability in cross-cultural perspective. The volume outlines criteria for such comparisons, including mind/body understandings, concepts of personhood, and values that determine an individual's social worth. Ingstad and Whyte have been criticized for failing to focus on social oppression exposed by considerations of political economy and for failing to account for the subjective experiences of disabled embodiment captured by phenomenological approaches. Nonetheless, their work is useful in that it serves to remind us that universal theories of oppression may obscure the diverse responses that specific cultures have had to disability, reinforcing misbegotten assumptions about the superior humanitarian impulses of the West.

Following on the work of Henri Stiker, Ingstad and Whyte's work reveals that there is a movement in many majority world countries to adopt Euro-American-style institutions and government procedures, often an artifact of colonialism. This style rests on the premise that equality equates with sameness, supporting uniform legal codes and uniform bodies and suppressing or replacing local or populist interpretations and practices even when they are beneficial to the disabled. Although there is a trend toward community-based rehabilitation (CBR), this appears to be driven more by cost concerns than by a desire to reimagine criteria for social belonging, encouraging input from disabled people themselves.

Matthew Kohrman (2003) offers an interesting ethnographic example of the ironies of a majority world country's struggles to establish criteria to determine eligibility for disability services and rights, placing his research in the context of modernity's nation-building projects. He conducted research in China on a state-run institution, the Disabled Persons' Federation. Founded in 1988 by Deng Pufang, Deng Xiaoping's eldest son, himself paralyzed in an attempted suicide during the Cultural Revolution, the Federation has attempted to redeem the moral status of the Communist Party by demonstrating its concern for China's most vulnerable citizens. Moreover, the state and the Federation have striven to prove to the rest of the world that China is deserving of first world status by devising statistical surveys that identify and count disabled people and by developing criteria for disability based on biomedical definitions.

The ironies are at least threefold. First, the criteria sometimes confuse and exclude persons applying for eligibility because they fail to consider functional limitations as imposed by disabling environments and because they ignore more fluid local categories. Second, government officials initially omitted mental illness because of its cultural associations with destabilizing social structures until pressure was brought from psychiatric elites who argued that recognizing mental illness is a mark of advanced civilization. Third, China established its goal for the total number of disabled to be located on the basis of a worldwide statistic of 10 percent first put forward by Rehabilitation International and then adopted by the United Nations. The statistic was not derived from rigorous evidence, but was meant to impress relevant national and international bodies that the magnitude of disability suggested that it was a pressing concern deserving immediate attention. However, when Chinese statisticians fell short of the 10 percent quota, they felt that they had lost face and embarked on another statistical count. Thus, unfortunately, the desire to be accepted as modern may actually draw energy away from more creative problem-solving forums that enable distinct nations to arrive at unique solutions.

Contemporary warfare, with its "advanced" strategies and technologies of death and destruction, serves as another catalyst for global inequality. The consequences of warfare are not random but intentional, such that "spoiled" and displaced bodies are evidence of the power of the victors over the vanquished, creating injuries and amputations that societies are unprepared for and generating refugees unhinged from familiar arrangements, social networks, and modes of survival. International policies, such as the 1997 Land Mines Treaty, set the tone for "fairness" in war, while reconstruction efforts are often hampered by a lack of consideration for disabled citizens. Modern nation-states also insist on preparedness for war, placing an emphasis on physical fitness as a requirement for full citizenship. Those who return from war may be classified as heroes or martyrs, potentially generating a two-tier system, with nonmilitary disabled citizens on the bottom rung of the social ladder.

John Hockenberry, a one-time reporter for National Public Radio, was stationed in Israel/Palestine during the first Intifada (Palestinian uprising that took place during the late 1980s). In his memoir titled *Moving Violations* (1995), he notes the enormous discrepancies he found between the conditions of the Israeli and Palestinian war wounded. The Israelis had lightweight, high-tech wheelchairs and were distributed vans with special government-issued license plates.

Elevated to the status of hero, they maneuvered their wheelchairs with militaristic confidence. Paralyzed Palestinians, on the other hand, were sequestered in rehabilitation hospitals, hopelessly awaiting the promise of cure in some other country. Reintegration into society was not a viable option for most, both because the role of martyr precluded a return to "normal" life and because old equipment, grinding poverty, and inaccessible terrain made it difficult for these individuals to return to their hometowns or villages.

Gender inequalities are another important factor to be taken into consideration in the analysis of global inequalities. Disabled girls and women are often the targets of various forms of violence, have their reproductive rights violated, are kept more sequestered than males, and are less likely than their male counterparts to have access to education and employment opportunities. Anita Ghai (2001) reports that disabled girls are particularly vulnerable in India for the reasons stated above. However, Ghai also notes, in an interesting twist, that disabled sons are thought to be a threat to "lineage capital" (a term borrowed from Emma Stone 2001), a form of capital that consists of the ability to fulfill expected family obligations, resulting in greater attention being paid to their rehabilitation needs.

Additionally, the voices of disabled women and girls may be dismissed and discounted, contributing further to a sense of nonpersonhood and invisibility. Veena Das and Renu Addlakha (2001) discuss the case of a woman in Delhi who was diagnosed with chronic schizophrenia and placed in a state-subsidized hospital. While there, she attempted to express concerns about her mistreatment by her husband and mother-in-law but was ignored because anything that she said was attributed to her "madness." In this case, the patriarchal structures of the state and the domestic spheres served to reinforce this woman's status as persona non grata.

Both disabled males and disabled females may be looked upon as lessening marriage opportunities for their siblings or otherwise symbolically polluting the kinship domain. Das and Addlakha recount the story of an Indian female born with a major facial blemish whose relatives wanted her quickly married off to a person of lower social standing as a means of containing the threat that she posed to their extended domestic circle. In this instance, her parents were her allies, ensuring that she acquired some education and allowing her to wait to get married until she found a suitable match. Such a stance necessitated that the parents be cut off from an ongoing relationship with their relatives. However, because they were a Punjabi family, displaced by the 1947 Partition between Pakistan and India, wartime conditions actually denaturalized taken-for-granted social arrangements. Moreover, when the woman married, she and her husband were able to take advantage of civil marriage statutes passed after India gained its independence from the British; this case provides an example of state policy helping to carve out new domestic practices that may prove beneficial to disabled citizens.

Finally, changing conventions of cultural representations of disability in art, film, literature, the media, and theater may create ruptures in ways of looking at and thinking about disability. Disrupting established narrative patterns by no means automatically undercuts entrenched inequalities, because old inequalities often resurface in new guise, sometimes rendering the processes of detection and interpretation multifaceted and opaque. Take the case in China of Liu Zheng's collection of photographs titled "My Countrymen." Before Mao Tse-tung's death in 1976, Chinese artists were expected to depict images of an idealized socialist society in which citizens were hardworking, physically fit, and mentally stable. Various genres of art have surfaced in the post-Mao era, some of which focus on unmasking the "reality" obscured by this ideal, and Liu Zheng's work falls within one such genre. Zheng photographs various categories of people living on the margins of society, including disabled people. While these categories may be reminiscent of Erving Goffman's typology of social stigma, as Wu Hung (2001) points out, there are aspects of Zheng's work that might strike one as disturbing. His juxtaposition of photos of disabled people with cadavers suggests an equation of disability with decay rather than a liminality that excites creativity or the forging of new norms. Zheng claims that as someone alienated from Chinese society, he feels an affinity with those photographs. However, even if these photos are aesthetically and empathically rendered, it still remains unclear as to whether they can be construed as progressive.

In recent decades disability rights activism has been sweeping the globe, confronting myriad inequalities. Global disability activism may be overlooked because of stereotypes that equate activism with fitness and the majority world with dependency and a passive femininity, making the pairing of disability and third world appear redundant. Activism may pose specific challenges for the disabled. In Canada, Vera Chouinard (1999) reports, a women's activist group was formed in 1977 called the Disabled Women's Network (DAWN). This organization made an effort to extend itself to women who had originally been excluded from the women's movement (people of color, immigrants, lesbians) in order to formulate broad-based objectives. Nevertheless, group members were faced with multiple constraints, such as lack of transportation, inability to afford the cost of conferences, inaccessibility of places in which to meet and places in which to stage protests, and uneven access to computer technology. Such obstacles, of course, are likely to be magnified in majority world countries, but as Anita Ghai recounts, even the urban slums of India are beginning to give rise to parental groups fighting for the rights of their disabled children and disabled people advocating for their own concerns. Moreover, as Chouinard points out, disabled activists in late-industrial societies are not necessarily guaranteed a voice because their bodies are often seen as lacking or contaminating corporate capital.

One of the benefits of globalization has been the circulation of information about global disability activism such that disabled activists can learn from each other and form coalitions. As with the minority world women's movement, however, disabled activists from first world countries need to exercise caution to avoid imposing their priorities and strategies on majority world activists who may face different conditions and political structures. It is equally important that the elites of majority world countries not be the sole decision makers regarding what discrimination and access issues are to be raised with local, national, and international bodies. A case in point is the Philippines, where a disabled talk-show host launched a campaign against disabled people in carnival freak shows. These entertainers protested his actions, noting that they preferred this form of employment to sheltered workshops, the only alternative supported by government officials for poor, disabled Filipinos.

This case underscores the importance of demanding economic and social rights and not simply focusing on individual civil rights. International disability rights assemblies, such as Disabled Peoples' International and representatives from the World Institute on Disability, have been working with the Union Nations to establish a convention that will recognize disability rights as human rights. Such a convention could prove useful to nations interested in developing their own policies and methods of implementation concerning disabled people. While such a convention would raise international awareness of disability issues, the process and outcome are also fraught with problems. For example, underscoring economic rights incites resistance from some minority world countries that benefit from the underdevelopment of the majority world. Additionally, there are problems with enforcing the stipulations of such a convention once it is forged and with ensuring broad-based input, including the most disenfranchised, into deciding the process of implementation.

GLOBALIZATION

Globalization is a process of change whereby local conditions or entities succeed in crossing national borders and reaching all over the world. Often associated with changes in global dimensions of politics, economics, and cultural practices, globalization is characterized by tensions, contradictions, and unequal power relations. Different regions of the world are at once implicated in multiple overlapping processes of many different globalizations. The globalization of disability issues constitutes one among many globalizations that simultaneously interact with, conflict, and relate to other globalizations. For example, economic dimensions of globalization conflict with disabled people's goals of social justice and equity when competition and deregulation processes involved in market economies exclude people with disabilities from full participation in society. Other major dimensions and processes of globalization that are pertinent to disability include the following: (a) the rapid spread of democracy and push for universal human rights, (b) technologies and the processes of communication and knowledge exchange, (c) social-political dimensions of education and the processes of changing negative beliefs and attitudes toward disability, and (d) health dimensions that produce processes of access to services and applications of medical research. These four broad areas constitute the major focus of disability in relation to globalization.

ECONOMIC DIMENSIONS OF GLOBALIZATION

With its intimate links to capitalization, globalization contains tendencies toward deregulation, decentralization, and privatization. These tendencies are most often associated with economic policies and practices of transnational corporations (TNCs), which exert pressures on industrialized states to shape events and decisions in developing countries. Currently, the top 200 TNCs have wealth equivalent to 28.3 percent of the world's gross national product, and five industrialized countries hold 90 percent ownership of these 200. Further, all industrialized states together comprise only 19 percent of the world's population yet control 71 percent of global trade in goods and services.

At the same time, 80 percent of the world's 600 million disabled people live in developing countries, yet these countries expend 20 percent of the world's health care moneys. Disability is also widely recognized as inextricably linked to poverty. The World Bank estimates that disabled people account for as many as 25 percent of the world's poorest. What is meant by *poor?* Half of the world's 6 billion people live on the equivalent of less than two U.S. dollars a day, and 40 percent of the people in Africa live on less than one U.S. dollar a day. Conditions linked to poverty, such as limited access to health care, food, education, and shelter, in addition to hazardous working conditions, increase the risk of disability. Impairments often lead to exclusion, unemployment, and further poverty, in turn creating and increasing the numbers of disabled people with impairments. The high unemployment rates of disabled people and their subsequent poverty is exacerbated by their countries' debts and privatization policies.

Global pressures for efficiency and competition in deregulated and privatized market economies have created conditions under which disabled people suffer greatly. First, free-market ideologies, by their very nature, create winners and losers, and inequalities are justified in terms of their contribution to economic growth. Second, because deregulation has weakened nation-states' ability to intervene and provide "safety nets," disabled people have lost income maintenance programs. Further, economic structural adjustment programs imposed by donor agencies such as the International Monetary Fund have been geared toward debt repayment. As a result, these programs have forced governments to reduce education and social services that are critical for disabled people in order to pay off these debts. Third, economic policies and interpretations of individual "rights" are increasingly in the hands of unelected technocrats in TNCs, whose interests are profits, not social justice, social responsibility, or equality.

On the positive side, the push to increase productivity, economics, and labor market participation rates has produced a global agenda for education reform, poverty reductions, and increased social responsibility. For example, the World Summit's Program of Action (1982) formally acknowledges conditions of poverty as a prima facie cause of disability. Further, one of the principal goals of the Program of Action is to ensure that society acknowledges and responds to the consequences of disability by securing the legal rights of the individual and by making the physical and social environment accessible. The Program of Action, ratified by 155 countries and in its fourth cycle of five-year review, now requires progress reports as well as resources and funding solutions to ensure access and equity for disabled people.

It is predicted that by the year 2025, the number of disabled people worldwide will have risen from the current 600 million to 900 million. The causes behind this projection can be directly linked to globalization and its effects. Global agendas are clearly driven by economic goals linked to development. These goals hold both a danger and a promise for the future of disabled people. On the one hand, the needs of large numbers of disabled people, coupled with an urgent need for economic development, have led many countries to focus on untapped sources of development by increasing the numbers of disabled people in the workplace. On the negative side, this focus on economic development and disabled people as workplace commodities has led to greater intolerance toward those disabled people who cannot work.

TECHNOLOGIES OF GLOBALIZATION AND UNIVERSAL HUMAN RIGHTS

Globalization has also produced positive benefits in the area of technological advances. Technologies of globalization, such as the Internet and advanced communication systems, have brought disabled people together to document and focus attention on the plight of disabled people and to insist on universal human rights. For example, Disability Awareness in Action (DAA) is an international coalition of the organizations Disabled Peoples' International (DPI), IMPACT, Inclusion International, and the World Federation for the Deaf. Largely linked through Internet communication, DAA has documented evidence of human rights abuses in 28 of the 30 articles of substantive rights contained in the Universal Declaration of Human Rights. As of March 2003, the DAA database contained a total of 1,910 reports of abuse affecting a known 2,466,348 disabled people. These abuses are widespread. For example, in the area of education alone, DAA has documented 118 cases affecting 768,205 people in 67 countries of the world.

Responding to this documentation and other reports, the United Nations Commission on Human Rights created the Global Rights campaign to address human rights abuses. Disability rights organizations such as the International Disability Alliance (IDA) have used this information to insist on a UN Convention on the Rights of Disabled People that would be legally binding on nation-states. The IDA's member organizations include DPI, Inclusion International, Rehabilitation International, the World Blind Union, the World Federation of the Deaf, the World Federation of Deaf-Blind, and the World Network of Users and Survivors of Psychiatry. DPI alone, as an international network of disabled people, works with organizations in 158 countries around the world.

The push for a universal declaration to address basic human rights of disabled people globally carries with it some problems and tensions. The primary tension is in the differences between the situation of disabled people in more advanced industrialized countries and the situations of those in poorer developing countries. More than three-fourths of the world's disability population struggles for the right to life. One-fourth of the population fights for quality of life—often framed in terms of choices, access, and equal opportunity. To many disabled people in developing countries, such quality-of-life issues often seem to be empty slogans because they fail to recognize issues of privilege, power, and control. The push for human rights and self-determination assumes that disabled people have autonomy and a real capacity for choice. Many disabled women and children around the world simply do not have this status or capability. Their lack of food and basic education also affects their ability to advocate for themselves—either individually or collectively.

Some disability scholars and advocates argue that laws regarding equal opportunity do not automatically or even probably lead to improved standards of living, nor do they necessarily lead to social change or change in economic policies. For example, in the United States, 14 years after passage of the Americans with Disabilities Act, unemployment of disabled people remains virtually at the same level as before the law went into effect.

On the other hand, many believe that these programs, declarations, and conventions constitute a universal moral imperative, bring human rights to center stage, and along with it, the right of the international community to intervene in specific countries to protect these rights. The work of DPI, IDA, DAA, and others has been the driving force behind the globalization of disability issues through the World Program of Action (1982), the United Nations Standard Rules on Equalization of Opportunities for People with Disabilities (1993), the World Summit for Social Development (1995), and the Education for All Framework for Action (2000) as well as the current campaign to secure a UN convention on the rights of disabled people.

In addition to human rights implications, the role of information and communication technologies in disseminating information in a knowledge-based economy carries with it social and political implications. Prominent among these implications is the issue of bridging the digital divide between haves and have-nots in different regions of the world.

SOCIAL-POLITICAL DIMENSIONS OF GLOBALIZATION

In a globalized world, strategies that recognize interactions among rights, culture, and political-economic policies become imperative. For example, decisions to allocate resources for education and health services may reveal more about societal beliefs or government priorities than they do about a given country's ability to fund these services.

Education is widely recognized as inextricably linked to development. In response, UNESCO in particular has launched a global inclusive education project to increase the number of disabled children and youth who have access to education as well as opportunities for participation in quality education. In 2001, UNESCO launched pilot projects in Cameroon, Dominican Republic, Egypt, Ghana, India, Madagascar, Mauritius, Nicaragua, Paraguay, South Africa, Vietnam, and Yemen. The global initiative, Education for All 2000, has as its primary millennium development goal universal education by the year 2015. Advocates as well as governmental bodies differ on the subject of the nature and extent of inclusion for people with disabilities. For example, many countries still offer segregated educational experiences for certain populations of disabled children and youth, such as for blind, deaf, and deaf-blind individuals. However, all agree on the importance of education, not only as a basic human right, but as a primary source of individual and collective enhancement and development.

In reaction to globalization, age-old prejudices have also been reawakened, to the detriment of disabled people. For example, many nation-states are pushing for a return to traditional cultural practices to stem the tide of globalization, which is seen as a threat to tradition. Some Islamic states, for example, have reasserted that amputation for theft and stoning to death for marital infidelity are central to Qur'anic law, which overrides human rights declarations pertaining to cruel and unusual punishment.

Both the Declarations of Asia and the Pacific and the Africa Decade of Disabled People list as key objectives the fostering of positive attitudes toward disability and the challenging of traditional practices and beliefs detrimental to disabled people. For international disability organizations, a primary goal is not only educating children and youth, but educating civil society as well as political and governmental representatives. Disabled Peoples' International's 2002 Sapporo Platform, developed by 3,000 delegates from more than 90 countries, urges members to take every opportunity to seek publicity and awareness in order to change negative images of disabled people. Inclusion International and virtually every recent declaration (such as those of the African Decade and the Asia and Pacific Decade) list social-political agendas on which global partnerships to promote good government and full participation of disabled citizens are prominent goals.

HEALTH DIMENSIONS OF GLOBALIZATION

The new universe of disability is shifting and expanding. The shift is evident in the new World Health Organization classification of people with disabilities. In 2001, the new International Classification of Functioning, Disability, and Health (ICF) replaced the old International Classification of Impairments, Disabilities, and Handicaps (ICIDH-2). The new ICF was developed using a process of consensus involving both developed and developing countries. Basically, the ICF organizes disability along two dimensions: functioning and disability (including body functions/structures and activities/participation in society). This ICF definition shifts the focus from disability as an innate deficit to disability as constructed through the interaction between the individual and the environment. This shift encourages a focus on the kinds and levels of interventions appropriate to the needs of individuals within specific contexts and is consistent with the social model of disability that is upheld by disability rights organizations. The ICF distinctions are seen as particularly important in many developing countries, where personhood often depends more on social identity and fulfilling family obligations than on individual ability.

The expanding nature of disability is apparent in proposals to include persons with active, acute conditions such as HIV/AIDS under the rubric of disability. Prevention of these conditions has become an important public policy goal worldwide and introduces a need to reconsider the conceptual basis and terminology associated with disability. For example, including HIV/AIDS in definitions of disability challenges the thinking of disability advocates who have sought to separate notions of disability from disease.

Forces of globalization are also apparent in the area of rehabilitation and health-related services in the changing of language, such as the shift from the term *barrier-free design* to *universal design. Accessibility* used to refer mainly to the built environment, but new dimensions encompassed in the concept of universal design now include age-related factors, gender, culture, social context, levels of decision making, and control over major life activities. Guidelines for planning and design based on principles of universal design are now available in such disparate locations as Lebanon, Malta, and Peru.

Finally, global advances in medical research, genetics, and biotechnology have implications for people with disabilities. Genetic research has many practical applications to health care. Inclusion International (a nongovernmental advocacy organization on behalf of people with intellectual disabilities) recognizes that genetic research can be beneficial but also argues that it may undermine human rights and has implications for autonomy and informed decision making. As an example of these concerns, a formal policy statement issued in 2003 by Disabled Peoples' International demands a prohibition on compulsory genetic testing. The policy also demands prohibition of pressure on women to terminate pregnancies when their unborn children are considered likely to become disabled. As these organizations note, advances in genetic research and its applications may substantially alter the global diversity that disability offers human society.

CHALLENGES FOR THE FUTURE

To address economic, technological, social-political, and health dimensions of globalization simultaneously, a growing number of people with disabilities, professionals working in disability fields, and disabled people's organizations are developing a form of disability politics referred to as a *twin-track approach.* In such an approach, disability issues are included as a crosscutting theme in all poverty reduction work, rather than as a "special issue" or convention. At the same time, local issues particular to a specific culture, context, or disability group are attended to. For example, Bangladesh used a twin-track approach to improve the situation of people with leprosy. To overcome the stigma of leprosy, health education for the society as a whole was coupled with socioeconomic rehabilitation of people with leprosy. This approach makes the assumption that removing prejudice (through education) facilitates early detection and prevention.

Another example of a twin-track approach is found in the work of disabled people's organizations in the Slovak Republic. The organizations collaborated to provide community-based services for persons with disabilities at the same time they created a database on the health care needs of disabled persons and undertook intensive education of the Parliamentary Commission for Health and Social Affairs. This twin-track approach assumes that rights in and of themselves do not equal or produce justice. In other words, social justice requires economic justice, and political democracy requires economic democracy.

The small but growing number of disability scholars and those working in disability professions who advocate the twin-track approach point us in a promising direction for the future. First, in terms of legal/policy issues, the choice may not be between a social welfare state and market economies, but a hybrid of what has been termed a *radical democratic socialism*. In this hybrid one type of politics can facilitate the other. Second, some disability advocates and scholars recommend that all of us who are concerned about global disability issues, as a collective, develop a "politics of hope." The critical task of such a politics of hope would be to develop not only universal human rights laws and conventions but also context-specific tactics or strategies for their implementation. Further, hope involves the recognition of the unacceptable nature of certain negative conditions and relations of globalization, coupled with a desire for change and the conviction that change is possible.

Because of the complex interactions among dimensions and processes of globalization, what is desperately needed is concerted action to bridge the economic, digital, and other divides between people with disabilities in different regions of the world. Ultimately, the advancement of people with disabilities in the twenty-first century and beyond requires a globalized agenda for action that addresses universal rights but at the same time is sensitive to particular historical, political, cultural, and economic conditions.

GODDARD, HENRY HERBERT (1866–1957)

American psychologist and educator

Henry Herbert Goddard was born in Vassalboro, Maine, and graduated from Haverford College in 1887. In 1899, he finished a Ph.D. from Clark University under G. Stanley Hall. In 1906, he became the director of the Vineland (New Jersey) Training School for the Feeble-Minded. Eventually receiving funding from the wealthy soap manufacturer Samuel Fels, Goddard carried out research and writing at Vineland that would gain him national notoriety. Between 1908 and 1910, he introduced an American version of the Binet and Simon intelligence test. At the 1910 annual meeting of the American Association for the Study of the Feeble-Minded, he coined the term *moron* to identify so-called high-grade imbeciles. In addition to intelligence testing and classification, Goddard's interests included eugenics. In regular communications with America's leading eugenicists, Goddard's writings reflected the linkage of intelligence, "feeblemindedness," criminality, and heredity—all prominent aspects of what Goddard (and others) called the "menace of the feebleminded." Among his writings are *The Kallikak Family: A Study in the Heredity of Feeble-Mindedness* (1912) and *Feeble-Mindedness: Its Causes and Consequences* (1914). In 1918, Goddard assumed the leadership of the Ohio State Bureau of Juvenile Research, and from 1922 to 1938 he was professor of psychology at the Ohio State University.

The definitive biography of Goddard is Leila Zenderland's *Measuring Minds: Henry Herbert Goddard and the Origins of American Intelligence Testing* (1998).

GOETHE, JOHANN WOLFGANG VON (1749–1832)

German poet, playwright, and novelist

Johann Wolfgang von Goethe was born on August 28, 1749, in Frankfurt am Main, Germany, and died on March 22, 1832, in Weimar. He was the central figure of the classical period of German literature and was knighted in 1782. He wanted to study philology and history, but as an obedient son he followed his father's orders and studied jurisprudence in Leipzig and Strasbourg. Beginning in 1771, Goethe practiced law in Frankfurt. His first historical drama *Götz von Berlichingen mit der eisernen Hand (Götz von Berlichingen with the Iron Hand)* was published in 1773. A year later he published the epistolary novel *Die Leiden des jungen Werthers (The Sufferings of Young Werther),* which was enthusiastically received and made him famous. In 1775, Goethe moved to Weimar at the invitation of Duke Carl August. There, in 1779, he became the head of the highest finance authority. Between 1786 and 1788, Goethe made the famous trip to Italy that accounted for his transformation to writing classical epics. In 1788, he met fellow author Friedrich Schiller (1759–1805) and, despite their different perspectives, these two important representatives of the classical period of German literature developed a productive creative friendship. Goethe's long-term relationship with Christiane Vulpius (1765–1816), a member of the working class with whom he had a son (August, 1789–1830), created a scandal in the distinguished and aristocratic city of Weimar. By this time, Goethe had completed his major body of literature, and therefore important works such as *Wilhelm Meister's Lehrjahre (Wilhelm Meister's Apprenticeship), Faust I,* and *Die Wahlverwandtschaften (Elective Affinities)* had already appeared when he published his scientific study *Farbenlehre (Color Theory)* in 1810. Goethe considered this study his principal work; however, this claim met with much disapproval.

Goethe's contemporaries described him as a disciplined, stately man, although they often deplored his crooked teeth; he was, however, often ill. For example, he suffered a heavy hemorrhage due to tuberculosis as a student. He also had chronic kidney disease as well as facial neurosis, and in 1823 he suffered his first cardiac infarction. Sometimes people speak of Goethe's "healthy depression." He himself argued that misfortunes and sufferings form human beings. In his comprehensive, collection of 400 poems, *West-östlicher Divan (West-Eastern Divan)*, from 1819, he states:

> Wenn der schwer Gedrückte klagt:
> Hilfe, Hoffnung sei versagt,
> Bleibet heilsam fort und fort
> Immer noch ein freundlich Wort.
>
> [Should the one oppressed bewail:
> That both help and hope must fail,
> Remedy that's still preferred
> Is an ever-friendly word.]
>
> From "Hikmet Nameh: Buch der Sprüche"
> ["Hikmet Nameh: Book of Proverbs"]

GRAMSCI, ANTONIO

(1891–1937)

Italian politician and theorist

Antonio Gramsci was a revolutionary from a poor Sardinian family who cofounded the Italian Communist Party in 1921 and inspired the Eurocommunist movement after 1945. His writings stress civil society, culture, praxis, and the struggle for intellectual "hegemony"—by which ideas become accepted as "normality" or are challenged.

Gramsci had a spinal deformity and never grew to average stature. As a child, he was strapped into a harness and suspended from the roof of a barn to "straighten him out." His impairment excluded him from military service, hence he became prominent in the Italian workers' movement in 1917 after other leaders were either mobilized or arrested. Elected to Parliament, he gave speeches that commanded attention for their content, not their force.

In 1926, Gramsci was arrested by the Fascists. At his trial, the prosecutor said, "We must prevent this brain from functioning for twenty years" (quoted in Fiori 1970:24). Although imprisonment segregated him from politics and ruined his health, it did not stop him from producing seminal Marxist analyses of history and culture in the form of the *Prison Notebooks,* which were later smuggled out of his cell. Gramsci's idea of the "organic intellectual" who expresses and defines the will of a movement still has resonance within disability studies.

GROUP THERAPY

The concept of group therapy covers a wide range of therapeutic (mainly verbal) activities in which people gather in professionally led groups to ameliorate suffering caused by psychological or somatic problems or difficult social circumstances. The field has multiple origins, and current theory and practice integrate material from different disciplines, including psychiatry, psychology, sociology, education, social work, and organizational theory.

Therapy groups have been used in medicine in a systematic way since the beginning of the twentieth century. Joseph Pratt, a Boston internist, is considered to be one of the pioneers, as he in 1905 gathered his tuberculosis patients in groups to teach them behavior and home-care measures he thought were crucial for the cure of their illness.

Therapy groups can be distinguished according to a number of different characteristics, including the following: They may make therapeutic use of the specific forces created by the group situation (dynamic, process-oriented groups) or they may use the group setting primarily as a time-saving device to deliver a message to several persons at the same time (didactic groups), they may be time limited or long-term, they may be closed or open for new members, and they may be homogeneous (e.g., only women, elders, or alcoholics) or heterogeneous (both sexes, different diagnoses, different ages). Group therapy may be the only treatment offered for a certain disorder, or it may be given in combination with other forms of treatment, such as medication or individual psychotherapy. It is also offered in many different settings, such as during hospitalization, in outpatient clinics, or in private practice. Most forms of group therapy involve a small group (6–10) of participants led by one or two therapists.

During the past few decades a wide array of self-help groups have appeared. These groups, which are based on principles of social support and mutual validation, may be very useful for patients and their families alike. Although such groups do not provide group therapy in a strict sense, they provide considerable benefit and reduce the amount of disability associated with chronic illness.

The goals of group therapy vary greatly and are related to the types of problems and levels of psychopathology of group participants (e.g., personality change, reduction in destructive drinking, improvement of social skills, learning to live with a chronic mental or somatic illness, or working through traumas). The effectiveness of group therapy for a wide range of different psychiatric/psychological disturbances has been documented through clinical experience and empirical research and can be summarized as follows: Group therapy is as effective as individual therapy for many conditions; group therapy based on cognitive behavioral theory may be most effective for specific disorders (e.g., social phobia), but for most disorders the empirical evidence for differential efficacy among various theoretical approaches (psychoanalytic, interpersonal, psychodrama) is not convincing. One reason for the current lack of clarity is that long-term (usually psychoanalytic) group therapy has been studied far less than short-term therapy.

GUGGENBÜHL, JOHAN JACOB (1816–1863)

German-Swiss physician

Johan Jacob Guggenbühl was, during his lifetime, one of the best-known men of science in Europe and America. In 1840, he opened a medico-pedagogical asylum for cretins on the Abendberg overlooking the village of Interlaken in the Bernese Alps of Switzerland. Combining an approach to education based on the senses, evangelical Protestant faith, and a spirit of experimentation in medical matters (dietetics, naturopathy, heliotherapy, electrotherapy), he was able to attract the support of physicians, educators, and philanthropists such as Father Grégoire Girard and Philippe-Emmanuel de Fellenberg. There were numerous visitors to the "holy mountain," fascinated as much by the beauties of nature as by the work of this "savior of the cretins" and as much by the professor's "system" as by the myth of the cretins' healing mountain.

The success met by Guggenbühl between 1840 and 1856, the date of the closure of "his" Abendberg, was equaled only by the doubts raised by this same success and the oblivion into which his pioneering work fell after his death in 1863. This neglect lasted until the rehabilitation of his reputation in 1905. Since that time, Guggenbühl has been recognized by history for the groundbreaker that he was: the founder of care for the mentally impaired in Switzerland, the precursor of medico-pedagogical treatment, and the pioneer of paedopsychiatry, even of sociotherapy.

GUILLAIN-BARRÉ-STROHL SYNDROME

Guillain-Barré-Strohl syndrome (GBS) is the most commonly employed eponym for acute inflammatory demyelinating polyradiculoneuritis—inflammatory loss of the outer coating (myelin). It is termed *polyradiculoneuritis* because it tends to affect a large number and variety of nerve types. Peripheral nerves are all of the nerves that connect the central nervous system (brain and spinal cord) to the rest of the body. These nerves carry orders for motor movement or sensory information back to brain and spinal cord. They also send information back and forth to the brain and spinal cord that regulates the automatic functions of the body, such as muscle tone, balance, blood pressure, breathing, temperature regulation, reaction of pupils, bowel function, bladder function, and sexual function. Therefore, with the loss of myelin—and in severe cases the nerve fiber (axon) itself—these important functions may be disturbed or lost.

Occurring worldwide and in all seasons, GBS is the most common cause of acquired dysfunction of the peripheral nervous system, with 30,000 to 500,000 cases each year. It was not clinically recognized until Jean-Baptiste Landry of France gave the earliest systematic description in 1859 of the most common type, onset in the feet with ensuing ascending paralysis. Many decades later GBS was clearly set apart from poliomyelitis, a clinically similar condition. GBS, it would be discovered, is a disease of the peripheral nerves themselves and includes both motor and sensory dysfunction since both modalities are carried in peripheral nerves. It would also become clear that GBS tends to be symmetrical, to be more gradual in onset than poliomyelitis, and to have better recovery rates.

The names of Georges Guillain, Jean-Alexandre Barré, and André Strohl are commemorated in the name of the disease because their detailed description of it made the clinical distinction between GBS and poliomyelitis quite clear *and* because they described test findings that distinguished the two conditions. They found that protein concentration is elevated in spinal fluid in GBS as it is in polio, but that, unlike in polio, very few inflammatory white cells are found in the cerebrospinal fluid of GBS patients. This finding remains important in diagnosis of GBS to this day. The distinction of GBS from poliomyelitis was a very important contribution to the understanding of the hierarchical organization of the nervous system.

GBS is an acute autoimmune condition. A respiratory or gastrointestinal infection usually occurs days to weeks before the onset of GBS. This infection appears to cause the immune system to mount an attack against myelin by way of a protein target. One theory suggests that this occurs because of (a) the expression of a similar protein on the surface of that particular infecting organism and (b) the fact that the protein on the invading organism has been selected as the target of the immune response that is attempting to destroy the invading organism.

People who develop GBS may be more vulnerable to an autoimmune attack either because of the inheritance of an immunoregulatory weakness or because they have delayed development of an inherited protection against autoimmunity. A third possibility is that experiences such as early childhood infections help the immunoregulatory system to develop properly and that individuals without the right kinds of such experiences may be more vulnerable to autoimmunity. For unknown reasons, males are at greater risk for GBS than females. Stimuli other than infection may also provoke GBS; these include such things as immunizations, bee stings, pregnancy, malignancies, and even other kinds of autoimmune conditions, an important example of which is systemic lupus erythematosis.

In GBS, a complicated cascade of immune manifestations attacks patches of myelin along the course of these nerves and, by removing this important nerve covering (which is somewhat analogous to insulation), may severely disrupt transmission along the central part of the nerve, the axon (more closely analogous to an electrical wire). In the most common ascending form of GBS, this can cause loss of all motor and certain sensory functions, particularly those governing joint position sense, that are involved in finding one's way while walking in the dark. In severe cases of GBS, the axon itself may be injured by intense inflammation, the importance of which is that although the recovery from demyelination may be excellent, recovery from axonal injury often is not.

Weakness ascending from feet to higher locations is usually the earliest and most noticeable sign of GBS. Progression to maximal weakness generally takes less than four weeks, usually about 12 days, followed by a period termed the *plateau.* If disease ascends high enough in the trunk, it may imperil breathing. Tendon reflexes are usually lost. In addition to sensory loss, odd sensations called *paraesthesiae* develop in about 70 percent of cases. Unsteadiness develops in many cases, due to weakness and sensory abnormalities. There is usually no fever as GBS develops. Various automatic cardiovascular, gastrointestinal, urinary, sexual, sweating, and other functions are lost in 25 percent of cases, and in some these losses may not be recovered. Changes in blood pressure and heart rhythm are particularly serious and, together with loss of breathing, are the most important causes of death in GBS. Many patients experience mild to severe pain. Sophisticated electrophysiological tests that involve electrical stimulation of muscles are positive in 90–99 percent of GBS cases.

It is of the greatest importance that GBS patients be carefully monitored for the development of serious complications such as failure of breathing (20 percent of cases), swallowing, and blood pressure fluctuations. Skillful management must be provided to prevent serious consequences of such deficits. Even without such potentially dire events, support must be provided for other disabilities, including management of problems with bowel and bladder function and prevention, in bed-bound patients, of the development of bedsores. Emotional support is also quite important. The onset of recovery in GBS usually starts within two to four weeks of onset of the plateau. Most patients, particularly children, who have sufficient support recover well from GBS without other interventions. However, there are treatments aimed at correcting the autoimmune process itself. These include use of anti-inflammatory drugs and techniques to remove circulating immune complexes from plasma. Some of these appear to shorten the duration and perhaps the severity of the disease.

Recovery may be a long process during which carefully designed physical, occupational, and other therapies may be important and provision must be made for residual automatic functions, particularly bladder and bowel problems. Disappointingly, many patients whose recovery is otherwise excellent have residual urinary or sexual deficits. Once the individual is ambulating well, it still may require many months before a sense of fitness and loss of excessive fatigue are achieved. Individuals who have had significant axonal involvement recover even more slowly, although as many as half of these recover completely within a year. A small number of patients who are initially labeled GBS turn out to have a difficult-to-manage chronic and recurrent peripheral neuropathic condition termed *chronic inflammatory demyelinatig polyneuropathy.*

—Robert S. Rust Jr.

▣ GUTTMANN, LUDWIG
(1899–1980)
German-English physician

Commonly known as "the founder of the Paralympic movement," Ludwig Guttmann was born in Upper Silesia, Germany, in 1899. He studied medicine and neurosurgery in Breslau and arrived in England as a refugee in 1939. As head of the Stoke Mandeville

Spinal Injuries Unit in Aylesbury from 1944 until 1966, he championed the concept of early treatment for injured servicemen in specialized spinal units and promoted the use of compulsory sport and physical activities as a form of rehabilitation, integration, and motivation.

Guttmann organized the first Stoke Mandeville Games for the Paralysed, held on July 28, 1948 (to coincide with the 1948 Olympic Games); that first event involved 16 competitors. The Games became international in 1952, and he founded the International Stoke Mandeville Games Federation (ISMGF), now the International Stoke Mandeville Wheelchair Sports Federation (ISMWSF). In 1960, the first Paralympic Summer Games were held in Rome following the Olympic Games, and the first Paralympic Winter Games followed in 1976.

Guttmann served as president of the International Sports Organization for the Disabled (ISOD) and as president of the International Medical Society of Paraplegia; he also founded the British Sports Association for the Disabled. Throughout his life, he worked to help integrate people with disabilities into society. Even after his retirement, he helped build facilities for athletes with disabilities. Among his many awards and honors, Guttmann was knighted in 1966.

GUTZLAFF, AGNES

(CA. 1836–1869?)

Chinese missionary and educator

"Agnes Gutzlaff" was the name given by Carl and Mary Gutzlaff to one of several young blind Chinese girls, orphaned or abandoned, whom they adopted while in Macau in the 1830s. She was sent to London for formal education at the London Blind School, enrolling on January 3, 1842, at age five and a half. Agnes completed 13 years of education in London and shortly afterward returned to China as a missionary to teach blind people, almost certainly the earliest trained missionary with such a role. She joined Miss Aldersey at Ningpo in June 1856, learned the local language, and began teaching blind children and adults to read using materials first in Lucas's symbols and then in Moon's embossed script. After Miss Aldersey retired, Agnes moved to Shanghai, living and working there independently from 1862 until her death around 1869. "She worked hard, lived sparingly, and saved money, and at her death her property was left to found a hospital called by her name" (*Fortieth Report* 1878). The "Gutzlaff Hospital," in a back street of the English settlement in Shanghai, was a small, low-budget, general-purpose institution. It was later incorporated into St. Luke's Hospital.

H

HANAWA, HOKIICHI (1746–1821)

Japanese bibliographer

Hokiichi Hanawa, the son of a humble farmer, lost his eyesight in early childhood. At age 13 or 14, he went to Edo (now Tokyo) and enrolled at a private school for blind youths, under Ametomi Kengyō. Hokiichi should have learned music and acupuncture, but it seems that he did not gain much proficiency in those skills. He succeeded in memorizing much Japanese classical literature under a famous teacher, Kamo no Mabuchi, who had just retired from active service. Later, Hokiichi became a notable professor of literature.

Hokiichi spent many years editing documents to compile the vast *Gunsho Ruijū* (*Classified Collection of Japanese Classics*) (1779–1819), in 530 volumes containing more than 1,200 books and documents. He was also obliged to raise funds over a long period to produce the collection from wooden printing blocks. Hokiichi is recognized as one of the founders of modern bibliographical work in Japan, setting high standards in a field that most people would have thought unsuitable for a blind person.

HAND AND ARM MANIPULATION

Hand manipulation is the action of using the distal portion of the arm and involves skillful use of the hand and fingers on objects in the environment. It includes "dexterous grasp and release patterns, isolated finger movements, and coordinated in-hand manipulation patterns when interacting with task objects" (Fisher 2003:195). Hand manipulation is a skill that contributes to functional performance and enables an individual to perform activities of daily living.

Problems with hand manipulation may be observed as "difficulty manipulating task objects, limited dexterity or difficulty with in-hand manipulation" (Fisher 2003:195) and may cause disruption of task performance or result in inefficient use of time or increased effort. This may result in the individual adapting posture and position of the body in relation to the object being manipulated.

Hand and finger manipulation deficits can be managed by either improving the actual skill or by compensating for the impairment. Compensatory strategies might include the following:

> Change the demands of the task (e.g., restructuring the time spent on a task on any given instance).
>
> Modify the environment (e.g., the social environment can be modified so that another individual can perform those tasks that require manipulation).
>
> Use other parts of the body (e.g., using a mouth stick to type in the absence of adequate or lack of hand manipulation).

Provide adaptive equipment (e.g., splints and other orthotic devices, gadgets such as an electric can opener, and electronic equipment).

HANDICAP

The term *handicap* was used during the twentieth century to apply both to the impairments of individuals and to certain ways of evening the chances of success among contestants in sporting contests. With the rise of the disability rights movement in the past quarter of the century, the term's association with paternalistic attitudes toward disability has made *handicap* objectionable to many activists. Folk etymologies have grown up to explain why the term is offensive. It is often claimed that the original meaning of handicap referred to the fact that people with impairments could make a living only by begging, "cap in hand." This etymology is mistaken. The *Oxford English Dictionary*, the best etymological source on the English language, shows a much more interesting and complex history of the term.

Handicap originally referred to a sort of gambling game, practiced between the fourteenth and seventeenth centuries. One move in the game involved two contestants placing their hands in a cap and removing them at the same time, either open or closed (hence "hand in cap"). The game involved estimating the difference in value between two items. Some value (called the "boot" or "odds") was added to one item to make it equal in value to the other. During the seventeenth century, the technique of equaling the values of two items by addition of a boot was adopted in horse racing. A "handicap race" is one in which the faster horse carries extra weight. The game of golf adopted a system in which less skilled golfers were allowed to deduct strokes from their score, to be competitive with more skilled opponents. In horse racing and the gambling game, the term *handicap* referred to the game itself, not to the factor (the boot) that evened its outcomes. In golf, the handicap is a benefit for the less skilled, not a penalty on the more skilled.

In the late nineteenth century, the term came to be applied to disadvantages themselves, though not yet to impairments. The first recorded use with respect to impairments was in a 1915 poster labeled "the Handicapped Child."

Impairments were commonly called handicaps during the twentieth century, but the older sporting uses continued. In 1980, the World Health Organization (WHO) introduced another new definition according to which *handicap* referred not to an impairment itself but to the disadvantages that resulted from social discrimination against people with impairments. But by this time the term was distasteful to many. *Handicap* was offensive by association. The folk etymologies about "cap in hand" begging are mistaken, but they reflect a very real distrust of traditional attitudes toward disability.

Unfortunately, the loss of the term *handicap* creates a semantic vacuum in the American vocabulary of disability politics. British activists (unlike Americans) use the term *disability* to refer to what the WHO called *handicap:* the disadvantages caused by discriminatory treatment of people with impairments. They distinguish between impairments (biological conditions) and disability or disablement (the consequences of social arrangements). Americans use the term *disability* as a synonym of *impairment.* How do Americans refer to the social disadvantages? The 1980 WHO vocabulary had distinguished disability from handicap, the same distinction as the British but with different terminology. But because the term *handicap* was rejected as offensive, both in Britain and the United States, Americans are left without a simple term to designate the disadvantages that social arrangements create for people with impairments.

HANDICAP INTERNATIONAL

Handicap International is an international nongovernmental solidarity organization, founded in 1982 in Lyon, France. The French section is at the origin of an international movement, with sections now existing in Belgium, Switzerland, Germany, Luxemburg, and the United Kingdom and representations in Denmark and the United States. Its goal is to ensure that people with a disability are able to regain their independence and their place in society, particularly in countries with difficult living conditions. The Blue Laces® are the symbol of this. The organization is active in various areas associated with all the causes of handicaps, both traumatological (e.g., land mines, road accidents) and infectious (e.g., polio, leprosy). Handicap International works especially in countries that are experiencing an acute or chronic crisis situation. Its activities are systematically based on a three-part approach: prevention, rehabilitation, and socioeconomic reintegration.

> *Prevention:* Preventing handicaps, for example, by mine clearance and removal of unexploded ordnance, road safety campaigns, and prevention of injuries caused by disabling diseases such as leprosy and polio
>
> *Rehabilitation:* Setting up centers for physical rehabilitation and rehabilitation and offering the required technical aids, physiotherapy, and rehabilitation programs
>
> *Reintegration:* Facilitating the reintegration of people with a handicap into their social environment by offering education and vocational training in a targeted way, promoting social reintegration, and improving the rights of people with a handicap

Handicap International works with local partners and government bodies within a contractual framework and helps them to take over the project after a specific period of time. Seventy percent of financial resources come from institutional funds and 30 percent from private donations.

Its activities began in 1982 when the first orthopedic centers opened in refugee camps in Cambodia, Thailand, Myanmar (formerly Burma), and Laos to help several thousand amputees. The use of simple and locally available materials is one of the major strengths that allows Handicap International to bring quick and efficient help and to train competent local teams. By 1986, the organization realized that providing artificial limbs is not enough, and consequently, it moved toward a more global approach to disability by creating networks of local educational workers and strengthening family and community groups.

By the beginning of the 1990s, the disability issue became enlarged to include people in situations of exclusion and vulnerability. Actions to prevent disability were undertaken. Handicap International started working on mental disability issues as a result of experiences with Romanian orphanages and the war in the Balkans. In 1992, the organization created its first two mine clearance programs in Cambodia and Kurdistan and took part in the creation of the international campaign to ban land mines.

The period 1993–1995 was characterized by the development of partnerships, both locally and internationally. National orthopedic and physiotherapy centers opened in various countries. Training leading to a degree was set up in Cambodia, Mozambique, and West Africa. Between 1996 and 2002, Handicap International took part in the development of national policies in favor of disabled people. In 1996, the organization received the Nansen Prize, the highest prize given by the UN High Commissioner for Refugees. A high point in its organizational history, the organization was the joint winner of the 1997 Nobel Peace Price for its leading role in the fight against land mines.

HANSELMANN, HEINRICH

(1885–1960)

Swiss educator and author

The Swiss special education pedagogue Heinrich Hanselmann was born in Wald bei St. Peterszell

(St. Gallen). Hanselmann was based out of Zurich. There, he was a cofounder of the Heilpädagogische Seminar (Special Education Seminar) and took over the direction of this special education training center in 1924. At the same time, Hanselmann and his wife, Annie (née Heufemann), founded and ran the appropriately named Landerziehungsheim für Schwererziehbare und Entwicklungsgehemmte (State Home for the Education of the Learning and Developmentally Disabled) in Albisbrunn bei Hausen am Albis (Zurich). In 1930, a year after he published his chief work, *Einführung in die Heilpädagogik* (*Introduction to Special Education*), Hanselmann was promoted to Extraordinary Professor of Special Education at the University of Zurich. He held this position, which was the first of its kind in Europe, until 1950. He died in 1960 in Locarno (Ticino).

The concepts of special education or special education pedagogy and *inhibited development* (as a synonym for *disability*) go back to Hanselmann, concepts that are still customary to use in German special education theory. In addition, he stressed that we should consider the question "Who is normal?" before we can occupy ourselves with the objectives and goals of special education. Special education has to focus on the whole person. For example, it is wrong to describe visually or hearing-impaired people as "so-called normal, albeit without the visual or auditory senses."

Hanselmann tried to popularize his views on special education. He supervised a private office for educational and marriage counseling and wrote columns in popular magazines, despite the fact that such behavior irritated many of his professional colleagues. Hanselmann saw himself as an educator of the people, following the tradition of Johann Heinrich Pestalozzi (1746–1827). His writings were accessible to most readers and were therefore widely disseminated. They carried such titles as *Sorgenkinder, daheim und in der Schule* (*Problem Children, at Home and in School*) (1934) and *Vom Sinn des Leidens* (*Making Sense of Suffering*) (1934). Through such disciplinary transgressive actions, Hanselmann hoped to be able to abolish the "Inselhaftigkeit der Heilpädagogik" ("solitariness of special education"), which he criticized.

HATHAWAY, KATHARINE BUTLER (1890–1942)

American author

Katharine Butler Hathaway was born in Baltimore, Maryland. At the age of five, she contracted tuberculosis of the spine. To prevent the infection from causing any deformities, Hathaway spent the next 10 years of her life strapped to a stretcher. After being liberated at the age of 15 feeling that her incarceration was completely in vain due to a residual curvature, Hathaway and most of her family fell under the assumption that her deformity and resultant impairments would prevent her from ever gaining a "normal" life (i.e., getting married and having children). Yet, despite the unavoidable internalizations of societal stereotypes regarding disabled people, Hathaway's journeys as a single, disabled young woman proved a hidden benefit, which allowed her to throw herself into her creative writing and artistic endeavors.

The Little Locksmith: A Memoir, first published in 1943, reflects the internal conflicts of being a disabled woman. Struggling with her body's difference, Hathaway nevertheless feels blessed that it has granted her an independence few of her contemporary able-bodied women were allowed. Having lived during the height of the eugenics movement in the United States, Hathaway's memoir reflects her unease at being a disabled person when people with disabilities were so disposable. Yet she recognizes that her society tends to be very ignorant with respect to the lives of disabled people. Throughout *The Little Locksmith,* Hathaway is continually revising the assumptions surrounding disability, sexuality, and gender, allowing the memoir to become a mode of resistance and social redress with respect to disability. By presenting her “counterstory,” she helped to challenge the power of eugenic master narratives and the subsequent demise of the disabled body.

HAÜY, VALENTIN (1745–1822)

French pedagogue

Valentin Haüy devoted his life to the education of the blind and created the first school for the blind in Paris, which served as a model for the entire world.

The brother of the founder of crystallography, Valentin Haüy perfected a system of raised letters (and not dots, as in Braille). From his concern that the blind not be reduced to begging, in 1784 he opened, at his own expense, the first free school in Paris for blind young boys and girls. With the support of the Philanthropic Society, this school became the Institution for Blind Children. It was nationalized during the French Revolution, and in 1791, by the decree of the Constituent Assembly, became the National Institute for Blind Young People (INJA, Institut National des Jeunes Aveugles).

An important member of the Arsenal section during the Revolution, he was one of the leaders of the theophilanthropic movement under the Directory. This was a cult of natural religion devoted to “bringing hearts together by preaching mutual indulgence and forgiveness of all wrongs.” Disagreeing with the trends taken by the Institution, which was progressively losing its educational character to the detriment of professional activity, he preferred leaving his post in 1802. Soon afterwards, he left Paris to devote himself to the education of the blind and deaf-mute at the request of the Russian czar. He lived in Russia from 1806 to 1817. When passing through Berlin in 1806, he inspired the creation of the Berlin School for the Blind and founded a similar school in Saint Petersburg in 1808.

HAY, WILLIAM (1695–1755)

English author

William Hay, author and member of the House of Commons as a loyal Whig from 1734 until his death, was arguably the first person in the history of English letters to claim disability as an identity in print. Attacked by smallpox as a young man, which left him both visually impaired and visibly scarred, a hunchback barely five feet high, Hay nevertheless insisted on accurate portraiture. His complete works contain a variety of political, religious, and belle-lettristic pieces, most important, “Deformity, An Essay” (1754), written in response to Francis Bacon’s influential “Of Deformity.” Fusing the scientific impulse to objectify “nature” with the premodern belief in disability as mark of divine punishment, Bacon argued that deformed persons, marked by nature, and “void of Natural affection, are “commonly even with nature” by acts of antisocial “revenge.” Removing deformity from the register of variable interpretation to that of scientific hypothesis, Bacon concluded, “It is good to consider of Deformity, not as a Sign, which is more Deceivable; But as a Cause, which seldom faileth of the Effect.” Hay contests Bacon’s theory by joining an alternative essayistic tradition of self-exposure practiced by his professed models, Michel de Montaigne and Alexander Pope, interpreting his deformity as a source of ineffable subjectivity and exemplary self-knowledge.

Balancing Christian stoicism with gentlemanly civility, he begins with a desire to "lay open my own Heart to the Reader" and concludes with the demand that his body be autopsied after death, "so that Mankind may be informed" of the effect of ingesting castile soap on bouts of the stone (kidney stone). Hay's deformity is a sign at the crossroads of literature and science; the ultimate evidence of his humanity is the clinical exposure of his body's interior in proof of a common disease.

HEALTH

The concept of health is the most central concept in medicine and in the health sciences in general. Health is, indeed, the foremost goal of medicine (Pellegrino and Thomasma 1981; Callahan and Hanson 1999). Health also has a prominent position in many life contexts and is a crucial condition for maintaining and executing a profession, for enjoying leisure activities, and indeed, for living a good life in general. For example, health is a formal prerequisite for performing certain tasks or taking up certain occupations, such as that of soldier, police officer, or firefighter. More compelling is the place of mental health as a condition for moral and criminal culpability.

It is significant that, in modern secular society, health has gained an extremely high position in many people's value hierarchies. A Swedish group of researchers (Kallenberg, Bråkenhielm, and Larsson 1997) asked a representative sample of Swedes what are the highest values in their lives. A vast majority of these people put health at the top of their lists, which also contained such values as wealth, high social status, and good family relations. This social judgment can be contrasted with the ancient Platonian more restricted evaluation of health. According to Plato, it is an unsound condition in a society when people concentrate on their health and want to consult a physician anytime and about any question (*The Republic*).

Etymologically, health is connected with the idea of wholeness. This is evident in the verb *heal*, with the sense of regaining wholeness. The healthy person is a person who is whole in the sense of having all the properties that should pertain to a human being. Health has thus traditionally been viewed as an ideal notion, a notion of perfection that very few people, if any, can completely attain. Today, health also sometimes functions as an ideal notion. This is, indeed, the case with the formulation of health by the World Health Organization (WHO) in its initial declaration, published in 1948: "Health is a state of complete physical, mental and social well-being and not only the absence of disease or injury."

The notion of health is the object of scientific study from several points of view and within several disciplines. Besides research by those in medicine, public health, nursing, and other paramedical disciplines, other investigations are based in anthropology, psychology, sociology, and philosophy. In some of these disciplines, the focus is on a particular aspect of the notion: for example, in psychology, the experience of health and illness, and in anthropology and sociology, health and illness as factors of social importance. Philosophical analyses of health have often involved an attempt to formulate global definitions of the idea. Thus, in the following, many references will be taken from philosophical theories of health.

THE VARIETIES OF HEALTH

Health, thus, is a notion primarily applicable to a human being as a whole. On the other hand, there are more specific derivative notions. Ever since antiquity, and reinforced by the Cartesian distinction between body and mind, it has been natural to separate somatic health from mental health. The interpretations of mental health have varied over time. The ancient notion of mental health was closely connected to morality, whereby the mentally healthy person was a person who lived a virtuous life, but this idea has lost most, though not all, of its significance today. The idea of spiritual health is also current in the health sciences although it is not systematically recognized. Bernhard Häring (1987:154) is a leading spokesman for a notion of health including a spiritual dimension: “A comprehensive understanding of human health includes the greatest possible harmony of all of man’s forces and energies, the greatest possible spiritualization of man’s bodily aspect and the finest embodiment of the spiritual.”

The various categories of health have connections to each other. Sometimes bodily health has been given priority in the sense that it has been viewed as a prerequisite for mental health. Galen (AD 129–ca. 199/216) in some of his writings attempted to explain mental properties of the person in terms of specific mixtures of the bodily parts (Galen 1997). Consider also the ancient proverb: *mens sana in corpore sano* (a healthy mind in a healthy body). In the modern discussion about mental illness, one position, favored in particular by medical doctors, is that all mental illness has a somatic background, that is, all mental illnesses—if they exist at all—are basically somatic diseases (Szasz 1974). The customary view, however, also in Western medicine, is that a person can at the same time be somatically healthy and mentally ill, or vice versa.

HEALTH AS ABSENCE OF DISEASE

Although health is often described in nonmedical terms and with reference to nonmedical contexts, it has its primary place and function as a medical concept. Health in the medical arena is contrasted in particular with disease, but also with injury, defect, and disability. Culver and Gert (1982) have coined the term *malady* to cover the negative antipodes of health. In many medical contexts (Hesslow 1993), and in some philosophical reconstructions of the notion of health (Boorse 1977, 1997), health has been defined as the absence of diseases or the absence of maladies. The perfectly healthy person therefore is the person who does not have any diseases or maladies.

If one looks at the relationship between the concepts in this way, the burden of definition lies on the negative notions. Christopher Boorse (1997), for instance, defined disease in the following terms: “A disease is a type of internal state which is either an impairment of normal functional ability, i.e. a reduction of one or more functional abilities below typical efficiency, or a limitation on functional ability caused by environmental agents.” The notion of functional ability, in this theory, is in turn related to the person’s survival and reproduction, namely, his or her fitness. From this analysis follows that we need not use the notion of disease to define health. The same idea can be formulated in the following positive terms: A person is completely healthy if, and only if, all his or her organs function with at least typical efficiency (in relation to survival and reproduction).

This idea of natural function is similar to, but not identical with, the one proposed by Jerome Wakefield (1992 and later), where the platform for analysis is biological evolutionary theory. The natural function F of an organ is, according to this idea, the function for which it has been designed through evolution. This means that the species in question (e.g., the human being) has been able to reproduce through history with the genetic setup for the function F. This idea has been criticized partly because it relates the idea of health in the present context to developments in the past.

HEALTH, DISEASE, AND ILLNESS

In many contributions to the theory of health, a distinction is made between the concepts of disease and illness (Boorse 1975; Twaddle 1979; Fulford 1989). The general idea behind this distinction—although it has been made in different ways by different authors—is that a disease is a deranged process in the person’s body, whereas an illness is the person’s negative experiences, for instance, pain or anguish, as a result of the disease. In addition, some theories include disability in illness; see below. The distinction between disease and illness has proved useful in several contexts, including the clinical one (Hellström 1993), for separating the disease as a pathological phenomenon from its impact on the person as a whole. (For a criticism of the distinction between disease and illness, see Sundström 1987.)

HEALTH AS BALANCE

An extremely powerful idea in the history of medicine is the one that health is constituted by bodily and mental balance. The healthy person is a person in balance, normally meaning that different parts and different functions of the human body and mind interlock harmoniously and keep each other in check. The Hippocratic (428–347 BCE) and Galenic schools were the first Western schools to develop this idea in a sophisticated way. They stated that a healthy body is one where the primary properties (wet, dry, cold, hot) of the body balance each other. In the medieval schools, following Galen, this idea was popularized and formulated in terms of a balance between the four bodily humors: blood, phlegm, yellow bile, and black bile (cf. humoral pathology).

The idea of balance is strong in several non-Western medical traditions. The *yahurveda* tradition in India, for instance, declares that there are three humors acting in the body, the breath (*vata*), the bile (*pitta*), and the phlegm (*kapha*). The proportions of the three humors vary from person to person, and their actions vary according to the season, the environment, the lifestyle of the individual, and his or her diet. In good health, the humors are in equilibrium. Disease is the result of their imbalance (Singhal and Patterson 1993).

Balance is a powerful idea also in modern Western thought, in particular, within physiology. The idea is often recognized under the label of *homeostasis* (the Greek word for balance). Walter Cannon's (1871–1945) classical work on homeostasis (1932) described in detail how the various physiological functions of the body control each other and interact in feedback loops to prevent major disturbances.

The idea of balance or *equilibrium* (the Latin word for balance) has a rather different interpretation in the writings of Ingmar Pörn (1993). Here balance is a concept pertaining to the relationship between a person's abilities and his or her goals. The healthy person, according to Pörn, is the person who can realize his or her goals and thus retain a balance between abilities and goals (cf. health as ability, below).

HEALTH AS WELL-BEING

It is an important aspect of health that the body and mind are well, both in order and function. But we may ask for the criteria of such well-functioning. How do we know that the body and mind function well? When is the body in balance?

A traditional answer is that the person's subjective well-being is the ultimate criterion (Canguilhem 1978). Simply put, when a person feels well, then he or she is healthy. This statement certainly entails problems, since a person can feel well and still have a serious disease in its initial stage. The general idea can, however, be modified to cover this case too. The individual with a serious disease will sooner or later have negative experiences such as pain, fatigue, or anguish. Thus, the ultimate criterion of a person's health is his or her present or future well-being. (For a different approach suggesting that complete health is compatible with the existence of disease, see Nordenfelt 1995 and 2000.)

It is a difficult task to characterize the well-being constituting health. If one includes too much in the concept, there is a risk of identifying health with happiness. It is, indeed, a common accusation directed against the WHO definition that it falls into this trap. Health cannot reasonably be identical with complete physical, mental, and social well-being, many critics say. The absurd conclusion of this conception could be that all people who are not completely successful in life would be deemed unhealthy.

Some authors (Gadamer 1993; Leder 1990) have pointed out that phenomenological health (or health as experienced) tends to remain as a forgotten background. Health is in daily life hardly recognized at all by its subjects. People are reminded of their previous health first when it is being disrupted, when they experience the pain, nausea, or anguish of illness. Health is "felt" only under special circumstances, the major instance being after periods of illness when the person experiences relief in contrast to the previous suffering.

Thus, although well-being or absence of ill-being is an important trait in health, most modern positive characterizations of health have focused on other traits. One such trait is health as a condition for action, that is, ability.

HEALTH AS ABILITY

A number of authors in modern philosophy of health have emphasized the place of health as a foundation for achievement (Parsons 1972; Whitbeck 1981; Seedhouse 1986; Nordenfelt 1995; Fulford 1989). In fact, they argue, in partly different ways, that the dimension of ability/disability is the core dimension determining whether health or ill health is the case. A healthy person has the ability to do what he or she needs to do, and the unhealthy person is prevented from performing one or more of these actions. There is a connection between this conception and the one that illness entails suffering. Disability is often the result of feelings such as pain, fatigue, or nausea.

The formidable task for these theorists is to characterize the set of actions that a healthy person should be able to perform. Parsons (1972) and Whitbeck (1981) refer to the person's wants, that is, the healthy person's being able to do what he or she wants, Seedhouse (1986) to the person's conscious choices, and Fulford (1989) to such actions as could be classified as "ordinary doings." Nordenfelt settles for what he calls the person's vital goals. These goals need not be consciously chosen (babies and people with dementia have vital goals). The goals have the status as vital goals because they are states of being that are necessary conditions for the person's happiness in the long run. Health in Nordenfelt's theory is thus conceptually related to, but not identical with, happiness.

Although it is evident that health, as ordinarily understood, is connected with ability and ill health with disability, one may still doubt whether the dimension of ability/disability can remain the sole criterion of health/ill health. An important argument concerns those disabled people who are not ill, according to common understanding, and who do not consider themselves to be ill. These people are to be classified as unhealthy according to the ability theories of health.

One answer to this question (Nordenfelt 2001) is that disabled people (given that their disability is assessed in relation to their individual vital goals) are all unhealthy. However, they are not all ill and they do not all have diseases. Another answer, proposed by Fredrik Svenaeus (2000), is that there is a phenomenological difference between the disabled unhealthy person and the disabled healthy person. The unhealthy person has a feeling of not being "at home" with regard to his or her present state of body or mind. This feeling is not present in the case of the disabled in general.

HEALTH AND VALUE: NATURALISTS AND NORMATIVISTS

A crucial theoretical problem in the characterization of health is whether this notion is a scientific one. One can ask whether health and its opposites can be given a neutral, rather than value-laden, description, or whether it follows by necessity that health is to be characterized as a "good" bodily or mental state. Proponents of the former view are often called naturalists, whereas proponents of the latter view are often called normativists.

Different theorists have arrived at different conclusions with respect to this issue. Boorse (1977, 1997) claimed that there is a value-neutral definition of the basic notion of disease. Donald Broom (1993), who analyzed the notions of animal health and welfare, came to the same conclusion. Wakefield (1992) argued for the thesis that the notion of disease has two parts, one of which is value neutral, namely, the one that refers to the natural function of organs. The other part of the concept refers to the value-laden notion of harm. Most other theorists, however, think that the notion of health and its opposites are with necessity value laden. Some argue that these values are universal (Pellegrino and Thomasma 1981), others that the values determining the concepts of health and illness are connected to the background cultures (Engelhardt 1996). The physician/philosopher Georges Canguilhem (1978), who wrote one of the most significant treatises of human health and illness of the twentieth century, though he drew almost exclusively on medical data, came to the conclusion that health is an evaluative concept in a strong sense. The healthy organism, says Canguilhem, is not an organism whose functions are normal in a statistical sense. The healthy organism is one that is "normative," that is, one that is capable of adopting new norms in life.

One can discern further differences in the contention that the notion of health is value laden. Some theorists (e.g., Khushf 2001) claim that the notion is value laden in the strong sense that its descriptive content can vary over time. As a result of this, the only element common to an ancient and a modern concept of health is that health is a "good" state of a person's body or mind. Others, like the ability theorists above, would claim that there is a common descriptive content, namely, the fact that health has to do with a person's abilities but that one needs to make an evaluation in order to specify what aspect or level of ability is required for health.

HEALTH AND CULTURE RELATIVISM

If health is a value-laden concept, then, as we have seen, some would argue that there are differences in the interpretation of health between cultures both historically and geographically. It is important to note that these differences can be more or less profound.

The concepts of health can vary from culture to culture because there are fundamental differences in the basic philosophy of health and health care, as between Western medicine and traditional Chinese medicine or the traditional Indian ayurveda medicine. Western medicine, which is to a great extent based on a naturalistic philosophy of people, arrives easily at a naturalistic understanding of health, whereas oriental schools with a holistic understanding of people in a religious context derive a notion of health that incorporates forces and developments that are partly supernatural.

The ways of and reasons for ascribing health to people may, however, vary even if there is a basic common theory of health and disease. Consider a particular physiological state, the state of lactase deficiency, which has the status of disease in a Western country but not in most North African countries. Lactase deficiency causes, in combination with ordinary consumption of milk, diarrhea and abdominal pain. Thus, in Western countries where people ordinarily drink milk, lactase deficiency will typically lead to illness. Therefore, this state ought to be included in a list of diseases in these countries. In North Africa, however, people rarely drink milk. Therefore, lactase deficiency seldom leads to illness. Consequently, it would be misleading to consider lactase deficiency a disease in this part of the world.

What makes the difference between the Western and the African cultures in this example is not different concepts of health and disease. It is a question of different lifestyles and different environments.

HEALTH AND ILLNESS AS GENDER DEPENDENT

Some theorists contend that the way we define and in general look at health and health care is dependent on our gender (Oakley 1993). This difference is well reflected in the traditional health professions. The traditional doctor is a man who is basically concerned with the physical condition of his patients. He sees his primary task as being to cure the diseases of the patient by use of well-established treatments often in the form of surgery and drugs. The traditional nurse is a woman who is basically concerned with the general well-being of the patient. She sees her primary task as being to care for the person as a whole. Caring, for her, means above all "relating to the ill person as a whole person whose psyche is equally involved with her or his soma in the illness in question" (Oakley 1993:40).

HUMAN BEINGS VERSUS ANIMALS AND PLANTS

Health, disease, and the other central medical concepts are not used only in the human context. We ordinarily ascribe health and disease also to animals and plants. Do we then apply the same concept of health?

In this case, the answers differ. The naturalists, who relate health solely to survival and reproduction, can easily transpose their concept to the world of animals and plants. The same could hold for balance theorists. It is more problematic to use the idea of health as ability or, even more, the idea of health as well-being all over the world of animals and plants. This can serve as an argument in favor of the naturalistic account. On the other hand, it can be argued that there is an enormous difference between the human context and the context of other living entities. Human beings live in complex societies with complex demands and with a system of health care that is supposed to serve the demands. It is no wonder that the concept of human health has evolved in directions quite different from the concepts of health concerning animals and plants.

WORLD HEALTH ORGANIZATION CLASSIFICATION

The WHO has issued roughly every 10 years a version of the International Classification of Diseases, Injuries, and Causes of Death (ICD) (the latest version from 1992 having the changed title "International

Classification of Diseases and Related Conditions"). The purpose of this classification is to provide an international taxonomy and nomenclature for the whole range of diseases and injuries. In the present version, there are 17 classes of diseases and injuries. In addition to this, there is a special heading for external causes of injury and poisoning. This classification plays an important role in medical statistics, in particular the statistics of causes of death.

The ICD fails, however, to reflect the full range of problems that lead people to seek medical help. It stops short at the consequences of disease, such as disabilities and handicaps. The latter are factors that intrude on everyday life and are directly observable by the bearer himself or herself. To fulfill the need for a theory and classification of consequences of disease, the WHO issued a tentative proposal for such a classification in 1980. This was the International Classification of Impairments, Disabilities, and Handicaps (ICIDH), renewed and finally accepted in 1993.

This classification is firmly placed in a health context. The key phenomena classified, impairments, disabilities, and handicaps, are viewed as typical consequences of diseases. This is clearly seen in the definition of the concepts. Disability, for instance, is defined in the following way: "In the context of health experience, a disability is any restriction or lack . . . of ability to perform an activity in the manner or within the range considered normal for a human being" (WHO 1980:28).

As a result of extensive testing and investigation, the ICIDH was finally (in 2001) replaced by a completely new taxonomy. This is the recently adopted International Classification of Functioning, Disability, and Health (ICF). Here the notion of health and its negative counterparts play a different and somewhat diminished role. Health is mentioned as a relevant category, and the ICF proposes definitions for concepts such as health states, health domains, and health conditions. However, since the classification is intended for several uses outside health care, the notions of health and ill health do not play a crucial role in the construction of the classification.

HEALTH CARE AND DISABILITY

The highest objectives of health care systems throughout the world can be framed within the context of the World Health Organization's (WHO) definition of health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity." The WHO Constitution (2004) further states that "enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being" and that "extension to all peoples of the benefits of medical, psychological and related knowledge is essential to the fullest attainment of health."

In addition to the obvious barriers created by issues of loss of mobility and communication deficits, research has established that individuals with disabilities have finance-related problems with access to health care. People with disabilities are more likely to put off or postpone medical care because they cannot afford it (28 vs. 12 percent in a recent U.S. survey). The same survey determined that persons with severe disabilities are almost four times more likely to cite lack of income as the number one reason why they were not able to get care when it was needed versus people with slight disabilities. Individuals with disabilities are four times more likely than people without disabilities to have special needs that are not covered by their health insurance. Meeting the health care objectives of the WHO faces steep barriers for persons with disabilities.

In the context of caring for persons with disabilities (e.g., physical, developmental, cognitive), health care providers' tasks can be described in the following distinct areas: physical access to health care, functional access to health care, fiscal access to health care, effective prevention of health care issues that create or worsen disabilities, effective intervention in the general health care needs of individuals who happen to have disabilities, effective provision of rehabilitation services to address the special needs of persons with disabilities, and equal employment opportunity for professionals with disabilities.

BACKGROUND

Since World War II, emerging social and scientific developments have improved the potential for individuals with disabilities and have had great impact on the provision of health care to this population. There are large, and growing, numbers of persons with disabilities in all parts of the world. While the consequences of disability vary throughout the world, variations in the health care available to persons with disabilities are the result of different socioeconomic circumstances and of the different provisions that nations make for the well-being of their citizens as well as the ignorance, neglect, superstition, and fear that greet such individuals throughout the world. Also, having disabilities is broadly associated with poverty, and poverty compounds the barriers to participation in the routine activities of the general population of a nation.

Since the 1960s, a new concept of addressing both the social and health issues associated with disabilities started to gain ground. The new thinking pointed to the correlation of the limitations experienced by those with disabilities, and the effect of the social and physical environment on those limitations. This thinking expanded during the UN Decade of Disabled Persons (1983–1992) to recognize the necessity of addressing both the individual needs (such as rehabilitation and technical aids) and the shortcomings of the society (various obstacles for participation). In 1975, the UN General Assembly adopted the Declaration on the Rights of Disabled Persons, which included a specific provision establishing the right to medical, psychological, and functional treatment.

In the United States, the Rehabilitation Act of 1973 and the Americans with Disabilities Act (ADA) of 1990 brought the force of the federal government into the effort to establish a clear and comprehensive prohibition of discrimination on the basis of disability.

The 1973 Rehabilitation Act, which covered all providers who were above a certain size and were receiving federal funds, was not as aggressively applied as it could have been and did not stretch to routinely extend the benefits of American health care to all persons with disabilities. Yet it did assert that in providing health, welfare, or other social services or benefits, a provider that is a recipient of federal health care dollars may not, on the basis of handicap,

> Deny a qualified handicapped person these benefits or services
>
> Afford a qualified handicapped person an opportunity to receive benefits or services that is not equal to that offered to nonhandicapped persons
>
> Provide a qualified handicapped person with benefits or services that are not as effective as the benefits or services provided to others
>
> Provide benefits or services in a manner that limits or has the effect of limiting the participation of qualified handicapped persons
>
> Provide different or separate benefits or services to handicapped persons except where necessary to provide qualified handicapped persons with benefits and services that are as effective as those provided to others.

In addition, the Rehabilitation Act mandated the use of assistive aids for those with impaired sensory, manual, or speaking skills, where necessary to afford such persons an equal opportunity to benefit from the service in question.

The ADA had significant impact on the provision of health care to persons with disabilities in the United States. The ADA continues to evolve through regulation and court decisions that extend the determination to make health care accessible to Americans with disabilities, and U.S. health care providers continue to evolve in their efforts to make health care seamlessly available to individuals with disabilities. Today, U.S. health care can be viewed as a leader in the effort to make health care services available to all regardless of disabilities. The effect of these changes in health care for the disabled can be described in several specific areas.

EQUITY: EQUAL ACCESS TO HEALTH CARE

The principle of equal rights implies that the needs of each and every individual are of equal importance, that those needs must be made the basis for the planning of societies, and that all resources must be employed in such a way as to ensure that every individual has equal opportunity for participation. This also applies to the provision of health care services.

Physical Access

Most licensed health facilities in the United States are operated under state and local regulations (as well as accreditation rules) that require clinical facilities that are physically designed for accessibility in wheelchairs or carts. The ADA imposed new thinking that required wheelchair accessible entry to all public and common areas, accessibility to public toilets, barrier-free entry, and improvement of access and navigation for the visually impaired. Wheelchair lifts, automatic doors, power-assist examination tables, Braille labeling of elevator instructions, audible signals on elevators, and Braille directional signs are all commonplace in U.S. health care facilities today.

Functional Access

Simple physical access does not ensure that individuals with disabilities will be able to make use of health care services in any useful way. Visually and hearing-impaired individuals have long been left outside the mainstream of much routine activity. This barrier to full participation is even greater in times of medical crisis. Section 502 of the Rehabilitation Act covering providers of care as "public accommodations" mandated that adaptive devices and access to signing interpreters be available for hearing-impaired patients. Section 504 of the Rehabilitation Act regulates providers of health care as recipients of federal funds through the Medicare and Medicaid programs. Numerous court cases in the United States have served to define the underlying policy of functional access, and expand the application of it through the regulation of those providers that participate in such federally funded programs. Such cases not only have a direct regulatory impact but also serve to create a "community standard of care" that has great impact on potential financial liability in the courts if the provider of care is accused of harming the patient as a result of withholding these services.

Financial Access

Even in the presence of accessible facilities with appropriate functional adaptations to provide adequate care for persons with disabilities, ability to pay for that care may remain a significant barrier to service. The UN addresses financial support for assistive devices in its Rules on the Equalization of Opportunities for Persons with Disabilities. The rules specify "that this may mean assistive devices and equipment should be provided free of charge" or at a lowered price to ensure affordability. The U.S. Rehabilitation Act requires that communications assistance be provided at the expense of the health care provider. In the absence of a universal health care plan in the United States, many persons with disabilities would still be confronted with affordability barriers given the substantial portion of the population lacking private health insurance. Many of these persons are, however, covered under the U.S. Medicare and Medicaid health insurance programs by virtue of their defining disability.

Additional barriers have historically existed for employed and insurance-eligible individuals. Persons with chronic diseases and disabilities often found themselves confronted with rejection by insurers, or exclusion from coverage of their specific health problems. The passage of the Kennedy-Kassebaum Act of 1996 placed some limitations on the exclusions that insurance companies can impose on accepting coverage of employee group members.

One specific area of broad exclusion has been private insurance coverage for mental health needs. In the United States, mental and developmental disabilities remain largely overlooked problems. There is evidence indicating that such coverage is affordable and that substantial savings are possible in reduced medical costs, crime, homelessness, increased worker productivity, and increased employment taxes. Yet several efforts to create federal statute or regulation requiring parity of mental health coverage with existing somatic illness coverage have repeatedly failed to gain passage. As a result, significant barriers to obtaining such services remain.

EFFECTIVENESS

Health care aimed at the issues of persons with disabilities must pursue the same broad goals of health care for any population, with the added burden of addressing the specific risks of disability.

Prevention

The reduction in incidence of disabling diseases and injuries is the first goal for the health care system. The term *prevention* means action aimed at preventing the occurrence of physical, intellectual, psychiatric, or sensory impairments (primary prevention) or at preventing impairments from causing a permanent functional limitation or disability (secondary prevention).

Primary prevention may include many different types of action, such as primary health care, prenatal and postnatal care, education in nutrition, immunization campaigns against communicable diseases, genetic testing, measures to control endemic diseases, safety regulations, programs for the prevention of accidents in different environments including adaptation of workplaces to prevent occupational disabilities and diseases, and prevention of disability resulting from pollution of the environment or armed conflict.

Secondary prevention may include early detection of, and intervention in, potentially disabling diseases. It may also include the development of more sophisticated diagnostic and interventional techniques and technology to enable more successful reduction of adverse outcomes of chronic diseases and critical injuries.

Health Maintenance

Persons with disabilities may have special needs related to their disabling condition that can cause specific challenges to their continuing overall health and well-being. In addition, loss of mobility or ability to communicate effectively can increase the likelihood of secondary failures of health providers to manage the continuing health of such individuals. While there has been a trend toward the development of generalists or primary care specialists to improve the coordination of health care services for the general population, it may be argued that the special needs of populations with disabilities require special understanding to fruitfully provide such continuing care. Several special efforts have produced noteworthy results. There has been some demonstration that focused efforts to care for those with severe developmental disabilities can result in reduction of adverse outcomes and hospitalizations when compared to mainstreaming the care of such persons. Rehabilitation specialists delivering continuing care to disabled patients exhibit greater focus on the corollary problems of mobility loss (e.g., spasticity, decubiti, infection) that can lessen the quality of health.

Rehabilitation

The term *rehabilitation* refers to a process aimed at enabling persons with disabilities to reach and maintain their optimal physical, sensory, intellectual, psychiatric, and/or social functional levels, thus providing them with the tools to change their lives toward a higher level of independence. Rehabilitation may include measures to provide and/or restore functions or compensate for the loss or absence of a function or for a functional limitation. The rehabilitation process does not involve initial medical care. It includes a wide range of measures and activities from more basic and general rehabilitation to goal-oriented activities, for instance, vocational rehabilitation.

EFFICIENCY

Persons with disabilities are members of society and have the right to remain within their local communities. They should receive the support they need within the ordinary structures of education, health, employment, and social services to maximize their ability to lead a productive life. Providers of health care cannot lose sight of the need to optimize the value of the provision of the care and to maximize the value of the outcome for an individual with disabilities. Certainly, keeping an individual within a local community and maximizing the possibility of a normal productive life is one of the needs that must be accommodated to achieve these goals.

Olmstead Decision

In the United States, several court decisions have served to define and expand expectations under the ADA. Key among these has been the court ruling known as the *Olmstead* decision, in which the U.S. Court of Appeals held that decisions regarding services and where they are provided must be made on the basis of the appropriateness for each particular individual and further that services should be provided in the most community-integrated setting possible. This and other cases have broadened the requirements to maintain the care of individuals with disabilities close to home and within the routine of a productive life. Largely applied to persons with mental disorders and developmental disabilities, the decisions have recently been applied to the deinstitutionalization of care for persons with spinal cord injury and other mobility deficits.

CONCLUSION

Health care has historically been driven by developments in technology and science. Health care for persons with disabilities brings to the formula the critical need for understanding the driving forces of ethics, philosophy, and social commitment. In this arena, the role of government regulation will surely play a continuing role.

HEALTH CARE SYSTEMS

In the early twenty-first century, the number of disabled persons continues to rise and their health care needs persist and multiply. At the same time, the health care systems they interact with are also constantly changing, reflecting responses to economic, political, and social forces. Those systems, composed of health care professionals (physicians, therapists, researchers), structural elements (hospitals, clinics, professional schools), and systems of payment for services (government, managed care organizations, insurers, voluntary organizations and other private sources) occur in different arrays, with subsequent differences in suitability and ease of access for persons with disabilities.

THE DISABLED AND MEDICAL CARE

Persons with disabilities depend on interaction with doctors and medical institutions. Even when well, the disabled must look to health care professionals for equipment, certification of disability and capability, rehabilitation or maintenance of status, eligibility for private and governmental supports, and entry to education and public services.

The professionals, however, are embedded in systems—both formal and implicit—that permit or constrain their abilities to perform effectively on behalf of their disabled clients. The systems in which they work and on which the disabled are dependent are the products of history, cultural norms and practices, national and local priorities, and legislative initiatives and rule, and these all determine the resources available to disabled persons.

Most people with disabilities are well, that is, not requiring acute medical care or interventions most of the time. The real continuing needs of the disabled in their everyday lives are for social and family supports, access to education and work, transportation, and living and working environments adapted to their disabilities; these are not areas in which health professionals necessarily have expertise or interest. Yet the dependence of disabled persons on medical and related systems for legitimation and entry to social and personal services requires that they understand and turn to the health care systems.

When problems are medical, the care of the disabled is rarely accomplished quickly; time required for their care is greater than that for nondisabled patients. Often physicians and other health care personnel are uncomfortable with patients with chronic problems that do not respond to acute care protocols. In addition, disabled persons often complain that medical professionals are eager to apply new and sophisticated technologies but overlook “low tech” interventions that might aid daily living.

While there has been significant movement in developed countries toward assessing the quality of medical care by looking at outcomes, almost all of the established outcomes and “best practice” protocols measure the success of acute illnesses and injuries. The desired outcomes for non-sick disabled persons are much less concrete and much more individual; even those who have degenerative diseases or periodic acute care needs spend most of their lives outside of hospitals and rehabilitation facilities. Thus, persons with disabilities do not fit well into either the standard treatments or the standard measures of quality used in acute care medicine.

HEALTH CARE SYSTEMS

Health care systems may be monolithic and governmentally structured, as in Canada, the Scandinavian countries, and the British National Health Service, or pluralistic and loosely organized, including both public and private sector components, as in the United States.

Systems begun in the 1980s organized around the concept of managed care at first offered great promise for comprehensive approaches for the disabled. However, the commercialization of such programs in the United States, with emphasis on cost containment and standardization of treatment, has led, in general, to disappointment for those with disabilities and chronic illness. Disabled persons often find their care needs are not met in health care programs and systems that depend on prescribed standards of care or “disease management” protocols for defined populations and illnesses. Wide variations in functional impairment and, thus, of the multiple health care services needed make generalizations about both services and reimbursement risky; each disabled person conforms only to a personal profile and, thus, challenges standardized programs of care. The service needs of most disabled people will continue for a lifetime; no defined period of treatment or financial coverage exists. Planners, policy makers, and insurers are reluctant to build or fund programs for individuals whose life expectancy, treatment duration, and intensity cannot be submitted to standard actuarial analysis, with predictable costs. State governmental forays into managed care in the Medicaid program in the United States have suffered from rising costs, often leading to restriction of the benefits and services most often needed by the disabled.

The training of health professionals, especially physicians, has not necessarily prepared them for the special needs of the disabled. The absence of such specific training puts physicians at a disadvantage in advocating for their patients in the health care systems. Medical care for the disabled often falls to the small group of physicians trained in physical medicine and rehabilitation, and a few generalists who choose to work with disabled and chronically ill patients. Within the medical care system, the disabled often confront fragmentation and lack of communication among medical specialists and between tertiary care centers, community agencies, and primary care physicians.

APPROACHES AND CHALLENGES

There are several promising alternatives that respond to the complex needs of the disabled and the inadequacies of acute care systems. Some centers have developed model comprehensive care programs with a case manager (really a care manager), whose responsibility is coordination and transmittal of information between medical professionals and community agencies on behalf of the patient and family. It is within such medical care programs that the disabled are likely to receive the most attentive and appropriate care. Unfortunately, this is not the dominant practice. Despite demonstrations that show improved outcomes, in both reductions in hospitalizations and in long-term costs of care, most medical organizations in the United States have not adopted the care manager model. Thus, disabled persons and their families or caretakers must de facto become their own care managers, an enterprise that can deplete already compromised reserves of energy, time, and funds.

In some states in the United States and in some countries (Sweden, the Netherlands), comprehensive programs for the disabled have grown out of integration of medical and social service programs; there are a few (usually academic) centers in the United States that have assembled such integrated approaches, using a combination of private, state, and federal funds.

Another trend that has benefited the disabled has been the growing practice of early discharge from hospital to long-term care at home and in the community. The home care movement has been propelled by a variety of factors, some well motivated, some suspect, including control of inpatient costs (the most expensive part of health care); improved technology allowing relatively complex interventions and treatments to be done in a home setting; recognition of the hazards of extended hospital stays (particularly infections), and acknowledgment of the psychological and social benefit of being in one's familiar surroundings. Where medical institutions and systems have extended their services and oversight into the home ("hospitals without walls"), there has been marked success in terms of recovery, maintenance of function, and patient and family satisfaction.

While there are clear benefits, home or independent care for the disabled and chronically ill creates new challenges for health care systems, many in previously unexplored territory. In choosing care at home, there is a transfer of responsibility and risk from the inpatient institution to the patient and family, which leads to important questions: What are the limits of the institution's (or health care system's) liability? What are the system's moral and legal responsibilities for adequate preparation and support of the home caretakers? Should the institution or system initiate a home care program in the face of inadequate continued funding and assistance from society and its formal (e.g., in the United States, local state and federal programs) and informal supports? Does the system's obligation to the patient and family end when they leave the hospital or rehabilitation facility?

The appropriate services for a disabled person at home may involve many agencies and organizations: physical, occupational, and speech therapies; vocational and educational services; the provision and maintenance of equipment and supplies; respite for caretakers; and modifications of the environment for accessibility and safety. Most of these are not attended to in traditional health care systems but (at least in the United States) are fragmented among many public and private agencies, a situation that demands constant initiative and vigilance from the caretakers, family, and the disabled persons themselves, adding to their already heavy logistical and psychological burdens. Advocates for the disabled note another paradox confounding home care: Both public and private insurance systems may pay for outsiders (e.g., nurses, therapists, attendants) to care for disabled persons at home or in school but do not recognize or reimburse for the large financial and emotional sacrifices made by family members when they perform the same tasks.
