Data Compression

Chang-Su Kim, *Seoul National University, Korea*
C.-C. Jay Kuo, *University of Southern California*

INTRODUCTION

Rapid advances in computing and communication technologies support lifestyles in the information age and the increasing demand for a wide range of multimedia services, including voice, audio, and video services. Multimedia data, however, require a vast amount of storage space or high transmission bandwidth. There are two approaches to support multimedia services. One increases the capacity of storage devices and transmission channels: the other compresses data compactly, thereby exploiting existing system capacity. The system capacity has increased continuously, but the need for more storage space and higher bandwidth has increased at an even faster pace. Moreover, new types of multimedia data are emerging. Therefore, extensive efforts have been made to develop data compression techniques to use limited storage space and bandwidth effectively.

Data compression is ubiquitous in daily life, and its application list is extensive. For example, it would take much longer to browse Web sites on the Internet that contain audiovisual information, if there were no data compression techniques. Data compression enables us to send photographs or music files efficiently via e-mail. Also, digital television broadcasting and the storage of high-quality video on digital video disk (DVD) are possible because of the video compression technology that efficiently compresses a huge amount of video data. Recently, mobile communication has become popular, and there is an explosive demand for mobile multimedia services, such as mobile Internet, m-commerce, and game services. Data compression is one of the key technologies that enables the transmission of multimedia data as well as voice over bandwidth–limited wireless channels.

Data compression can be classified into two categories (Witten, Moffat, & Bell, 1999): lossless and lossy techniques. In lossless compression, an encoder compresses the source data in such a way that the decoder can reconstruct the original data exactly from the compressed data. The lossless property is essential in some applications, such as the compression of texts, medical imaging, and satellite imaging for remote sensing, for which even small changes in data may lead to undesirable results. Also, lossless compression techniques are used to archive numerous types of data without loss of information.

In contrast, lossy compression attempts to achieve better compression by allowing loss of information during the compression procedure. There is a trade-off between the accuracy of the reconstructed data and the compression performance. Audio and video data are usually compressed in a lossy way, because the human perceptual system can tolerate a modest loss of audiovisual information. Moreover, audio and video data require a much larger storage space than text. For example, consider a video clip with a frame rate of 15 frames/s. If each frame consists of 176 × 144 pixels and the color information of each pixel is represented with 24 bits, the video clip requires the transmission bandwidth of about 9 Mbps. Suppose that we want to transmit the clip over 56-Kbps modem. The compression performance is often measured by the compression ratio, defined by

$$\frac{\text{Original data size}}{\text{Compressed data size}}.$$

In this case, we need a very high compression ratio, about 160 (= 9 Mbps/56 Kbps), thus it is reasonable to select lossy compression techniques.

In 1948, Shannon established the field of information theory (Shannon, 1948), which measures the amount of information in data quantitatively. Since the late 1960s, the subject of data compression has undergone extensive study, and numerous concepts and algorithms have been developed. In this chapter, we survey compression techniques and exemplify their application areas. It is organized as follows: First, we describe lossless and lossy compression techniques. Second, we present application areas of text compression, speech and audio compression, and image and video compression.

LOSSLESS COMPRESSION

In lossless compression, an exact duplicate of the original data can be reproduced after the compression and decompression procedures. We introduce several concepts and tools for lossless compression in this section.

Examples of Codes

In most digital computers, data are represented by binary numbers. Also, data are converted into binary numbers before the transmission over digital communication channels. Data compression or coding refers to the mechanism of assigning binary descriptions to samples of data source in a compact way. The set of binary descriptions is called a code, and each description is called a codeword.

Suppose that a communication system transmits a sequence of symbols (or samples) selected from an alphabet $\{A,B,C\}$, and that the probabilities of the symbols are given by

$$p(A) = 0.5, \quad p(B) = 0.25, \quad p(C) = 0.25. \tag{1}$$

Table 1 shows four example codes for this alphabet. The average length of a code is defined by

$$L = p(A)l(A) + p(B)l(B) + p(C)l(C),$$

where $l(A)$, $l(B)$, and $l(C)$ are the numbers of bits assigned to symbols A, B, and C, respectively. Code 1 seems to be most efficient because it requires the least number of bits to transmit each sample on the average, but it cannot be used in the communication system, because more than two sequences of samples can yield the same binary sequence. Let us assume that the decoder receives the binary sequence 10. It can be seen from Table 1 that both C and BA are encoded into the same sequence 10. Therefore, the decoder cannot determine whether it is generated by C or AB. To avoid this ambiguity, a code should be uniquely decodable, that is, every distinct sequence of samples should be mapped into a different binary sequence.

Code 2 is a uniquely decodable code. In Code 2, no codeword is a prefix of any other codeword. Thus, Code 2 is also called a prefix code. Figure 1(a) is the tree representation of Code 2. Each codeword is a leaf node, because Code 2 is a prefix code. Therefore, every binary sequence can be deciphered without ambiguity by traversing the tree. Let us decode 01110. Starting from the root node, the decoder traverses to the left child if the input bit is 0 and to the right child otherwise. When the decoder meets a leaf node, it outputs the corresponding symbol and starts again from the root node. Thus, 01110 can be deciphered into 0 11 10 = ACB. Note that every prefix code is a uniquely decodable code, and each codeword in a prefix code can be decoded instantaneously without reference to future codewords.

Table 1 Examples of Codes

Symbol	Probability	Code 1	Code 2	Code 3	Code 4
A	0.5	0	0	0	11
B	0.25	1	10	01	0
C	0.25	10	11	11	10
Average length		1.25	1.5	1.5	1.75

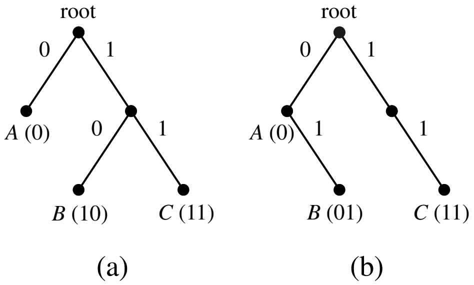

Figure 1: Tree representations of (a) Code 2 and (b) Code 3 in Table 1.

Not every uniquely decodable code is a prefix code, however. Code 3 is a uniquely decodable code, but not a prefix code. Figure 1(b) shows its tree representation. The codeword for A lies on the path from the root node to the codeword for B, because 0 is a prefix of 01. Therefore, when the decoder meets 0, it needs to check future bits to properly decode symbols. When 0 is followed by an even number of 1s, it is decoded into A. Otherwise, it is decoded into B. For example, 011110111 is decoded into 0 11 11 01 11 = $ACCBC$. In the worst case that a binary sequence is a concatenation of a single 0 and an infinite number of 1s, the Code 3 decoder need check infinitely many future bits to decode the first sample. The decoding of a nonprefix code hence may incur an unbounded delay and is more complex than that of a prefix code.

The goal of data compression is to find an optimal uniquely decodable code that provides the minimum average length. It can be shown (Cover & Thomas, 1991) that the minimum average length can be achieved also by a prefix code. Therefore, we can restrict our attention only to the set of prefix codes, which can be instantaneously decoded. Code 2 actually achieves the minimum average length. Code 4 is also a prefix code but less efficient than Code 2. It assigns a longer codeword to the symbol A than the symbol B, although A is more probable than B. It is readily seen that an efficient code should assign longer codewords to less probable symbols.

Entropy

In 1948, Shannon published "A Mathematical Theory of Communication," which founded the field of information theory. He developed a set of concepts that are necessary to understand the process of communication quantitatively. One of the concepts is entropy, which measures the amount of information or uncertainty in a data source. More specifically, the entropy of a data source is the number of bits required on the average to describe a sample of the data source. The entropy depends only on the probability distribution of the symbols if the symbols of the data source are independent and has nothing to do with what the data represent.

As mentioned previously, an efficient code should assign longer codewords to less probable symbols. Thus, the information or uncertainty of a symbol should be defined to be inversely proportional to its probability p. To find an adequate inversely proportional function, let us consider an alphabet that consists of 16 equiprobable symbols. Because the symbols have the same probability (1/16), they should be assigned the codewords of the same length. Obviously, the optimal code consists of the 4-bit binary representations of decimal numbers 0–15:

0000	0001	0010	0011	0100	0101	0110	0111
1000	1001	1010	1011	1100	1101	1110	1111

Hence, a symbol of probability 1/16 has 4-bit uncertainty. Similarly, considering an alphabet that consists of 2^n equiprobable symbols, it can be realized that a symbol of probability $1/2^n$ has n-bit uncertainty. In general, a symbol of probability p has $\log_2(1/p)$-bit uncertainty. Note that $\log_2(1/(1/2^n)) = \log_2 2^n = n$.

Consider a random data source X consisting of n symbols, which have probabilities $p_1, p_2, \ldots, p_n$. The entropy $H(X)$ of the data source is the average uncertainty of the symbols and thus given by

$$H(X) = \sum_{i=1}^{n} p_i \log_2 \frac{1}{p_i}. \tag{2}$$

This derivation of entropy is oversimplified. The entropy can be derived rigorously from three axioms (Shannon, 1948). Moreover, the entropy has the profound meaning that at least $H(X)$ bits/sample are required to encode a data source X losslessly, no matter what compression scheme is employed. In other words, $H(X)$ is the fundamental lower bound for the average length that a code can achieve. For example, the entropy of the alphabet in Table 1 is

$$0.5 \log_2 \frac{1}{0.5} + 0.25 \log_2 \frac{1}{0.25} + 0.25 \log_2 \frac{1}{0.25} = 1.5.$$

Therefore, no code can achieve less than 1.5 bits/sample on the average, which is the average length of Code 2 in Table 1.

Huffman Coding

Huffman coding constructs an optimal prefix code that provides the minimum average length (Huffman, 1952). It is based on the observation that the optimal code should allocate longer codewords to less probable symbols. Let us consider a random data source with n symbols. Without loss of generality, it is assumed that

$$p_1 \le p_2 \le \cdots \le p_{n-1} \le p_n,$$

where p_i denotes the probability of the ith symbol. Then, the codeword lengths should satisfy

$$l_1 \ge l_2 \ge \cdots \ge l_{n-1} \ge l_n,$$

where l_i is the codeword length of the ith symbol. Note that if $l_1 > l_2$, the last $(l_1 - l_2)$ bits of the longest codeword can be trimmed without violating the prefix condition. In other words, the code is not optimal. Hence, l_1 should be equal to l_2. Moreover, the two longest codewords should differ only in the last bit. If this is not satisfied, we can also trim the last bits of the two codewords without violating the prefix condition.

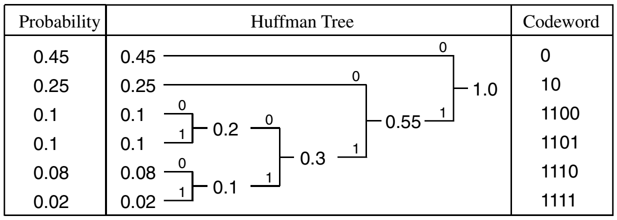

Figure 2: Construction of a Huffman code.

As shown in Figure 1(a), a prefix code can be represented by a binary tree. The above observations mean that the two least probable symbols should correspond to the two deepest nodes in the tree, and the two nodes should be siblings. Therefore, we can construct the optimal tree using a bottom-up method. Figure 2 illustrates how to construct a Huffman code. First, we merge the two least probable symbols while assigning 0 and 1 to the last bits of the corresponding codewords. The merged node is treated as a new symbol with the probability 0.1, which is the sum of the two child node probabilities. Second, we find again the two least probable symbols. There are three symbols with the probability 0.1 at this stage. We merge arbitrary two symbols among the three symbols into a new symbol and assign the probability 0.2 to the merged symbol. Proceeding in this way, we can merge all the nodes into the root node. Then, the original symbols are assigned the codewords that are the top-down concatenations of branch bits.

It can be shown (Cover & Thomas, 1991, Chapter 5) that the average length $L(X)$ of the Huffman code for a random data source X satisfies

$$H(X) \le L(X) < H(X) + 1. \tag{3}$$

For example, the entropy of the probability distribution in Figure 2 is 2.0872, whereas the Huffman code achieves the average length 2.15. $L(X) = H(X)$, if and only if the probability of each symbol is equal to 2^{-k} for some nonnegative integer k.

The upper bound in Equation 3 indicates that the Huffman coding scheme introduces at most 1 bit overhead compared with the entropy. This overhead may cause a problem in some situations. Suppose that a communication system transmits samples selected from an alphabet $\{A, B\}$, and $p(A) = 0.99$ and $p(B) = 0.01$. The entropy of the alphabet is 0.0808. As shown in the left column of Table 2, however, the Huffman code requires 1 bits/sample on the average, which is about 12 times higher than the entropy. We can reduce the overhead by encoding n consecutive samples simultaneously. In the middle column of Table 2, two consecutive samples are grouped into a block, and the Huffman code is constructed for the set of possible blocks. The Huffman code introduces at most 1-bit overhead per block, hence at most 0.5-bit overhead per sample. In general, if we design the Huffman code for

Table 2 Huffman Coding of Grouped Samples

No Grouping			Grouping of 2 Samples			Grouping of 3 Samples		
Symbol	Probability	Code	Block	Probability	Code	Block	Probability	Code
A	0.99	0	*AA*	0.9801	0	*AAA*	0.970299	0
B	0.01	1	*AB*	0.0099	10	*AAB*	0.009801	100
			BA	0.0099	110	*ABA*	0.009801	101
			BB	0.0001	111	*ABB*	0.000099	11100
						BAA	0.009801	110
						BAB	0.000099	11101
						BBA	0.000099	11110
						BBB	0.000001	11111
Average bits/sample = 1			Average bits/block = 1.0299 Average bits/sample = 0.515			Average bits/block = 1.06 Average bits/sample = 0.3533		

n sample blocks, it incurs only $1/n$-bit overhead per sample. Therefore, by increasing n, we can achieve an average bits/sample arbitrarily close to the entropy, which is the theoretical lower bound.

Arithmetic Coding

Huffman coding may require the grouping of infinitely many samples to achieve an average bits/sample equal to the entropy. The grouping of samples introduces transmission delay, however, and requires a higher computational load and a larger storage space for the codeword table. Arithmetic coding is an alternative coding scheme that provides a near-optimal compression performance without requiring the grouping of samples. It treats a whole sequence of samples, called a message, as a single unit but can be implemented to generate output codewords incrementally as samples arrive (Bell, Cleary, & Witten, 1990).

In arithmetic coding, a message is mapped to an interval of real numbers between 0 and 1. The interval length is proportional to the probability of the message and any number in the interval can be used to represent the message. Less probable messages yield longer sequences of bits, and more probable messages yield shorter sequences of bits.

For example, suppose that the alphabet is $\{A, B, C\}$, and the symbol probabilities are $p(A) = 0.6$, $p(A) = 0.3$, and $p(C) = 0.1$. As shown in Figure 3, the messages starting with A, B, and C are, respectively, mapped to the half-open intervals [0, 0.6), [0.6, 0.9), and [0.9,1), according to their probabilities. Let us encode a message BCA. Because it starts with B, it is first mapped to the interval [0.6, 0.9). Then, the interval is divided into three subintervals [0.6, 0.78), [0.78, 0.87), [0.87, 0.9), corresponding to the messages starting with BA, BB, BC, respectively. Note that the length ratio of the subintervals is set to

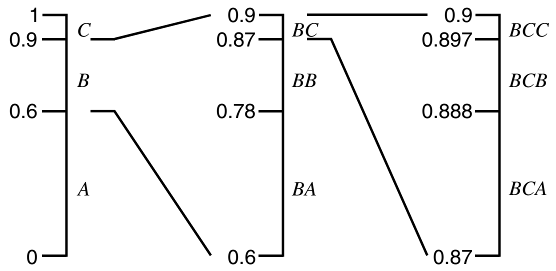

Figure 3: Illustration of arithmetic coding.

$$0.18 : 0.09 : 0.03 = 6 : 3 : 1 = p(A) : p(B) : p(C),$$

and 0.18, 0.09, 0.03 are the probabilities of the messages starting with BA, BB, BC, respectively. Similarly, [0.87, 0.9) is further divided into three subintervals, and the messages starting with BCA are mapped to [0.87, 0.888).

The two end points can be written in binary numbers as

$$0.87 = \frac{1}{2} + \frac{1}{2^2} + \frac{1}{2^4} + \frac{1}{2^5} + \cdots = 0.11011\cdots$$

and

$$0.888 = \frac{1}{2} + \frac{1}{2^2} + \frac{1}{2^3} + \frac{1}{2^7} + \cdots = 0.11100\cdots.$$

The prefix '0.' can be omitted, since every number within the unit interval [0, 1) is less than 1. The interval [0.87, 0.888) can be represented in the binary form [11011..., 11100...). The encoder can transmit an arbitrary number within this interval to specify that the message starts with BCA. For example, it can transmit the sequence of three bits, 111, which corresponds to 0.875 in decimal. Then, the decoder can follow the same division procedure in Figure 3 and know that 0.875 lies within the interval [0.87, 0.888), hence the message starts with BCA.

The decoder cannot, however, determine when the message ends; 0.875 also lies within the interval [0.87, 0.8808), which corresponds to the set of messages starting with $BCAA$. Thus, it can also specify the message $BCAA$. To make the arithmetic code uniquely decodable, we can add a special symbol to the alphabet, which indicates the termination of a message. If the special symbol is assigned a small probability and a message is long, the addition of the special symbol leads to only a minor degradation in the compression performance.

Arithmetic coding is superior to Huffman coding in many respects. It can achieve a near-optimal performance without grouping of samples. Also, it can be easily used in an adaptive way. In some applications, the probability distribution of alphabets cannot be predetermined and should be trained and updated based on the statistics of the data stream itself. To be adaptive to the change in the probability distribution, Huffman coding should regenerate the codeword table (Gallager, 1978), which is computationally inefficient. In contrast, arithmetic coding can adjust itself to the updated probability distribution simply by changing the length of intervals in the division procedure.

Dictionary Coding

Both Huffman coding and arithmetic coding implicitly assume that a data source generates a sequence of independent samples and do not consider the dependence between samples. Samples are dependent on one another in many data sources, however. For example, consider the following words from a text source:

Inte*net, bus*nes*, comp*ter, d*ta, compre*sion,

where * denotes a missing letter. We can reasonably recover the words to

Internet, business, computer, data, compression,

based on our knowledge of frequently used words. In other words, the missing letters can be retrieved by exploiting the dependence between letters, that is, by the context.

Dictionary coding achieves data compression by replacing blocks of consecutive samples with indices into a dictionary (Bell et al., 1990, Chapter 8). The dictionary should be designed to contain symbol blocks that are frequently used. If sufficient prior knowledge of a particular data source is unavailable, the dictionary can be built adaptively from the source itself. Many adaptive dictionary coding schemes are modifications of one of two approaches, LZ77 (Ziv & Lempel, 1977) and LZ78 (Ziv & Lempel, 1998). Popular file compression tools such as ZIP and ARJ are variations of LZ77. LZW is one of the most popular modifications of LZ78 and is used in the Unix command "compress," the V.42 bis standard for data compression over modem, and the graphics interchange format (GIF) for compressing graphical images.

Let us describe the encoding and decoding procedures of LZW. The encoder parses an input sequence into nonoverlapping symbol blocks in a dictionary and represents each block with its index to the dictionary. The blocks in the dictionary are also referred to as the words. The dictionary is initialized with the single symbols in the alphabet and grows during the encoding procedure. Suppose that the alphabet is $\{A, B\}$, and an input sequence is given by $ABABABBBBA$.

The encoder first parses the longest word in the dictionary from the input sequence. As shown in Table 3, the initial dictionary contains two words A and B. Thus, the longest word is A and is represented by the index 1. Then it is concatenated with the next sample B to form a new word AB in the dictionary. Similarly, the next longest word B is represented by the index 2 and is concatenated to the next sample A to form a new word BA. In this way, the input sequence can be parsed into

Table 3 Dictionary Construction in LZW Coding (input sequence = *ABABABBBBA*).

Index	Dictionary	Comment
1	A	initial
2	B	dictionary
3	AB	$(A) + B$
4	BA	$(B) + A$
5	ABA	$(AB) + A$
6	ABB	$(AB) + B$
7	BB	$(B) + B$
8	BBA	$(BB) + A$

$$(A)_{AB}\,(B)_{BA}\,(AB)_{ABA}\,(AB)_{ABB}\,(B)_{BB}\,(BB)_{BBA}\,(A),$$

where the parsed words are enclosed in parentheses and the newly formed words in the dictionary are written as subscripts. Consequently, the input is represented by the index sequence

$$1 \quad 2 \quad 3 \quad 3 \quad 2 \quad 7 \quad 1.$$

The decoder can reconstruct the input sequence from the index sequence by emulating the behavior of the encoder. It also starts with the initial dictionary, consisting of two words A and B. Thus, the first index 1 is decoded into A, which should be concatenated to the next sample to form a new word in the dictionary. The decoder looks ahead at the next index 2 that corresponds to a word B and inserts the new word AB into the dictionary. Similarly, the decoder reconstructs a word B from the second index 2, looks ahead at the next index 3 to find out that next sample is A, and inserts a new word BA into the dictionary.

Proceeding in this way, the third and fourth indices 3 are decoded into AB, respectively, and two new words ABA and ABB are inserted into the dictionary. Then, the decoder reconstructs the word B from the fifth index 2. The next step is to look ahead at the next index 7 to find out the next sample, denoted by *, and concatenate B and * to construct a new word B^* in the dictionary. This requires caution. Note that the index 7 cannot be directly parsed into a word, because the dictionary contains only six words and the seventh word is being constructed at this stage. We know, however, that the seventh word starts with B, thus the next sample * is B. Therefore, the seventh word in the dictionary is BB, and the decoder can continue.

Adaptive dictionary coding can be used to compress all types of data, thus being classified as a universal coding scheme. Care should be taken with its use, however. It can compress a data source effectively, provided that the source generates frequently recurring patterns or groups of samples. Text data provide a good example. In contrast, dictionary coding is not the most efficient way to compress natural image data, speech, and so on, which contain relatively few repetitive patterns. These data can be more effectively compressed by employing other approaches that are described later.

Run-Length Coding

Run-length coding (Jayant & Noll, 1984, Chapter 10) is suitable for compressing data that contain large segments of constant sample values. It replaces a sequence of samples by a sequence of pairs, $\{(s_k, r_k)\}$, representing sample values s_ks and run-lengths r_ks. For example, suppose that an input sequence is given by

$$AAAABBCCCBBBBBB.$$

It starts with a run of As with length 4, followed by a run of Bs with length 2. Thus, the first pair is $(A, 4)$ and the second pair is $(B, 2)$. In this way, the input sequence is converted into

$$(A, 4), (B, 2), (C, 3), (B, 6).$$

The sequence of pairs $\{(s_k, r_k)\}$ is usually encoded using the Huffman coding technique. Separate Huffman codeword tables can be constructed for the sample values s_ks and the run-lengths r_ks, or one table can be constructed jointly for the (s_k, r_k) pairs.

Run-length coding can compress binary and facsimile images effectively, which contain long runs of black (0) and white (1) pixels. Because white and black runs alternate, the colors (or sample values) of runs need not be encoded. To avoid ambiguity, the color of the first run is assumed to be white, and the white run of length 0 is encoded if the sequence starts with a black pixel. For example, a sequence of pixels

000111110111001

is converted into a sequence of run-lengths

0, 3, 5, 1, 3, 2, 1.

The decoder can know from the first run-length 0 that the sequence starts with a black pixel and interpret the following numbers as the lengths of black and white runs alternately.

LOSSY COMPRESSION

Lossless compression schemes can encode only data sources with discrete alphabets. Many data sources are analog however; that is, their symbols may have arbitrary values from a continuous range of amplitudes. The lossless description of a continuous sample requires an infinite number of bits. Thus, a finite representation of a continuous sample inevitably incurs some loss of precision, called quantization error. Moreover, even if a data source has a discrete alphabet, lossy compression techniques can describe a discrete sample more compactly by allowing some distortion.

In rate distortion theory (Cover & Thomas, 1991, Chapter 13), it was shown theoretically that there is a trade-off relation between the bit rate (in bits/sample) and the distortion. As more distortion is allowed, the data can be compressed more compactly. The goal of lossy compression techniques is to minimize the distortion subject to a given bit rate requirement or, equivalently, to achieve the lowest bit rate subject to a given distortion requirement.

A measure of distortion should be defined before describing lossy compression techniques. The most common measure is the squared error, defined by

$$d(x, \tilde{x}) = (x - \tilde{x})^2,$$

where x is the original sample and $\tilde{x}$ is the reconstructed sample. Also the mean squared error between two vectors $\mathbf{x} = (x_1, x_2, \ldots, x_n)$ and $\tilde{\mathbf{x}} = (\tilde{x}_1, \tilde{x}_2, \ldots, \tilde{x}_n)$ is defined by

$$d(\mathbf{x}, \tilde{\mathbf{x}}) = \frac{1}{n}\sum_{i=1}^{n}(x_i - \tilde{x}_i)^2.$$

The squared error distortion is simple to use and has the intuitive meaning that it measures the power of the error signal. Thus, it is used in this section to evaluate the performances of lossy compression techniques.

Scalar Quantization

Quantization is the process of representing a large or infinite set of values with a smaller set (Gersho & Gray, 1991, Part II). In scalar quantization, the input and output sets are composed of scalar values. An N-point scalar quantizer partitions the real line into N cells $R_i = \{r : x_{i-1} < r \leq x_i\}$ for $i = 1, 2, \ldots, N$, and maps input values within a cell R_i to an output point y_i. Suppose that we have a data source modeled by a random variable X with probability density function (pdf) $f_X(x)$. Then, the quantizer yields the average distortion or the mean squared error given by

$$\begin{aligned} D &= \int_{-\infty}^{\infty}(x - Q(x))^2 f_X(x)\,dx \\ &= \sum_{i=1}^{N}\int_{R_i}(x - y_i)^2 f_X(x)\,dx, \end{aligned}$$

where Q denotes the quantizer mapping. Because the quantizer has N output points, each output point can be represented with $\lceil \log_2 N \rceil$ bits, where $\lceil a \rceil$ denotes the smallest integer greater than or equal to $\lceil a \rceil$. In other words, the bit rate of the quantizer is given by

$$R = \lceil \log_2 N \rceil \qquad \text{(bits/sample)},$$

when fixed-length codewords are used to encode the output indices.

For example, Figure 4(a) shows the input–output graph of an 8-point quantizer, whose mapping Q is given by

$$y = Q(x) = \begin{cases} 3.5\Delta & \text{if } x > 3\Delta, \\ 0.5(2n-1)\Delta & \text{if } (n-1)\Delta < x \leq n\Delta \ (n = -2, \\ & \quad -1, \ldots, 3), \\ -3.5\Delta & \text{if } x \leq -3\Delta. \end{cases}$$

Except for the two outer cells, every cell has the same length Δ. Thus, this quantizer is called a uniform quantizer. The bit rate is 3 bits/sample when fixed-length

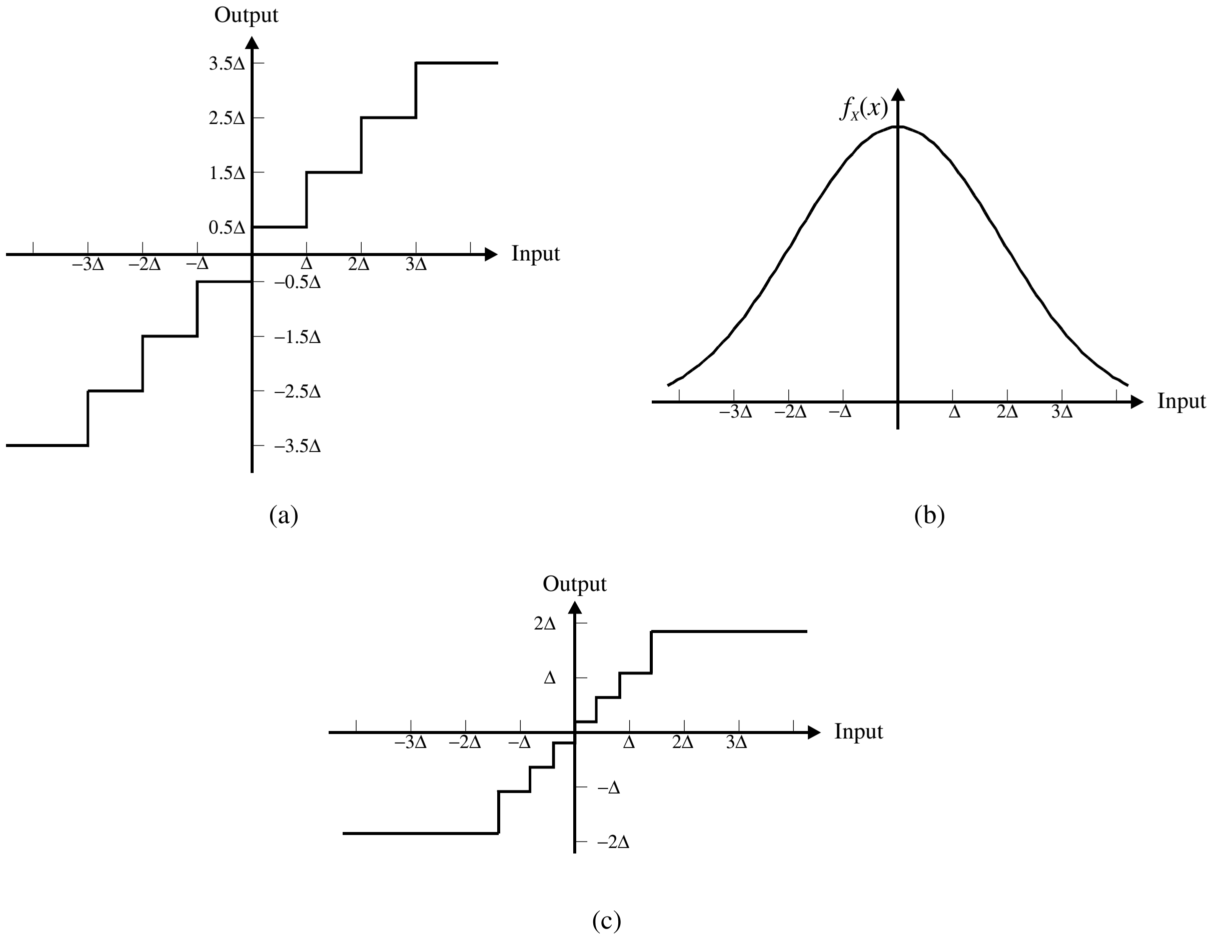

Figure 4: (a) A uniform quantizer, (b) a probability distribution function (pdf) of a random variable, and (c) Lloyd quantizer for the pdf in (b).

codewords are employed, because the quantizer has 8 output points. Output points can be described more compactly, however, because they do not have the same probability. Suppose that a random variable X has a probability distribution function (pdf) $f_X(x)$ shown in Figure 4(b). The probability P_i of the ith output point is given by

$$P_i = \int_{R_i} f_X(x)\,dx \quad (1 \le i \le 8).$$

Note that the fourth and fifth output points have higher probabilities than other points. Therefore, entropy coding schemes such as Huffman coding and arithmetic coding can achieve higher compression ratio than the fixed-length coding, by exploiting the nonuniform probability distribution of the output indices.

In practice, for a random variable with a pdf shown in Figure 4(b), the uniform quantizer is not the optimal 8-point quantizer that yields the lowest average distortion. Notice that a quantizer can reduce the average distortion by approximating the input more precisely in regions of higher probability. The optimal quantizer should make cell sizes smaller in regions of higher probability.

The Lloyd algorithm (Lloyd, 1982) is an iterative method that finds a locally optimal quantizer for a given pdf, which is based on two sufficient conditions for the optimal quantizer. First, an output point y_i should be the centroid of the corresponding cell R_i,

$$y_i = \frac{\int_{R_i} x f_X(x)\,dx}{\int_{R_i} f_X(x)\,dx}. \tag{4}$$

Second, a cell boundary point x_i should be the midpoint between two adjacent output points,

$$x_i = \frac{y_i + y_{i+1}}{2}. \tag{5}$$

The Lloyd algorithm first determines output points by Equation 4, after fixing boundary points. These output points are then used to select boundary points by Equation 5. These two steps are repeatedly applied until the change between the obtained average distortions becomes negligible. Because each step reduces the average distortion, the Lloyd algorithm always converges to a locally optimal quantizer. Figure 4(c) shows the Lloyd quantizer for the pdf in Figure 4(b). It can be observed that the Lloyd algorithm assigns smaller cell sizes around the origin to approximate regions of a higher probability more accurately.

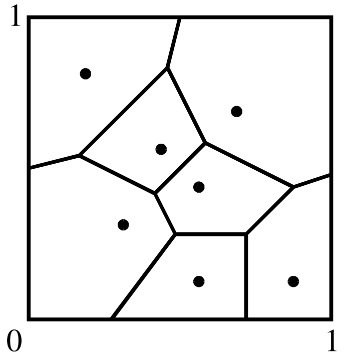

Figure 5: An example of a two-dimensional vector quantizer.

Vector Quantization

As shown in Table 2, the overhead of Huffman coding can be reduced by grouping samples together and encoding them as a single block. Moreover, as in dictionary coding, the grouping makes it easy for the encoder to exploit possible dependencies between samples. Vector quantization is the generalization of scalar quantization that quantizes a block of scalar samples jointly.

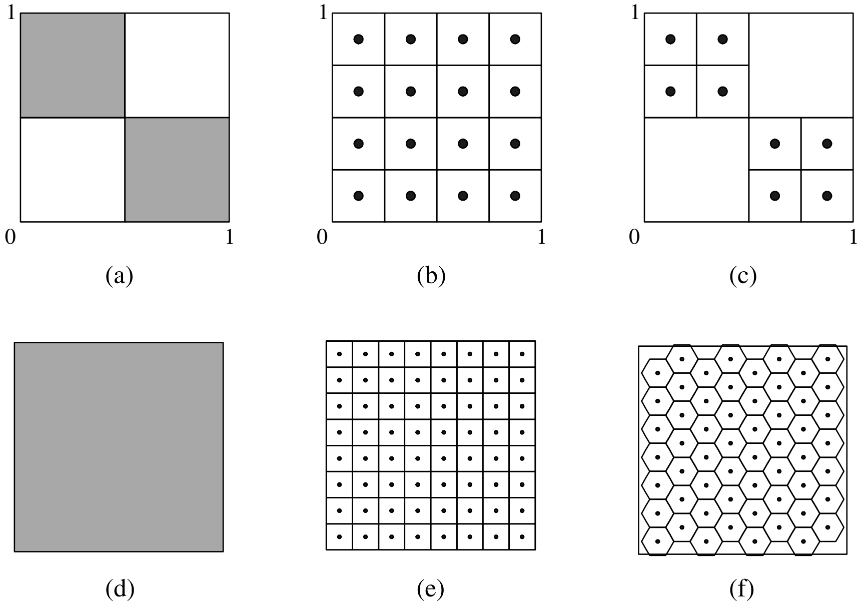
Figure 5 illustrates an example of two-dimensional vector quantizer, which partitions a unit square $[0, 1] \times [0, 1]$ into 7 cells. The black dot in a cell depicts the output point of the cell. In this quantizer, the configuration of these cells is completely determined by the locations of the output points. More specifically, the ith cell C_i is given by

$$C_i = \{x \in [0, 1] \times [0, 1] : d(\mathbf{x}, \mathbf{y}_i) \leq d(\mathbf{x}, \mathbf{y}_j) \text{ for } 1 \leq j \leq 7\},$$

where $\mathbf{y}_i$ denotes the ith output point. A vector $\mathbf{x}$ belongs to the ith cell if $\mathbf{y}_i$ is the nearest output point to $\mathbf{x}$ among all output points. This configuration of cells is called the Voronoi diagram of output points, and the quantizer is called the nearest neighbor quantizer. With the nearest neighbor quantizer, the encoder needs to store only the codebook consisting of output points, without requiring any information on the geometrical configuration of cells. For an input vector, the encoder compares its distances to the output points and records the index of the nearest output point.

If a set of output points is fixed, the Voronoi diagram is the best configuration of cells that minimizes the average distortion (Gersho & Gray, 1991, Chapter 11). Also, as in Equation 4, the output points should be centroids of the corresponding cells to minimize the average distortion. Therefore, in the same way as the Lloyd algorithm, we can design a locally optimal vector quantizer for a pdf by refining the configuration of cells and the locations of output points iteratively. This is called the generalized Lloyd algorithm (GLA).

Vector quantization has several advantages over scalar quantization (Gersho & Gray, 1991, Chapter 11). First, it can effectively exploit possible correlations between samples. Consider a two-dimensional random variable $\mathbf{X} = (X_1, X_2)$ that is uniformly distributed over the two shaded quadrants in Figure 6(a). Because the marginal pdf of X_1 or X_2 is uniform over the interval [0, 1], its optimal scalar quantizer is a uniform quantizer. If we encode each component independently by a 4-point uniform scalar quantizer, the unit square is partitioned into 16 rectangular cells as shown in Figure 6(b). This scheme requires 2 bits per component. However, note that components X_1 and X_2 are correlated with each other and the probability density over the upper right and lower left quadrants in Figure 6(a) is zero. Therefore, we can encode variable $\mathbf{X}$ with an 8-point vector quantizer in Figure 6(c),



(a) (b) (c)

(d) (e) (f)

Figure 6: Advantages of vector quantization over scalar quantization (Gersho & Gray, 1991, Chapter 11): (a) the probability density function, (b) the scalar quantization for (a), (c) the vector quantization for (a), (d) the probability density function, (e) a square cell partitioning for (d), (f) a hexagonal cell partitioning for (d).

which requires only 1.5 bits per component while achieving the same distortion as given in Figure 6(b).

As shown in Figure 6(b), scalar quantization of each component leads only to a rectangular cell partitioning in the two-dimensional space. Similarly, it leads only to a cubic cell partitioning in the three-dimensional space, and so on. In contrast, vector quantization has a freedom in choosing multidimensional cell shapes. Therefore, even if the components of a multidimensional variable are statistically independent, vector quantization can provide better performance than scalar quantization. For example, suppose that the components of a variable $\mathbf{X} = (X_1, X_2)$ are independent of each other and uniformly distributed as shown in Figure 6(d). Figures 6(e) and (f) are a square partitioning and a hexagonal cell partitioning for this pdf, respectively. The square cells and the hexagonal cells are of the same size. Thus, if we assume that the number of output points is very large and the boundary effects are negligible, the hexagonal partitioning requires the same rate as the square partitioning. Notice, however, that the hexagonal partitioning provides lower average distortion than the square partitioning, because the maximum distance between two points within the hexagon is smaller than that within the square.

Vector quantization is used to compress various kinds of data, including speech and image data. The main drawback of vector quantization is that it often requires a large storage space and high computational complexity. Consider a vector quantizer for image data, which encodes each 8×8 pixel region as a block at the rate of 0.5 bits per pixel. Each block is encoded with $32 = 8 \times 8 \times 0.5$ bits and the codebook is, hence, composed of $2^{32} \cong 4 \times 10^9$ vectors. If each pixel value is represented with a single byte, both the encoder and the decoder require about $8 \cdot 8 \cdot 4 \times 10^9$ bytes ($\cong$ 256 Gbytes) to store the codebook. Also, if the nearest neighbor rule is used to find the codeword, a brute-force encoder would compute 4×10^9 vector distances to encode each block, which is not acceptable in most applications. Hence, to reduce the storage space and the computational burden, several techniques have been developed such as lattice vector quantization, tree-structured vector quantization, and shape-gain vector quantization (Gersho & Gray, 1991, Chapter 12).

Predictive Coding

Many data sources generate a sequence of samples that are highly correlated to one another. Hence, in many cases we can predict the future sample based on the past and current samples, although perfect prediction is not necessarily possible. Prediction plays an important role in data compression systems because it enables the removal of redundancy in data to achieve a high compression ratio. In predictive coding, the encoder predicts each sample from the previous ones and transmits the prediction error instead of the original sample. Then, the decoder makes the same prediction as the encoder and uses the prediction error to compute the original sample. The entropy or energy of the prediction error is generally lower than that of the original sample; thus the prediction error can be more compactly compressed with lossless or lossy compression tools.

Let us consider an image compression system. Figure 7(a) shows the “Lena” image and its enlarged face

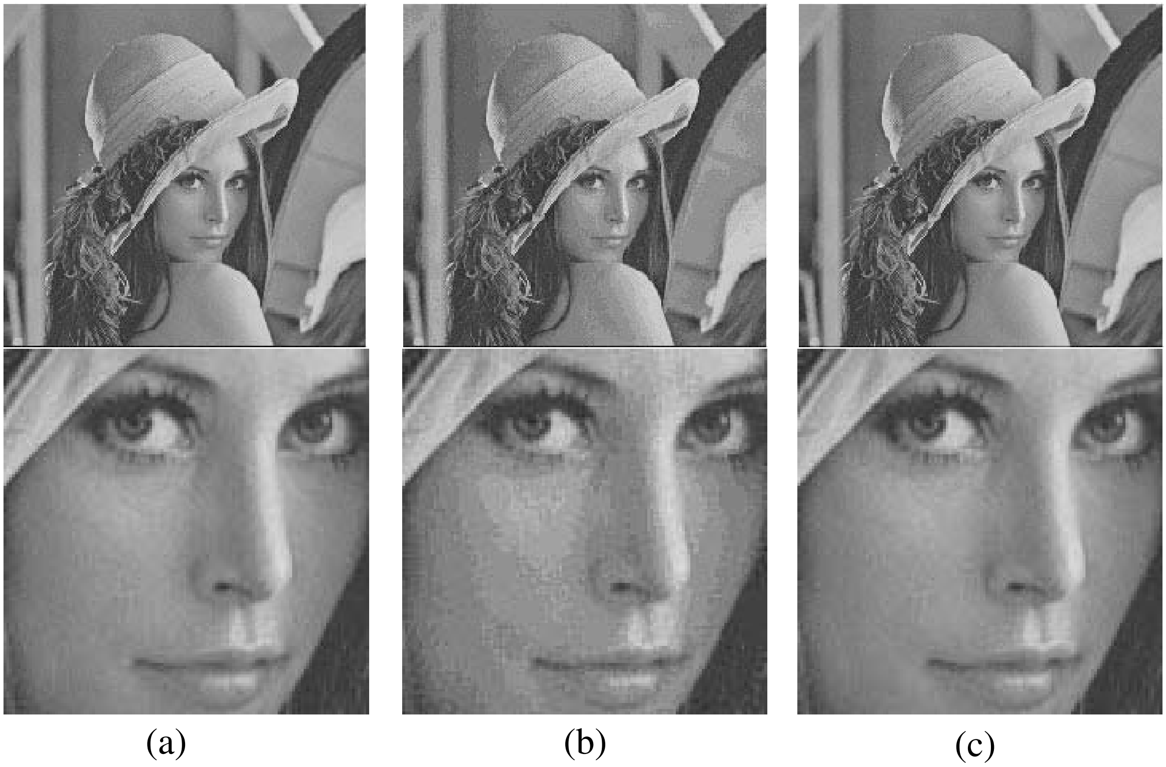


Figure 7: Lena images: (a) the original image, (b) the quantized image, and (c) the image obtained by predictive quantization.

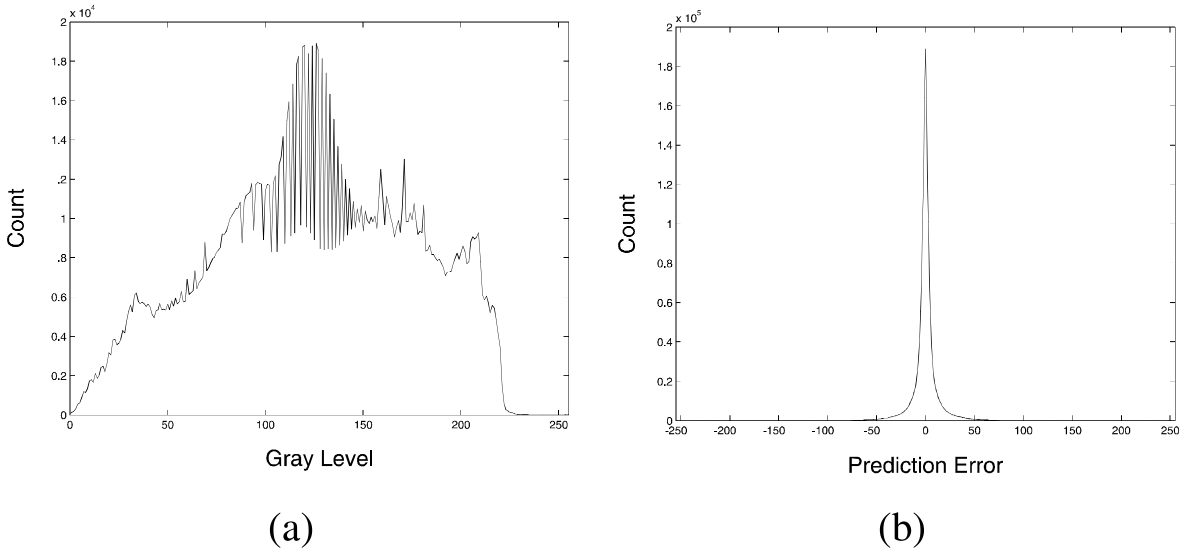

Figure 8: Histograms of (a) original gray levels and (b) prediction errors.

region. The image consists of 512 × 512 pixels. Each pixel has a gray level within [0,255] and is represented by a single byte. Figure 8(a) is the histogram of gray levels obtained from seven other test images. For each gray level, the histogram shows the number of pixels in the test images that have that gray level. Thus, after normalization, the histogram can be employed as an approximation of the pdf of gray levels. Based on the approximation of the pdf, we can design a 16-point scalar quantizer using the Lloyd algorithm. The 16 output points are

$$\{16,\ 30,\ 42,\ 58,\ 70,\ 84,\ 98,\ 114,\ 129,\ 143,\ 159,\ 173,\ 187,\ 200,\ 209,\ 217\}.$$

Figure 7(b) is the image quantized by this quantizer. It can be observed that the quantization error degrades the image quality. The rate is 4 bits per pixel, and the mean squared error is 18.974.

We can achieve better performance using predictive coding techniques, because adjacent pixels in typical images have similar gray levels. Suppose that the encoder compresses pixels in a raster scan order. Figure 8(b) is the histogram of prediction errors, when each pixel is predicted from the average of the past three pixels: left, upper, and upper right pixels. Note that the prediction errors are concentrated around 0 and much more compactly distributed than the original pixel values in Figure 8(a). For this distribution, the codebook of the 16-point Lloyd quantizer is given by

$$\{-56,\ -35,\ -25,\ -19,\ -15,\ -11,\ -7,\ -3,\ 0,\ 4,\ 8,\ 12,\ 17,\ 21,\ 32,\ 53\}.$$

Figure 7(c) is the image obtained by predictive quantization. During the prediction, the encoder uses the reconstructed values of past three pixels, instead of the original values, to avoid the mismatch between the encoder and the decoder. Then, the encoder quantizes the prediction error and transmits the output index to the decoder. In the decoder, the same prediction is performed, and then the quantized error is added to the prediction value to reconstruct a pixel. Note that Figure 7(c) provides better image quality than Figure 7(b). The mean squared error is 5.956.

The general structure of a predictive quantization system (Gersho & Gray, 1991, Chapter 7) is shown in Figure 9. This system is also called differential pulse code

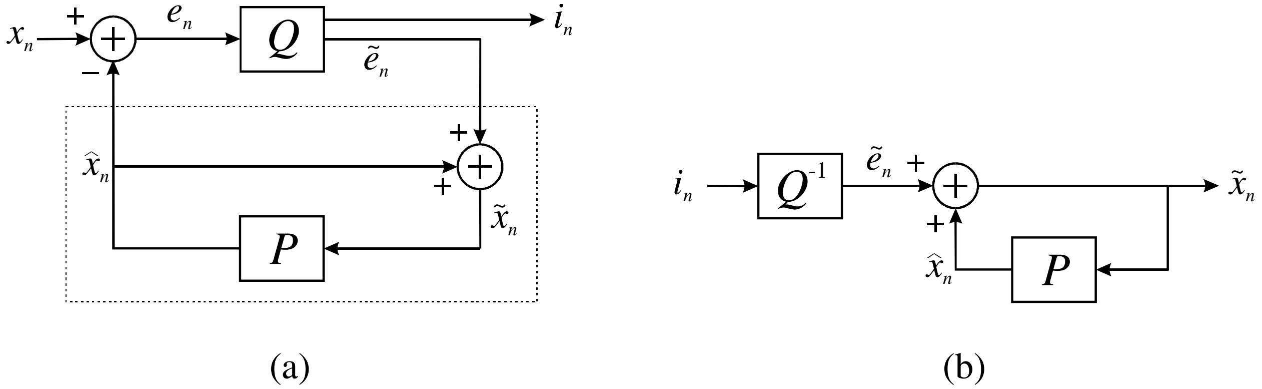

Figure 9: (a) The differential pulse code modulation (DPCM) encoder and (b) the DPCM decoder.

modulation (DPCM). The predictor P generates the prediction $\hat{x}_n$ of the nth sample x_n, based on the past reconstructed samples $\tilde{x}_{n-i}$ $(i = 1, 2, \ldots)$. The most common predictor is the linear predictor, given by

$$\hat{x}_n = \sum_{i=1}^{m} a_i \tilde{x}_{n-i}, \tag{6}$$

where a_i is a weighting coefficient. The quantizer Q quantizes the prediction error $e_n = x_n - \hat{x}_n$ into an output point $\tilde{e}_n$ and transmits the output index i_n. In the decoder, the dequantizer Q^{-1} converts the index i_n into the output point $\tilde{e}_n$ and adds it to the prediction $\hat{x}_n$ to reconstruct $\tilde{x}_n$.

A portion of the encoder, depicted as a dotted box in Figure 9(a), mimics the decoding operation, and uses the reconstructed samples in the prediction to avoid the mismatch between the encoder and the decoder. For example, consider a predictive quantization system, which uses the previous sample as the predictor and quantizes the prediction error to its nearest integer. Suppose that the encoder uses the original samples in the prediction and the input sequence is given by

$$0,\ 0.3,\ 0.6,\ 0.9,\ 1.2,\ 1.5,\ 1.8,\ 2.1,\ 2.4, \ldots.$$

Then, all the prediction errors are 0.3 and quantized to 0. Therefore, the decoder reconstructs the input sequence as an all-zero sequence, given by

$$0,\ 0,\ 0,\ 0,\ 0,\ 0,\ 0,\ 0,\ 0, \ldots.$$

In this case, the mismatch between the encoder and the decoder causes more and more errors in later samples due to error accumulation. On the other hand, if the encoder uses the reconstructed samples in the prediction, the decoder reconstructs the sequence as

$$0,\ 0,\ 1,\ 1,\ 1,\ 2,\ 2,\ 2,\ 2, .$$

and the mismatch problem is avoided.

Transform Coding

In transform coding, a sequence of source samples is represented by another sequence of transform coefficients, the energy of which is concentrated in relatively few coefficients. Because the coefficients have different statistics, they can be quantized more effectively than the original samples. In the decoder, the quantized coefficients are inverse transformed to reconstruct signal samples.

The discrete cosine transform (DCT) (Jayant & Noll, 1984, pp. 558–560) provides excellent energy compaction for highly correlated data. The DCT of a sequence $\mathbf{a}$ is related to the discrete Fourier transform (DFT) of the symmetric extension of $\mathbf{a}$ and can be computed by fast algorithms based on the fast Fourier transform (FFT). Thus, it is employed in several image and video compression standards. The DCT of an N-point sequence $\mathbf{a} = (a_0, a_1, \ldots, a_{N-1})$ is defined as

$$x_j = c_j \sum_{i=0}^{N-1} a_i \cos\left[\frac{\pi(2i+1)j}{2N}\right] \quad \text{for } j = 0, 1, \ldots, N-1,$$

where $c_0 = \sqrt{1/N}$ and $c_j = \sqrt{2/N}$ for $j = 1, 2, \ldots, N-1$.

The sequence of transform coefficients $\mathbf{x} = (x_0, x_1, \ldots, x_{N-1})$ can be inverse transformed into the original samples by

$$a_i = \sum_{j=0}^{N-1} c_j x_j \cos\left[\frac{\pi(2i+1)j}{2N}\right] \quad \text{for } i = 0, 1, \ldots, N-1.$$

This can be rewritten as

$$\mathbf{a} = \sum_{j=0}^{N-1} x_j \mathbf{b}_j,$$

where $\mathbf{b}_j$ is a basis vector, the ith element of which is equal to $c_j \cos[(\pi(2i+1)j)/(2N)]$.

Figure 10 shows the eight basis vectors for the 8-point DCT. When j is low, the samples in $\mathbf{b}_j$ are slowly varying, and the coefficient x_j represents a low-frequency

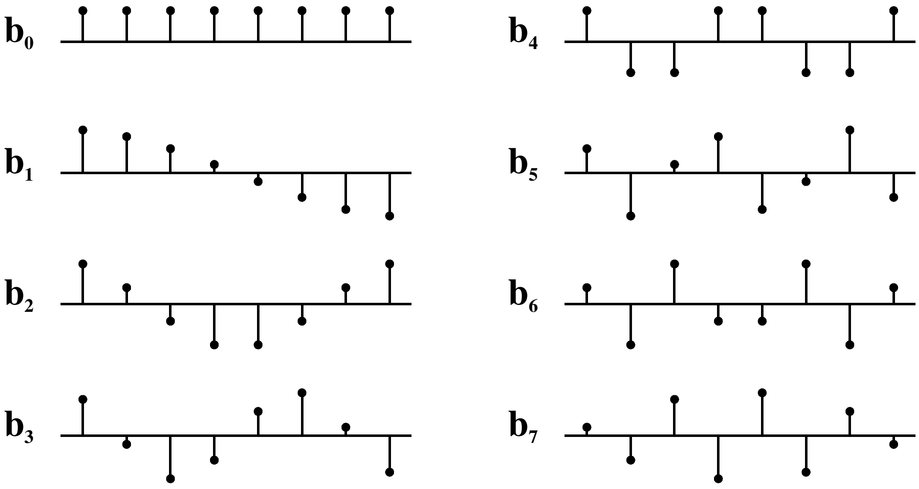

Figure 10: Basis vectors for the 8-point discrete cosine transform.

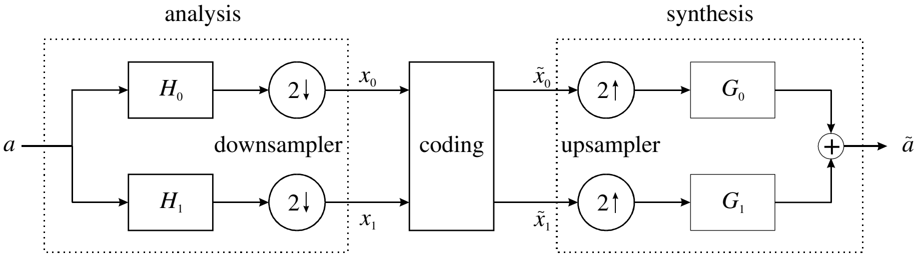

Figure 11: A subband coding system.

component in the signal. On the other hand, when j is high, x_j represents a high-frequency component corresponding to rapid variations between samples. As mentioned previously, many data sources generate a sequence of samples that are highly correlated. In such a case, high-frequency coefficients usually have smaller magnitudes than low-frequency coefficients. For example, consider the sequence of samples

$$(97,\ 102,\ 117,\ 135,\ 139,\ 140,\ 137,\ 130).$$

The 8-point DCT of these samples yields the coefficients

$$(352.5,\ -37.5,\ -25.2,\ 2.1,\ 1.8,\ 4.1,\ -0.7,\ -1.1).$$

Note that most energy is concentrated in the first three coefficients. Let us assume that the encoder transmits only the first three coefficients, after quantizing them into the nearest integers. Then, the decoder fills in the other coefficients with zeros and performs the inverse transform on

$$(353,\ -37,\ -25,\ 0,\ 0,\ 0,\ 0,\ 0)$$

to obtain approximate samples

$$(95.1,\ 104.6,\ 119.3,\ 132.7,\ 140.0,\ 139.9,\ 135.4,\ 131.4).$$

The approximation errors are relatively small, although only the first three quantized coefficients are employed in the reconstruction. In image compression systems, the two-dimensional DCT is employed, and the transform coefficients are encoded by more sophisticated coding schemes, such as zonal or threshold coding (Jain, 1989, pp. 508–510).

In most applications, the length of a signal is unbounded or too large to be transformed as a whole. Consequently, a source signal is partitioned into blocks of samples and the DCT is applied independently to the blocks. In this case, the DCT is called a block transform. The DFT, the DST, and the Hadamard transform are other examples of block transforms (Jain, 1989, Chapter 5). The main disadvantage of block transforms is that they cannot exploit possible correlations between blocks.

Subband and Wavelet Coding

Being different from block transforms, the subband transform involves no partitioning of samples, and thus possible correlations between blocks can be exploited. Figure 11 shows a 2-channel subband coding system, which transforms an input sequence into two frequency subbands. First, the encoder applies two analysis filters H_0 and H_1 to an input sequence, a, respectively. Then, the outputs are downsampled by a factor of 2 to generate two sequence x_0 and x_1. In general, H_0 is a low-pass filter and H_1 is a high-pass filter. Thus, x_0 represents low-frequency components in the original sequence, whereas x_1 represents high-frequency components. x_0 and x_1 can be quantized and coded differently according to their characteristics. In the decoder, the quantized sequences $\tilde{x}_0$ and $\tilde{x}_1$ are upsampled by inserting a zero between every two consecutive samples and then applied to synthesis filters G_0 and G_1 to reconstruct the input sequence approximately.

The analysis and synthesis filters can be designed so that the decoder reconstructs the original sequence losslessly, when there is no quantization error (i.e., $\tilde{x}_0 = x_0$ and $\tilde{x}_1 = x_1$). If this condition is satisfied, the set of the analysis and synthesis filters is called the perfect reconstruction filter bank. Several methods were proposed for the design of perfect reconstruction filter banks, driven by applications of subband coding of speech and image signals (Vetterli & Kovacevic, 1995, Chapter 3).

In the wavelet representation, a signal is hierarchically decomposed using a family of basis functions, which is built by scaling and translating a single prototype function (Mallat, 1989). The wavelet transform facilitates the multiresolution analysis of a signal, by reorganizing the signal as a set of details appearing at different resolutions. The wavelet transform has a close relationship with the subband transform, and the discrete wavelet transform (DWT) can be obtained by applying the two-channel subband transform to the low-pass subband recursively.

Figure 12 shows the subband decomposition of the "Barbara" image. First, we filter each row using two analysis filters and then downsample the filtered sequences to obtain low-(L) and high-(H) frequency subbands. In this figure, the 9-7 filter bank (Antonini, Barlaud, Mathieu, & Daubechies, 1992) is employed. Then, in the same way as the row decomposition, we decompose each column to obtain LL, LH, HL, and HH subbands.

This two-dimensional subband decomposition is recursively applied to the LL subband to obtain the DWT. Figure 13 shows the three-level wavelet decomposition of the "Barbara" image. The LL_3 subband approximates the original image at the coarsest resolution. The HL_i subbands contain vertical edge components at different resolutions ($i = 1, 2, 3$). Similarly, the LH_i and HH_i subbands

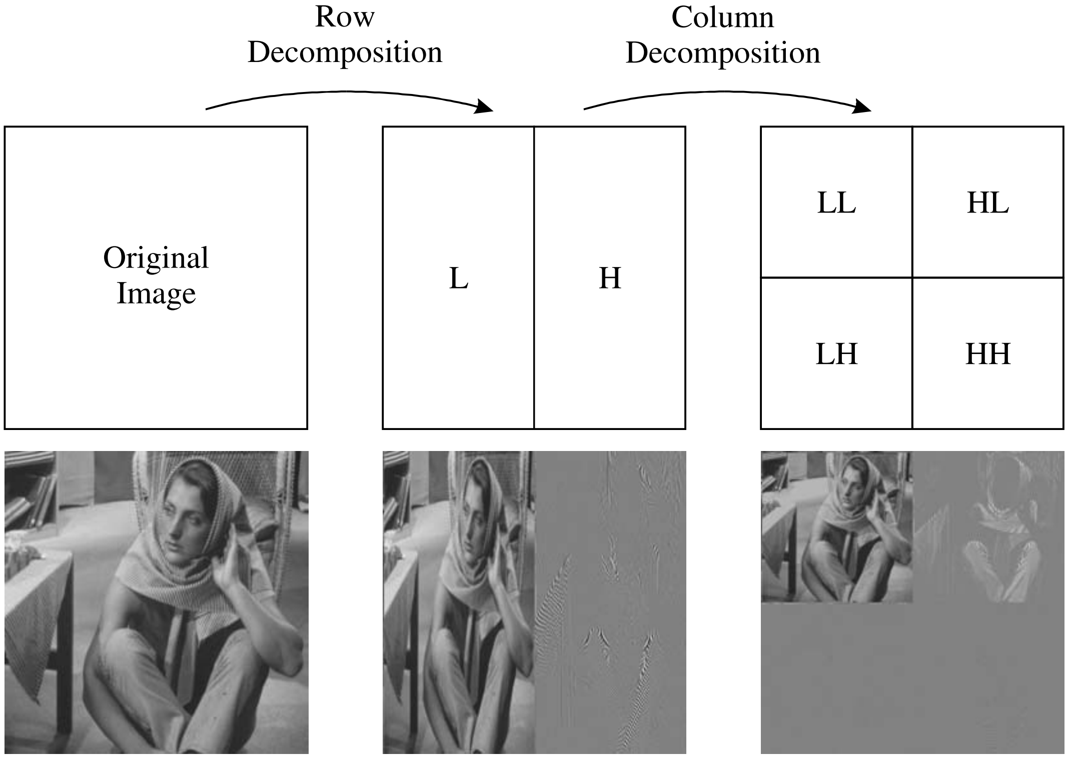

Figure 12: Subband decomposition.

contain horizontal and diagonal details, respectively. It can be seen that most signal energy is concentrated in the coefficients in the LL_3 subband. Therefore, the wavelet coefficients can be compressed effectively based on the adaptive quantization, by allocating a higher bit rate to the LL_3 subband than the other subbands (Vetterli & Kovacevic, 1995, Chapter 7).

Shapiro (1993) proposed an image compression algorithm, called embedded zerotree wavelet (EZW). His algorithm exploits interband correlations of DWT coefficients using zerotrees. Figure 13 illustrates a zerotree. The 21 coefficients, depicted by dots, represent the horizontal edge components of the same region in the original image. Thus, if the one coefficient in the LH_3 subband is less than a threshold, it is probable that the other 20 coefficients in the finer subbands also are less than the threshold. In such a case, the 21 coefficients are said to form a zerotree. Shapiro combined the concept of zerotrees with bit-plane coding and adaptive arithmetic coding to compress the DWT coefficients efficiently. The DWT is also used in the recent image compression standard JPEG2000 (Taubman & Marcellin, 2002).

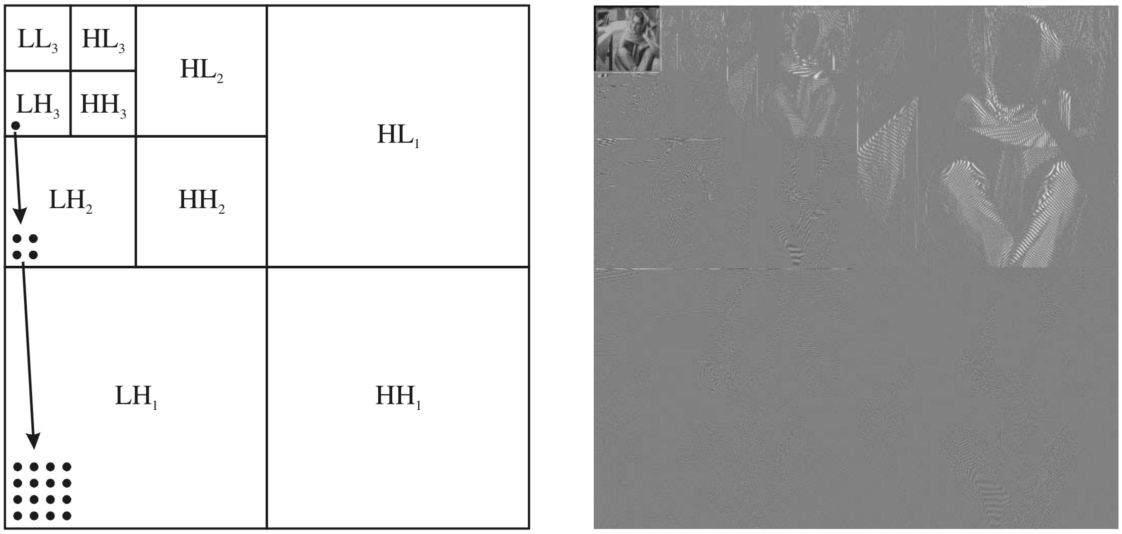

Figure 13: Three-level wavelet decomposition.

APPLICATIONS

A data compression system can be conceptually divided into a data modeler and a parameter coder. To compress a certain type of data, its characteristics should be first analyzed and modeled. Then, according to the data model, parameters are extracted from input data and compressed using one or more techniques in the previous two sections. The compression performance depends on how accurately the source data are modeled as well as how efficient the parameter coder is.

For example, letters in a text can be modeled as independent variables and each letter can be Huffman encoded, irrespective of its position in the text, according to the probability distribution of letters. Alternatively, we can adopt the model that the probability of a letter depends on the preceding letter, and design several Huffman codeword tables, one for each preceding letter. Similarly, the preceding *n* letters can be employed as a conditioning class, and a Huffman codeword table can be designed for each conditioning class. As *n* increases, the characteristics of text data can be more accurately approximated and text data can be more compactly encoded at the cost of higher complexities of the encoder and the decoder (Bell et al., 1990, Chapter 2).

Therefore, when designing the data modeler and the parameter coder, we need to consider several requirements of an individual application, including the desired compression ratio, tolerable distortion, and complexities of the encoder and the decoder. We describe main approaches and application areas of text compression, speech and audio compression, and image and video compression in the sections that follow.

Text Compression

By reducing the sizes of text files, we can use the limited storage space in a computer more effectively and save the communication time for sharing files between computers. In Unix environments, “compress” and “gzip” are often used as file compression tools. In personal computer environments, ARJ and ZIP are popular compression tools. These are all variations of Lempel-Ziv dictionary coding techniques. They can losslessly compress typical text data to 30–40% of its original size, because text data contain many redundancies and frequently recurring patterns.

Recently, context-based adaptive arithmetic coding has been studied to compress text data more efficiently (Witten, Neal, & Cleary, 1987). Moffat, Neal, and Witten (1998) reported that their arithmetic coder requires 2.20 bits/letter for a text file excerpted from the *Wall Street Journal*, whereas the gzip utility requires about 2.91 bits/letter. The text file has the zero-order letter entropy of 4.88 bits/letter, which is the minimum required bit rate when letters are modeled as independent variables.

Speech and Audio Compression

Speech and audio compression is used in many applications, including digital telephony, voicemail, voice recording, digital audio broadcasting, and digital audio storage. Speech and audio signals differ in dynamic ranges and listener expectations of offered qualities (Noll, 1997). Telephone speech has the frequency range of 300–3,400 Hz, and users are accustomed to tolerating some distortions. Telephone speech is often sampled with a sampling rate 8 KHz, and each sample is represented with 8 bits. Without compression, it requires the bit rate of 64 Kbps. On the other hand, high-quality audio has the frequency range of 20–22,000 Hz. On compact disks (CDs), audio signals are sampled at 44.1 KHz, and each sample is represented with 16 bits. Thus, each second of stereo music requires 176,400 (= $44{,}100 \times 2 \times 2$) bytes of data, corresponding to about 1.41 Mbps.

A popular speech coding technique is code-excited linear prediction (CELP) (Gersho, 1994). In CELP, the decoder generates the speech signal as the response of a synthesis filter to an excitation signal. The encoder periodically updates the synthesis filter by analyzing the speech waveform and determines the excitation signal for each segment of the waveform. The excitation signal is compressed by using vector quantization. A set of excitation vectors are stored in a codebook. For each time segment, the encoder transmits the optimal codeword to the decoder, which can generate the best approximation of the original waveform. The synthesis filter parameters are also quantized and transmitted to the decoder every 20 to 30 ms. CELP has been studied extensively, and many variations have emerged. It is the basis of many speech coding standards, such as G.723.1 and AMR. G.723.1 was standardized by International Telecommunication Union-Telecommunication Standardization Sector (ITU-T), and AMR by European Telecommunications Standards Institute (ETSI). G.723.1 supports 5.3 Kbps and 6.3 Kbps and is employed in video-conferencing applications. AMR supports eight bit rates between 4.75 Kbps and 12.2 Kbps and was adopted as the speech coder for the third-generation mobile communications by the 3rd Generation Partnership Project (3GPP).

Early work on audio compression is based on uniform or nonuniform scalar quantization of audio samples. However, these schemes cannot exploit statistical dependencies between samples, and thus cannot achieve a sufficiently high compression ratio. Most of recent audio compression algorithms rely on the subband or the block transform to decompose audio signals into several spectral components (Gersho, 1994). In human perception of audio signals, one sound can mask or block the perception of another sound. Based on the masking models, bits are allocated across the spectral components to reduce the required bit rate while maintaining the same perceptual quality. The Moving Pictures Expert Group (MPEG) has developed a series of audiovisual standards (Noll, 1997). MPEG-1/Audio consists of three audio coding schemes, called Layer 1, Layer 2, and Layer 3, which require bit rates between 32 Kbps and 448 Kbps. Among them, Layer 3 is the most involved and provides the best compression performance. It is also known as MP3 and popularly used for transmitting audio data over the Internet or storing music files in storage devices. MPEG-1/Audio has been extended to MPEG-2/Audio and MPEG-4/Audio, which provide better compression performance and support the coding of various kinds of audio data, such as the multichannel audio signal and synthetic speech.

Image and Video Compression

One of the earliest applications of image data compression is binary image coding for facsimile transmission. There are several compression standards for binary images, including MH, READ,MR, MMR, JBIG, and JBIG2 (Sayood, 2000, pp. 169–174). JBIG and JBIG2 provide better compression performance than other standards and are based on context-based adaptive arithmetic coders, called the QM coder and the MQ coder, respectively.

JPEG is a compression standard for gray-level and color images and is popularly used to transmit still images over the Internet or store photographs in digital cameras (Taubman & Marcellin, 2002, Chapter 19). It partitions an input image into blocks, consisting of 8 × 8 pixels, and transforms each block using the two-dimensional DCT. Then, each transform coefficient is quantized by a uniform quantizer. After the quantization, many coefficients are zeros because of the energy compaction property of the DCT. To encode consecutive zeros effectively, the quantized coefficients are zigzag scanned and run-length encoded with Huffman codewords. JPEG2000 is a recent compression standard for still images, which provides better performance than JPEG (Taubman and Marcellin, 2002, Part II). In JPEG2000, an input image is transformed into several subbands by using the DWT, and the bit-planes of subbands are transformed into a bit stream by an algorithm known as EBCOT and then encoded by the MQ coder. In addition to superior compression performance, it also supports efficient progressive compression, which is highly desirable when transmitting images over slow communication links. The decoder can first decode a coarse image and then gradually increase the image resolution or pixel accuracy as more data are received.

Compression technologies also offer the possibility of transmitting or storing a vast amount of video data in a compact way and are essential in many applications, such as digital television and high-definition television (HDTV) broadcasting, video on demand, videophone, and videoconferencing. Many efforts have been made in the video compression technology, and several international standards have emerged to support a wide range of applications (Sikora, 1997; Sullivan & Wiegand, 1998):

- ITU-T H.261: A video coder for videophone and videoconferencing applications. It was designed to compress video sequences, which consist mainly of head-and-shoulders of people. Its target bit rate range is 64–2,048 Kbps.
- ITU-T H.263: The first video coder designed specifically to support very low bit rate applications. Its target bit rate range was originally designed to be about 10–30 Kbps but has been broadened to 10–2,048 Kbps, because it provides better performance than the H.261 coder at any bit rate.
- MPEG-1: A video coder for storing movies on CD-ROM, covering bit rate range of 1–2 Mbps. It can provide VHS videotape quality at about 1.5 Mbps.
- MPEG-2: A video coder for digital TV/HDTV broadcasting and for storing video on DVD. It was designed to transmit high-quality, multichannel, multimedia signals at 2–15 Mbps.
- MPEG-4: A video coder similar to H.263, but it includes several functionalities to support flexible representation of visual data, such as object-oriented coding and three-dimensional mesh coding.

These standards compactly encode video sequences by exploiting temporal and spatial correlations via motion compensated prediction and DCT, respectively. More specifically, each frame is predicted blockwise from the previous frame using motion vectors. Then the residual frame consisting of prediction errors is encoded using a block DCT in a manner similar to JPEG.

CONCLUSION

Data compression is one of the key technologies that enables Internet and mobile communications. It has been extensively studied since the late 1960s, and various compression algorithms have been developed to store and transmit multimedia data efficiently. In this chapter, we classified data compression into lossless and lossy techniques and described key algorithms for each class. We then surveyed application areas of text compression, speech and audio compression, and image and video compression.

As new types of data emerge, researchers are considering modeling and compression techniques for them. For example, the compression of three-dimensional images is an important research topic, because three-dimensional images have the potential to be used in many applications, such as video gaming, virtual reality, and e-commerce. Progressive compression and error-resilient coding are also important issues, because they are essential in transmitting multimedia data over wireless channels that are bandwidth-limited and error-prone.

GLOSSARY

Code A set of binary descriptions assigned to samples of data source.

Codeword A binary description in a code.

Compression ratio The ratio of original data size to compressed data size.

Data coding A synonym for data compression.

Data compression A mechanism of representing data in a compact way.

Decompression A mechanism of reproducing original data from compressed data.

Decoder A device that reproduces original data from compressed data.

Encoder A device that compresses data.

Entropy The amount of information in a data source, or the minimum number of bits required on average to describe a sample of the data source.

Lossless compression Compressing data such that an exact duplicate of the original data can be reproduced at the decoder.

Lossy compression Data compression that allows loss of information.

Data Mining in E-commerce

Sviatoslav Braynov, *State University of New York at Buffalo*

INTRODUCTION

Data mining in e-commerce is a rapidly growing field, the development of which is driven by the explosive growth of online information and the economic need to provide personalized products and services. Although data mining applications have been around for several decades, e-commerce provides new challenges and new opportunities for the field. First, e-commerce data differs significantly from standard offline data in that it is distributed, highly volatile, unstructured, and heterogeneous. Second, e-commerce creates better opportunities for studying customers' behavior and providing highly personalized content.

This chapter is intended to help business managers and application developers in understanding the emerging field of mining e-commerce data, and attempts to accomplish the following:

- To summarize the driving forces for using data mining applications in e-commerce
- To provide an overview of existing technologies that can be used for mining e-commerce data
- To survey novel data mining applications, such as recommender systems, systems for log file analysis, Web marketing systems, and systems for customer profiling
- To summarize the open problems and current trends in data mining applications in e-commerce

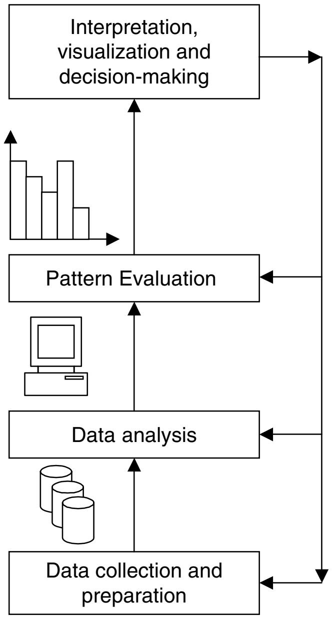
DATA MINING IN E-COMMERCE

Basic Definitions

Data mining tools and applications perform data analysis and reveal interesting data patterns contributing to business strategies, market research, inventory management, and so forth. In a broad sense, the term "data mining" usually refers to the nontrivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data (Fayyad, Piatesky-Shapiro, Smyth, P., & Uthurusamy, 1996). There are several other terms with similar meaning, such as knowledge mining, knowledge discovery in databases, pattern analysis, and so on. Data mining is an interactive and iterative process consisting of several steps:

- Specification of the problem: Developing an understanding of the domain knowledge and identifying the goal of the data mining processes.
- Data collection and preparation: Removing noisy and inconsistent data, handling missing data fields, dimensionality reduction, transformation into forms appropriate for mining, integration of multiple data sources, and so on
- Analysis of data with data mining techniques: Applying a particular data mining method to extract data patterns
- Evaluation of the results according to previously established measures: Separating truly interesting patterns from uninteresting, spurious, and irrelevant patterns
- Interpretation and visualization of the results
- Making decisions or acting on the results

The main steps in a data mining process are shown in Figure 1. The data mining process may be iterative and contain repetitions and loops between any two steps. Data mining usually aims at achieving one of two goals: (a) verification and validation of previously discovered patterns and (b) the discovery of new patterns. When new patterns are discovered, they can be divided into two groups: descriptive and predictive. Descriptive patterns explain the general characteristics of data, whereas predictive



Interpretation, visualization and decision-making
Pattern Evaluation
Data analysis
Data collection and preparation

Figure 1: The main steps in the process of data mining.

patterns help make predictions about future trends, find missing or unavailable data, and so on. Predictive patterns are usually discovered by building models based on a set of training data. The success of predictive models usually depends on the training data used to generate the model.

Driving Factors for Data Mining in E-commerce

E-commerce Data

E-Commerce is an ideal domain for data mining. Compared with traditional offline business, e-commerce provides *large quantities of data* that keep growing at exponential speed. The enormous amounts of data generated from a Web site, for example, could provide meaningful insights into what type of visitors are likely to make purchases, what are the most typical navigation patterns, and what pages are most/least visited. The fast-growing e-commerce data exceeds human abilities for data collection, analysis, and decision making. Manual data analysis tools, such as statistical packages and query tools, are extremely time-consuming and fail to provide important data patterns. What makes e-commerce especially attractive for data mining is the ability to both generate and collect data automatically. Online transactions provide the opportunity to design, implement, and employ systems specialized in collecting data for the purposes of data mining (Kohavi & Provost, 2001). E-commerce systems can collect data that is otherwise difficult or costly to access and are able to keep track of customers' actions in virtual stores, that is, what articles they look at, how they browse a catalog, what items they put into their shopping cart. In contrast, tracking costumers in brick-and-mortar stores with in-store videos is difficult and costly.

Quality of data is another feature that makes e-commerce especially suitable for data mining. Collecting data electronically could significantly reduce the noise associated with manual data entry and processing. Noisy and corrupt data can hide some important patterns, introduce inconsistencies, or lead to misleading interpretations. Many online data collection systems provide validation functionality that helps correct erroneous data. For example, many Web-based hypertext markup language (HTML) forms automatically validate the user's input and check for inconsistencies.

Another factor facilitating data mining in e-commerce is *the measurable return on investment* (Kohavi & Provost, 2001). The Web allows for direct detection, collection, and analysis of revenue-related events such as Web site hits, clickstreams, purchasing events, and so on. Data mining results could be directly transformed into numeric measures of the success of Web design and the efficiency of marketing campaigns. In addition, data mining results are directly actionable by changing the Web sites design, improving inventory and category management, or targeting particular customers via Internet marketing. After interpreting the results of data mining, business analysts could pass recommendations to the developers of the online store, who will make necessary changes to improve, for example, the store's banner efforts, product assortment, checkout process, and product layout.

Another important advantage of e-commerce data mining is the possibility of conducting controlled experiments and measuring their effect on business goals. Direct marketing, for example, can target particular control groups, and the results can be data mined for predictive behavior modeling of consumers.

Mass Personalization

Personalization is an important driving factor behind the success of data mining applications in e-commerce. Personalization is the use of technology and customer information to tailor e-commerce interactions between a business and each individual customer (http://www.personalization.org). In general, personalization refers to making a Web site more responsive to the users' individual needs. This includes providing individually tailored products, services, and information. The goal of personalization is to serve customers better by anticipating their needs, customizing services and products, and establishing a long-term relationship encouraging customers to return for subsequent visits. Personalization is playing a constantly increasing role in e-commerce, in which customer experience is crucial to building customer loyalty to an online store. Personalization is usually based on building predictive models of customer behavior, preferences, and interests. Given its ability to build successful predictive models, data mining is an excellent personalization approach for building customer profiles, providing recommendations to the customers, and delivering personalized Web content. Most of the existing personalization tools make extensive use of different data mining techniques.

OVERVIEW OF BASIC DATA MINING TASKS AND TECHNIQUES

Data mining is an interdisciplinary field with a large variety of methods and algorithms developed in different research areas such as artificial intelligence, pattern recognition, machine learning, statistics, and databases. Its primary focus is on data representation, data storage and access, efficiency and scalability of algorithms, human–machine interaction, visualization, and so on. Data mining techniques may have different goals depending on the intended results of the data mining process. Most common data mining tasks include the following:

- **Classification:** the task of mapping a data item into one of several predefined classes. Each class is associated with a class label attribute, and the process of classification can be viewed as assigning labels to data items. In some cases, classification could be implemented as either supervised or unsupervised learning. In supervised learning, a training set is used in which the class label of each data item is known beforehand. The training set is analyzed by a classification algorithm, and the algorithm is then applied to a test data set to estimate the accuracy of the classification. Whereas supervised learning uses a training set in which the class label of each data item is known, in unsupervised learning the class labels and the number of classes may not be known in advance. Common applications of classification include, for example, loan payment prediction, customer credit policy analysis, and customer segmentation for target marketing.
- **Regression:** the analysis of the dependency of some variable (called the dependent variable) upon the values of other variables (called the independent variables). Regression could be linear (with linear dependency among variables) or nonlinear. Regression can be viewed as a special type of prediction in which one could predict the value of the dependent variable using the known values of the independent variables. Regression has multiple applications in e-commerce. For example, it can be used to predict the consumer demand for a new product as a function of advertising expenditures.
- **Clustering:** the task of grouping data items into classes based on the similarity between items. Clustering is a typical descriptive task in which the data is described using a finite set of categories or clusters. Clustering is used in marketing, for instance, to segment customers based on their purchasing patterns and demographic characteristics.
- **Dependency analysis:** the task of finding a model that describes dependencies between variables or attributes. Dependencies can be described at the structural or quantitative level (or both). The structural level specifies the direction of dependencies, that is, which variables are dependent on other variables. The quantitative level, on the other hand, specifies the strength of dependency between variables. Dependency analysis is used in numerous applications including learning propensity to purchase, real estate appraisal, fraud detection, and so on.
- **Change and deviation detection:** the task of discovering changes in data from previously measured values, or discovering data items that are significantly different from the remaining set of data. Deviation detection is used to detect unusual usage of credit cards or telecommunication services. It is also used in customized marketing for identifying groups of customers with extremely low or extremely high incomes.

The rest of this section provides a brief overview of the most common techniques used in data mining. Because of the wide variety of techniques the overview is by no means exhaustive.

Association Rule Mining

Association rule mining looks for interesting relationships among items in a given data set. It explains which attributes or which items tend to appear together. For example, the information that customers who buy coffee and sugar also tend to buy milk could be represented by the following association rule:

$$\text{buy}\,(X, \text{coffee}) \text{ and buy}\,(X, \text{sugar}) \Rightarrow \text{buy}\,(X, \text{milk})$$

In general, an association rule is an implication of the following form:

$$A \Rightarrow B,$$

where A and B are sets of items. Several items constitute a transaction. A transaction is defined as a set of items bought together.

The intended meaning of this association rule is that consumers who buy all items in itemset A also tend to buy all items in itemset B. Because thousands of association rules can be generated from large transaction databases, some weak and nonsignificant associations have to be filtered out. To eliminate spurious associations, two measures of rule interestingness are used: minimum support and minimum confidence. The minimum support measure ensures that the co-occurrence of itemsets A and B is frequent enough to signal a strong correlation between all items. In the example, a minimum support of 10% means that in at least 10% of all transactions, consumers have bought coffee, sugar, and milk. In other words, a minimum support of x% means that at least x% of transactions contain all items in A and B. The minimum confidence measure ensures that there is a strong relation between itemset A and itemset B. That is, the occurrence of itemset A implies the occurrence of itemset B with high probability. A minimum confidence of 60% means that at least 60% of consumers who purchased coffee and sugar also bought milk. In other words, a minimum confidence of x% means that at least x% of transactions containing all items in A also contain all items in B.

Association rule mining can be divided into two phases: (a) mining frequent itemsets, that is, itemsets occurring at least as frequently as some predefined threshold, called minimum support count, and (b) generating association rules from frequent itemsets. Usually only strong association rules are generated, that is, association rules satisfying minimum support and minimum confidence.

One of the most popular algorithms for mining frequent itemsets is Apriori (Agrawal & Srikant, 1994). As the name suggests, Apriori uses prior knowledge to reduce the size of the search space. Another efficient algorithm for association rule mining is the frequent pattern growth

(FP-growth), which uses divide-and-conquer strategy and compresses the database representing frequent items into a frequent-pattern tree (Han, Pei, & Yin, 2000).

Association rule mining can be used for dependency analysis, classification, and prediction. Common applications include market basket analysis, customer segmentation, and fraud detection.

Bayesian Belief Networks

A Bayesian belief network (BBN) is a directed acyclic graph (i.e., a graph with pointed arcs and no cycles) in which the nodes represent random variables and arcs represent probabilistic dependency. Each BBN incorporates two types of knowledge: structural knowledge, specifying which variables are dependent on each other, and quantitative knowledge specifying the strength of the dependencies. Structural knowledge is captured by the topology of a BNN, whereas quantitative knowledge is captured by conditional probability distributions describing the relationship between a node and its parents. One or more nodes in a network could be selected as output nodes representing particular classes. This makes BBN useful for probabilistic classification, for which the result is a probability distribution over classes.

A BBN is usually trained using a set of training examples. Two components of a BBN can be learned: graphical structure and conditional probabilities. The training is based on a theorem proved by Thomas Bayes, an 18th-century clergyman. The theorem specifies how conditional probabilities are updated as new data are observed. There are a variety of learning algorithms for BBN, depending on whether the structure is fixed or unknown and whether variables are hidden or observable. Bayesian belief networks are typically used for dependency analysis and classification.

Decision Trees and Rule Induction

A decision tree is a special type of tree where each nonterminal node represents a test on an attribute of a data item, each branch represents an outcome of the test, and terminal nodes (leaves) represent classes or class distributions. To classify a particular data item, one starts at the root node and tests the attribute values of the item against the decision tree by tracing the tree from the root to a terminal node. When a leaf is reached, the data item is classified as one belonging to the class associated with the leaf. An example of a decision tree indicating whether a consumer is likely to buy an insurance policy is shown in Figure 2. Each leaf node represents a class: buys or doesn't buy. Nonleaf nodes represent test on an attribute: age or income.

A decision tree can easily be converted to a set of if–then classification rules. A single rule is created for each path from the root to a leaf node. Each test along the path corresponds to a conjunction in the left-hand side (the *if* part) of the rule. For example, the decision tree in Figure 2 can be converted to the following set of rules:

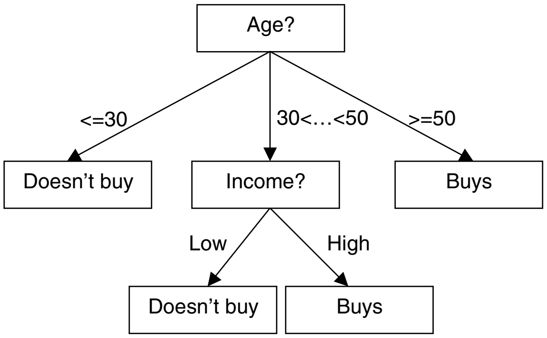


Figure 2: An example of a decision tree.

IF Age < = "30" THEN buys_insurance = "No"

IF Age > "30" AND Age < "50" AND Income = "Low" THEN buys_insurance = "No"

IF Age > "30" AND Age < "50" AND Income = "High" THEN buys_insurance = "Yes"

IF Age > = "50" THEN buys_insurance = "Yes"

One of the most widely used algorithms for decision tree induction is ID3. It uses an information-theoretic measure of the quantity of information, called entropy, defined in the late 1940s by Claude Shannon. The algorithm starts at the root node and incrementally builds the tree by selecting one attribute test for each node. From among all remaining attributes, the algorithm selects the attribute with the greatest entropy reduction. In this way, the algorithm minimizes the information needed to classify data items and the expected number of tests.

Artificial Neural Networks

An artificial neural network is a parallel and dynamic system consisting of many interconnected input/output units, designed to model the behavior of biological neurons. Each unit has many inputs that combine into a single output value. Units are connected, so that the outputs from some units are used as inputs to other units, and each connection has a weight associated with it. All inputs to a single unit are combined as a weighted sum, and the resulting input value is transferred to an output value via an activation function. The most common activation functions are step activation function, linear function, logistic sigmoid function, and hyperbolic tangent function.

An artificial neural network can learn a model of the training set that can subsequently be used for classification or prediction. The goal of the training is to adjust the weights so that the output of the network is as close to the desired output as possible, for as many examples of the training set as possible. The most common learning technique, back-propagation, was developed by John Hopfield. Back-propagation calculates the output for every example from the training set, finds the error by taking the difference between the calculated result and the expected result, and feeds the error back through the network. During the back-propagation phase, the weights are adjusted to minimize the error.

As with its biological counterpart, every unit in an artificial neural network has the property that small changes in inputs can have large effects on the output and vice versa. The property that small changes matter is usually called nonlinear behavior. What makes neural networks especially attractive is their ability to model this nonlinear behavior, their robustness, and their fault tolerance. When they degrade, they tend to degrade gracefully, making the reduction in performance less obvious. In addition, they are tolerant to noise in the input data. On the other hand, neural networks have been often criticized for their poor interpretability. It is difficult for a human expert to associate any meaning with the learned weights.

Clustering Techniques

Clustering is the process of grouping data into clusters, based on the principle of maximizing intraclass similarity and minimizing interclass similarity. In other words, objects in one cluster are similar to one another and are dissimilar to objects from other clusters. A typical application of cluster analysis is discovering homogeneous subpopulation of customers in marketing databases and characterizing each population based on purchasing patterns.

There are a variety of clustering algorithms. A good review of clustering algorithms is provided by Jain, Murty, and Flynn (1999). In general, major clustering algorithms fall into the following classes:

- **Partitioning algorithms:** Given a set of *n* objects, a partitioning algorithm creates k, $k \leq n$, clusters. Such an algorithm usually starts with some initial partitioning and then iteratively improves it by reallocating objects from one cluster to another. Typical examples of partitioning algorithms are the *k*-means algorithm and the *k*-medoids algorithm.
- **Density-based algorithms**: Many partitioning algorithms cluster objects based on the distance between them, thus allowing only for spherical-shaped clusters. Density-based algorithms, on the other hand, can discover clusters of arbitrary shape. The clusters are continuously enlarged until their density exceeds some predefined threshold. DBSCAN and OPTICS are examples of density-based clustering algorithms.
- **Hierarchical algorithms:** These algorithms could be either top-down or bottom-up. A bottom-up (or agglomerative) algorithm starts with each object forming a separate cluster. Then the algorithm successively combines clusters into larger ones until some termination condition is met. A top-down (or divisive) algorithm starts with all objects forming one cluster and successively splits the clusters into smaller clusters. AGNES and DIANA are, respectively, an agglomerative and a divisive algorithm.
- **Grid-based algorithms:** These algorithms divide the object space into a finite number of cells forming a grid structure. The clustering is performed on the grid. Typical examples of grid-based algorithms include CLIQUE and STING.

Genetic Algorithms

Genetic algorithms and evolutionary programming are algorithmic optimization techniques inspired by natural biological evolution. A genetic algorithm starts with a population of individuals and successively applies selection, crossover, and mutation operations to maximize a fitness function. Each individual is usually represented as a string over a finite alphabet, and every string has its own fitness. In the crossover operation, substrings from a pair of individuals are swapped to form a new pair. In the mutation operator, randomly selected bits in an individual's string are changed. From every population, a new population is formed which consists of the fittest individuals in the population and the offspring of these individuals, produced by crossover and mutation operators. The process of generating populations based on previous populations continues until no further improvements are possible or some termination criterion is met. Genetic algorithms are easily parallelizable and can be used for both classification and optimization problems. The major drawback of genetic algorithms is that they may get stuck on local optima and never find the best solution.

WEB MINING

The term "Web mining" usually refers to the overall process of discovering potentially useful and previously unknown information from Web documents and services. Web mining could be viewed as an extension of standard data mining to web data (Kosala & Blockeel, 2000). Compared with standard data mining, Web mining differs in the type of data, the way the data is collected, and the nature of the patterns discovered. Good reviews of Web mining are provided by Mena (1999) and Srivastava, Cooley, Deshpande, and Tan (2000). Web mining could be divided into three areas: web usage mining, web content mining, and web structure mining.

Web Data

Web mining data can be collected at the server-side, client-side, proxy servers, or obtained from corporate databases. Most of the data comes from the server log files. Every time a user requests a Web page, the Web server enters a record of the transaction in a log file. Records are written in a format known as the Common Log File format (CLF), which has been standardized by the World Wide Web consortium (W3C). Different servers may extend this format in their own way. The most useful fields of a CLF record are the Internet Protocol (IP) address of the host computer requesting a page, the Hypertext Transfer Protocol (HTTP) request method, and the time of the transaction. The IP address field helps identify individual users, if they use a static IP address. All records with the same IP address are combined to track the user navigation. The HTTP method indicates what the user is looking for and which pages he or she has requested. The time of the transaction helps detect how much time the user has spent on every page.

Although CLF is supported by the majority of log-file analysis tools, it has several drawbacks, the main one being the fixed number of fields. In many cases, it is desirable to record more information or to omit some information to improve efficiency. As a solution to these problems, the W3C has proposed the Extended Log File format (ELF). ELF provides the following additional functionalities:

- Permits control over the data recorded
- Supports needs of proxies, clients, and servers in a common format
- Allows exchange of demographic data
- Allows summary data to be expressed

One of the most useful extensions to the CLF is the referrer field, which identifies the site visited before coming to the current page. Referrer information answers the important question of where customers are coming from. If a visitor is coming from a search engine site, the referrer information can even tell you which key words have been used to find the current page. Knowing the search key words helps management and business analysts better understand the identity of a Web site and the reasons customers are visiting the site.

Although server log files are rich in information, the data is stored at a very detailed level that is difficult for humans to understand. In addition, the size of log files is usually extremely large, often ranging into gigabytes per day. The best way to summarize and analyze log files is with traffic analysis and monitoring software. Log file analysis tools import the information recorded in server log files into a database from which they can generate reports. Such reports usually summarize data and provide quantitative and qualitative analysis. The reports could be fine-tuned to meet different needs. A Web designer, for example, could receive an analysis of how visitors navigate the site, which are the most and the least visited pages, and how much time visitors spend on the Web site or on a particular page. Advertisers can run reports on the number of clicktroughs for a banner or a product, the keywords that bring the most traffic to the Web site, demographic statistics and users' locations, routes visitors make to the Web site, and so on.

The interest in interpreting Web usage data has spawned a large market for log file analysis tools capable of summarizing, analyzing, and visualizing Web usage information. There is a great number of commercial off-the-shelf log file analysis tools such as WebTrends, NetTracker, and Astra. Most of the tools produce reports on factors such as Web site visitor patterns, referring sites, navigation paths, demographics, and cookie information. Some log file analysis packages, such as Astra, provide visualization tools capable of displaying aggregate counts and spatial views of Web traffic over time. More sophisticated visualization tools can summarize large quantities of data, visually orient data from different perspectives, and proactively expose trends.

It is worthwhile to differentiate between log-file analyzers and sniffers. A network sniffer is a system for interception and analysis of packets transmitted through a network. It is usually installed on a local network computer, and it is able to observe all traffic, including packets not addressed to the chosen computer. A network sniffer is an alternative solution to the problem of tracking visitors' behavior. It is especially attractive in cases in which a Web site is deployed on many Web servers, because the sniffer can collect information from all these servers at once.

Another data source for Web mining are cookies containing state related information, such as a user ID, passwords, shopping cart, purchase history, and customer preferences. Cookies help keep track of several customer's visits and build a customer's profile. Some marketing networks, such as Doubleclick, use cookies to track customers across many Web sites. Other tracking devices, currently producing a lot of controversy, are Web bugs, or clear GIFs (graphical interchange format). A Web bug is a hidden image in a Web page that activates a third-party spying devise without being noticed by Web page visitors. Web bugs are usually used for tracking users' purchasing and browsing habits.

Web Usage Mining

Web usage mining is applying the techniques of data mining to Web data to understand and predict user behavior. To build better predictive models, some additional domain knowledge is generally used, such as concept hierarchies, a Web site topology, navigation templates, and so on. Some Web usage mining applications directly access Web data using some preprocessing techniques. Other applications transform and save Web data as relational databases before using it. The main goals of Web usage mining include improving the effectiveness of Web sites, providing personalized Web content, and eliciting users' needs and preferences. Because of the special importance of Web usage mining to e-commerce, we discuss in separate sections two common types of Web usage mining: clickstream analysis and Web site evaluation.

Clickstream Analysis

Clickstream analysis is a special type of Web usage mining that provides information essential to understanding the effectiveness of Web site design, marketing and merchandising efforts. The concept of clickstream usually refers to a visitor's path through the Web site. It contains the sequence of actions entered as mouse clicks, keystrokes, and server responses as the visitor navigates a Web site. Clickstream data can be obtained from a Web server's log files, commerce server database, or from client-side tracking applications. Analyzing clickstream data is of special importance to online marketing and merchandizing. Web metrics have been developed to help evaluate the effectiveness of online marketing. The most common metrics include impression (a measure of how many times a banner is displayed), clicktrough rate (the ratio of the number of times a banner is shown to the number of times it is clicked on), conversion rate (the percentage of visitors who made purchases), and banner ad return on investment (the amount of profit generated by visitors referred by a banner ad). Clickstream analysis tools usually classify hyperlinks by their merchandising or marketing purposes (for example, a hyperlink could be a cross-sell link referring to a complementary product). This helps in tracking and measuring traffic on hyperlinks. Many Web log analysis tools provide standard reports on clickstream patterns that analyze, summarize, and visualize Web usage patterns. One common drawback of log-file analysis tools is the passive interpretation of clickstream data in the form of noninteractive static diagrams and charts. To overcome these limitations of log-file analysis packages, Lee, Podlaseck, Schonberg, and Hoch (2001) developed an interactive visualization system, providing interactive interpretation of clickstream data. The system analyzes the effectiveness of a Web site by using two visualization techniques: visualization of sessions using parallel coordinates and visualization of product performance using starfield graphs. Starfield graphs are general purpose analysis tools for finding patterns in multidimensional data. The starfield display helps identify the relative significance of different products and find out whether they are over- or underexposed on a Web site.

Web Usage Mining for Web Site Evaluation

Early methods for measuring and studying the quality of Web sites were based on interviewing or questioning representative groups of customers. Such methods tend to incur significant overhead in terms of establishing an experimental environment and selecting a representative group. In addition, these methods are difficult to tailor to individual customers and difficult to perform on a regular basis.

Because the activities of all users are recorded in log files and can be easily associated with e-commerce servers' data, data mining provides a natural way to evaluate the quality and measure the success of commercial Web sites. Within the framework of Web-based marketing, two measures of a Web site's success have been traditionally used: contact and conversion efficiency (Spiliopoulou & Pohle, 2001). The contact efficiency is the percentage of visitors engaged in exploring the Web site, whereas the conversion efficiency is the percentage of visitors that purchased something or achieved the site's goal. In addition, the quality of a Web site could be measured on the basis of factors such as response time, quality of navigation, accessibility of a page, time spent, and so on.

To improve their Web sites, some companies employ clustering methods to discover correlated but not linked pages. The results are used to generate dynamic pages, pointing to all related topics within a Web site. Another method uses conjoint analysis to find a Web site's optimal shape from a user's point of view. The principle of conjoint analysis is that different visitors attach values to all the attributes of a Web site. The total value of a Web site is usually the sum of the values of its components. After finding the optimal value and the optimal Web site configuration for a visitor, individualized layouts can dynamically be generated for different users.

Another common technique is to find the most frequent paths in a Web site and to suggest them to new and inexperienced visitors. Most frequent navigation paths show general tendencies when browsing a Web site, and they are usually extracted using association rule discovery or sequence mining. It is of significant importance to the success of the site that the most frequent paths are optimized with respect to the site's business goal. The IBM SurfAID goes one step further by trying to discover the evolution of navigation patterns for a particular time spot, using association rules and time series analysis.

The Web Utilization Miner (WUM; http://wum.wiwi.hu-berlin.de) is a Web-mining tool especially designed for analyzing and improving Web sites. WUM differentiates between action pages and target pages. Action pages are defined as pages invocation of which indicates that the user is pursuing the site's goal (purchasing a product, providing information, etc.). Target pages are pages on which the site's goal is usually achieved. WUM identifies all pages with low contact efficiency, allowing for improving the structure of a Web site. In addition, it analyses the conversion efficiency for all active sessions to identify pages that cause difficulties for visitors.

Web Content Mining

Web content mining relates to the discovery of useful information from the Web documents, which may consist of text, audio, video, image, and metadata. A subfield of data mining, called multimedia data mining, specializes in mining multiple types of data. Another data mining subfield, termed knowledge discovery in texts, deals with semistructured or unstructured data, such as HTML documents. Most applications in the area of Web content mining represent unstructured documents as vectors of words and their frequencies (Baeza-Yates & Ribeiro-Neto, 1999). Some preprocessing, such as Latent Semantic indexing, is usually applied to reduce the dimensionality of the vector space. The applications in Web content mining range from text classification and categorization, event detection and tracking, and text clustering, to finding sequential patterns and associations in text documents. Topic detection and tracking (TDT) is an interesting new line of research in Web content mining (Allan, Carbonell, Doddington, Yamron, & Yang, 1998). Topic tracking is the process of monitoring a stream of news stories to find which of them are tracking the same event. Topic detection involves detecting the occurrence of a new event such as stock price or interest rate change, in a stream of news stories from multiple sources.

Web Structure Mining

Web structure mining tries to discover the network structure and the topology of the Web hyperlinks. It is especially useful for categorizing Web pages and for finding hidden relationships between Web sites. PageRank was one of the first algorithms measuring the relative importance of web pages based on the graph structure of the Web. The algorithm was developed by Sergey Brin and Lawrence Page and is used by Google to rank Web pages based on their relevancy. The rank of a Web page is defined as a weighted sum of the ranks of all pages pointing to the page. In another interpretation, the rank of a page is the probability that a random surfer visits the page.

Another page ranking algorithm, called hubs/authorities model, was proposed by Kleinberg. The hubs/authorities was inspired by social network analysis and discovers specific types of pages based on their incoming and outgoing links. In the hubs/authorities model, pages with many links pointing to them are called authorities in the sense that they are considered to deliver relevant content. Pages with many outgoing links are called hubs in the sense that they are considered to point to similar content. The main idea behind the hubs/authorities model is that good hubs point to good authority pages, and good authority pages have been pointed to by good hubs.

DATA MINING AND PERSONALIZATION

Businesses use personalization techniques to increase sales, perform target advertising, improve customer service, make Web sites easier to use, increase customer base, develop customer loyalty, and so on. Database marketing, for example, makes extensive use of personalization techniques to market a particular product to a specific customer or group of customers. In this section, we discuss two major personalization areas: customer profiling and recommender systems.

Customer Profiling

One of the key issues in developing e-commerce applications is the construction of profiles for individual customers, providing information about who these customers are and how they behave. Electronic profiling is based on the customers' online behavior and transactional histories, which can be captured by registration forms, log files, cookies, and collaborative software. Most of the work on individual profiling is proprietary and has been done in the industry.

A profile is a collection of data describing an individual user or a group of users. There are two main types of customer profiles: factual and rule-based (Adomavicius & Tuzhilin, 2001). A factual profile usually contains demographic attributes (e.g., address, education, gender, income level), and some additional transactional data (e.g., maximal purchase amounts for a customer, favorite products). Factual profiles have been used by Engage Technologies (http://www.engage.com). Whereas factual profiles describe who the customer is, rule-based profiles describe what the customer does. Such profiles usually contain association rules describing the customers' behavior. The rules can be defined by a human expert or extracted from transactional data using data mining methods. Rule-based profiles have been used by Broad Vision (http://www.broadvision.com) and Art Technology Group (http://www.atg.com).

The rule-based profile-building process usually consists of two main steps: rule discovery and rule validation. Various data mining algorithms can be used for rule discovery, such as Apriori, FP-Growth, and CART. A special type of association rules, profile association rules, has been proposed by Agrawal, Sun, and Yu (1998). A profile association rule is one in which the left-hand side consists of customer profile information (e.g., age, salary, education). The right-hand side includes customer behavior information (e.g., buying beer, using coupons). Agrawal et al. (1998) proposed a multidimensional indexing structure and an algorithm for mining profile association rules. Profile association rules are especially useful for segmenting users based on their transactional characteristics and for deriving customers' behavioral attributes from their transactional attributes.

One of the problems with many rule discovery methods is the large number of generated rules, many of which, although statistically acceptable, are spurious, irrelevant, or trivial. Postanalysis is usually used to filter out irrelevant and spurious rules. Several data mining systems perform rule validation by letting a domain expert inspect the rules on one-by-one basis and reject unacceptable rules. Such an approach, however, is not scalable to large numbers of rules and customer profiles. Another solution was proposed by Adomavicius and Tuzhilin (2001). The idea behind the solution is that many users share common or similar rules that can be validated together. Rules are collected into one set, and several rule validation operators are applied iteratively to the set. The collective rule validation allows a human expert to reject or accept a large number of rules at once, thereby reducing validation effort.

Another interesting application of user profiling is personalized Web search and information retrieval. A personalized Web browser is capable of learning user's access behavior. A typical example is Letizia (http://www.media.mit.edu), which monitors the user's browsing behavior, develops a user profile, and searches for potentially interesting pages. The user profile is developed in nonintrusive ways while the user is browsing the Web. Another approach is to seek the user's help and ask the user to rank pages. Based on the rankings and the content of the pages, a browser can learn a user profile and help predict which pages are of interest to the user.

Recommender Systems

Recommender systems (Schafer, Konstan, & Riedl, 2001) have been used in B-to-C e-commerce sites to make product recommendation and to provide customers with more information to help them decide which product to buy. Recommender systems provide a solution to the problem of how to choose a product in the presence of overwhelming amount of information. Many e-commerce sites offer millions of products, hence choosing a particular product requires processing of large amounts of information, thereby making consumer choice difficult and tedious.

Recommender systems contribute to the success of e-commerce sites in three major ways (Schafer et al., 2001). First, they help improve cross-sell. Cross-sell is usually improved by recommending additional products for the customer to buy. For example, by looking at the products in the customer's shopping cart during the checkout process, a system could recommend additional complementary products. Second, recommender systems could help convert occasional visitors into buyers. By providing a recommendation, a retailer could deliver customized information, increase the amount of time spent on a Web site, and, finally, increase the customer's willingness to buy. Third, recommender systems help build loyalty and improve customer retention. Personalized recommendations create a relationship between a Web site and a customer. The site has to invest additional resources into learning customers' preferences and needs; and customers have to spend time teaching a Web site what their preferences are. Switching to a competitor's Web site becomes time-consuming and inefficient for customers who have to start the process of building personalized profiles from the beginning. In addition, customers tend to return to Web sites that best match their needs.

Recommender systems use different methods for suggesting products (Schafer et al., 2001). One of the most common is item-to-item correlation. This method relates one product to another using purchase history, attribute correlation, and so on. For example, CDNOW suggests a group of artists with similar styles to the artist that the customer likes. Another recommendation method is user-to-user correlation. This method recommends products to a customer based on a correlation between that customer and other customers visiting the same Web site. A typical example is "Customers who bought." When a customer is buying or browsing a selected product, this method returns a list of products purchased by customers who purchased the selected product. Other recommendation methods include statistical summaries (Top-10 list), expert reviews, and customers' comments, among other information.

Collaborative filtering (CF) was one of the earliest recommender technologies. CF systems make a recommendation to a target customer by finding a set of customers, called a neighborhood, that have similar taste with the target customer. The neighborhood includes customers who have a history of agreeing with the target user. Products that the neighbors like are then recommended to the target customer. In other words, CF is based on the idea that people who agreed on their purchasing decisions in the past are likely to agree in the future. The process of CF consists of the following three steps: representation of products and their rankings, neighborhood formation, and recommendation generation.

During the representation stage, a customer-product matrix is created, consisting of ratings given by all customers to all products. The customer-product matrix is usually extremely large and sparse. It is large because most online stores offer large product sets ranging into millions of products. The sparseness results from the fact that each customer has usually purchased or evaluated only a small subset of all products. To reduce the dimensionality of the customer-product matrix, different dimensionality reducing methods can be applied, such as latent semantic indexing and term clustering.

The neighborhood formation stage is based on computing the similarities between customers and grouping like-minded customers in one neighborhood. The similarity between customers is usually measured using either the correlation or the cosine measure. After computing the proximity between customers, a neighborhood is formed using clustering algorithms.

The final step of CF is to generate the top-N recommendations from the neighborhood of customers. Recommendations could be generated using the most frequent item technique, which looks into a neighborhood and sorts all products according to their frequency. The *N* most frequently purchased products are returned as a recommendation. Another recommendation technique uses the discovery of association rules. It finds all rules supported by a customer, that is, the customer has purchased the products from the left-hand side of the rule. Then the products from the right-hand side of the rule are returned as a recommendation.

Another recommendation technique is content-based recommendation (Balabanovic & Shoham, 1997). Although collaborative filtering identifies customers whose tastes are similar to those of the target customer, content-based recommendation identifies items similar to those the target customer has liked or purchased in the past. Content-based recommendation has its roots in information retrieval (Baeza-Yates & Ribeiro-Neto, 1999). For example, a text document is recommended based on a comparison between the content of the document and a user profile. The comparison is usually performed using vectors of words and their relative weights. In some cases, the user is asked for feedback after the document has been shown to him. If the user likes the recommendation, the weights of the word extracted from the document are increased. This process is called relevance feedback.

However, content-based recommender systems have several shortcomings. First, content-based recommendation systems cannot perform in domains where there is no content associated with items, or where the content is difficult to analyze. Second, only a shallow analysis of very restricted types of content is usually performed. To overcome these problems, a new hybrid recommendation technique has been proposed (Melville, Mooney, & Nagarajan, 2002). It is called content-boosted collabo rative filtering. The technique uses a content-based predictor to enhance existing user data and then provides a recommendation using collaborative filtering.

DATA MINING IN WEB MARKETING

Data mining applications help marketers discover new behavioral and attitudinal customers' characteristics. The four main Internet marketing activities include discovery and analysis of customer attraction, sequential pattern discovery for customer retention, rule induction, clustering for cross-selling, and preempting departure (Buchner, Anand, Mulvenna, & Hughes, 1998).

Customer Attraction

The three major goals of customer attraction analysis are as follows: selection of new prospective customers, acquisition of selected customers, and dropping out existing nonprospective customers. Web site visitors are usually grouped into clusters: no customers (visitors who never made a purchase), irregular customers, and regular customers. Association rules could be used for describing the behavior of each group of customers. To increase the conversion rate of irregular customers, or to retain regular customers, dynamically generated Web content could be displayed to each group.

Customer Retention and Sequential Patterns

In e-commerce, where competitors are only one click away, retaining customers is an extremely challenging task. Sequential pattern discovery helps marketers find intertransaction and navigation patterns across time. In intertransaction patterns, the presence of a set of items is followed by another item within a particular time interval. Navigation patterns are similar to intertransaction patterns with the only difference that they capture sequence of frequently visited pages. The techniques used for sequential pattern discovery are usually based on association rule discovery and cluster analysis. Data is usually collected from transactional databases and from the Web server's log files. The discovery of visitors' sequential patterns allows marketers to predict users' visits, and purchasing and browsing patterns, and helps them target advertising, such as banner selection and e-mail marketing.

Cross-Selling

The goal of cross-selling is to extend horizontally or vertically the purchasing activities of existing customers. A common data mining method for cross-selling is attribute-oriented induction based on a hierarchy of Web pages. Attribute-oriented induction is a learning-by-example technique that extracts generalized data from databases. When a user visits a page, the page is replaced by its corresponding more general page from the hierarchy, thereby providing the visitor with more choices.

Customer Departure

The goal of customer departure analysis is to predict and prevent customer exit by taking appropriate action, such as targeted promotion or content targeting. Customers depart from a Web site when they either move to a competitor or stop purchasing a certain product or service. Because a customer departure is not directly observable, a use-defined threshold interval is chosen, in which no activities have been recorded. Log files from certain period to the last activity are analyzed to find the characteristics of the customers who left the Web site.

DATA MINING IN MARKET BASKET ANALYSIS

The goal of market basket analysis is to determine which products are purchased together by a customer, that is, which products a customer puts into his or her shopping cart or "market basket." Market basket analysis provides several advantages to businesses. First, it helps retailers better design store layout or online catalogs by combining and displaying together all products that are likely to be purchased together. Second, market basket analysis helps direct marketers target particular customers based on their purchasing histories. Third, knowing which products sell together can help inventory management.

A special type of market basket analysis is differential analysis. In differential analysis, data mining analysts compare results, for example, between different stores, between customers in different segments, or different seasons of the year. Differential analysis helps analysts filter out spurious patterns and discover patterns that apply to specific subsets of data. Rule induction is usually used for market basket analysis. Most commercially available data mining systems, such as Nuggets, IBM Intelligent Miner, and Clementine, provide tools for mining association rules.

Market basket analysis can be applied outside retail industry. Some other applications include the following:

- **Analysis of credit card purchases:** Items purchased using a credit card can be used to predict future purchases.
- **Analysis of telephone calling patterns:** By identifying which services tend to be purchased together by telecommunication customers, companies can bundle these services together and increase revenue.
- **Identification of fraudulent medical insurance claims:** Unusual combinations of medical insurance claims can signal fraudulent behavior.
- **Analysis of banking services:** By identifying specific services (car loans, certificates of deposit, etc.) that are likely to be purchased together, banks can offer customers other services that are likely to be purchased together with the services customers already purchased.

CONCLUSION

E-commerce companies can greatly benefit by deploying data mining technologies. The fast-growing e-commerce data exceeds human abilities for data collection, analysis, and decision making. Web mining can help businesses reveal important data patterns, build customer profiles, improve the efficiency of Web sites, and perform controlled experiments, among other things. Data mining helps address the fundamental issue of personalization by providing solutions for understanding customers' behavior, and generating personalized content. To meet the constantly increasing information needs of the highly competitive e-commerce markets, new techniques for collection and analysis of Web data have been developed, such as log-file analysis and recommender systems.

Because of the large variety of data mining applications in e-commerce, this overview is by no means exhaustive. There are many other data mining applications in e-commerce including applications in financial modeling and fraud detection. Financial modeling uses predictive models, such as artificial neural networks and regression, for portfolio optimization, investment selection, and trading models. Carlberg & Associates, for example, developed a neural network model for predicting the Standard & Poor's 500 Index, using interest rates, dividends, earnings, and oil prices. LBS Capital Management, an *Inc.* 500 fund-management company, uses expert systems, neural networks, and genetic algorithms for asset management and risk analysis. The FALCON fraud assessment system from NHC uses neural network to detect suspicious credit card transactions. Many retail banks use it for fraud protection.

Although promising, data mining in e-commerce is still in its infancy. The Web presents new problems and challenges to traditional data mining. The main obstacles to successful mining of e-commerce data are as follows:

- **The unstructured web data:** Web data is usually stored in different formats on different media.
- **Low-quality data:** Web server logs cannot accurately identify sessions or users. It is usually difficult to detect critical events using server logs.
- **Scalability:** Most Web data mining algorithms cannot process the amount of data generated at Web sites.
- **Data integration:** Integration of Web usage data with Web content and Web structure data. Integration of data from various sources in different formats.

There are several directions for future research and development. An interesting direction for e-commerce data mining is discovering unexpected information, that is, information that cannot be anticipated by the user. Most of the data mining applications essentially look for information matching some previously established expectations in the form of predefined models. Recent work by Liu, Ma, and Yu (2001) proposes data mining methods that help find unexpected information from competitors' Web sites. Unexpected information may include unknown services, products, or information that competitors have. With this information, a company can design countermeasures to improve its competitiveness.

Topic detection and tracking (Allan et al., 1998) is another promising direction for e-commerce data mining. TDT is a Defense Advance Research Projects Agency (DARPA) sponsored initiative that finds and tracks new events in a stream of broadcast news stories. TDT could help businesses detect the appearance of new topics, such as the release of a competitive product, price dynamics, customers' feedback, or financial news, and track their evolution.

The main promise of data mining technology is its ability to cope with and exploit the ever-growing amount of online data. As competitive pressures increase, data mining is going to play an ever-increasing role for the success of e-business.

GLOSSARY

Artificial neural network A nonlinear technique based on a model of a human neuron; a neural net is used to predict outputs from a set of inputs.

Association rule An if–then rule describing how often certain items have occurred together.

Clustering The process of grouping the data into clusters based on the principle of maximizing intraclass similarity and minimizing interclass similarity.

Collaborative filtering Recommendation technology that makes a suggestion to a target customer by finding a set of customers that have similar taste.

Content-based recommendation Recommendation technology that makes a suggestion to a target customer by finding items similar to those the target customer has liked or purchased in the past.

Customer profile A collection of data that describes an individual user or a group of users.

Data mining The nontrivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns in data (Fayyad et al., 1996).

Decision tree A tree representing a collection of tests that lead to a class or a value.

Genetic algorithm An optimization algorithm based on natural evolution concepts such as genetic combination, mutation, and natural selection.

Log file A file generated by Web servers that keeps a record for every transaction.

Personalization The use of technology and customer information to tailor e-commerce interactions between a business and each individual customer.

Data Warehousing and Data Marts

Chuck Kelley, *Excellence In Data, Inc.*

INTRODUCTION

Data warehousing and data marts bring a new way for organizations to learn about their internal and external customers, vendors, and employees. The problem is that while tremendous amounts of data have been captured, there has not been an environment in which the user community could share the knowledge gained from and with their customers, vendors, or employees. With the advent of the Internet, ways must be devised to capture data, transform that data into information, and provide access to that information.

The Internet provides a strong environment where the organization can share information within the user community, whether they are employees, vendors, or customers. The sharing of information can provide value to their customers, thereby becoming a competitive weapon. This competitive weapon will help organizations to grow.

Information technology (IT) organizations have embarked on data warehousing and data marts as a method of accomplishing the transforming of data into information and have been providing tools to allow the knowledge workers to "mine" the data to find knowledge. Once this knowledge has been "mined," there must be a process in place to make sure that this new knowledge is true. Once it is determined to be true, then the new knowledge must be fed to the operational systems and the user community. The highly generic formula (Kelley, 2001)

$$\text{Value of Data Warehouse} = \text{Quality of Knowledge} \times \text{Organizational Reach}$$

is a strong requirement for data warehousing on the Internet. In this formula, the more people that learn about high-quality knowledge, the more value the data warehouse adds to the organization. The Internet provides the wide organization reach to that knowledge. The value of the data warehouse will vary, based on each organizations' ability to change, the subject areas defined, and the quality of the data, to name a few.

How do organizations get to this environment? By building a data warehouse architecture that focuses on

Capturing data;
Cleaning the data (thereby providing high-quality data);
Transforming that data into information; and
Delivering the data to the user community.

THE DATA WAREHOUSING PRIMER

Where Did the Data Warehouse Come from?

Data have been captured by transaction systems since the beginning of the computing age. Until recently, there has been no easy way to get the captured data to the user community. Giving access directly to the transaction systems has proven to be bad for performance and the results may not be high-quality or integrated data. Examples of why this is true are below:

More data remain in the transaction system for no apparent reason other than that is where they are stored today (bad performance).

It is hard to tune a system to do both transactions (four reads and five writes) and analysis (read a million rows and aggregate) (bad performance).

Transaction systems are about capturing data, not capturing the highest level of quality data (not high-quality data).

Transaction systems are about doing one job, not worrying about whether they capture the exact same data that another transaction system captures just so that they can be tied together (not integrated).

The data warehouse was developed to solve the needs of the user community concerning these issues.

Data warehousing provides an integrated, historical collection of data. Historical information allows the user community to do trend analysis over a long period of time. There is no longer a need to keep all the history in the transaction systems, unless it is required by the application. This makes them leaner and meaner, so that they can perform like they should.

By taking all the data from the transaction systems and putting it in an integrated collection of data designed for the user community, the data warehouse provides the much needed holistic view of the customer and their relationship(s) with the organization.

The Data Warehouse Environment

Data warehousing is an environment that allows user community to access data that have been structured for query. Querying is asking questions and getting results that will allow the user to "perceive" information that will be more valuable to the user community. Sometimes this can be a multi-step process. Think about how decisions are made. An "Ah, Ha!" is the ultimate goal. "Ah, Ha!" can be defined as finding something not known before that may be of value to the user community.

This "Ah, Ha!" might take a significant number of steps. The first query might start with a tremendous number of rows. An anomaly might be perceived in the data. Looking at that subset of data might lead the user down a path that may or may not be fruitful. (However, one could say that it will always be fruitful because information was learned that was not known previously!) If not, then back up to the previous data set and try another path through the data. Eventually, some knowledge will be gained from this process of thought. That knowledge might be as simplistic as "the data shows no trend" toward your hypothesis or "there is a relationship between abnormally large purchases (using credit cards) of clothes and the likelihood of that person declaring bankruptcy."

Data warehousing, if built properly, provides the environment to peruse the data to find new knowledge and generate value.

The data warehousing environment has been through a lot of changes since the early 1990s. The largest areas of change are in (1) the implementation of the data warehousing environment and (2) accessing the data in the data warehouse via the Internet. There are two major concepts strongly associated with the implementation of a data warehousing environment—(1) the data warehouse and (2) data marts.

Data Warehouse

The data warehouse is defined as a (1) subject-oriented, (2) integrated, (3) time variant, (4) nonvolatile collection of data in support of management's decisions (Inmon, 1992).

Subject oriented—Subject oriented means that each area of the data warehouse is built to solve a business problem. That problem can be (but is not limited to) (1) understanding your customer's buying habits, (2) processes that affect the quality of your product, or (3) efficiency of your staff. Subject areas have no application flavor at all. In fact, they will typically take data from multiple applications to create a single subject area. For example, a bank may create a customer data warehouse that contains transactions from the checking accounts, saving accounts, loan department, and investments. While each has its own application, the subject area within the data warehouse would look nothing like those applications.

Integrated—Integrated means that there is a single uniform representation of data stored in the data warehouse. If some of the manufacturing plants keep track of copper wire in centimeters, others in millimeters, and others in inches, there needs to be a uniform way of storing this in the data warehouse. That way, analysis can be done without having to remember that unit of measure each plant uses, or worse yet, adding quantities together without realizing the units of measure are different. Integration also allows the organization to implement their standardized definitions.

Time variant—All data as they enter the data warehouse are accurate at some point in time. Associating all pieces of data with a moment in time allows the user community to understand trends, correlations, etc. over time.

Nonvolatile—Nonvolatile is a synonym for read-only. Having data change in the data warehouse means that we can restate history—never (OK, never say never!) a good thing to do. If data are valid as of one moment, they need to be associated with that moment of time in the data warehouse.

While the data warehouse is always shown as a large monolithic database, it can be a distributed database (Inmon & Kelley, 1993). Distributed databases add a level of complexity in the creation of the data warehouse. This complexity includes the following:

The coordination of extracts of the source systems;
The use of different algorithms for calculations; and
The synchronization of loads into the data warehouse.

During the early days, there were introductions to the data warehouse defined as wholesale/retail models of data warehouse. The wholesale data warehouse was in fact, conceptually, a monolithic data warehouse. The retail data warehouse was a subset of the data warehouse, fed from the data warehouse, but containing only the data required for that business area. Another way the data warehouse was described is that the enterprise data warehouse feeds the departmental data warehouse that feeds the personal data warehouse. What happened over time is the renaming of these fed systems (retail, departmental, and personal data warehouses) as data marts.

The task of building the enterprise data warehouse has become unyielding. The pressure to get something out to the user community became quite overbearing. Therefore, there is a push to build data marts. The term data mart can be described as avoiding the impossibility of tackling the enterprise data warehouse planning job all at once (Kimball et al., 1998).

Data Marts

Data marts came into place originally as a way to describe a subset of data produced from the data warehouse. The data mart concept has grown to be a lot more than that.

Now, the data mart is built without the data warehouse. The question that must be asked is, "How is the plethora of data marts being controlled?" Most data marts are being built without a framework of the concept of the data warehouse in mind. A mechanism to tie the data marts together is needed—conformed dimensions (Kimball et al., 1998) (dimensions will be discussed in the section Creating the Data Model). A conformed dimension is data that have the exact same meaning as that used in multiple data marts. Therefore a customer dimension in one data mart would closely resemble a customer dimension in a second data mart. Without the concept of conformed dimensions, stovepipe data marts will most likely be created. Stovepipe data marts will not allow the user community to do cross-data mart analysis, and hence, cross-business analysis.

With the exception of the enterprise data warehouse-only environment (see the next section), a data mart is where the user community accesses the data. Data marts are created to do specific studies using on-line analytical processing (OLAP) techniques including ROLAP (relational OLAP), HOLAP (hybrid OLAP), DOLAP (desktop OLAP), MOLAP (multidimensional OLAP), and data mining. OLAP and data mining are discussed elsewhere in the Internet Encyclopedia.

Architectures of the Data Warehouse Environments

There are three primary architectures of the data warehousing environments. They are as follows:

Enterprise data warehouse-only (Figure 1);

Enterprise data warehouse feeding data marts (Figure 2); and

Collection of data marts (Figure 3).

Enterprise Data Warehouse-Only

The enterprise data warehouse-only environment is created with a single data warehouse database. The user community will query directly to the data warehouse for the business needs. The pros of this environment are that it

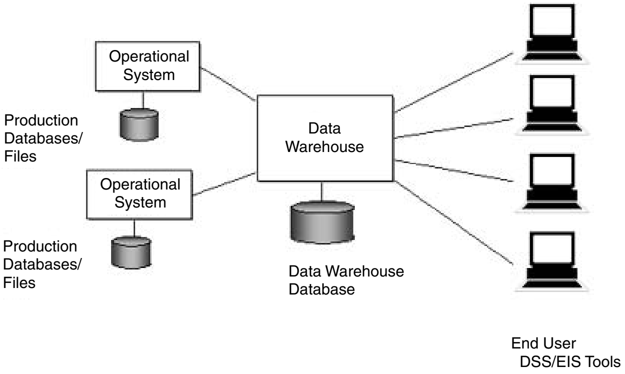

Figure 1: Enterprise data warehouse.

Is the easiest to implement and understand;

Provides for a single point of authority of the data;

Is the easiest to synchronize; and

Provides for a single query point of data for the user community.

The cons for this environment are that

It may need lots of network bandwidth since the user community can be everywhere;

Your database vendor needs to support large tables with lots of parallelism; and

The environment will eventually require large time windows for the extraction, transformation, and load processes (discussed in the section The Extraction, Transformation, and Load (ETL) Processes).

Enterprise Data Warehouse Feeding Data Marts

This environment generally allows access to the data warehousing environment via data marts only. The enterprise data warehouse keeps the data accurate and feeds the data to the data marts. The pros of this environment are that

It gets data closer to the user;

It has a faster response with smaller data sets;

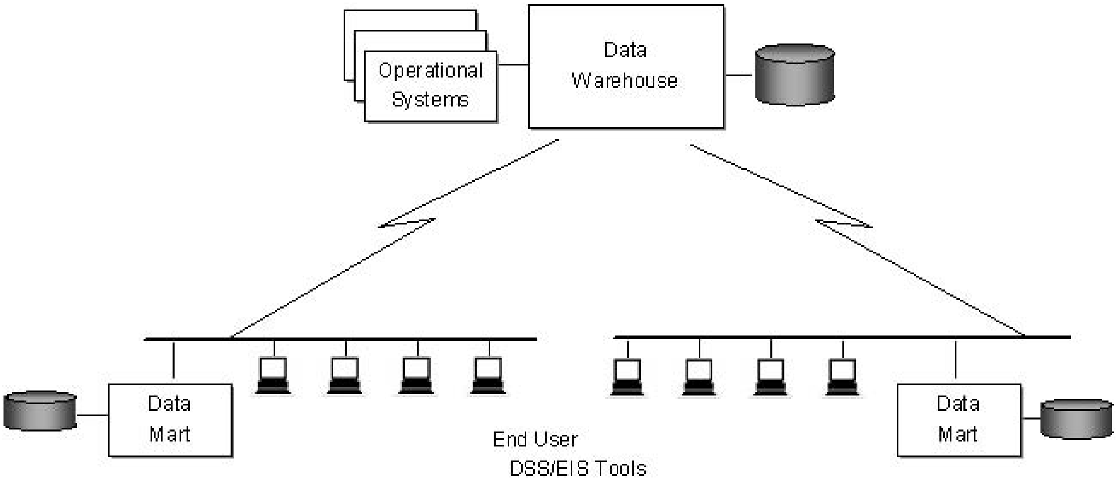

Figure 2: Enterprise data warehouse feeding the data marts.

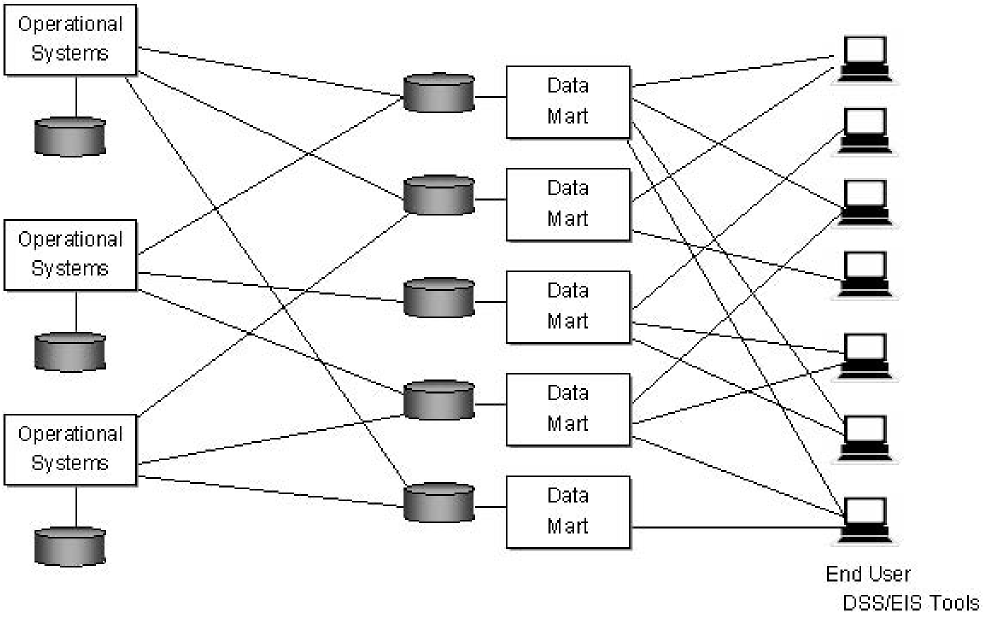

Figure 3: Data warehouse as a collection of data marts.

It can be more finely tuned to usage patterns; and

Data marts are fed from a single authority of data.

The cons of this environment are that

It requires more CPU and disk resources;

Depending on how many data marts, more network bandwidth may be required to move the data; and

Depending on how many data marts, a longer time window for building the data marts will occur because of pushing more data out to data marts.

Collection of Data Marts

A collection of data marts is probably the most complex of the environments to create properly and the one most pushed onto organizations by accountants (money people), consulting organizations, and vendors. Most consulting organizations and vendors offer a "build a data mart in 90 days"-like promotion. If everyone in your organization built data marts without coordinating the efforts, stovepipe data marts will most likely be the outcome.

The pros for this environment are

Smaller, more manageable data sets;

It allows for quick implementation; and

It is generally within someone's budget to "purchase."

The cons for this environment are

Without conformed dimensions, each data mart will have its own reality and will not provide an enterprise-wide view; and

This environment is the most complex to implement due to synchronization and integration issues.

BUSINESS DRIVERS OF THE DATA WAREHOUSE

The business problem that data warehousing first tried to solve was a simple major economic principle—competition. It is competition that is at the heart of business decisions. As the global economy continues to emerge, the information economy will come to an end. Product differentiation may no longer form the basis of competitive advantage. Capturing data, transforming data into information, discovering knowledge from that information, and delivering that knowledge across the organization will become important. Why? Because the only sustainable advantage will be creating *knowledge* and using that knowledge to create *value*. The Internet will be critical in the delivering that knowledge and value to the user community.

Other business drivers of the data warehouse can be noncompetitive items, although they could be interpreted as competitive. These items include quality assurance, medical research, fraud detection, and national security. The largest benefit of the data warehouse environment is that it can provide information and knowledge to help the organization create value for its user community.

Information is the link between an organization's business strategy and how to implement it. A data warehouse allows the organization to measure the success of the strategy. The business value drivers are

The user community can manage their business by accessing the critical information when and using whatever method they desire. That leads to the ability to generate more value for the user community.

The user community can create reports themselves and will no longer be required to wait long lead times for IT to produce reports for them.

The organization can move from tactical-only environment to a "culture of analysis" environment. No longer will the user community spend all of their time doing the tactical tasks, but will start to perform more strategic tasks.

Through the Internet, the flow of data from one part of the organization to other parts will increase, thereby increasing knowledge and value throughout the organization.

With faster access and better information, organizations can make faster adjustments to the marketplace.

STEPS TO CREATING THE DATA WAREHOUSE ENVIRONMENT

Building the data warehouse environment is an easy to talk about but not trivial process. Care must be given to build it in an iterative fashion. Just because the first step is completed doesn't mean it is finished. It is the starting point for the next iteration. As Heraclitus the Obscure (who was born at Ephesus about 530 BC) said, "There is nothing permanent except change." The user community generally does not know what they want until they see something. Once they see something, it will help them define what they really want. Why? Because they are caught up in dealing with the problems of the tactical data (i.e., they are too busy trying to get the data they need to solve their day-to-day activities) that they cannot think about the strategic needs. Tactical issues must be solved before the user community will think strategically.

There are five steps in creating the data warehouse environment. They are

Create the data model;

Define the metadata world;

Build and execute the extraction, transformation and load processes;

Define the hardware architecture; and

Create the user community's world.

Creating the Data Model

Data models are the schematic to the data warehouse environment. It is a representation of how data relates to other data. There are three major data models/schemas used within the data warehouse environment. They are

Star schema;

Snowflake schema; and

Relational (normalized) schema.

Star Schemas

The star schema was introduced through a process called dimensional modeling. Star schemas have two major classes of data—(1) facts and (2) dimensions. Facts are the metrics or measures of the organization that reflect how the organization is doing. Examples of facts include

Quantity sold,

Total revenue,

Revenue per available room (RevPAR),

Number of calls,

Length of calls,

Discounts,

Number of pay-per-views watched,

Total cost, and

Temperature, volume, and pressure.

Dimensions are how the user community wants to look at the metrics "by." Examples of dimensions include

RevPAR "by" day (fact is RevPAR and dimension is time (day));

Total revenue "by" product, "by" day, "by" customer (fact is revenue and dimensions are product, time (day), and customer);

Profit "by" store "by" product "by" month (fact is profit and dimensions are store, product, and time (month)); and

Top 10 customers "by" quarter (fact is unknown at this point, but most likely total revenue or quantity sold and dimensions are customer and time (quarter)).

Facts are created on the basis of granularity of data. Granularity is the level of depth that a fact is stored. Facts are at the intersection of the dimensions. Figure 4 shows a sample star schema.

In this example the fact can be said to be "On this day (time dimension) this product (product dimension) was sold at this store (store dimension) to this customer (customer dimension) for these metrics (fact)." It is critical that the granularity is always kept intact. Having different granularities cause major data anomalies and produce metrics that cannot be added.

Snowflake Schemas

The snowflake schema is similar to the star schema except the dimensions are broken out (normalized) into separate tables. Figure 5 shows an example of a snowflake schema for a different product dimension (not the same product dimension shown in the star schema).

There are two major reasons data modelers want to snowflake—(1) save disk space and (2) less chance of update anomalies (Kimball, 1996) (the major point in normalization).

Compared to the whole data warehouse or data mart, the fact table is the largest and will make up (generally) 80+% of the total size of the data warehouse or data mart. If there is a 50% savings of the remaining 20% for the dimensions, it still will be negligible. The second reason for the snowflake schemas is the less chance of update anomalies. Since the data warehouse or data marts are nonvolatile (read-only), then that should not be a concern.

There are good reasons for the snowflake schema. If the tool chosen by the user community to access the data mart works better with a snowflake schema, then build that data mart with a snowflake schema.

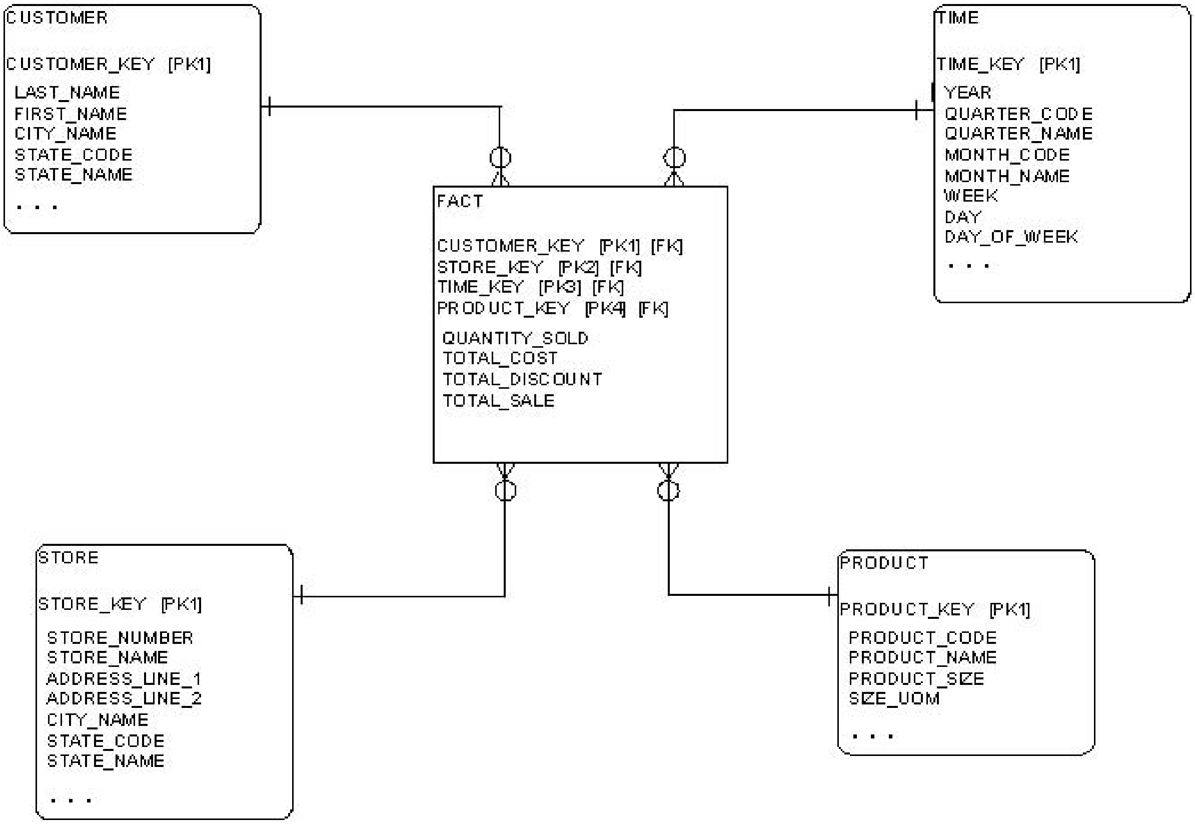

Figure 4: Star schema.

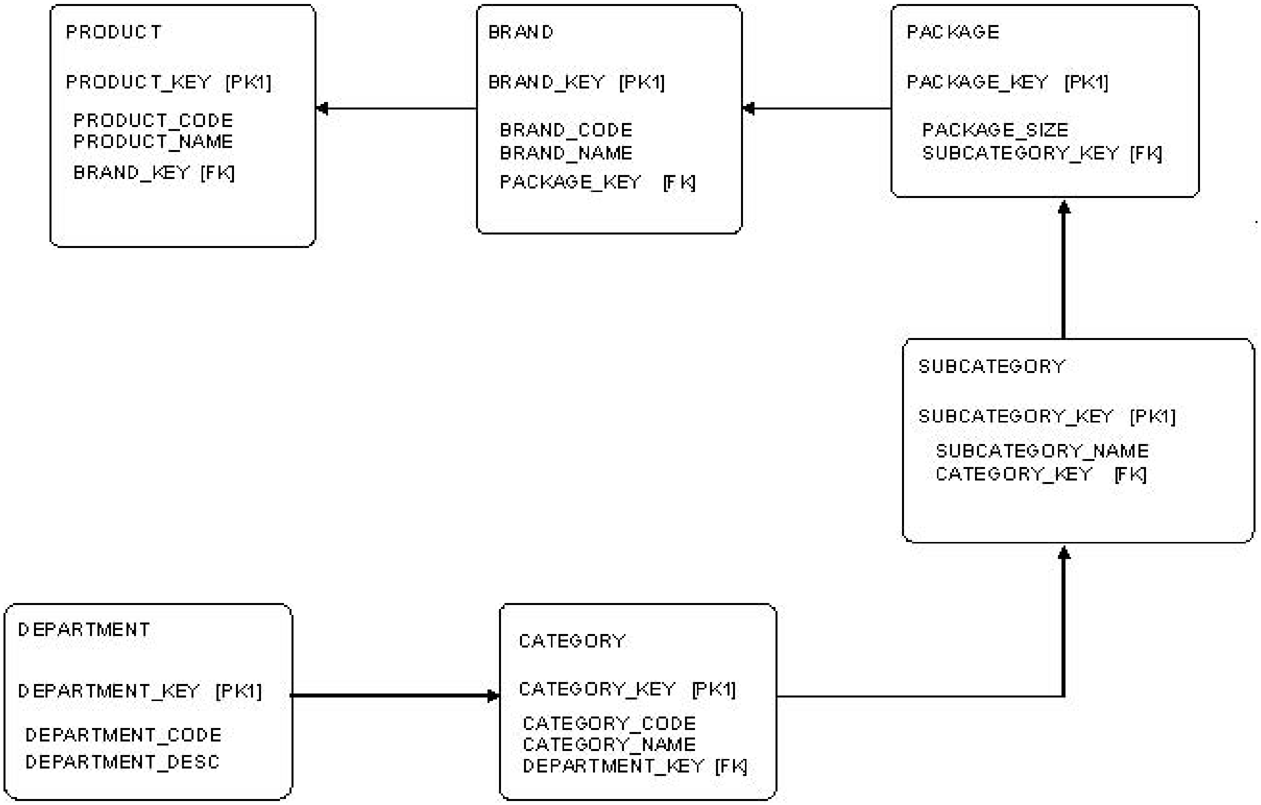

Figure 5: Snowflake product dimension.

Relational (Normalized) Schemas

The relational schema (normalized data structures) is the third data model used in the data warehouse environment. It is built using the modeling technique normalization.

Normalization splits tables into multiple tables to eliminate redundancies and possible update anomalies. The concept here is that there should be a single (well, as few as possible) instance of a value. For example, let us say you have two tables—orders and customers. If there are a lot of orders stored for a single customer and the customer moves, then changes in the customer address column(s) in the customer table is all that is needed. By updating the address at only one place gives the system less chance of data anomaly. If you were to store the customer information in the order, then you would have to change all of the orders associated with that customer. While this is a simplistic example, it applies to complex situations. The relational (normalized) schema is commonly used in the enterprise data warehouse where the user community queries the data from the data marts.

Defining the Metadata World

Metadata is a critical piece to tie all the pieces of the data warehouse/data mart process. It is the central repository of data about data. Metadata is the blueprint of how the data warehouse was built and what it means. Just as there are different types of blueprints, there are different types of metadata. They are (1) business metadata, (2) technical metadata, and (3) contextual metadata.

Business Metadata

Business metadata describes the data from an organizational perspective. It is written in the terms that the organization understands. Business metadata won't contain transformation rules like "Projected Profits = Column ASP039a × 0.67 – column ASP016c." It would contain "Projected Profits equals Projected Income times Percentage after GM&A Costs minus Projected Costs." Business metadata should contain items like

Confidence in data;

Confidence in data quality;

Who is responsible for the data (data steward);

How the data was calculated;

Definition of terms; and

Valid values.

Technical Metadata

Technical metadata describes the data as required by the IT group to understand how the data warehousing environment was or is to be built. Technical metadata contains items like

What is the system of record for each piece of data?

What are the columns extracted from the source systems?

What are the rules for filtering the data out of the extraction?

What are the transformation rules that convert and summarize the data into the data warehouse?

What are the fields in the data warehouse and what are their meanings?

What were the data reconciled with and what are the values?

Contextual Metadata

Contextual metadata is the hardest metadata to collect, but some of the most important metadata there is. Contextual metadata comes from systems outside of your normal transaction system and helps put context around the data. If you were running a campaign for soft drinks during the July 4th holiday (U.S. Independence Day during the heat of the summer), you might look to see how sales were during the past five campaigns. Let us say that 1995 had $1.0 million in sales, 1996 had $1.1 million, 1997 had $0.5 million, 1998 had $1.25 million, and 1999 had $1.5 million. Contextual metadata might keep track of the weather at each store location and when you drill down, you may find that in 1997 it rained. All of the 4th of July celebrations were called off and so no one bought soft drinks.

Contextual metadata might contain

Stock market trends;

Weather reports;

Political issues;

Religious issues;

Court actions; and

Headlines of the day.

Most organizations make metadata a "nice to have" requirement because they do not wish to take the time and effort required to originally build the metadata repository and keep it functional. However, metadata is critical to the total success of the data warehousing organization. Why? Because it is the only place that documents the true business rules as well as changes to these rules over time.

Several factors as to why metadata is needed in the data warehouse environment are (Marco, 2000)

Current systems are inflexible and nonintegrated;

The existing data warehouse and data marts need to grow;

Business users' needs are not being fulfilled;

Organizations need to reduce the impact of employee turnover; and

Organizations need to increase user confidence in data.

Without a robust, architected metadata environment, these issues will have a hard time being met.

The Internet provides the best solution for the presentation of metadata. As more organizations provide more flexibility in work environments (work at home, VPN via Internet, etc.), using the same tool (the browser or other Web-enabled technologies) and the same techniques (search, point, and click) that the user community uses when accessing the data warehouse or data mart continues to drive metadata to be accessed via the Internet.

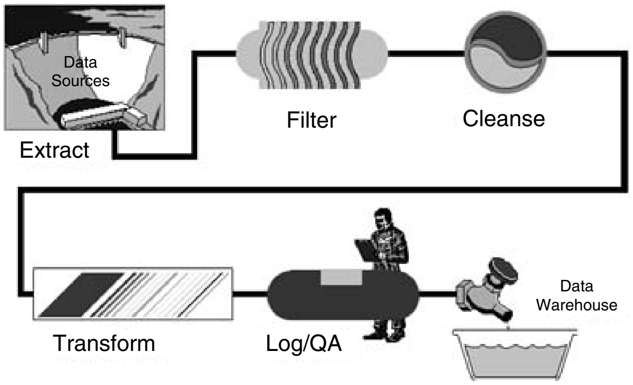

Figure 6: Information sourcing window.

The Extraction, Transformation, and Load (ETL) Processes

The extraction, transformation, and load (ETL) processes are needed to move the data from the operational systems, whether they are order entry, reservations, or Internet clickstream data, into the data warehouse and from the data warehouse to the data marts. The information sourcing workflow is broken into five processes (Figure 6):

Extract—This process takes data from the operational systems. The output of this process is raw data.

Filter—This process takes the raw data and discards "noise" data from the data set. The output of this process is dirty data.

Cleanse—This process takes the dirty data and checks the data quality and corrects the data, if possible. The output of this process is clean, high-quality data.

Transform—This process takes the clean data and restructures and summarizes the data. The output of this process is clean, consistent, summarized, and useful data.

Log/QA/Metadata—This process takes the useful data and does a final check to make sure the data passes the quality assurance test (reconciliation) and produces the metadata for the workflow. The output of this process is verified data and metadata.

Extraction

Extraction is the pulling (or pushing) of the data from the operational systems to the ETL process. The goal of the extraction component is to take only the necessary data from the operational systems and prepare it to go through the rest of the ETL process.

In order to do this, the system of record (best source of data) needs to be determined. The system of record is the best data for this part of the data warehouse. For data warehouses whose goal is to understand sales in a store, determination must be made as to which data best represent the sales data. This could be cash register receipts or it could be inventory brought in. The system of record is determined by looking at all of the sources of the data and choosing the most accurate. The system of record of store sales could be the source of data coming into the store versus the source of data being sold from the store. The output from the extraction process is a subset of raw data that will be processed.

Filter

Filtering the data takes the raw data and discards the "noise"—purely operational—data. For example, date_last_printed is probably not something that the data warehouse user community would want to do analysis on. Neither would flags and switches be useful in the data warehouse. The result of the filtering process is dirty data, but data that will most likely be needed later in the process.

Cleanse

Once the data have been filtered, there needs to be some cleansing to make that dirty data clean. Cleansing the data is important so that you won't have lots of duplicates that seem good, but really aren't. Customer names and addresses always need cleansing. If a query requests the top five customers and the results showed

AT&T
A T & T
A T&T
International Business Machines
IBM

there would be a high degree of skepticism about the validity of the data.

Data quality is extremely important in the data warehouse due to the fact the skepticism about the validity of the data in the data warehouse will kill the usefulness of the data warehouse environment. Data quality is more than cleaning names and addresses, although that is a large component of it. It is also about making the data consistent across multiple systems. Issues like single code definitions and consistent abbreviations for consistent retrievals across different source systems will help an organization with its analysis.

There are a number of products and services in the data quality marketplace. Some organizations are exploiting the Web by providing cleansing tools accessed via the Internet using an application programming interface (API). This allows for the cleaning and merging of the data into high-quality output without purchasing the product.

Poor data quality can undermine the organizations ability to focus on the customer efficiently. For example, poor data quality in a customer relationship management (CRM) system might

Cause the inability to track a customer through all facets of your supply chain;

Not allow the cross- or up-selling of the customer; or

Increase returned e-mail or paper mail (snail-mail), which increase the costs of marketing and hurt customer satisfaction.

However, a return on investment (ROI) study should be made on the data quality process to make sure that the implementation meets the needs of the organization without too high a cost.

The output of the cleansing process is clean, high-quality data.

Transform

Once the data are clean, there needs to be a process that transforms the data into the new data structures as well as summarizes the data. For example, if keeping the number of pay-per-view movies each customer watched during a day was the subject area being built, then there would be a single row in the fact table showing a customer watched three movies during that day. There may not be a need for a finer level of granularity, e.g., a separate row for each movie—unless that someone was running for public office! The output of the transform process is clean, consistent, and thus useful data.

Log, Quality Assurance Checks, and Metadata

The last step in the process is to take the useful data and run some quality assurance checks and to make sure the data reconcile with the source data. There are multiple ways to do this. Some of them are (1) check totals against the source file, (2) compare the totals to a report generated from the source system, and (3) compare the results to a previous day's data to make sure it is in the ballpark (within a certain percentage, for example). Once that has been accomplished, log that fact in the metadata and publish the data.

The Hardware Architecture

The server that houses the database for the data warehouse and data marts needs to provide for a completely different type of computer environment than the transaction/OLTP systems. There are three computer architectures that could be used in the data warehousing environment. They are

Symmetrical multiprocessing (SMP) architecture (Figure 7);

Clustered architecture (Figure 8); and

Massively parallel processing (MPP) architecture (Figure 9).

Symmetrical Multiprocessing (SMP) Architecture

Symmetrical multiprocessing (SMP) architecture (see Figure 7) is a share-everything architecture. The memory and disk are accessible to all the central processing units (CPUs) in the box. This provides for a scaleable environment, to some point, so that additional CPUs will increase the performance of the data warehousing environment. SMP is proven technology and has been around for quite awhile. Most general-purpose database systems (DBMSs) work well in the SMP environment. A variation on SMP is the nonuniform memory access (NUMA) style of SMP. While SMP accesses memory uniformly across all processors, NUMA promises increased performance by having non-uniform memory access. For example, a two-processor NUMA machine may have one processor accessing 60% of the memory and the other 40% of the memory. While the architecture looks promising, there are not many implementations of NUMA to date.

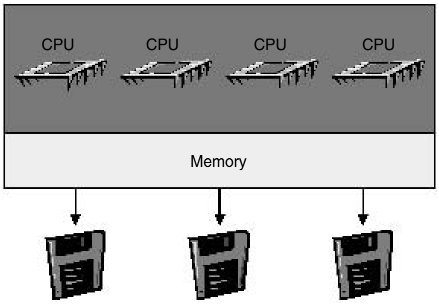

Figure 7: Symmetrical multiprocessing (SMP) architecture.

Clustered Architecture

Clustered architecture (see Figure 8) is a group of systems (single CPU or SMP) loosely coupled together with a high-speed interconnect. Each system has its own memory but is able to share the disks. Clustered architectures provide strong failover capabilities, which are good for transaction systems, but of less value for the data warehouse or data mart. Most general-purpose DBMSs work in a clustered architecture, but have many limitations for performance. Real-time data warehouses make use of the clustered architecture.

Massively Parallel Processing (MPP) Architecture

The massively parallel processing (MPP) architecture (see Figure 9) is a share-nothing architecture. It does not have

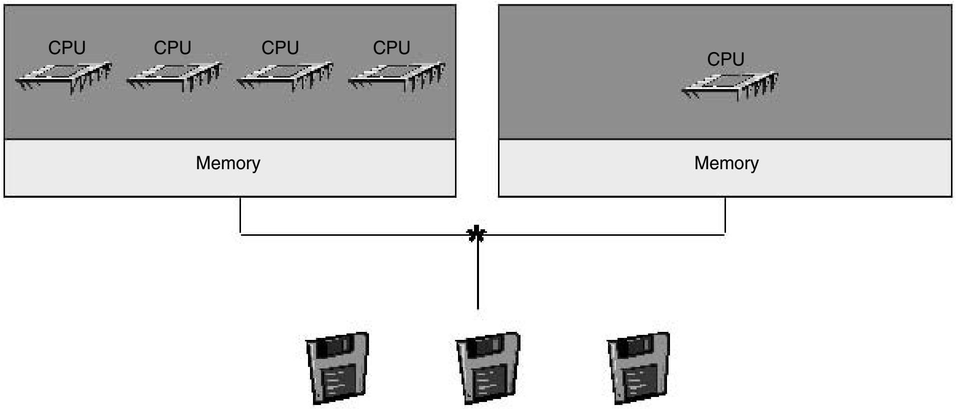

Figure 8: Clustered architectures.

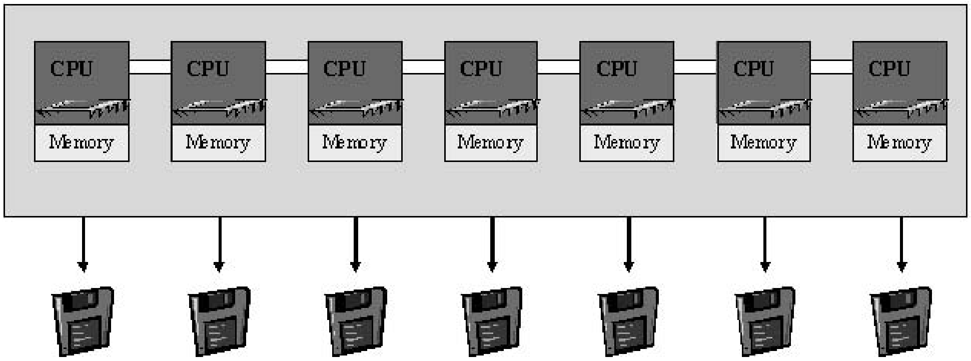

Figure 9: Massively parallel processing (MPP) architecture.

sharing of memory or disks. However, there is a high-speed interconnect that ties the CPUs together. MPP architectures are perceived to be highly scaleable. However, few proven data warehouse implementations are available. Most of the DBMSs do not (yet) take advantage of the MPP environment. Teradata, one data warehouse DBMS, actually is written to run like a MPP environment. It is done in software instead of hardware or in a combination of software and hardware.

The End-User Access World

Internet query tools are quickly replacing the first generation of desktop tools in the Decision Support System/Executive Information System (DSS/EIS) world. Accessing the data requires three components—(1) connecting to the appropriate data source, (2) executing queries against the data, and (3) viewing the results in a meaningful way.

Most tools for accessing the data warehouse in the market today are Web-enabled. This allows the data to be shared across the whole organization. This sharing of the information allows for highly interactive, collaborative analysis that helps organizations keep costs down. This sharing produces a better targeting of customer that can lead to higher retention of the customer base. Marketing knows that it is cheaper to retain a customer than to get a new one.

The user community should help in choosing the products that will solve their needs. IT should never try to force products on the user community. Some of the pitfalls when choosing an end-user tool include

Failure to ease the burden of data identification, definition, and access method;

Failure to adequately train the end-user community and IT;

Failure to provide data in a timely fashion; and

Failure to understand the users' requirements for data access.

To be successful, IT needs to ensure the data access tools and components work together seamlessly. This may mean building a data mart for the tool. If the tool works best in a snowflake schema, then build a data mart using the snowflake schema.

Tools for the user community are plentiful. The tools come with different styles of data manipulation and presentation:

Managed query;

Integrated query and analysis using OLAP operations (such as slicing, dicing, roll-up, drill-down, drill-across);

Visualization techniques; and

Data mining.

Each of these styles may be needed for your user community to be effective. OLAP and data mining are covered elsewhere in *The Internet Encyclopedia*. Today, these styles are done primarily in the tools used, but a strong trend in database technology is the extending of the functionality of transaction databases to include OLAP and data mining operations.

Another important task for a successful user community is that IT needs to set user expectations and monitor them during data access. Remember, returning 10 million rows back to the desktop in 10 seconds is not feasible. Depending on your network, it could take an hour or more.

The Internet and the tools available with an Internet interface are going to define the user perception of the data warehousing environment. Care needs to be given to make sure that they fit in the larger organizational strategy.

Some data warehouse activity cannot get true user feedback unless the organization specifically asks for it or the customer specifically gives it. These organizations can still use data warehousing to provide much value to the end-user. We can see examples of this in many places. On the Internet, go to http://www.Amazon.com and search for your favorite author or the title of your favorite book. Quickly, it gives you a list of other books by the same or by a different author on the same subject that others have purchased that might be of interest to you. Some quick market basket analysis has been done and the results of that were provided to you. Now with the Internet and clickstream data, you can study the purchasing habits of your customers to see whether any new patterns are starting to show up or whether you are benefiting from this new knowledge (market basket analysis). Measurement of the effectiveness of the new knowledge and the implementation of the new strategy is starting to become very precise.

THE CLICKSTREAM DATA WAREHOUSE

The Internet has had a major influence on processing today. The potential (and promise) of the Internet can be seen in understanding what a visitor or potential customer is doing at your Web site. Every click made can be captured and loaded into the data warehouse or data mart, unless you are barred from collecting this information by law as the Federal Government is. This is called clickstream data. The analysis of these data is called clickstream analysis.

The clickstream provides the ability to "watch" what the customer is doing. A Web site owner will be able to see what the customer is looking at and infer what they are not looking at. Then by looking at what the customer purchased, intelligence can be gathered about user perception. The Internet provides a wealth of knowledge for the user community over brick-and-mortar stores.

Some of the knowledge available from clickstream data is

What is the customer looking for?
What are they comparing it to (at your Web site)?
What did they purchase?
Was your site easy to navigate?
How long did they browse at your site?

The problem with clickstream data is that it must be looked at in chronological order (for the most part). There are only a few instances where looking at certain click instances can gather knowledge. Chronological order may mean capturing time down to the second, not just the day like most data warehousing environments.

A second problem deals with the voluminous amount of data associated with the series of clicks in a clickstream. There needs to be a process in place to capture, transform, and load the data for analysis, not only for immediate business needs but also for historic analysis. Both will be extremely useful for the user community.

The Internet, with this clickstream data, is a start at getting into the thoughts of the customer. Transaction data are not always trustworthy (although it seems we believe it wholeheartedly today!) to provide a picture of what is the preference of the customer. If Henry Ford had created a data warehouse early on in the days of automobile and did analysis on colors of cars that people bought, black-colored cars are all that would be available. All the transactions would have color = black, so why paint a car any other color? (*Note:* Henry Ford is credited to have said you can have any color automobile you want, as long as it is black.)

Clickstream data can deliver much business intelligence. Capturing the appropriate data will help to understand the reasons why customers buy or not. The Internet, with the clickstream data, is in its infancy state in capturing this data. Analysis on the data is being done mostly by the early adopters.

Another type of clickstream data is metadata clickstream data. Metadata is the central repository of data about data. Analyzing clickstream data about usage of metadata can help the organization understand how well the user community is able to find data within the data warehouse.

PRIVACY

Since so much data are being captured via the Internet and transaction systems, it will not be long before there is more sharing of data between organizations. Today, there is a desire among some customers for more privacy. Most organizations have an opt-out process, which allows the customer to notify the organization that it does not want the organization to provide the customer data to other organizations. This is being done through Web pages as well as interactive voice response systems. It is expected that governments will require organizations to have an opt-in process. The opt-in process allows the customer to notify organizations that the customer would like to have his or her data provided to other organizations.

CONCLUSION

The Internet plays an important role in the data warehouse and data mart environment. With the ability to access data from anywhere in the world with your Web browser, the user community is asking to see relevant data in a timely fashion using the Internet. Data warehousing has evolved due to the inability of the user community to gain access to the data. Today, an architected environment needs to be defined and built—regardless of whether you build a collection of data marts or a data warehouse feeding data marts. One thing is for sure—the data warehouse environment is *not* an archival system and *not* an audit system. The data warehousing environment *is* a tool for the analysis of data.

Building the data warehouse and data mart environment will take some time mostly due to the fact that the user community does not know what they want until they actually start seeing data. This goes against the grain of what is being taught in colleges and universities today about how to build systems.

However, for organizations to grow and become more prosperous, they need to be able to

capture data;
transform that data into information;
discover new knowledge from that information;
test that the new knowledge is true; and
deliver the new knowledge to the user community.

Clickstream data are providing organizations with data that helps get into the thought processes of their customers. While this analysis is still in its infancy, it is already providing new knowledge for the data warehouse. This will allow organizations to produce more targeted advertising campaigns, better focused one-to-one marketing, and stronger customer relationship management.

This is the *value* of the data warehouse.

GLOSSARY

Clickstream analysis Analysis of a visitor's clicking through a Web site.

Clickstream data The data collected as a visitor to a Web site "clicks" from page to page.

Database A system that provides for the storage and retrieval of data.

Data warehouse An environment that captures all of the data used for analysis for an organization—whether this environment is a monolithic database, distributed database, or a collection of data marts is determined by the requirements.

Data mart A platform for a subset of data warehouse data for analysis serving a single department, subject area, application, or limited part of the organization.

Knowledge The learning of something new to help an organization provide better products and services.

Normalization A data-modeling technique for transaction systems that breaks apart tables to minimize redundancy and to alleviate update anomalies, with the most common degree being third normal form.

OLAP (online analytical processing) A type of computer processing that enables the user community to analyze data in a fast and consistent way, with typical operations including drill-down, roll-up, drill across, reach through, and rotation.

OLTP (online transaction processing) A type of computer processing that captures information and responds immediately (online) to user requests (transactions).

Snowflake schema Part of the dimensional model that normalizes (or breaks apart) dimensions of a star schema to a group of tables in order to alleviate redundancy and possibly update anomalies.

Source system A system, usually a transaction system, that feeds the data warehouse, consisting of external data, spreadsheets, and documents.

Star schema Part of a dimensional model, which has a central fact table surrounded by dimension tables (i.e., points of a star).

Strategic Dealing with the forwarding thinking of an organization as to where and how the organization should change.

Tactical Dealing with the day-to-day issues of the organization.

Transaction system A system that runs the day-to-day business (e.g., reservations system, accounting systems, manufacturing systems) in either an online or batch processing environment.

User community Any group of people who the data warehouse/data mart provides value to, which can include employees, vendors/suppliers, or customers.

Denial of Service Attacks

E. Eugene Schultz, *University of California-Berkeley Lab*

WHAT ARE DoS ATTACKS?

Background

News about some kind of disruption or prolonged outage of computing services due to malicious activity or programs seems to surface almost every day. Consider, for example, how in late 2001 a flood of network traffic brought the *New York Times* network to a standstill. Earlier that year, the Web server of the Computer Emergency Response Team Coordination Center (CERT/CC) was brought down by a denial of service (DoS) attack. A series of DoS attacks in February 2000 brought down numerous systems used by ZDnet, eTrade, Amazon.com, eBay, and others, severely disrupting these companies' ability to conduct ebusiness transactions. Other large companies that have been successfully targeted for denial of service attacks include Microsoft and Yahoo!

Although the public may not know exactly what DoS attacks are, the DoS attacks certainly know something about them. CloudNine, an Internet service provider (ISP) recently went out of business. Several media sources attributed CloudNine's business failure to a series of DoS attacks that this ISP encountered. About the same time that CloudNine went out of business, the University of Colorado shut down what was then the Internet's oldest Internet relay chat server because of repeated denial of service attacks. A recent study conducted at the University of California at San Diego indicated that approximately 4000 DoS attacks occur every week. (See Lemos, 2001, available at http://news.com.com/2100-1001-258093.html?legacy=cnet).

DoS attacks have grown from a relatively rare phenomenon to a frequent occurrence in recent times. Whereas 10 or 15 years ago DoS attacks were relatively unheard of, the relative proportion of DoS attacks has in recent years increased dramatically. CERT/CC has repeatedly stated that more DoS attacks are reported to this organization than any other type of attack.

First we'll turn our attention on how DoS attacks can be distinguished from other types of undesirable events and other types of attacks.

Distinguishing DoS Attacks

DoS Attacks versus Other Damaging and Disruptive Events

What distinguishes DoS from other damaging and disruptive events? DoS attacks are designed to disrupt, overwhelm, and/or damage computing resources and data. The fact that they are *designed* to cause disruption, damage, and so forth implies *intention* on the part of the attacker(s). Many disruptive and damaging events occur in normal computing environments. Examples include allowing disks to fill up, running software with bugs that cause the software to crash frequently, misconfiguring routers, firewalls, and Domain Name System (DNS) servers, faulty system configurations that result in floods of broadcasts or other undesirable events, and faulty network configurations that result in poor traffic flow. These events do not normally constitute DoS attacks, however, because they have not been deliberate. Human error is in fact a far greater cause of loss in the world of computing than intentional attacks (Schultz & Shumway, 2001). Still, DoS attacks are a major (and ever growing) source of concern.

DoS Attacks versus Other Types of Attacks

DoS attacks are at least to some degree different from other types of attacks. Information security has three widely recognized goals—confidentiality of data, integrity of data and systems, and availability of data, systems, networks, and services. (Many experts feel that focusing exclusively on these goals represents too narrow a view of the goals of information security, however. They assert that other goals such as nonrepudiation of actions and transactions, i.e., being unable to deny that one has initiated an action, business order, and so forth, and accountability, i.e., having records of each user's actions performed on computing systems and networks, are also among the major goals of information security.) DoS attacks target primarily availability. To this end, DoS attacks can be distinguished from attacks geared toward copying or stealing confidential data or tainting the integrity of data and/or systems. DoS attacks can, however, overlap with attacks on integrity—someone who breaks into a system and changes key parameters in critical system files to out-of-range values is in effect attacking not only the integrity of the system, but also its availability. Depending on the particular changes made, the victim system might not only crash, but may not even be bootable—something that is likely to constitute a serious loss of availability over a prolonged period of time.

Motivations for Launching DoS Attacks

Why do attackers launch DoS attacks? Although we cannot usually be sure of the exact motives of anyone who launches a DoS attack, case studies in which DoS attacks' origins have been traced to individuals indicate that in many cases DoS attacks are launched with one or more distinct motives:

Retribution, Hostility, and/or Frustration

The perpetrator may be an employee or ex-employee of a corporation who perceives that s/he has not been treated fairly. The perpetrator may accordingly try to get even with the person or organization perceived as causing the inequity. In one case a database programmer wiped out the entire customer database of an insurance company in retaliation for his employment having been terminated. In another more recent case Timothy Lloyd was convicted and sentenced to 41 months in jail for planting a "time bomb" in the network of his employer, Omega Engineering, causing 12 million dollars in damages. (A time bomb is a destructive program that activates when the system clock reaches a certain time; see Gaudin, 2002, available at http://www. nwfusion.com/news/2002/0304lloyd.html.) Lloyd apparently planted the time bomb because of growing frustration due to what he perceived as diminishing ability to influence his work environment.

Need to Gain Recognition or Regain Lost Status

Sometimes perpetrators launch DoS attacks, usually in the form of some kind of sabotage, then rush in and solve the problem they have introduced quickly in the hope of being recognized as a "hero." Because they have created the problem, they can quickly solve it. Having quickly solved it makes them appear to have incredible abilities.

Political Activism

In some cases the perpetrator of a DoS attack may be politically motivated; the DoS attack(s) may represent an attempt to register a protest against the actions and/or policies of a particular organization or government. In 1989, for example, a perpetrator launched a worm called "WANK" (Worms against Nuclear Killers) to protest the U.S. National Space Aeronautics Administration's (NASA's) impending launch of a rocket containing a nuclear-powered energy generator. The terrorist attacks in the U.S. on September 11, 2001 also convince many information security experts that widespread attacks on computers and networks can and will be launched by organizations such as the one reportedly responsible for the September 11 attacks.

Gaining Control over Computing Resources

Perpetrators of DoS attacks have sometimes launched attacks to monopolize computing resources. Chat channel users (often but not always members of the "hacker" community) have, for instance, initiated DoS attacks to take over chat channels. Owners of certain Web sites have reportedly brought down competing Web sites for extended periods.

Attacking for the Sake of Attacking

Yet another motivation for initiating DoS attacks has been to bring systems and/or services down simply for the sake of doing so—a manifestation of "electronic vandalism."

"Fame and Glory"

Sometimes individuals have launched DoS attacks to gain notoriety—to bring them attention (often thereby elevating their status in "hacker circles").

Information Warfare and/or Economic Espionage

In a number of cases individuals have initiated DoS attacks as part of an apparent information warfare or industrial espionage effort. When the U.S. military bombed Yugoslavia in 1999, for example, individuals within Yugoslavia countered by launching flooding attacks against U.S. military systems in the Pentagon. A similar scenario occurred in 2001 after a U.S. spy plane crash-landed within the territory of the People's Republic of China (PRC). For weeks DoS and other attacks on U.S. computing systems originated from IP addresses within the PRC.

Now that we have explored the reasons for perpetrating DoS attacks, let's next focus on why attempted DoS attacks have such a high probability of succeeding.

Why DoS Attacks Succeed

DoS attacks are not only frequent, but the probability that they will succeed is high. Why do DoS attacks succeed as often and well as they do? Let's consider several explanations.

Internet Design

The Internet itself has not been designed with security in mind. The Internet was originally built for providing free and easy access, not for assuring confidentiality of data, integrity of data and systems, continuous availability of services, and so forth. It is safe to say that few if any of those who originally designed and implemented the Internet ever imagined that people would deliberately try to interrupt or corrupt services delivered over the Internet, bring down critical network devices, and so on. If you want security on the Internet, you have to provide it yourself.

Many if not most protocols and services do not incorporate protections against DoS attacks. If you look at the RFCs (Requests for Comments—see http://www.ietf.org) for networking protocols and services, you'll see that many of them address security concerns, but that few of them include mechanisms for staving off DoS attacks. Patches that fix vulnerabilities in major implementations of these protocols and services often have been developed as an afterthought, but add-ons seldom address software problems as effectively as addressing requirements during the initial development cycle. One of the best examples of a protocol that offers little protection against DoS attacks is the UDP (User Datagram Protocol) protocol. UDP incorporates virtually no reliability mechanisms; it is sessionless, connectionless, and "unreliable" (although extremely conducive to good network performance). It is often easy to simply flood another system with UDP traffic, causing a certain service or often the system itself to hang or crash. Any service (such as the Network File System or NFS in Unix and Linux, and Simple Network Management Protocol or SNMP) based on UDP (as well as other protocols) is thus a prime candidate for DoS as well as other types of attacks.

Bug-Ridden Software

Numerous vulnerabilities in many software products have been identified over the years. Many of these vulnerabilities can be exploited to produce DoS conditions. Buffer overflow attacks, to be covered shortly, provide one of the best examples. Worse yet, certain vendors' products, most notably Microsoft's, are interrelated—failure in the functionality of one can result in massive failure. Their products are deployed so much that they comprise what functionally constitutes an "information technology monoculture." When there is a DoS susceptibility problem in one product, many related products have an elevated susceptibility to DoS attacks, leading to the potential for widespread havoc and disruption.

Increased Popularity of DoS Attacks within the "Hacking Community"

Whereas break-ins were in many respects the modus operandi within the "hacking community" several years ago, DoS attacks are ostensibly often now more valued within this community. With a single DoS attack an attacker can cause considerable trouble, thus gaining considerable notoriety within this community. Consider the recognition that "Mafia Boy," a Canadian teenager, gained after he reportedly initiated successful DoS attacks against several companies that made front-page news in February 2000.

Slowness in Recognizing the Problem

Computing itself is still to a certain degree unreliable. It is easy to confuse unreliability with susceptibility to DoS attacks. Additionally, for many years people did not take DoS threats very seriously because other problems such as break-ins into systems caused more loss and disruption at that time.

Corporations are not deploying necessary countermeasures. A report written by the National Academy of Science's Computer Science and Telecommunications Board (CSTB) asserts that U.S. corporations are not deploying security countermeasures needed to defend their computing assets from cyberattacks (National Academy of Sciences, 2002). This failure to adopt necessary measures also elevates the likelihood of successful DoS attacks.

We'll now consider the amount of damage and disruption that DoS attacks cause or potentially *can* cause.

The Toll

Losses associated with any type of information security attack are difficult to pinpoint with any precision. Consider that one estimate of the collective losses due to the distributed DoS attacks (to be covered shortly) against several U.S. corporations in February 2000 was five billion dollars. Was this estimate believable? No one really knows. Undoubtedly, the victim companies experienced a substantial level of financial loss—one that at least to some degree adversely affected each company's "bottom line." DoS-related losses are, however, generally attributable to a number of sources, including the following:

Down time in business-related or other critical systems. This source of loss constitutes an operational disruption that generally has the worst impact in billing and other types of financial systems in which down time of only a few minutes can be financially costly. Consider also the impact upon safety of a DoS attack on a flight control or plant process control system. Disruption of ongoing computing operations not only means that personnel time will be wasted, but also that somehow the down time will be made up in a manner that does not conflict with ongoing computing operations. This is often a far greater problem than anyone other than operations specialists and senior level management can readily understand.

The cost. The cost of investigating and repairing the problem adds quickly. Manpower, particularly time devoted by technical staff, is by no means cheap. Finding the cause of a successful DoS and correcting the problem can involve a significant manpower investment. Additionally, because it is frequently so difficult to trace the real origin of DoS attacks, investigations of the cause of DoS attacks are often more lengthy and complicated than for other types of attacks. (In many DoS attacks the source (origination) address in packets sent to victim systems is spoofed (falsified), making tracing the real origin of the attack more difficult. "Spoofing" means using an IP source address other than the real address of the machine from which this kind of attack is launched.)

Legal costs. Although so far legal costs associated with DoS attacks have been relatively rare so far, the fact that eTrade was sued by a customer who complained that he suffered stock market losses as a result of the DDoS attack against this company is significant. The cost of prosecuting suspected perpetrators of DoS attacks could also add to the financial toll of such attacks.

Loss of customer or third-party partner confidence and reputation. Disruption of access to services that customers and/or third-party business affiliates experience negatively impact confidence in the service supplier or other organization that experiences a DoS attack.

Interestingly, of the three major goals of information security, confidentiality, integrity, and availability, availability is in many organizations the most important. Confidentiality breaches can allow valuable or private information fall into the wrong hands, integrity compromises can cause people to doubt data and whether systems and network devices are working properly, but interruption of availability can bring organizations completely to their knees, so to speak.

DoS attacks are not likely to impact every type of site and organization equally. The next subsection discusses the types of sites that are most likely to be most negatively impacted by these attacks.

What Types of Sites Are Most Vulnerable?

Although predicting the magnitude of loss resulting from a DoS attack is by no means an exact science, some types of sites and computing environments are more likely to suffer damage and loss than others. The amount of probable loss depends on the types of damage and disruption (as discussed earlier) as well as factors such as the impact of down time upon an organization's business or mission. As mentioned previously, even a short down time in a billing system can have very adverse consequences for an institution. Someone from a stock brokerage firm that was one of the first to offer Internet-based transactions to customers told me that a certain newspaper reporter monitored that firm's Web site on a 24/7 basis and wrote a news article whenever the Web server was not functional. *As a general rule, the more critical continuity of services and operations are to an organization and the more mission critical the type of operational services, the more adverse the potential impact of DoS attacks is.*

The following are some representative types of sites that tend to be most vulnerable to DoS attacks:

Financial institutions and financial transaction processing centers

Stock and commodities trading centers

Military operations control centers

Transportation control centers (particular air traffic control centers, airports, and space flight centers)

Emergency response operations centers

Telecommunications operations centers

Plant process control centers

Security operations command centers

You may at this point have the impression that gigantic organizations with large, continuity-dependent operations centers are the only ones highly vulnerable to DoS attacks. Although it is true that risk due to the threat of DoS attacks is considerably elevated in such centers, DoS-related risk in small to medium-sized businesses is also often very high. Why? Because small to medium-sized businesses may operate with a minimum of monetary reserves or may face tight deadlines that affect the survival of the business. A DoS-related incident may be sufficient to disrupt operations to the point of forcing a smaller company out of business.

Now that we have considered the basics of DoS attacks and their impact, it is time to next consider the types of DoS attacks that can be found on the Internet and elsewhere.

TYPES OF DoS ATTACKS

To date numerous high-level types of DoS attacks have been identified. They may overlap with each other—they are by no means mutually exclusive of each other. Types of DoS attacks include the following.

Hardware and/or Software Sabotage

In a sabotage attack someone attempts to damage one or more hardware components and/or something related to the software within one or more systems. Normally a hardware attack requires physical access to hardware components. Someone who gains direct access to a system could, for example, damage the keyboard, video display terminal, any peripheral device such as an attached printer or mouse, or the CPU by deliberately dropping any of them. Alternatively, someone with physical access to a Unix or Linux machine may be able to boot the system in single-user mode, thereby gaining complete control over the system (often without having to even enter a password). Someone who cannot gain physical access can nevertheless damage system components such as hard drives by crashing the system suddenly. Another kind of sabotage attack involves integrity compromises in routers, firewalls, DNS servers, or ordinary systems (including applications that run on systems). An attacker can use methods such as unsecured Trivial File Transfer Protocol (TFTP) access to a router to put an altered access control list (ACL) that rejects incoming traffic or crafting bogus query replies that populate the DNS table of a DNS server with garbage, resulting in network failure. Critical system configuration files, binaries, databases, and so forth in virtually any system are also at risk of unauthorized alteration as a result of a wide variety of attacks, including breaking into a system, leaving the system dysfunctional, or causing it to crash.

Shut-Down or Slow-Down Attacks

Shut-down attacks are similar to sabotage attacks, except that the goal of a shut-down attack is not to cause damage, but rather simply to take one or more systems down. The attacker might power the system down, or remotely cause it to shut down by invoking a remote shut-down function. As mentioned previously, however, a nongraceful shut down can easily also result in damage to hard drives. Additionally, a perpetrator can slow down a system or network without shutting any system or device down. Although potentially less damaging to an organization's operational and business needs, a slow-down attack can nevertheless fulfill the intentions of someone bent on getting even with an organization or individuals.

Flooding Attacks

In flooding attacks someone or a program running on behalf of someone sends so many packets or data that they overwhelm the receiving system, service, or application. The best-known form of flooding attack is probably a SYN flooding attack in which the three-way handshake involved in establishing a TCP (Transmission Control Protocol) connection is misused. Normally in the first part of this handshake a system sends a SYN packet to another system. If a malicious system sends many SYN packets without responding to the target system's response, the target system may tie up system resources (e.g., memory) waiting for the malicious system's response.

System Resource Starvation Attacks

As mentioned previously, types of DoS attacks may overlap with each other. The previously mentioned SYN flooding attack is a flooding attack that results in resource starvation. Consider the effect of running the following routine on a Unix system:

```
while true
do
mkdir foo
chdir foo
done
```

In many Unix systems this will generate so many i-nodes (file system objects that hold file parameters such as ownerships and permissions, times of access and modification, and the size of each file) that the system may run out of resources and crash. A Windows NT attack tool named "CPU Hog" informs the victim system that it runs with a level of privilege unknown to the victim. The system feeds the process threads at the expense of other, unprivileged threads, causing the system to crash several seconds after this program starts to run.

Buffer Overflow Attacks

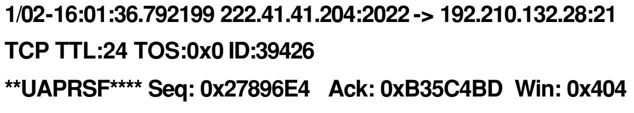
In a buffer overflow attack a program receives too much input for the amount of memory allocated. An attack can be as simple as sending a message with an excessively long subject line or using FTP (the file transfer protocol) to request a file with an excessively long name or to change directories, again with an excessive number of characters in the argument that follows the cd command. The excess input may be written into memory, resulting in the execution of rogue commands or programs, or it may simply cause the application (and possibly also the system shortly afterward) to crash because the application (and subsequently also possibly the system) goes into an abnormal running state.

Packet Fragmentation Attacks

Sometimes in the course of networking packets that are too large for routers or other network devices to handle are created and then sent over the network. Certain kinds of network devices, routers in particular, often cannot deal with such oversized packets. Packets are often consequently fragmented (broken into smaller pieces); each packet fragment will travel over the network until it reaches the destination system. If everything goes well, the destination system will then combine the fragment into one packet so that it can process the packet data appropriately. Numerous DoS attacks abuse packet fragmentation in one way or another such that the receiving system processes fragmented packets in a manner that causes it to hang or crash. One possible attack, for example, is to simply flood a system with fragmented packets. Another is to send fragments that overlap with each other in what is called a "Teardrop attack," where the overlapping packet fragments cause the reassembled packet to have values that are out of the permissible range. If the receiving system is not programmed to check and drop fragments constructed in this manner, it will go into an abnormal operating condition and crash. Yet other examples are the "Ping-of-Death" and "SSPing attack" in which a Windows 95/98/NT system is sent a series of fragmented IP packets. When the system combines the fragments, they now form a larger packet than the system can process, causing the system to freeze. "Jolt" and "Jolt2" attacks are similar, except that in these attacks multiple identical fragments are sent to the victim system (which in this case is a Windows 95/98/NT or 2000 system), causing massive CPU overutilization.

Malformed Packet Attacks

In malformed packet attacks the problem is that the program that implements a particular network service has not been written to detect and screen out malformed packets. RFCs define how packets for various networking protocols should be formed. Normal network programs form and then send packets that conform to these RFCs. An attacker can, however, use such a program to send packets with unconventional ("illegal") values, possibly that are out of range or are missing entire fields, to crash victim systems because they "spin out of control," possibly overallocating memory or using all available CPU. An example is a "Land attack" in which an attacker sends one or more packets that have the same source and destination addresses, something that confuses the receiving system to the point that it crashes. Another example is a "Bubonic attack" in which a barrage of psuedo-random TCP packets with identical TCP sequence numbers, source and destination ports, and other packet header information is sent to a victim Windows 2000 system and certain versions of Linux, causing it to crash. Still another example is a "Christmas Tree attack" in which the attacker sends a packet with every option set for a particular protocol being used. The most common type of Christmas Tree packet has all the TCP flags, SYN, URG, PUSH, FIN, etc., set. If the operating system of the target host has weaknesses in its TCP/IP stack implementation, the packet may crash or disable the system. Figure 1 shows a Christmas Tree packet captured by Snort, an intrusion detection tool, sent from IP address 222.41.41.204 to 192.210.132.28. Note in the beginning of the bottom line that all TCP flags, URG



```
1/02-16:01:36.792199 222.41.41.204:2022 -> 192.210.132.28:21
TCP TTL:24 TOS:0x0 ID:39426
**UAPRSF**** Seq: 0x27896E4   Ack: 0xB35C4BD  Win: 0x404
```

Figure 1: A Christmas Tree packet.

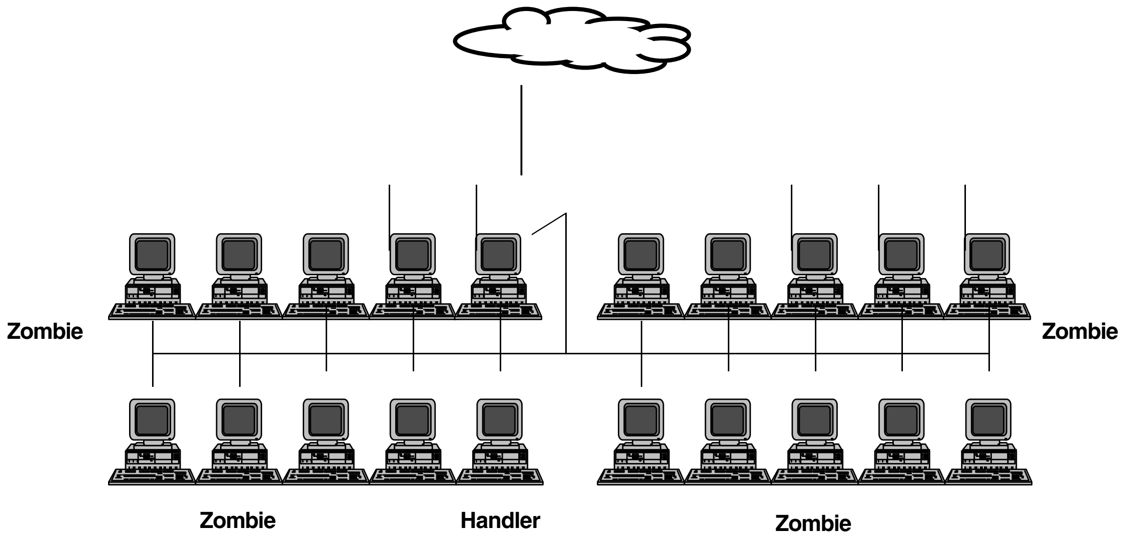


Figure 2: How zombies and a handler might be planted in a small network.

(U), ACK (A), PSH (P), RST (R), SYN (S), and FIN (F) are set.

"Boomerang" Attacks

In a "boomerang attack," the attacker spoofs the IP address of the intended victim host. In this kind of attack the attacker sends packets that elicit some kind of reply. If the attacker sends enough packets initially, a large volume of replies is returned to the victim, causing it to hang or crash. A representative type of boomerang attack is the "Smurf attack," in which the attacker sends many ping packets to systems within a network. A ping request in effect asks "Are you there?" Each pinged host replies, but each reply goes to the intended victim, overwhelming it.

Distributed Denial of Service (DDoS) Attacks

In DDoS attacks an attacker plants programs ("zombies") that unleash a DoS attack (for example, by releasing a huge volume of packets within a network or by releasing malformed or fragmented packets when they receive a signal from a specialized machine called the "handler"). Normally there are multiple handlers, one for each part of the victim network. Each handler receives its signal from a master system that starts the DDoS attack. The zombies and handlers are normally installed in systems well in advance of the intended date on which the DDoS attack is to occur. Figure 2 depicts a network in which zombies and a handler have been installed in a small network. The master is not shown here because the master is often outside of the victim network.

A set of conventions (e.g., special types of ping-like conventions) is typically used to keep the zombies and handlers and also the handlers and master in touch with each other before the attack is launched. This also enables the attacker to inventory how many zombies and handlers are in place and functional. In 2001 CERT/CC was the victim of a DDoS attack in which a vast number of large, fragmented UDP packets was sent to CERT/CC's Web port from numerous zombies. Web servers can usually deal with IP packet reassembly in a reasonable and efficient manner. Packet fragments must be stored until the servers receive every packet fragment; however; storing packet fragments in this manner consumes system resources. When too many packet fragments arrived, the Web server was overwhelmed, causing it to crash and resulting in a prolonged outage.

DDoS attacks constitute a particularly high level of threat because of the potential for massive outages. Nondistributed attacks are far less likely to cause a catastrophic condition—to reach a threshold necessary to disrupt traffic flow throughout an entire network, for example. Individual systems can do only so much, and networks and the systems therein have built-in mechanisms to correct errors and unusual conditions up to a certain point. So, for instance, when one machine is flooding another with packets, the latter is likely to send ICMP (Internet Control Message Protocol) "source quench" packets that suppress the former's packet sending. However, many systems, in this case, zombies, working in orchestration to attack the network are too much for normal correction mechanisms. In one case an attacker installed over one hundred zombies within an organization's network. When the zombies released a massive barrage of packets, the entire network went dead and could not be used for several days while technical people attempted to diagnose what was wrong and to bring the network back up. Many types of DDoS programs use stealth techniques to hide the presence of zombies and handlers, as well as to make the network communications between both unreadable through the use of encryption. Some recent types of DDoS programs even wait to create zombies—they create a process on each compromised system that later creates zombie programs, making detection of zombies even more difficult. The sheer number of DDoS tools (Trinoo, Stacheldracht, Tribe Flood Network (TFN) and its many variants, Shaft, and more) freely available on the Internet is another factor that elevates the level of threat from DDos attacks.

We've seen that there are many types of DoS attacks, each with potentially debilitating effects. Let's move on to the practical application of this chapter, namely how to prevent these kinds of attacks in the first place.

PREVENTION OF DoS ATTACKS

What can an organization do to prevent DoS attacks? This section addresses this topic by considering a number of alternatives. These alternatives are once again not necessarily mutually exclusive.

Risk Management Considerations

As mentioned earlier, for many reasons DoS attacks are likely to be successful. It follows that preventing DoS attacks altogether is no easy task. From a risk management perspective, therefore, a mitigation strategy that dictates prevention at all costs is not only likely to be unrealistic from a technical perspective, but also is likely to entail excessive cost in a cost–benefit analysis. A more realistic strategy is to determine the types of DoS attacks that could occur, the likelihood of occurrence of each, and the expected loss. Countermeasures that mitigate risk can then be deployed on a priority basis, with the risks that compromise the largest expected loss addressed before others until available resources are exhausted. So if, for example, extended downtime for billing systems due to sabotage or shut-down attacks were considered the greatest risk, priority in resource allocation could be devoted to controls that counter this threat. Classic risk management models would generally dictate this type of approach. Although this approach seems intuitive, it is at least to some degree flawed by inherent limitations of risk assessment methods. Simply put, these methods (especially quantitative risk assessment methods) imply a level of objectivity and precision that are simply not present. Furthermore, new instantiations of DoS attacks are constantly emerging, changing the relative risk of each identified source. Finally, although virtually every information security professional agrees that some form of risk analysis and risk management occurs in the course of conducting information security-related activity, the more formal the risk analysis and risk management method deployed, the more cumbersome and costly these methods are. By the time the output of these methods is available, the output is already likely to be out of date. In short, risk management-based methods of dealing with DoS threats (or any others, for that matter) are anything but a panacea.

What is the alternative? One of the most popular is the "due care" or "baseline controls" (or also what is somewhat arrogantly termed "best practices") approach in which an organization learns of the controls posture of other peer organizations and tries to deploy roughly the same controls posture. "Controls posture" means the type and amount of controls deployed. If, for example, other responsible peer organizations deploy a certain set of business continuity measures (as discussed shortly), an organization could exercise due care by deploying the same measures. One of the chief advantages of the due care approach is that organizations tend to adjust their controls posture based on real outcomes. If a financial organization does not deploy adequate perimeter control measures (e.g., firewalls), security-related costs due to intrusions, successful DoS attacks, and so forth can become intolerably high, prompting the organization to tighten its perimeter security. The due care approach tends also to be financially less costly; it can be based on normative data concerning actual controls deployment from various sectors, including the government, financial, transportation, and manufacturing sectors. On the other hand, many information security professionals are skeptical of this approach, which they often claim is too general to work in specific organizations that have specific business and security needs.

The debate between advocates of classic risk-based methods and the due care approach will continue. Notwithstanding, some kind of risk management activity is necessary to deal with DoS threats. At a minimum, organizations need to anticipate and prepare for worst-case DoS scenarios. Sadly, most organizations (i.e., those who experienced the massive DDoS attacks in February 2000) do not realize just how much disruption to ongoing operations and the financial impact of worst-case scenarios until after they occur. Consider, too, how little prepared most organizations currently are for a massive cyberterrorist attack designed to produce widespread disruption and panic.

Policy Considerations

Policy is in many respects the beginning point in countering DoS attacks. An organization's information security policy must at a minimum delineate baseline security measures needed to fend off DoS as well as other types of attacks. Policy provisions must also spell out actions (such as whether to bring in law enforcement) that are and are not to be taken in case of DoS attacks as well as punishments for employees, contractors, and others who initiate such attacks. Service providers (such as ISPs) and third-party business partners should establish clear expectations concerning the level of security to be provided for customers and business affiliates. One of the best ways to convey these expectations is through policy statements that can be communicated to employees through memorandums, Web site postings, e-mail messages, and so forth.

Business Contingency Measures

Given the vulnerability of today's systems, networks, and software to DoS attacks, it is naïve to assume that these attacks can be prevented altogether. Fallback measures, measures that enable an organization to carry on its business despite computing and network outages, are thus essential. Business continuity measures collectively provide one of the strongest sets of measures that minimize the impact of DoS attacks. Some of the major types of business contingency measures include the following.

Hot Sites

Hot sites are computing sites to which current computing operations can be rolled over in case of outage or disruption. The beauty of hot sites is that if set up properly, they provide an almost seamless method of operational continuity, although they tend to be rather financially costly.

Cold Sites

Cold sites are like hot sites, except that operations cannot be immediately rolled over to cold sites. Cold sites must first be brought into operational status.

Uninterruptable Power Supplies (UPSs)

UPSs are attached to computing systems and network devices in a manner such that if an electrical failure occurs, the computer or device keeps running because of availability of UPS-supplied power. The cost of UPSs has declined over the years to the point that UPSs are widely used in many organizations.

Redundant Array of Independent Drives (RAID)

RAID is a hardware solution that allows uninterrupted access to data on disks. A disk controller ensures that data are written to multiple disks. If one disk fails, data can be quickly accessed in one or more redundant disks.

Failover Systems and Devices

Failover systems and devices are redundant to those they support, such that if the primary system or device goes down, the failover one is immediately used. Failover systems are particularly important whenever there is a single point of failure, such as a firewall or router; single points of failure often exacerbate the impact of DoS attacks.

Firewalls

Firewalls are systems located between two networks that analyze and selectively handle (e.g., filter out, allow to pass through) traffic. Firewalls put up a barrier to attacks and undesirable types of network traffic. To the degree that DoS attacks can be prevented in the first place, properly configured firewalls are in many experts' minds the best single defense against this kind of attack. Although there are many different types of firewalls and various depths at which firewalls can analyze and handle traffic, the ability to filter traffic, i.e., allow it through or reject it, is the most basic firewalling function for stopping DoS attacks. Firewalls can, for example, block all incoming echo requests. One of the easiest types of DoS attacks to perpetrate is to send echo requests to another system. That system will reply with echoes that go right back to the original system, something that will trigger more replies, and so on, until both systems are flooded to the point of crashing. Using a firewall to block all incoming traffic destined for the echo port (TCP and UDP port 7) goes a long way in preventing echo storm attacks initiated from outside a network. They can also drop fragmented packets, probably the best measure against packet fragmentation attacks. Higher-ended firewalls such as application firewalls can even analyze input such as user commands to prevent commands (e.g., rm–rf *.* in Unix) that could cause DoS from reaching the intended victim(s). (rm means remove or delete. rm–rf *.* will recursively delete all directories and files, starting with the current directory, and without any prompt that allows confirmation of this drastic command.)

Routers

If properly configured, routers can serve as "low-level firewalls." They can filter packets according to their source and destination IP addresses, ports, and so forth. They can also drop fragmented packets. In so doing, routers can also help prevent certain types of DoS attacks.

Packet Filters and Personal Firewalls

Packet filters and personal firewalls are like miniature firewalls that run on systems to protect them from undesirable traffic. Packet filters are more basic—they allow or deny traffic based on rules such as the source of the traffic or the destination port. Personal firewalls generally go farther—they not only serve as packet filters, but they can also often block dangerous programs from being downloaded from Web sites, stop malformed packets from reaching a system, provide detailed log data, and so forth. One of the chief advantages of both is that they work regardless of whether an attack has been initiated from outside or inside a network. If configured properly, they (like firewalls and screening routers) block traffic that if allowed through would result in DoS.

Limiting Services

Many network services have vulnerabilities that leave the systems on which these services run vulnerable to DoS attacks. The recently mentioned echo service is one such service. The SNMP service is another. An attacker may be able to flood a system with SNMP traffic, causing it to crash. Other services that have proven especially conducive to DoS attacks include the character generator (chargen), WINS (the Windows Internet Name Service), POP (the Post Office Protocol), RPC (the Remote Procedure Call), the NetBIOS session service in Windows systems, and IMAP (the Internet Message Application Protocol). Running only the services necessary for business and operational needs is a good way of limiting the potential for successful service-related DoS attacks.

Patch Installation

Many vulnerabilities that if exploited can result in DoS have surfaced over the years. Attackers generally begin attacking by remotely scanning systems for vulnerabilities, then follow up with attacks that exploit the vulnerabilities they have discovered.

Most operating system and applications vendors produce patches, software, and other solutions that correct the vulnerabilities. Promptly installing patches is thus one of the best ways to prevent DoS attacks.

Quality of Service (QoS) Mechanisms

QoS (not to be confused with DoS) mechanisms have been developed to improve the quality of networking. These mechanisms include (among other things) a range of architectures, protocols, and routing mechanisms to boost performance and reliability. One of the side effects of the use of QoS is to make networks less vulnerable to DoS attacks. QoS mechanisms thus provide another defense against DoS attacks.

Intrusion Detection

Intrusion detection in simple terms is the process of discovering unauthorized use of computers and networks. Intrusion detection systems (IDSs) are somewhat limited in dealing with DoS attacks because they are post hoc in nature; they tell you that something is wrong only *after* something bad occurs. Nevertheless IDSs can be useful in helping prevent DoS attacks in that once they detect a DoS attack against one system, the data about the origin of the attack can be used to block ("shun") the IP address of the apparent attacking system at the entrance to a network (i.e., by modifying access control lists in the

Table 1 Preventative Measures against DoS Attacks

Preventative Measure(s)	Function or Mechanism	Effectiveness
Business continuity measures	Varied (ranges from simple hardware solutions to an entire hot or cold site)	High
Firewalls	Varied, ranging from packet filtering to connection analysis and management	High
Routers	Packet filtering	Medium to high
Packet filters and personal firewalls	Packet filtering and logging (plus additional functions in personal firewalls)	High
Patch installation	Correcting vulnerabilities	High
QoS mechanisms	Varied (throughput regulation, allocating priorities to network applications, etc.)	Medium
Intrusion detection	Detecting attacks	Low to medium
Third-party software	Varied (virus and worm detection and eradication, integrity checking, etc.)	Variable (depends on type and quality of software)

router and/or firewall), thus helping prevent further attacks of this nature.

Third-Party Software Tools

Finally, a variety of third-party software tools may potentially prevent at least some kinds of DoS attacks. The previously mentioned packet filters and personal firewalls are readily recognizable examples of such tools, but there are many others, too. Anti-virus software can, for example, help prevent DoS by detecting and eradicating self-reproducing programs such as viruses as well as many Trojan horse programs that users would otherwise download into their systems. Special software such as vulnerability scanners can detect DDoS zombies and handlers through methods such as determining whether certain ports known to be used by DDoS tools are listening for input. For example, many versions of Trinoo utilize UDP port 27444 by default. If port 27444 on a system is listening, a Trinoo zombie may be installed on that system. (Note that the netstat command can also list listening ports on a system.) Other software uses cryptographic algorithms to detect changes in files and directories, some of which may be due to insertion of malicious programs that can cause systems and applications to crash or hang. Simply having software that can detect the presence of DoS tools does little good, however. It is necessary to not only systematically use this software at defined intervals, but also to ensure that the integrity of these tools is intact. Attackers love to modify these tools to make them unable to detect anything. Keeping these tools offline and loading them only long enough to run them is the wisest course of action.

Table 1 summarizes the types of preventative measures that can be used against DoS attacks and the relative effectiveness of each.

CONCLUSION

By now you should realize that DoS attacks constitute an extremely serious problem that has proven costly to many organizations. If anything, the problem is likely to become worse because systems, networks, applications, and the Internet itself are not really built to withstand these or any other type of attacks. With the increased threat of terrorist attacks also comes the likelihood that terrorist organizations will launch DoS attacks to accomplish their purposes. Yet the Internet community depends on continuous computing and network services. What can we do?

Unfortunately, there is no "silver bullet." Appropriate legislation would, however, be a good starting point. Government representatives need to take the threat of these attacks more seriously and must draft and pass legislation designed to more severely punish perpetrators of DoS and other kinds of cyberattacks. Considerably more funding for research on detection and prevention of DoS attacks would also constitute a big step forward. However, the ultimate responsibility is senior management's. Senior management must quit viewing attacks designed to compromise confidentiality and integrity as the "worse case" outcomes and must pay more attention to DoS attacks. Senior management must determine what the worst case DoS scenarios are and ensure that their organizations are prepared to deal with them.

The good news is that appropriate measures for preventing DoS attacks are not terribly different from those for dealing with other kinds of security-related attacks. Key measures include creating a sound policy and procedures, adopting the necessary technical countermeasures, being vigilant in detecting and analyzing anomalies, and responding promptly and effectively to incidents that occur.

GLOSSARY

Baseline controls An approach to information security in which an organization learns of the controls posture of other peer organizations and tries to deploy roughly the same controls posture.

Boomerang attack A type of DoS attack in which the attacker spoofs the IP address of the host that is the intended victim; the attacker sends packets that elicit some kind of reply, but if the attacker sends enough packets initially, a large volume of replies is returned to the victim, causing it to hang or crash.

Bubonic attack A type of attack in which a barrage of psuedo-random TCP packets with identical TCP sequence numbers, source and destination ports, and other packet header information is sent to a victim Windows 2000 system and certain versions of Linux, causing the system to crash.

Buffer overflow attack A type of attack in which a program receives too much input for the amount of memory allocated.

Christmas Tree attack An attack in which the attacker sends a packet with every option set for the TCP protocol.

Cold sites Operational sites to which computing operations are transferred after they are brought into operational status.

CPU Hog A Windows NT Trojan horse program that feeds its process threads at the expense of other, unprivileged threads, causing the system to crash several seconds after this program starts to run.

Denial of service (DoS) attacks Attacks are designed to disrupt, overwhelm, and/or damage computing resources and data.

Distributed denial of service (DDoS) attacks Attacks in which an attacker plants cooperative programs designed to unleash a massive DoS attack against a network.

Due care See baseline controls.

Failover systems and devices Redundant systems and devices that are immediately used if the primary system or device goes down.

Handler A type of program in a DDoS attack that controls zombies that have been planted in systems.

Hot sites Computing sites to which current computing operations can be rolled over in case of outage or disruption.

Jolt and Jolt2 attacks Attacks in which multiple identical fragments are sent to the victim system, causing massive CPU overutilization.

Land attack An attack in which an attacker sends one or more packets that have the same source and destination addresses, confusing the receiving system to the point that it crashes.

Master A type of program in a DDoS attack that controls handlers that have been planted in systems.

Packet fragmentation attacks Attacks in which packets are fragmented (broken into smaller pieces) in such a way that the receiving system processing them hangs or crashes.

Ping-of-death An attack in which a Windows 95/98/NT system is sent a series of fragmented IP packets, which when combined form a packet larger than the system can process, causing the system to freeze.

RAID (redundant array of independent disks) A hardware solution that allows uninterrupted access to data on disks if one disk fails.

Shaft A type of DDoS tool.

Shut-down attacks Attacks in which the purpose is to shut down but not delay systems or networks.

Slow-down attacks DoS attacks in which the purpose is to delay but not shut down processing activities of systems and/or networks.

Smurf attack An attack in which the attacker sends many spoofed ping packets to one or more systems within a network, causing the victim(s) to become overwhelmed with replies.

Spoofing Using an IP source address other than the real address of the machine launching this kind of attack.

SSPing An attack in which a Windows 95/98/NT system is sent a series of fragmented IP packets, which when combined form a packet larger than the system can process, causing the system to freeze.

Stacheldracht A type of DDoS tool.

TCP (Transmission Control Protocol) A protocol designed for reliable network communication between systems.

Teardrop attack A type of DoS attack in which the overlapping packet fragments cause the reassembled packet to have out-of-range values; if the receiving system is not programmed to check and drop fragments constructed in this manner, it will go into an abnormal operating condition and crash.

Tribe flood network (TFN) A type of DDoS tool.

Trinoo A type of DDoS tool.

TFTP (Trivial File Transfer Protocol) A protocol designed for efficient but not secure file transfer.

UDP (User Datagram Protocol) A protocol that is sessionless, connectionless, and unreliable.

Uninterruptable power supply (UPS) A hardware device attached to computing systems and network devices in a manner such that if an electrical failure occurs, the computer or device keeps running because of availability of UPS-supplied power.

Zombie A type of program in a DDoS attack that launches the attack after its handler instructs it to do so.

Developing Nations

Nanette S. Levinson, *American University*

INTRODUCTION TO THE INTERNET AND DEVELOPING NATIONS

Today, 580.78 million people use the Internet. Only 5.12 million of these are in the Middle East; 6.31 million are in Africa; and 32.99 million are in Latin America. This compares with 167.86 million in the Asia/Pacific region, 182.67 million in the United States and Canada, and—the largest number—185.83 million in Europe (*How many online?*, 2002). Focusing in on specific countries within a region, one can start with South Africa where there are 238,462 Internet hosts or with Chad where there is one Internet host or Sudan where there are none. These data continue to indicate there is a global digital divide. Within developing nations themselves, there are large disparities between urban and rural areas and between elites and others in the country, making the gap between a developing country and other developed countries even more significant.

With regard to the language of the Internet, approximately 68.4% of the information on the Internet is in English. About 5.9% is in Japanese, with 5.8% in German, 3.9% in Chinese, 3% in French, and 2.4% in Spanish. Languages with between 1 and 2% each are Russian, Italian, Portuguese, and Korean. Other languages total 4.6% (Global Reach, 2002). Access issues clearly relate to the languages of content available on the Web. (It is interesting to note that the governments of China, Japan, and Korea recently agreed to a project promoting automatic translation of Web content into each other's languages to foster information sharing and Asian content on the Web for their citizens.)

Going beyond these numbers raises a set of very complex issues and challenges. To examine these issues calls for a systems-based perspective that recognizes and captures the possible interconnections among developed and developing nations as well as among governments, the private sector, international organizations, the growing nongovernmental organizational sector, and individual networks of experts and interested individuals such as those focusing on human rights or environmental issues. It also calls for new ways of highlighting such interconnections. No longer can we focus solely on a nation-state in discussing the Internet and development. The uneven yet increasing globalization and regionalization of economies, media, and knowledge provide an important backdrop.

Another area of change is what we mean by "developing" in the year 2003 and beyond. In the immediate post World War II era, "developing" was used to refer to the political development of a country. The model of development was the United States or other major Western democracies. This view of development placed the mass media in a key role in the development of democracy. Political development was viewed as separate from economic development. Little attention was paid to social development. Approaches to understanding economic development involved a stage theory of development whereby a foundation had to be laid for achievement of each succeeding step. Today, the words "development" and "developing" encompass a much broader definition, linking the individual to the nation-state and beyond. These words no longer convey only a stage approach. Rather, there are some instances of "leapfrogging" both social and economic development, especially using new information and communication technologies.

APPROACHES

There are four main analytic approaches to the Internet and developing nations. The first is rooted in the dependency paradigm, which has at its center a core–periphery relationship. Developed nations are at its core and developing nations are at its periphery; the core exploits and impacts the periphery (Van Rossem, 1996). The evolutionary approach argues that the environment selects out forms such as organizational forms that are to survive (Hannan & Freeman, 1988; Modelski, 1990). The institutional approach focuses on the role of institutions and institutional change in effecting development (Westney, 1993). It highlights three explanations for change: mimetic, normative, and coercive isomorphism (Powell & DiMaggio, 1991). Organizations or nation-states adopt a specific change because others are doing it (despite whether there are data regarding success of that change), because they ought to be doing it, or because some external power says they need to do it. Finally, an interorganizational approach captures the flow of resources (information, money, labor, raw materials, etc.) within groups of like and/or unlike organizations across complex organizational and cross-national boundaries.

This perspective allows for an understanding of a developing nation's potential to move beyond country-based competencies to the ability of its organizations to access and utilize a wide array of external resources and potential partners. Since the Internet itself is a network (a series of interconnected nodes), using an interorganizational perspective moves beyond a focus on core and periphery to incorporate a network of national and transnational factors and players. These include players such as the World Bank and the International Monetary Fund as well as multinational corporations, governmental organizations, nongovernmental organizations, and principled issues networks such as those focusing on human rights.

THE INTERNET AND DEVELOPING NATIONS: WHAT EXISTS

The Technology Achievement Index

Each of the above approaches can shape the views and policies of a developing nation regarding the Internet. No matter what the analytic approach, there are actions that developing nations can and do use to promote the Internet and foster innovations in support of development writ large. The 2001 United Nations Development Programme's *Human Development Report* presents for the first time a technology achievement index (TAI). This measure attempts to quantify how well a specific nation is doing with regard to four dimensions: creation of technology; diffusion of recent innovations; diffusion of old innovations; and human resource skills. Their measure of diffusion of recent innovations uses two indicators. First is the number of Internet hosts per capita (calculated from International Telecommunications Union data). Second is the amount of high- and medium-technology exports as a share of all exports (calculated from United Nations Statistical Division data). Telephones (both wired and cellular) and electricity are the indicators used to measure diffusion of old innovations. These measures are also useful in serving as foundations for understanding Internet use in developing nations.

The 2001 TAI has data for 72 countries. These data indicate that there are four main country groupings: first is leaders in technology achievements such as the United States and Finland. Second is potential leaders with high rankings on human resource skills and the wide diffusion of technologies but lower measures of innovation; such countries include Spain, Italy, and the Czech Republic. The third grouping is the dynamic adopters. These countries have high human resource skills, are home to high-tech industries, but have a history of slow or incomplete diffusion of old innovations. A number and, indeed, the majority of nations in this grouping are developing nations such as Brazil, China, India, Indonesia, South Africa, and Tunisia. The final grouping is called the marginalized set. Here, many parts of a country have not benefited from old technology being diffused nor is there evidence of the skills base for the diffusion of new technologies. Countries in this grouping include Nicaragua, Pakistan, and Senegal.

Public Policies

One key for developing nations with regard to the Internet is public policies. Such policies cover a range of areas and involve discussion with the private sector, nongovernmental organizations, and international organizations and institutions. Three themes emerge as central: transparency, stability, and adherence to the rule of law. A recent trend is the energetic involvement of the private sector in attempting to shape such policies. Associations of leaders of corporations and private sector associations especially in the technology sector have been formed to influence Internet-related policy making at both the nation-state and international organization levels. An example of such an initiative is the Global Business Dialogue formed in January of 1999 by chief executive officers of major companies involved in electronic commerce.

Currently, Internet costs are especially high in most developing nations. According to the 2001 *Human Development Report* (p. 81), the cost of being connected to the Internet in Nepal is 278% of the average monthly income there compared with 1.2% in the United States or 60% in Sri Lanka. Competition in Internet service providers (and privatization of telecommunications) is helpful in bringing down costs but needs to be combined with regulation, which helps to lessen the chance of private monopolies replacing the old public ones. Very recent data indicate a shift toward nation-states playing a larger role again in previously privatized or partially privatized telecommunications settings (Delaney & LaTour, 2002).

The promotion of research and development including fostering university–private sector efforts in research and development through, for example, matching funds or funds for science parks, also contributes to a more successful Internet utilization in developing nations. Additionally, policies that help small and medium-sized businesses and ensure entrepreneurship and venture capital make a difference. (Crafting a vibrant venture capital sector is not easy; it requires a relatively sophisticated financial system, ties to venture capital firms and entrepreneurs in other parts of the world, and strong educational systems—each of these elements presents big challenges, especially to the least developed nations.)

Much has been written about the role of education in fostering the Internet in developing nations, beginning with universal primary education and moving to solid secondary and tertiary education that includes strong verbal and mathematical training as well as teamwork and creativity enhancement. Recent research also highlights the need for excellent cross-cultural communication and trust-enhancing skills (Cogburn & Levinson, 2003). Finally, literacy is essential for effective Internet use in developing nations. This includes general literacy and computer literacy. Innovative approaches to computer literacy range from mobile kiosks for computer training in villages to cross-national alliances for Internet activities to provide vital knowledge to help small communities' economic endeavors. (Examples of alliances focused on developing nations include those which provide, via the Web, sophisticated weather information for fishing villages, Web sites promoting local crafts and obviating the need for third parties in the selling process, and distance education initiatives that recognize local cultures and often utilize local content on the Internet.)

Additional policies highlight training for current workers to support computer literacy and pave the way for successful innovation. Companies in many developing nations lack funds to support training efforts. Governmental policies providing even partial incentives and creative use of the Internet can help with training improvement. The UN *Human Development Report* recommends, with a view toward developing nation policy making, that a nation-state conduct inventories of skill levels, availabilities, and needs on a regular basis; not overlook helping small and medium-sized businesses, and provide information and incentives for such target businesses; and set up opportunities for recent secondary school graduates to get training (partially financed) in accredited private training centers for both urban and agricultural sectors.

These broad measures target the basic absorptive capacity or knowledge and skills base for a developing nation with regard to the Internet and related information and communication technology development. However, as the approaches summarized at the beginning of this chapter indicate, there are (depending on the specific analytic approach adopted) roles for developing nation governments in working with international institutions, regional organizations, and individual citizens. One example is a partnership between the International Telecommunications Union and Cisco Systems to provide Internet skills-related training in 50 new training centers in developing countries during 2003 including several centers in Africa, Saudi Arabia, and Tanzania focused on Internet skills development for women (ITU, 2002).

Secondly, there are policies that relate to the Internet and government functions within a developing nation. The term "e-government" comes into play here. From easy access to government information (including such things as databases on resources within a nation or even environment-related data) to services including electronic voter registration and voting, e- mail capabilities, and Web sites of elected officials and government offices, the Internet has great potential. Some governments have even developed Web portals, highlighting, in user-friendly ways, information resources and online services for their country as well as opportunities for foreign investment. (This potential is tempered by problems of access, literacy, and even possible corruption.)

Thirdly, there are policies that relate directly to Internet- and business-related research and development and cross-border Internet business. Countries with limited resources need to set priorities and goals within these far-ranging possibilities. One example is the government of Malaysia and its priority to develop a multimedia super corridor along with supporting policies and practices (Kushairi, 2002). Additionally, some governments are banding together at the regional level to pool scarce resources to address such priorities. In particular, there are regional efforts such as those in Asia to promote infrastructure for electronic commerce on a region-wide basis.

These efforts also relate to the promotion of interoperability and standards-setting that includes the participation of developing nations. Recently, the telecommunications ministers from China, Japan, and Korea discussed plans for a common wireless standard to promote economic development. Their actions demonstrate a regional approach to standards development in support of electronic commerce. (See ITU SPU, 2002a, for a report on the convergence of mobile telephony and the Internet.)

The policy approaches highlighted above focus mainly on strengthening economic development. There is another set of policy approaches evident in a minority of developing nations, which focuses on control of the Internet. A December 2002 study at the Harvard Law School examined China's possible blocking of Web sites over a six-month period (Zittrain & Edelman, 2002). It found that China had the tightest control of any other country during that period; it blocked access to 19,032 Web sites. Sites dealing with Taiwan or Tibet and portions of search portals such as Google were blocked at all or some portion of the time during the test period. The study also compared its findings on China with an earlier study it conducted on the blocking of Web sites in the Middle East. It reported that China exercised more broad but less in-depth control than Saudi Arabia.

Additionally, while China has shown great interest in promoting the growth of the Internet for economic purposes, it has pursued a multitiered strategy with regard to control. In July of 2002, a number of Web portals operating in China as well as Chinese businesses and research institutions signed a voluntary "Public Pledge on Self-Discipline for China Internet Industry." The pledge includes sections on preventing cybercrime and avoiding intellectual property infractions as well as on the blockage of any sites that would affect China's social stability or would bring harm to China (Bodeen, 2002).

The themes of intellectual property protection are particularly significant in the context of the Internet and developing countries. The World Trade Organization TRIPS agreement provides that the least developed countries have extra time until the year 2006 to implement systems of intellectual property rights using an agreed-upon set of minimum standards such as patent protection (United Nations Development Programme 2001, p. 103). There is still concern with the protection of the rights of communities and indigenous peoples. In addition, there is the need to balance protection with access to innovation.

Cybercrime is also an issue with regard to the Internet and developing countries. Some computer viruses have been tracked to individuals in developing nations such as the Philippines. Many developing nations have neither laws dealing with crime in cyberspace nor the technical skills necessary for investigative efforts. Since

11 September 2001, concerns about cyberterrorism have increased. There is significant discussion regarding the prevention of cyberterrorism and its possible forms and impacts as well as the need for international cooperation. There have been recent efforts to share expertise regarding cybercrime prevention and enforcement. In August 2002, the U.S. Department of Justice, the FBI, the U.S. Department of State, and AID held a training program in Moscow in conjunction with the Asia-Pacific Economic Cooperation Forum. This cooperative effort followed the signing of a counterterrorism declaration by the U.S. and Southeast Asian foreign ministers. The declaration particularly focused on strengthening and harmonizing laws related to cybercrime. The European Union has also been active in plans to combat cybercrime (*European Union Information Society,* 2002).

Finally, public policies need to focus on sustainability issues, ensuring that development with regard to the Internet becomes routinized and institutionalized, thus promoting long-term economic growth and positive social development. The systems approach (mentioned earlier), which calls for recognizing complex interconnections among state and nonstate actors, is particularly important in planning for sustainability. Policies that forge and reinforce embeddedness—links at different levels of groups of organizations—promote sustainability.

Barriers to Internet Development

There are at least 19 barriers that have been listed by Mansell and Wehn (1998) as hindering the development of the Internet and related capabilities in developing countries. There may be a very small domestic market and/or low levels of demand. Past government policy may not have included incentives for technology development. Perhaps companies have all been small and have not yet formed a network or alliances with companies from neighboring or from developed countries. There probably is no history of venture capital in the country. Nor is there easy access to credit for small and medium-sized businesses. Links between university, industry, and research institutes (if any) are weak or nonexistent. There is no relevant vocational training and an absence of flexibility and concomitant weak information management practices. Finally, there is little information and computer literacy among managers.

With regard to multinational and information and communication technology firms, there are few, if any, links. Labor costs within the country are high due to the lack of trained manpower. There is little expertise about a quality focus or about current software tools and development methods. The infrastructure is either weak or nonexistent or partially available in urban centers. Also weak is the knowledge base for marketing outside of a country. Finally, the government sector itself is a poor user of information and communication technologies in conducting its own business. Also it has few, if any, partnerships with the private sector.

Sometimes there is mistrust or a "not invented in this country" perspective, or there are problems in figuring out user needs, especially with regard to rural sectors or sectors with different cultures.

Understanding local culture is central. A major barrier is the absence of both local content and local language. What this often means is, then, an inability to promote social change and development. The software industry is located primarily in developed nations, although there are clusters within developing nations (such as Bangalore in India). Also, most software documentation is written in English—another barrier. A major problem is intellectual property rights violations and the absence of intellectual property laws in many developing nations. (See the earlier discussion of the World Trade Organization TRIPS Agreement.) Yet another hindering factor introduced earlier is the lack of ability to market outside of a developing country. While there are ways to deal with each possible barrier described above, many developing nations currently face these factors and are just beginning to grapple with them. The barriers appear to be greatest for the least developed nations.

STRATEGIES

Skills Inventories

Skills inventories need to highlight skills and knowledge resources both within and without developing countries' borders. Skills can be classified according to government workers, universities, research centers (if any), and the population at large. Particular attention needs to be paid to the education system from preschool through tertiary education and to training in the private sector (if any). Basic literacy is a foundation skill.

A second skill set is the ability to participate in networks and in knowledge sharing. This includes the ability to interface with computers, send electronic mail, and research on the Internet. Most importantly, it calls for a new way of thinking and interacting—an ability to think and work in network terms. Here, universities within a country or distance education partnerships can play a special role in developing a country's intellectual capital. A third skill is technical abilities that allow networks to function within a country, although this skill set is not required for the entire population. Vocational training programs can equip a subset of students with such expertise. Control and management skills are requisite for the survival of the Internet in developing nations. Such skills require budget and accounting expertise as well as managerial abilities and are required for effective government, nongovernmental organization, and private sector managers at all levels.

There is a fifth set of skills: leadership skills within government and within the populace. Leadership skills are vital to recognize where a nation is with regard to the Internet and information and communication technologies and to inspire a nation's advancement through, even partially, the Internet and related technologies. The ability to dialogue across generational borders and to communicate a vision to one's country and to leaders of all sectors as well as citizens is a vital and vibrant need. Also, most of all, leadership—a new kind of leadership—requires effective communication with leaders of other developing nations as well as with nongovernmental organization, international organization, and private sector leaders and other heads of government from around the world.

Developing Nations and Outside Factors

In addition to differences within developing nations and within regions, there are major differences with regard to Internet usage and policies as a result of factors from outside the borders of a given nation. A recent study of developing nations in five regions of the world finds that international forces are behind Internet usage within all countries in the study (Franda, 2002). At the same time, this study highlights the sovereignty of developing nations in their role as gatekeepers related to technology and innovation. The Internet has not undermined the power of state government. Rather, some developing nations evidence a pattern of limitation of Internet access and usage to specific elite segments of their population: the military, scientific, or other elites in a nation.

Evidence of 13 types of developing nation control from this study indicates specific limitations:

1. Laws that restrict or censor the Internet with regard to security, defense, pornography, criticism of leaders and their families, discussion of religion that might foster dissent, and related restrictions. (See the earlier-cited cases of China and Saudi Arabia.)
2. Laws that require registration with the government in order to access the Internet.
3. Penalties for putting items on the Web that violate a nation's laws.
4. Restriction of sites to which a citizen may gain access.
5. Shutting down of cybercafés where using the Internet may violate a nation's laws.
6. Restriction of uses of encryption technologies.
7. Restriction of licenses to universities and/or publishers and holding such institutions responsible for the behavior of those from within them for their usage of the Internet.
8. Requirements for Internet service providers to work with a government's intelligence and security agencies, thus giving such agencies access to e-mail messages and Internet content and then sharing with other governments' agencies.
9. Requirements that Internet service providers are responsible for Internet use and content that undermines national laws.
10. Allowing government intelligence agencies to review Internet e-mail and content.
11. Sending reminders or threats of possible disconnection of service in the event national laws are broken.
12. Making arrests related to violation of Internet-related laws.
13. Establishment of government monopolies over the Internet and related technologies to ensure complete control (Franda, 2002).

Additionally, there are reports of hackers at work breaking into targeted Web sites; of traffic analyses, tracking Internet messages and their flow; and of dissemination of incorrect or misleading information to cause confusion among dissident groups. In sum, privacy issues are central to a discussion of the Internet and developing nations. When attention to privacy issues is lacking, there is little opportunity for promoting the vision of open and electronic governance or—similar to the vision of the role of the mass media in the political development approach—the promotion of the Internet in building and strengthening democracy. Even attempts to work for Internet content in languages other than English can be viewed as opportunities for more, rather than less, local government control. The absence of policies regarding privacy protection and the Internet in many developing nations serves as a barrier to the development of an environment supportive of electronic commerce.

The Internet, Developing Nation Governments, and Diasporas

The Internet lends itself well to serving as a possible vehicle for linking more effectively homelands and diasporas as well as diasporas with no one single national home, especially in cases where there is an educated, dispersed population with Internet access. Diaspora-related Web sites can provide both socialization and identity-building for younger generations and also integration and identity reinforcement for older generations. The above-discussed Franda study provides information on how developing nation governments use the Internet successfully to link to diasporas (e.g., the worldwide community of individuals from India). Alternatively, diaspora communities themselves can design Web sites with no connection to a nation-state government.

There is much potential for governments to use diaspora Web sites to link homeland resources to external resources. Some countries have used Web sites to reverse a possible "brain drain," highlighting government policies (and related incentives) to lure former citizens back to their homeland. Others have used such Web sites for primarily political purposes—to maintain and enhance support for specific policies.

Developing Nations Policies: Overview

From a policy and nation-state perspective, there are many ways to consider what a nation-state ought to be doing. There are policies that relate to the Internet and business per se, including telecommunications, foreign direct investment, education, research and development, and tax policies. Some of these have been introduced earlier in the discussion of general public policies. One way to think about nation-states' policy roles is in the traditional terms of telecommunications policy, technology policy, industrial policy, and media policy. Each of these policy areas overlaps when it comes to the Internet and developing nations. However, the policy domain extends beyond individual countries' policy-making roles.

Building Infrastructure

A focus on building an appropriate infrastructure constitutes a basic strategy. A major challenge in many developing nations is not just the cost of access, as noted earlier, but just gaining access. There is a large gap in developing nations compared to developed nations even in terms of fixed-line telephones. In some countries, there are inordinate waits for a fixed-line telephone, even if the money is available to pay for the service. Electricity is often unreliable. One possible answer to the issue of the absence of fixed-line telephones and the unreliability of power sources is wireless. Recently, there has been a large growth in wireless, both in developed and developing nations. The 2002 International Telecommunications Union report on "Internet for a Mobile Generation" (ITU SPU, 2002b) highlights the convergence between mobile and the Internet and its potential for major economic growth. Yet a great deal of capital investment—especially for developing countries—is necessary. The report highlights Korea with its fast-growing mobile penetration rates as a possible model for a mobile information society in the future.

Another element is the development of policies that increase competition and bring down costs. Still another is the creation of innovative programs targeted at increasing access such as the program described next: The Grameen phone program that originated in Bangladesh provides an example of programs that build on local culture, provide opportunities for local entrepreneurs, and, most importantly, offer connections for local people at lower costs than fixed-line options. The Grameen Phone Program is modeled on the successful Grameen Bank Program. In fact, the Grameen Phone Program is spreading from Bangladesh to other developing countries. One example is the Grameen Phone Sewa Initiative, which is now about five years old. It focuses on villages in rural India. Escotel, a provider of cellular phones, makes one cellular phone available to each of a number of villages in rural India. The connections are free and airtime is subsidized. Operators recoup their investment in the phone in five to six months. However, most significantly, people in the village now do not have to walk days to make a call or to do business. Both Escotel and the Grameen initiative are doing well in India. These initiatives provide foundations for alternative access to the Internet in the future, given the convergence of Web and cellular technologies now being developed.

Information and Communication Technology Initiatives

A number of developing country governments have introduced information and communication technology initiatives as a central part of their technology policy programs. Malta is focusing on seven priorities: ensuring an information technology culture, promoting skill development related to information and communication technologies, promoting investment in information technology, helping organizations use information technology effectively, fostering an information technology industry within Malta that is export-oriented, using information technology effectively to deliver government services, and enhancing sector cohesion through information technology (Mansell & Wehn, 1998). Malaysia provides another example. Despite the Asian financial crisis, it continues its goal, as noted earlier, of a major global multimedia corridor and has thus far attracted over 500 companies from both inside and outside the country to its plan.

Another set of initiatives comes from the university sector. The Massachusetts Institute of Technology is now in its first year of implementation of its OpenCourseWare project (http://www.ocw.mit.edu). As of September 2002, it had placed 38 out of about several thousand courses on the Web. (This usually includes the syllabus, lecture notes, and any related materials.) MIT plans to complete the project in 2007. MIT reports that during the first month of operation, 315,000 people visited the site, with at least 30% from outside of the United States (Olsen, 2002). This project allows universities and individuals around the world access to MIT's detailed curriculum including computer science courses.

A second initiative involving the Massachusetts Institute of Technology along with Stanford and six other universities is the Open Knowledge Initiative (OKI). This project focuses on developing open (not proprietary) technical specifications for learning management systems (Web-based software that enables online class rosters, class outlines, assignments, discussions, and other classroom aids) (Olsen, 2002). The OKI project outcomes can assist developing nations in several ways: cutting development costs, and allowing organizations to take advantage of new applications with greater technical ease and increased system stability. There are several other similar attempts to share course syllabi and materials. What would be important as a next step is a mutual exchange, recognizing the knowledge base that developing country institutions may want themselves to contribute in a multidirectional learning experience. Another next step may be automatic or other translation of materials to match the language(s) of the country in which they are being used.

Guidelines for Initiatives

An important element for ensuring success of these strategies is the actual structure for dealing with such issues within the government. One of the major themes of the past decade has been both privatization of previous government monopolies of telecommunications and the separation of regulation and operation within government agencies. Setting up agencies that deal with regulation not operation of telecommunications, information, and media is a recent development in many developing nations.

The United Nations Commission on Science and Technology for Development has crafted guidelines for nations regarding information and communication technologies (Mansell & Wehn, 1998). First, there is a focus on information and communication technologies such as the Internet in social development. Great potential for social development exists through the effective use, for example, of the Internet as a tool for health education, prevention, and education. Second, there is a need to train and provide adequate human resources for the Internet and development-related initiatives. Third, there are new forms of organization and skills necessary for this information-intensive era. Each country needs, fourth, to have an effective information infrastructure with concomitant-trained human resources. Fifth, each country needs to focus on those most disadvantaged such as women and the poor in order to ensure appropriate training, access, and implementation. Sixth, countries need to consider partnerships with foreign companies and plans to stimulate direct foreign investment to meet market and growth needs. Seventh, there needs to be networks of expertise developed related to Internet and information and telecommunication technology development opportunities. Eighth, developing countries need to become key players at global tables determining standards, policy positions, and the like.

To carry out such guidelines, it is important that a country, as noted earlier, have an overall strategy for information and communication technologies. Such a strategy needs to recognize the regulatory and business environment worldwide. If there is to be a business environment conducive to markets, there must be stability, rule of law, and transparency with regard to policy. The costs of financing need to be considered as well as the need to serve the poor and rural areas. Participatory planning should be a key part of these considerations. Additionally, the strategy should address the development of human resources within the country. Issues of social development cannot be forgotten. At the same time, there needs to be a focus on ways to attract resources as well as on shaping a climate conducive to new business both indigenous and foreign.

The field of biotechnology provides an example for understanding the Internet and developing nations. Based on research in biotechnology, it is clear that the locus of innovation is no longer individual organizations. Rather, it is in networks of organizations and learning. Thus, developing nations need to think about not just a dyadic relationship with Internet and related technologies. They need to think about building relationships, informal or formal, with other developing nations, with other nations in a region, and with nongovernmental organizations. They also need to consider, as noted above, their relationships with their indigenous private sector and with foreign companies.

Examples of Initiatives

Developing nations' governments are working together, especially in response to the World Trade Organization. There are strong regional activities in Africa, Europe, and Asia, building upon active regional organizations such as ASEAN. There is also innovation. In September 2002, Egypt announced free Internet service, leading to growth in Internet use and access. Botswana is linking its legislators online and allowing citizens to follow the proceedings of their parliament. Linking to nongovernmental organizations, Bulgaria is working with municipalities in an anti-corruption initiative. Finally, in Sao Paulo, Brazil, the government is working with a nongovernmental organization to set up 100 telecenters to train people and small companies in computer usage. The South African government has established an information and communication technologies advisory board. This is an effective option for countries who wish to gain knowledge about the field yet retain their independence in policy making. An advisory board allows government officials to tap the knowledge resources of nongovernmental, university, think tank, and private sector organizations.

Even nongovernmental organizations are forming formal networks with one another and with governments of developing nations. One World is a partnership of nongovernmental organizations, formed to share knowledge. Recently, One World founded the Digital Opportunity Channel, working with another important category of organization, a foundation (in this case, the Benton Foundation) and with funds from two governments (United Kingdom and the Netherlands). The Digital Opportunity Channel is a Web site created to promote information flow and information sharing, about efforts to bridge the digital divide.

Yet another pattern (and developing nation governments often work with all of these aforementioned categories) is a developing nation government working with international organizations such as the United Nations Development Programme and international institutions such as the International Telecommunications Union. Starting in the 1990s, Estonia worked with the United Nations Development Programme to promote computer use by its citizens. Now, 100% of the new generation of Estonian students is computer literate.

Another major role is being played by groups of developed nation governments. The powerful Group of Eight has established a Digital Opportunity Task (DOT) Force and has also worked on an Africa Action Plan. The DOT Force is focusing on access, skill development, entrepreneurial enhancement, local content and applications, and health care. It recently announced an entrepreneurial network initiative. The DOT Force has established numerous partnerships including nongovernmental organizations and the private sector. For example, the DOT Force Entrepreneurial Network involves Accenture, Hewlett-Packard, Telesystem, and Open Economies (a policy center at the Harvard Law School).

Individual developed nations also have programs focused on providing assistance, especially to the least developed nations, with a focus on information and communications technologies and the Internet. For example, the U.S. Department of State through AID offers projects to assist governments with information technology-related development projects (U.S. AID Leland Initiatives, 2001). Additionally, the government of Japan provides a wide range of technology-related support from technical expertise sharing and technical training to professional exchanges (*New Breeze,* 2002).

Similar to nongovernmental organizations, the private sector is also learning to shape both informal and formal networks to promote learning, change, and their goals. As noted earlier in the chapter, heads of major multinationals from a range of countries have formed the Global Business Dialogue to promote electronic commerce. They are particularly focused on forming the policy framework for electronic commerce in emerging economies. Again, network organizational forms are key to the work of the Global Business Dialogue. Among its many partnerships, the Global Business Dialogue is working with e-ASEAN to focus on the necessary policy and legal infrastructure as well as a network infrastructure specifically for that region. It also signed an agreement to work on e-government and e-learning for the Asia-Pacific region. There are similar agreements with South Africa and with Egypt.

The work on e-government involves the following components, each of which has implications for any developing nation's use of the Internet for governance and government services: provision of online information (whether health or tax or governance-related); provision of online transactions and online services; design of an intranet within the government; design and assurance of security; design of electronic procurement; design of electronic learning; provision of adequate and secure technological infrastructure; provision of knowledge management; and design of electronic democracy.

The Global Business Dialogue also deals with cybersecurity issues and protection, essential to ensure the growth of electronic commerce in developing and developed nations alike. It is also thinking about the impact of electronic commerce, especially in terms of costs for small and medium-sized businesses. It works for increased and more effective cooperation between industry and government. Finally, it is promoting discussion and concern with cyber ethics.

There are numerous examples of nongovernmental organizations working not just with governments in developing nations, but also directly with individuals or informal groups. PEOPLink is a nongovernmental organization that used to sell items on the Web for artisans from a number of developing nations including Cameroon, Haiti, and Nepal. The idea was to cut out the middlemen. What is particularly fascinating is that recently PEOPLink announced that it is transforming its Web site so that, using the newest technology, artisans can sell directly online to people anywhere. This is an unusual e-commerce application that demonstrates the power of the Internet in transforming not just how Web sites operate but how artisans in developing nations may directly and effectively market and sell their wares.

Developing Nations and International Institutions and Organizations

There are a number of international institutions and organizations that are important in any discussion of the Internet and developing nations. Starting with two of the oldest (both a part of the United Nations Systems), the United Nations Development (UNDP) and the International Telecommunications Union (ITU) indicate ways in which organizations founded in eras without computer-related technologies have changed and adapted to this new telecommunications and Internet arena. Both UNDP and ITU have very active programs to work with developing nations, especially the least developed nations and with other partner organizations (and, especially increasingly over time, with the private sector). The UNDP has a networking and information technology observatory that deals with issues for developing nations (UNDP, 2002).

The ITU has numerous conferences and summits focused on Internet-related issues in developing nations. It highlights success stories related to the use of information and telecommunications technologies in developing nations. In 1995, the World Bank established a global grant program called InfoDev, which focuses on providing support of new information and telecommunication technology-related ideas to reduce poverty (*ICT Stories*, 2002). These organizations also provide knowledge resources related to the Internet and gender and the Internet and the environment.

An area where there needs to be more developing nations participation is in the area of global governance of the Internet. ICANN, the International Corporation for Assigned Names and Numbers, now manages the global system of domain names with the goal of maintaining the stability and also the security of the Internet. It has a Governmental Advisory Committee (GAC) with representatives of governments. Minutes of this Committee indicate that not enough developing nation governments send representatives to the ICANN meetings where decisions are made. (Naturally, there are costs involved to send representatives to such meetings.) Of particular importance for governments represented at ICANN is discussion of top-level country code domain names. Some developing nations such as Tuvalu have sold their country code domain name to a private sector organization (.tv in the case of Tuvalu) in order to raise funds for their country. Currently, ICANN is undergoing "evolution and reform" in terms of its structure and operations. The presence of a large number of developing nations in these deliberations would surely strengthen the outcomes.

CONCLUSION: FACILITATING FACTORS

In thinking about the Internet in developing nations, there are some important mechanisms at work that may be overlooked. The Internet itself as a technology or group of technologies that is, by design, a network facilitates the formation of additional networks. As noted earlier using the example of the biotechnology field, networks support the kind of learning that is important in this new information-intensive era. There is power through participation in networks to cut down on uncertainty and also to share what is tacit knowledge. Participating in alliances or partnerships or networks allows for complex learning (not just one-way learning or old-fashioned one-way diffusion of a model developed outside of a developing nation). Once networks are forged, their links are the conduits over which all sorts of resources including knowledge, influence, labor, materials, and money may be exchanged. In other words, networks of organizations and individuals promote interorganizational learning of many types and can build the absorptive capacity of organizations and even countries and regions.

One factor central to understanding the complex relationship between the Internet (or any technology) and any individual organization, country, or region, as well as sets of such, is culture. The cultures of participating organizations in a network and/or in a country or region shape and, in turn, are shaped by technologies as well as participants' cultures. Cultures influence how individuals and groups view concepts such as research, conduct negotiations, and make decisions. Many of the success stories highlighted by partnerships and networks focused on the Internet and developing nations come about because the participants recognize the roles of culture in their projects and in dealing with change. Change is a key element in development; Internet technology itself is central to the pace, depth, and nature of change.

Leaders of developing nations, international organizations, international institutions, nongovernmental organizations, private sector organizations, and related networks of organizations need to be able to design, manage, and respond to change. Most importantly, they need to be able to coach and to work well in networked situations. The Internet itself, by virtue of its information intensity and its technological makeup, is a vehicle of change—change that subtly but strongly impacts all elements and groups within its domain. Change can also be negative; today there are cases of cybercrime and cybercorruption in developed as well as developing nations. Thus, there is a need to ensure that government leaders as well as leaders of burgeoning private sector and nongovernmental sector organizations have the special skill set to deal with change in a networked world, and to propel development forward in an effective, ethical, and empowering way.

GLOSSARY

Absorptive capacity The degree of foundation present and necessary in an organization or country for using effectively new knowledge or new skills or new technologies.

Cybercafé A place where people come to use computers and access the Internet.

Diaspora Groups of people with similar ethnic and/or political identities who are dispersed, either voluntarily or not, around the world.

Diffusion of innovations The way in which an invention or a newly created process is disseminated and used.

Domain name The letters following the "dot" in an Internet address such as .gov, .edu, .com, or .org.

Electronic commerce An organization's or set of organizations' conduct of business functions via the Internet, which may be only business to business (known as B2B) or business to consumer, or both.

Electronic governance A country's use of information and communication technologies to conduct its business using the Internet, including access to government services and government information.

Globalization The increasing interconnection of elements such as the economy or knowledge or even nations as a result of the Internet and related technologies.

Infrastructure The physical (such as computers) and nonphysical (such as technically skilled human resources) elements necessary for the provision of basic information services in an organization or country and for subsequent growth.

Internet host A computer that allows many users to access network services (including the Internet) through it.

Interorganizational learning The process of identifying, acquiring, and using knowledge through being a part of a connected set of organizations such as those organizations participating in an alliance.

Isomorphism The processes of change which are either mimetic (through copying), normative (through doing what is right or what an organization ought to do), or coercive (through force of law or power).

Regionalization The process of increasing connections, both formal and informal, among a group of countries within a specific geographic region such as the Americas, Asia, Europe, or Africa.

DHTML (Dynamic HyperText Markup Language)

Craig D. Knuckles, *Lake Forest College*

INTRODUCTION

The *hypertext markup language* (HTML) is used to instruct a given piece of software how to "mark up" information for human viewers— the font sizes and faces, text colors, background colors, page layout, and so forth. A digital document composed of HTML is called an HTML document. An HTML document, which contains only plain text, is very different from its rendition, which is a visual display created by software according to the HTML markup instructions in the document. The rendition of an HTML document is called a Web page.

Many types of software can render HTML documents and create Web pages, but by far, Web browsers are the type of software most commonly used for that purpose. An HTML document stored on a local hard drive can be loaded into a Web browser and rendered as a Web page. Thus, the act of creating a Web page rendition from an HTML document has nothing to do with the Internet. The computer need not even be connected to the Internet. This is really no different from loading a word processing document into a piece of word processing software to see a rendition of that type of digital document.

The term hypertext refers to text with hyperlinks, or simply links. Text without links is simply text. HTML-rendering software, such as Web browsers, have the ability to retrieve and render new hypertext documents at the request of a user clicking a link. The rest of the name HTML designates it as a markup language. Markup instructions tell the rendering software about the document's logical structure and, to some extent, how its rendition should be formatted. HTML alone does not specify how humans can interact with the Web page. Hyperlinks provide for the only interactive capability of Web pages created using only HTML. That linking ability aside, a Web page rendition is inherently static. It can't interact with the user.

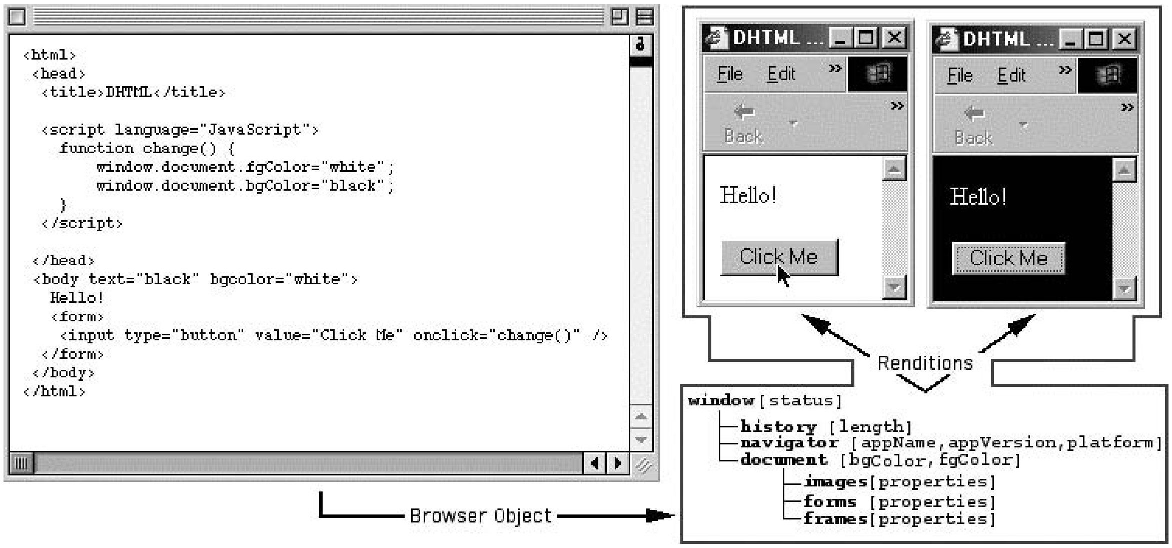
The reason HTML-created Web pages are inherently static stems both from the fact that HTML is only a markup language, albeit for hypertext, and from the fact that its transport protocol is *stateless*. The *hypertext transport protocol* (HTTP) is specified at the beginning of *a uniform resource locator* (URL), such as http://www.cubs.com, that requests an HTML document from over the Internet. The protocol is designated as stateless because it specifies that an HTML document, and objects such as graphics that are to be embedded in the Web page, be transferred to the Web browser and then that the connection to the remote Web server be terminated. HTTP does not provide for a continued transaction state between a Web browser and Web server.

That means that user interactivity can't be achieved in a rendered HTML-generated Web page through continuous support from the Web server. If fact, the legacy of an HTML document retrieved via HTTP from over the Internet is a Web page rendition that is no different from an HTML document loaded into the browser locally from the hard drive using no Internet connection whatsoever. Whether loaded locally or over the internet, a Web page rendition is static. A new connection to Web server is only invoked when the browser requests a new HTML document (or other resource) from the server. That just results in another static rendition in the Web browser.

Indeed, Tim Berners-Lee invented the World Wide Web around 1990 in an effort to mobilize information about current physics research on the Internet. The newly created HTML needed only to specify an electronic document's logical structure so that rendering software could understand how to display it. The newly created HTTP needed only to transport the documents to the rendering software over the Internet. Once retrieved, the HTML document provided for a static information display. Hyperlinks provided for a means to retrieve related information for static display. At the onset, Berners-Lee did not foresee that commercialization of the Web would lead to dynamic interactive effects in Web pages.

WHAT IS DHTML?

Dynamic HTML (DHTML) refers to a means for making a rendered Web page capable of customized interaction with the user without further Web server connections. A DHTML-enabled Web page has interactive capabilities that are handled entirely by the browser software on the user's computer. This is the abstract notion of DHTML. Typical DHTML interactive effects are triggered when a user passes the mouse over a region of the Web page and then something in the Web page changes. Examples of such changes include one graphic being replaced by another or a hidden layer in the Web page becoming visible. As the Web has evolved, Web page authors have sought to improve the functionality and aesthetics of a user's



```
<html>
 <head>
  <title>DHTML</title>

  <script language="JavaScript">
    function change() {
         window.document.fgColor="white";
         window.document.bgColor="black";
    }
  </script>

 </head>
 <body text="black" bgcolor="white">
   Hello!
   <form>
    <input type="button" value="Click Me" onclick="change()" />
  </form>
 </body>
</html>
```

Figure 1: A basic DHTML effect.

viewing experience. Indeed, a Web site that piques a user's interest is more likely to receive a return visit from that user. Through DHTML, the Web has achieved a level of interactivity sufficient to satiate many Web surfers' desires for instant interactive gratification, yet without taxing the Internet's infrastructure with superfluous, time-consuming network transactions.

Of all the Web-related technologies, DHTML is perhaps the most poorly named. A reference to "the dynamic hypertext markup language" leads one to think of a self-contained language, perhaps a big brother of HTML, used to enable dynamic interactive effects. But DHTML is not a self-contained language. A more accurate appellation for DHTML would be "dynamic Web pages using JavaScript." DHTML is actually a marketing term invented by the software vendors Netscape and Microsoft during the browser wars as they expanded on the dynamic capabilities of their browsers in efforts to gain market share.

The world has come to know DHTML as summarized by the following "equation."

$$\text{DHTML} = \text{HTML} + \text{CSS} + \text{DOM} + \text{JavaScript}$$

HTML is defined by the international standard W3C HTML 4.01 Recommendation. The *cascading style sheet* (CSS) language and the *document object model* (DOM) are defined by the international standards W3C CSS Level 2 Recommendation and W3C DOM CORE Recommendation, respectively. JavaScript, formally ECMAScript and defined by the international standard ECMAScript 262, is the scripting language used to provide programming support for Web browsers.

DHTML is a term that encompasses the ways the four distinct technologies on the right side of the above equation interact to create dynamic effects. There is no well-defined "language" specification for DHTML, nor even a definition of what DHTML should accomplish. Abstractly, DHTML enables interactivity in Web pages without the need for extra transactions with Web servers. Concretely, DHTML refers to what the imaginations of Web programmers have been able to accomplish by integrating HTML, CSS, DOM, and JavaScript.

The full strength of those four technologies need not be brought to bear to create DHTML effects. Very basic DHTML effects can be created using HTML, JavaScript, and a "subset" of the DOM, called the *browser object*. Such a very basic DHTML effect is illustrated in Figure 1. As this article progresses through the evolution of DHTML, its full strength will become apparent.

An HTML document is shown on the left of Figure 1. The body of the HTML document contains only one word and a clickable button. When the HTML document is loaded, the Web browser creates a browser object, which is the browser's in-memory representation of the Web page it creates from the HTML document and the window that contains it. That object is stored in the computer's RAM (random access memory) for quick access and holds the current state of the browser window and the Web page rendition. A partial depiction of the browser object is shown in the lower right of Figure 1.

The data about the current state of the window and Web page rendition is carried by the object in its *properties,* a few of which are shown in square brackets. Properties are basically ordinary programming variables, which are bound into the browser object's *hierarchical* structure. The hierarchical structure of the browser object is depicted in Figure 1. However, that depiction is a purely abstract visualization of the object. A browser does not display such a tree structure, but it makes the properties of the browser object available to the programmer through the hierarchy.

Properties of the browser object are accessed by using "dot notation" to progress down into the hierarchy. For example,

```
window.history.length
```

accesses the current window object maintained by the browser. A history object, which records information about the Web pages that have been displayed in the window, is associated with the window object. Its length property is a variable that contains the number of Web pages that have been loaded into the window since it was opened.

The variable

```
window.document.bgColor
```

is more pertinent to Figure 1. This refers to the document object (Web page) contained in the current window. The document object has several properties that contain data about the current Web page in the window. In particular, the bgColor property contains the page's current background color.

The left-most browser window in Figure 1 reflects the initial state of the document object as determined by the HTML instructions—black foreground (text) color and white background color. DHTML effects are created by changing the state of the browser object on a *user event,* in this case the user clicking the button. The onclick *event handler* defined for the "click me" button calls a JavaScript function named change(). That function is defined in a script included in the head section of the HTML document.

On the button-click event, the JavaScript function changes the state of the browser object by reversing the foreground and background colors of the document object. The effect on the Web page is immediate, and the user sees white text on a black background. The two browser windows in Figure 1 show the Web page before and after the button click. They do not represent two different browser windows. Rather, the DHTML effect triggered by the user event changes the state of the browser object and, hence, the Web page rendition. Moreover, the DHTML effect is instantaneous, with no Internet transaction involved.

The details of a specific example sometimes serve to overshadow the underlying concept, which can be quite simple when considered in more generality. Figure 2 shows the broader concept of DHTML implementation. This diagram doesn't reflect what CSS or the full DOM bring to DHTML. Those additions add nothing to the general concept, just more flexibility and many more details regarding implementation.

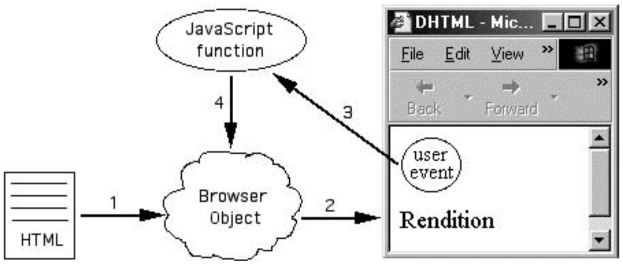


Figure 2: The general concept of DHTML. 1. The browser parses the HTML document and creates an in-memory (RAM) browser object, which stores the properties of the Web page as specified by the HTML document. 2. The Web page rendition reflects the current state of the Browser object. 3. A user event causes a JavaScript function to be executed by the browser. The JavaScript function is in a script contained in the HTML document. 4. The JavaScript function changes the state of the browser object. This causes an instantaneous change in the state of the Web page rendition.

Steps 2 through 4 as shown in Figure 2 need not be a one-time sequence of events. In fact, a sequence of user events can trigger a sequence of DHTML effects: event calls function -> function updates state of browser object -> rendition state changes -> event calls function -> repeat process. As the result of repetitive user events, DHTML can actually create animations in a Web page.

The types of user events that trigger DHTML effects are varied. For example, the act of the user loading a Web page into a browser (the onload event) can trigger DHTML effects from the onset. But most often, DHTML effects are triggered by the user sometime after the page is fully rendered. Some common events, which are user actions for which the browser is basically sitting there "listening," are listed below.

Onclick—The user clicks the mouse on a certain region of the Web page.

Onmouseover—The user moves the mouse over a certain region of the Web page.

Onmouseout—The user moves the mouse back out of a certain region of the Web page.

Onmousemove—The user merely moves the mouse.

The DHTML effects initiated by such events vary widely.

When defining a technology, it is often instructive also to define what it is not. Java Applets and Flash animations are the most common technologies that can be misconstrued as being DHTML. Java Applets and Flash animations are basically small applications (hence the term Applet) that can be embedded in a Web page. In both cases, the Web browser requires a helper application to execute the embedded technology. Java Applets require a Java virtual machine (JVM), and Flash animations require a Flash plugin for the browser. Both of these technologies increase the runtime overhead of the browser and are not favored for simple visual DHTML-style effects. The increased overhead for the browser, and the fact that a given user might have to install the helper application just to see the effect, are the main reasons why DHTML is favored for relatively simple interactive enhancements. But when interactive needs become elaborate, such as for small video games embedded in Web pages, Flash and Java are certainly worth the extra overhead they incur.

Many books have been written on how HTML, CSS, DOM, and JavaScript work together to create DHTML. A book by Knuckles (2001) provides such coverage from the ground up and assumes no prior programming experience. A book by Teague (2001) provides more elaborate coverage of specific effects that can be created using DHTML.

THE EVOLUTION OF DHTML

At the dawn of Web time (circa 1990), Web pages contained only text and hyperlinks. The initial goal of HTML, and its transport protocol, HTTP, was to mobilize information on the Internet. There was no initial intent for fancy visual effects. The goal was a Web of information, interconnected via hyperlinks. That goal has been realized far beyond the original expectations. The Web now mobilizes billions of HTML documents.

Nonetheless, the first 5 or so years of the Web's existence featured only Web pages with hyperlinks. The Web did not explode until Marc Andreessen developed an application, called Mosaic, that enabled Web pages to contain graphic images: hence its name. This was the first piece of software that had functionality resembling that of what we today call Web browsers. Andreessen went on to form Mosaic Communications Corporation, which was later renamed Netscape Communications. The release of Netscape Navigator version 2 for all major computing platforms (Microsoft's Windows, Macintosh, and Unix) caused the Web to ignite. The evolution of DHTML begins there.

Netscape 2 (March 1996)

Netscape Navigator 2 (NN2) introduced JavaScript 1.0, which provided the first scripting support behind Web pages. Prior to this, the only interactivity provided by Web pages was clicking hyperlinks. Now, programmers could write scripts to respond to user events and provide simple interactivity.

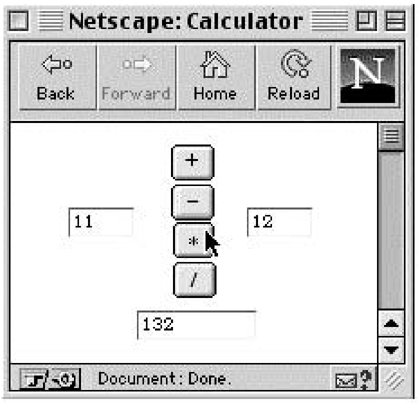
Client-side processing of user data was one important feature enabled by JavaScript 1.0. The browser object supplied by NN2 was sufficient to allow JavaScript 1.0 to manipulate data entered into HTML forms. The simple calculator utility rendered in NN2 shown in Figure 3 demonstrates that. Only the relevant parts of the HTML document and browser object are shown. Remember that this is purely an abstract depiction of the hierarchical object maintained in RAM by the browser. From this, it is apparent how the JavaScript references to the objects are formed using the dot notation.

When the HTML document is loaded into the browser, the browser object is initialized to reflect the current state of the document. The browser object hierarchy reflects the containment relationships. The window contains the document. The document contains the form, whose name is calcForm. The form contains the text fields, whose names are num1, num2, and result. The value properties of the text fields contain the data entered into the fields. In this case, all three text fields in the Web page are initially empty when the page first loads.

In Figure 3, the user has entered two numbers and clicked the multiplication button. The JavaScript function, which would be included in a script in the HTML document, first retrieves the two numbers from the browser object. It then calculates the result and assigns that result to the third text field. When the user clicks the button, the update to the browser object is instantaneous, and the answer immediately appears in the third text field. Again, no extra transactions with the server are involved.

Data processing on the client has become a staple of Web programming. Real Web applications use a mixture of client-side processing and server-side processing to process user information, such as personal information, credit card numbers, and airline flight choices. It is interesting to note that this is not considered DHTML by many, although it meets the abstract definition of DHTML given above. Colloquially, the term DHTML is generally used to refer to fancy visual effects rather than data processing. Nonetheless, the addition of HTML forms and JavaScript in NN2 introduced the world to the Web as a computing platform rather than just a means of displaying information.

The browser object of NN2 did allow for some effects that are sometimes placed under the umbrella of DHTML, although the term was yet to be coined. Those effects were mostly limited to changing the state of the browser window. Examples include changing the tool bar, status bar, or size of the browser window. Figure 4 shows a simple



part of Browser Object

```
window
 └─document
     └─calcForm
         ├─num1[value]
         ├─num2[value]
         └─result[value]
```

the script

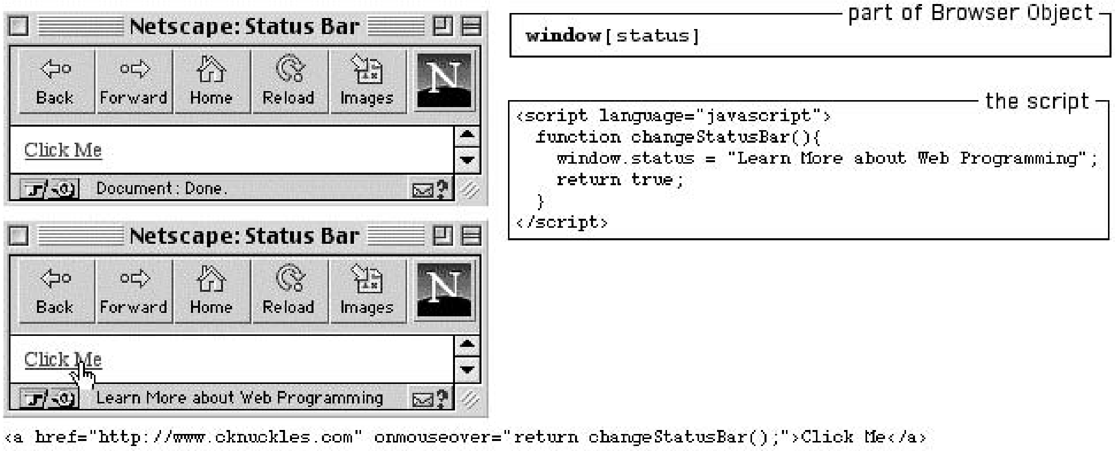
```
<script language="javascript">
  function calculate(operation){
    var num1=parseFloat(window.document.calcForm.num1.value);
    var num2=parseFloat(window.document.calcForm.num2.value);

    var result = eval(num1+operation+num2);

    window.document.calcForm.result.value=result;
  }
</script>
```

```
<form name="calcForm">
  <input type="text" name="num1" size="5" />
  <input type="button" value="+" onclick="calculate('+')" />
  <input type="button" value="-" onclick="calculate('-')" />
  <input type="button" value="*" onclick="calculate('*')" />
  <input type="button" value="/" onclick="calculate('/')" />
  <input type="text" name="num2" value="" size="5" />
  <input type="text" name="result" value="" size="10" />
</form>
```

Figure 3: A calculator in a Web page in Netscape Navigator 2.



Document: Done.

Learn More about Web Programming

```
window[status]
```

```
<script language="javascript">
  function changeStatusBar(){
    window.status = "Learn More about Web Programming";
    return true;
  }
</script>
```

```
<a href="http://www.cknuckles.com" onmouseover="return changeStatusBar();">Click Me</a>
```

Figure 4: A simple interactive effect in Netscape Navigator 2.

"DHTML" effect in NN2 that places a description about the nature of a hyperlink in the status bar when the user passes the mouse over the link. Only the relevant parts of the HTML document are shown.

The browser window in the upper left of the diagram shows the link, which gives no indication of to what Web page it points. The second browser window shows the result of the onmouseover event. The status bar is at the very bottom of the browser window. The JavaScript function called by the onmouseover event simply changes the status property of the window in the browser object to create this effect.

Although this effect is more like "dynamic browser window" than DHTML, these types of interactive visual effects are what DHTML is inherently about. It was not until around 2 years after NN2 was released that the term DHTML was coined in earnest. But simple browser window effects would come to be part of what DHTML encompasses. In the mean time, Netscape Navigator 3 and Internet Explorer 3 would add yet more to the foundation that would become DHTML.

Netscape 3 and Explorer 3 (Late 1996)

The Web was moving very quickly. In the same year they released NN2, Netscape released version 3 of their browser (NN3). Also, Microsoft entered the browser market with their release of the Internet Explorer 3 (IE3) software. For all practical purposes, this was the first commercial version of their browser, the 3rd-version designation being intended to indicate their software was on equal footing with NN3.

With NN3, Netscape released JavaScript 1.1, and with IE3, Microsoft released JScript. JScript is a scripting language reasonably similar to JavaScript. Web developers tended to stick to the common subset of JavaScript and JScript, which was adequate for most scripting purposes. NN3 dominated the browser market at this time, and JScript would never really gain its own identity.

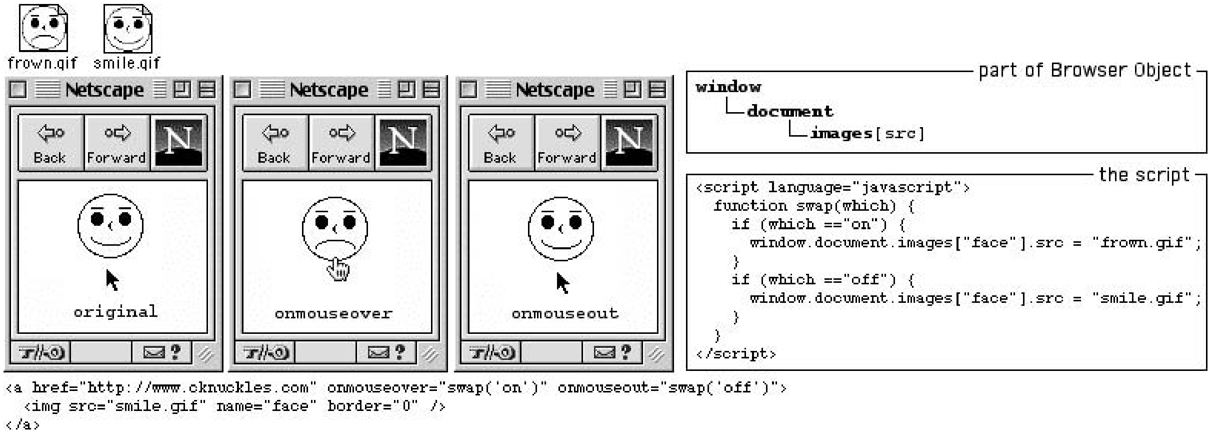
The biggest difference between the two Web browsers was that they featured substantially different browser objects. Again, Web programmers tended to stick to a common subset of the two browser objects to achieve cross-browser compatibility. The commonality between the browser object of NN3 and that of IE3 became what the world would come to know as *the* browser object. Figure 1 depicts part of the browser object, which is actually much more extensive.

The representation of HTML forms in the browser object, as shown in Figure 3, became the mainstay for data collection and manipulation in Web browsers. Although that capability was present in NN2, NN3 and IE3 featured the robust form manipulation capabilities that are still an integral part of e-commerce data-collection activities today. The browser object did, and still does, provide for full manipulation of text fields, checkboxes, radio buttons, pop-up menus, and all other form elements to which we have grown accustomed.

But the browser object only allows for a few DHTML effects. The "windowing" effects, most notably the pop-up windows that typically contain advertisements, were inherited by both browsers from NN2. The most notable new addition that NN3 and IE3 added to the visual effects arsenal was rollover graphics. The rollover graphic effect is created when the mouse rolls over (onmouseover) a graphic embedded in a Web page, causing that graphic to be replaced with a different one. When the mouse rolls back off the graphic (onmouseout), the original graphic is substituted back into place. This effect is most commonly used for graphics that are active as hyperlinks in Web pages. The fact that the mouse causes the image to change indicates to the user that the image is, in fact, active as a link.

Figure 5 shows how a rollover graphic is accomplished. As shown at the top of the figure, two distinct graphic image files are used, smile.gif and frown.gif. When the HTML file is first loaded into the browser, the original image on display is the smiley face. When the user passes the mouse over the image, the onmouseover event handler calls the swap() JavaScript function to "turn on" the rollover. When the mouse passes off the graphic, the onmouseout event handler turns the rollover back off by returning the original smiling image. As the two images are swapped in and out of the browser object, it simply appears to the user that the face changes.

Both swaps are accomplished by changing the source of the image in the browser object. Figure 5 only shows



```
window
  └─document
      └─images[src]
```

```
<script language="javascript">
  function swap(which) {
    if (which =="on") {
      window.document.images["face"].src = "frown.gif";
    }
    if (which =="off") {
      window.document.images["face"].src = "smile.gif";
    }
  }
</script>
```

```
<a href="http://www.cknuckles.com" onmouseover="swap('on')" onmouseout="swap('off')">
  <img src="smile.gif" name="face" border="0" />
</a>
```

Figure 5: An image rollover in Netscape Navigator 3.

the relevant part of the browser object. As specified by the HTML code, the name of the image in the browser object is face. When the JavaScript function changes the source of the image, the change is instantaneous from the user's perspective. But for the change to be instantaneous, the graphic that is to replace the one originally on display needs to be downloaded from the Web server at the time the Web page is retrieved. If the replacement graphic is not "preloaded" into the browser's memory, then an extra transaction with the Web server at the time the rollover is triggered is necessary to retrieve it. That defeats the purpose of browser-handled interactive effects. The JavaScript code necessary to preload the replacement image is not shown in Figure 5.

The most prevalent use of rollovers on the Web has been, and continues to be, for navigation tabs and bars. In these situations, there are typically several images that are swapped in and out. It is not uncommon for rollover displays to use 10 or 20 different graphics. Figure 6 shows two typical rollover displays. The horizontal navigation bar (nav bar) on the left features several menu tabs. The upper picture shows the menu bar in its initial state, indicating that the user is viewing the home page. The lower picture shows the menu bar when the mouse passes onto the preface tab. When the mouse is moved back off the preface tab to a location not on the nav bar, the display reverts to its initial state. Or, if the mouse is passed onto a different tab, that tab becomes highlighted. When the user actually clicks on a tab, a new page is loaded containing the same nav bar, but the default highlighted tab then corresponds to that page.

Such nav bars are often comprised of several images, one for each tab, which fit together seamlessly. The rollover display then requires an active, and a nonactive version of each image. Thus, the nav bar on the left of Figure 6 would require 12 different graphics, and each rollover action would replace two tabs—make one inactive and one active. Alternately, the whole nav bar could be one graphic. That requires one version of the nav bar for each active tab. That would require only six different graphics in Figure 6. A rollover action would swap the entire graphic in or out depending on which tab the mouse passed over. The user would not notice the difference between a display that uses six graphics and one that uses 12.

The vertical nav bar shown on the right on the right of Figure 6 could come from an online tutorial, for example. Such nav bars often just highlight the particular link over which the mouse passes, but this one swaps in arrow graphics pointing to the mouseover link. The central graphic is divided into an image map of different regions, one region for each lesson link. There is a stack of a blank white graphic on either side of the central graphic. This rollover effect does not replace the central graphic when the mouse passes over it, but it replaces the white graphic on either side of the mouseover region with an arrow graphic. There are only four graphics used to create this rollover display: the central graphic containing the lessons, the blank white image that is replicated in stacks on either side of the central image, and the two arrow graphics that are swapped in for the appropriate white "dummy" images.

When the mouse is moved up and down over the different lessons in the central graphic, the arrows move with the mouse, creating a simple animation-type effect. It is up to the imaginations of Web designers how rollovers can be employed to create novel DHTML effects. At the

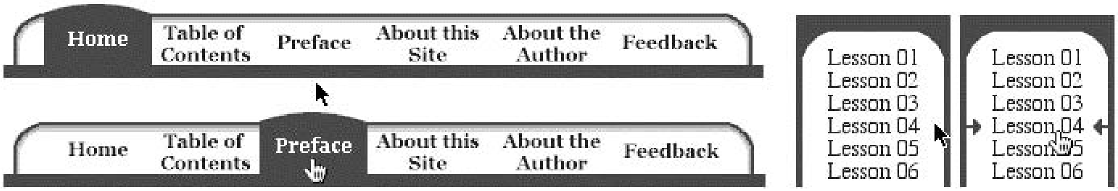


Figure 6: Typical uses of rollover graphics.

time of NN3 and IE3, effects such as those shown in Figure 6 were considered very fancy and sophisticated in Web pages. Multiple rollovers were at the pinnacle of Web page design.

This was also the era in which "browser sniffing" was born. Web programmers began to insert into Web pages JavaScript code that would "sniff out" the type of browser that was viewing the page. The properties of the navigator object in the browser object, shown in Figure 1, contain information about the browser's vendor, its version, and even the platform (Mac, Windows, Unix/Linux) on which it is running. (Ironically, that object is still named navigator, even in current Explorer browsers.) Once the JavaScript code determines the particular browser with which it is dealing, it can get the most out of the particular browser object.

At this time in Web history, the cross-browser multiple rollover is the effect of choice and is, in fact, the seed that sprouted into DHTML. It is not entirely clear exactly when the term materialized, but it was right around the time that rollover graphics became widely popular. It is clear, however, that the term proliferated as marketing jargon used by the browser vendors Netscape and Microsoft to tout the dynamic interactive capabilities of their newly released version 4 browsers.

Netscape 4 and Explorer 4 (1997)

Microsoft and Netscape were desperately locked into the "browser wars" at this time. Netscape was the spark that had ignited the Web, but Microsoft ruled the majority of desktop computing with its Windows operating system. It was that edge that eventually won the war for Explorer. But at this point in time, the battles still raged on.

In efforts to capitalize on the new idea of DHTML, Netscape Navigator 4 (NN4) introduced a new HTML layer element, with which multiple layers of content could be superimposed in one browser window. In contrast, Internet Explorer 4 (IE4) pushed the use of CSS and the *z*-index to create multiple layers. Regarding a flat browser window as a two-dimensional *x–y* coordinate plane, the *z*-index adds a third dimension. Netscape's HTML layer element also adds a third dimension, but not using CSS.

Both layering techniques turned the once "flat" Web page into three-dimensional *x-y-z* coordinate space. It's not that layers could appear to "pop out" at the user, but one layer could be moved independently of other layers by a JavaScript function as the result of a user event. Such effects are the cornerstone of "modern" DHTML. Prior to layers, a Web page layout was like a picture frame with multiple holes into which pictures could be inserted. The holes were in fixed locations in the page, and one could only swap images of the proper size in and out of a hole. This analogy explains rollover graphics rather well.

A layered Web page is more like a stack of loose pictures on table. One can shuffle the pictures around, leaving some partially covered, completely hiding some, and revealing others that were not previously visible. A picture can move in its own layer, independently of pictures in other layers. Hiding, revealing, and moving layers is the basis for much of "modern" DHTML.

But due to the radically different DHTML implementations by the two browsers, "modern" DHTML was largely a lost cause in this era. Industrious Web designers constructed rather elaborate JavaScripts to sniff out browsers in order to move layers in both implementations. But the majority of Web sites stuck to rollover graphics. Indeed, the Web had moved quickly in terms of browser versions, and a significant portion of the Web still used version 3 browsers. Most any Web site wanted their pages to work properly in everyone's browser. Many sites even avoided rollover graphics in this era because they wanted to sell products to those still using NN2.

Modern Browsers

It turns out that CSS and the *z*-index used for layers would be the future of DHTML. CSS, which adds to HTML the ability to exactly control the markup of Web pages, enables advanced page layout and many new and exciting DHTML effects. CSS is fully supported (for the most part) by modern Web browsers. That includes IE5+, NN6+ (a NN5 version was never released), Opera 4+ (a browser gaining popularity in Europe), and Mozilla 1+ (from the open source Mozilla project). These browsers are compatible (again, for the most part) due to the emergence of accepted international standards for Web technologies. These standards have enabled a whole new generation of DHTML effects. Modern DHTML is discussed below, following a brief overview of the international standards that enable the modern DHTL effects across different computer platforms and browser types.

THE STANDARDIZATION OF DHTML

Although it's not well-defined as a distinct technology, DHTML has become predictable because the technologies of which it is comprised have been internationally standardized. DHTML's aggregate technologies became uniform international standards beginning around 1998. The standards continue to evolve, but the following core standards on which DHTML is currently based are stable and widely supported by modern Web browsers (NN6+, IE5+, and Opera 4+).

HTML 4.01: This World Wide Web Consortium (W3C) standard has been stable since 1999. One goal of HTML 4.01 was to keep the language small, relegating many Web page formatting tasks to CSS (see W3C HTML 4.01 Recommendation, 2002; Graham, 1998, 2000; Knuckles, 2001).

CSS Level 2: This W3C standard has been stable since its revision in 1999. The main goals of CSS are to provide for elaborate formatting potential for Web pages, and to keep rules for how a Web page should look separate from the data that comprises the Web page. Most "modern" DHTML effects are created by changing style properties after the Web page is fully loaded (see W3C CSS Level 2 Recommendation, 2002; Sklar, 2001.

ECMA Script: This standard, developed by the European Computer Manufacturing Association (ECMA) and approved by the ISO/IEC (International Organization for Standardization/International Electrotechnical

Commission), has been stable since 1999. It is usually called JavaScript and is based mostly upon JavaScript 1.1. It does contain some features from JScript (see ECMAScript 262 Standard, 2002; (Gosselin, 2000; Knuckles, 2001).

DOM: DOM is a standardized API (application programming interface) that exposes an electronic document's logical structure to programming languages. This is a W3C standard, most of it stable since 1998, the rest since 2001. Different levels of the DOM specification are relevant to DHTML (see W3C HTML DOM CORE Recommendation, 2002; W3C HTML DOM Recommendation, 2002).

DOM Level 0 (DOM0): DOM0 is implicitly defined as the common subset of the browser objects of NN3 and IE3. DOM0 is the browser object that has been used for all DHTML examples so far in this chapter. This is the API used ubiquitously for manipulating HTML forms and creating older DHTML effects, such as window manipulation and rollover graphics.

DOM Levels 1 and 2 (just DOM): Exposes the complete logical structure of a document to a programming language. DOM is quite general and is used to expose XML (extensible markup language) documents to various programming languages (JavaScript, Java, Perl, C++, etc.). DOM is used for an API in many applications, not just Web browsers.

A specialized subset, called *HTML DOM,* is geared for HTML, JavaScript, and Web browsers. HTML DOM is backward compatible with DOM0, meaning that the browser object is a "subset" of the HTML DOM. HTML DOM adds the ability to manipulate CSS properties in a Web page using JavaScript.

MODERN DHTML

DOM0, the browser object, is sufficient for such things as manipulating windows, manipulating HTML forms, and creating rollover images. Expanding on DOM0, HTML DOM exposes CSS style properties to JavaScript and features "tree traversal" methods used to access HTML elements. Traversing an object tree can be done using full reference through the hierarchy. For example, the long DOM0 references used in Figures 3 and 5 are window.document.images['imageName'].src and window.document.calcForm.result.value.

In DOMO, objects such as forms and images are found at predictable locations in the object tree, so accessing them using full object reference is not a problem. However, the HTML span and div elements, which are generic containers that allow CSS styles to be applied to specific parts of Web pages, can be nested unpredictably in HTML documents. That means that it is more difficult to find such objects in the DOM tree using full reference from the tree's root.

The HTML DOM allows an HTML element, such as span or div, to be assigned unique ID (identification). Then an element can be directly "plucked out" of the DOM object tree, regardless of its location within the hierarchy, using it's unique ID. For example, suppose an HTML document contains a block division that is used to apply a CSS style class named myStyles.

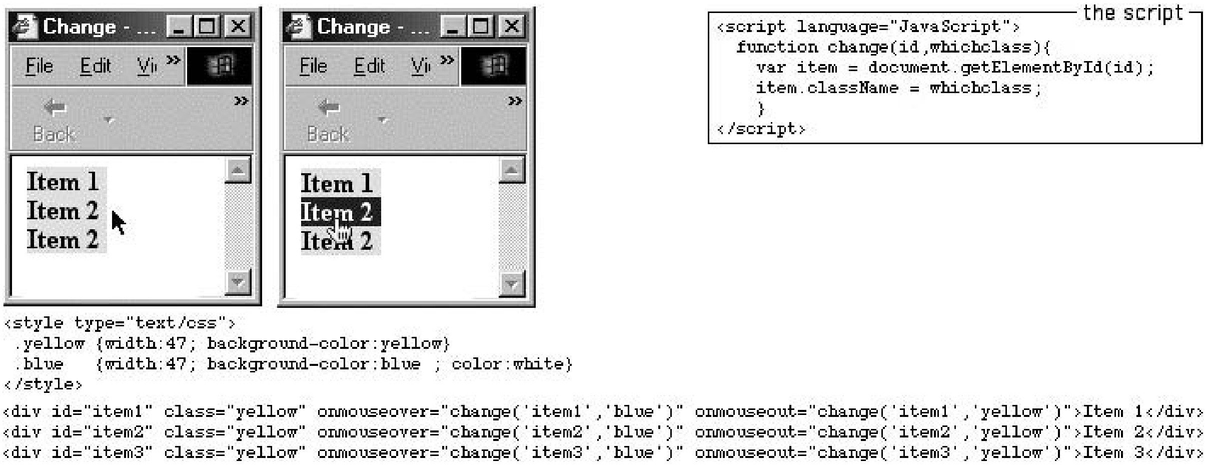
```
<div class="myStyles" id="block1">content
  of block </div>
```

Regardless of where the div element appears in the HTML document, hence regardless of how "deep" it may be in the DOM hierarchy, HTML DOM allows it to be accessed directly.

```
document.getElementById("block1")
```

Once accessed in a script, the CSS style properties of the block can be changed to create DHTML effects. But note that using the HTML DOM to access styles in this way is only viable in the most current browsers (i.e., version 6+ of NN and IE).

Three simple DHTML effects can be used to explain many of the most useful effects. Those simple effects are changing the appearance of an object, moving an object on the screen, and changing its visibility status. A simple appearance change is demonstrated in Figure 7. The menu is created from three div blocks, each assigned the yellow style class. That class features black text on a yellow

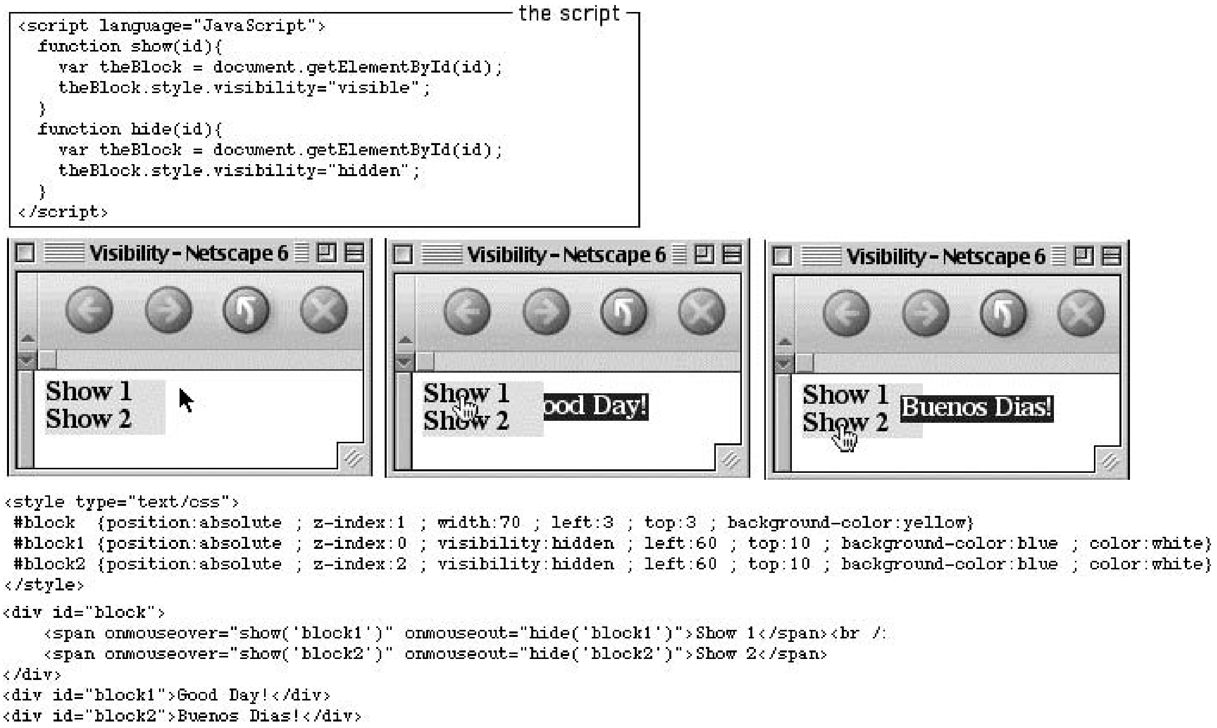


```
<script language="JavaScript">
  function change(id,whichclass){
    var item = document.getElementById(id);
    item.className = whichclass;
    }
</script>
```

```
<style type="text/css">
 .yellow {width:47; background-color:yellow}
 .blue   {width:47; background-color:blue ; color:white}
</style>
```

```
<div id="item1" class="yellow" onmouseover="change('item1','blue')" onmouseout="change('item1','yellow')">Item 1</div>
<div id="item2" class="yellow" onmouseover="change('item2','blue')" onmouseout="change('item2','yellow')">Item 2</div>
<div id="item3" class="yellow" onmouseover="change('item3','blue')" onmouseout="change('item3','yellow')">Item 3</div>
```

Figure 7: Changing CSS classes.



```
<script language="JavaScript">
  function show(id){
    var theBlock = document.getElementById(id);
    theBlock.style.visibility="visible";
  }
  function hide(id){
    var theBlock = document.getElementById(id);
    theBlock.style.visibility="hidden";
  }
</script>
```

```
<style type="text/css">
 #block  {position:absolute ; z-index:1 ; width:70 ; left:3 ; top:3 ; background-color:yellow}
 #block1 {position:absolute ; z-index:0 ; visibility:hidden ; left:60 ; top:10 ; background-color:blue ; color:white}
 #block2 {position:absolute ; z-index:2 ; visibility:hidden ; left:60 ; top:10 ; background-color:blue ; color:white}
</style>
<div id="block">
    <span onmouseover="show('block1')" onmouseout="hide('block1')">Show 1</span><br /:
    <span onmouseover="show('block2')" onmouseout="hide('block2')">Show 2</span>
</div>
<div id="block1">Good Day!</div>
<div id="block2">Buenos Dias!</div>
```

Figure 8: Changing CSS visibility properties.

background. When the mouse passes onto one of the blocks, onmousover calls a JavaScript function that changes the style class of that particular block to the blue class. The blue class features white text on a blue background. When the mouse passes back off of the block, onmouseout again calls the function, which changes the block's style class back to its original yellow class. Figure 7 shows both the onmouseover and onmouseout states of the menu. In appearance, this effect is similar to that created by rollover graphics.

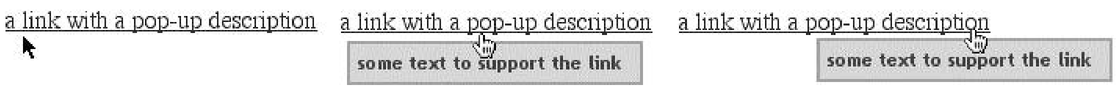
Figure 8 demonstrates the dynamic effect of changing the visibility status of each of two div blocks. The example also demonstrates layering with the CSS *z*-index. When this page first loads, only the main menu appears in the browser window. The styles for the other two blocks, block1 and block2, are set so that those blocks are not visible when the page first loads. When the mouse passes over the "show 1" span of the main menu, onmouseover calls a JavaScript function that causes block1 to become visible. Because block1 has a *z*-index of 0, it is partially obscured by the menu block, whose *z*-index is 1. The blocks are positioned on the page in such a way that the layering is evident due to the overlap of the blocks.

When the mouse passes back off of "show 1," onmouseout calls a function causing block1 to become hidden again. Similarly, passing the mouse onto "show 2" causes block2 to become visible. But block2 partially obscures the menu block because its *z*-index is 2.

One common DHTML effect enabled by layering and visibility control is pop-up text. Figure 9 shows a hyperlink with extra text support that pops up when the mouse passes over the link. When the mouse passes back off the link, the pop-up text disappears. Moreover, as shown in the middle and on the right (Figure 9), the location of the popup text block depends on the location at which the mouse passes onto the link. That technique involves "capturing" the exact position of the mouse on the screen at the time of the onmouseover event. The JavaScript code for that is much too involved to show here.

There are at least two ways the pop-up box shown in Figure 9 can be accomplished. First, the block can be toggled back and forth between a *z*-index that is below the main content layer of the Web page and one that places it above the main content layer. Second, the most common method, is simply to change the visibility status of the pop-up block depending on whether the mouse is over the link or not. A given Web page may have many blocks not initially visible, either because of layering or because of visibility status, that pop up on user events.

Going beyond text that merely supports navigation, entire navigation menus can be caused to pop up on user events. Those menus can themselves contain navigation links. Figure 10 demonstrates that effect. When the user passes the mouse over (or clicks on) one of the menu tabs at the top of the Web page, a menu appears. The user can



a link with a pop-up description
a link with a pop-up description
some text to support the link
a link with a pop-up description
some text to support the link

Figure 9: A hyperlink with pop-up text.

then select a link from the menu to follow. If they chose not to follow a link in the menu, passing the mouse off of the pop-up menu causes it to disappear. In functionality, this DHTML effect is similar to the drop-down menus provided by most software in a Windows environment.

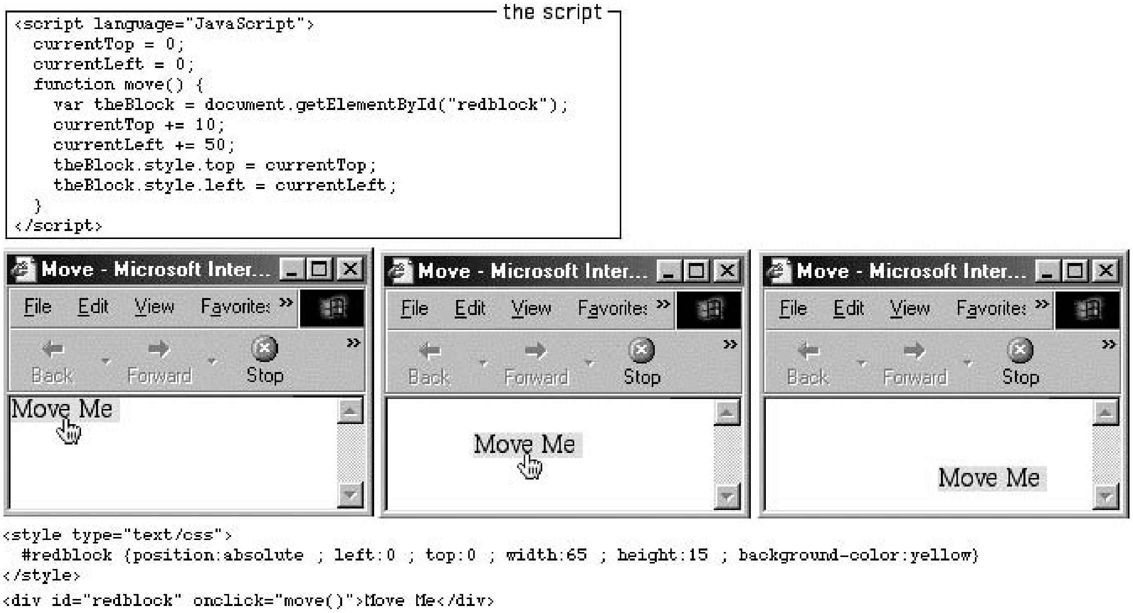
Figure 11 demonstrates the movement of blocks using DHTML. When the page first loads, there is one yellow div block positioned on the page in the upper left corner of the browser window. Clicking on the block invokes a JavaScript function that adds 10 to the *y*-coordinate of the block and 50 to the *x*-coordinate. When those new coordinates are assigned to the appropriate style properties of the block, its position on the screen moves instantaneously. Figure 11 shows the original block position and then its position after two movements caused by mouse clicks.

All the code aside, the concept demonstrated in Figure 11 is quite simple. A user event calls a JavaScript function that moves a block by a certain increment. A sequence of events, in this case mouse clicks, causes a sequence of movements. It is possible for one user event to trigger an entire animation. This is accomplished when the function that causes the incremental movement is called repetitively in an automated fashion. The function below, given in pseudo code, demonstrates how that works.

```
function moveBlock() {
  move the block by some increment
  if ( the block should move again ) {
     setTimeout("moveBlock()", 100)
  }
}
```

Again, the concept is fairly straightforward. Some event calls the moveBlock() function, which moves an object by some small increment. If the block is supposed to keep moving (i.e., the condition that stops the movement is not met), then the moveBlock() function is automatically called after a timeout. Here the timeout is 100 ms (0.1 s). The “speed” of the animation is determined by the timeout delay. When the movement increment is small and the timeout is relatively short, the repetitive function calls cause repetitive incremental movements of the object, thereby creating an animation that appears continuous on the screen.

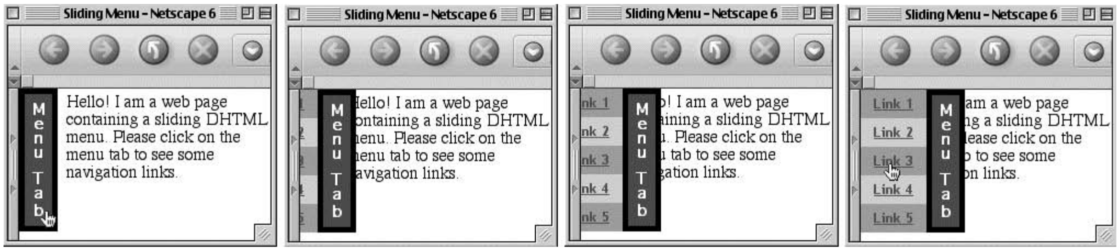
Figure 12 shows a practical application of DHTML animation. When the page first loads, all the user sees is a Web



```
<script language="JavaScript">
  currentTop = 0;
  currentLeft = 0;
  function move() {
    var theBlock = document.getElementById("redblock");
    currentTop += 10;
    currentLeft += 50;
    theBlock.style.top = currentTop;
    theBlock.style.left = currentLeft;
  }
</script>
```

```
<style type="text/css">
  #redblock {position:absolute ; left:0 ; top:0 ; width:65 ; height:15 ; background-color:yellow}
</style>
<div id="redblock" onclick="move()">Move Me</div>
```

Figure 11: Moving objects using DHTML.



Hello! I am a web page containing a sliding DHTML menu. Please click on the menu tab to see some navigation links.

Figure 12: A sliding menu.

page with a menu tab protruding from the upper left corner. A mouse click on the menu tab triggers a JavaScript function that repeatedly calls itself using a timeout. The menu then moves relatively quickly onto the screen until the condition of the far left portion of the menu reaching the edge of the window stops the animation. Reclicking on the menu tab causes the menu to recede from the screen in a similar fashion. In a regular-size Web page, that tab might be only be an inch or two (3 to 5 cm) tall and would not dominate the Web page, as it does in this illustration.

Many DHTML effects are not so practical and are intended for show. One such example utilizes layers to create a rather novel effect. The page shown in Figure 13 features black text on a black background. Hence, no text is visible without help. The page background has a *z*-index of 0, and the text in the page has a *z*-index of 2. The help comes from a white graphic, whose *z*-index is 1, and which follows the mouse. As the mouse moves closer to the text in the page, the white graphic moves under the black text (*z*-index 2), but over the black background (*z*-index 0). Thus, the text becomes visible to the extent that the white graphic has passed under it.

Many DHTML effects that feature things that follow the mouse around the screen are much more elaborate than that shown in Figure 13. However, the basic principle is the same. On each onmousemove event, the on-screen coordinates of the move are captured from the DOM using a JavaScript function. Then, the function updates the coordinates of the object(s) following the mouse to reflect that movement. In practice, mouse-following effects are rarely used because often such movement distracts and annoys users to a greater degree than it amuses them or provides added functionality to the Web site.

Many DHTML scripts can be downloaded for free on such sites as Dynamic Drive and webbedENVIRONMENTS. Some are relatively simple and, after a careful reading of the instructions provided, can easily be adapted to fit specialized needs. Others are extremely elaborate. Those can be used as is but require a knowledgeable programmer to modify. Some are practical, such as navigation menus, but many are just novelties, as shown in Figure 13. In the end, the possible DHTML effects in Web pages are limited only by the imaginations of Web programmers.

THE FUTURE OF DHTML

As of 2002, when this article was written, the "modern" DHTML effects described above were just starting to find widespread use on major commercial sites. Major sites can't afford to lose business from their pages not working properly in all browsers. Thus, content development usually lags at least one browser version behind the most current ones. The technologies might evolve fairly quickly, but widespread implementation is contingent on the diminishing market share of older Web browsers.

One CSS feature that bodes well for the future prospects of DHTML is the pseudo-style class, the most notable being the hover pseudoclass for hyperlinks. The hover pseudoclass features a built-in onmouseover event handler that changes the style properties of the hyperlink to those specified by the hover pseudoclass when the mouse passes over the link. This DHTML effect uses no JavaScript whatsoever. Figure 14 demonstrates two hover links. This effect is viable in version 5+ browsers.

The hyperlink on the left in the figure is initially not underlined. When the mouse passes over the link, its CSS properties are automatically changed to a hover pseudoclass, which specifies underlined text. In contrast, the hyperlink on the right is initially underlined. When the mouse passes over that link, it's hover pseudoclass causes it to become rendered as white text on a black background.

It is possible that future revisions of the CSS standard will include more pseudoclasses that feature built-in event handling and interactivity. It is also possible that Web browser vendors will extend the hover pseudoclass

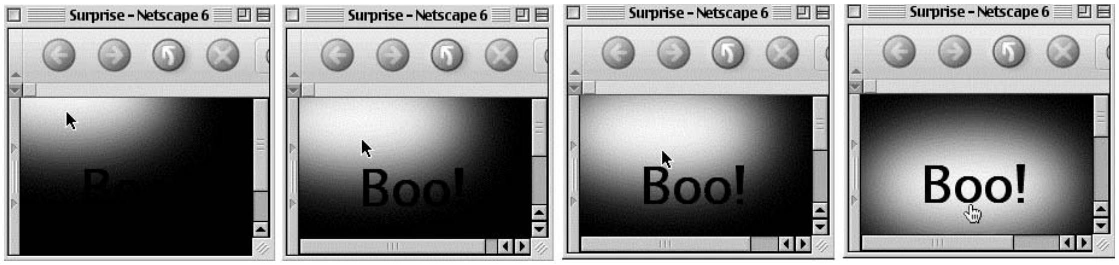


Figure 13: Following the mouse.

Click Me
Click Me
Click Me
Click Me

Figure 14: CSS hover links.

to HTML elements other than the anchor element, which creates hyperlinks. For example, if an automated hover pseudoclass could be assigned to a generic div container, the DHTML effect shown in Figure 7 could be accomplished without using JavaScript. When software vendors implement practical innovations, the World Wide Web Consortium (W3C) is often not far behind in creating an international standard, provided standardization is warranted.

The *scalable vector graphics* (SVG) W3C recommendation (W3C Scalable Vector Graphics Recommendation, 2001) also bodes well for the future of dynamic effects in Web browsers. Scalable vector graphics are like those that can be created using the "draw" utility of word processing software. Also, they have become a staple layout feature for such software as Microsoft's PowerPoint. These easily created and manipulated graphics soon will be viable in Web pages. The SGV recommendation features DOM access and a JavaScript binding that will allow DHTML style effects using vector graphics. Of course, it will take several years before major Web sites employ such technology. DHTML will likely take on a whole new look by the time version 6 browsers are considered outdated.

CONCLUSION

Some definitions of DHTML regard it as including only the modern, CSS-enabled effects demonstrated above. Indeed, the term DHTML was invented around the time HTML DOM first enabled those more elaborate effects. However, when defining DHTML according to what it accomplishes and how it is implemented, as opposed to defining it in marketing terms used to tout new features added by browser vendors, it takes on more breadth and scope.

DHTML effects are implemented when JavaScript code, usually called in a function as the result of a user event, changes the state of the Web browser's in-memory object representation of the Web page. Changing the state of the browser's object, whether DOM0 or HTML DOM, changes the Web page rendition. Under this general definition, common effects enabled by DHTML include browser window manipulation, image rollovers, hidden layers that pop up, and objects that move in Web pages. Technically, the manipulation of data in HTML forms fulfills the general definition of DHTML, but that capability is usually classified as client-side data processing in Web browsers.

DHTML should not be confused with embedded technologies such as Java Applets and Flash. Those technologies require helper applications, usually called browser plugins, to execute in Web browsers. These technologies are much more powerful than DHTML, but they use more resources on the client computer and may even require intermittent or continuous interaction with the Web server. DHTML is, and will continue to be, favored for adding fast and efficient interactive capabilities to Web pages.

For Web developers who do not wish to write customized JavaScript code or develop highly customized DHTML effects, numerous Web sites offer free DHTML scripts and tutorials on how to use them. Moreover, many software packages automatically create DHTML effects in a visual environment. Macromedia's Dreamweaver and Fireworks are the two most notable applications with that capability. Adobe's GoLive is also worth mentioning. But such software often generates cumbersome and inefficient JavaScript code. Worse yet, proprietary software often generates code that is not browser neutral. Nonetheless, DHTML-creating software allows inexperienced Web developers to quickly create interactive DHTML-enabled Web pages.

GLOSSARY

Browser object A Web browser's in-memory (RAM) representation of a Web page.

Cascading style sheets (CSS) Provides precise formatting and layout instructions to augment HTML.

Document object model level 0 (DOM0) The browser objects used by Internet Explorer 3 and Netscape Navigator 3.

Dynamic HTML A collection of technologies and techniques that allow Web pages to be interactive without further transactions with a Web server.

ECMAScript The official standard, called JavaScript in common parlance.

Event When a user moves the mouse or clicks on a region of a Web page.

Event handler A trigger in place to deal with user events. Event handlers are usually used to call JavaScript functions.

HTML DOM An extension of the browser object.

Hypertext markup language (HTML) Instructs software how to render a Web page.

Hypertext transport protocol (HTTP) Stateless protocol that coordinates transport of HTML documents on the Internet.

JavaScript A scripting language used to provide programming support for Web browsers.

Pseudoclass A CSS style class that has built-in behavior. The hover pseudoclass creates DHTML link rollovers.

Rendition Interpretation and display of an HTML document by software. The rendition of an HTML document is called a Web page.

Rollover A DHTML effect triggered when the mouse passes over a region of a Web page. Rollover graphics refers to rollovers causing graphic images to be replaced in Web pages.

Scalable vector graphics (SVG) Will play a big part in the next generation of Web page design and DHTML.

***z*-index** The layer-creating CSS property. Usually used to layer HTML div containers.

Digital Communication

Robert W. Heath Jr., *The University of Texas at Austin*
Atul A. Salvekar, *Intel, Corp.*

INTRODUCTION

Digital communication is the process of conveying digital information from a transmitter to a receiver across an analog channel. The origin of the binary data is known as a *source;* the destination of the binary data is known as a *sink*. While binary data may be derived from an analog source such as music or a digital source such as a Web page, the means by which the binary data were created has little influence on the operation of the digital communication system. Digital communication could also be defined for nonbinary sources, but for current transmission systems this is not standard.

The principles of digital communication have been recognized and rediscovered many times during the past few thousand years. Early forms of digital communication used technology such as smoke signals, torch signals, signal flares, or drums. Most of these systems were visual, meaning that the message was conveyed through sight by signaling according to some prearranged code. One of the more successful signaling systems is the heliograph, discovered in ancient times and still in use today, which uses reflections of the sun from a small mirror to convey digital signals. Digital communication using electrical signals is more recent and dates back to the invention of the telegraph by Samuel Morse in the 1830s. The telegraph used Morse code, which is essentially a mapping from letters to quaternary sequences (long pulses, short pulses, letter spaces, and word spaces), to convey digital information over long distances via cable. Marconi patented a wireless telegraph in 1896—this is the origin of wireless digital communication. The facsimile (fax) machine is a sometimes surprising example of early digital communication. First patented in 1843 by Alexander Bain, the fax machine both then and now scans documents line by line and digitally encodes and conveys the presence or absence of ink.

Despite its early beginning, digital communication fell out of prominence with the invention of the telephone in 1875. The telephone is an example of an analog communication system that conveys a continuous source (in this case speech) instead of digital information. With the availability of computers beginning in the 1960s, and the resulting need to exchange digital data over great distances, interest in digital communication and digital communication systems reemerged.

Digital communication systems offer a number of advantages over comparable analog systems. A basic advantage is that they are fundamentally suitable for transmitting digital data. Digital communication systems, however, offer other advantages including higher quality compared with analog systems, increased security, better robustness to noise, reductions in power, and easy integration of different types of sources, e.g., voice, text, and video. Because the majority of the components of a digital communication system are implemented digitally using digital signal processing, digital communication devices take advantage of the reductions in cost and size enjoyed by digital signal processing technology. In fact, the majority of the public switched telephone network, except the connection from the local exchange to the home, is digital.

All aspects of the Internet are enabled by digital communication technology. The backbone of the Internet is digital communication over optical fibers. All last-mile access technologies, despite the different transmission media, are fundamentally digital including voice-band modems, cable modems, and digital subscriber lines. Local area networks use different digital communication technologies such as IEEE 802.3 (Ethernet) for wired access or IEEE 802.11 for wireless access. Metropolitan area networks, such as IEEE 802.16, use digital communication to cover larger geographic areas. Digital communication allows remote access to the Internet via cellular systems through CDPD in first generation systems and GPRS, HDR, or EDGE in second generation systems. Third generation cellular systems harmonize voice and data access because they have been designed with Internet access in mind.

This chapter presents the fundamentals of digital communication. Many topics of relevance to digital communication are treated elsewhere in this encyclopedia. A more thorough description of wireline communication media, wireless media, and radio-frequency communication are available in other chapters of this encyclopedia. Readers who are interested in only a cursory overview can read the

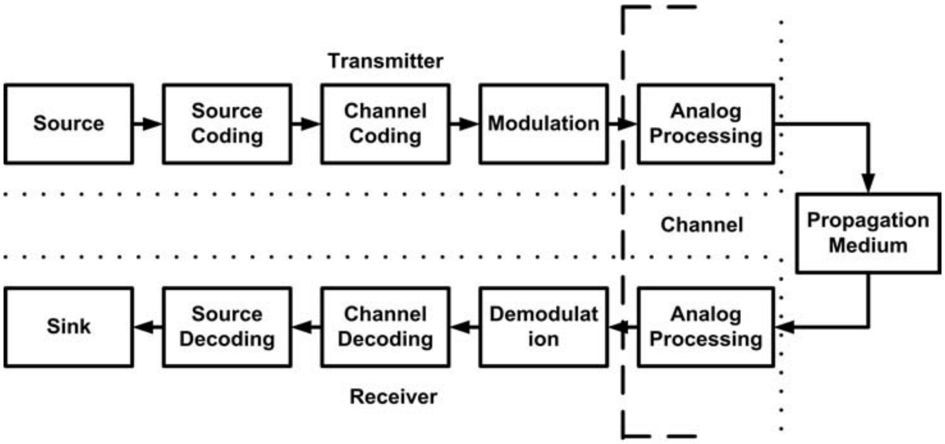

Figure 1: The components of a typical digital communication system.

section Fundamentals of Digital Communication. Those who want a more thorough treatment beyond this chapter should read Important Concepts in Digital Communication as well as consult selected references as described in the conclusion.

FUNDAMENTALS OF DIGITAL COMMUNICATION

Digital Communication System Overview

A typical digital communication system is illustrated in Figure 1. There are several steps in the transmission and reception process, some of which involve digital signal processing (DSP) and some of which involve analog processing. So it is important to distinguish that while digital communication involves the transmission of digital information, the transmission and reception process involves both digital and analog processing. In this chapter we focus on the digital signal processing aspects of digital communication.

The block diagram for a typical digital communication system in Figure 1 is divided into three parts: the transmitter, the channel, and the receiver. The transmitter processes a bit stream of data for transmission over a physical medium. The channel is the physical medium, which adds noise to and distorts the transmitted signal. It accounts for the propagation medium as well as any analog effects in the transmitter and receiver. The receiver attempts to extract the transmitted bit stream from the received signal.

The first basic transmitter block is devoted to source encoding. The purpose of source encoding is to compress the data by removing inherent redundancies. The input to the source encoder will be called $s[n]$, the source sequence. The output of the source encoder will be called $i[n]$, the information sequence. Source encoding includes both lossy and lossless compression. In lossy compression, some degradation is allowed in order to reduce the amount of data that need to be transmitted. In lossless compression, redundancy is removed, but when the encoding algorithm is inverted the signal is exactly the same. In other words, if f and g are the source encoding and decoding processes, then $\hat{s}[n] = g(i[n]) = g(f(s[n]))$, for lossy compression $s[n] \cong \hat{s}[n]$, and for lossless compression $s[n] = \hat{s}[n]$. Data compression is treated in more detail in the chapter *Data Compression*. So, from the source encoder, $s[n]$ is transformed into $i[n]$, both of which are in bits. The bit rate R_b is the rate at which information bits are transmitted through the channel.

The next block is the channel coder. Channel coding adds redundancy to the information sequence $i[n]$ in a controlled way to provide resilience to channel distortions and to improve overall throughput. Using common coding notation, for every k input bits, or information bits, there is an additional redundancy of r bits. The total number of bits is $n = k + r$; the coding rate is defined as k/n. Two types of channel codes are prevalent: forward error correction codes and error detection codes. Forward error correction codes are used to provide redundancy that enables errors to be corrected at the receiver. They come in varieties such as trellis codes, convolutional codes, and block codes (Bossert, 1999). Error detection codes, CRC (Cyclic Redundancy Check) codes being the most common, provide redundancy that allows the receiver to determine if an error occurred during transmission. The receiver can use this information either to discard the data in error or to request a retransmission.

Following channel coding, the bits are mapped to *waveforms* by the modulator. This is the demarcation point where basic transmitter-side digital signal processing for communication ends. Typically the bits are mapped in groups to *symbols*. Following the symbol mapping, the modulator converts the digital symbols into corresponding analog waveforms for transmission over the physical link. This can be accomplished by sending the digital signal through a digital-to-analog (D/A) converter into a shaping filter and, if needed, mixing it with a higher frequency carrier. Symbols are sent at a rate of R_s symbols per second, also known as the baud rate; the symbol period, $T_s = 1/R_s$, is the time difference between successive symbols.

The signal generated by the transmitter travels through a propagation medium, which could be a radio wave through a wireless environment, a current through a telephone wire, or an optical signal through a fiber, to the receiver.

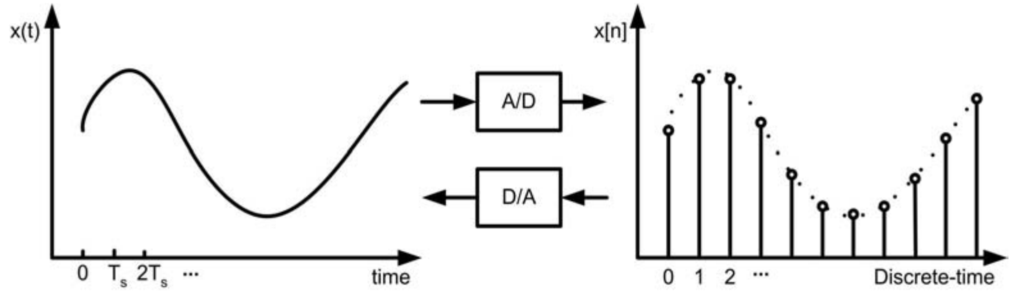

Figure 2: The relationship between a continuous-time signal and a discrete-time signal.

The first block at the receiver is the analog front end (AFE), which, at least, consists of filters to remove unwanted noise, oscillators for timing, and analog-to-digital (A/D) converters to convert the data into the digital regime. There may be additional analog components such as analog gain control and automatic frequency control. This is the demarcation point for the beginning of the receiver-side digital signal processing for digital communication.

The channel, as illustrated in Figure 1, is the component of the communication system that accounts for all the noise and intersymbol interference introduced by the analog processing blocks and the propagation medium. Noise is a random disturbance that degrades the received signal. Sources of noise include the thermal noise that results from the material properties of the receiver, the quantization noise caused by the D/A and the A/D, and the external interference from other communication channels. Intersymbol interference is a form of signal distortion that causes the transmitted signal to interfere with itself. Sources of intersymbol interference include the distortion introduced by the analog filters as well as by the propagation medium.

The first digital communication block at the receiver is the demodulator. The demodulator uses a sampled version of the received waveform, and perhaps knowledge of the channel, to infer the transmitted symbol. The process of demodulation may include equalization, sequence detection, or other advanced algorithms to help in combatting channel distortions.

The demodulator is followed by the decoder. The decoder essentially uses the redundancy introduced by the channel coder to remove errors generated by the demodulation block. The decoder may work jointly with the demodulator to improve performance or may simply operate on the output of the demodulator. Overall, the effect of the demodulator and the decoder is to produce the closest possible $\hat{\imath}[n]$ given the observations at the receiver.

The final digital block is the source decoder, which essentially reinflates the data back to the form in which they were sent: $\hat{s}[n] = g(\hat{\imath}[n])$. This is basically the inverse operation of the source encoder. After source decoding, the digital data are delivered to higher level communication protocols that are beyond the scope of the chapter.

For Internet traffic, common transmitters/receiver pairs include digital subscriber line modems, fiber optic transceivers, local area networks, and even storage devices like disk drives. While their physical media are diverse and the speeds at which they transmit may be significantly different, the fundamental model for each of these digital communication systems is the same.

Processing in the Digital Domain

There are three basic classes of signals in digital communication: *continuous-time, discrete-time,* and *digital.* Continuous-time signals are those whose value at time t is $x(t)$, where t and $x(t)$ can take values on a continuum—for instance, the real number line or the complex plane. Discrete-time signals take values only at integer times n, but the signal $x[n]$ takes values on a continuum. Finally, digital signals are those that have values at integer times and take on values on some finite (perhaps countably infinite) set.

The link between the analog and the digital domains is through the D/A and the A/D, as illustrated in Figure 2. At the transmitter, the D/A converts a digital signal $x[n]$ to an analog signal $x(t)$ essentially by letting $x(nT_s) = x[n]$ and interpolating the remaining values. At the receiver, the A/D samples the received signal $y(t)$ at some period T (typically a fraction of T_s) to produce $y[n] \cong y(nT)$, where the approximation arises because $y[n]$ is quantized to some set of values. This new signal is called $y_d[n]$ and is the digital waveform derived from the continuous-time waveform $y(t)$.

The Nyquist sampling theorem gives flexibility in the choice of whether to process $y(t)$ or $y[n]$. Ignoring quantization noise, the Nyquist sampling theorem states that if the inverse of the sampling rate is greater than twice the maximum frequency in $y(t)$ (or equivalently the bandwidth), then there is no loss in the sampling process. This implies that any processing done on the continuous-time waveform can be done equally well on the sampled waveform given that the conditions stated in the Nyquist sampling theorem are satisfied. Several practical considerations, however, make digital the domain of choice.

The biggest advantage of doing as much processing as possible in the digital domain is that it allows full exploitation of the benefits of digital technology. Many digital platforms exist that are highly customizable and easy to alter—for instance, field programmable gate arrays (FPGAs) and digital signal processors. This hardware has been designed to have very good tolerances and reproducibility. As the DSP machinery is easy to change, it is also well suited to applications where parameters may need to be adjusted over time. Analog circuitry, on the other hand, can be extremely bulky and expensive to produce. Moreover, if a change has to be made to the design,

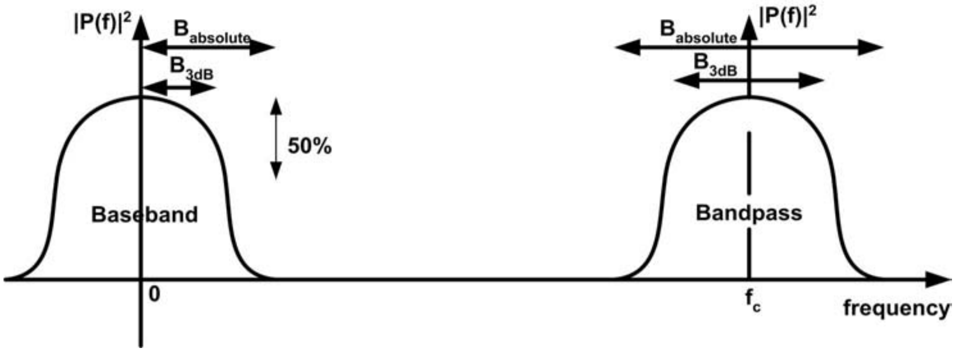

Figure 3: Illustration of two different notions of bandwidth in baseband and bandpass signals.

analog equipment may need to be redesigned as well. For these reasons, processing in the digital domain has become very relevant to digital communication. This does not mean that all analog processing can be obviated. For instance, the fundamental noise limits for a modem may be the noise produced by the analog components or the A/D converter. Another advantage of processing in the digital domain is a byproduct of Moore's law. The shrinking of transistor size offers both dramatic increases in processing power and significant reductions in overall cost. Thus, doing the majority of the processing in the digital domain improves cost, performance, and flexibility.

Key Resources: Power and Bandwidth

The two primary resources in any communication system, both digital and analog, are power and bandwidth. Systems whose performance is limited by the available power are power-limited while those that are limited by bandwidth are bandwidth-limited. Most practical systems are to some extent both power- and bandwidth-limited.

The power of a signal is roughly defined as the average energy over time. Mathematically, this is often written as $P = \lim_{T\to\infty}(1/T)\int_{-T/2}^{T/2}|x(t)|^2dt$. Power may be measured in watts but is more often measured in decibels relative to one watt (dB) or one milliwatt (dBm). The decibel is a relative measure that is defined as $(P/Q)_{dB} = 10\log_{10}(P/Q)$. When used to measure the power of P in dB, Q is assumed to be 1 watt, while to measure the power of P in dBm, Q is assumed to be 1 milliwatt.

There are two different but related notions of power in a communication system: transmitted power and received power. Naturally, the transmitted power is the average energy over time of the transmitted signal while the received power is the average energy over time of the received signal.

The transmitted power in a communication system is limited by the maximum power available to transmit a signal. Generally system performance is better if there is high transmitted power (and thus received power). Practical constraints on cost, properties of the transmission medium, battery life (in mobile systems), or regulatory constraints, generally motivate having a low transmitted power.

Since propagation media are lossy and dispersive, the received power is a function of the transmitted power and the channel. In all media the loss due to the channel increases as some function of the distance between the transmitter and receiver. Thus the larger the distance, the smaller the received power.

The minimum received power required at the receiver, known as the *receiver sensitivity,* is determined by the parameters of the system, the quality of the hardware, as well as the desired operating characteristics. The range of the system can be inferred from the ratio of the maximum transmitted power to the minimum received power. Generally, increased data rate at a given bandwidth or lower bit error rates increases the required minimum received power.

Besides power, *bandwidth* is the other design constraint in a communication system. Unfortunately, there are many definitions of *bandwidth* and different notions are used in different systems. The most generic definition of the bandwidth of a signal $x(t)$ is the portion of the frequency spectrum $X(f) = \int_{-\infty}^{\infty} x(t)e^{-j2\pi ft}dt$ for which $X(f)$ is nonzero. Since the true bandwidth of a finite duration signal is infinite, systems often use the "3 dB bandwidth," which is the contiguous range of frequencies over which the power spectrum is at least 50% of the maximum value. Other definitions of bandwidth are also possible; see Couch (2001) for details.

It is important to note that the definition of bandwidth differs depending on whether the communication system is *baseband* or *bandpass.* Baseband communication systems operate at DC while bandpass communication systems convey information at some carrier frequency f_c. Figure 3 illustrates the different bandwidth notions of absolute and 3dB bandwidth in each of these types of systems.

The bandwidth available in a communication system depends on the transmission medium. In wireless systems, bandwidth is a precious and expensive commodity that is regulated by the government. Thus while the theoretical bandwidth of the wireless medium is significant, only a fraction is available to a given communication system. In wireline systems, the bandwidth is determined by the type and quality of the cable and the interconnects. Generally, the larger the bandwidth, the larger the potential data rate that can be supported. Exploiting larger bandwidths, however, typically requires more sophisticated receiver processing algorithms and more expensive analog components.

Bandwidth and power are related through the concept of the power spectral density (PSD). The PSD is a measure of the power in a signal as a function of frequency. The integral of the PSD is hence the power of the signal.

Measures of Performance

There are a number of potential measures that are used to evaluate the performance of a digital communication system. The choice of a performance measure depends significantly on the application and other aspects of the system. Broad classes of performance measures include the probability of error, the outage probability, and the capacity. In this chapter we will discuss the probability of error and capacity. The probability of error is a measure of the rate at which errors occur, while the capacity is a measure of the maximum data rate that can be supported by a channel with a given SNR and an arbitrarily small probability of error.

Of the two measures, the probability of error is the more pragmatic indicator of system performance. There are various flavors of the probability of error including the probability of bit error, the probability of symbol error, and the probability of frame error. Equivalently, these measures are known as the bit error rate (BER), the symbol error rate (SER), and the frame error rate (FER). Often the SER and the FER can be determined from the BER; therefore the BER is the most common performance metric.

Essentially the BER provides the average number of bit errors. For example, a BER of 10^{-2} means that on an average about one bit out of every one hundred will be in error. The BER can be measured at various places in the receiver but is typically most meaningful after demodulation (the uncoded BER) and after error correction (the coded BER).

The performance needs of the application determine the required BER. For example, voice communication in cellular systems might require a coded BER of 10^{-2}, while data communication in the same system might require a coded BER of 10^{-5}. In most communication systems the uncoded BER is a function of the data rate and the modulation scheme and can be readily related to the *signal-to-noise ratio* (SNR). The SNR is essentially the ratio of the received signal power to the noise power in the signal bandwidth. Thus the BER is a function of both the received power and the bandwidth of the signal though more generally the channel model also plays a role.

The fundamental limit to data communications can be most simply described by the so-called capacity of a channel, C, which is the maximum average number of bits that can be supported by a channel with a given SNR at an arbitrarily small probability of error. The capacity is measured in units of bits per second and is essentially a bound on the achievable data rate. Often the capacity is normalized by the bandwidth. The normalized capacity C/B measures the bits per channel use in units of bits per second per hertz. Unlike the BER, the capacity provides an upper bound (instead of the actual performance) of a communication system, since it is optimized over all possible modulation and coding schemes. Like the BER, the capacity is typically a function of the SNR, the bandwidth, and the channel.

The capacity is a measure for determining the fundamental limit on the data rate imposed by the given communication channel. The BER is more useful for evaluating the performance of an actual coding and modulation scheme. Typically, a target BER will be defined and a coding and modulation scheme will be proposed to achieve the largest data rate possible R. Naturally, it should be the case that $R < C$. Spectrally efficient digital communication systems have a rate R that closely approaches the capacity C for the desired operating point.

IMPORTANT CONCEPTS IN DIGITAL COMMUNICATION

Modulation

The modulator in a digital communication system maps binary data onto waveforms for transmission over the physical channel. The modulator maps a group of bits (or symbols) onto a finite number of waveforms during each symbol period. Binary modulations map each bit to one of two possible waveforms, while M-ary modulations map each group of $\log_2 M$ bits to one of M possible waveforms. The analog waveforms are designed with the constraints of the channel such as the bandwidth or the carrier frequency in mind.

There are two basic forms of modulation, namely linear modulation and nonlinear modulation. Linear modulation schemes are typically more spectrally efficient; that is, they are able to come closer to the capacity. Nonlinear modulations typically have other properties, such as constant envelope, that make them easier to implement and less susceptible to various impairments in the channel. The choice of a modulation scheme depends on the desired throughput, the target bit error rate, the spectral efficiency of the modulation scheme, the power efficiency of the modulation scheme, robustness to impairments, and the implementation cost and complexity.

Modulations may also have memory or be memoryless. When a symbol is a function of only the bits from the current symbol period, it is said to be memoryless. When a symbol is a function of the bits from previous symbol periods, the modulation is said to have memory. Having memory in the modulation scheme may have some practical advantages, such as reducing the peak-to-average ratio of the transmitted signal or simplifying noncoherent detection at the receiver. Modulations with memory can also provide some additional resilience to errors; thus they are sometimes called coded modulation schemes.

To illustrate the concept of modulation, in particular linear modulation, let us first define the concept of a signal space and then relate that to common modulation formats found in practice. A vector space is defined to be a set of vectors (in this case continuous signals), $\{\phi_i(t)\}$, with two operations: (1) addition of those vectors (i.e., $\phi_i(t) + \phi_j(t)$ is defined and is an element of the vector space) and (2) multiplications of those vectors by a scalar (i.e., $k\phi_i(t)$ is defined and is an element of the vector space). Some other technical rules for being a vector space can be found in Anton and Rorres (1991). In communications, typically these vectors are orthogonal; that is,

$$\int_{-\infty}^{\infty} \phi_i(t)\phi_j(t)dt = \delta_{ij}, \tag{1}$$

where δ_{ij} is 1 for $i = j$ and 0 otherwise. Since these waveform vectors are orthogonal, they are also a basis for the vector space, and are sometimes referred to as basis functions.

A digital communication system may be baseband or bandpass depending on whether the symbols are conveyed at baseband (DC) or at some carrier frequency (see Figure 3). ADSL (asymmetric digital subscriber line) is an example of a baseband communication system. Most digital communication systems are bandpass, including all narrowband wireless systems, optical systems, and cable modems. Though bandpass systems convey information at a carrier frequency, the modulator and demodulator do not need to generate signals at that carrier frequency. Instead, the modulator and demodulator work with the *baseband equivalent* waveform. At the transmitter, the *upconverter* in the analog processing block converts the baseband equivalent signal to the bandpass signal by shifting it to the desired carrier frequency. At the receiver, the *downconverter* in the analog processing block shifts the bandpass signal down to zero frequency. The advantage of the baseband equivalent notion is that it makes the digital operations of the communication system independent of the actual carrier frequency.

Let us first consider baseband pulse amplitude modulation (PAM). PAM transmission is used in HDSL (high bitrate digital subscriber line), ISDN, and optical transmission. It is a linear and memoryless modulation. An M-PAM system is a form of M-ary modulation in which $m = \log_2 M$ bits at a time are mapped to an element of the set of M possible amplitudes, $\mathcal{C}_{PAM}$, which is the constellation. For 4-PAM, a set of possible amplitudes is $\mathcal{C}_{PAM} = \{-3, -1, 1, 3\}$, which are equally spaced apart. A pulse-shaping filter $\phi(t)$ with a bandwidth B is modulated to produce the transmitted waveform $x(t) = \sum_n x[n]\phi(t - nT_s)$, where $x[n] \in \mathcal{C}_{PAM}$. So the set $\mathcal{C}_{PAM}$ is the constellation, $x[n]$ is the symbol transmitted starting at time nT_s, and $\phi(t)$ is the basis waveform. The spectrum of the PAM waveforms is determined by the pulse-shaping filter $\phi(t)$. The choice of a pulse-shaping filter is a complicated one involving several competing requirements, including resistance to timing jitter, minimized spectral bandwidth, and noise immunity.

A nice generalization of PAM that is preferable for bandpass systems is known as quadrature amplitude modulation (QAM). As with PAM, QAM is a linear and memoryless modulation. An M-QAM modulation is defined for M that is a power of 4. Let $m = 1/2 \log_2 M$ and consider the same set of 2^m possible amplitudes $\mathcal{C}_{PAM}$ and pulse-shaping waveform $\phi(t)$. For M-QAM, at some carrier frequency f_c, the transmitted waveform is

$$x(t) = \left(\sum_n i[n]\phi(t - nT_s)\right)\cos(2\pi f_c t) - \left(\sum_n q[n]\phi(t - nT_s)\right)\sin(2\pi f_c t), \tag{2}$$

where $i[n] \in \mathcal{C}_{PAM}$ corresponds to the symbol transmitted on the inphase component $\cos(2\pi f_c t)$ and $q[n] \in \mathcal{C}_{PAM}$ corresponds to the symbol transmitted on the quadrature component $\sin(2\pi f_c t)$. Assuming that f_c is much greater than $1/B$ the modulated inphase and quadrature components are orthogonal and thus QAM has double the data rate of a PAM system, which would use only the inphase or quadrature component. Of course, recalling the discussion about Figure 3, note that a bandpass QAM system also uses twice the bandwidth of a baseband PAM system; thus the spectral efficiency of QAM at bandpass and PAM at baseband is the same. The ordered pair $(i[n], q[n])$ is the symbol transmitted starting at time nT_s, and $\phi(t)\cos(2\pi f_c t)$ and $\phi(t)\sin(2\pi f_c t)$ are the basis waveforms, using the narrowband approximation. For M-QAM, the constellation $\mathcal{C}_{QAM}$ is composed of all possible ordered pairs that can be generated from choosing the $2^m - PAM$ points for the inphase and quadrature components. Thus the M-QAM constellation has two dimensions. The baseband equivalent of the QAM signal in (2) is a complex function and is given by

$$\sum_n (i[n] + jq[n])\,\phi(t - nT_s),$$

where $j = \sqrt{-1}$. Quadrature amplitude modulation schemes have complex baseband equivalents to account for both the inphase and quadrature components. The spectrum of the QAM waveform is determined by the pulse-shaping filter $\phi(t)$ and is shifted in frequency by f_c. PAM and QAM modulation are illustrated in Figure 4.

Not all bandpass systems are capable of using QAM modulation. For example, in optical transmission, phase information is not available, so the constellations are defined for positive amplitudes only. If the constellations values are 0 and A, this is known as on–off keying (OOK).

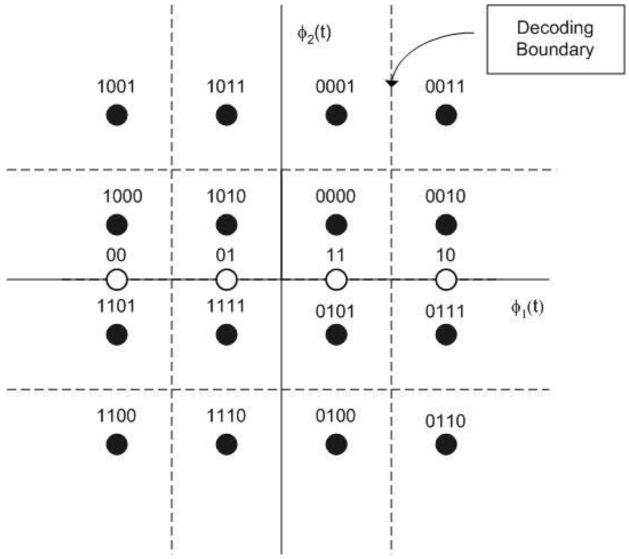

Figure 4: Signal space illustration of PAM and QAM signalling. The solid black circles are QAM and the white circles are PAM. The numbers above represent the mapping of bits to the constellation points.

Another common form of modulation is multicarrier modulation, in which several carriers are modulated simultaneously. These carriers can be thought of as a basis waveform modulated by sinusoids of differing frequencies. This is not easy to accomplish, so an IFFT (inverse fast Fourier transform) is used to approximate this operation. The IFFT of a set of constellation points is in fact the sum of a set of sampled sinusoids at differing frequencies multiplied by the constellation points. In the digital domain, each of these waveforms can be independently demodulated. These samples are sent through a single pulse-shaping filter (basis waveform) and transmitted through the channel. The receiver samples the waveform and performs the inverse operation, an FFT. Multicarrier modulation has become important because of its robustness to impulsive noise, its ease of equalization, and its ability to do spectral shaping by independently controlling the carriers. Discrete multitone (DMT) is the most common baseband version of multicarrier modulation, while orthogonal frequency division multiplexing (OFDM) is the most common bandpass version.

Intersymbol Interference Channels

After modulation, the analog waveform $x(t)$ corresponding to an input sequence of bits is transmitted over the communication medium. Communication media, whether fiber optic cable, coax cable, telephone cable, or free space, generally have a dispersive effect on the transmitted signal.The effect of the medium on $x(t)$ is often modeled using a concept from signal processing known as a linear and time-invariant (LTI) system. The linearity implies that if $y_k(t)$ is the response to $x_k(t)$ then $\alpha y_1(t) + \beta y_2(t)$ is the response to the input signal $\alpha x_1(t) + \beta x_2(t)$. The time-invariance means that the response to $x(t+\tau)$ is $y(t+\tau)$; that is, the behavior of the channel is not a function of time. Practically all physical channels are time-varying (due to changes in environmental factors), especially wireless channels; however, over short periods of time, they can be modeled as time-invariant. Optical channels can also exhibit nonlinear behavior and thus other models may sometimes be appropriate.

The LTI assumption about the communication medium allows the distortion to the input signal to be modeled using the convolution operation

$$y(t) = \int_{-\infty}^{\infty} h(\tau)x(t-\tau)d\tau.$$

The function $h(\tau)$ is known as the impulse response of the channel and includes all the analog effects such as filtering at the transmitter and receiver, in addition to the distortion in the medium. From basic Fourier transform theory, LTI systems have the nice property that in the frequency domain $Y(f) = H(f)X(f)$, where $Y(f)$ is the Fourier transform of $y(t)$, $H(f)$ is the Fourier transform of $h(t)$, and $X(f)$ is the Fourier transform of $x(t)$. Essentially, the channel acts as a frequency-selective filter that operates on the input signal. LTI systems induce distortion that is multiplicative in the frequency domain.

In an ideal channel, $|H(f)| = 1$ and there is no distortion (only a delay) of the input signal. Equivalently, in the time domain an ideal channel produces $y(t) = ce^{jd}x(t-\tau)$, where τ is an arbitrary delay. When the channel is not ideal, a more serious problem known as intersymbol interference (ISI) is encountered. To illustrate this concept, suppose that $x(t)$ is generated at baseband using PAM as described in the previous section.

In the absence of a channel, ideal sampling of $y(t)$ at the receiver at time mT_s (more details on this in the next section) results in $y[m] = \sum_n x[n]\phi(mT_s - nT_s)$. The pulse-shaping filter $\phi(t)$, however, is often a Nyquist pulseshape, which means that $\phi(0) = 1$ and $\phi(nT_s) = 0$ for $n \neq 0$. Thus sampling at time mT_s yields the symbol $x[m]$. Now consider a nonideal channel. Let $\tilde{\phi}(t)$ be the convolution of $\phi(t)$ and $h(t)$. For a nontrivial channel, it will generally be the case that $\tilde{\phi}(t)$ is no longer a Nyquist pulseshape and thus $y[m] = \sum_n x[n]\tilde{\phi}((m-n)T_s)$. In this case there are multiple superpositions of symbols at each sampling instant—this leads to intersymbol interference. Compensation for intersymbol interference is known as equalization and is an important part of the receiver processing when ISI is present.

Noise and Interference

Noise and interference are the most ubiquitous forms of degradation in any communication system. Essentially, both can be modeled as random disturbances that are unrelated to the desired signal. Intersymbol interference also results in degradation; however, the effect is different because it causes the signal to interfere with itself. Noise usually refers to the disturbances generated in the receiver as a result of the analog components, analog-to-digital conversion, and material properties of the receiver. Generally, noise can be reduced by using higher quality materials but never eliminated. Interference usually refers to disturbances generated by external signals. Typically interference has more signal structure than noise and thus it can be mitigated by more complex processing at the expense of higher cost.

There are various sources of noise in communication systems. Common examples include thermal noise, shot noise, and quantization noise. Thermal noise is a result of the Brownian random motion of thermally excited electrons. It is generated by resistors and the resistive parts of other devices such as transistors. Shot noise is more impulsive and may be more related to the signal, for example, the random arrival rates of photons in optical systems. Quantization noise is a result of digitizing the amplitude of the discrete-time signal and is often modeled as another source of thermal noise. We will focus our explanation on thermal noise.

Because noise is fundamentally not deterministic, it is often modeled as a random process. For thermal noise, the Gaussian random process has been found to be adequate for the job. When used to model thermal noise, the process is assumed to be zero mean, uncorrelated from sample to sample and to have a variance σ^2 that is generally proportional to kBT_e, where k is Boltzmann's constant ($1.23 \times 10^{-23} J/K$), B is the signal bandwidth, and T_e is the effective noise temperature of the device. T_e is a parameter determined by the analog portion of the receiver. For thermal noise, the variance increases linearly as a function of the bandwidth. Thus signals with larger bandwidths incur an additional noise penalty, while at the same time enjoying a higher signaling rate.

The effect of thermal noise is additive; therefore the received signal can be written $z(t) = y(t) + v(t)$, where $v(t)$ is a realization of the noise process. Since $v(t)$ is unknown to the receiver, its presence degrades the performance of subsequent processing blocks. The severity of thermal noise is quantified by the SNR.

The origin of interference is usually an undesired communication signal. Examples include adjacent channel interference, crosstalk, and co-channel interference. Adjacent channel interference refers to the interference caused by signals operating in adjacent frequency bands. Since practical signals cannot have a finite absolute bandwidth, when the carrier frequencies of two different signals are close to each other there is often leakage from one signal to the other. Crosstalk is a form of interference in wireline systems. It results from electromagnetic coupling among the multiple twisted pairs making up a phone cable. Co-channel interference is the wireless equivalent of crosstalk. Because of the limited availability of frequencies, wireless cellular systems reuse each carrier frequency. Essentially, co-channel interference is the interference among users sharing the same communication frequency.

Like thermal noise, interference is also additive. Thus a signal with interference may be written $z(t) = y(t) + \sum_k y_k(t)$, where $y_k(t)$ refers to the distorted interfering signals. Performance degrades because $y_k(t)$ is both random and unknown at the receiver. More generally, noise is also present; thus

$$z(t) = y(t) + \sum_k y_k(t) + v(t).$$

In some cases, the interference is modeled as another Gaussian noise source. Then performance is characterized by the signal to interference plus noise (SINR) ratio, which is essentially $P_y/(P_i + P_v)$, where P_y is the power in the desired signal, P_i is the power in the sum of the interfering signals, and P_v is the power in the noise. Systems for which $P_i \ll P_v$ are called noise-limited, while those for which $P_v \ll P_i$ are called interference-limited. If the source of the interference is crosstalk or co-channel interference, then the interfering signals $\{y_k(t)\}$ all have a structure (modulation, coding, etc.) similar to that of the desired signal. In this case, advanced signal processing algorithms can be used to mitigate the impact of the interference. Examples of algorithms include joint demodulation, where all the signals are demodulated simultaneously, interference cancellation, where the interference is partially cancelled, and optimum filtering, where filters are constructed that partially eliminate the interference. Removing or mitigating interference improves performance by reducing the required transmitted power to achieve a given BER for a given data rate or by allowing the data rate at a given BER to be increased for a given transmitted power.

Timing and Synchronization

Prior to demodulation and symbol recovery at the receiver a number of timing and synchronization tasks need to be performed, including phase synchronization, frequency synchronization, symbol timing, and frame synchronization. Synchronization is performed to ensure that the transmitter and receiver operate in a synchronous manner. The process of synchronization typically involves estimation of the synchronization error, followed by its correction. Typically the processing required for synchronization is done in a mixture of the analog and digital domains.

In bandpass systems, information is modulated onto sinusoids as illustrated in the QAM example in (2). To demodulate this signal at the receiver, these sinusoids must be exactly reproduced. The problem of ensuring that the phases are accurate is known as phase synchronization. The problem of estimating the transmitted carrier frequency is known as frequency synchronization. Estimating and tracking the phase of the sinusoid is typically more difficult than the frequency; however, phase differences can sometimes be included as part of the channel and removed during equalization.

At the receiver, the A/D samples the analog waveform for subsequent digital processing. Optimal processing requires two aspects of symbol synchronization: symbol timing and sampling clock recovery. Symbol timing is knowing exactly where to sample the received signal. Even in systems with ideal channels, symbol timing errors can lead to intersymbol interference. Often the symbol timing problem is solved by oversampling the received signal and choosing the best subsample. Sampling clock recovery refers to ensuring that the sampling period T_s at the receiver is identical to that at the transmitter. Sampling clock recovery is typically more important in baseband systems because in bandpass systems the sampling clock can be derived from the carrier.

In systems where the fundamental unit of information is a frame and not a symbol, an additional synchronization step is required. This process, known as frame synchronization, is required to determine where the beginning of the frame is located. Frame synchronization is often assisted by the presence of synchronization sequences that mark the beginning of the frame.

Demodulation

The goal of the demodulator is to convert the sampled received waveform back into a sequence of bits. Demodulation is obviously highly dependent on the modulation and the channel; therefore this section provides only a cursory overview.

The first step in the demodulation process is to sample the waveform. Typically, this is done using a front end filter that filters out unwanted noise, followed by a sampler. The sampled data come from an A/D converter, so the data are in the digital domain. The sampled signal includes residual noise left after filtering, the noise from the sampling device, and the signal of interest. For example, assuming perfect timing, synchronization, and no interference, in the presence of an ideal channel the sampled PAM signal at the receiver $y(nT_s)$ is

$$y[n] = x[n] + v[n],$$

where $x[n]$ is the transmitted PAM symbol and $v[n]$ represents the sampled thermal noise and the quantization noise. The samples $y[n]$ are sent through a decision device that processes the data to make a decision. Typically, the decision device determines the most likely symbol from the given constellation that was transmitted. An inverse symbol mapping operation then converts the symbols to bit form.

Because the noise is unknown to the receiver, the role of the decision device is to produce its best "guess" about the transmitted data. One common criterion is to find the symbol that is the most likely input given the observations. If X and Y are vectors representing the input $x[k]$ and the output $y[k]$, respectively, then

$$\hat{X} = \arg\max_{X} P(X|Y),$$

where $P(X|Y)$ is the probability that $x[k] = X$ given the observation of $Y = y[k]$. The maximization is taken over all possible points in the constellation to find the point with the maximum conditional probability and is called the maximum a posteriori decision. When the source data are equally likely, it turns out that this is equivalent to the maximum likelihood detection rule, which is given by

$$\hat{X} = \arg\max_{X} P(Y|X).$$

In this case the decision rule determines the symbol that was most likely to have produced the observation. For the additive white Gaussian noise channel (AWGN), the above conditional probabilities have a known form. In the AWGN channel there is no intersymbol interference and the only source of degradation is uncorrelated Gaussian noise. For instance, when the input symbols are equally likely, it turns out that the detection principle is simply to minimize the Euclidean distance between the observation and the set of possible inputs,

$$\hat{X}[k] = \arg\min_{x[k]\in C} ||y[k] - x[k]||^2. \tag{3}$$

In this case, the detector is known as a slicer. The operation of the slicer can be described using Figure 4. For a QAM/PAM waveform, if a received sample is within a decoding boundary of a point, it is mapped to that point. Because of the simple decoding boundaries, the test is essentially a series of threshold tests; hence the name slicer.

In the absence of an ideal channel, even with perfect timing and synchronization, there will be intersymbol interference and thus the sampled PAM signal may have the form

$$y[n] = \sum_{l=0}^{L} h[l]x[n-l] + v[n],$$

where $h[l]$ is the sampled equivalent channel impulse response. Optimum decoding requires considering the channel response in the decision device. Due to the memory in the channel it is no longer possible to make a decision on a symbol-by-symbol basis. Instead, sequences must be decoded. Thus given a sequence of observations $\{y[p]\}_{p=0}^{P-1}$ we must determine the sequence $\{x[n]\}_{n=0}^{N-1}$ that was most likely to have been transmitted. We allow for $P \geq N$ at the receiver to account for multiple observations of the received signal, via oversampling or multiple antennas, for example. Clearly the complexity of the search grows with both N and P. Using the fact that the memory of the channel is finite, however, allows lower complexity approaches such as the Bahl, Cocke, Jelenick, and Raviv (BCJR) algorithm to help in maximum a posteriori decoding and the Viterbi algorithm for maximum likelihood decoding (see, e.g., Wither & Kim, 2002, for details).

Alternatively, to correct for intersymbol interference, many transmission systems use equalizers that attempt to remove the effect of the channel prior to the slicing operation. Some common equalizers are zero-forcing equalizers (ZFE) that invert the channel, minimum mean squared error (MMSE) equalizers that include the effects of noise, and decision feedback equalizers (DFE) that use the detected symbols to remove some portion of the trailing intersymbol interference. Equalization generally gives inferior performance relative to sequence decoding but offers much lower complexity.

A PERFORMANCE EXAMPLE

The AWGN channel provides an analytically tractable baseline case to which performance in other channels can be compared. First consider the capacity of the AWGN channel. It can be shown in this case that the capacity expression is remarkably simple,

$$C = B\log_2(1 + SNR), \tag{4}$$

where B is the channel bandwidth. The theoretical spectral efficiency that can be achieved in this channel is thus C/B bits per second per Hertz. The normalized capacity as a function of SNR is illustrated in Figure 5.

The capacity expression in (4) provides an interesting means of evaluating system performance. For instance, if a coded system provides 3 dB increased immunity to noise, the SNR will increase by a multiple of 2 ($10\log_{10} 2 \cong 3\,\mathrm{DB}$). Hence the amount of information that can be transmitted will increase by about 1 bit per transmission

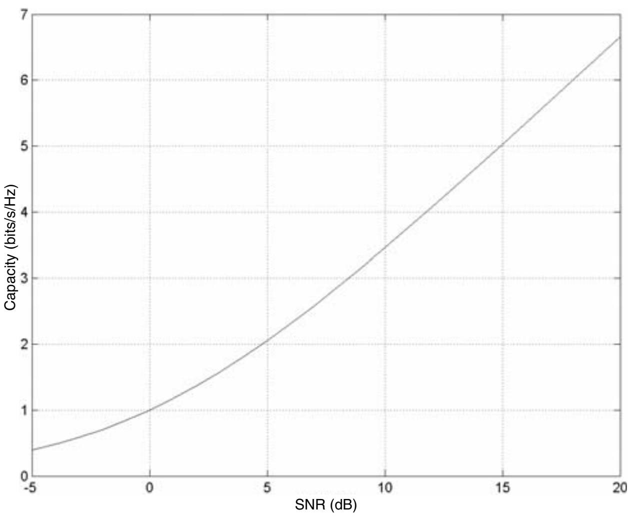

Figure 5: The normalized capacity of an AWGN channel as a function of the SNR.

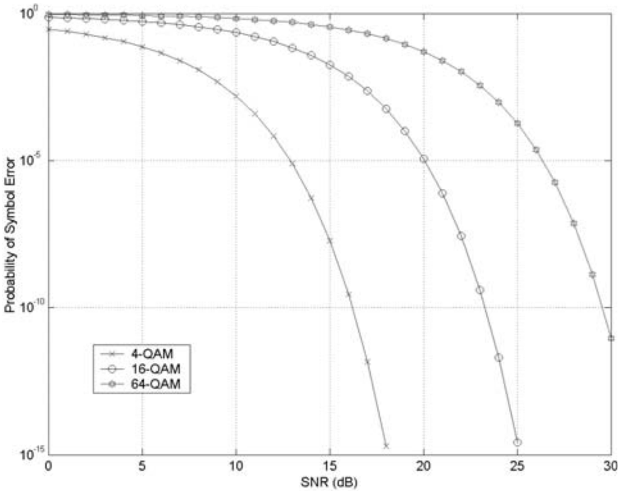

Figure 6: The symbol error rate for QAM transmission in an AWGN channel as a function of SNR.

for high SNR because $\log_2(1 + 2 \cdot \text{SNR}) \cong \log_2(2 \cdot \text{SNR}) \cong \log_2 2(\text{SNR}) + 1$.

Unlike the capacity, the symbol error rate in an AWGN channel is a function of the modulation scheme that is employed. For uncoded M-PAM or M-QAM transmission, the probability of symbol error is given by

$$P_e = 2\left(1 - \frac{1}{M}\right) Q\left(\sqrt{\frac{3\,SNR}{M^2 - 1}}\right) \quad \text{for PAM} \qquad (5)$$

$$= 4\left(1 - \frac{1}{\sqrt{M}}\right) Q\left(\sqrt{\frac{3\,SNR}{M - 1}}\right)$$

$$-4\left(1 - \frac{1}{\sqrt{M}}\right)^2 \left(Q\left(\sqrt{\frac{3\,SNR}{M - 1}}\right)\right)^2$$

$$\text{for QAM,} \qquad (6)$$

where $Q(x) = 1/\sqrt{2\pi} \int_x^\infty e^{-t^2/2} dt$ for $x \geq 0$ is the area under the tail of the Gaussian probability distribution function. The probability of symbol error for QAM transmission is illustrated in Figure 6 as a function of SNR. Notice how the error rate is exponentially decreasing as the SNR increases. For a given probability of error (at high SNR), observe that there is approximately a 6 dB difference between the SNR required for 4-QAM and 16-QAM or between 16-QAM and 64-QAM.

By inverting the formulas in (5) and (6), for a target probability of error, a useful expression for the maximum spectral efficiency obtained is

$$R = \log_2\left(1 + \frac{SNR}{\Gamma}\right), \qquad (7)$$

where the gap, Γ, can be calculated as a function of M and the target probability of error. Conveniently, (7) allows direct comparison with the capacity in (4). The gap, Γ, effectively determines the loss in capacity, i.e., the difference between the actual spectral efficiency and the maximum spectral efficiency. Coded modulation schemes generally reduce the gap (towards the ultimate limit of $\Gamma = 1$). The effect of coding is most often expressed in dB as the coding gain, ϕ_{dB}, making the effective gap smaller, so that $\Gamma_{db}^{\text{new}} = \Gamma_{dB} - \phi_{dB}$.

CONCLUSION: ADDITIONAL RESOURCES

Digital communications is a broad area that draws on many different but related aspects of electrical engineering. Perhaps the standard academic references for digital communication are *Digital Communications* by John G. Proakis and *Digital Communication* by Edward Lee and David Messerschmitt. The text *Digital Communications* by Bernard Sklar provides an intuitive presentation of the concepts of digital communications. A good online manuscript is John Cioffi's. A good technical discussion of digital communication in wireless systems is found in *Principles of Mobile Communication* by Gordon L. Stuber. The standard reference for digital signal processing is *Discrete-Time Signal Processing* by Alan V. Oppenheim and Ronald W. Schafer. For a basic reference on vector spaces, *Elementary Linear Algebra: Applications Version* by Howard Anton and Chris Rorres is a good text.

There are many advanced concepts in digital communication that were just barely covered. For example, *Elements of Information Theory* by Thomas M. Cover and Joy A. Thomas provides a more thorough introduction to information theory. The book *Synchronization Techniques for Digital Receivers* by Umberto Mengali and Aldo N. D'Andrea provides a current treatment of synchronization in digital communication systems. Forward error correction is a topic that was only briefly mentioned yet is of significant importance. A classic reference is *Error Control Coding: Fundamentals and Applications* by Shu Lin and Dan J. Costello. A text that treats some current topics is *Fundamentals of Codes, Graphs, and Iterative Decoding* by Stephen B. Wicker and Saejoon Kim.

Current research in digital communication appears in a variety of journals including the *IEEE Transactions on Communications*, the *IEEE Transactions on Signal Processing*, and the *IEEE Transactions on Information Theory*, among others.

GLOSSARY

A/D Analog-to-digital converter.

AFE Analog front end.

Bandpass A type of communication signal that has information modulated onto a carrier.

Baseband A type of communication signal that does not have information modulated onto a carrier.

BER Bit error rate.

Capacity The maximum data rate at which nearly errorless transmission can occur.

Carrier Name for the high-frequency sinusoid that shifts the spectrum of a baseband signal to higher frequencies, making it bandpass.

Channel Coding The process of adding redundancy to a transmitted data stream for the purpose of improving resilience to errors caused by the channel.

CDPD Cellular digital packet data.

D/A Digital-to-analog converter.

Demodulation The process of extracting transmitted digital data from the continuous waveform observed at a receiver.

Downconversion Process of converting a bandpass signal to a baseband signal by removing the carrier frequency.

DSP Digital signal processing.

EDGE Enhanced data rates for GSM evolution.

FPGA Field programmable gate array.

HDR High data rate.

GPRS General packet radio service.

Modulation The process of converting digital data to continuous waveforms for transmission on a communication medium.

PAM Pulse amplitude modulation.

PSD Power spectral density is a measure of the power in a signal as a function of frequency.

QAM Quadrature amplitude modulation.

Receiver Sensitivity The minimum required signal level for a receiver to be able to demodulate a received signal at the desired quality.

SNR Signal to noise ratio. Essentially the ratio of the received signal power to the noise power.

Source Generic name for the component that generates the information stream which is the input to a transmitter.

Source Encoding The process of removing redundancy from the information stream provided by a source.

Symbol A representation of a set of bits in the digital or analog domain.

Synchronization The process of ensuring that a transmitter and receiver operate in a synchronous manner.

Upconversion Process of converting a baseband signal to a bandpass signal by increasing the carrier frequency.

Digital Divide

Jaime J. Dávila, *Hampshire College*

INTRODUCTION

Broadly speaking, the term "digital divide" refers to the difference in access to computers and the Internet that exists among different groups. In the following paper I will present a historical overview of this issue, its most important characteristics, and how it manifests domestically and internationally. In addition, I will discuss several ways in which the situation is being dealt with and propose possible solutions.

On October 10, 1996, President Clinton and Vice President Gore addressed the public at the Knoxville Auditorium Coliseum (Clinton & Gore, 1996). The main topic of their presentation dealt with the government's effort to build a bridge to the 21st century. During the conversation, they talked about the existing digital divide, demonstrating the importance being given to this issue by high-ranking government officials. Since then, the term has come to be synonymous with the different levels of access to the Internet experienced by different groups of people. In the first of several government policy documents dealing with this issue, the importance of closing the digital divide is defined as important because "... individuals' economic and social well-being increasingly depends on their ability to access, accumulate, and assimilate information" (United States Department of Commerce, 1995).

In the following pages I will present a more formal definition for the term digital divide, as well as how it manifests among different groups, both in the United States and internationally. Finally, I will present a series of conclusions and recommendations regarding possible ways to solve this important issue.

GOVERNMENT DEFINITIONS

The first official report by the federal government having to do with inequities in access to the Internet was made available to the public in July 1995 (United States Department of Commerce, 1995). The NTIA (National Telecommunications and Information Administration), an agency within the United States Department of Commerce, was created in 1978 to serve as the President's principal adviser in matters related to telecommunications and information policy issues. In the first of a series of reports, the NTIA reported that specific groups across the nation were lagging behind in their home access to computers and connectivity to the Internet. The most important variables defining these groups were economic status, ethnicity, age, educational level, and geography. Three years later, the Department of Commerce (1998) reported that although the number of U.S. houses with computers and connections to the Internet had increased, the percentage difference, among groups based on ethnicity, income, education level, and age, between those with and those without Internet access had, in fact, grown. In addition, they reported that single-parent households were also considerably less likely to have Internet connectivity.

The last of the reports published under the *Falling Through the Net* series was published in 1999. *Falling Through the Net: Defining the Digital Divide* (Department of Commerce, 1999b) reported that, although 40% of households had computers and 25% of households had Internet connectivity, the differences between the different groups continued to exist. According to the report,

> The 1998 data reveal significant disparities, including the following: Urban households with incomes of $75,000 and higher are more than twenty times more likely to have access to the Internet than rural households at the lowest income levels, and more than nine times as likely to have a computer at home. Whites are more likely to have access to the Internet from home than Blacks or Hispanics have from any location. Black and Hispanic households are approximately one-third as likely to have home Internet access as households of Asian/Pacific Islander descent, and roughly two-fifths as likely as White households. Regardless of income level, Americans living in rural areas are lagging behind in Internet access. Indeed, at the lowest income levels, those in urban areas are more than twice as likely to have Internet access than those earning the same income in rural areas.

In fact, for many of these groups, the percentage difference between having and not having Internet access was found to have increased through the years.

> The gaps between White and Hispanic households, and between White and Black households, are now approximately five percentage points larger than they were in 1997. . . . The digital divides based on education and income level have also increased in the last year alone. Between 1997 and 1998, the divide between those at the highest and lowest education levels increased 25 percent, and the divide between those at the highest and lowest income levels grew 29 percent. (Department of Commerce, 1999b)

On a more positive note, the report found that the differences based on ethnicity disappeared for annual household incomes above $75,000. This suggested that lower equipment costs could make the divide disappear from other economic sectors.

In February 2002, under a new federal government, the NTIA generated a report on the issue of the digital divide with a very different outlook. Based on the most recent census data, a record number of Americans were making use of computers and the Internet. In a new report, the United States Department of Commerce (2002) reported

> Between December 1998 and September 2001, Internet use by individuals in the lowest-income households (those earning less than $15,000 per year) increased at a 25 percent annual growth rate. Internet use among individuals in the highest-income households (those earning $75,000 per year or more) increased from a higher base but at a much slower 11 percent annual growth rate . . . Between August 2000 and September 2001, Internet use among Blacks and Hispanics increased at annual rates of 33 and 30 percent, respectively. Whites and Asian American and Pacific Islanders experienced annual growth rates of approximately 20 percent during these same periods. . . . Over the 1998 to 2001 period, growth in Internet use among people living in rural households has been at an average annual rate of 24 percent, and the percentage of Internet users in rural areas (53 percent) is now almost even with the national average (54 percent).

CLASS VERSUS ETHNICITY

Looking at the possible exclusion of a group of citizens from benefiting from technology shows how important it is to identify factors influencing this exclusion. Two of the most commonly cited factors are class and ethnicity. Novak and Hoffman (1998) found that income is a better predictor of access to computers at home, and that educational level is a better predictor of having access to computers at work. At the same time, the Benton Foundation (1998) reported that for households earning under than $40,000/year, white Americans are close to twice as likely to have computers or Internet access at home than African Americans. The numbers are similar when comparing white Americans with Latinos (Becht, Taglang, & Wilhelm, 1999) : For households earning under than $15,000, the gap between non-Hispanic White and Hispanic households rose substantially, from 5.6% to 8.1% between 1994 and 1998. For households earning between $15,000 and $34,999, the disparities between non-Hispanic White and Hispanic households increased by 46% or (4.0 percentage points). A White, two-parent household earning under than $35,000/year is nearly four times more likely to have Internet access than Hispanic households in that same income category.

One proposed solution to this problem is to effectively increase the use of more publicly available Internet access points. For example, those citizens who lack Internet connectivity at home could gain it at schools, libraries, or community centers. Although in theory this seems to be a good idea, it is one that has to be approached, analyzed, and improved on carefully. Although 98% of schools in the United States have computers, the ratio of students per computer is 30% higher in schools where 80% or more of the student body participates in free or reduced-cost lunch programs. In schools where more that 90% of the student body is from minority groups, the student-to-computer ratio is 74% higher (Educational Testing Service, 1997). The problem is even bigger when measuring Internet access. Among schools with a student body composed of 50% or more minority students, Internet connectivity is available in 22% fewer schools (National Center for Education Statistics, 1997). A study carried out by the Educational Testing Service also found that schools in low-income areas are close to 25% less likely to have Internet connectivity than those in high-income areas (Benton Foundation, 1998).

With regard to public libraries, a study performed by the U.S. National Commission on Libraries and Information Science (1998) revealed that although a high percent of public libraries across poverty classifications have public Internet access (92.8%–95.6%), the percentage of libraries located in poor communities is very low (2.0%). In addition, although schools, public libraries, and community centers can provide valuable connectivity services, access to the Internet at public spaces will necessarily have characteristics different from access at home. Issues based around waiting in queues, time limits, and privacy can all lead to less than positive experiences for those who do not have Internet access from home. For example, even though most unemployed people access the Internet from outside their homes, most unemployed people using the Internet to look for jobs were doing it from their houses (U.S. Department of Commerce, 2000).

OTHER DISTINGUISHING FACTORS IN THE UNITED STATES

There is a notable difference in computer ownership and use of the Internet depending on geographic location. In 2001, although 57.4% of households in urban houses outside of inner cities had access to the Internet, the number was 3.5 percentage points lower for rural households, and 7.7 percentage points lower for inner city households (United States Department of Commerce, 2002). This number is particularly significant because it includes access to the Internet at any location, inside or outside the home, and translates to less than half of households in inner cities having access to the Internet.

In terms of gender, computer usage and Internet access has come to match general population percentages in the United States (United States Department of Commerce, 2002). In 2001, 53.9% of men and 53.8% of women had access to the Internet. There are other ways, though, in which women are being left behind in terms of technology. One of them, regarding women connected to the Internet in countries other than the United States, will be discussed in this chapter in a later section, on the international digital divide. In addition, there are significant differences in number of women versus men in technology education.

The American Association of University Women Educational Foundation (2000) reported that although they comprised 51% of the U.S. population, in the year 2000, females obtained only 28% of the degrees in computer science (down from 34% in 1984) and comprised only 20% of the IT workforce.

Finally, serious consideration should be given to the way in which disabled people access the Internet. Those who are visually impaired, or have problems working with a mouse as a pointing device, can have great difficulty navigating and taking advantage of the opportunities offered by technology as a communication medium. In 2000, the U.S. Department of Commerce (2000) reported that although 56.7% of U.S. citizens accessed the Internet (either from inside or outside their homes), only 28.4% of people with disabilities did. Only 22.5% of people with difficulty using their hands and 21.1% of people with vision problems used the Internet. In September 2000, President Clinton assigned $16 million to the Department of Education to promote technology programs for the disabled, and an additional $9 million to Americorps volunteers working with Internet for the disabled. In addition, modifications made to the U.S. Rehabilitation Act now require government web pages to meet certain criteria to make them more accessible to people with disabilities (CNN, 2000a).

THE TECHNOLOGY S-CURVE PROCESS

Recent analysis of the digital divide problem argues that the differences seen among different groups are closing and will continue to close as more and more people come online. This can partly be explained by standard processes of technology diffusion. Rogers (1983) defined five types of innovation adopters: innovators, early adopters, early majority, late majority, and laggards. He further argued that all technologies have a diffusion rate into general society. At first very few people use the technology. With time, more individuals start to use the technology, until a saturation point is reached. After this saturation point, the rate at which additional people start using the technology for the first time decreases, with the total number of users staying close to constant. According to Rogers, the rate at which a new technology is adopted by the general population is a factor of five characteristics: its relative advantage over the technologies that it replaces; how compatible it is with the values and experiences of the adopters; how complex the technology is perceived to be; how easy it is for people to try out; and how easy it is for others to see the results of adopting it. Many of these factors were, in fact, empirically identified by the general population in a survey carried out by Katz and Aspden (1997). Given these factors, only a small percentage of the population is bound to try any new technology soon after it is introduced. But as prices drop and the effects of the technology are made public, more people start using it. Figure 1, reproduced with small modifications from the United States Department of Commerce (2000), shows a typical S-curve. If this pattern applies to computers and the Internet, then the current digital divide will naturally close with time. Although Leigh and Atkinson (2001) report that other technologies introduced during the 20th century (such as telephones, radios, and

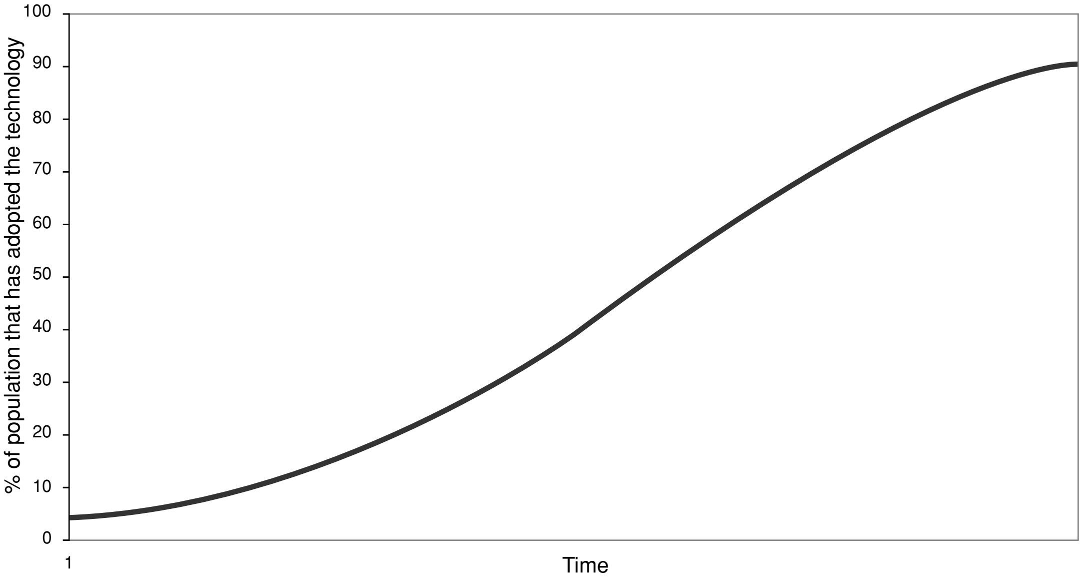

Figure 1: Typical technology S-curve.

television) grew to almost 100% penetration among U.S. households, the trend might not apply to Internet connectivity. As evidence, Internet penetration reached 30% of the U.S. population in seven years, making it a faster growing technology than telephones, television, or video cassette recorders (VCR; Leigh & Atkinson, 2001), but it failed to have any significant increase between November 2000 and April 2002 (Taylor, 2002). This can mean one of two things: Either we have reached the top of the S-curve, in which case the percentage of users will not continue to expand, or Internet penetration will behave in differently than the S-curves seen with other technologies, in which case the S-curve theory of penetration cannot be used to make predictions about the future expansion of the Internet.

ACCESS VERSUS SKILLS

In addition to access to computers and the Internet, the digital divide includes issues around the training and skills necessary to take advantage of both of these resources once they are attained. Warschauer (2002), for example, has documented the results of several Internet connectivity projects. In one of them, four towns in Ireland were given government funds to use to turn themselves into "Information age towns." With less money, three of these towns were able to create more successful programs than the town that received the highest per capita amount. The distinguishing factor was "... developing awareness, planning and implementing effective training, and setting up processes for sustainable change, rather than merely on purchase of equipment" (Warschauer, 2002).

Warschauer discusses a similar example in a classroom setting in Hawaii, where two schools made clearly different use of computers and technology (Warschauer, 2000). Although both schools used technology to improve the educational opportunities available to their students, differences were evident. The school in the more economically affluent community used computers to develop academic and scientific skills, where the students in the poorer school were involved with tasks more directed toward the workforce. This difference was matched by a series of goals and expectations set by the teachers at each of the schools.

Being able to efficiently use the Internet, with its multitude of information, requires a series of different but related skills. Carvin (2000) identifies six types of literacy skills needed by a user in order to take full advantage of the Internet: basic literacy (the ability to read and write); functional literacy (the ability to apply basic literacy to everyday tasks); occupational literacy (the skills necessary to succeed in a professional setting); technological literacy (the ability to use technological tools); information literacy (the ability to determine the quality of informational sources); and adaptive literacy (the ability to develop new skills).

Parallel to the issue of skills development, the relevance of available content can control the benefit any community can obtain from being connected to the Internet. This becomes particularly important for low-income communities, for whom this new medium might be one of very few avenues for improvement. An audit performed by the Children's Partnership (Lazarus & Mora, 2000) revealed that technologically underserved U.S. Citizens found the Internet lacking in local information and cultural diversity. In addition, their study found that although 22% of the population of the United States does not have proper "everyday" literary skills, most of the text available online is written assuming that the audience has at least an average level of literacy.

THE INTERNATIONAL DIGITAL DIVIDE

As is to be expected, the number of people connected to the Internet outside of the United States varies greatly, from numbers as high as 60%, for the population in Canada (Mandel, 2002), which is higher than in the United States, to less than 0.04% in Ethiopia (International Telecommunications Union Statistics, 2002). Although many countries in Europe, Asia, and the Pacific are starting to catch up with the United States and Canada in terms of Internet use, they are still lagging (Campbell, 2001). The problem is even greater when we look at countries in Africa and Latin America.

Norris (2001) analyzed data on Internet usage for Portugal, Greece, Germany, Spain, France, Belgium, Austria, Ireland, Italy, the United Kingdom, Luxembourg, Holland, Finland, Denmark, and Sweden. In all these countries, income, educational level, gender, age, and type of occupation (managerial versus manual work) was a strong indicator of Internet connectivity. The problem of a gender-based digital divide, now apparently absent in the United States, is a major problem in countries outside Europe. Of the total number of people connected to the Internet, only 22%, 38%, and 6% are women from the regions of Asia, Latin America, and the Middle East, respectively (Hafkin & Taggart, 2001).

There are also drastic domestic differences within developing countries. Income, education, geographic location, and gender all seem to influence connectivity into such required communication links as telephones (Grace, Kenny, & Qiang, 2001). Most organizations evaluating a nation's readiness to deploy and take advantage of the Internet identify five critical areas: the availability and cost of connection lines, such as telephones and cellular phones; government leadership in areas related to the Internet; current computer infrastructure, such as number of computers per capita; training of the local workforce; and local climate for electronic commerce.

Connectivity

Many of the differences in access to the Internet run parallel to access to telephone lines. In the United States, where close to 54% of the citizens have access to the Internet, 94% of households have telephone connections (U.S. Department of Commerce, 1999b). In contrast, Africa, which lags any other continent in Internet usage, has a total of 14 million telephone lines (fewer telephone lines than either Manhattan or Tokyo (Nkrumah, 2002)). Ethiopia, which has only 1.1 Internet users per 10,000 citizens, has only 0.32 telephone lines per 100 habitants (BBC News, 2000). This problem is particularly severe in light of the difficulty of providing connectivity to remote parts of a country. This creates a domestic digital divide in countries where towns and villages are far removed from urban centers.

Another factor related with telephone lines is the cost per minute of connecting to the Internet. In many countries, charges for telephone calls are accrued on a per-minute basis. The Organization for Economic Cooperation and Development (2000) has found strong correlations between the price per minute for telephone calls and the number of Internet hosts in different countries. This is particularly important in light of another of the factors that seems to foster domestic connectivity: local climate for electronic commerce.

Government Leadership

Different national governments have implemented a variety of plans to reduce their domestic digital divide. The one common thread among all of them is their signaling that access to the Internet is an important national issue. In the United States, President Clinton (White House Web Site, 2000) presented a budget in February 2000 that included several key items designed to increase Internet access across the nation. Among other things, his proposal called for $2 billion in tax incentives for private companies donating hardware and training to technology centers; $150 million to train new teachers in the best ways to use technology; $100 million to create community technology centers; $25 million to encourage the private installation of Internet connectivity to underconnected communities; and $10 million to train native Americans for careers in information technologies. In Brazil, the government intends to provide Internet terminals at post offices in cities with 6,000,000 or more habitants (Rebeto, 2001a). In addition, it is providing Internet-ready home computers for as little as $15/month (Bebeto, 2001b). The Australian government has put in place a series of initiatives to bring both connectivity and training to all of its population, at a total cost of close to $426 million (Australian National Office for the Information Economy, 2000).

Current Computer Infrastructure

In many countries, we see a close correlation between the number of computers per person and the number of people accessing the Internet. On one end of the spectrum is the United States, where in the year 2001, 66% of the population owned computers and 54% of the population had access to the Internet (U.S. Department of Commerce, 2002). At the other end of the spectrum, as reported by Tran and Barrett (2001), in Bolivia only 0.75% of the population owns a computer and only 0.98% have some type of access to the Internet (NUA, 2002). One simple explanation for this relationship is that a high number of people access the Internet from their households. Additionally, local companies are bound to facilitate Internet points of access if they feel there is an audience ready to subscribe to that type of service.

Technology Training

It is not enough to have a computer and network connectivity to take advantage of the Internet. Potential users need to understand what they have to gain from using the medium, and they need to know how to access its features. Both national governments and private institutions can play important parts in delivering this knowledge to citizens. In Jordan, for example, the government has established a program to teach Information Technology at academic institutions across the country (Niewiaroski, 2002). In addition, they have started partnerships with private companies, such as AOL, Microsoft, Oracle, and Cisco, to retrain computer graduates and keep them up to date with the latest technologies. In Mexico, the Technological Institute of Monterrey now offers technology courses on the latest IT topics to its own population as well as to other Latin American countries (McConnel International, 2001). Many of these initiatives share the common thread of being partnerships between public, private, and educational institutions.

E-commerce Climate

A final characteristic for successful national Internet inclusion is the ease with which companies can establish electronic commerce and transactions. This benefits nations in three ways: It provides additional avenues for job creation and national economic development (Asian Productivity Organization Secretary-General, 2000); it stimulates local and international entrepreneurs to assist with other items necessary for generalized Internet participation, because they gain from an increase in online customers; and it provides incentives for citizens to acquire training in information technologies, because companies will now require a trained workforce.

At the same time, nations that have a stable base of Internet users, as well as a developed computer infrastructure, can more readily attract e-business companies. Reports by the Organization for Economic Cooperation and Development (2000) demonstrate strong correlations between the number of Internet users, the cost of connecting, and the number of secure servers for its member nations.

In this way, then, connectivity, government leadership, computer infrastructure, a trained local workforce, and a positive electronic commerce climate form the cornerstones of Internet development for any country. All these factors feed off each other in a systemic process. For example, local governments have the primary responsibility for providing connectivity, but they usually come into partnerships with private industries in order to facilitate the rigorous task of wiring a nation. Private industries, at the same time, take benefit of government subsidies in exchange for providing hardware and training to the general population.

ADVANTAGES OF BEING CONNECTED

The advantages provided by the Internet are many, but all deal with issues of acquiring and communicating information. The most immediate of these advantages vary depending on the user and his or her location. In the United States, for example, 53.9% of unemployed people who use the Internet from their homes and 29.8% of unemployed people who use the Internet from outside their homes use it to look for new jobs (U.S. Department of Commerce, 1999a). Additionally, between 36 and 38% of people who use the Internet from any location are either taking online courses or doing academic research.

For countries around the world, taking advantage of new technological opportunities can be crucial for national economic development. Campbell (2001) has found a strong correlation between the number of technology users and the percentage of growth in employment.

Citizens of a connected nation can follow the work of their elected representatives more easily. Many elected government officials can be contacted via the Internet. The U.S. House of Representatives can be reached at http://www.house.gov. The U.S. Senate can be reached at http://www.senate.gov. The State of Texas Legislature can be reached at http://www.capitol.state.tx.us/fyi/fyi.htm. These Web sites not only provide information, they also allow for easier contacting of elected officials. A new way for citizens to participate in government is evolving out of these communication media. Information about government rules, regulations, and benefits can be found online. For example, the state of Oregon provides such information at http://www.oregon.gov. This type of Web site directs citizens to the correct office for the services they might be looking for and, in some cases, allows visitors to request services online. Labor unions now use the Internet to inform and organize their members (CNN, 2000b). Union members are thus kept better informed and are in closer contact with the people they elect to act as their representatives.

In October 2000, 45% of the African-Americans who used the Internet reported looking for health information (Associated Press, 2000). High school technology education programs are training young programmers living in urban neighborhoods, allowing them to enter the workforce and command salaries of up to $150/hr (Clewley, 2001). This offers a group of typically disenfranchised citizens skills that are in high demand, turning technology into an engine capable of propelling people into better lifestyles. In Sierra Leone, a local entrepreneur has started a program where young rebel soldiers are able to trade their arms for computer training, with the goal of turning them into the center of a software outsourcing business within 3 years (Hermida, 2002a).

In Argentina, as part of a series of activities designed to put pressure on government officials, protesters have set up a number of Web sites documenting their dissatisfaction with recent economic rulings (d'Empaire, 2002). In Kosovo, Albanians and Serbians are coming together and using the Internet to make their environmental problems known (Hermida, 2002a). By using the Internet as a medium to communicate their problems to others, these groups and individuals are now better able to obtain assistance for their causes.

The number of programs like those mentioned above is too extensive to list here. These programs, and others like them, have very different flavors and approaches, depending on the countries in which they are being implemented. What all of them have in common is their use of the Internet as a powerful communication mechanism, as well as the door to new economic opportunities. As such they can serve as tools for increasing equality, bringing new opportunities to disadvantaged communities. If, on the other hand, the divide between those who have access to the Internet and those who do not is not closed, it may well serve as a mechanism to exacerbate economic and social differences between the haves and the have nots.

SOLUTIONS TO THE DIGITAL DIVIDE

Given the facts outlined throughout this chapter, a pattern of solutions to the problem of a digital divide starts to emerge. In most nations, and in particular in the United States, the government must be an active participant in efforts to provide equal access to members of different communities. As an example of a similar process, telephone penetration in the United States increased dramatically during the 20th century. An important reason for this phenomenon was federal government legislation, such as the Communications Act of 1934, which defined the ways in which private companies were to benefit from their efforts to provide telephone connectivity to the United States. By participating in the creation of the necessary infrastructure, private companies gain the creation of potential customers.

Federal governments can also help to close the digital divide by directly allocating funds to entities wiring and equipping computer centers in public spaces. An example of such a program is the Neighborhood Networks program of the U.S. Department of Housing. Since 1995, this program has been providing funds for the establishment of computer centers within low- or moderate-income multifamily housing. A similar initiative, commonly known as the E-rate program, allocated federal funds to the development of computer access at public and private schools and libraries. A study performed by the Urban Institute (Puma, Chaplin, & Pape, 2000) reported that most of these funds went into public schools, particularly in the poorest communities.

In the international arena, governments can use special incentives and regulations to create market environments favorable to private institutions. These institutions are then stimulated to help develop the physical and human infrastructure that allows citizens to become connected. As the governmental budget of a particular nation decreases, the economic contribution of the private sector becomes more important.

For those individuals and groups whose economic situation does not allow them to gain access to the Internet at home, libraries and community centers will become critical points of Internet connectivity. Once again, public and private coalitions are central to continuing to implement these possibilities. Government entities can provide incentives to the private sector to donate equipment and/or training to public schools, libraries, and community centers. Programs such as CTCNet and Americorps have invested in both creating community centers and training the community how to take advantage of technology. This type of initiative needs to receive both public and private funds to continue doing the job. In both the domestic and international arena, the success of these programs will be dependent on integrating these efforts with the search and implementation of solutions to the problems of each community. Once in progress, these types of government/community programs have the ability to empower citizens who have traditionally been marginalized. A study on the effect of the CTCNet program (Chow, Ellis, Mark, & Wise, 1998) found that females, people of all ages, and members of minority groups all made extensive use of community computer centers associated with this program. Participants used the Internet for such things as expanding their skills and looking for jobs. In addition, interviewees reported an increase in personal effectiveness, as well as a sense of community building. Of the people polled in the survey, 94% reported positive feelings about using the community centers.

Partnerships between public and private entities have demonstrated great ability to assist in connecting individuals in low-income communities. The *Computers for Youth* program (http://www.cfy.org), for example, has created a partnership between private companies, branches of the federal government, universities, and other educational institutions in order to place computers in predominantly Black and Hispanic households.

Governments and institutions in developed countries have the ability to greatly assist developing countries eliminate internal and international digital divides. The Global Digital Opportunity Initiative is a result of studies prepared by the Group of Eight Nations (G8). In it, the Markle Foundation, for example, has come into partnership with the United Nations Development Program and several key computer technology companies to provide pro bono consulting services to countries interested in creating strategies for local Internet development (Sullivan, 2002).

Colleges and universities are also important players in providing Internet access to those who currently lack it. Their ability to both establish community programs and do research about the subject makes them an important information clearinghouse. Of particular interest is their ability to embed training into community activities, and also their ability to disseminate results and findings. An example of this is currently being carried out by the Stanton/Heiskell Center for Public Policy in Telecommunications and Information Systems, at the City University of New York Graduate School. In 1990, this research center placed networked computers in the homes of 125 students from typically underserved communities (Stanton/Heiskell Center, 1998). At the conclusion of their 7-year program, a series of findings was disseminated to the public. In addition, newer pilot programs were established to examine questions that arose from their original research. Not surprisingly, public and private institutions were instrumental in funding and facilitating these programs.

In relation to access for disabled people, economic stimulus and publicity should be used to encourage companies to develop accessible software and hardware. An example of increased software accessibility will be seen in additions to Macromedia's Flash, which is widely used to create interactive Web sites. Jason Smith, an independent software programmer, has created an addition to the standard Flash program that will allow computer screen-reading packages to read captions in the Flash animations (Delgado, 2002).

Finally, a certain sector of the population will adopt the use of Internet connectivity only after being educated about its advantages. Some people, particularly in the United States, have reported not being connected because they do not see the utility of using the Internet (U.S. Department of Commerce, 2000). Given the number of uses the Internet can have, it is safe to say that these people are not aware of the opportunities the medium offers them. Schools, community centers, libraries, and other public spaces can help with this population by holding programs that communicate the benefits of the Internet to those who have the infrastructural requirements to enjoy it but are not convinced of its utility. These public groups, in turn, will need public and private economic assistance to carry out this type of educational program.

CONCLUSION

The digital divide is a problem affecting broad sections of our communities, both in the United States and internationally. Because of the Internet's potential to benefit its users, not solving this divide can cause the difference in quality of life to increase dramatically through the years. Efforts to solve the issue of the digital divide must deal with developing infrastructures, providing training, and empowering communities to integrate the Internet into their normal everyday activities. The results of projects carried out at different levels across the world indicate that programs aimed at closing the digital divide are most effective when they integrate the participation of governments, private institutions, community groups, and the general citizenry.

GLOSSARY

Connectivity Refers to the availability of physical media through which communication can take place.

Domestic/national Unless otherwise specified, domestic and national terms are relative to the United States of America.

Ethnicity Affiliation based on membership in a particular racial, linguistic, or cultural group.

Infrastructure The resources necessary to for participation in a given activity.

Digital Economy

Nirvikar Singh, *University of California, Santa Cruz*

INTRODUCTION

> IT and the Internet amplify brain power in the same way that the technologies of the industrial revolution amplified muscle power.
>
> —Bradford DeLong, Professor of Economics, University of California, Berkeley, quoted in Woodall (2000, p. 6)

The purpose of this chapter is to explain what the digital economy is and how it fits into broader economic trends that are shaping the economies of the United States and other countries. Essentially, the digital economy refers to the use and impact of digital information technology in various forms of economic activity. As such, the term includes more specific activities such as e-commerce and e-business and is closely related to terms such as knowledge economy and information economy.

All groups in the economy are affected by the pervasive use of information technology; this includes consumers, business firms, and governments. Activities that are not directly commercial, such as personal communications, are also affected. The fundamental driving force is the falling costs of processing, storing, and transmitting information that has been put into digital electronic form. These declines in costs have made innovations possible that permit easy and widespread communication over extensive networks, the existence of large and rich databases of information and knowledge that are freely or easily accessible, and the ability to conduct most or all stages of economic transactions over long distances, without relying on alternative methods of information exchange.

The further results of these expanded capabilities for accessing, using, and sharing information in digital form include new and more efficient ways of organizing markets; new and more efficient methods for businesses to communicate and transact with each other and with consumers, employees, and job seekers; dramatically lower costs for individuals in locating or gathering information of all kinds, including market- and product-related information; changes in the organization of business firms and in their strategic behavior; and changes in the overall societal organization of work, leisure, and general communities of shared interest.

The essay is organized as follows. We provide some data on the size and growth of the digital economy and e-commerce and discuss the measured impacts of information technology on the economy as a whole, as well as some of the problems of measurement. We describe changes in the nature, structure, and performance of firms and markets as digital technologies help make information more ubiquitous and as information increases in importance as an economic good. We examine several aspects of government policy with respect to the digital economy, including contracting, privacy, competition policy, regulation, and international trade. We discuss broader implications of the information revolution, examining how it changes the ways in which individuals work, play, and interact within organizations and communities. A short summary concludes the chapter.

INFORMATION TECHNOLOGY, THE DIGITAL ECONOMY, AND E-COMMERCE

Although there is no absolute agreement on what the "digital economy" is, this section provides a working definition, discusses how the term is related to e-commerce and e-business, and discusses the measurement of the digital economy, and the impacts on overall economic activity.

Defining the Digital Economy

A computer is essentially a machine for storing and processing information. Although one might count the abacus or mechanical, gear-based calculating machines as computers, the term typically refers to electronic machines that use on–off electrical signals to convey and process information. The two states, "on" and "off," based on whether an electric current is flowing or not, represent the digits 1 and 0. These are "binary digits" or "bits." Ultimately, all information that is input to a computer and is processed by it is translated into bits. *Information technology* (IT) therefore refers to anything connected to this process of storage, processing, and transmission of information converted to digital form. The use of IT for purposes related to economic transactions gives us the term *digital economy*. Here is one possible definition:

The digital economy involves conducting economic activities electronically, based on the electronic processing, storage, and communication of information, including activities that provide the enabling physical infrastructure and software.

Dramatic and rapid reductions in the costs of processing information, storing it, and sending it to others (see Table 1) have made the uses and benefits of IT potentially span the whole economy, leading to an "information revolution." On the basis of these falling costs, we have seen innovations such as personal computers, color graphics, point-and-click interfaces, and other developments that have made IT much easier to use. The Internet and the World Wide Web are the latest elements of the progress of IT over the last half-century, adding easy two-way communication of rich information (text, graphics, audio, video, etc.). The changes that the increased importance of IT brings about in people's daily lives are captured in the term "*new economy*." The term suggests that IT and the Internet shift the focus of economic activity to information, and away from traditional activities such as manufacturing. Similar terms are perhaps more descriptive: *knowledge economy*, *information economy*, and digital economy. The last of these, as noted, emphasizes the fundamental technology that drives everything: the conversion of information to digital form.

The terms "information economy" and "knowledge economy" focus on what is being digitalized. Information and knowledge are related, but distinct concepts. Information is more general and basic; it connotes anything that can be put into concrete form before digitalization. For example, a popular song is information, from an IT perspective. The sounds can be reduced to a digital form that can be stored, transmitted, and processed by various kinds of computers. If a person internalizes information about the song (its title, tune, lyrics, etc.), then that constitutes knowledge, just as the ability to write computer programs that allow users all over the world to share songs is knowledge. To push these examples further, the particular song-sharing software program is also information. In this case, knowledge helps to produce and transmit information. People can also gather information, process it in some way, and gain knowledge, as when they study how to program in a particular computer language. Some of the same distinction comes up in the differences between copyright and patent law, protecting different kinds of intellectual property rights—copyright law protects particular expressions of ideas, or information, whereas patent law protects inventions, or the ideas themselves, if they are useful knowledge. In all these cases, digitalization (through the use of IT generally, and the Internet in particular) amplifies the benefits of knowledge and makes the spread of information easier. This is one of the foundations of the digital economy.

Table 1 Falling Costs of Computing (U.S. $)

Costs of computing	1970	1999	2003
1 Mhz of processing power	7,600	0.17	0.02
1 megabyte of storage	5,260	0.17	<0.01
1 trillion bits sent	150,000	0.12	<0.01

Source: 1970 and 1999, Woodall (2000, Chart 1); 2003, author's estimates from various sources.

E-commerce

E-commerce (or *electronic commerce*) is a popular term that emphasizes the use of the Internet and associated aspects of IT for business purposes. Although businesses previously adopted IT for many internal and "back-end" activities, the Internet and World Wide Web have allowed business–consumer (*B2C*) commercial interactions to be more closely and comprehensively mediated by IT. Examples of e-commerce include buying retail items using a Web interface and paying for them by providing credit card information online; downloading media-player or other software (possibly free) over the Internet; checking the news, weather, and movie reviews on a portal, possibly "paying" for these services by giving attention to online advertisements; going to an auction Web site, and bidding on collectibles or other items; and paying a monthly subscription for Internet access, to chat online with friends or others one meets in cyberspace.

More formal definitions of e-commerce encompass all the above examples, and include commercial transactions between any kinds of organizations, not just B2C interactions. Here are two general definitions:

> Electronic commerce refers generally to all forms of transactions relating to commercial activities, including both organizations and individuals, that are based upon the processing and transmission of digitized data, including text, sound and visual images. (*Measuring Electronic Commerce*, 1997)

> In ever greater numbers, people are shopping, looking for jobs, and researching medical problems online. Businesses are moving their supply networks online, participating in and developing online marketplaces, and expanding their use of networked systems to improve a host of business processes. And new products and services are being created and integrated into the networked world. (*Digital Economy,* 2000, p. 7)

The scope of what constitutes commercial transactions is taken to be quite broad in these definitions. Information gathering or exchange that does not directly involve a direct monetary payment may still have an economic motivation. Even leisure-related activities typically require some measured economic activity. In the example of using the Internet for chatting, one pays for access to the infrastructure that enables the leisure activity. Activities that involve the government (e.g., filing one's individual tax return electronically over the Internet) are not "commercial" in the narrow sense, but are clearly related to economic activity that is measured in the national accounts statistics.

Of course, not all IT-based activities qualify as e-commerce in the sense of involving the Internet. For example, many home activities involving PCs do not involve Internet use at all: record keeping, children's homework, creating (paper) greetings cards, typing holiday newsletters, and so on. Similarly, small retail stores may have computerized inventory systems that have no links to any other computer. However, this gap between computer use and Internet use is shrinking, and for many individuals and businesses, using computers or IT automatically means using the Internet.

E-business

The encompassing definition of e-commerce presented earlier includes a broad range of online transactions and interactions that are connected to some economic motive. Therefore, this is broader than the term e-business, defined as the use of IT, including networked computing, by business firms. For example, if individuals transact directly online, so that no business firm is directly involved, then that would qualify as e-commerce, but not e-business. Similarly, we include government–individual transactions in e-commerce but not in e-business.

E-business (and therefore e-commerce) includes not just transactions across firms or individuals but also activities that take place within the boundaries of a business but do not cross them. Internal accounting, inventory control, and other forms of business record keeping and tracking have been electronically based in industrial countries for over a decade, especially in larger businesses. These purely internal records and transactions, when handled electronically, are often what e-business is taken to refer to. The use of IT provided cost advantages over traditional means (i.e., paper) in terms of storage, manipulation and retrieval of large amounts of information, provided that the scale of use was large enough to spread the substantial fixed costs initially associated with IT investments. In fact, until computers became affordable as household items as a result of falling costs and associated innovations, large organizations were the only purchasers of IT products and services.

In fact, the digital economy, in the form of business-to-business (B2B) transactions based on older electronic communication methods (electronic data interchange or EDI, using proprietary software and dedicated communication links), substantially predates the Internet and the World Wide Web. Electronic links between financial firms, and between large retailers and their suppliers, were two prominent examples of this form of e-business, or B2B e-commerce. The Internet and World Wide Web have extended the economic feasibility of such links to a much wider range of businesses, through their use of shared networks and non-proprietary communication software, and the resulting reduction in the costs of information exchange. Advances in ease of use and speed of transmission have also contributed to this trend, by further increasing accessibility and flexibility. Another potential impact of these developments, which supports the use of broader definitions of terms such as e-commerce and e-business, is the blurring of the boundaries of the firm, as information flows more freely across firms as well as within them.

SIZE, GROWTH, AND IMPACT OF THE DIGITAL ECONOMY

The size and growth of the digital economy can be gauged in several ways. Basic measures of numbers of Internet users, Web sites, and so on are popular. These do not directly measure economic activity that takes place online, though the provision of Internet access is itself an economic activity. More direct measures are figures on transactions that take place online, as well as the share of IT-related activities in the overall economy. This section examines in turn these different approaches to measuring the digital economy and its impacts.

Internet Use

Three kinds of statistics that are often used to gauge the growth of the digital economy are the number of people with Internet access, the number of unique Web pages, and the number of Web sites. The U.S. Department of Commerce, using data from the U.S. Census Bureau, reported that 143 million Americans, or 54% of the population, were using the Internet in September 2001, up from 117 million 13 months earlier (*A Nation Online,* 2002). (See http://osecnt13.osec.doc.gov/public.nsf/docs/Evans-Census-Online. Nielsen NetRatings estimated a higher number of Americans, 168 million, online in January, 2001 [NUA, 2001].) Furthermore, a broader cross-section of Americans is using the Internet, reducing fears of a "*digital divide*." In particular, the growth in Internet use during this period was fastest among Americans with household income less than $15,000 a year.

The Internet is also increasingly global, with the worldwide number of users estimated at 619 million, of whom over half used another language than English (see http://www.glreach.com/globstats/ where links to the original data sources are available). With the exception of the U.S. and a few European and Asian countries, the numbers of Internet users are still low relative to population sizes, reflecting generally lower levels of income in much of the world, but as costs continue to fall, even poor villagers in Asia, Africa, or Latin America are beginning to use the World Wide Web to get weather and crop price information or to check on village land ownership records from government Web sites. Table 2 gives a sampling of Internet use by language, from Global Reach (2003).

Table 2 Global Internet Use

Language	Internet users (millions)	Total population (millions)	Percentage of world economy
English	230.6	508	33.4
European languages (excl. English and Spanish)	176.9	868	25.0
Spanish	47.2	350	8.9
Arabic	5.5	300	1.6
Chinese	68.4	874	13.0
Japanese	61.4	125	8.0
Korean	28.3	78	2.0

The number of unique World Wide Web pages was reported to be more than one billion by January 2000, up from just 100 million in October 1997 (Inktomi, 2000, and Yahoo, 1997). The number of Web sites in May 2003 was about 40 million, up from 19,000 in August 1995 (BBC, 2002, and Netcraft, 2003). The graph of Web sites (Figure 1) is representative of the kind of growth that the Internet and World Wide Web have seen, in terms of availability and of use, with rapid early growth, slowing down dramatically, and declining slightly, in 2001–2002, although the latest figures (May 2003) indicate a resumption of growth (Netcraft, 2003).

Of course, the numbers of users or Web sites does not indicate how much time people actually spend online and how that time impacts economic activity. In particular, they do not tell us how much money people spend directly or indirectly as a result of their Internet use. For that, one would use the approach of national income and product accounting, which estimates value added in market transactions. There are problems with this way of measuring economic activity, such as the failure to account for the value of time used in nonmarket transactions, or in activities that affect market transactions, but official methods of calculating economic activity are the best we have. (For example, time spent in gathering information that affects purchase decisions is not valued in national accounts. Shifts in this activity from traditional, physical methods [such as browsing print media, telephoning, and driving around to stores] to online search will not show up in the data, except as changes in business spending [from magazine ads to Web ads], or even *reductions* in economic activity [less spending on magazines by consumers].) In particular, they are designed to capture market-based economic activity relatively well and to avoid problems such as double counting.

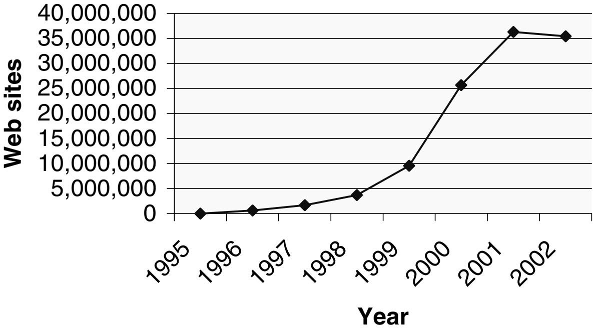

Figure 1: Growth in Web sites. Source: Constructed from data retrieved from BBC (2002) and Netcraft (2002).

Types and Measures of Online Transactions

The problem of double counting is avoided when one looks at final sales to consumers. B2C e-commerce seemed to hold out great potential in 1999 and the early part of 2000, resulting in a rather frenzied burst of entrepreneurial activity backed by eager venture capitalists. This fever has cooled, but the growth remains. The U.S. Bureau of the Census estimated electronic retail (*e-tail*) sales in 2001 to be $32.6 billion. This figure grew to about $43 billion in 2002, though even after this impressive growth, online sales remained only about 1 to 2% of all US retail sales. (These statistics are reported at http://www.census.gov/mrts/www/current.html, which also gives historical data, calculation methods and charts. Other surveys give somewhat higher figures. For example, AOL reported that its members alone spent $33 billion online in 2001 [Kane, 2002]. However, this may include travel spending, which, if excluded reduces estimates considerably. The figures reported in the text exclude travel spending, which would add another 50% to those figures if included [ComScore, 2002]. Figures for 2002 are from news reports on CNet.) In Europe, figures for online retail sales are less standardized, but one estimate for 2002 put them at about $30 billion, or comparable to the U.S. figures in magnitude. The estimate is from Forrester Research, as reported in the International Herald Tribune (Selby, 2002). Gartner, another IT research firm, estimated somewhat higher numbers (Gartner, 2002), but they seem too high compared to U.S. figures, given somewhat lower Internet penetration in Europe. Higher numbers for Europe may include travel and financial services transactions. See OECD (2002) for a discussion and detailed comparisons. Statistics for online retail sales in Asia are even less reliable, but one can estimate them to be about one fourth to one third of European figures, based on various Internet sources.

B2B transactions may involve products that are indistinguishable from consumer products (computers and office supplies, for example). The only difference is that they are sold to businesses rather than to households or consumers. However, a large segment of B2B transactions involve raw materials and intermediate products, as well as services that are specific to businesses (for example, accounting, human resource management, and, increasingly, information technology services). Although estimates of B2B e-commerce vary widely, it is widely agreed that the numbers are much more substantial than those for B2C e-commerce. The reasons have to do chiefly with the historical scale of IT, compounded by the cost-saving incentives of businesses in competitive markets. As noted in the earlier discussion of e-business, Internet-based e-commerce represents the impact of cost reductions in expanding the size of the communications network, and hence the market, from large firms to small ones, and to households.

There is a conceptual problem with most estimates of B2B e-commerce, which simply add up revenues from a variety of firms. Because B2B transactions involve intermediate products and services, aggregating revenues across businesses will involve double counting. Still, one can use the numbers, and changes in them, to get some idea of the importance of B2B e-commerce. Although the U.S. Census Bureau does not yet estimate B2B e-commerce, private forecasters do. Table 3 presents a range of estimates and forecasts, based on a combination of surveys and guesswork. (One area where differences in estimates can arise is with respect to EDI, which uses private networks and proprietary software, and has been restricted to larger firms. For example, the Boston Consulting Group estimated U.S. EDI for 1998 at $571 billion, dwarfing its estimate of Internet-based B2B e-commerce of $92 billion. At the same time, they projected EDI to grow only slowly, to $780 billion in 2003, while projecting U.S. Internet-based B2B e-commerce to be $2 trillion in 2003.) Although the numbers vary quite a bit, reflecting differences in who was surveyed, and possibly how e-commerce is defined, they are all of similar orders of magnitude, and all project substantial growth. Although actual estimates for 2002 are not available at the time of writing, they were probably substantially lower than the forecasts, given the slowdown in the global economy and in business investment (particularly IT investment). One can safely conclude that B2B e-commerce substantially exceeds B2C in size and is growing somewhat faster on average. Finally, the cost advantages of using the Internet, plus the benefits of being part of a larger network, are expected to cause a relative shift to the Internet from EDI. For example, retailer Sears Roebuck, one of the pioneers of EDI, has an EDI system that costs it about $150 per hour. Internet-based exchange with its suppliers could reduce this figure to as little as $1 an hour. (See Guy, 2000.) Small businesses, in particular, can use Internet-based e-commerce where EDI would not be economical. Furthermore, electronic marketplaces are potentially economically viable using the Internet but not with traditional EDI.

Table 3 Worldwide B2B E-commerce Estimates* ($ billion)

Source	2000	2001	2002 (forecast)	2003 (forecast)
eMarketer	278	474	823	1,409
Forrester Research	604	1,138	2,061	3,694
Gartner Group	433	919	1,929	3,632
Goldman Sachs	357	740	1,304	2,088
IDC	282	516	917	1,573

*Estimates are from surveys; source: eMarketer (2002).

One final category of e-commerce is consumer-to-consumer (*C2C*). Although firms such as eBay have entered the popular imagination through their electronic auctions for collectible or unique items, the value of C2C transactions is quite small. In fact, eBay now handles B2C and B2B transactions as well. Although its own revenues are still only in the hundreds of millions, these revenues represent only its commissions on transactions, which are therefore considerably larger in volume. Again, the total value of a transaction does not represent the economic value added by an activity. If a used item is bought and sold through a dealer, the dealer's profit is a better measure of the value created in the overall transaction, and this is what is measured in the national accounts. Thus eBay's revenues may be a good indicator of the importance of C2C e-commerce. Of course, a used item sold privately (say, in a flea market) will not show up at all in official accounting.

Information Technology and GDP

E-commerce, measured as actual transactions conducted online, represented only a small fraction of the U.S. Gross Domestic Product (GDP) of $10.2 trillion in 2001. However, overall spending on information technology (IT), a more liberal measure of the digital economy, is substantial. Although IT is more than just e-commerce, increasingly the boundaries are getting fuzzy. Networks exist within corporate walls and simultaneously are part of the larger network of the Internet. Telecommunications infrastructure that carries telephone conversations is also used for World Wide Web data. Total IT spending in the U.S. (without any double counting) now makes up about 7% of GDP, or over 700 billion dollars. See Jorgenson (2001) for detailed estimates. Figures from IT market research groups such as International Data Corporation (IDC) are a little higher. This includes hardware, software, services, and telecommunications spending. Of course, this means that there is still a substantial part of economic activity that is not directly related to information technology. However, it is a reasonable forecast that the 7% figure will increase over the next few decades. A slightly different measure, ICT value added as a percentage of business sector value added, yielded an average of close to 10% for 25 OECD countries in 2000, with the U.S. being somewhat above this average, and extremes ranging from over 15% for Ireland and Finland to about 5% for Greece and Mexico. (The 'C' refers to 'communication,' which has become increasingly digitalized, and is counted with IT in many statistical and conceptual exercises.)

One factor working against an increase in IT as a proportion of GDP is the fall in the costs of IT. The empirical regularity observed by Intel co-founder Gordon Moore, and enshrined as "Moore's Law," says that the number of transistors per microprocessor doubles every 18 months. This ability to pack more and more circuitry on tiny wafers of silicon keeps on reducing the cost of processing power. Similar factors are at work in storage and communication of information, resulting in enormous reductions in the overall cost of computing (recall Table 1). To the extent that only expenditures are measured when economic activity is calculated, some of the impact of the digital economy is being missed. For a simple example, a $2,000 home computer is many times faster than a $2,000 home computer available five years ago; it has much more storage capacity; and it can communicate much faster with other computers than was possible half a decade earlier. Even neglecting adjustments for inflation (which would mean that the $2,000 computer now is cheaper in real terms), the same amount of money spent now allows one to work more quickly and effectively, or to enjoy one's leisure more. Thus, the same spending on information technology today gives much more "bang for the buck" than five years ago.

The changes in computing go beyond having more capacity or saving time and encompass activities that were impossible in the past: online games, music listening and sharing, interactive distance learning, and so on. Again, these increased capabilities are not fully accounted for in the standard accounting of economic activity. Of course, these measurement problems have always existed. Innovation that introduces new products or improves the quality of old products has always been difficult to account for. One might argue, however, that IT has accelerated innovation and magnified the problem of underestimating the benefits of certain economic activities (Brynjolfsson & Hitt, 2000).

The problem of accounting for improvements in quality and variety goes beyond IT. If IT can be used to more effectively design new products or improve the design of existing products, then its value will be greater than is simply reflected in spending on IT itself. In other words, better, cheaper, more versatile computers make it possible to have better, cheaper, more varied cars, houses, toys and so on. This is partly what Brad DeLong (see Introduction) means when he says that IT amplifies brainpower. For example, in crash testing new cars, actually crashing a car could cost something like $60,000 each time. This is how it used to be done, with the results analyzed partly by computer. Simulating the entire crash on a computer can now instead be done for close to $100 (Woodall, 2000, p. 5).

Despite the seemingly obvious benefits of IT illustrated above, one paradox that proponents of the new economy have faced has been the lack of hard evidence for these benefits in the overall GDP data, measuring economic activity. A particular problem has been that increased investment in IT did not appear to be improving productivity in any measurable way. The conclusion of skeptics has been that much of this IT spending had no real impact. We turn to this issue next.

Information Technology, Productivity, and Growth

Much of the attention to productivity growth has been with respect to the United States, which has spent the most on IT and which had a prolonged slowdown in productivity growth in the 1970s and 1980s. Early investments in IT seemed to have no countervailing impact to reverse this slowdown. Analysis of the introduction of electric power 100 years ago (David, 2000) suggests that the benefits of innovation can take decades to appear in quantifiable form. This seems to fit with what happened in the last five years of the 20th century, when U.S. productivity growth did increase substantially, just as the penetration of PCs into homes approached 50% and as the Internet took off.

Other work on the recent U.S. experience (Gordon, 2000) suggests that the increase in productivity growth was confined to a small segment of the economy (computers and durable goods). Furthermore, the productivity boost may have been entirely the result of the prolonged economic expansion in the U.S. (productivity rises during economic booms). This skeptical view is supported by studies that find that productivity gains have been low in sectors where IT investments have been high. For example, measured productivity in banking and education actually fell from 1987 to 1997, even though these were the sectors with the highest spending on IT as a proportion of output. Possible explanations for the failure of IT investments to show up as improved productivity include the inability to account for time savings, increased outputs of public knowledge, availability of greater variety, and general improvements in the quality of products and services. Thus, some of the most important benefits of the digital economy could also be the ones that slip through the cracks in measuring economic activity.

Despite these caveats, two recent, comprehensive analyses, by Jorgenson (2001) and Stiroh (2002), suggest that IT has been an important contributor to productivity growth in the 1990s. Jorgenson directly traces this impact to the rapid fall in the prices of semiconductors and of IT products in general, especially after 1994. For 1995–1999, Jorgenson estimates that two thirds of the United States' productivity gains were the result of IT use. Stiroh goes even further, with a detailed, industry-level analysis of the U.S. He finds that the U.S. productivity revival was indeed broad-based, that much of it took place in IT-producing industries, and that industries that were IT-use-intensive also had higher productivity gains. Thus Stiroh's work appears to tilt the scales in favor of a positive assessment of the impacts of the digital economy, at least for the U.S.

Daveri (2000) also reaches positive conclusions with respect to the impact of IT on overall economic growth. His exercise includes 18 OECD countries, and his results for the U.S. are broadly similar to those of Jorgenson and Stiroh. For Canada, Japan, Australia, New Zealand, and 13 European countries, he obtains varied results, with Canada, Australia, New Zealand, the Netherlands, and the U.K. having relatively high contributions of ICTs to growth, with Italy and Spain at the other extreme. Daveri also discusses why his results are more positive than those of another cross-country study (Schreyer, 200), which uses a narrower definition of IT. Note that these studies use data for 1991–1997, and therefore miss the end of the 1990s, when significant growth in IT, as well as overall growth, took place.

IMPLICATIONS FOR MARKETS AND ORGANIZATIONS

This section discusses how the use of IT and the Internet affect the structure and outcomes of markets and the organization and strategies of firms. The consequences of the special nature of information as an economic product are also emphasized.

Information and Markets

The most basic way that the information revolution changes the economics of the marketplace is in making information about all kinds of products and services more widely available. Although basic models of the market system often take it for granted that information about products and about buyers and sellers is abundant, in practice, this is not the case. In fact, one of the virtues of the competitive market system is its ability to economize on the use of information. Textbook competitive markets cannot overcome some kinds of lack of information: for example, the quality of a product may be observable to sellers who provide it, but not to buyers. In practice, many kinds of institutions arise to overcome informational problems: brand names, warranties, consumer protection laws, and so on. Business firms and other organizations may themselves be viewed partly as a response to information problems that prevent the use of markets for all transactions (Coase, 1937). The market economy can be viewed as a scene of constantly shifting attempts to create advantages over competitors by finding opportunities for greater efficiency or satisfying wants more effectively.

In this situation, the availability of greater information about products and services may upset existing institutions, changing the relative costs and benefits of current ways of doing things. How firms organize their own internal operations and transactions can change, and how they interact with consumers can also change. New kinds of firms may arise simply to manage the new possibilities for market interaction. For example, firms may specialize in providing price or quality comparisons to consumers, in ways that were not cost-effective before. Firms may find it easier to outsource manufacturing, because they can maintain closer links with suppliers through regular information exchange. Other firms may provide combinations of services that were impossible or unlikely in the past, combining traditional media content (news, entertainment, and product information) with individual services such as auctions and communications.

From the perspective of consumers, or buyers more generally, the Internet lowers search costs by providing large amounts of product-related information "anytime, anywhere." In addition to information from sellers, buyers can also more easily access information from intermediaries that rank products or make price comparisons, or from other buyers. In consumer markets, this ability to gather information from dispersed buyers represents a major extension of "word-of-mouth" methods of sharing information.

Preliminary work on the functioning of markets online suggests that there are measurable effects of the greater availability of information. A survey by Smith, Bailey, and Brynjolfsson (2000) examines the evidence on four dimensions of price competition in B2C online markets, as compared to traditional transactions mediated through physical stores:

Price Levels: Are posted prices lower online?

Price Dispersion: Are prices of online sellers less spread out?

Price Adjustment: Do sellers adjust posted prices more finely or frequently online?

Price Sensitivity: Are buyers more responsive to price changes online?

Overall, the results of various empirical studies indicate that prices are lower online, there is less price dispersion, and prices are adjusted more often and in smaller increments. All of these conclusions are consistent with the general hypothesis that online markets are more competitive. The results on price sensitivity are mixed and may be related to factors that cannot be controlled for, such as differences in the characteristics of online consumers. The lack of evidence for perfect competition (persistence in price dispersion, for example) can be explained by the continued importance of factors such as trust and reputation and of continued switching costs associated with search that is still costly (though less so) and with investments by consumers in seller-specific information, loyalty programs, and so on.

On the other hand, the studies discussed above examine only posted price markets. Possible efficiency gains exist through the better matching of buyers and sellers in markets that otherwise relied on more costly methods of intermediation. In addition to online auctions of collectibles and other "used" items, job markets, personal-relationship matching markets, and many fragmented B2B markets appear to have taken off precisely because the Internet and Web allow buyers and sellers to match more efficiently, creating higher value matches, as well as lowering costs associated with agreeing on a price and completing a transaction.

Finally, the Internet expands markets across national boundaries and impacts international trade through its ability to increase the quantity and richness of information that is available. The kind of information that the Internet can provide does not remove the potential need for traditional face-to-face interactions, at least when a relationship is being formed. However, it reduces the cost of much of the search process, in terms of where a potential buyer might want to invest more time and money in gathering the information necessary to decide whether or not to transact. Furthermore, once a relationship is established, the ongoing costs of routine information exchange and even transactions are reduced. In this case, the products that are traded may well be traditional physical products; e-commerce does not involve transforming the products, but rather changing the nature of the search and transaction processes. Even in this case, the savings in terms of transaction costs may be substantial enough to significantly boost international trade. For small consumer items such as handicrafts, the Internet and Web provide a cost-effective way for even rural artisans to advertise globally.

Information as an Economic Product

A basic impact of the information revolution is on information itself as an economic good. The best-known example of the magnitude of this impact is what happened to the *Encyclopedia Britannica*. The *Britannica* was the premier encyclopedia, with thousands of pages of articles by renowned experts. It sold for thousands of dollars, priced to recover the cost of a well-paid direct sales force as well as the printing cost for its two dozen volumes. This business was destroyed by the ability to put a reasonably large amount of information on a single CD-ROM, sold for under a hundred dollars, or even bundled in "free" with a home computer system. CD-ROM encyclopedias were inferior in academic quality, but were "good enough" for most people, and the price was right.

The ability to store, process (including copying), and transmit large quantities of digital information at lower and lower costs is now the central characteristic of information as an economic product. A world where the marginal costs of providing information approach zero is a world where businesses that deal in information have to find new ways to provide value to consumers, ways for which they can actually charge enough to recover the costs of producing the information in the first place. In order for them to do this, information has to be bundled, it has to be personalized, and it has to be managed within a service that creates a long-term relationship with the buyer. To the extent that other products and services have also been bundled with information in the marketplace, and that this bundling changes, firms have to create new bundles of value. For example, online retailers try to provide their customers with suggestions and ideas, based on tracking the buying and browsing patterns of individual customers and those with similar interests. This is not dissimilar to the old personalized service in the local store, but can be done on a scale that was earlier impossible.

The ability to process large quantities of information in increasingly sophisticated ways is at the heart of the information revolution, extending not only to the ability to make suggestions about existing products, but also to the ability to design products in collaboration with individual customers and to do it at a large scale. *Flexible mass customization*, the ability to quickly satisfy the diverse wants of large numbers of individual consumers, is one of the possible pillars of business strategy in the digital economy.

The special nature of information (including knowledge) as an economic product also raises concerns for legal definition and enforcement of property rights, which is crucial for all market economies. In the digital economy, knowledge is increasingly important as a driver of economic activity and growth. To play this role, it must be part of the system of economic incentives. Knowledge is legally characterized as *intellectual property* (IP), but this is fundamentally different from physical property and requires its own system of legal definitions and rights. Thus, IT and the Internet amplify not only brainpower, but also the importance of the legal system that governs the economic rewards to brainpower. Furthermore, technological advances that make copying and sharing of information of all kinds incredibly quick and inexpensive are having a major impact on legal issues relating to intellectual property. We give a sample of the issues here.

Briefly, there are four areas of IP law: (1) trade secret law, which protects valuable information, not generally known, that has been kept secret by its owner; (2) trademark law, which protects words, names, and symbols used by manufacturers and businesses to identify their goods and services; (3) patent law, which protects new, useful, and "nonobvious" inventions and processes; and (4) copyright law, which protects original "works of authorship." All these concepts of intellectual property predate e-commerce by centuries, having developed along with capitalism and the industrial revolution. The information revolution provides some new challenges in this arena, especially in the area of copyright law, though patent law also has been stretched by the information revolution and the rise of e-commerce, and issues of trademarking have arisen with respect to basic online activities such as the use of hyperlinks on the World Wide Web.

Until a 1981 Supreme Court case, the United States Patent and Trademark Office was reluctant to grant patents on inventions relating to computer software. They reasoned that patents could not be granted for scientific truths or mathematical expressions of it, and viewed computer programs as mathematical algorithms, which are not patentable. In the early 1990s the courts clarified that an invention including software was patentable if the software controlled real-world processes, or numbers that represented real-world concepts. The commercial use of IT fits this description in ways that were unimaginable in 1981, and software patenting has exploded in the last few years. E-commerce software patents include broad (many argue, too broad) ideas such as "one-click buying" and "reverse auctions." In addition, the increased use of IT to govern internal business processes such as inventory control and workflow has also generated numerous software patents.

Copyright law differs from patent law, in preventing the copying of the expression of ideas, but not of ideas themselves. Therefore, copyright law does not protect against someone stealing an invention or someone else independently creating a similar expression. However, copyright does provide some protection against "nonliteral infringement," such as the near duplication of screen displays. The primacy of information products, or "content," in e-commerce, and the ease with which digital information can be copied and distributed have made copyright law for the Internet a major area of concern.

Market Structure and Strategy

The nature of information, where marginal costs of delivery are small and fixed costs of production may still be large, is often alleged to favor *winner-take-all* outcomes. This is reinforced by the benefits of creating and controlling large networks: consumers will presumably join the network that is already large, to get the highest benefits of being able to select a transaction partner from a bigger pool. Thus buyers will look on eBay, because it is the largest online auction site, whereas sellers will list there for the same reason. The size advantage associated with these *network externalities* keeps reinforcing itself. On the other hand, if individuals can simultaneously participate in more than one network, and if a smaller, competing network can offer a price break to attract them, then the advantage of the winner will be limited, and taking all may not be feasible.

Focusing on information leads to a different emphasis in terms of the economics of business strategy. Pure price competition has to be less important than competition along an array of different dimensions, because price competition in a world of high fixed costs and low marginal costs will lead to firms losing money. For example, the Bertrand model of price competition suggests that firms with homogeneous products will be pushed toward pricing at marginal cost, making it impossible to recover their sunk fixed costs. Pricing itself becomes more complex, with greater possibilities for differentiating across consumers and over time, and is joined by marketing, advertising, product differentiation, and ways of raising the costs for customers to switch to competitors. All these dimensions of strategy exist independent of the Internet and e-commerce, but they become more salient in a world where information technology operates throughout the stages of production (what business strategists call the "value chain"), as well as in the interaction of buyers and sellers in the marketplace. The ability to gather information about buyers and sellers, to organize this information, and to analyze it creates the potential to integrate the different dimensions of strategy in ways that were not possible earlier.

One can distinguish between two separate aspects of firms' strategies, and how they can change as a result of information technology and the Internet. First, firms can create more value, by meeting consumer wants more effectively. Thus, being able to elicit consumer preferences more directly and at lower cost potentially allows firms to design products and services that create greater consumer surplus. The design, manufacture, and delivery (in the case of digital products such as content or software) of these products can also be more efficient, through the use of IT within the firm and in its communications with its suppliers (its "supply chain"). Furthermore, consumer tastes can not only be better matched on average, but also through greater customization, where products and services can be designed and manufactured to precisely meet individual tastes, as specified by the customer online. This customization is particularly valuable for information products, such as content, and also for very personal items such as cosmetics and beauty products. Again, the use of IT internally and through the supply chain allows the more flexible approach to production required by mass customization. Where the products and services are digital, product differentiation can also include bundling in new ways. For example, online portals provide bundles of content and services that are not matched by traditional media companies or content aggregators such as newspapers and magazines.

The second aspect of business strategy is value capture. In this case, the greater ability to gather information about buyer preferences through tracking online behavior—including observational and information-gathering behavior as well as buying patterns—allows pricing to be more finely tuned, so that prices are closer to buyers' maximum willingness to pay. Thus, the ability to potentially use online interactions to gather and analyze buyer information allows greater value capture through various kinds of price discrimination. In such cases, product differentiation may be an important supporting strategy for value capture, in addition to its role in value creation. Product differentiation can reduce the ability of competitors to undercut a price discrimination strategy. The ability to vary prices more easily and often in online markets may also be used as part of a price discrimination strategy, just as seasonal sales are used in traditional retailing. Bundling of products is another example of how firms may tailor products to capture greater value from buyers, though it is not always used for this purpose.

A slightly different way of analyzing business strategies in e-commerce is to think of online shopping as offering a bundle of three different categories of goods and services: the products themselves, the service of time in physically assembling the order and delivering it, and an information service that is made possible by the infrastructure of the Internet and the World Wide Web. The digital information processing and communication capability of this infrastructure is what makes the bundling of the other two services economical. In the case of many physical products, such as groceries, the service of assembling the order and delivering it would not be cost-effective without it. The nature of the information service is what clearly distinguishes catalog shopping for physical products from online shopping. In the case of shopping in a store for physical products, the bundle offered to the buyer is more different, because in store shopping the buyer bears the costs of "last-mile" fulfillment, i.e., bringing the product home. In the case of digital products and services, the differences are greatest as compared to traditional methods, because the product itself can be delivered over the same infrastructure that is used for ordering. As one might expect, online transactions for digital products and services provide greater potential for changing ways of doing business. In the case of physical products, online transactions must still rely on physical delivery using conventional transportation methods.

Changes in Firm Organization

The use of digital technologies has several different possible implications for the organization of firms. A simple hypothesis is based on the transaction cost theory of the firm (Coase, 1937), which argues that firms exist to overcome transaction costs associated with market exchange. If using IT and the Internet reduces market transaction costs, by increasing the speed and richness of information flows, then firms will be replaced by markets. Although this argument has merit, the use of IT within firms also improves, so the opposite case can be made, that firms are able to become larger as a result of information technology. Certainly, the globalization of firms in areas such as sourcing inputs, or serving different geographic markets, appears to be aided by the use of IT, and the Internet in particular.

One reason that firms will not disappear is that factors such as the need to control complementary assets, especially different kinds of skilled labor or human capital, are a reason for the existence of firms that is not removed by improved information flows. In general, one can argue that efficient incentive provision—for current effort as well as investment-related activities—often requires the use of hierarchical organizational forms, rather than pure reliance on market transactions.

Nevertheless, two trends are evident, and both appear to be accelerated by the developments in IT and communications. First, the growth of markets, which has been driven by lower transportation costs and trade barriers and by higher incomes, as well as dramatically improved communications, permits greater outsourcing, and therefore some decrease in vertical integration of firms (Brynjolfsson & Hitt, 2000, p. 36). This is an example of Adam Smith's classic maxim that the division of labor is limited by the extent of the market. Contract manufacturing is an important example of this phenomenon, where the supply chain becomes more geographically dispersed as well as being more divided among different firms.

Second, even when they do not outsource, firms themselves are becoming more decentralized, as they incorporate IT into their internal business processes. For example, Brynjolfsson and Hitt (2000) summarize a study of large firms that found that greater internal levels of IT use were associated with "increased delegation of authority to individuals and teams, greater levels of skill and education in the workforce, and greater emphasis on pre-employment screening for education and training" (p. 35). Other studies indicate that the IT investments of decentralized firms are more productive and have such firms have higher market values, suggesting that market pressures will favor greater decentralization in the long run.

From the Chandlerian perspective of scale and scope (Chandler, 1990), the above factors pull in different directions. Firms can become more specialized, because their ability to serve geographically dispersed markets is enhanced by the Internet. For example, niche retailers can potentially sell globally, as their marginal costs of reaching new customers are substantially reduced. Trading off scope for scale means that the overall impact on firm size is indeterminate. In general, however, the lower cost of entry into online business—a Web site is cheaper to set up and operate than a physical store—suggests that smaller firms will thrive. At the other extreme, large firms can expand their scale and scope more easily using online presence and interactions, and especially in the case of digital products and services, offer very large ranges of offerings. Therefore one plausible prediction is that the size distribution of firms will become more spread out, with firms in the middle losing out to those at either end (e.g., *The Economist,* 2002).

Returning to globalization, an important consequence of digitalization is the ability to deliver digital products and services across national boundaries, using the Internet. A related issue is the impact of greater information availability, which expands market reach. In both cases, the ability to complete transactions online is an additional feature, though not an essential one. Skills provision and financial services provision are examples of electronic delivery across national boundaries. Small IT projects may be handled entirely online. In other cases, there is typically some face-to-face meeting (high-bandwidth information exchange) and agreement, followed by more routine exchanges or deliveries of services that take place online. The outsourcing of software development from the developed world to countries such as India and Israel represents an important example of such activities. In another example, retail financial services may be conducted entirely online across national boundaries. An investor in Europe trading in U.S. stocks can fill out the application forms, transfer money into a U.S. account, and trade without using paper or moving from his or her screen. Commissions earned by the online brokerage then represent a payment for services that are international.

A final aspect of changes in firm organization in the digital economy is related to the new kinds of products, services, and delivery methods that are possible. In many cases, new types of digital economy firms are essentially new intermediaries, providing expertise or reputation, or economizing on transaction costs. The following classification of firms is in terms of how they combine information, time services, and physical goods and services in new ways in their offerings to customers.

Information request services provide general information on demand through search engine technology, a very basic aspect of the World Wide Web.

Content providers package particular sets of content, rather than enabling general searches for any kind of information, and represent a new kind of media firm.

E-tailers are a carryover from the world of physical retailing, including catalog sales, offering a different bundle of physical products, time, and information services than traditional retailers.

Exchanges and brokers operate electronically without physically bringing together buyers and sellers or the objects being sold and act as "market-makers" or "market-expanders."

Community creators provide online mechanisms for communication and for collaboration.

Infomediaries focus only on providing information pertaining to potential market opportunities and are potentially neutral with respect to buyers and sellers.

Portals are aggregators, or diversified firms, combining the six types of firms above.

Infrastructure providers make and sell the hardware, software, and services that allows other firms to process, store, and send the information that makes their businesses possible. These include communications equipment, Web hosting equipment, connectivity services, hosting services, and many kinds of software developers.

As the seventh category itself suggests, there are many overlaps and combination possible in these functions within different digital economy firms.

GOVERNMENT POLICIES

Any market economy relies on government regulation to maintain a framework of laws and property rights that allow production and exchange activities to occur in a stable environment. The rise of the digital economy has several impacts on government management of the economy and the legal environment within which it functions. We briefly examine several of these impacts in this section.

Contracts

Traditional commercial transactions are governed by well-defined laws and legal precedents. In particular, there is a clear concept of what constitutes a legally binding contract. Paper documents with signatures are the norm for contracts. Sometimes, notarization to authenticate the signatures is required. There are also disclosure requirements and escape clauses, particularly for consumers transacting with businesses. The legal issues in e-commerce contracting revolve around how identities can be verified, signatures can be authenticated, and content can be protected when information is stored, processed, and transmitted electronically.

Security of content is provided by encrypting (encoding or scrambling) that content. Encryption is an old idea, but information technology permits the use of more powerful mathematical algorithms and therefore more secure encryption. Security is different from integrity of content. Authentication of content integrity and of the sender's identity use mathematical ideas and technology similar to those for encryption. In physical markets, checking IDs or signatures is a well-established procedure. Even over the telephone, ID can be checked by providing certain information that authenticates identity (the last four digits of a social security number, for example). Digital signatures achieve similar goals for electronic communications: they can identify the sender and also authenticate content.

The growth of e-commerce itself will depend on the ability of two parties to complete a contract, sign it in a legally binding manner, and transmit it, all purely electronically. The technology is not the stumbling block to this goal. The issue is one of clear, generally agreed-on legal standards. For example, in the U.S., in June 2000, the President signed (electronically as well as with the traditional pen) a bill that sets these standards and will make it possible for businesses to close deals with electronic contracts and digital signatures. Similar legislation has been passed in other industrial countries.

Electronic contracts are especially attractive for B2B transactions. However, the possibility of electronic contracting will probably require some updating of rules that protect consumers. Because a large percentage of households are still not online, presumably consumers should still have the right to have all contract details and subsequent pertinent notices on paper, without financial penalty. This makes the cost saving that electronic dealings offer to businesses harder to achieve, but presumably these will come with time, as electronic communication become cheaper and more ubiquitous. The technology of digital certification will also have to become more widespread and widely understood for it to serve the everyday needs of B2C transactions.

Intellectual Property

Phenomena such as the widespread copying of digital music, using file-sharing software available from many different commercial and noncommercial providers, have heightened concerns about enforcement of copyrights on the Internet. Some have called for more stringent copyright laws, and, in the U.S., the Digital Millennium Copyright Act (DMCA) of 1998 did introduce some additional protections in the guise of updating previous law to cover new technologies. However, it may be that existing laws are quite sufficient, as court rulings against Napster and others suggest, as long as the interpretation of the laws is strong enough.

The DMCA included penalties for cracking protections designed to protect unauthorized copying. However, the legal application of the DMCA has had an effect on free speech, with examples such as a professor of computer science forgoing presentation of a research paper outlining methods of overcoming copy protection, in the face of a threatened lawsuit. Lobbying by industry groups that have ownership interests in copyright has also motivated potential U.S. legislation that requires copy protection to be hardwired into consumer electronics items. In such cases, the doctrine of "fair use" in copyright law also appears to come under attack. In the U.S., the DMCA was complemented by another law, extending copyright protections by 20 years. Although European copyright laws have not tilted so much against users, the U.S. is a global leader in the production of copyrighted material such as music and films.

In the arena of patents, it has been court interpretations rather than new legislation that have increased the scope of patent law, with hundreds of relatively broad software patents being granted in recent years. It has been suggested that a new category of patents, with a shorter lifetime, be granted for software, but this is likely to create further problems for assessing patent applications. It also misses the real problem, which is that of inadequate resources in the U.S. PTO. Again, the U.S. is the largest market for intellectual property, and U.S. patent rules are disproportionately significant in the global context. In general, the apparent broadening of both copyright and patent protection can be seen as a response to a situation where intellectual property is increasingly important for creating economic value, but also easier to copy or imitate. Thus, it is a symptom of the digital, information, or knowledge economy.

Privacy

The digital economy, with its greater flows and tracking of information, raises serious concerns about privacy. Information about consumers allows firms to increase profits through various kinds of price discrimination. At the same time, some consumer information can help firms to tailor their products more effectively to consumer preferences. Privacy concerns often center on how the information is collected—do consumers realize that their behavior online is being tracked, or that cookie files are being deposited on their computers?

Further issues arise with respect to who else may properly see the information collected. A customer may not mind a seller tracking his or her buying habits in order to serve him or her better, but may not want the firm to sell that information to other firms. A related issue is the use of such information for mass marketing e-mail, commonly known as "spam." Employees, too, may find that their electronic communication and Internet browsing from work can be monitored by employers with great precision and intrusiveness. Finally, there are all kinds of information that various public agencies collect. Often such agencies are required to make that information available in response to requests from members of the public. However, making that information available online makes access much easier and broader than other forms of availability, with possible negative consequences.

The U.S. Congress was actively considering Internet privacy legislation after a report from the Federal Trade Commission in mid-2000 indicated that self-regulation was not working uniformly, with some Web sites proving resistant to privacy concerns. One stumbling block for legislative agreement was the simple issue of whether businesses should be required to explicitly get consumers to "opt in" to allow their personal data to be used beyond the specific transaction or relationship, or whether the burden should be on consumers to explicitly "opt out." Businesses naturally favored the latter approach, which gave them much more leeway. Business-supported groups have tried to argue that privacy legislation would be inordinately costly, and also that consumers do not care enough for it to be worthwhile. On the other side are groups such as the American Civil Liberties Union and Consumers Union that want stronger safeguards against data-collection practices that do not involve explicit consent.

The aftermath of September 11 has tilted the scales against strengthening of privacy, because security has become a much greater concern. Therefore, it seems unlikely that any meaningful Internet privacy legislation will be passed any time soon in the U.S., leaving its online privacy laws some way behind those of the European Union, which protect consumer privacy more stringently.

Antitrust and Regulation

Antitrust laws are designed to prevent monopolization of industries, as well as anticompetitive practices such as price fixing. Does the digital economy require modifications in the government's enforcement of antitrust policy, or even a change in the antitrust laws themselves? There are three key areas in which the proponents of a modified approach to antitrust make their points. First, there is the argument that antitrust enforcement must account for the impacts on future innovation. The second argument is that network externalities and the economies of scale associated with information goods make monopolies more likely or more natural ("winner takes all"), and hence they must be tolerated—otherwise there will be no market or unnecessarily high costs. The third argument is that complementarities in information goods require firms to cooperate in ways that might seem collusive by more traditional measures.

Considering the first of these, the increased importance of technological innovation, and of patenting, certainly makes these variables more important in a firm's business strategy, but it does not, by itself, imply that antitrust law has to change. Firms can profitably innovate, using patent law, without having to run afoul of antitrust law. Second, network effects are demand-side economies of scale, which can interact with the usual cost-side economies of scale to promote market dominance. If information goods are subject to both kinds of economies of scale, one might have to be resigned to more case of "natural" monopoly, driven purely by the structural characteristics of the market, rather than any illegal behavior. However, the importance of such natural monopolies is probably overstated, and their persistence is unlikely if the protection for patents is not too stringent. (Arguments relating to network externalities as well as to innovation have been made in the Microsoft antitrust investigations, both of which concluded with out-of-court settlements. One can argue that any monopoly that Microsoft might have is related more to traditional anti-competitive practices such as the nature of its contracts with distributors, rather than any special features of the digital economy. In the European Union, there is an ongoing antitrust investigation of Microsoft.) Finally, technology goods have to work in systems and are characterized by strong complementarities. This often requires firms to collaborate in research and development, as well as in production and installation. However, as long as single firms, or firms acting together, do not engage in behavior that reduces competition or harms competitors, there is no violation of antitrust laws. What is needed is not a reform of the laws, but simply enforcement by government officials who understand technology well enough to sort out different kinds of cooperative behavior among technology-oriented firms.

Laws to manage privacy issues and antitrust laws can both be considered as major examples of regulation of private economic activity by the government. They are not the only ones. There are specialized regulations for different sectors of the economy, such as financial services and telecommunications. There are also regulations meant to protect certain groups, or to control certain types of activity. For example, pornography and hate materials are controlled, and gambling is a heavily regulated activity. All these forms of regulation are affected by the Internet. Much of the problem is simply in the freedom with which information can be disseminated and shared on the Internet. The location of activities is also a problem: for example, online gambling can escape controls that are designed to operate within geographic jurisdictions. Controls on forms of payment, using the major credit card companies, for instance, can be a way to solve the jurisdictional problem. The credit card companies cannot afford to be partners in crime. Here the law needs to change to deal with ability of digital activities to escape the requirement of meeting in a particular place.

In the case of financial services, the issues have to do with the quantity and the veracity of information that is made available. The Internet makes scams easier to implement in some ways, but the basic laws do not need to adjust. In the case of telecoms, regulatory issues are centered on the technological changes that digitalization has introduced, making more effective competition possible. The U.S. Telecom Act of 1996 began the process of moving regulation into the modern era. Some regulation is still needed because parts of the network are still potential monopolies. Local telephone companies—the so-called Baby Bells—in particular, have maintained their strongholds. Regulations to allow interconnection to parts of the Baby Bell networks by competing carriers have not really enabled the latter to gain significant market shares. While protecting their traditional markets in voice communications, the Baby Bells have been lobbying for the ability to compete more freely in markets for data communications, that is, the underpinnings of the Internet.

International Trade

Countries often have customs duties or tariffs on imports, and these clearly affect international trade. They may also use quantitative restrictions on the entry of certain goods and services. An extreme case of this would be a total ban. Various reasons for restricting international trade do exist: government revenue raising, control of undesirable materials, protection of some domestic groups, and so on. Individual country choices made without coordination may lead to outcomes that are worse for all countries. Therefore, in order to try to achieve some measure of cooperation that can improve outcomes, trading nations use the World Trade Organization (WTO) to frame and enforce rules for international trade. Having such an organization does not remove conflicts, but it provides a mechanism for more orderly handling of disputes, as well as a clear set of "rules of the game."

The current provisional WTO agreement is that trade restrictions should not apply to electronic transmissions over the Internet. In the example of a European purchasing U.S. stocks or a U.S. hotel room while on vacation, this leads to a symmetric treatment of online and offline transactions. In other cases, however, there is a difference. Thus, purchasing a large number of music CDs from another country might be subject to a customs duty (small purchases from abroad are exempt in the U.S., though not in many countries), but obtaining the same quantity of music as electronic files would escape the import tariff. This is superficially similar to the issue of sales taxation within the U.S., but here we are looking across national borders, and in the U.S. sales tax case, the tax must be paid if the transaction is in-state rather than across states. Hence the two cases are somewhat different, though broadly related in spirit.

A further issue with respect to information products in particular is the blurred line between goods and services. For example, software development is a service that is now offered across national boundaries. Also, software is typically licensed rather than sold, and leasing software is common. Because traditional services, such as those in the financial sector, have been treated under a separate set of rules (the General Agreement on Trade in Services, or GATS), which is newer and more restrictive than the rules for goods or products, there is disagreement as to which set of rules should govern software. Countries such as the United States, which are producers and net exporters of information and related services, argue for the application of the rules for conventional trade, rather than the GATS.

WORK, PLAY, AND COMMUNITIES

Work is a large fraction of our lives. It is useful to recognize how drastically work was altered by the industrial revolution, the introduction of factories, and the rise of large corporations. Cottage or home production became relatively insignificant, as mechanization and economies of scale caused work to be concentrated in factories and offices. Now IT has loosened the bonds of location, making work once again more flexible for many.

Location of Work

Several trends have driven the changes in work. First, the increase in the importance of services relative to manufacturing, and of the information economy in general, reduced the proportion of factory jobs. Next, the falling cost of computing power allowed many tasks to potentially be performed at home, rather than in the office. Most importantly, the Internet has removed the isolation of the home worker. Communication and collaboration can take place among workers in different locations. Physical proximity for many jobs becomes only a part-time requirement.

Some of the change is just in freedom of location. However, as we discussed in a previous section, some of the change is in the nature of the firm itself, sometimes reducing the bonds that define a firm. Employees in such cases can become independent contractors, with their own capital (human and physical), almost harking back to the preindustrial era of home production.

Another change that comes from the falling cost and increasing versatility of communication over the Internet is in the global distribution of work. The customer in the U.S. may have a telephone query answered by someone in Ireland, India, or the Philippines. Computer programming or program testing assignments may be sent over the Internet wherever people with those skills are available, to be completed and sent back the same way. The supply of some kinds of skills becomes global rather than local or national.

There is also a time dimension to this geographical dispersion of work. Time differences across the globe allow 24-hour customer service to be more cost-effective. In areas such as software development, they also allow global shift work. For example, two project teams in the U.S. and India can collaborate to achieve an almost continuous workflow, utilizing the night-and-day time difference between the two countries. However, the ubiquity of digital communication devices means that the notion of times and places where work does not intrude is severely eroded. A knowledge worker may find she is expected to access her e-mail via a wireless handheld computer at home, on vacation, and in general outside the normal place and time of work.

Leisure Activities

Leisure activities in the industrial age have been shaped by scale and specialization, just as happened in the case of work. Sports and the performing arts have become large-scale spectator or audience events. Radio and television introduced broadcasting, creating mass markets for entertainment while removing locational barriers. Recording technologies expanded the scope for listening to music or watching movies, while introducing greater choice into consumer decisions. All these developments in people's leisure activities are enhanced and broadened by the Internet. Inexpensive digital recording and transmission of music and video provide a range of options unimaginable in the past.

Perhaps the greatest impact of the substitution of bandwidth for being in the same place has been in game playing. One can play traditional games, such as bridge and chess, over the Internet, with opponents and partners who may be anywhere in the world. More widespread is the enormous expansion of online game playing. Computer games become virtual worlds where individuals act out their fantasies and try out strategies. Game characters take on lives of their own, becoming valuable commodities themselves for game players who want to win any way they can. At one level, the interaction is no different from that of board games that have been played for hundreds or thousands of years, that of stylized competition. However, the complexity of such games has increased exponentially, and the Internet has demolished distance in creating communities of game players.

Just as IT has allowed work to intrude into leisure spaces, it has also allowed the reverse phenomenon to take place. Workers who sit at a computer may play solitary games. If they have Internet access, they may engage in all kinds of leisure activities, including browsing news and entertainment content, shopping, and chatting as well as game playing. Hence, employers may respond with new kinds of monitoring and restrictions, as was discussed earlier in the context of privacy.

Online Communities

From online game players to members of a project team designing a software program, people at work and play form communities based on shared goals or interests. Information technology allows these communities to be freed from the need to share a physical space. Interactions take place on computer screens instead of face-to-face, but the interactions that are possible in cyberspace are getting richer and richer, allowing more and more communities to form. In particular, work collaborations of increasing complexity are becoming possible on the Internet, with simultaneous or asynchronous participation in activities involving product research, design, and development.

Work and play are not the only glue that binds communities. Any kind of shared interest can provide the impetus. Sufferers from a disease, fans of a rock star, or collectors of sports memorabilia can join together to exchange information, ideas, and experiences over the Internet. These communities may provide commercial opportunities, because they provide access to that ever-scarcer commodity, "attention," but they may also lead to more profound social changes. Political organization, in particular, takes on a new dimension, perhaps expanding the scope of democracy, while definitely changing its nature. Possibilities exist for Internet-based comment, feedback, and even voting by citizens in communication with their governments.

Perhaps the most remarkable change of all is how, in just a few short years, the majority of people in the industrialized world have come to take for granted so many possibilities that alter their lives and may reshape the social fabric. The Internet, at its core, is a very human-centered development. This may seem somewhat paradoxical. The underlying information technology is complex and abstract. But the Internet and its associated technologies allow people to be creative, to express their individuality, and to communicate and connect with other individuals in new ways and with new freedom. This extension of basic human capabilities, amplifying humanity and not just brainpower, is why the Internet excites so many and inspires sometimes-overstated rhetoric.

CONCLUSION

The digital economy is much more than simply online shopping. It involves a fundamental transition that has been taking place for over two decades and that is based on the rapidly falling costs of processing, storing, and transmitting information in digital electronic form. Some of this transition was obscured by the dot-com mania, which often focused on using the Internet as a marketing and retailing channel. In fact, the digital economy includes this as just a small part. The internal organization of firms is changing, their nature is changing, the kinds of interactions that are possible between different economic agents are changing, and the locations of different activities are changing. Measures of the digital economy can understate or overstate the current impacts, but they do seem to emerge in recent academic work, and the impacts appear to be increasing.

GLOSSARY

Bandwidth Most often informally used to refer to the speed with which digital data can be transferred over a specific connection (telephone wire, cable, optical fiber, or wireless). It also has a more precise technical meaning, with similar implications, e.g., 10 Mbps, or 10 megabits per second.

Cyberspace All electronic interactions and data, especially those that are mediated by the Internet. The term was coined by William Gibson in his science fiction novel *Neuromancer*.

Digital divide A situation where particular socioeconomic groups have access to the Internet and information technology at levels that are substantially higher than other groups.

Digital economy A term that emphasizes the importance for the overall economy of information that is stored, processed, and exchanged in digital electronic or optical formats.

E-business A subset of e-commerce, including all electronically aided transactions and activities of businesses, among which are internal accounting, inventory control, and communications.

E-commerce Short form of electronic commerce; refers to doing business electronically, based on the electronic processing, storage, and communication of information, and includes activities that provide the enabling physical infrastructure and software.

E-commerce interaction types: B2B, B2C, C2G, C2C, B2E Acronyms for different interactions, implicitly, but not necessarily, electronic, between businesses, consumers, governments, and employees.

EDI Electronic data interchange—the use of proprietary software and leased telecommunications lines for communication between firms, typically at different points of the value chain.

E-tailing Electronic retailing.

Flexible mass customization The ability to quickly satisfy the diverse wants of large numbers of individual consumers.

Information economy A term that emphasizes the importance for the overall economy of all kinds of information, including entertainment, news, market and business information, research, and personal communication.

Information revolution A term that emphasizes the dramatic effects of the steep fall in the costs of processing, storing, and communicating information as a result of advances in information technology.

Information technology Any aspect of technology, including hardware, software and services, that involves data in digital electronic or optical formats, including technologies for processing, storing, and transmitting such data.

Intellectual property Useful inventions, original expressions of ideas, and names or symbols used in business, the ownership of which is protected by various categories of law (trade secret, patent, copyright, and trademark).

Knowledge economy A term that emphasizes the importance for the overall economy of all kinds of knowledge, including various types of expertise, skills, and understanding of particular markets, with an implicit emphasis on mathematics, science, and technology.

Moore's Law An empirical regularity, described by Intel co-founder Gordon Moore, that the processing power of microprocessors doubles every 18 months; therefore an indicator of the rapid pace of innovation in the digital economy.

Network externalities A situation where the value of being part of a network depends on the number of other members of a network—typically this value is positive. For example, if the value of a network with n members to an individual depends on the number of possible connections in the network, it is proportional to $n(n-1)/2$ ("Metcalf's Law"), and the marginal value of an additional member is proportional to n, the network size.

New economy A term that encompasses the ideas behind the terms "digital," "information," and "knowledge" economy, but also sometimes connotes that the working of the economy is changed, either because information is a good with high fixed and low marginal costs, so competition is less stable, or because faster information flows reduce adjustment times and hence swings in the economy.

Online Being actively connected to, or being a user of the Internet (and possibly other electronic networks).

Supply chain The portion of a firm's value chain that involves its suppliers.

Value chain A schematic representation of a firm's stages of production, possibly including activities that take place upstream or downstream of the firm's own activities. Examples of value chain stages include inbound logistics, production operations, outbound logistics, marketing and sales, and after-sales support.

Winner-take-all A market situation where the leader dominates because high fixed costs and low marginal costs of producing information favor one or a few large firms, or because users of a network get much higher benefits when the network is larger.

Digital Identity

Drummond Reed, *OneName Corporation*
Jerry Kindall, *Epok Inc.*

WHAT IS DIGITAL IDENTITY?

Digital identity means many things to many people. In general, the term refers to the class of technologies, standards, services, and applications that enable a real-world identity to be represented digitally on a network and that manage the data related to the identity (its *attributes*) and control access to various network resources. Technically, any addressable resource on a network has identity; to many people, though, the term is most meaningful when describing how an individual user's personal identity and personally identifiable data are modeled, represented, controlled, and shared on the network.

Digital identity touches on issues of trust, privacy, security, and interoperability that are becoming vital to the evolving Internet. As e-commerce and e-business become everyday realities, consumers want to control information about themselves, and at the same time to be able to share it with trusted parties. For their part, businesses want to serve consumers better by knowing more about them, while needing to comply with consumer privacy concerns and regulations. And from a technology standpoint, the rapidly growing Web services infrastructure requires a way to authenticate users that is not tied to network location or device. The solutions to these problems are all aspects of digital identity.

DIGITAL IDENTITY AND PRIVACY

Public awareness of privacy issues has been steadily increasing over the past decade, in large part because of the increasing use of the Internet and its ability to permit data sharing on a scale never possible before. Telemarketing, junk faxes, and unsolicited bulk e-mail ("spam") are small but annoying signs of the growing erosion of privacy. Consumers have begun to push back, not only by calling for legislation but by demanding products and services to protect their privacy. A good example is telephone services. Phone companies used to offer only one privacy service (an unlisted phone number). Now most offer Caller ID, which lets subscribers see who is calling before picking up the phone; Caller ID Blocking, which lets subscribers keep people who have Caller ID from finding out who they are; and finally Anonymous Call Blocking, which automatically rejects calls from people who use Caller ID Blocking.

A more serious problem is the relatively new crime of identity theft, in which an individual's personal information (usually stolen from a wallet or snatched from the mail) is used to impersonate him or her for the purposes of fraud. For example, an identity thief might obtain enough personal information to obtain credit and write bad checks in another person's name and then leave him or her stuck with the aftermath. Victims of identity theft often face years of frustrating harassment from creditors as they try to clear their records. Ultimately, every law-abiding citizen pays the price for these losses.

In the United States, civil libertarians have long been sounding the alarm about the amount of personal information stored in government databases. After September 11, 2001, many Americans have said they are willing to sacrifice some privacy to feel more secure, but to others, the existence of government surveillance systems such as Carnivore and Echelon points to an Orwellian future. Of what worth is security, they argue, if it comes at the cost of important Constitutional protections? Some also fear that safeguards against misuse of information stored in corporate databases are insufficient. They warn that employers, for example, might eventually use medical records to deny employment to those with unfavorable health conditions (or, as DNA testing becomes more precise, even to those with the *potential* to develop such conditions) by "partnering" with health insurers and hospitals to share this information.

These concerns have spurred a flurry of legislative action internationally. In the United States, the Gramm–Leach–Bliley Act (GLBA) makes financial institutions provide their customers with a written privacy policy, regulates how they can share their customers' personal data for marketing purposes, and requires them to allow consumers to opt out of marketing from nonaffiliated third parties. Also in the U.S., the Health Insurance Portability and Accountability Act (HIPAA) is intended to guarantee security and privacy of personally identifiable health information, while requiring that standard data formats be used in order to allow these data to move with the patient to competing healthcare and insurance providers. In the

U.K., the Data Protection Act requires firms to tell consumers upon request exactly what personal data about them the firms have in their files and also establishes guidelines for collecting, storing, and sharing this information. The European Data Directive establishes a clear and stable regulatory framework for the movement and storage of personal data for the entire European Union.

What impact will digital identity technology have on privacy issues? The long-term effects of any new technology are impossible to predict, but there are reasons to believe that many of these effects will be positive. Digital identity technologies allow individual users to set the terms under which their personal data can be shared with others and for what purposes these data may be used. Unless the requester of the data agrees to respect these terms, the protocol does not allow the data to be shared. In this scenario, digital identity provides a way for organizations to demonstrate compliance with privacy regulations. In fact, in the coming years, the authors believe that a key role of government will be to make agreements between digital identities legally binding, which has the potential to strengthen consumer privacy significantly.

The other, potentially more troubling, side of the digital identity coin is the technology's ability to link data stored in numerous databases into a coherent "virtual" view of an entity. Corporations and governments have collected thousands of pieces of information about every customer and citizen. Currently, this information is in thousands of separate databases, which makes it a limited threat to privacy. Digital identity has the potential to unify these databases not just within a single organization, but also across trust domains—meaning that the data kept about consumers by different companies might eventually be compared and coordinated. This sounds scary, but the technical and business challenges involved in this kind of consolidation of personal data are not trivial, and digital identity is hardly a "silver bullet" for solving them. Clearly, though, there is a vital role for government here, with legislation requiring companies to tell consumers upon request what personal data they keep, where they come from, and who else they will be shared with being a *minimum* requirement. An even stronger solution would be to require any data held by a corporation about an individual in a digital identity be electronically accessible and editable by the individual who is the source of the data. However, this might be achieved even without legislation if consumers demanded that the companies they dealt with simply subscribe to the data stored in their personal digital identity using permission-based links, rather than keeping their own private copy of the information. This is an area in which consumer lobbies and civil liberties watchdog groups could have significant leverage by educating the public on the issues—and now is the time to start.

The government, in addition to regulating digital identity, also will become a significant user of this new technology. In the United States, the Federal government alone maintains thousands of databases in its hundreds of agencies; each of the 50 states (plus territories) also has a government, and there are thousands of county and municipal governments below them, each with its own databases about the citizenry. Consolidating all these bits of data could save billions of taxpayer dollars and enable a new level of government effectiveness and service. In particular, the United States's new Homeland Security department is intensely interested in digital identity technology as a means of allowing the country's various local, state, and Federal intelligence, law enforcement, and emergency response agencies to aggregate the data each agency has, until now, maintained separately. Homeland Security has already stated their intent to aggregate information collected by other parties (such as library checkout records or bookstore purchase records) as well.

For obvious reasons, this new capability worries civil libertarians deeply. In itself, the deployment of digital identity technology for law enforcement and intelligence is not particular cause for alarm; with 280 million people living in the United States, it is unlikely that a given individual's information would come under scrutiny without good reason. The more important issue is defining what constitutes "good reason." Once the information has been aggregated, it can be "mined" to look for suspicious patterns, and the individuals identified could then have their activities tracked electronically. (Of course, data mining can be done without digital identity technology, and to some extent it already is.) Any surveillance technique based on data mining will inevitably result in a lot of innocent people being put under surveillance, at the very least having their records flagged for closer attention. It may be just a computer scan at first, but at some point this practice becomes an invasion of privacy and a violation of civil liberties.

To be fair, law enforcement is involved in an information arms race. There have already been reports in major news outlets of organized crime using data mining to identify and assassinate informants in their ranks, and it would be ridiculous to deny the same technology to police merely because it might be abused. But the need for security must be balanced with the need to preserve the civil liberties that modern democracies were founded upon. Citizens should demand due process and accountability from their governments and must remain vigilant to abuse. Data mining can and should be held to the same legal standards and privacy expectations as other forms of police work.

DIGITAL IDENTITY AND WEB SERVICES

The increasing prominence of Web services as a new way to achieve cross-application and cross-domain data integration is also highlighting the need for digital identity. Because Web services are almost as new as digital identity, it is worth taking a brief look at them here.

The term "Web services" has caused a lot of confusion among the uninitiated. Most Internet users have bought something at amazon.com, searched the Web using Google, or used their banks' Web sites to check their checking account balances. These are services available on the Web, but they are not "Web services" in the sense we're talking about here. In the enterprise, the term "Web services" applies in a very specific way to automated application-to-application communications—it is an extension of the similar use of the word "services" in a local computing environment.

To further explain the difference between the Web and Web services, we will compare the two directly. A Web site is designed to be used by human beings, and it includes site-specific formatting and graphics for, among other things, branding purposes. For example, Bank of America's Web site looks nothing like Citibank's, and neither looks anything like Bank One's. This is inconvenient if a computer program, rather than a person, wants to access data offered by a Web site. Suppose, for example, a user of a personal finance program wants to automatically import her checking register into the program from a bank's Web site. To do this, the personal finance program needs to know how to find that information on every bank's Web site. That would require the developers of personal finance programs to provide a different interface module (to extract the desired information from the Web page) for every bank in the world, and this is completely impractical. A much better answer is a standard interface for all bank Web sites that lets personal finance software, once properly authenticated, retrieve a customer's checking register.

The Web services paradigm is an attempt to address this problem and others like it, which are legion. Four key standards are involved. First, the Extensible Markup Language (XML) is an established W3C format for data representation (World Wide Web Consortium, n.d.). The Simple Object Access Protocol (SOAP) is a W3C specification that defines how programs running on one computer can request that certain operations be performed on another. The Web Services Description Language (WSDL) is an XML schema for describing a Web services interface in a standard, machine-readable format. Lastly, Universal Description, Discovery, and Integration (UDDI) allows a Web site to automatically discover which services are available from a given provider and determine how they should be accessed. All of these either are already open standards or are in the process of being standardized, and an overwhelming number of major industry players (including IBM, Microsoft, Sun Microsystems, HP, and BEA Systems) have thrown their weight behind the concept.

With Web services, applications and portable devices can access specific information and services over the Internet without a full-fledged Web browser. When a harried traveler is checking a flight departure time on his cellular phone, he or she doesn't want the whole American Airlines Web site, and he or she doesn't want to try to use Internet Explorer on the phone's tiny screen. He or she just wants to punch in the flight number and find out whether he or she can make the flight or not. This is a perfect application for Web services. At the same time, Web services allow Internet applications to begin communicating directly with each other, as well as with users. For example, a Web portal might use Web services to retrieve top headlines from a news site and then format them according to the portal's own look and feel before delivering them to the user.

As with Web sites, some Web services are public, whereas others are accessible by subscription only or only to certain users (for example, a company might operate some Web services only for its employees). It is necessary to authenticate users before allowing them to use these restricted services. Requiring separate credentials for each service quickly becomes a headache, especially when a single user might access the service from a mobile device, from one or more Web portals, and from a desktop application. What is needed is some way to ascertain the identity of users no matter how they access a given Web service, to model users as independent digital entities rather than only representing the devices they use. *This is digital identity.* To complete the circle, digital identity services can themselves be provided as one or more Web services, making them widely available to users everywhere.

DIGITAL IDENTITY ILLUSTRATED

A simple example will serve to illustrate the basic model of digital identity. In modeling an information system, a common object-oriented methodology involves thinking of the system in terms of actors who engage in transactions with each other. For example, when a customer withdraws money from an automated teller machine, there are three actors: the customer, the ATM, and the bank mainframe with which the ATM communicates to verify the customer's balance before dispensing money. The actors and the actions between them can be represented using a sequence diagram like that in Figure 1.

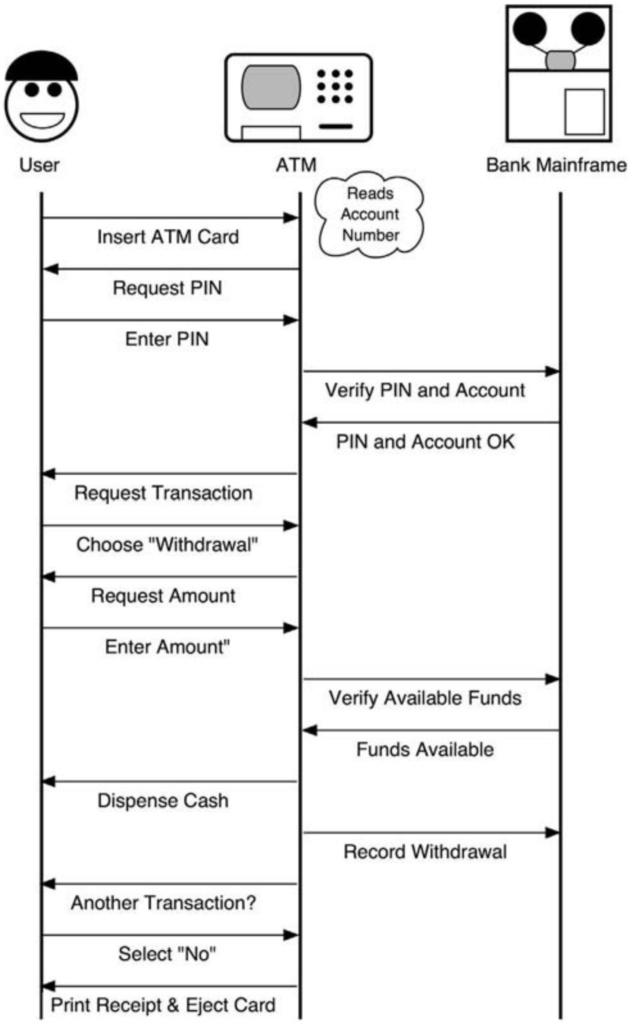

Figure 1: Sequence diagram for ATM withdrawal.

In this use case, the ATM has interactions with the user in which it asks for information such as a personal identification number (PIN) and the amount to be withdrawn. The ATM also has interactions with the bank mainframe, asking it to verify the account's current balance and telling it to record the withdrawal. (For clarity, this diagram does not show exceptions, such as what happens when there are not enough funds in an account to cover a withdrawal request.) These various interactions are possible because the bank owns all the data involved in the transaction. The bank balance is stored in its computer (along with a PIN), and although the account number is stored on the ATM card which the customer carries, that number is issued by, and thus in that sense belongs to, the bank.

The bank has plenty of other information on its customers, too: their mailing addresses for statements, their Social Security numbers (SSNs) for reporting interest income to the IRS, and their complete transaction histories. Though it describes customers, this information, too, belongs to the bank in the sense that customers do not have the authority to change it, even though they are the source of much of it. If a customer wants to change the address to which statements are mailed, for example, he or she must provide the new address to the bank so it can be entered into their systems.

The ATM system works because the all the actors involved in ATM transactions can trust each other, and they trust each other because the bank controls all the information involved. The ATM knows that it can trust the balance data, because it knows it is connected to the bank's mainframe and not to some other computer. The bank's mainframe knows that it can trust the ATM, because it has provided credentials that prove it is an ATM owned by the same bank. And the ATM and bank know that they can trust the customer at least modestly, because someone has inserted a card with an account number issued by the bank and entered the correct PIN number for that account. In digital identity terminology, the bank's ATM system comprises a single *trust domain.* All the information in the system is owned by a single entity, and all the components of the system are deemed trustworthy. The bank considers the other information customers have given it (such as mailing address and SSN) to be trustworthy as well, because it is in its systems and thus under its control.

To keep this scenario simple, it was assumed that the bank that owns the ATM is the bank where the customer has the account. In the real world, of course, banks join ATM networks; customers can use their cards at any ATM in a network that their banks are members of (although the banks may charge fees). To achieve this, the member banks have had to agree on a common protocol for exchanging data. Each bank has had to decide what credentials it will accept from other banks' ATMs to verify that they are in fact legitimate ATMs and what credentials the users of these ATMs will have to provide. They have also had to agree on what data will be provided over the network, and they have taken steps to protect the security and integrity of the data as they flow from point to point. In doing so, the banks have enlarged their trust domain to encompass all banks on the network, at least for ATM-related transactions.

With digital identity standards, trust domains can be expanded even further. What if not just banks but *every person and business in the world* could communicate and exchange data with anyone, just like the member banks of an ATM network? What is necessary to establish trust between all these entities? And what will such a world be like?

DIGITAL IDENTITY AND THE CONSUMER

Consumer digital identity applications are the obvious place to start exploring digital identity, as these have received the lion's share of media attention. Microsoft Passport, the Liberty Alliance, and Extensible Name Service (XNS) from the XNS Public Trust Organization (XNSORG) all initially led with consumer-facing applications.

The *digital wallet* is the most common example. A typical digital wallet contains a customer's mailing address, his or her preferred shipping addresses, and information about the credit cards he or she frequently uses for online purchases. When using a digital wallet to check out at an electronic storefront, the customer simply chooses the address and credit card to be used for the order from a pop-up list, rather than being forced to enter this information at each new store. Even more conveniently, when the customer moves or is issued a different credit card number, he she simply changes the appropriate fields in the wallet—once. The simpler a site makes the purchase process, the more likely it is to close the sale (Amazon's patented One-Click ordering is a case in point), so the digital wallet is potentially a big win for both consumers and merchants—as well as for banks, who earn a fee on credit card transactions.

Single sign-on (or SSO) is another consumer service. SSO lets users log on, or *authenticate,* at one Web site and then use that authentication at other participating Web sites. For example, after users log onto a Microsoft Passport account, they can get access to Hotmail, the Microsoft Network, Expedia, eBay, and other Web sites without having to enter their passwords again. It is particularly convenient to combine this with the digital wallet feature, making the wallet even more attractive for users.

Microsoft Passport is currently the most widely deployed single sign-on and digital wallet service at present, although adoption by consumers, vendors, and content providers has been slower than Microsoft had hoped. (A large percentage of the sites that accept Passport are owned by or affiliated with Microsoft.) Part of the reason for the slow uptake is that Passport is, at this writing, a centralized service. Microsoft stores all Passport data, including transaction records, on its own servers. Early technology adopters tend to be just the sorts of users who will insist on the privacy and security of their personal information, and Microsoft will have to provide more than convenience to win their trust. The Liberty Alliance specifications and XNS both support a feature called *federation,* where users can choose from a number of hosts for their personal data and cooperating sites can share authentication seamlessly, much like an ATM network.

Microsoft has stated that Passport will also move to this model.

But although digital wallets and SSO are part of digital identity, they are by no means the whole picture. It is, in fact, possible to implement these sorts of applications without even really modeling the underlying identity. A more robust conception of digital identity provides an infrastructure for a wide variety of applications.

THE IDENTITY WEB

To better understand the emerging vision of digital identity, we will look at the characteristics of a hypothetical full global identity infrastructure. Keep in mind that no such thing exists yet, and no one organization will build it. Instead, people and companies will begin using smaller identity-related applications as these applications become compelling. In fact, at first, users might not even realize they are using something called "digital identity." But as more and more people use identity services, they will naturally want these services to work together, further increasing their value in a classic network effect. This in turn makes additional identity applications more and more compelling, which brings more users into the identity fold, which further increases the network effect. This eventually results in the *Identity Web*—a global interlinked digital identity community, the virtual world in which, with the proper permissions, everyone can share anything with anyone.

To benefit from the network effect, naturally, identity applications must be interoperable, which means that a standard identity protocol must be adopted by all players. As of this writing there are two key digital identity standards emerging: XNS and the specifications from the Liberty Alliance Project. Both are open public standards. XNS is licensed by the not-for-profit XNS Public Trust Organization (XNSORG) (see XNS Public Trust Organization, n.d.), which recently contributed the XNS specifications to a new technical committee at OASIS (the Organization for the Advancement of Structured Information Standards), a global not-for-profit consortium that already maintains many of the key XML interoperability standards (Organization for the Advancement Information Standards, n.d.).

The Liberty Alliance is publishing its own specifications, though it may eventually contribute its work to another established standards body (some public reports have mentioned OASIS). Liberty's 65 members include American Express, MasterCard, Visa, America Online, Intuit, RSA Security, Sony, Sun Microsystems, Verisign, Fidelity Investments, Novell, Citigroup, Hewlett-Packard, Nokia, Vodafone, General Motors, Cisco Systems, Bank of America, PriceWaterhouseCoopers, EDS, Cisco Systems, Earthlink, OneName, and many others. This impressive array of members demonstrates the importance of interoperability to major corporations and provides enterprise customers with the assurance that Liberty standards will be viable from both technical and business standpoints (Liberty Alliance, n.d.).

The following sections draw on concepts from both of these emerging standards, with particular focus on XNS—largely because the authors are coauthors of the XNS specifications, but also because it reflects the broadest vision of digital identity available in the marketplace to date.

IDENTITY DOCUMENTS AND ADDRESSING

In XNS, the core concept of digital identity is the *identity document,* an XML document that stores the data for which any given real-world entity is authoritative. People own their names and addresses, for instance, so this information would best be stored in an individual's personal identity document. An identity document can represent a person, a corporation or other organization, a software application, a server, or even a directory category such as "plumbers"—any entity that has attributes that might be useful to share with others. (In the case of the "plumbers" category, the attributes being shared might be a definition of the category "plumber," a list of other associated categories, and a list of pointers to other identity documents that all belong to plumbers—a digital identity Yellow Pages.) Applications can query an identity document for just the attributes they are interested in; it is not necessary to retrieve and parse an entire document.

The identity document is hosted by an *identity service provider* on an *identity server.* As with Web hosting services, in the Identity Web there would be a multitude of identity service providers a user could choose to host his or her identity. Strong encryption would be used to ensure that only authorized users had access to the information in the identity document. Because digital identity is by its nature peer-to-peer (any identity can talk to any other identity), particularly savvy users could even choose to host their identities on their own computers for additional peace of mind.

To access the identity document itself and link to the information stored in it, an addressing scheme is needed. Standard URIs (uniform resource identifiers) such as HTTP URLs, which are used to address documents on the Web, do not have the full range of functionality required by digital identity infrastructure. For example, links between identities should continue to work even if a digital identity moves to another host. (The details of how links are used to share data will be revealed shortly, but for now it suffices to note that broken links would render some shared data inaccessible, limiting the utility of sharing data in the first place.) To provide this higher level of functionality, XNS uses a new form of URI called an *XRI* (extensible resource identifier). An XRI can be either an identity ID or an identity name. An *identity ID* is a string of numbers and other characters that forms a permanent address for an identity. Technically, an identity ID resolves to the URI where the given identity is hosted, and although the identity ID never changes, the URI it resolves to can change if the identity is moved to a different host. Each attribute stored in an identity document, as well as the identity document itself, has an ID, and this ID, too, is the same as long as the object exists. In XNS, document and attributed IDs are assigned and resolved by the ID service.

Identity IDs, however, are identifiers only a computer could love. They will be assigned more or less arbitrarily and are structural rather than semantic. Typically, a lot of numbers and punctuation will be involved, making IDs even less human-friendly than phone numbers. Just as DNS was invented to allow human-friendly host names to be assigned to computer-friendly IP addresses, so digital identity needs a way to make identity IDs easier for people to use. Enter the *identity name.* The XNS Name service allows any object with an identity ID (that is, an identity document or an attribute stored in it) to be assigned any number of names, which can be changed at the identity owner's whim. The naming service also allows an identity owner to organize the attributes stored in his or her identity document into categories or folders. For instance, phone numbers could be stored in a collection called "phone," allowing a cellular phone number to be named something like "=JohnSmith/phone/mobile." It is important to remember that although an identity document or an attribute might be located by name initially, when a link is established, it always uses the unbreakable ID.

In the beginning, it is likely that organizations will operate their own ID and name resolution services for customers and partners. For example, a bank might offer identity services to its customers, which would work with the bank's merchants but with no one else. In other words, the bank would provide ID and name resolution services only for its customers and merchants. The identities findable through a single resolution service are referred to as a *community.* Using the process of federation, which was mentioned earlier in the context of consumer identity services, communities can agree to share these services and thereby merge their smaller communities into larger ones. As identity services become more popular, a demand will eventually arise for *global community services* that, like the global Internet's DNS, allow any identity in the world to be found by its name or ID.

IDENTITY LINKING

Once attributes have been stored in identity documents that can find each other by ID or name, the stage is set for letting these identities share data. *Linking* is the way information from one identity is shared with another (see Figure 2). Links are almost always made using IDs, and because IDs never change over the life of an object, links between IDs never break while the linked objects exist. When one identity needs information that is controlled by another identity, the first identity simply links to the data in the second, forming a conduit through which data can flow. Then the two identities agree as to how the shared data will be kept current in the second identity—that is, how they will be synchronized.

An example will make the linking concept clearer. A person's mailing address, for all practical purposes, belongs to the person who lives at that address. (Street addresses are actually assigned by the city, but the city rarely changes them. More commonly, people change their own addresses—by moving. Thus, a mailing address can reasonably be treated as an attribute of an individual's identity.) A bank needs a mailing address to send statements, so the customer provides this information, and the bank puts it into its system. As noted earlier, however, the bank controls that copy of the address. If a customer moves, he or she must ask the bank to change it—even though it is *his or her* address! Change-of-address forms are so unremarkable that it barely seems that this is a problem worthy of solving. But just envision all the copies of information that people and companies keep about other people and companies; a vast amount of storage is used for redundant copies of all this information, and an equally vast amount of effort is expended on keeping all the copies current.

Linking addresses this problem head-on. In our example, the bank would simply link to a mailing address stored in the customer's identity document, using the address's immutable ID. To the bank's systems, it looks just as if a copy of the customer's mailing address is stored in their database. However, the customer's copy of the mailing address, stored in his or her identity document, is *authoritative,* meaning the customer can change it and the bank has to go along. When the customer moves, he or she simply

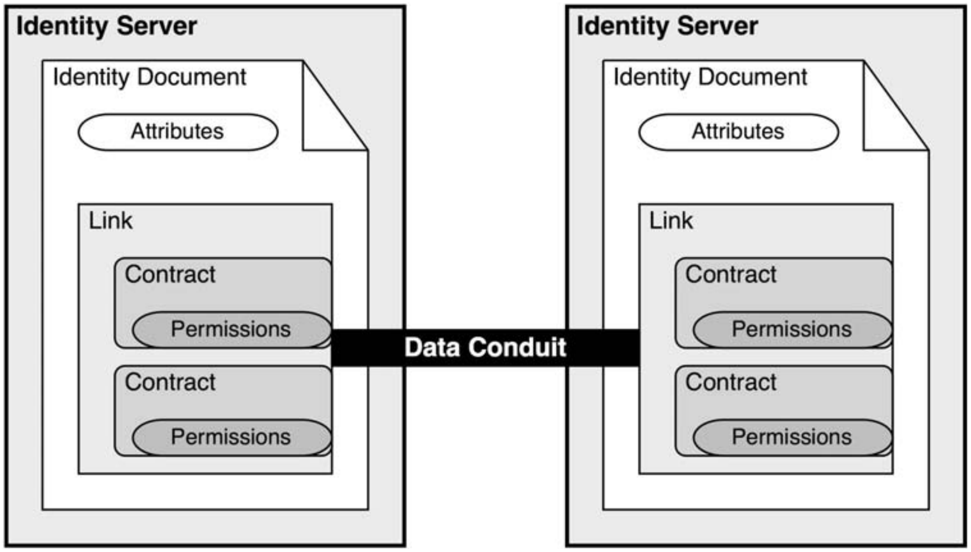

Figure 2: An identity link establishes a conduit between two identity documents.

updates the address stored in the identity document, and the identity service provider then sends a digitally signed copy of the updated address to the bank. The bank's system verifies the digital signature to make sure the update is genuine and then automatically stores the new address in the customer database. In essence, by eliminating redundancy, digital identity turns the world into an object-oriented, distributed, well-normalized database.

Of course, some of the technical details have been glossed over. The XNS protocol actually gives the bank in this scenario several options for synchronizing with a customer's identity data. For example, instead of having updates "pushed" to them, the bank could simply retrieve a copy from the customer's identity document any time they needed it by sending a digitally signed request to the customer's identity provider. Or the bank could just be notified that the address has changed and use some other method to update its database (for example, mailing a confirmation form to the new address to verify that it is correct). The exact details of how updates are handled will depend on the implementation, but regardless of how updates are accomplished, linking of identity data is arguably the most important concept in the sphere of digital identity.

Linking also provides the means to consolidate multiple digital identities that represent the same real-world entity. For example, a bank maintains a digital representation of each customer's account balance and activity. This information actually is part of an individual person's identity—it is his or her account, money, and transactions—but, for security reasons, the bank must maintain the authoritative copy. (It just wouldn't do to let people change their own account balances!) In an identity-centric world, the bank might do this by creating an identity document on its identity server for each of its customers. The attributes of these documents would be customers' various accounts, and each account would have a balance and a transaction history associated with it, among other things. So an individual's bank-hosted identity represents the real-world person just as much as his or her personal identity, hosted elsewhere, that contains his or her mailing address. We might call one the "financial identity" and the other the "household identity." By creating a link between the financial identity and the household identity, the customer can create a single *virtual* identity document that allows him or to view all his or her personal information (including the portions maintained by the customer, the bank, the customer's doctor, and other parties) in one place. Any number of third-party digital representations of a single real-world identity could be linked in this fashion.

A final application for linking is to intentionally split a single identity's attributes into two or more locations for security reasons, for much the same reason that banks maintain account balances rather than allowing customers to do so. For example, using linking, a cellular phone can become a digital wallet. By storing credit card numbers on a smart card inside a phone and configuring the phone to require its owner to "unlock" it using a PIN before it releases a credit card number, users can enjoy increased security for online shopping. To complete an online purchase, the phone must be turned on, it must have the user's (encrypted) smart card installed, and the user must approve the purchase by entering the PIN. This makes it very difficult for anyone but the legitimate owner to use a digital wallet for purchases without the owner's knowledge or approval. Using linking, however, users could still see this information as part of their main identity and update it as easily as any other information in their profiles—once they have logged in, of course.

DATA SHARING PERMISSIONS AND CONTRACTS

So far, this hypothetical identity Web is a framework for sharing everyone's identity data freely with everyone else. This utopia cannot exist, because people simply are not willing to share all of their personal data with everyone who might want it. Indeed, people are very discriminating with their personal information. We only give our credit card information to merchants we trust. We only give out direct e-mail addresses to others if we believe we won't get more junk mail by doing so. We pay extra to have our telephone numbers not listed in the telephone directory. Therefore, one of the driving principles of digital identity is to give control of private data back to the people and organizations to whom it belongs. A digital identity infrastructure must support flexible privacy control at the protocol level to gain the trust of users.

The XNS digital identity infrastructure handles privacy through a data structure called a *contract* that defines the terms under which data may be shared. For example, a contract between a personal identity and a merchant identity might specify that the shipping address stored in the identity document will be used only to fulfill the current order and not to mail advertising; the merchant will not retain the address in its systems any longer than is necessary for the purposes of shipping the order; and the merchant may not share the address with any other parties without customer consent.

How are contracts established? By a process called *negotiation.* (The XNS Negotiation service is an implementation of the privacy framework developed by the International Security, Trust, and Privacy Alliance, ISTPA [International Security, Trust, and Privacy Alliance, n.d.]) In a transaction between a customer and a merchant, the merchant identity would present to the customer identity a proposed contract indicating what information is needed, what it will be used for, how long it will be kept, and with whom it may be shared. If the customer has previously told her identity service provider what terms he or she finds acceptable and provided preferred values for the kinds of data the merchant wants, negotiation could be completed entirely without human intervention. More commonly, the customer would insist on having the opportunity to review and approve the terms and select the data to be shared before finalizing the transaction. The resulting contract records the mutually agreed upon terms and governs the links between the two identity documents between which the data will be shared. When a permission requirement has been established on a data attribute stored in an identity document, it becomes impossible for other identities to access that data without first agreeing to a contract.

Because the resulting data structure is *called* a contract, the obvious next question is whether it is legally binding. At this writing, the issue has never been tested in court. But the law in many countries is moving steadily toward accepting digital signatures as legal proof of assent. Using established cryptographic techniques, it is possible to provide assurance of the identities of the parties agreeing to the contract and to prevent repudiation, so eventually contracts between digital identities may be as binding as written contracts between real-world parties.

Even without the weight of the law behind them, data-sharing contracts will make it easier for consumers to access and update the personal information that businesses keep about them, as well as allowing consumers to hold businesses more accountable for the ways they use their customers' data. Although some companies might not care for this level of accountability at first, eventually businesses will embrace it wholeheartedly, for a simple reason: contract-based data sharing provides a foundation of trust for building closer, more profitable relationships with customers, employees, suppliers, and partners.

OTHER DIGITAL IDENTITY SERVICES

Being able to locate identity documents and forge permission-protected data-sharing links between them makes a wide variety of digital identity applications possible. This is the foundation of XNS and also of Liberty Phase 2. Indeed, analysts predict that data sharing will be the single largest purpose for which digital identity technology will be used, especially in the near term. Beyond sharing, however, digital identity enables other services that will make the Internet and many common communication functions safer, easier, and faster.

Many of these are *trust services*—services that make it easier to perform trusted digital transactions, just as credit cards made it easier to perform trusted mail-order transaction. For example, an *authentication* service is needed to prove that a digital identity represents a real-world principal and to assert that real-world identity across trust domains. Once a user logs into his or her digital identity, in other words, other services can tell that he or she is the same person who created the identity, and therefore these services can be assured that they are dealing with a single individual at all times. This enables single sign-on and customization features and also supports the creation of contracts between identities.

Certification service allows digital identities to make assertions about the truth of the data stored in them. A third party, called a *certifying authority,* provides a cryptographic signature that essentially claims that it has inspected the data in question and found them to be complete and accurate. A real-world example is a driver's license. It would be much better to keep a digitally signed version of a driver's license in an identity document rather than just including the raw data the license contains; the digital signature would allow this credential to be used as proof of age, for instance. Without a verifiable digital certification from the state of origin, the merchant would have no reason to trust the information. Certification supports the mapping of real-world identity credentials into the digital realm and thus gives digital contracts their force.

A *session* service combines authentication and certification to support a browser-based single sign-on (SSO) solution. The third party in this case is a *session server,* which issues a cryptographic token certifying that acceptable credentials were presented to begin a session. This *session token* then either is accepted by various Web resources in place of traditional credentials (such as a user ID and password) or is transparently mapped to acceptable local credentials. The Liberty Alliance version 1.0 protocols are essentially a federated session service.

A *hosting* service allows one identity to host another. When an identity document is hosted by an identity server, the hosting service is the service responsible for establishing the new identity's persistent address. In XNS, the identity server itself is represented by an identity document. Identities hosted by a server are registered with the server's *host identity* so that they can be located by name and ID.

Finally, in an extensible identity protocol, some way must be provided for applications to discover new identity services they do not know about. In XNS, this is accomplished with the Discovery service, which designates a *publishing identity* for each service's definition and allows the service's data formats and message descriptions to be retrieved in standard formats including XML schema (XSD) and Web services definition languages (WSDL). The Discovery service allows anyone to define new identity services that are completely interoperable with existing identity applications.

In XNS 1.0, the 10 services ID, Name, Discovery, Hosting, Data, Folder, Authentication, Certification, Session, and Negotiation—plus the Core service, which defines data formats and an abstract base class for messages—compose the base services. These are, in the authors' estimation, the absolute minimum requirements for a fully functional identity infrastructure. In a future version of the XNS specifications, additional services are planned, including the following:

Reputation service will allow the trustworthiness of an unknown identity to be evaluated based on the opinions of other identities;

Introduction service allows two identities that currently link to a third identity to cut out the middleman and link directly—essentially a "three-way negotiation" or "friend-of-a-friend" service;

Directory service provides the ability to register and locate participating identities not just by name and ID but by certain attributes (for example, locating all identities at a specific company or in a particular geographic area).

Thanks to the extensible architecture of XNS and its Discovery service, further services can be developed as needed by anyone who needs them.

DIGITAL IDENTITY AND ENTERPRISE APPLICATION INTEGRATION

Large companies contain vast repositories of identity data. An LDAP directory server contains identity data; so does a customer relationship management system, an accounting system, or an order processing system. Even a network management tool, an e-mail server, or a collaboration server could be viewed as containing identity data. (Anything that stores and manages data about entities can be considered as an identity application in a loose sense.) None of these tools are designed to talk to each other, even though the benefits of doing so might be enormous.

The problem is compounded in obvious ways when companies join forces; it is not uncommon for a large enterprise to have several separate, incompatible information systems performing the same functions for its various divisions, like a fossil record of the company's merger history. This is the redundancy problem from this chapter's very first example—the same information stored in many places, wasting vast amounts of storage and requiring enormous effort to keep in sync—written *very* large. The biggest corporations have hundreds or even thousands of different mission-critical databases stored in mutually incompatible systems around the world.

Addressing these issues in a comprehensive way all at once can be mind-bogglingly expensive and time-consuming. Designing, implementing, and testing just data format conversions can take thousands of engineer-hours. Then there is the expense of replacing the legacy systems with more modern software and the inevitable headaches that come with trying to tie it all together, not to mention the additional time required for retraining employees on the new systems.

Envisioning digital identity as an integration layer on top of existing enterprise information systems makes it possible to undertake enterprise application integration (EAI) in small, easily managed pieces. The legacy systems are kept intact and remain authoritative, with the data needed for a given application transparently mapped into identity documents using standard EAI *adapters* that serve as bridges between the identity server and the legacy systems. Using this approach, new integration applications can be built on top of the identity layer rather than talking directly to the enterprise layer and can be developed with modern object-oriented methodologies, with the legacy systems treated more or less as black boxes. Companies can begin with the proverbial "low-hanging fruit"—the most obvious enterprise integration projects with the clearest potential for substantial return on investment or the best chance to achieve a new competitive edge. As these projects prove themselves out, more projects can be undertaken with increasing confidence, until at some point the network effect comes into play and the ROI of identity solutions already implemented increases exponentially by allowing new connections to be made. In the coming identity-centric world, it will eventually become a competitive disadvantage to store identity-related data in places where they cannot be shared (given appropriate permissions) with others.

An example will serve to illustrate how digital identity can be used for integration. Suppose two mail order companies merge into one bigger company that now has two separate systems for processing orders and for mailing catalogs. An identity-based approach to integrating these systems, to allow customer service representatives to access all data stored in both systems without even having to know that there *are* two separate systems, would be to create an identity document to represent each customer. By means of adapters, individual data elements in identity documents would be retrieved from the existing systems. The identity document stores any record keys necessary for finding the appropriate data in the two systems. When an application asks the identity server for the catalog mailing address from a customer's identity document, the identity server retrieves the data "on the fly" from the mailing list application. Requesting the last order date causes the identity server to query the order-processing system for this bit of information. If the customer's entire identity document were requested, all the information needed from all systems involved would be retrieved behind the scenes, by means of adapters, and stitched together into an identity document conforming to the syntax required by the standard (for example, XML). When an application changes something in the identity document, the adapters write the changes back out to the legacy systems. Adapters can also take care of any necessary protocol details (e.g., interfacing with the desired network stack), do encoding conversions (e.g., EBCDIC to Unicode), and provide caching services and even encryption and decryption.

The application never needs to know or care that any of this is happening; it uses the same simple, standardized object-oriented methods to read or write data regardless of where it is stored and how it must be accessed. Existing applications that are used with the legacy data systems can remain authoritative or can even be run simultaneously with the identity-based applications. In fact, if desired, the legacy systems can even be switched out from under the identity layer—suppose they need to be upgraded for other reasons—and, assuming the appropriate adapters have been written for the new systems, the identity-based applications will never notice. The adapter approach also makes it possible for system integrators to build generic solutions for common integration problems; for each installation, they need only write adapters and perform the specific customization necessary to get the new applications running on top of a particular client's legacy data stores. Figure 3 shows how the resulting system looks at a high level.

Once a data source becomes identity-enabled, it is easy to add functionality incrementally. The first step might be to integrate the order processing and mailing list systems of two merged companies, as described above, so that customer data are more accurate and customer service staff can work more efficiently. The next step might be to add a Web interface to the system so that customers can access and update this information on their own, reducing staffing needs for the call center. Next, the accounting system might be integrated to allow customers to see and pay their invoices online. Then the company might offer to integrate its order-processing system with its identity-savvy institutional customers' inventory systems, so that their stock can automatically be replenished when it runs low. Each step adds real value, each has measurable ROI, and each can be accomplished in a relatively short time with relatively few development resources thanks to the standardized identity programming interface.

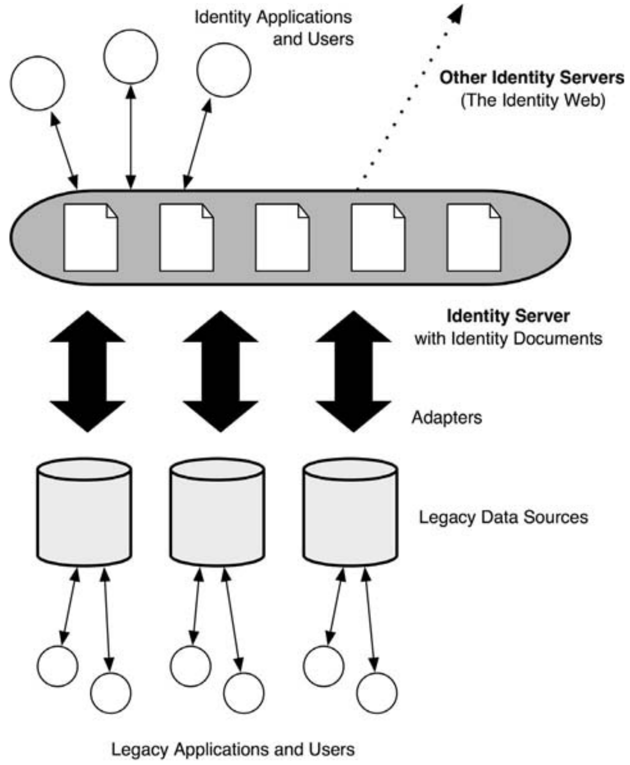

Figure 3: Digital identity as an enterprise integration layer.

Stunning feats of integration like these can be accomplished without digital identity—Wal-Mart's integration of its suppliers into its own data processing operations is the textbook example. However, doing it the old-fashioned way requires expenditure of money and development resources in direct proportion to the number of data already stored in legacy "silos," and it is difficult for most enterprises to justify the expense of many such projects on a ROI basis. Identity-oriented development promises to do for enterprise systems integration what object-oriented programming did for software engineering: make it simpler, quicker, less error-prone, and less resource-intensive. Suddenly, many projects that did not originally make financial sense look feasible, and they look even more attractive as the network effect made possible by open standards takes hold.

Our prediction is that the enterprise is where most identity-related development will occur over the next few years. Consumers will come to rely on identity-based services provided by these companies more and more, often without knowing (or needing to know) that these services are in fact founded on digital identity technologies. For example, companies will start allowing customers to share their account information with their strategic partners. Meanwhile, grass-roots understanding of privacy issues will slowly but inexorably lead to consumer demand for identity applications and for true control over their own data. Consumer-protection legislation and regulations will drive enterprises to adopt technologies with strong privacy safeguards, lending additional weight to the benefits of digital identity. Network effects will, finally, lead to the Identity Web, a global hyperlinked collection of personal data shared, by mutual agreement, among people, companies, and other organizations. By the end of this decade, the most compelling reason to use identity-based solutions in the enterprise will be that your customers, vendors, partners, and competitors are already using them.

THE IDENTITY PLAYERS

This chapter has already touched on the efforts of One-Name Corporation, XNSORG, and the Liberty Alliance in the realm of digital identity and has touched on Microsoft's Passport. We can characterize these efforts as "pure" identity plays.

Liberty's Phase I specification defines a single sign-on (SSO) service based on the security assertion markup language (SAML), wherein existing accounts at multiple sites that have agreed to share authentication can be linked. Sun Microsystems is already supporting Liberty Phase 1 in its directory server. Phase 2, due early in 2003, is a more sophisticated protocol that allows any Liberty-compliant service to federate with any other—without pre-existing partnerships—and to share more attributes between accounts.

Unfortunately, Liberty proceedings are not open to the public, and until the specification is officially released, Liberty members are subject to strict nondisclosure agreements. For this reason, few details about Liberty's plans for Phase 2 are available to the general public. However, it is worth noting that the consortium's strategy has generally been to use existing standards when possible, as evidenced by the use of SAML in Phase 1; it is therefore not unreasonable to expect Phase 2 to be built at least partly on applicable Web services standards.

Microsoft's trustworthy computing initiative, popularly known by its code name, "Palladium," aims to add permissions to document-sharing of all kinds through a combination of security and identity technologies. The industry perceives trustworthy computing as being driven in large part by the desire of content providers (such as the music and motion picture industries) to control how their content is being used and protect it from piracy, but Microsoft recognizes that consumers will use a system with such restrictions unless it also provides compelling benefits for them as well. The carrot Microsoft offers with Palladium is to give *everyone* the ability to apply the same industrial-grade restrictions to information he or she creates. This in itself is not strictly an identity-related development; however, also as part of Palladium, Microsoft is providing wider access to the Passport technology including, in an unprecedented move for Redmond, sharing Passport Manager source code with selected partners and customers. (Passport Manager is the software module that allows a Web site to join the Passport network and access shared user data.) As mentioned earlier, Microsoft has promised that Passport will support federation based on the Kerberos 5.0 standard soon, so individual communities can begin using it now and decide later how they want to hook up (Microsoft Trustworthy Computing and Passport, n.d.).

These three are not the only players, though—only the most visible. Enterprise software vendors are also moving into digital identity. Many of the identity data in the enterprise are housed in directory servers, which are used to control access to corporate network resources as well as to store contact information. Manufacturers of directory and access-management products have a natural interest, therefore, in providing their customers with the integration and data-sharing tools they will need in an identity-centric world. Not surprisingly, vendors of access-control products—including IBM, Microsoft, Netegrity, Novell, Oblix, and Sun—are already beginning to tout digital identity functionality and interoperability for their products.

Current directory products do not scale well across trust domains—meaning that they are better suited to controlling access within an enterprise than across multiple enterprises—but some vendors already offer *metadirectory* products that can consolidate enterprise directories into one virtual directory. This monolithic approach does not offer the advantages of the Web architecture that will eventually evolve with digital identity; however, enterprises will continue to turn to these working solutions in the short term while identity standards shake out. At that point, it would be natural for these vendors to begin adding support for standards-based distributed identity.

As described earlier, digital identity has the potential to introduce a major paradigm shift in the EAI category. Where the traditional EAI approach is monolithic and expensive, the digital identity approach offers low up-front cost and incremental deployment. These are such powerful advantages that it is likely that EAI vendors such as BEA, SeeBeyond, TIBCO, and webMethods will eventually be compelled to use this approach and may in time become leading vendors of enterprise digital identity solutions.

THE FUTURE OF DIGITAL IDENTITY

This chapter has presented the authors' vision of how digital identity will, through links between identities that share data, eventually form an Identity Web similar to the current World Wide Web of documents. The initial growth of the Identity Web will be driven, like the early stages of the WWW, by early adopters, though early on, more businesses than consumers will see and exploit the potential of digital identity.

As digital identity infrastructure grows, it will have progressively wider applications in many product categories. For example, e-mail vendors could use digital identity protocols to provide permission-based mail filtering. Senders of mail would have to prove their identity and agree to a privacy contract before being permitted to send mail to a given address, potentially putting an end to "spam" once and for all. By the end of the decade, any product category that involves sharing information is likely to include digital identity features, particularly if it involves digital rights management (DRM).

Despite the possible privacy and civil liberties pitfalls, which continue to require close scrutiny, the concepts embodied by digital identity have the potential to have enormous net positive social and technological impact in the coming years. It is too bad that the word "revolutionary" has been tarnished by its application to so many half-baked technologies—if ever a new technology deserved that adjective, it is digital identity.

GLOSSARY

Adapter In enterprise application integration, a software module that serves as a bridge between an identity server and legacy systems.

Authentication The process of proving that a user is an authorized user of a network resource by presenting credentials such as a user ID and password (colloquially known as "logging on").

Community The group of identities that can be located through a given address resolution service.

Contract A list of mutually agreed permissions for sharing data between identities via an identity link.

Digital identity An emerging technology and application category that revolves around the logical modeling of real-world actors (such as people and companies) and their attributes and the permission-based sharing of these attributes between actors on a network.

Digital wallet A popular consumer digital identity application that stores customers' shipping addresses and payment methods to speed checkout at e-commerce Web sites.

Extensible name service (XNS) An open, XML-based digital identity protocol licensed by the not-for-profit XNS Public Trust Organization (XNSORG).

Extensible resource identifier (XRI) A new form of URI that provides the functionality necessary for addressing identity documents; can be either an ID or a name.

Federation The process whereby separate communities share address resolution services, thus merging two or more communities into a larger one and giving users a choice of which provider to use.

Global community services A publicly accessible identity address resolution service that allows any digital identity to be located by any other, much as the existing domain name service (DNS) allows any Internet-connected system to locate any other.

Host identity The identity that represents an identity service and is responsible for hosting other identities.

Identity document A document, stored on an identity server, that stores the attributes of some real-world actor (such as a person, a company, a device, or an application).

Identity ID An immutable, machine-readable identifier that resolves to the network endpoint where an identity document is stored; identity IDs never change as long as the document exists and are the foundation of identity links.

Identity link A "pipe" between two identities for the two-way synchronization of shared attributes.

Identity name A human-readable semantic identifier for an identity document that can be resolved to an identity ID.

Identity server Software that stores identity documents and provides identity services for those documents.

Identity service provider An organization that provides storage for identity documents.

Identity Web The global interlinked digital identity community (see *Community*), analogous to the World Wide Web of documents.

Liberty Alliance An industry consortium founded by Sun Microsystems to deliver and support federated network identity solution for the Internet.

Negotiation The process of agreeing upon permissions for sharing data between identities via an identity link. These permissions are embedded in a *contract*.

Passport Microsoft's consumer digital identity service, based on the Kerberos authentication protocol.

Publishing identity The identity that makes available the definition of an identity service so that the service can be discovered by identity-savvy applications.

Single sign-on (SSO) A digital identity application that allows users to log in once to gain access to multiple participating Internet sites, rather than having to enter credentials separately at each site.

Trust domain Technically, a set of network resources the access to which is controlled by a given directory server; in practice, the network resources a user can access with a single set of credentials; more generally, a set of network resources that trust each other, such as an ATM network.

Trust services Identity services that make it easier to perform trusted digital transactions; examples include authentication and certification.

Web services A new model for inter-application communication over the Internet using standardized protocols (XML, SOAP, WSDL, UDDI); the extension of the concept of local computing services to the Web.

Digital Libraries

Cavan McCarthy, *Louisiana State University*

INTRODUCTION

Defining Digital Libraries

Digital libraries combine the advantages of digital access with the services and quality information traditionally found in libraries. They can be characterized as the "high end" of the Internet: that sector of the Internet that maintains a tradition of shared resources and easy access while offering quality content from authoritative sources, such as the Library of Congress and major universities.

The author has developed the following definition of a digital library: a system that permits, via the Internet and the World Wide Web (WWW), easy access to a collection of high-value, quality digital content, which has been selected and organized to facilitate use and is supported by appropriate services. The digital content may reflect the traditional textual orientation of many libraries or take advantage of the WWW's facilities to deliver graphics and multimedia. The term digital library is also used to refer to quality information and referral services, whose organization reflects the traditional structure of library services.

The major textbooks for the field offer the following definitions of digital libraries:

> Digital libraries are organized collections of digital information. They combine the structuring and gathering of information, which libraries and archives have always done, with the digital representation that computers have made possible. . . . [T]he digital library must have content; it can either be new material, prepared digitally, or old material, converted to digital form. (Lesk, 1997, pp. xix, 2)

> An informal definition of a digital library is a managed collection of information, with associated services, where the information is stored in digital formats and accessible over a network. A crucial part of this definition is that the information is managed. . . . Digital libraries contain diverse collections of information for use by many different users. Digital libraries range in size from tiny to huge. They can use any type of computing equipment and any suitable software. The unifying theme is that information is organized on computers and available over a network, with procedures to select the materials in the collections, to organize it, to make it available to users, and to archive it. (Arms, 2000, p. 2)

As is common in areas that are still establishing their fields of activity, there are problems in reaching a precise definition. Three parallel terms exist: digital, electronic, and virtual libraries. These are normally used interchangeably (Saffady, 1995). In practice, digital library is the general term in North America whereas electronic library is preferred in Europe. Schwartz (2000) analyzed no fewer than 64 different formal and informal definitions of "digital library."

Advantages of Digital Libraries

The advantages of digital libraries are as follows.

Remote Access: It is no longer necessary to go to a library; resources and information services can be consulted from any location worldwide via the Internet without having to travel.

THE BRITISH LIBRARY

The Gutenberg Bible

Enlarged Image

Current Page: 1r (Volume1)

King's copy (paper)

Figure 1: Decorated page from a Gutenberg Bible, digitized by the British Library.

Simultaneous Access: An unlimited number of persons can access the same resource, even read the same page of the same text, simultaneously.

24/7 Access: Digital libraries, like the Internet, are normally available 24 hr a day, every day of the year.

Digital Texts: These can be easily updated, printed, copied, and even manipulated. Digital texts offer exceptional facilities for manipulation or modification, but this must, of course, be done while respecting copyright and avoiding plagiarism.

Free: Access to many systems is free to users, reflecting the free access principles established both in libraries, especially public libraries, and on the Internet itself.

Indexing: Texts in digital libraries are frequently indexed word for word, and indexes often cover the contents of many texts. Go to the Victorian Women Writers Project, at http://www.indiana.edu/~letrs/vwwp/index.html, and enter a relevant word, such as "suffrage" to test the index. Traditional book indexing is typically limited to a few words per page, printed in the back of that specific book.

Browser Access: Popular browser software, such as Internet Explorer and Netscape, which Internet users are accustomed to using to obtain information, are used to provide access to digital libraries.

Rare Materials: Older, out-of-copyright, and unusual materials can be made widely available via digital libraries. Copies of the earliest printed books, Gutenberg bibles, are available, from the British Library (Figure 1; http://prodigi.bl.uk/gutenbg/default.asp) and from Goettingen, Germany (http://www.gutenbergdigital.de/). The Library of Congress' copy is being digitized as this article is being written.

Preservation of Originals: Old, fragile materials can be repeatedly examined through the Internet, with no possibility of harming the originals. For example, it is difficult to imagine a writing media more fragile than papyrus, but a large collection of papyrus documents can be examined at the Advanced Papyrological Information System (http://sunsite.berkeley.edu/APIS/) with no risk whatsoever to the originals.

Links: Digital resources can include hyperlinks to other relevant sources, such as contents lists, citations, other documents, information sources, specialized data bases, dictionaries, and human help (via e-mail or chat-style virtual reference service systems). A sophisticated example is offered by the Perseus classical studies system (http://www.perseus.tufts.edu/). This links each Greek or Latin word in the digitized texts to dictionaries and word frequency lists.

Reliability: Digital libraries do not have the problems common in traditional libraries, such as books being unavailable because they're on loan, misplaced, or lost; pages torn out or effaced; missing periodical issues, supplements, or indexes. Plus, being accessed via the Internet, this medium is always "up" or "on."

Figure 2: Texts by African American women writers of the 19th century have been digitized by the New York Public Library, Schomburg Collection.

Costs: Initial digitization and setup is expensive, and systems require constant maintenance and updating. However, the cost per use of heavily used systems can be low, and often materials are only available with great difficulty in traditional form.

Service and Social Impact: Digital collections can disseminate the culture and achievements of minority groups. A typical example is the texts by African American Woman Writers of the 19th century from the New York Public Library's Schomburg Collection (Figure 2; http://digital.nypl.org/schomburg/writers_aa19/).

Limitations of Digital Libraries

The limitations of digital libraries are as follows.

Reading from Computer Screens: People do not like reading lengthy texts on computer screens. Print quality is considered poor and computer screens have a horizontal, cinema orientation, rather than a vertical, page-format, layout. This leads to two subsidiary problems. (a) Printers are almost essential as adjuncts to digital library usage. Readers still prefer hard copies in many cases, and paper consumption continues to increase in the midst of the digital revolution (Emmott, 1998). (b) There is a lack of adequate specialized reading devices for digital texts, especially electronic books. Consumers have shown little interest in the early reading devices, which were considered expensive and more awkward to use than the printed books they were supposed to replace. Improved and cheaper laptop computers may fill the gap, but equipment has not quite reached that stage.

Limited Collections: At the moment, digital libraries exclude most modern commercially published books and most copyright-protected resources (i.e., exactly the texts for which there would be the greatest demand). The Internet Public Library links to "over 20,000" online texts (http://www.ipl.org/reading/books/). This is similar to the total cited by the Online Books Page, a wide-ranging catalog of online books, which covers about 16,000 titles (http://digital.library.upenn.edu/books/). Neither the Library of Congress nor any other major library intends to digitize the whole of its book collection. It is not certain when commercial publishers, who are afraid of losing control over digital versions of their texts, will make major investments in this field. Paid-access, subscription-oriented digital libraries also offer limited collections. Questia offers 45,000 complete books and 25,000 journal articles (http://www.questia.com); NetLibrary offers 40,000 books (http://www.netlibrary.com/).

Digital Divide: Access to high technology and hands-on training are essential for digital library consultation. This greatly limits their value in developing countries and communities that are disadvantaged, or unfamiliar with computers. If these difficulties can be overcome, digital libraries have a major potential for reducing divisions within society, because they make information more widely available.

Finance: Digital libraries require significant funding at a time when financing for libraries is stagnant. Libraries have paid significant sums to install computers and guarantee Internet access; many public and school libraries also pay to filter Internet access. Libraries now offer Web access to their catalogs and have subscribed to electronic journals, databases, and closed-access e-book systems. There is little extra money left to digitize their collections.

Personnel Problems: Librarians and systems analysts with training and experience in planning and mounting a digital library are still few in number. Education for digital libraries is based on "on the job" experience. The domain is not yet well developed within most academic curricula.

Content Description: It is often difficult to know what might be offered by a digital library before accessing it. Cataloging is complex; digital library materials can be available in different formats: ASCII/HTML/.PDF; indexed/not indexed; with high/low resolution images; and so forth.

CATEGORIES OF DIGITAL LIBRARIES

Despite their short history, digital libraries already demonstrate remarkable diversity. Traditional libraries divide their resources into books, periodicals, and so forth; audiovisual materials are located in different sections than are, for instance, manuscripts. The digital library uses a computer screen as its interface, so distinctions of this nature are less important. Many digital libraries can present a variety of materials with equal facility. This overview begins with systems offering multimedia materials, then goes on to discuss specific categories, such as digital books, photographs, and ephemera.

Multimedia Collections

The major multimedia collection, and doubtless the most important digital library, is the American Memory Project, the Historical Collections of the National Digital Library, maintained by the Library of Congress (http://memory.loc.gov/). This now includes over 100 collections, a total of seven million digital items, including photographs, manuscripts, rare books, maps, sound recordings, and moving pictures. The foundations for this were laid as early as 1982–1987, with the production of optical discs. A 1989–1994 program was originally based on CD-ROMs, but it happened to coincide with the beginning of the WWW (Arms, 1996). The year 1994 marked the beginning of the National Digital Library Program (NDLP). Many important collections became available toward the end of that decade. Much digitization was undertaken as collaborative efforts between the Library of Congress and major U.S. universities. Seventeen such collections were awarded development funds; the collections are listed at http://memory.loc.gov/ammem/award/online.html. A typical example is the Traveling Culture collection from the University of Iowa (Figure 3; http://memory.loc.gov/ammem/award98/iauhtml/tccchome.html). This preserves 8,000 brochures

used to publicize Circuit Chautauqua, a system that sent lecturers and serious performers from city to city in the midwest in the early 20th century. Ephemeral materials of this nature are essential for a rounded view of cultural life, but access to the originals was highly restricted. In an arrangement typical of these collaborative efforts, collection details and thumbnail images are loaded by the Library of Congress while the user who requests a full-size image is switched seamlessly to a University of Iowa libraries server.

Several specific collections from the American Memory system are discussed in relevant subject categories below.

Another source of multimedia digital libraries is the Berkeley Digital Library SunSITE (http://sunsite.berkeley.edu/), a collaborative initiative by the Library of the University of California at Berkeley and Sun Microsystems. Their Jack London Collection (http://sunsite.berkeley.edu/London/) offers multiple approaches to this multifaceted author. The collection includes the full text of many of London's books, reproductions of letters and documents, photographs, and audio. It is further supported by a biography, a list of frequently asked questions, listserv, recommended links, and so forth.

The Florida Center for Instructional Technology of the University of South Florida produced the Teacher's Guide to the Holocaust (Figure 4; http://fcit.coedu.usf.edu/Holocaust/), a multimedia collection with a strong message. This offers the text of primary source materials, photographs, films, and music, backed up by maps, bibliographies, and glossaries.

As disk space continues to become more affordable and more bandwidth is available, we can expect to see more multimedia collections.

Book-Oriented Collections

Early digital libraries concentrated on books and were mostly initiated at North American universities. Project Gutenberg (http://promo.net/pg/ or http://gutenberg.net/) is often considered the first significant digital library. It was founded in 1971 by Michael Hart, who was given time on the University of Illinois mainframe computer. The first text distributed was the *Declaration of Independence*, which Michael Hart personally keyboarded. Project Gutenberg has always concentrated on simple presentations, originally FTP downloads of "plain vanilla" ASCII texts, which can be read on almost any computing platform. Many of Project Gutenberg's more than 4,000 texts are now available in HTML, and the volunteer-supported project has numerous mirror sites.

The University of Virginia Electronic Text Center (http://etext.lib.virginia.edu), founded in 1992, now offers 70,000 humanities texts, which have been downloaded more than six million times. Nearly 10,000 of the texts are modern books in English. They are divided into subject groupings, such as the Salem Witch Trials (Figure 5; http://etext.lib.virginia.edu/salem/witchcraft/).

The Center also offers much valuable information on digitization, and links to other English-language full-text Web resources (http://etext.lib.virginia.edu/eng-oth.html). It is one of the few digital libraries with

significant offerings in the area of downloadable books, for Palm Pilots or MS Reader (http://etext.lib.virginia.edu/ebooks/ebooklist.html). This is clearly an area with huge potential, as the 1,800-volume collection attracts approximately 300,000 downloads monthly.

The University of Michigan has played a major role in digital library and electronic journal activities. It is responsible for one of the most significant book-oriented projects, the Making of America (http://moa.umdl.umich.edu/). This concentrates on primary source materials for 19th-century American social history from the antebellum period through reconstruction. It contains 8,500 books and 50,000 journal articles, which sophisticated software presents in a choice of image, text, or .pdf files, in normal, large, and small size. The University of Michigan also offers further texts, outside the scope of the Making of America collection, from its Humanities Text Initiative (http://www.hti.umich.edu/index-all.html). Of special interest here is the American Verse Project, preserving pre-1920 American poetry (http://www.hti.umich.edu/a/amverse/).

The American Memory collections of the Library of Congress do include books, but these are mostly specialized collections, such as the 170 Sunday school books published in America between 1815 and 1865, from Michigan State University Libraries and Central Michigan University Libraries (Figure 6; http://memory.loc.gov/ammem/award99/miemhtml/svyhome.html).

A similar specialized collection is the 200 dance instruction manuals digitized at http://memory.loc.gov/ammem/dihtml/dihome.html. The major strength of American Memory is not in the number of books digitized but in the depth and quality of its special collections.

The motto of Bartleby.com is “Great books online” (http://www.bartleby.com/). It offers the classics of English and other literatures and is also strong in authoritative reference materials. It was named after a character from Herman Melville and was founded as a personal research project by an enthusiast in 1993. The first book published was Whitman’s Leaves of Grass.

The Alex Catalogue of Electronic Texts is a collection of public domain documents from American and English literature as well as Western philosophy (http://www.infomotions.com/alex/). It began as a gopher service in 1994.

The English server (http://eserver.org/), founded in 1990 at Carnegie Mellon University, now hosted at the University of Washington, offers over 30,000 texts, including articles, academic resources, and poems. In an unusual collaborative arrangement, most materials are produced or edited by nearly 300 members. Materials are divided into over 40 subject categories and texts may be available in either ASCII or HTML. Resources also include 40 full-length books by major authors.

Image-Oriented Collections

The largest and most important collection of historical photographic images is that devoted to Farm Security Administration photographs (Figure 7; http://memory.

12,000 photographs of the Mid-Atlantic states New York, New Jersey, and Connecticut from the 1850s to the 1910s, from the Robert N. Dennis Collection of Stereoscopic Views

Figure 8: Stereoscopic views were popular a hundred years ago, and are again available after digitization by the New York Public Library.

loc.gov/ammem/fsowhome.html). This contains about 160,000 black and white photographs, focusing on American rural life during the Depression. Keyword, subject, creator, and geographic indexes are available.

Earlier, equally fascinating, views can be found in "Small-Town America" (Figure 8): stereoscopic views of the mid-Atlantic states, from the 1850s to the 1910s, from the New York Public Library (http://memory.loc.gov/ammem/award97/nyplhtml/dennhome.html).

The stereoscopic views are available in both front and back views. It is especially interesting that the advanced technology of a century ago, stereoscopic views, is being preserved by today's most advanced communication medium, the Internet.

The Bancroft Library at the University of California, Berkeley, offers the California Heritage Collection. This is an online archive of more than 30,000 images illustrating California's history and culture (http://sunsite.berkeley.edu/CalHeritage/).

Manuscripts

Digital libraries have led to a blurring of the previously strict line between archives and libraries. In fact digital libraries often include significant content of historical manuscripts. The American Memory collection includes the papers of George Washington at the Library of Congress (http://memory.loc.gov/ammem/gwhtml/gwhome.html), a total of 60,000 items. Abraham Lincoln's papers are also available, in approximately 61,000 images and 10,000 transcriptions (http://memory.loc.gov/ammem/alhtml/malhome.html).

Ephemeral Materials

The Internet is an excellent medium for ephemeral materials, so it is no surprise that digital libraries frequently preserve and disseminate ephemera. A well-organized example is the Broadside ballads collection of one of Britain's oldest libraries, the Bodleian Library of Oxford University (http://www.bodley.ox.ac.uk/ballads/). Three thousand items of Historic American Sheet Music from the collections of Duke University can be found at http://memory.loc.gov/ammem/award97/ncdhtml/hasmhome.html. Spanish Civil War posters were digitized at the University of California at San Diego (Figure 9; http://orpheus.ucsd.edu/speccoll/posters/table.html).

Audio and Motion Picture Files

Simple audio and visual files are already available within digital libraries, a trend that, no doubt, will increase rapidly in the future. The section above on multimedia digital libraries gave several examples of systems, which offer partial audiovisual content. A major site dedicated to audio files is History and Politics Out Loud (http://www.hpol.org/). There it is possible to hear a variety of political rhetoric, from Franklin Roosevelt's speech asking Congress to declare war on Japan, to Bill Clinton trying to explain away his relationship with Paula Jones.

Here the Spanish conflict is presented as the struggle of man against beast. The revolutionary--red--hued, naked, and muscular--wields his hammer against a serpent coiled about his body; the man's nakedness reflects the purity of his cause, in contrast to the insidiousness of the coiled snake of fascism. The caption announces that the poster was produced by the anarcho-syndicalist trade union *Confèderación Nacional del Trabajo* (CNT) in conjunction with the international anarchist organization *Asociación*

Figure 9: Spanish Civil War poster, digitized at the University of California, San Diego.

Perhaps the most fascinating cinematographic content in digital libraries is found in the Early Motion Pictures collection of the American Memory collection: (http://memory.loc.gov/ammem/vshtml/vsfilm.html). This preserves and disseminates numerous short films from the dawn of the cinema.

A series of nearly a thousand films is freely available from the Internet Archive (http://www.archive.org/movies/index.html). These are mostly short films, illustrating various aspects of American life in the 20th century.

Electronic Journals (E-journals)

Scientific and professional journals have long been vital elements of library collections. Their electronic equivalents, e-journals, became an area where digital penetration has been intense, and often both commercially driven and controversial. The field can be divided into three major categories: commercial, semicommercial, and free e-journals.

The commercial e-journal field has roots going back to the second half of the 20th century, when the journal field came to be dominated by a small number of specialized publishing houses. They gained a reputation for constantly increasing prices in excess of inflation. As faculty and researchers considered journals essential for research, libraries were under pressure to keep subscribing to ever more expensive periodicals. This had a negative impact on other library areas, notably, book budgets.

Any ideas that the introduction of e-journals would automatically lead to a decrease in journal prices were soon dispelled. Major publishers now offer both paper and electronic versions of their journals; there is often little cost advantage in subscribing to electronic versions alone. In fact, libraries may end up subscribing to bundles of e-journals, including titles in which they have little interest. Prices for the bundles increase, occupying ever larger portions of library budgets. Cancellation of individual titles brings little relief, and librarians complain that they are unable to publicly discuss their contract terms (Foster, 2002). Access to electronic versions of established journals is limited to identifiable members of universities and similar institutions and is controlled by a small number of established publishers and subscription agents. These closed-access systems have little impact on the Internet in general. Major systems include Elsevier, a leading name in scientific journal publishing, which maintains Science Direct (http://www.sciencedirect.com/), offering controlled electronic access to 1,700 titles, and 3.9 million articles. Blackwell's Synergy system permits nonsubscribers to purchase single items (http://www.blackwell-synergy.com/). Ebsco, long-established as an agent fulfilling library journal subscriptions, now permits libraries to access over eight 8,000 e-journals (http://www.ebsco.com/ess/services/online.stm). Because of the volatility of e-journals and the potential loss of long-term electronic access, libraries prefer to purchase e-journal subscriptions via established sources.

This situation has come to be called the Serials Crisis by faculty and librarians, whose opinions are disseminated in Create Change (http://www.arl.org/create/home.html). This site states that the 121 members of the Association of Research Libraries spend about $480 million per year on journal collections, an average of about $4 million each. A consortium of 80 Ohio academic libraries was spending about $19 million annually for access to about 4,500 journals (Foster, 2002). Faculty and researchers write journal articles and donate them to journal publishers, normally without receiving royalties. They also generally work free of charge as referees and editors for scientific journals. These same journals are then sold back to the libraries of their institutions at a steep price. Electronic journals are seen as a way out of this situation. One solution is offered by SPARC, the Scholarly Publishing and Academic Resources Coalition (http://www.arl.org/sparc/home/index.asp?page = 0), which has set up a collaborative system for academic e-journal production. Intermediate, semicommercial approaches are offered by Project Muse, of Johns Hopkins University Press (Figure 10; http://www.press.jhu.edu/muse.html), and JSTOR, the scholarly journal archive (http://www.jstor.org/), organized by the University of Michigan. Project Muse offers reasonably priced access to over 100 titles. JSTOR works on a nonprofit basis and handles backfiles of over 200 titles. They both limit access to members of subscribing institutions.

The International Consortium for the Advancement of Academic Publication, based at Athabasca University, Canada (http://www.icaap.org/), offers a collaborative system for publishing specialized e-journals.

The field of free e-journals has also expanded rapidly. The Internet Library of Early Journals, a cooperative UK program, offers free access to six key 18th and 19th century journals (http://www.bodley.ox.ac.uk/ilej/). A significant portion of the e-journal field can be searched database style via the Electronic Journal Miner set up by the Colorado Alliance of Research Libraries (http://ejournal.coalliance.org/). Their site also lists other guides to e-journals (http://ejournal.coalliance.org/info/other.html). Three thousand titles are listed at the Internet Public Library (http://www.ipl.org/reading/serials/). An additional list of e-journals can be found at the World Wide Web Virtual Library (http://www.e-journals.org/). The Association of Research Libraries published the first printed list of e-journals in 1991, with 173 pages. The latest edition of its Directory of Scholarly Electronic Journals and Academic Discussion Lists (2000) has over 1,100 pages and includes nearly 4,000 peer reviewed journals (http://www.arl.org/scomm/edir/index.html).

Theoretically, electronic journals offer additional advantages in relation to traditional journals because they can incorporate audio, music, short films, animations, and so forth. So far, this potential has been underexplored. Animated displays of physical data can be found in a SPARC journal, the *New Journal of Physics* (go to http://www.njp.org and look for papers which include multimedia elements).

Newspapers present difficult problems of storage, analysis, and retrieval of information. NewspaperArchive (Figure 11) is a well-indexed source: Five newspapers are

free; a subscription is charged for full access. In April 2002, this Cedar Rapids company claimed to have over one million pages available online, and to be adding 11,000 to 14,000 pages a day (http://www. newspaperarchive.com/default.asp).

Electronic Theses and Dissertations (ETDs)

Theses and dissertations are produced in high-tech institutions and universities and are of interest to highly literate users, who are accustomed to retrieving information via the Internet. These are generally produced according to standardized print formats, and they have also traditionally been difficult to obtain. The potential for electronic theses and dissertations is therefore great; constraints seem to be the lack of standardized delivery systems, and the fear of some authors that wider thesis availability might prejudice later book publication. A general reference point is the Networked Digital Library of Theses and Dissertations (NDLTD; http://www.ndltd.org/). A founding member of this was Virginia Tech, which now offers unrestricted access to over 2,000 digital theses (http://scholar.lib.vt.edu/theses/). Experience shows that digital availability stimulates use and promotes the author's reputation. West Virginia University reports over 1.4 million hits on its digital theses collection (http://www.wvu.edu/~thesis/News/WVU_ETDS_Over_1_Million_Served.htm). Usage of digital theses far outpaces consultation of paper equivalents. The "champion" thesis at WVU had been accessed 13,000 times. An interesting intermediate solution is offered by MIT (http://thesis.mit.edu/), which permits reading of theses in a presentation that inhibits online printing; interested persons can buy .pdf versions online, or purchase paper copies which are then sent by mail.

Pointer or Signpost Sites

The first attempt to produce a guide to the WWW was by the creator of the WWW, Tim Berners-Lee, shortly after he created it. The WWW Virtual Library, a cooperatively updated system, can still be found at http://vlib.org/Home.html.

Sites that simply direct users to Internet resources are considered digital libraries when they are organized in a manner similar to libraries. The most significant of these services is the Internet Public Library (http://www.ipl.org), originally set up in 1995 as a class project at the School of Information at the University of Michigan (Magpantay, J. A. et al., 1997). It has sections for reference and texts, magazines and newspapers, teens and youths, and so forth.

Those who really love libraries will enjoy lists of Web resources classified by the Dewey Decimal Classification system (http://www.oclc.org/oclc/fp/worldwide/web_resources.htm or http://bubl.ac.uk/link/ddc.html). BUBL, originally the Bulletin Board for Libraries, also offers subject area access to the Internet (http://bubl.ac.uk/link/). A major British contribution to Internet information retrieval is the creation of subject gateways

for specific subject areas. Probably the most successful of these is the Edinburgh Engineering Virtual Library (http://www.eevl.ac.uk); there is also ADAM (Art, Design, Architecture and Media Information Gateway; http://www.adam.ac.uk), Organizing Medical Networked Information (OMNI; http://omni.ac.uk), and the Social Science Information Gateway (http://sosig.ac.uk). A general resource, linked to these British sites, is the Resource Discovery Network, a gateway to, or a directory of, gateways (http://www. rdn.ac.uk/).

Infomine was founded by librarians at the University of California, Riverside, in 1994 (http://infomine.ucr.edu/). It offers both directory and search access to 23,000 Internet resources. The California State Library maintains the Librarian's Index to the Internet, which includes 6,400 Internet resources (http://lii.org/).

Project i-DLR was developed by faculty and students at the University of Missouri-Columbia (http://whistletest.coe.missouri/~rafee/iDLR/index.php) to provide access to educational materials in support of digital library concepts and practices.

Commercially Oriented Digital Libraries

The history of the Internet, so far, can be divided into two major phases. The first was exploration and initial content creation, led by academics and enthusiasts. This was followed by the arrival of commercial interests, who looked around and asked how they could make money out of this. It is notoriously difficult to make money from library services and so far there has been considerable difficulty in establishing successful, commercially profitable, digital libraries covering a wide range of materials. The situation was worsened by the dot-com shakeout of late 2000 to mid-2001. Probably the most successful system to date is NetLibrary (Figure 12; http://www.netlibrary.com/), which offers 40,000 titles and has always concentrated on selling through libraries. NetLibrary permits simultaneous access to only a limited number of copies of each book. This appears strange in view of the Internet's capability of generating an unlimited number of copies of a digital text, but this restriction encourages publishers to join the system. Rapid printing of multiple pages is also inhibited.

In 2002, NetLibrary was sold to OCLC (Online Computer Library Center; http://www.oclc.org/home/), a cooperative system that supplies automated cataloging data to more than 40,000 libraries. The OCLC's stability and the ease of access to libraries should guarantee a bright future for NetLibrary.

Another major commercial digital library initiative is Houston-based Questia (http://www.questia.com/), which claims to be the world's largest online library of books. It digitized a core collection in the humanities and social sciences, excluding business and science texts, and offers 45,000 complete books and 25,000 journal articles. There is an excellent advanced software interface and full access costs $19.95 a month. The third player in this field is ebrary (http://www.ebrary.com/), financed by major publishers, including Random House and McGraw–Hill. This

Figure 13: Rosetta Books specializes in the publication of downloadable e-books.

was being launched in 2002 with a business model that permitted consumers to view pages free but charged them to print.

The Association for Computing Machinery (ACM) is an outstanding example of a professional association that has been able to successfully implement a paid-access digital library, the ACM Digital Library (http://portal.acm.org/). It has, of course, a major advantage, in that it is aimed at an audience with a very high level of computer literacy. Niche services offered by professional associations may in some cases offer greater potential than purely commercial systems.

This chapter deals above all with libraries viewed via the Internet, but an important parallel area is springing up: that of commercially produced e-books downloaded to user's devices. The possibilities exploded into public view in the year 2000, when half a million people downloaded Stephen King's e-book, Riding the Bullet. Notable among specialized publishers of downloadable e-books is Rosetta Books (Figure 13; http://www.rosettabooks.com).

Rosetta Books received considerable publicity in 2001 when Random House tried to stop them from distributing electronic versions of works by Kurt Vonnegut, William Styron, and Robert B. Parker. The judge ruled in favor of Rosetta Books, determining that ebooks are a separate medium from the original product, because they offer full-text searching, hyperlinking, and other electronic advantages (Random House, 2001). Palm Digital Media at Peanut Press (http://www.peanutpress.com/) offers 5,000 titles for sale. PalmBooks links to over 1,600 free texts readable on Palm hand-helds (http://www.palmbooks.org/default.asp). For a general overview of downloadable e-books, look at the relevant subdivision of the major online bookshop sites, Barnes and Noble (http://www.bn.com/) or Amazon (http://www.amazon.com/).

PROCEDURES AND PRACTICES IN THE DIGITAL LIBRARY FIELD

Selection and Collection Development

The first step in digital library creation is to identify and select appropriate originals for dissemination in digital form. The basic principles are similar to those of traditional library collection development policy: to select quality materials of high potential demand for the intended audience of end users. In many cases, rare books, photographs, and ephemera from special collections maintained by university libraries will form the nucleus of successful digital libraries (Love, 1998). If a formal project is to be submitted to a funding body, they will need to know as exactly as possible how many items will be scanned and processed. Digital selection, unlike traditional selection, is not constrained by lack of physical space, or by the range of materials available from traditional publishers.

Copyright

Beyond any doubt, the major constraint on the digital library field comes from the copyright laws. These were written to control physical objects and adapt poorly to digital environments. Constitutionally, copyright is granted

for "limited times," but terms have been extended, largely in response to pressures from film studios. The Sonny Bono Copyright Act, 1998, fixed copyright at the life of the author plus 70 years. Pre-1978 works in copyright are protected for 95 years from the date copyright was first secured. Most materials produced in 1923 or after are protected by copyright. Consult the Public Domain and Copyright How-To page of Project Gutenberg (http://promo.net/pg/vol/pd.html) or "When works pass into the public domain" (http://www.unc.edu/~unclng/public-d.htm). Note that all works are protected—books, films, photographs, ephemera, newspapers—anything fixed in tangible form, whether or not anybody is interested in protecting their rights in these materials. In 1930 about 10,000 books were published in the United States; today fewer than 200 are still available from publishers (Brief, 2002). The other 9,800 may well include texts, which might usefully be made available to the public in digital form, but they continue to enjoy full copyright protection until 2019. No institution could risk digitizing them, for fear that rights-holders might suddenly appear.

In many cases, digital libraries find it simpler to limit themselves to pre-1923 materials, to avoid the troublesome process of identifying rights-holders. Most book publishing contracts signed in the United States in the 20th century state that rights return to the author a few years after the book goes out of print (Lynch, 2001). When the authors die, these rights pass to their descendents. This has created a huge class of "orphan books," items for which no rights-holder can be traced. The situation is even less clear for photographs and ephemera. If the rights-holder can be identified, the digital library has to go through a lengthy, often expensive, and sometimes fruitless process of negotiating rights.

One solution is to work with copyright-free niche collections, which avoid copyright problems. The Government Publications from World War II at Southern Methodist University (http://worldwar2.smu.edu) can be freely disseminated, because U.S. government publications are not copyrighted. A similar example comes from the Truman Presidential Library and Museum (http://www.trumanlibrary.org/), which, like many of the Presidential Libraries under direction of the National Archives and Records Administration (NARA), provides access to records that are in the public domain. The University of Iowa maintains medical documentation on its Virtual Hospital and Virtual Children's Hospital sites (Figure 14; http://www.vh.org or http://www.vch.org). These are based on noncopyright government publications and texts contributed by faculty of the University of Iowa.

Also in the medical field, PubMed, set up by the National Library of Medicine, facilitates public awareness of 11 million items of medical literature (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi). There are no copyright problems because they offer abstracts rather than full text.

Another possibility is to concentrate on tribute sites, for which permission is normally readily given. The Jack London tribute site at Berkeley SunSITE has already been cited; SunSITE maintains a similar site for the anarchist and feminist Emma Goldman (http://sunsite.berkeley.edu/Goldman/). This includes selected texts, documents, and even newsreel footage.

Further possibilities are opened up by licensing systems, such as Open Content (http://opencontent.org/index.shtml), which does for publications what Open Source licensing does for software. Open Content is freely available for modification, use, and redistribution; but if someone else bases a work on Open Content, the result must also be made available as Open Content. The license relieves authors of liability or implication of warranty and insures that they will be properly credited when Open Content is used. Others may modify and redistribute the content if they clearly indicate the changes that have been made.

Digitization of Materials for Digital Libraries

High-quality scanning is typically used for images incorporated into digital libraries. It is standard practice to produce three files. First there is an archival or master file normally in .tiff format (tagged image file format); this will be carefully archived but may not be available to the public. Next come the viewing or access files, normally in .jpg format (Joint Photographic Experts Group), although Adobe's .pdf (portable document file) system can also be used. These are currently the most popular formats for general image display. Finally, it is common to produce a thumbnail image, usually a small .jpg file or .gif (graphic interchange format), for quick-reference and table-of-content purposes. A useful summary of current practice can be found in the Arizona State Library, Archives and Public Records' Digitization Guidelines (http://www.lib.az.us/digital/dg_a4.html). These suggest, for photographic reproductions, a resolution of 600 dpi (dots per inch) for archive images, 300 dpi for viewing images, and 72 dpi for thumbnails.

Digital libraries also need to convert page images to text that can be manipulated. This would now normally be HTML text, although early systems used plain ASCII .txt files. Conversion to text is undertaken using quality OCR (optical character recognition) software, such as Omnipage Pro (University of Virginia Electronic Text Center, 1998). Even first-class scanning software can confuse certain words, for example clean/dean or modern/modem. Careful proofreading is therefore essential. The problem is especially acute in digital libraries, which pride themselves on offering quality content but which process a large proportion of older and specialized texts, with rarely used terms, unusual spellings, unusual fonts, and so forth. Highly qualified personnel are required to proofread such texts.

Text Indexing

Complete, word-by-word text indexing is a valuable feature of most digital libraries. Specialized software for this area includes the XPAT search engine, part of the University of Michigan Digital Library eXtension Service (DLXS) software suite (http://www.dlxs.org/). This software can be seen in action in one of the most daunting indexing challenges faced by a digital library, the Legacy National Tobacco Documents Library (LNTDL; http://legacy.library.ucsf.edu/index.html). The collection contains over 20 million documents, obtained through the legal discovery process for a lawsuit, relating to scientific research, manufacturing, marketing, advertising, and sales of cigarettes.

Another specialized example is the Simple Web Indexing System for Humans-Enhanced (SWISH-E; http://swish-e.org/). This Open Source software is used to enable full-text indexing of many sites, including the Berkeley Digital Library SunSITE (http://sunsite.berkeley.edu/cgi-bin/search.pl), and even the Apache Web Server site (http://search.apache.org/).

Metadata

The addition of Metadata or subject terms adds significant value to digital records. The American Memory collections are especially notable for enriching records with numerous Library of Congress subject headings. The best-known system, specifically developed for a digital environment, is the Dublin Core, first developed at a meeting in Dublin, Ohio, in 1995. The Dublin Core Metadata Element Set (http://dublincore.org/documents/dces/) specifies metadata elements such as title, creator, subject, and rights (for digital rights management information).

The use of metadata is clearly demonstrated in Figure 15, from the Louisiana State University Digital Library (http://www.lsu.edu/diglib/).

The source code for the page, containing the photograph of a famous building in the French Quarter of New Orleans (http://APPL005.lsu.edu/FJC.nsf/AllDocView/fj000127?OpenDocument), includes the following metadata; "DC" identifies this as Dublin Core metadata.

```
<META name="DC.Title" content="LaBrauche
  House"
<META name="DC.Creator" content="Johnston,
  Frances Benjamin, 1864-1952"
<META name="DC.Subjects" content="Historic
  buildings";"Architecture, Domestic";
  "Wrought-iron";

Metadata creation requires highly trained analysts, similar to traditional catalogers, normally working with a list of acceptable terms. It can therefore add significantly to both the value and the cost of systems.

XML: Extensible Markup Language

Digital libraries often employ a markup language (such as extensible markup language, XML), to give additional structural meaning to the text. The best-known markup language, hypertext markup language (HTML), the basis of the WWW, defines the appearance of specific blocks of text, which can appear as bold, centered, and so forth. XML uses a similar system of tags in pointed brackets, but it can specify semantic elements. It can identify a specific piece of text as being an author's name, an article title, an abstract, and so forth. XML is better thought of as a toolkit for developing a markup language, whereas HTML is a simple markup language with fixed capabilities. HTML basically controls presentation and is not extensible. One of the most easily consulted examples of XML in a digital library context is that created by the National Library of Medicine to facilitate communication of abstracts of medical literature to PubMed. An extract is presented below.

```

This abbreviated example is for the journal *Science*, volume 271, issue 5. The full example, which includes authors and their addresses, title, and abstract of the paper, can be consulted at http://www.ncbi.nlm.nih.gov:80/entrez/query/static/spec.html#ExampleXMLfile.

The use of XML and other markup languages in digital libraries is a complex subject; a useful introductory overview of the field can be found on the University of Virginia's Electronic Text Center's Standards page (http://etext.lib.virginia.edu/standard.html). This also covers other systems used in the field, such as Standard General Markup Language (SGML), Text Encoding Initiative (TEI), and Electronic Archival Description (EAD).

Computing Systems

Special-purpose software solutions include the University of Michigan DLXS software suite (http://www.dlxs.org/), which can be seen in action in Michigan's Making of America collection (http://moa.umdl.umich.edu/).

The Greenstone Digital Library software is an interesting free Open Source software suite for digital libraries (http://www.greenstone.org/english/home.html). It

was developed at a university in New Zealand, and its major application is the New Zealand Digital Library (Figure 16; http://www.nzdl.org/cgi-bin/library). It offers multiscript capabilities and has also been used for collections of United Nations documents relevant to developing countries.

Open Source software is widely used for server software and in academic environments. It is therefore natural that it is often preferred for digital library database work. The best known standardized language for databases is SQL (Structured Query Language).

In the digital library field, it is normally applied via Open Source server-side database software, of which PostgreSQL and MySQL are frequently cited as powerful alternatives. A combination of MySQL with PHP has drawn much attention recently. PHP (http://www.php.net) is a server-side Web-scripting language whose predefined function set easily interfaces with MySQL. The Digital Library Toolkit (Noerr, 2000) contains a useful overview of software. ColdFusion is a commercial database software alternative.

Z39.50 compliant software will be required to query traditional library catalogs and bibliographic databases (*Biblio Tech Review*, 2001). It is often considered too complex for large-scale application in an Internet environment. One possible solution is the Open Archives Initiative (OAI; http://www.openarchives.org/), which is based on Harvester/Server Architecture. Participating data stores would make simple metadata available in standardized format. Information systems would harvest relevant metadata, which would then be used to power relevant subject gateways. The model is being tested with Americana, environmental information, and academic publications (Digital Library Federation, 2001).

Maintenance and Management

Digital libraries require constant maintenance and updating. Links to external sources have to be checked frequently. In a major system this will be done nightly, by a dedicated program. An e-mail address for contact will have to be given, and somebody will have to field the often surprisingly wide range of messages received from the general public. Major pointer systems will offer a question answering service, such as that maintained by the Internet Public Library (http://www.ipl.org/ref/QUE). This requires a major investment of time and intellectual effort. Digital library interfaces may be modern now, but will eventually become tired, old-fashioned, and in need of updating. The successful management of digital libraries requires a rare combination of computational, organizational, bibliographic, and aesthetic skills.

Preservation

Preservation is a vital element of digital library activities and touches on two distinct areas: preservation of physical originals and preservation of digital masters. Originals of photographs and broadsides will normally be retained, even after digitization. Books, which may be printed on brittle paper and may have been unbound to facilitate digitization, can be more difficult to preserve. Microfilm has been the standard answer, but libraries have recently been criticized for failing to retain the originals of microfilmed newspapers (Baker, 2001). In the future there will, no doubt, be strong pressure on libraries to preserve originals after digitization, especially when they are the last available copies.

Protection of digital masters is the second level of preservation activities. Libraries have traditionally thought in terms of centuries. Computer software only lasts a few years before being replaced by new, and often incompatible, systems. Procedures today include saving .tiff files on CD-ROMs or on digital tape, and carefully refreshing digital files at regular intervals.

For a fascinating, publicly visible digital preservation service, see the Internet Archive and the Wayback Machine (http://www.archive.org/index.html). This permits nostalgic surfing through the Web of several years ago, and access to special collections recording specific events.

Resources in the Digital Library Field

The Digital Library Federation (http://www.diglib.org) is a Washington-based consortium of 30 major institutions. It maintains a guide to Public Access Collections at http://www.hti.umich.edu/cgi/b/bib/bib-idx?c = dlfcoll. This offers database-style access to more than 370 digital libraries. Important general information sources for the digital library field include Berkeley's SunSITE (http://sunsite.berkeley.edu/). Resource pages are maintained by Candy Schwartz at Simmons (http://web.simmons.edu/~schwartz/dl.htm), Ben Gross at Illinois (http://www.canis.uiuc.edu/~bgross/dl/), and Tom Kochtanek and Rafee Kassim at Missouri (http://whistletest.coe.missouri.edu/~rafee/iDLR/index.php). Chowdhury (2000) compares the information retrieval features of 20 important digital libraries. Major textbooks for the field have been authored by Lesk (1997) and Arms (2000). For an excellent recent printed overview of the field, see Fox (2002).

The digital library field is often financed by special government grants. Of vital importance to digital library development in the United States was the National Science Foundation's Digital Libraries Initiative. Phase 1 projects, 1994–1998, are at http://www.dli2.nsf.gov/dlione/ and were discussed by Fox (1999). Phase 2 projects can be seen at http://www.dli2.nsf.gov/ and were summarized by Lesk (1999). An important current source of finance for digitization projects in the United States is the Institute of Museum and Library Services (IMLS; http://www.imls.gov/index.htm). For examples of IMLS support, see http://www.imls.gov/closer/cls_po.asp. Research in the digital library field has been reviewed by Chowdhury (1999).

As might be expected, the digital library field is well served by e-journals. The principal U.S. e-journal is *D-lib Magazine*, published by the D-Lib Forum (Figure 17; http://www.dlib.org/).

Figure 17: D-Lib Magazine is the principal United States e-journal for the digital library field.

From Britain come *Ariadne* (http://www.ariadne.ac.uk/) and the *Journal of Digital Information* (JoDI; http://jodi.ecs.soton.ac.uk/). The major U.S. conference in this area is the Joint Conference on Digital Libraries (JCDL), sponsored by ACM and the Institute of Electrical and Electronics Engineers (IEEE). The European equivalent is the European Conference on Research and Advanced Technology for Digital Libraries (ECDL).

CONCLUSION

Standards

We are still in the early stages of digital library development. Different systems are being used. Procedures for digitization, subject analysis, and indexing are emerging and will, no doubt, become standardized in the near future. Cross-collection indexing is especially important in increasing access to digital texts.

Copyright

Copyright laws are a major constraint on the growth of digital libraries, because they automatically make many decades of intellectual effort unavailable for digitization. In the near term, content creators benefit from copyright protection, but the situation is confused by publishing contracts and long-term extension of copyrights. Publishers benefit from a few profitable items, but much more material is lost without significant gain to anyone. In a digital world, materials that are not available via the Internet will, in effect, almost cease to exist. They fall into the same category as oral tradition in a print society. It is also difficult to forecast how the copyright laws might be changed when publishers look on digital rights as a guarantee of future profitability.

Distance Education

More attention is being paid to distance education, especially for specialized graduate level courses. But it is difficult to see how distance education programs can be successful unless supported by adequate access to digital information.

Reading Devices

Digital development is now in a curious intermediate situation. Digital media offer clear advantages for storage and wide-area delivery of text that can be manipulated on a computer. Readers, however, still prefer the traditional end-user interface, the printed book, rather than computer screens. Early electronic reading appliances have not been successful with consumers. It is probable that the solution will shortly emerge in the convergence of the laptop computer with personal digital assistants (PDAs) and mobile telephony. This appliance would be even more attractive to the public if it were to include a digital camera, a digital recorder, and a GPS. This would create a highly portable, multifunction, use-anywhere communication and support device, which might rapidly become

American Memory is a gateway to rich primary source materials relating to the history and culture of the United States. The site offers more than **7 million digital items** from more than 100 historical collections.

Figure 18: The American Memory Historical Collections, maintained by the Library of Congress, contain more than 7 million digital items in over 100 collections.

the preferred interface for digital library consultation. Lynch (2001) points out that the new technologies have a potentially steep social price, because they provide new levels of control, monitoring, and usage restrictions for digital books. The paradox is that unless publishers are able to establish what they consider adequate levels of control, in-print books may not move to digital form. They certainly will not migrate quickly or in large numbers. It is likely that publishers will favor appliance book readers, but it is also possible that print-on-demand publishing (POD) will occupy a significant niche in the future.

The Future of Books

It is not helpful to speak of "books" in general in this context. Periodicals have undergone major changes recently, but various categories were affected differently. Weekly illustrated magazines, such as *Life*, were unable to compete with television. Abstract journals were swallowed up by online databases. Bulletins of professional associations were made redundant by discussion lists. Mimeographed poetry migrated to the Internet. But mass market magazines seem secure and local newspapers receive strong support from local advertising. A similar patchwork can be expected in the book world. Reference books, such as encyclopedias, have already largely gone into digital form. Academic publishing may well transfer to a digital environment. At least two sharply different areas should survive. Mass market paperbacks should continue to serve environments with limited access to digital libraries. Quality hand printing will continue to produce beautiful, but attainable and collectible, books. It would be wrong to say that the physical book will disappear in the digital environment. Media such as theater and wood engraving have not disappeared, although the rise of alternatives has confined them to a more limited strata of the population.

The Future of Digital Libraries

Kurzweil (1999) makes wide-ranging prophecies for the penetration of society by computers. He forecasts that by 2019, most useful 20th century documents will have been digitized; paper documents will rarely be used. The problems of digitization seem too massive for such a rapid change. The hybrid library, simultaneously storing hardcopy books and offering digital access to specialized materials, seems a more probable model for the medium term.

The long-term perspectives for digital libraries seem excellent. Libraries will, no doubt, continue to make quality and older materials available. If publishers are able to develop secure business models that guarantee significant commercial returns from digital information, they will, no doubt, migrate in force to the digital environment. Digital libraries have made a solid start, have been widely accepted, and can be expected to continue to contribute to society.

GLOSSARY

American Memory The Historical Collections of the National Digital Library, maintained by the Library of Congress (Figure 18; http://memory.loc.gov/); one of the world's largest digital libraries, with over 100 collections, a total of seven million digital items, including photographs, manuscripts, rare books, maps, sound recordings, and moving pictures.

Digital library A system that permits, via the Internet and the WWW, easy access to a collection of high-value, quality digital content, which has been selected and organized to facilitate use and is supported by appropriate services. The digital content may reflect the traditional textual orientation of many libraries or take advantage of the WWW's facilities to deliver graphics and multimedia. The term digital library is also used to refer to quality digital information and referral services whose organization reflects the traditional structure of library services.

Digitization Process of converting analog documents (e.g., paper, film, maps) to digital form.

Electronic journals (e-journals) Journals, such as scientific and professional journals, available in digital form.

Electronic theses and dissertations (ETDs) Theses and dissertations available in digital form.

Indexing The process of systematically generating pointers or keys to the content of texts, permitting readers to go directly to pages that contain specific words or deal with specific topics.

Internet Public Library Major library-style information source (http://www.ipl.org) originally set up in 1995 as a class project at the School of Information of the University of Michigan.

Metadata Data about data. Keys, guides, or indications of the content of a document.

Multimedia digital library Digital library that delivers content in a variety of formats: text, photographic images, audio, short films, and so forth.

Pointer or signpost sites Sites that do not offer their own content but direct users to Internet resources. These are considered digital libraries when organized in a manner similar to libraries.

Project Gutenberg One of the longest running digital libraries (http://promo.net/pg/or http://gutenberg.net/), founded in 1971 by Michael Hart. It has always concentrated on simple, copyright-free texts that can be read on almost any computing platform. Now offers more than 4,000 texts and is supported by a network of mirror sites.

Signpost sites See Pointer or signpost sites.

Digital Signatures and Electronic Signatures

Raymond R. Panko, *University of Hawaii at Manoa*

INTRODUCTION

When we send letters, we sign them to indicate that they are from us. When we sign contracts, we are expressing our willingness to abide by the terms of the contract. We cannot later repudiate the contract because our signature binds us. Signing is also possible in the electronic world, and it generally serves the same purposes.

There are three related terms we use in this article. An *electronic signature* (e-signature) is any signing method that is used with computers and networks. It is the broadest concept. It includes such things as clicking a button to indicate that we accept the terms of a program's end-user licensing agreement.

More narrowly, there are two general ways to add signature blocks to outgoing messages. Digital signatures are signature blocks created with public key encryption. Message authentication codes (MACs) also are per-message signature blocks, but they are created using hashing. MACs are also called key-hashed message authentication codes (HMACs).

In our discussion, we begin with the narrowest and most familiar technology, digital signatures. We then discuss MACs and, finally, electronic signatures broadly.

BACKGROUND

Applicant, Verifier, and True Party

A prime reason for electronic signing is authentication. In authentication, there are two main parties. The *verifier* wishes to determine the identity of the *applicant*—the party wishing to have his or her identity authenticated. Applicants are sometimes called supplicants.

In addition, the *true party* is the person the applicant claims to be. (The applicant may be an impostor.) The person who signs the document is the *signatory*; this may be the true party or someone authorized by the true party to sign for the true party.

Key-Based Authentication

As discussed in the chapter on authentication, authentication can be based on something the person knows (such as a reusable password), something a person is (biometrics), or some other distinguishing characteristic.

Digital signatures and MACs are based on the applicant knowing a secret key. Digital signatures are based on public/private encryption key pairs and require the applicant to know the true party's private key. MACs require the person wishing to be authenticated to know the symmetric key the true party shares with the verifier.

Threat Model

In normal authentication, the biggest danger is that the *applicant* is an impostor who tries to impersonate the true party in one or more transactions. This danger also is a key element in electronic signature threat models.

In addition, there is a danger that the true party will later falsely repudiate messages and contracts that he or she signed electronically, claiming that these were signed by an impostor. Against this threat, we would like to have nonrepudiation, that is, the ability to provide proof that the true party actually did sign the messages or contracts.

In simple authentication, the *verifier* is assumed to be the "good guy." However, electronic signatures should also protect the true party from verifier malfeasance. For instance, the verifier might fabricate a message or contract, add a false signature, and then claim that the true party sent the signed message or contract.

While the true party and verifier are communicating, an *attacker in the middle* may insert a single fabricated message into an ongoing dialog. Or an attacker in the middle might delete a message or simply replay an earlier message. Initial authentication at the start of a dialog will not protect against such attacks.

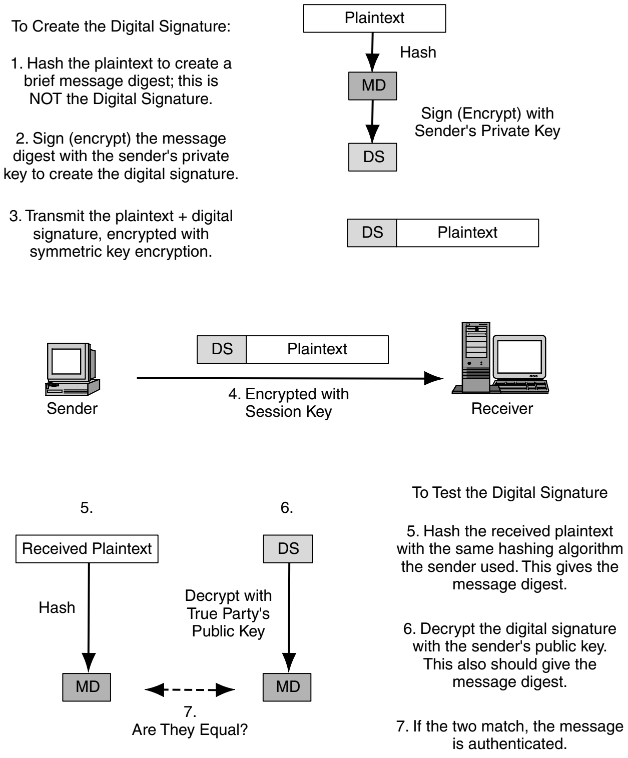
DIGITAL SIGNATURES

Digital signatures are used in message-by-message authentication. A digital signature is a block of bits attached to each outgoing message to prove the sender's identity. This greatly reduces attacker-in-the-middle threats. t also provides nonrepudiation on a message-by-message basis. Figure 1 illustrates the process of creating and verifying digital signatures.

Creating the Digital Signature

The sender creates a message to be sent. In cryptographic terminology, this is the plaintext or original plaintext. The name is a bit misleading because the message may not be limited to text, but for historical reasons, the term plaintext remains in use.

The sender/applicant will have to sign something (encrypt it with his or her private key) for authentication to be possible. However, public key encryption is very processing-intensive, so it can only be used on small blocks of bits—not on large messages.



To Create the Digital Signature:
1. Hash the plaintext to create a brief message digest; this is NOT the Digital Signature.
2. Sign (encrypt) the message digest with the sender's private key to create the digital signature.
3. Transmit the plaintext + digital signature, encrypted with symmetric key encryption.

Are They Equal?

Figure 1: Digital signature creation, transmission, and verification.

To create something small to sign, the sender's software first hashes the original plaintext message. Hashing is a mathematical process that can be applied to a string of bits of any length and that will produce a result (called a hash) that has the same short length no matter how long the input string is. For instance, the MD5 hashing algorithm always produces a hash of 128 bits, whereas the SHA-1 hashing algorithm always produces a hash of 160 bits. So message digests will be either 128 bits or 160 bits, depending on which of these hashing algorithms is used.

The hash of the original plaintext is called the message digest. The message digest is not the digital signature itself but rather the basis for creating the digital signature.

The applicant/sender wishes to authenticate himself or herself using something only the true party should know. This is the true party's private key. If someone is given a public key–private key pair, he or she should guard the private key jealously. However, their public key is not secret and can be shared freely.

Therefore, the applicant/sender signs the message digest with his or her private key, that is, encrypts the message digest with his or her private key. The result of this encryption is the digital signature.

Transmission and Confidentiality

After creating a digital signature, the applicant/sender creates a composite message by concatenating the bits of the digital signature to the bits of the original plaintext message. We will call this the composite message. (Terminology here is not standardized.)

Next, the applicant/sender normally encrypts the composite message with the symmetric key that he or she shares with the verifier/receiver. This provides confidentiality, meaning that no one can read the original plaintext en route. Note that this step has nothing to do with authentication, and it is possible to wish to have authentication without confidentiality. However, confidentiality is normally desired during transmission.

Symmetric key encryption is used rather than public key encryption because the composite message may be quite long. As noted earlier, public key encryption is unfeasible for long messages. Symmetric key encryption, in contrast, is efficient enough for longer messages.

The applicant/sender now transmits the composite message encrypted with symmetric key encryption to the verifier/receiver. This message cannot be read en route by an attacker in the middle.

The verifier/receiver decrypts the transmitted message using the symmetric key it shares with the applicant/sender. This restores the composite message.

Verification

Now it is time for the verifier/receiver to verify the authenticity of message. This involves recomputing the message digest in two ways and comparing the results.

One way to recompute the message digest is to rehash the original plaintext. The applicant/sender hashed the original plaintext message to create the message digest.

The verifier/receiver rehashes the original plaintext message using the same algorithm the applicant/sender used. Hashing is a repeatable process, meaning that the verifier/receiver will get the same resulting hash the applicant/sender obtained. This, of course, is the message digest.

The second way is to decrypt the digital signature. The digital signature was created by encrypting the message digest with the true party's private key. The verifier/receiver, in turn, decrypts the digital signature with the true party's public key, which is widely known. Public key encryption is reversible, so this decryption will give the message digest.

In the final step, the verifier/receiver compares the two computed message digests. If they are the same, then the digital signature was created with the true party's private key. If the message digest was encrypted with an impostor's private key, decrypting the digital signature with the true party's public key would not give the message digest. Only the true party would know the true party's private key, so the message is authenticated.

Benefits

Digital signatures provide three important benefits. One is message-by-message authentication. This guards against the insertion of a fabricated message in a dialog's message stream by an attacker in the middle.

A second benefit is message integrity, that is, proof that a message has not been tampered with en route. If an attacker has deliberately modified a message or if there has been a technical transmission error, the two message digests will not match. The verifier/receiver will discard the message.

The third benefit is nonrepudiation. If the message was signed by the true party, then the true party cannot disclaim responsibility for the message without arguing that he or she lost control of the private key, which itself may be considered negligence. If a private key is stolen, of course, it can be used as a rubber stamp to sign documents. However, for nonrepudiation, the verifier/receiver must keep the original composite message so that authentication can be verified in court or by an expert.

The Problem of the True Party's Public Key and Digital Certificates

Digital signature verification requires the verifier/receiver to know the true party's public key. This seems simple, but it is fraught with danger. For instance, suppose the applicant/sender sends the verifier/receiver a public key claiming that it belongs to the true party. If the applicant/sender is an impostor, of course, he or she will send his or her own public key rather than the true party's public key. If the verifier/receiver accepts this impostor's public key as the true party's public key, the impostor will be "verified" as the sender of all messages. This is public key deception.

To guard against such deception, the verifier/receiver must get the true party's public key from a trusted third party. As discussed in the chapter on public key infrastructures (PKIs), organizations called certificate authorities (CAs) provide such information in the form of digital certificates. To use digital signature authentication, the verifier/receiver needs to get the true party's digital certificate from a trusted certificate authority.

There is a great deal of confusion about digital certificates. The main thing to keep in mind is that the essential information that digital certificates provide is the true party's name and the true party's public key. Anyone claiming to be the named true party should be able to create digital signatures that can be tested with the public key enclosed in the digital certificate.

A digital certificate generally does not vouch for the trustworthiness of the party named in the digital certificates. Although some CAs provide compensation if a named party behaves badly, few do. Vouching for trustworthiness is not what digital certificates are designed to do. Digital certificates are designed to tell you the public key of the named party.

At the same time, companies and individuals who do behave badly may have their certificates revoked before the expiration date on the digital certificate. CAs maintain certificate revocation lists (CRLs) of such digital certificates.

Of course, if the verifier/receiver contacts the certificate authority, the authority will not send the verifier/receiver a revoked certificate. However, it is crucial for the verifier/receiver who gets the digital certificate from another party, for instance the applicant/sender, to check the certificate authority's CRL to be sure that the certificate has not been canceled.

The certificate authority also has a private key and a public key. The CA adds a digital signature to every certificate it creates, signed with the CA's private key. Popular CAs have public keys that are well known, so it is easy for verifier/receivers to check any digital certificate sent to them. As noted earlier, digital signatures provide message integrity, ensuring that the digital certificate has not been modified, say by entering an impostor's public key in place of the true party's public key.

In practice, every browser today comes with the ability to read digital signatures automatically, without the user's intervention. Browsers also come with the public keys of several root certificate authorities, so they can also handle most digital certificates. What the user sees is merely a notification that a particular document came from a particular, named entity. When this notice appears, the user can feel confident that the message really did come from that person or organization.

MESSAGE AUTHENTICATION CODES (MACs)

Message authentication codes (MACs) are similar to digital signatures. Both are blocks of bits appended to original plaintext messages. However, although digital signatures are created using public key encryption, MACs are created using hashing. Figure 2 illustrates the creation, transmission, and use of message authentication codes.

Speed

The main advantage of MACs over digital signatures in processing speed. Public key encryption used in digital

signatures is very slow, even if only the message digest is encrypted. In contrast, the hashing used in message authentication codes requires far less processing time. Quite simply, MACs place much less of a load on the machines of both the applicant/sender and the verifier/receiver.

Symmetric Key

The applicant/sender and the verifier/receiver share a single key in hashing. Each uses this key both to create MACs and to verify MACs.

Often, the symmetric key used for MAC authentication is different from the symmetric key used for confidential transmission. In such cases, the two parties have at least two symmetric keys that they share.

Creating a Message Authentication Code

To create a MAC, the applicant/sender again begins with the message to be sent—the original plaintext. Next, the applicant/sender appends the symmetric key to be used in MAC creation to the original plaintext message.

Next, the sender hashes the combined original plaintext and symmetric key with either MD5 or SHA-1 to create a hash of 128 bits or 160 bits, respectively. This hash is the message authentication code.

Transmission

To transmit the message, the applicant/sender appends the MAC to the original plaintext message. This is the composite message that actually will be transmitted.

Next, for confidentiality, the applicant/sender normally encrypts the composite message with a different symmetric key shared by the two parties. The applicant/sender then transmits the resultant cipher text. Interceptors will not be able to decrypt the cipher text back to plaintext because interceptors will not have the shared symmetric key used for confidentiality.

The verifier/receiver undoes the encryption for confidentiality by decrypting the cipher text with the shared symmetric key used for encryption. This gives the verifier/receiver the composite message consisting of the original plaintext plus the MAC.

Verifying the MAC

Verifying the MAC is simple. The verifier/receiver takes the plaintext and appends the symmetric key used for authentication. The verifier/receiver then hashes the plaintext plus key using the same hashing algorithm the applicant/sender used. This should give the MAC transmitted with the message.

If this process successfully reproduces the MAC, then the sender must know the symmetric key used for authentication. Only the true party and the verifier/receiver should know this key. The MAC must have been created by the true party.

Benefits

Like digital signatures, MACs provide authentication. Also like digital signatures, MACs provide message integrity. If the message is altered en route either deliberately or by transmission errors, the verification process will not reproduce the MAC, and the message will be discarded.

Lack of Nonrepudiation Assurance

MACs really prove that someone who knows the symmetric authentication key created the MAC. Obviously, this could be the true party acting as the applicant/sender.

However, although it is easy to overlook the fact, the verifier/receiver could also have created the MAC because the verifier/receiver also knows the symmetric authentication key. Why would a verifier/receiver fabricate a MAC? The answer is that the verifier/receiver may be dishonest and wish to claim that the true party sent a message that the true party never sent, for instance a message agreeing to a dubious contract.

Thanks to the possibility of verifier/receiver misbehavior, MACs cannot provide nonrepudiation. A dishonest true party can repudiate a legitimate message claiming that the verifier/receiver really created it. In court cases, jurors would have to decide who to believe—hardly an easy undertaking. Where nonrepudiation is an issue, MACs are dangerous.

IPsec

One reason to consider MACs is that they are the default message-by-message authentication mechanism in IPsec (IP security) standards. These are increasingly being used in virtual private networks (VPNs) to ensure confidentiality, authentication, message integrity, and other benefits in dialogs between partners. If IPsec does become very widely used and if MACs continue to be the default authentication/integrity method, the lack of nonrepudiation could become a serious problem for business transactions.

OTHER ELECTRONIC SIGNATURE TECHNOLOGIES

Digital signatures accompanied by digital certificates are the gold standard in electronic signature technologies, and MACs are good despite their lack of nonrepudiation. However, quite a few other types of e-signature technologies are possible and may make sense in particular situations.

Typed Signatures and Scanned Physical Signatures

In the simplest e-signature methods, the sender merely types his or her name at the end of a message or includes a scanned copy of his or her written signature. Although typed signatures and scanned physical signatures are allowed under most e-signature regulations, they are not likely to stand up in court because they are so easily forged.

Click Agreements

When you purchase software, you typically are required to click on a dialog box button to show that you accept the user licensing agreement. Click agreements generally are difficult to enforce in court because of the difficulty proving who actually clicked on the button.

However, enforceability often is not the goal. Rather, click agreements often serve primarily to create a ceremony in which the person formally makes a commitment. This brings the seriousness of the situation to the person's attention. In addition, when people make explicit commitments, they may be more likely to keep them.

Authenticated Sessions

Many transactions are sessions in which the two parties exchange a long series of messages. With various mechanisms, it is possible to authenticate the user at the beginning of the session and perhaps occasionally during the session to ensure that the person is still there. Although less secure than digital signatures and MACs, which authenticate every message, authentication at the beginning of a session (initial authentication) provides some assurance that a certain party is sending the messages.

Most initial authentication systems rely on reusable passwords, which people (or software processes) use each time they log in for a certain period of time.

The problems with reusable passwords are well known. Unless the system enforces strong passwords, people tend to use easily guessed passwords that can be cracked in a few seconds by a password-cracking program. People also tend to write their passwords somewhere, often on their computer monitors.

A more subtle problem is lost passwords. About a quarter of all calls to help desks are for lost passwords. The help desk operator can perform a "password reset," giving the account a new password. However, there is danger in giving out for new passwords over the telephone. The caller may be an imposter, not the real account holder. Although some password reset systems require the caller to answer questions that only the true account holder should know, most of these questions are easily guessed if the impostor has done his or her research.

Another means of authentication is access cards and tokens. If you have stayed at a hotel room recently, you probably were given an access card that allowed you into your room. Most such access cards have magnetic stripes containing information that allows access to the room; smart card versions have microprocessors and memory for more sophisticated identity checking.

Even if you get a key, the key is likely to be a physical token that contains access information. Plugging it into the door allows the door reader to query a central system for access permission. There also are tokens that plug into the USB ports of personal computers for access to those machines.

Another type of token requires the user to enter a PIN number on a small (generally) numerical keypad. The token then shows a temporary password on its display. The user must use this temporary password to log into a computer system.

Access cards and tokens provide good security, but they are easily lost or stolen. There must be a quick way to disable lost access devices as well as a way to reissue them in ways that impostors cannot exploit.

Another approach to handling authenticated access sessions at Web sites is visit traces, recording the paths users take through them, including click agreements they have made. Documentation that a person saw certain information can be convincing evidence in court and may prompt a person to drop repudiation claims. However, visit trace logs must be secured against tampering by the logkeeper if they are to be useful in court.

Biometrics

One form of authenticated session technology is biometrics. It is new and complex, so we will give it its own section.

"Biometrics" comes from the words "bio," meaning biological life, and "metrics," meaning measurement. Some types of biometrics measure bodily dimensions, such as fingerprints, iris patterns in the eye, and facial features. Other types measure activities, such as motions and pressures involved when in signing a name or the temporal patterns of password typing.

The advantage of biometric authentication is that it does not require the applicant to carry something that can be lost and (usually) does not require the applicant to remember anything. Despite jokes to the contrary, we never actually forget our heads at home. A major hope is that biometrics will replace reusable passwords as the dominant form of authentication.

A major problem with biometrics, however, is that there are serious disagreements over the error rates involved in biometric measurements. Many vendors make impressive claims about accuracy, but these often are based on tests conducted under ideal conditions and may not be representative of accuracy in the real world.

There are two basic types of errors in biometrics, indeed in all access control methods. False acceptance rates (FARs) verify or identify someone who should be rejected. High FARs means impostors are getting in and forming a strong basis for repudiation. A failure to test FARs may make access data difficult to defend in court.

At the opposite end of the spectrum is false rejection rates (FRRs). FRRs tell you what percentage of legitimate applications are rejected. Although FRRs do not harm security, significant FRRs may make a system unacceptable to users. Many systems allow applicants to attempt to authenticate themselves several times to reduce FRRs.

Another issue in biometrics is user acceptability. For instance, some users may refuse to use a fingerprint system because of its criminal connotations. Others will reject systems they fear may harm them; for instance, some people believe that eye identification systems shoot laser beams into their eyes. Still others reject systems that are difficult to use, such as iris scanning systems, which require proper eye placement. In general, if a significant number of users refuse to use the system, the loss in revenues and other values may make the system completely cost ineffective.

Another problem with biometrics is that the different technologies vary widely in cost and accuracy. Selecting a biometric method is an important task. Not surprisingly, the most expensive methods tend to be the most accurate. In addition, the cost of biometric readers and other system components may be prohibitive.

A final problem is that we do not yet have comprehensive standards for biometrics. As a consequence, choosing biometric authentication today generally means getting locked into a single vendor.

None of the Above

The last alternative in e-signatures is simply not to use them. In many cases, the benefits may not be worth the costs and damaged user relationships.

SELECTING AN ELECTRONIC SIGNATURE METHOD

Selecting an electronic signature method is not a technical decision. It is a business decision. Like any business decision, it requires the selector to understand the business situation before considering anything else.

Some e-signature systems serve closed communities, such as individual corporations or consortia of firms. Others serve open communities, such as a vendor and its customers. In open communities, it is difficult to impose stringent e-signature requirements. For instance, in consumer e-commerce, it is traditional in the SSL/TLS encryption methodology that is used in almost all transactions to require the merchant but not the consumer to have a digital signature and digital certificate. Note that e-signature implementation can be asymmetrical, with different requirements imposed on the two sides. In addition, in an open community, the general lack of e-signature and PKI standards and the need to coordinate rollouts in many firms tends to require long lead times.

There are two forms of authentication, verification and identification. In verification, the person claims to be a particular person, for instance by typing in an account name. The authentication system then only has to see whether the password typed or the other authentication data given is correct for the account. If so, the applicant is verified as the true account holder. In identification, the applicant does not claim a particular identity. The applicant provides authentication data, and the identification system matches that data against that of *all* the accounts in the identification database. If the best match that is selected meets closeness-of-fit criteria, the applicant is identified as that person (or software process) in the database. Identification is more difficult than verification and thus has higher error rates. It also may lack the intentionality that is normally present in signing activities and so may not be enforceable in court.

Security Requirements

Signatures of any kind exist to validate agreements. To be effective, they must be safe from use by impostors and from other security threats.

In security, one must always consider threat severity, which is the likely cost of a security incursion times the probability an incursion will take place. It is, in other words, the expected value of loss from a threat. If the threat severity is low and is likely to remain smaller than the cost of implementing an e-signature system, then implementing the system will not make economical sense.

In general, e-signatures should be viewed as security techniques, and security always must consider risk management—the balancing of risks and countermeasure costs. Generally speaking, however, the more expensive the transaction, the more expensive the e-signature.

Key length is an important security concern when private keys are used to sign documents or message digests. Documents that must be kept secure for many years must be signed with longer keys than documents whose signatures only have to be verifiable for a few years. However, longer keys mean longer processing times and therefore higher costs. The period of sensitivity is a crucial determinant of key length.

Legal Goals

Another consideration in selecting an electronic signature technology is a firm's legal goals. Many countries require that contracts worth over a certain amount of money be signed to be valid. In U.S. commercial law, for instance, contracts over $500 or lasting a year or more must be signed to be valid. If the goal is to meet this requirement, even the least-secure e-signing methods may be acceptable.

As noted earlier in this chapter, one consideration is whether or not to create a ceremony of commitment, in which a person must explicitly, through an action, acknowledge ownership of a document. Again, if this is the main goal, even nonsecure e-signing methods may be acceptable.

If the goal is nonrepudiation, then a stronger e-signature method is needed. The only method available today that provides strong technical nonrepudiability is use of digital signatures, which require a PKI for digital certificates. As noted earlier, it is necessary to keep the ciphertext version of the digital signature so that the decryption can be tested in court.

Although technical nonrepudiability is good, juries are likely to decide contested cases. If the complainant is more believable than the defendant, the jury may disregard the defense's argument that the e-signature method used does not provide technical nonrepudiation. If the defendant is more believable, the jury may side with the defense even if a digital signature and digital certificate are used.

Suitability

Another consideration in selecting an e-signature methodology is whether the system can be implemented. One question to ask when considering the various methods is what, in any given firm, is technically feasible. Some choices may not be feasible, and some that are may be outside the firm's resources to implement it. PKIs are especially problematic.

Of course, the firm must consider the cost of implementing a system, including the cost of the technology itself and the cost of installing it. In addition, electronic signature processing slows computer processing often enough to require upgrading to faster hardware.

The last major consideration in determining the suitability of a method is whether users will accept it. As noted earlier, fingerprints, iris scanning, and other techniques may offend users or make them uncomfortable. The company must also consider the cost of lost business if some users refuse to use e-signatures and therefore stop doing business with the firm. On the other hand, a firm may gain revenues if it develops a reputation for having strong security in general.

Obviously, individual home consumers are unlikely to be willing to get digital certificates unless they see strong benefits from doing so. As a result, most firms are unlikely to require consumers to use digital certificates for fear of losing business.

LEGAL AND REGULATORY ENVIRONMENT

One consideration that is especially difficult to discuss cleanly is the legal and regulatory environment of electronic signatures. Laws vary around the world and even within countries. Few of these laws, furthermore, have been tested in court. Regulation of certificate authorities and other aspects of electronic signatures barely exists, even in countries that have begun to back legislation with regulation.

In the United States, a number of states created electronic signature laws before the federal government created the Electronic Signatures in Global and National Commerce Act, better known as E-SIGN, in 2000. As the name states, E-SIGN governs only national (interstate) commerce. No court cases have yet appeared to test this area.

Quite a few states have created their own electronic signatures laws. In 1999, before Congress acted, the National Conference of Commissioners on Uniform State Laws adopted the Uniform Electronic Transactions Act (UETA), and a number of states based their laws on this act. However, past court rulings have found that many intrastate activities affect interstate commerce and so are governed by federal laws.

In 1999, the European Parliament and the Council of the European Union created Directive 1999/93/EC, On a Community Framework for Electronic Signatures. This directive did not create laws but rather directed the member countries to create e-signature regulation. The first country to do so was Ireland, in July 2000. Germany followed in May 2001.

Elements

The simplest element in electronic signature laws is whether legal validity has been established. As noted earlier, most jurisdictions require that contracts worth more than certain amount of money be signed to be valid. Almost all e-signature laws provide the weak protection of saying that contracts cannot be invalid simply because they are signed electronically. This does not ensure that a particular e-signature methodology will stand up in court if one side repudiates the document.

One consideration in selecting an electronic signature technology is whether a country's e-signature law allows all types or only some types of electronic signatures. The U.S. E-SIGN Act is intentionally vague, not mentioning specific e-signature technologies. The EC Directive mentions several specific technologies but does not limit itself to them.

The EC Directive defines an electronic signature in general as "data in electronic form which are attached to or logically associated with other electronic data and which serve as a method of authentication." The EC Directive also specifies *advanced e-signatures,* which basically are digital signatures based on qualified certificates—the strongest type of electronic signature. These advanced signatures are given a certain degree of privileged status, which is reasonable because of their strength. Most important, advanced electronic signatures are viewed as equivalent to hand signatures in legal proceedings.

Another consideration is whether e-signatures are permitted for all types of documents or only some. For instance, in the United States, the federal E-SIGN law forbids certain documents to be signed electronically because of potential harm to consumers. These exclusions were not present in early versions of the laws, which failed to pass because of insufficient consumer protection. Among the documents excluded are wills, trusts, adoptions, divorces, other family court matters, court documents, utilities cancellation notices, notices of foreclosures, eviction notices, insurance cancellations, warnings about the transportation of hazardous materials, and the repossession of primary residences.

Another key consideration in selecting an electronic signature technology is whether one side can force the other side to accept electronic signatures or whether using e-signatures is voluntary. Early versions of the U.S. E-SIGN law were rejected by Congress because they failed to say explicitly that people cannot be forced to accept electronically signed documents. The final E-SIGN Act says that consumers must be notified of options, including the mandatory option of paper-only transactions, must give consent, and must demonstrate the ability to store and access digital documents.

Digital signatures require digital certificates from certificate authorities. A major issue is whether a country will regulate certificate authorities. The U.S. E-SIGN Act leaves everything to industry. The EC Directive, in contrast, specifies that each country should establish a regulatory framework within the country for certificate authorities and related services, such as registration services, time stamping services, and directory services (Article 1a).

CONCLUSION

Documents of importance have always had to be signed, whether by hand or with a signing device, such as a signet ring or a Japanese hanko. Electronic signatures merely extend this long-standing practice to the electronic world.

Although electronic signatures are increasingly recognized as legitimate, the choice of which electronic signature technology to use is complex. Using a digital signatures accompanied by a digital certificate is the legally strongest valid way to sign a message, but the public key infrastructures that support digital certificates are not well established or standardized. Consequently, many firms will turn, at least initially, to less rigorous forms of electronic signing, which are easier to implement but cannot provide strong guarantees.

In addition, although technical considerations are important, many cases end up in court, and juries are not always swayed by technical arguments.

GLOSSARY

Access cards Have magnetic stripes containing information that allows you into, for instance, a hotel room. Smart card versions have microprocessors and memory for more sophisticated identity checking.

Advanced e-signatures In the European Union electronic signature directive, digital signatures based on qualified certificates.

Applicant The party wishing to have his or her identity authenticated.

Attacker in the middle Party who may insert a single fabricated message into an ongoing dialog, delete a message, or replay an earlier message.

Authentication data Where an identification system matches user-supplied data against all accounts in the identification database to determine who the user is.

Biometric authentication The authentication of a person based on body measurements.

Ceremony of commitment Act of signing a document that results in heightened awareness of the gravity of the situation on the part of the signer.

Certificate authorities (CAs) Organizations that create and distribute digital certificates.

Certificate Revocation List (CRL) List of a certificate authority's certificates that have been revoked before the termination date listed on the certificate.

Click agreements Electronic signatures created by the user clicking on a button that says, for example, "I agree."

Digital certificates Documents that give a named party's public key and other information.

Digital signatures Signature blocks created with public key encryption. They are created by encrypting message digests with the applicant's private key.

Directive 1999/93/EC European Union electronic signature directive to the EU member nations.

Electronic signature (e-signature) Any signing method that is used with computers and networks.

E-SIGN U.S. electronic signature law.

False acceptance rates (FARs) Percentage of times a person is authenticated when he or she should not be.

False rejection rates (FRRs) Percentage of times a person is not authenticated when he or she should be.

Hashing A mathematical process that can be applied to a string of bits of any length and that will produce a result (called a hash) that has the same short length no matter how long the input string is.

Identification Process in which the applicant does not claim a particular identity. When the applicant provides authentication data, the identification system matches the data against all the accounts in the identification database to determine who the applicant is.

Message authentication codes (MACs) Per-message signature blocks, created using symmetric key encryption. MACs are also called key-hashed message authentication codes (HMACs).

Message digest The result of hashing a plaintext message. This is the first step in creating a digital signature.

Message integrity Proof that a message has not been tampered with en route to its destination.

Nonrepudiation When the sender cannot plausibly claim that a message did not really come from him.

Password reset Gives an account a new password when a reusable password is forgotten.

Period of sensitivity Period of time during which a file must be kept confidential.

Public key deception Process in which an impostor sends his own public key, claiming that it is the true party's public key.

Repudiate When a party claims that she did not send a message apparently sent from it.

Reusable passwords Passwords used repeatedly. Most passwords are reusable passwords.

Scanned physical signatures Electronic signatures formed by scanning a written signature and inserting the image in the document as a signature block.

Signatory Party who actually signs the document. May be the true party or someone or something to which the true party delegates signing authority.

Supplicant Another name for an applicant.

Tokens Physical devices used to authenticate a person.

True party The person or object the applicant claims to be.

Typed signatures Electronic signatures in which the sender merely types his or her name.

Validity Characteristic of a document that allows it to be presented as evidence in a court.

Verification When the person claims to be a particular person, for instance when typing in an account name.

Verifier The party wishing to determine the identity of the applicant.

Visit trace A list of the locations a user has visited at a Web site.

Disaster Recovery Planning

Marco Cremonini, *Università di Milano, Italy*

INTRODUCTION

For many years, corporations have placed most of their critical information assets into automated systems and, more recently, they have adopted business models largely based on the Internet. While allowing for more efficiency, cost reduction, and competitive advantage, these developments have also increased the dependency on the information technology (IT) infrastructure and therefore of the potential economic losses caused by its failure. More than ever today a loss of access to the IT infrastructure will prove to be in many cases fatal for the business of affected companies. It is therefore crucial for companies to consider precise plans for counteracting possible events that may cause such interruptions. Examples of companies that failed to recover their businesses after a prolonged interruption of IT functions, due to floods or fires, for example, are well known and documented (Hiles, 2002; Kaye, 2001; Noakes-Fry & Diamond, 2001; Toigo, 1999, 2001a).

The disaster recovery planning process consists of a set of activities aimed at reducing the *likelihood* and the *impact of disasters* on critical business assets (NIST, 2002; Toigo, 1999; Wold, 2002). Note that, while the term disaster recovery has been traditionally associated with protecting against external catastrophic events (e.g., floods, fires, earthquakes), we adopt in this chapter a broader definition of disaster recovery, which includes also business continuity planning, and therefore the consideration of failures to technological equipments and software.

E-business and Internet connections are shortening recovery-time requirements and changing the way we think about disaster recovery planning: full 24 × 7 operation and "zero downtime" are now commonly seen as a business necessity. While traditional countermeasures to face natural disasters should still be provided, a wide spectrum of other risks (e.g., cyberattacks) must be considered. Also, critical business processes must be analyzed and recovered much faster than in the past: downtimes of days (the usual time window for natural disasters) are definitely no longer sustainable for Internet-based businesses.

Especially after the year 2000, companies have made massive investments in re-engineering their business processes, and many of them realized that those investments need protection from events other than natural disasters, including outages, power failures, security incidents, and misconfigurations. New methodologies, techniques, and commercial products have been developed to manage backups and to speed up recovery. Thanks to these advancements, it is now possible to plan for a recovery time of just a few hours (still far, however, from the "zero downtime" dream sought by many and sold by others).

Nevertheless, many enterprises still have minimal contingency plans in place to ensure business continuity for their business requirements. Managers fail to plan for disaster recovery in the development life cycle of their projects, resulting in more risks and exposures than in the past. From a technological standpoint, some managers and planners still do not understand the intrinsic fragility of the new architectures for e-business to which they are migrating. As a consequence, they do not fully understand the increased requirements for business continuity, do no plan for the inevitable failures, do not mitigate the risks, and are not prepared to sustain the consequences.

In this chapter we address the problem of disaster recovery planning. The remainder of the chapter is organized as follows. First, we present the risks, that is, the main causes of failures that must be accounted for in disaster recovery planning. Then we discuss the possible costs that companies may sustain if they unsuccessfully respond to failures. We continue with illustrating the main phases of the disaster recovery planning process, including the risk management phase, to which a whole section is then devoted. The chapter then presents backups and alternate sites as main techniques for recovering data and providing for the continuity of the business processes in the occurrence of failures. We also discuss failure issues in the emerging Web-hosting service scenario. Finally, we provide a reference template for disaster recovery planning.

RISKS, OR THE CAUSES OF FAILURES

Failures in the IT infrastructure may have many causes that, with a broad classification, can be grouped as

Natural, such as, flood, fire, tornado;

Human, such as operator error, sabotage, network intrusion, malicious code, and denial of service; and

Environmental, such as equipment failure, software error, telecommunication network outage, and electric power failure.

Different failure causes differ in terms of *likelihood of occurrence* and *potential damage* that they can cause. For instance, events like sabotage, floods, or fire, usually considered in traditional disaster recovery, are rare but, when they happen, they turn out to be catastrophic. On the other hand, events like equipment failures or software errors are less catastrophic in nature, but may occur frequently and represent almost day-to-day problems for system administrators. Usually, these latter types of failures are not devastating for a company, and in past years (in the pre-Internet age), they were not included in disaster recovery planning. However, with today's companies relying more and more on networked systems, complex distributed multicomponent architectures, and the Internet as a primary business strategy, short but frequent downtime periods can become a major problem in terms of competition, reputation, and revenue losses (Kaye, 2001; Toigo, 2001b). For each possible cause of failure, likelihood of occurrence and possible damages must both be considered in disaster recovery planning.

Figure 1 shows the results of a first study mentioned in (Kaye, 2001) on the causes of IT failures.

According to this study, only 20% of downtime is caused by technology failures including hardware (servers and network devices), environmental factors (e.g., cooling and power outages), and natural disasters. By contrast, 40% of downtime is caused by application failures, which include bugs, operating system crashes, performance slowdown, incorrect updates, and changes to software. The remaining 40% of failures is due to human errors. In other words, according to these results, only 20% of downtime is caused by problems in the basic IT infrastructure, while the remaining 80% of failures is due to people and process issues, including software that provides for the business services and management operations (Kaye, 2001; Noakes-Fry & Diamond, 2001, 2002).

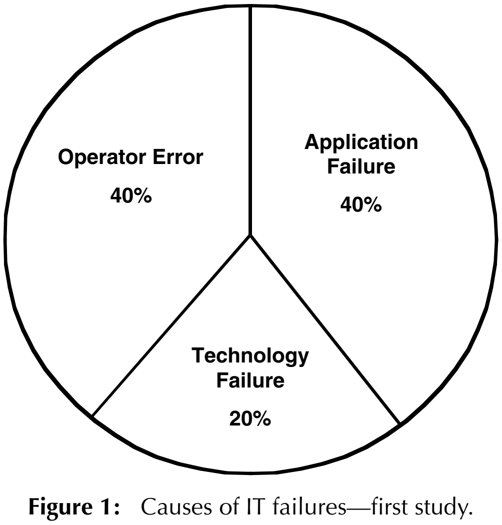

Figure 1: Causes of IT failures—first study.

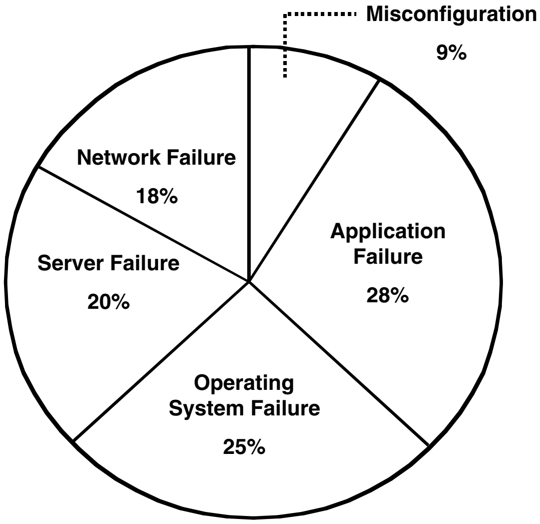

Figure 2: Causes of IT failures—second study.

A second study mentioned in Kaye (2001) investigates the technological components that fail. The results are illustrated in Figure 2.

According to this study, all the main components of the IT infrastructure, that is, network, servers, operating systems, and the applications, fail with comparable frequency, with a predominance of applications and operating systems. Yet, mere human errors or unskilled staff that lead to misconfigurations will cause a significant amount of outages (Kaye, 2001).

Although the two studies may appear contradictory, they are not, as they have adopted different classifications: the first study explicitly classifies human errors, while the second study includes them in the involved technological components. Merging the findings of the two studies, and reasoning on the different perspectives underlying them, can result in the statistics illustrated by Kaye (2001) as in Figure 3.

According to these consolidated results, the most frequent causes of outages are application bugs and connectivity failures. Applications frequently fail because of all sort of problems, including code bugs, bad design, weak requirement analysis, inconsistent tests, misconfigurations, erroneous installation or deployment, incompatibility with the run-time environment, and interference with other applications. As for connectivity failures, this last study estimates that misconfiguration of devices, routers, switches, or DNS should be expected to be higher than the 9% estimated in the study reported in Figure 2. Other frequent causes of outages are network partitioning and Internet service provider (ISP) failures. It is interesting to note how hardware failures represent only a small portion of the risks. As a matter of fact, there are now many reliable hardware vendors in the market and the

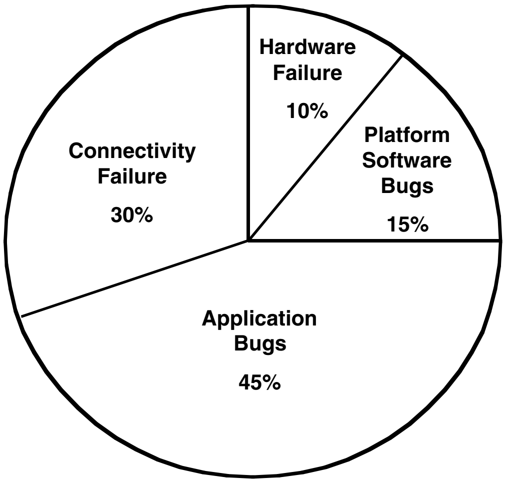

Figure 3: Causes of IT failures—consolidated results

quality of their products has improved in the years. The suggestion from experienced disaster recovery planners is then to select products and vendors with good reputation and just be skeptical about the latest news from the industry because they often provide exciting new features but at the price of less reliability. Similarly, also platform software (e.g., operating systems, DBMSs) is not one of the major risks, since products are generally reliable or could be configured and managed in order to maximize their reliability.

LOSSES, OR THE COSTS OF FAILURES

Internet-based companies, which require connectivity and availability of their Web sites 24 hours a day, 7 days a week, 365 days a year, have suffered all sorts of system and/or network outages in the past few years.

The cost of a disaster or a service interruption is not only the cost of the loss of business in the downtime frame. There are many associated factors that produce costs and losses, including

Brand image recovery;
Loss of share value;
Loss of interests on overnight balances;
Delay in customer accounting;
Loss of control over debtors;
Loss of credit control and increased bad debit;
Delayed benefits of profits from new projects or products;
Loss of revenue for service contracts;
Cost of replacement of building, plant, equipment, software;
Loss of customers;
Loss of profits;
Liability claims; and
Additional costs for advertising and marketing.

For instance, the brand value of most companies, while not reflected in their balance sheets, is one of their most valuable assets, reaching dozen of millions of dollars for some companies.

Also, statistics have demonstrated that the share price of a corporation suffering a disaster falls by around 5 to 8% within the first few days after a disaster. Recovery of the share price depends on the efficiency in recovering critical business functions. Past cases have shown that efficient recovery has let companies regain the confidence of financial analysts soon, and their share values have rolled back to the prices preceding the disaster, and even increased by 10 to 15% in the following 100 days. Companies that recovered with many difficulties, instead, were penalized with more share values falls, around 15% on average (Hiles, 2002).

A classification of losses should include (Kaye, 2001)

Fixed-asset losses. Fixed-assets of an IT infrastructure generally include the hardware and software used in the corporate business working. Fixed-asset losses can be caused by computer failures, fire, and thefts. Usually these risks can be mitigated through warranties, service contracts, and insurances.

Third-party liabilities. Depending on the type of business, a company can be exposed to third-party liabilities. These may be caused by an interruption in service provision or by the accidental disclosure of sensitive data after a security incident. Third-party damages are often covered by insurances.

Loss of intellectual property. The loss of data, application code, and sensitive information related to business processes can severely affect the company business. Backup and recovery strategies can be used to mitigate these losses.

Losses of revenues and profits. The loss of revenues and profits is the most evident type of risk in which a company may incur after a disaster or an outage. For companies that rely heavily on the Internet for their business, even short losses of connectivity or unavailability of their corporate portals can result in huge losses of revenue and profits.

As illustrated in Table 1, which shows some figures resulting from a study by META Group (DiNunno, 2000), depending on the type of industrial sector, the cost of downtime can reach noticeable values.

These figures show how important it is for companies to have a good disaster recovery plan in place. Statistics have shown that a typical organization may spend three or more times its normal annual marketing budget in the aftermath of a disaster to retain customer confidence and to retain or regain market share.

THE DISASTER RECOVERY PLANNING PROCESS

Disaster recovery planning consists in a set of activities aimed at reducing the *likelihood* and the *impact of disaster events* on critical business assets (NIST, 2002; Toigo, 1999; Wold, 2002). Disaster recovery planning is as complicated as any major system development project, with many stages of analysis and an overall activity encompassing

Table 1 The Cost of Downtime—(a) Loss of Revenue per Hour, (b) Loss of Hourly Revenue per Employee

(a)	**Revenue/hour**	**Industry sectors**
	$3,000,000 – $2,000,000	Energy, telecommunication
	$2,000,000 – $1,500,000	Manufacturing, financial institutions
	$1,500,000 – $1,000,000	Insurance, retail, pharmaceutical, banking, information technology
	$1,000,000 – $500,000	Food/beverage processing, consumer products, chemicals, transportation, utilities, health care, professional services
	$500,000 – $300,000	Electronics, construction and engineering, media, hospitality and travel

(b)	**Revenue/employee-hour**	**Industry sectors**
	>$1,000	Financial institution
	$1,000 – $500	Energy
	$500 – $200	Insurance, retail, utilities, construction and engineering
	$200 – $100	Telecommunication, food/beverage processing, consumer products, chemicals, transportation, health care, manufacturing, information technology, pharmaceutical, banking
	<$100	Professional services, hospitality and travel

all critical assets, business functions, and technological solutions.

Phases of Disaster Recovery Planning

A disaster recovery planning project begins by considering the *risks* and how to provide for their management so to make their occurrence tolerable to the organization (Noakes-Fry & Diamond, 2001, 2002; Toigo, 1999; Wold, 2002). The disaster recovery planning, which needs senior management approval to start, consists of (i) planning the actions to contain and recover from an emergency (e.g., procedures, teams, objectives) and (ii) preparing the agreements and the procedures for the collaboration among teams from different branches of the organization and with external partners. The collaboration procedures can be defined by a cross-functional team that includes top management, a purchasing representative, IT team members, maintenance personnel, and software user departments.

Another cross-functional issue that the disaster recovery planner should define together with top management and the public relation staff concerns possible interviews and news coverage. The importance of this issue depends on the exposure of the organization and can then vary depending on the business sector. In certain cases (e.g., financial institutions, government agencies or Internet-based companies) misleading press information can result in extremely high losses, affecting brand image and share values, and imposing costs for subsequent advertising/marketing campaign. Consequently, the disaster recovery plan should make sure that everyone in the organization understands who the media contact person is so that uninformed members of the organization do not make comments that are not in line with the public relations goals of the organization.

Once the project's development phase is completed, all procedures should be tested and personnel should be adequately trained. Testing helps identify possible weaknesses in the plan and evaluate the ability of recovery teams to implement the plan efficiently. Plan testing for the IT infrastructure should include (NIST, 2002).

System recovery on an alternate platform from backup media or mirrored sites;

Internal and external connectivity;

System performance using alternate equipment;

Restoration of normal operation; and

Notification procedures.

In addition to these IT-specific actions, all procedures for physical risk containment and recovery should be tested, including

Personnel evacuation plan; and

Alternate facility activation and recovery.

Training should make personnel aware of the disaster recovery procedure and provide those teams more involved in handling an emergency with sufficient experience to be able to execute their tasks with minimal support of documentation (as documentation might be unavailable in the first moment of an emergency). Plan elements that could be the subject of training include (NIST, 2002).

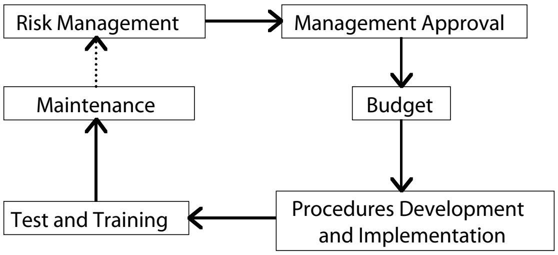

Figure 4: Disaster recovery planning project.

Purpose of the plan;

Cross-team coordination and communication;

Reporting procedures;

Security requirements; and

Team- and individual-specific processes.

When the plan is effective, it must be maintained, with periodic review, revision, and maintenance. Figure 4 summarizes the phases of a typical disaster recovery planning project (Kaye, 2001).

A disaster recovery planning should encompass all the IT infrastructure's components. In particular, all data repositories and all critical assets should be considered. More and more data are stored in a variety of supports and media, not just on mainframes and database servers; desktops and portable systems often hold important information (NIST, 2001; Takemura & Taylor, 1996). IT platforms to be considered in the planning should then include

Desktop computers and portable systems;

Servers;

Web sites;

Local area networks;

Wide area networks;

Distributed systems; and

Mainframe systems.

For each IT platform type, the *requirements* to recover each platform should be formally documented and considered in the analysis stage, and the *solutions* for addressing the event of a disaster should be detailed. The technical solutions should encompass *preventive* countermeasures (to avoid the failures) and *recovery* actions (to minimize the damage and re-establish the normal system operation in case of failures). Related documentation should describe

The frequency of backups and offsite storage of data;

The production and safe storage of an up-to-date copy of all applications and operating systems, together with their configurations, patches, and installation;

The redundancy of critical components;

The documentation of system installation, configuration, and requirements;

The interoperability between system components and between local and remote site equipment; and

The requirements for power management systems and environmental controls.

Business Impact Analysis

Convincing corporate management to invest in disaster recovery planning is often a greater challenge than dealing with the technical problems of backing up critical systems, minimizing the downtime, and maintaining the network connectivity. As it is often noticed, unfortunately, security investments usually receive low priority by managers, who prefer to invest in facilities and features that improve the business productivity, and realize the importance of protecting against disasters and a system's disruptions only after they happen. To complicate matters, the management decision of investing in disaster recovery capabilities is not a one time event, but must be sustained over the time, since every disaster recovery plan needs to be regularly tested, reviewed, and updated to be effective. Also, disaster recovery planning needs to be managed, improved, and updated with respect to the modification of the IT infrastructure and critical assets. For these reasons, the management consensus is vital for every disaster recovery plan that, in the best of circumstances, will provide for disaster avoidance by detecting and reacting to potential problems before they become disasters. Experienced disaster recovery planners usually observe that there are typical issues that should be justified to senior management and, among them, the most relevant is to carefully justify the plan's expenditures. Disaster recovery plans should be adequately documented with in-depth analysis of the risks addressed in the plan, the benefits for the corporation, the possible impact on business of a weak or insufficient disaster recovery plan, the estimates of the cost of downtime, and the possible reductions of insurance costs (Kaye, 2001; Toigo, 1999).

The impact of a disaster from a financial and an economic standpoint (Hiles, 2002) can be determined by means of a *business impact analysis* (BIA), whose objectives are to correlate each system component with the critical services it provides so as to characterize the consequences of the disruption of the component. A BIA therefore should

Identify critical IT resources. Different components, applications, services, and processes can have a different importance on the system services and functionalities. It is therefore important to determine priorities on the system functions and consequently on the resources for their support. Identification of critical resources includes PCs and portable systems (especially those of top management and system administrators).

Identify disruption impacts and sustainable time window in which recovery should take place. As we have already noted, timeliness is a key factor in recovery. The BIA must then identify, for each resource, the maximum time window for which the resource can be denied and the possible cascading effects that the outage can have on other processes. This includes identifying financial and nonfinancial costs associated with a disruption.

Develop recovery priority. Based on the criticality of resources and on the associated sustainable time window and cost consideration, recovery strategies can be prioritized so to optimize allocations and expenditures for the recovery process.

The BIA can provide input to the risk management process (see next section) on business risks that may not otherwise be identified. It can then be used to raise awareness of disaster recovery planning on senior management and focus individuals on their potential responsibilities, possible solutions, and costs.

THE RISK MANAGEMENT PROCESS

Risk is defined as the possibility of suffering harm or loss. Risk management is the process of planning for such eventuality. The goal of risk management is not to eliminate all risks (which would be impossible in practice), but rather to find an *acceptable balance between reducing risk and preparing the organization for losses*. The risk management process can be summarized in three steps:

Risk analysis: (i) identify the types of losses that may occur; (ii) determine the causes and the likelihood of possible losses; and (iii) estimate the resulting costs for the organization.

Risk mitigation: (i) identify actions to reduce or eliminate the likelihood of occurrence of each risk; (ii) determine the cost of those actions; and (iii) produce a cost/benefit analysis of the actions with respect to each risk.

Risk transfer: (i) Address the losses that may occur despite preventive actions and (ii) consider transferring them to insurers or third parties like service providers, vendors, or outsourcers in general.

We next examine each of these three steps in more details.

Risk Analysis

Risk analysis has two objectives:

Identify business processes and their associated IT infrastructure resources, such as the data, applications, systems, and networks used in supporting the corporate business. Business processes should be classified with respect to criticality in case of failure; and

Identify existing risks to the business processes and IT infrastructure.

Basically, risk analysis is concerned with identifying potential losses and the risks that might cause them. As already discussed, risks include failures of connectivity, hardware and software, as well as security incidents and natural disasters (Kaye, 2001; Toigo, 1999; Wold & Shriver, 2002). All the types of risks that can cause system disruption, namely natural, human, and environmental causes, should be analyzed and prioritized in disaster recovery planning. For each failure cause, a disaster recovery planner must define approaches to manage the risk and estimate the trade-off between sustaining the possible losses and implementing a disaster recovery strategy.

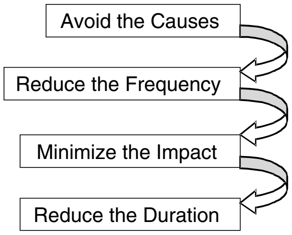

Figure 5: Risk mitigation process.

Risk Mitigation

Risk mitigation is a process aimed at limiting the likelihood of risks and the potential losses that risks can cause (Kaye, 2001). As sketched in Figure 5, the process is composed of the following phases:

Avoid the causes. Make conservative and prudential technology choices for critical assets: avoid technology risks by developing services in a robust manner and with the support of reliable platforms instead of adopting the latest technology (usually riskier), unless it has proven to give a sensible competitive advantage.

Reduce the frequency. All IT infrastructure components should be chosen among those ensuring a low rate of failure. Operating systems and software/hardware platforms of different vendors (or different versions produced by the same vendor) often have different failure frequencies. Reliability, and not just performance and features, should be carefully evaluated when technology is purchased to enforce the risk management strategy.

Minimize the impact. Since the frequency of failures and outages can never be reduced to 0, a risk mitigation strategy should analyze all possible single points of failure, whose failure may lead to major losses in terms of downtime and extent of service interruption. Redundancy is the typical strategy that can be applied to servers, network devices, and internal components.

Reduce the duration. Minimizing the duration of downtime is the ultimate goal of every disaster recovery plan: the more the downtime, the more the revenue loss. Many strategies can be adopted to speed up the recovery of data and functions. These may involve on-site hardware spares, on-site staff, efficient backup solutions, and alternative operative locations.

Risk Transfer

Risks that cannot be sustained by a company can be transferred to a third-party that assumes the risks in exchange of a service fee (Kaye, 2001). Hiles (2002) estimated that, on average, up to 40% of actual losses could be transferred, but no more than that. Risk transfer can assume two forms: *insurance* or *outsourcing*.

Insurance is the traditional way of transferring risks that cannot be mitigated with in-house solutions or transferred by purchasing the service outside. Most insurers offer coverage even for risks related with Internet-based threats like intrusions or denial of service attacks. With *outsourcing,* a third-party provides a specific service in place of an in-house solution. This third party can then assume the risk of losses that the company may incur by refunding the fee paid by the company (as in the case of Web-hosting services) or reimbursing the losses (as in the case of vendors). Risk transfer is established via a contract that usually includes a service level agreement (SLA) that should guarantee the company that purchases the service. This is a suitable solution in many situations, but the trade-off between the cost of possible downtime, if the service is realized in-house, and the cost of the purchased service with a certain quality level should be carefully evaluated. A careful evaluation of the return on the outsourcing investment should therefore be done in order to figure out whether the strategy is convenient (downtime costs versus service fees). Consider, for example, the case of Web-hosting services, where outsourcing is the common choice today. When a critical service is purchased from a vendor, instead of managing it in-house, it is typical to sign an agreement concerning the level of service guaranteed. In case of networked services, Web hosting, mainframe hosting, and so forth, the parties agree on a certain uptime guarantee, expressed as a percentage of time of availability (usually a value between 99 and 100%) of the purchased service. Clearly, the more the uptime guarantee, the more the cost of the service. However, how should a company decide which is the proper uptime guarantee value?

Kaye (2001) shows, as illustrated in Figure 6, the typical relationship between the amount paid for a certain service level and the value (i.e., the benefit that the company receives) of the increasing percentage of uptime guarantee (or, conversely, the decreasing downtime).

This reference relationship is meant to say that generally, after a certain percentage of uptime guarantee, the cost that a company would pay for a given service level is not worth the benefit gained. In fact, the revenue losses would be less than the cost paid and the investment would not yield a positive return.

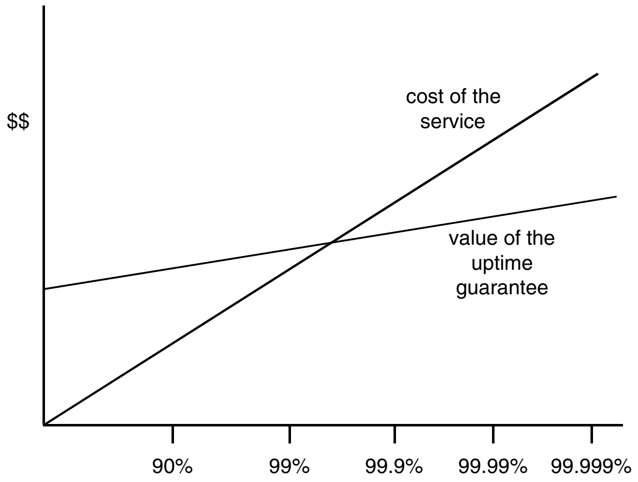

Figure 6: Uptime value vs cost.

Let us discuss this more with an example taken from Kaye (2001). Consider a company with $50 million in revenues and 15% pretax net profit. Increasing from 99 to 99.9% uptime will lead to increased revenues of $183,960 per month and profits of $27,594. If the cost of the service is less than $27,594, then the investment is worthwhile. If the company wants to upgrade from 99.9 to 99.99%, than the increase in monthly revenue is just $18,396 and $2,759 for profits. Hence, in this case the raise of the service cost should be much smaller, less than $2,759, to be convenient.

The example, clearly, is oversimplified since in practice a company should consider its business strategy and all the costs involved (e.g., loss of competitive advantage, market positioning, reputation, third-party liabilities) in order to evaluate the investment. However, the decreasing value of upgrading the service level is usually confirmed in most situations and should be carefully evaluated, possibly with formal models, to establish the return of the investment (Toigo, 2001b).

BACKUP AND RECOVERY

The goal of disaster recovery is to provide the ability of recovering the critical business functions of an organization in the occurrence of a disaster. One of the most important requirements for an effective recovery is the *availability* of *all the company's data* as well as of *the configuration of all critical components of the IT infrastructure* (e.g., backup of servers and network devices configuration, patches, passwords, routing tables, and firewall's rules). Although the need for maintaining backup copies of the data is well recognized, the need for a copy of all system configurations, in order to effectively restore the functionality of the IT infrastructure, is often overlooked. The reason why this requirement is so frequently overlooked is due to its intrinsic organizational nature: system management and day-to-day administration of the IT infrastructure (like changes in routing tables or firewall rules, or installation of patches) must be fully documented. Also, procedures should be put in place to make sure that every modification to system components (the critical ones, at least) is reported in a backup copy. Effective recovery requires also that *media for custom and purchased software* together with their *license information* should also be secured. Finally, the disaster recovery plan itself should be backed up. It may seem obvious that the disaster recovery plan will be available when an emergency calls for its activation, but this means that a complete copy of the disaster recovery plan should be kept in a safe place (e.g., offline at an alternate site). The need to back up all the information and elements needed to fully restore a system applies even when a comparable system is kept offline; the offline system maintains the exact level of operating system patches and operating system "state."

Some considerations should be devoted to backup requirements for desktop computers and portable systems, which have some peculiarities with respect to servers. In particular, when the PC data backup process is not automated (e.g., saving data on a fileserver to be regularly backed up), which is frequently the case, a user's duty of

Table 2 Example of Data Classification for Backup and Recovery

Classification	Definition
Critical	Data that must be preserved for legal reasons, for use in business-critical processes. Must be restored as soon as possible in the event of a disaster.
Vital	Data needed for important, but not critical, business processes. A loss of this data would represent severe damage and economic loss for the company. These data may have privacy requirements.
Sensitive	Data used in normal business operations, data that could be reconstructed from alternative sources in the event of loss but at some cost.
Noncritical	Data that could be reconstructed with minimal costs in the event of loss. No privacy or security requirements.

saving critical data on a backed-up server should be ruled by an appropriate usage policy (i.e., a document possibly subscribed by each user stating, among others, that each user should take care of saving his/her critical data on a backed-up server). The policy should be enforced by intermediate managers and users should be trained about the importance of this recovery requirement. Providing an automatic backup process and restoration for PCs requires *interoperability and platform standardization*. It is then usually recommended to have homogeneous platform operating systems, configurations, and applications among the organization's PCs and portable devices (NIST, 2002).

Backups should be kept in a safe place, where they cannot be affected by the consequences of a disaster, so to enable their *recovery* if the original is compromised or unavailable. For decades this has been the golden rule of disaster recovery, especially for mainframe-centric IT infrastructures. Traditionally, backup has been seen as a batch process running during night hours and storing on tapes all relevant information produced that workday. Although this solution is still used in a large number of organizations and is well suited in many circumstances, in many others cases this scenario is now anachronistic. With the increase of Web-based services and extranets, applications and business processes tend to be active on a 24 × 7 basis. As a consequence, there is no longer the notion of "night hours," which is meant to be that window of inactivity of business transactions perfectly suited to take a snapshot of data. In many real-world scenarios, transactions are always running and information is always accessed and possibly updated. In addition, data are growing every year at a terrific rate. Many commentators are commonly referring to the ever-growing amount of data to manage, back up, and restore as "the explosion of data," to stress both the impressive growth and the chaotic nature (Campbell, 2000; Kaye, 2001; Nicolett & Berg, 1999; Toigo, 2001a).

Backup and recovery planning should achieve two fundamental goals:

Backup should be made with a minimal impact on the production environment and, ideally, should be performed without blocking transactions execution.

Recovery should be efficient so as to minimize the time frame necessary to restore the data and bring the system back to its operational state. The efficiency of the recovery process is the key factor in the company's effective restoration of its business functions.

Backup and Recovery Techniques

The definition of data recovery strategies requires effective backup strategies to be in place. These, in turn, require the analysis of data to define priorities and criticality, so as to provide means to perform the backup process efficiently. The classification of business-critical data is needed to better organize their backup, optimize recovery, and therefore minimize downtime, all of which should follow the evolution of the company's business processes and the corresponding flows of information. Table 2 illustrates a simple typical data classification schema (Kaye, 2001).

To better maintain a clear identification and classification of data, a formal policy should be adopted. The goal of the policy is to establish who is in charge of formally classifying data for each business unit, department, or workgroup; and define a uniform classification methodology for the whole organization corresponding to the recovery priorities and requirements in the event of a disaster.

Some of the main strategies and technologies for backing up data are summarized by Toigo (1999) as follows:

Server image backup. Image backup creates a physical image of an entire disk. It operates at physical disk level by transferring sectors of physical data storage blocks from hard disks to tapes. It has fast transfer rates and provides a complete server backup by transferring the entire content of a hard disk as a single unit. This technology requires the system to be inactive during the backup.

Snapshot or versioning backup. This technique is fast because after an initial complete image backup, it proceeds incrementally by backing up the modifications only. It works with block-level copies on a partition basis. It is widely used in traditional tape-based backup systems.

Full-volume backup on a file-by-file basis. Complete data sets are copied over the production network to backup devices. A process controlled by a server initiates the transfer to backup devices.

Incremental or differential file backup. Files are compared with their version in the preceding backup and only changed files are backed up again. *Differential* backup is meant to keep separate versions of the same backed up files, while *incremental* backup just keeps the last versions.

Backup using object replication. Logical objects are defined by software, including disk partition tables, boot volume, security information, system volume, and user data volumes. Logical objects are regarded as a single logical unit and all data can be copied at once.

Electronic tape vaulting. It replaces the manual procedures for handling tapes stored in offsite storage facilities and for moving tapes between locations. It exploits a wide area network connection between the company facility and the offsite storage facility where tapes are stored to provide for immediate access to data stored on tapes. Technologies like shadowing and multiplexing controllers allow duplicating backup data streams in two or more tape devices simultaneously. This way a company could make both a local backup (for complete recovery in the event of a disaster) and an electronic vaulting on a remote storage facility (to preserve data from disaster, like flood or fire, affecting the company site).

Remote disk mirroring. It is another alternative to physically handling tapes. With remote mirroring, the content of disks is duplicated in near real time to a remote disk volume. The same concept is applied to RAID (redundant array of inexpensive disks) technology as a means of fault tolerance instead of disaster recovery.

Selecting an *offsite storage* facility is the safest choice for preserving backups. The remote storage facility should be chosen because it will be unaffected by the same disasters that might affect the main company site. The remote site could be a branch of the company or a commercial system recovery facility offering this service. While companies with decentralized sites could choose to keep backups among their different sites, several commercial storage facilities offer backup storage as a service, including media transportation, safe storage, and recovery (NIST, 2002; Nicolett & Berg, 1999; Toigo, 1999). When selecting an off-site storage facility and vendor, there are some key factors to keep in mind:

Geographic area. Distance from the organization and the possibility of the storage site being affected by the same disaster as the organization (locations geographically close to the organization are likely to be affected by the same natural disasters).

Accessibility. Length of time to retrieve the data from storage and the storage facility's operating hours.

Security. Security capabilities of the storage facility and employee confidentiality, accordingly to the data's sensitivity and security requirements.

Environment. Structural and environmental conditions of the storage facility, like temperature, humidity, fire prevention, and power management control.

Cost. Cost of shipping, operational fees, and recovery services.

ENSURING CONTINUITY OF OPERATIONS: ALTERNATE SITES STRATEGY

Disaster recovery plans have traditionally accounted for natural disasters as the first threat to an organization. Hence, beside the safe storage of data backups, it has been necessary to provide an organization with a plan for the continuation of its business functions while severe damages occurred to its site and hardware assets. A disaster recovery plan should then include a strategy to recover and perform system operations at an alternate facility. Generally, three types of alternate site strategies are possible (NIST, 2002):

A dedicated site owned or operated by the organization;

A reciprocal agreement with an external entity (e.g., a business partner); and

A commercially leased facility.

As prospective alternate sites are evaluated, the disaster recovery planner should ensure that the system's security, management, operational, and technical controls are compatible with the prospective site. Controls may include measures for network security, such as firewalls and intrusion detection systems, and physical access controls. If the service is purchased from a vendor, an SLA must be negotiated carefully. The SLA must clearly state all conditions like testing time, workspace, security requirements, hardware requirements, telecommunication requirements, support services, and recovery time frame. The disaster recovery planners should be aware that a commercial facility usually hosts many customers, which may all be simultaneously affected by the same natural disaster. Hence, the commercial facility could be asked to recover different customers simultaneously and it may not have enough resources to do it properly. In this case, the commercial facility would tend to set priorities among its customers and not treat all of them at the same level of service. Unfortunately, this scenario is realistic and for this reason it is extremely important to negotiate a clear and extremely detailed SLA with the commercial vendor, in order to set once and for all how possible disasters should be addressed and how priority status is determined. Regardless of the type of alternate site strategy, the alternate facility could provide different services and have a different level of readiness with respect to the goal of immediate resumption of all business functions. There is a typical classification that also reflects the different commercial services offered on the market (NIST, 2002; Nicolett & Berg, 1999; Toigo, 1999):

Cold site. It typically consists of a facility with adequate space and infrastructure (electric power, telecommunication connections, and environmental control) to support the IT infrastructure. The cold site contains neither IT equipment nor office automation equipment, like telephones, fax machines, or copiers. The organization leasing a cold site should provide for all the necessary equipment.

Table 3 Alternate Site Characteristics

Site	Cost	Hardware equipment	Telecom	Setup time	Location
Cold	Low	None	None	Long	Fixed
Warm	Medium	Partial	Partial/full	Medium	Fixed
Hot	Medium/high	Full	Full	Short	Fixed
Mobile	High	Dependent	Dependent	Dependent	Not fixed
Mirrored	High	Full	Full	None	Fixed

Warm site. It is a partially equipped office space containing some hardware, software, telecommunication, and power sources. The warm site is kept in an operational status to be promptly made fully operational in the event of a disaster at the company's main site.

Hot site. It is a fully functional and immediately ready facility equipped with all the needed hardware, software, telecommunication, and power sources. Hot sites are usually staffed 24 hours a day, 7 days a week. Recovery of business functions is guaranteed to be extremely fast.

Mobile site. It is a self-contained, transportable shell equipped to restore immediately the subset of the most critical business functions, including telecommunication facilities. Major commercial vendors lease these mobile sites and keep them located in strategic places to let them reach most of the industrial plants in a relatively short time. However, to guarantee an on-time recovery by means of a mobile site, a company should sign agreements with vendors to have the mobile site ready in a time frame compatible with the business requirements.

Mirrored site. It maintains an almost exact replica of the IT infrastructure of the company's main site and is always ready to recover all the business functions. Recovery is almost immediate through a mirrored site. It is often owned and operated by the company, given the high degree of customization and specificity.

Table 3 summarizes the characteristics of the different alternate sites as classified in NIST (2002).

The solutions listed in Table 3 differ in terms of cost and timeliness. Cold sites are less expensive to maintain but require considerable time to acquire and install the necessary equipment. Going down the list, we find solutions that result in more expensive costs but provide greater availability. Mirrored sites are the most expensive solution and provide almost 100% availability (i.e., minimal downtime). Remote mirroring has gained large popularity as a reliable solution for disaster recovery; we therefore discuss it in more detail next.

Remote Mirroring

Advances in networking technology have put the basis for many commercial systems on remote mirroring for safeguarding corporate data and providing fast recovery. However, sometimes the expectations that planners place on remote mirroring solutions are not realistic. Also, solutions based on remote mirroring tend to be complex, both architecturally and in data management, to satisfy to the high requirements from companies. This may lead to a lack of robustness of the recovery system, misconfiguration, and improper array maintenance. The consequence could be the loss of synchrony between arrays or the storage of corrupted data. If this happens, in the event of a recovery, the result could be a multiplication of the disaster, since the risk is to recover corrupted or incoherent data (Kaye, 2001; Toigo, 2001a, 2001b). Also, remote mirroring does not provide for zero downtime, which is considered a requirement by some senior managers. Remote mirroring, if configured properly and implemented with high-level technology, could be very fast, much faster than many other recovery alternatives, but it cannot reduce the downtime to 0. Hence, remote mirroring is not the panacea that makes the nightmare of downtime disappear: risk management and disaster recovery planning are still mandatory. Moreover, remote mirroring is subject to data gaps, since some sort of asynchrony is usually implemented (e.g., the mirroring between the secondary and the tertiary arrays of Figure 7). Possible consequences of incoherent recovered data should be carefully analyzed in the planning stage. These may provoke the loss of commercial orders, payments, or shipments, if data gaps are not identified and handled properly. Solutions designed to be completely synchronous exist but come at a high price in terms of performance and system latency. In fact, the problem in remote mirroring has been traditionally the latency caused by the distance, possibly many hundreds of miles, between the sites, in particular when the mirroring is synchronous (i.e., writes to production disks waits for the mirrored writes to be completed and acknowledged).

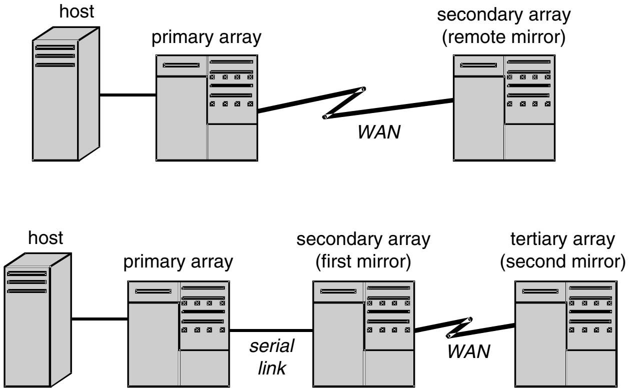

Figure 7: Remote mirroring configurations.

Starting from the mid-1990s, the cost of high-speed bandwidth WAN decreased and vendors realized those architectures that made remote mirroring one of the best solution at affordable costs for many companies. The typical improvement was to provide for three arrays, adding an intermediate site between the company and the final remote storage facility (Toigo, 1999). Figure 7 shows the traditional and the enhanced schema for remote mirroring. The benefit of the enhanced schema is twofold. First, the link between the company site and the secondary array could be a high-speed serial one, thus reducing the latency in synchronous mirroring. Second, the mirroring between the secondary and the final arrays, connected with a WAN, could be realized asynchronously, hence optimizing the mirror operation, while not affecting the robustness of the disaster recovery solution.

BACKUP AND RECOVERY FOR WEB-BASED HOSTING SERVICES

Web-hosting service (WHS) providers are commercial vendors that may store hundreds of Web sites in their systems. Moreover, the service effectively hosted may be complex, not just a Web site. WHS can be composed of *n*-tier architectures with Web portals, application servers, middleware layers, and community services. Due to this increasing complexity, nowadays it has become common for an organization to purchase the Web management and hosting service instead of implementing it in-house. However, like other outsourced services, even for Web hosting, customers should evaluate carefully how the service is provided and consider which guarantees the vendor provides in the event of an outage (Scott, D., & Natis, Y., 2000).

The primary deployment options for Web-based applications are *Internet data centers*. A growing number of enterprises are considering dual-site application architectures, which split application traffic between two active sites. The active sites could be corporate data centers, commercial data centers, or both. One aspect to consider carefully when services from commercial data centers are purchased is the large number of simultaneous recoveries they must provide for all their customers in the event of an outage. Thus, similarly to what we observed for remote mirroring, the customers of a Web-hosting service should make sure that the outsourcer has a robust disaster recovery plan and, through clear service level agreements, that she has a contractual responsibility to effectively execute it (Kaye, 2001; Toigo, 2001b).

Different technological options can be used for storage management of Web sites and Internet applications (Kaye, 2001):

Direct attached storage (DAS). The disk drives or arrays are directly connected to an individual server.

Capacity: ≤ 200 GB

Features: Well-suited for few Web servers with infrequent updates. Good reliability using RAID for databases.

Network attached storage (NAS). High-performance general-purpose file servers connected to Web sites via LANs.

Capacity: ≤ 10 TB

Features: Well-suited for several Web servers with frequent updates. Very good reliability for databases, if clustered.

Storage area networks (SAN). High-performance special-purpose storage systems connected to Web servers via dedicated fiber optical links.

Capacity: 100 GB–100 TB

Features: Not economically convenient for Web servers. High reliability for databases.

Global storage systems (GSS). A technology for geographically replicated file systems.

Capacity: 300 GB–100 TB

Features: Very good for Web accesses and frequent updates. Not well-suited for databases.

Networked storage solutions, however, could pose special difficulties that might significantly degrade their speed to that of some tape-based solutions. For instance, in a SAN, domain servers, routers, and software delivering virtual volumes to SAN servers form a networked infrastructure that poses an increased management burden on the IT staff and is more prone to failures than simpler solutions.

Most e-business applications hosted in Internet data centers are based on *n*-tiers architectures. These multitier platforms typically include one or more Web servers, application servers used to integrate Web technology with legacy systems, connectors and adapters, database servers storing data, and authentication and authorization servers filtering the user accesses and incoming connections. This complex architectural design and the interconnection of several components are clearly more prone to failures than centralized monolithic systems. These failures, often implying short but frequent outages, must be handled carefully in the planning stage or in negotiating SLAs with vendors. Selection of components and replication strategies should be required with the goal of minimizing downtime in mind.

In addition to this class of system failures, e-business needs to face the growing rate of network attacks and denial of service. Many commentators are now commonly reporting "the convergence of disaster recovery and network security" for e-business applications, meaning that the two areas have much in common and more and more interdependencies. From a disaster recovery planning viewpoint, intrusions and security incidents are another cause of downtime to be considered in the risk management stage, in the BIA, and in the selection of vendors. Internet data centers should provide for a staff skilled in network security and for robust security architectures and policies (Kaye, 2001; Toigo, 2001a, 2001b).

DISASTER RECOVERY PLANNING TEMPLATE

This section provides a reference template for disaster recovery planning derived from Brooks, Bedernjak, Juran, and Merryman (2002). It is only intended as one possible example of a disaster recovery planning template, since an actual plan should meet the peculiar requirements of each organization. Further examples and interesting readings for the definition of a disaster recovery plan could be found at Toigo (1999) and DRJ (2002).

A plan could have the following schema:

Introduction

Purpose. The purpose of the plan should be shared and fully understood by the personnel involved. For example, recall that in the event of a disaster, the plan provides for precise procedures to activate the plan, to recover from the disaster, and to restore normal operations. Other key actions to be introduced are the identification and classification of assets and services, the assignment of responsibilities and roles to personnel to be carried out during the interruption of normal operations, and the coordination required with other staff involved in the recovery phase, e.g., vendors and local or government agencies.

Scope. The scope of the plan describes which measures the organization has put in place in the event of a disaster. For example, which alternate site strategy has been set, whether a hot site is ready to recover critical operations, how long the alternate facility could be effectively used to back up the IT infrastructure, and how long could be the estimated unavailability of the main IT functions until activating the alternate facility (this is strictly dependent on the business sector so the range could stem from 48 hr or more of inoperability to immediate switching to a mirrored site in case of a failure).

Assumptions. The introduction could even highlight what will need to be fully operational and organized for the plan to be successful. For instance, it should be assumed that preventive safety measures must be followed, in particular in the case of a natural disaster. Thus, the sprinkler system, fire extinguishers, generators, etc. must be fully operational and properly maintained. Assumptions related to the IT infrastructure usually refer to the availability of the UPS (uninterruptible power supply) to back up a temporary power failure and to the safety of data backups in a site not affected by the disaster. Other assumptions could be related to the effectiveness of SLAs with service providers, e.g., which actions are to be carried out by the providers, which resources should be available, and how communication should be done. Of overall importance is the availability of a consistent copy of the configuration of all critical components of the IT infrastructure, which must be backed up in a safe place.

IT Infrastructure and Responsibilities

System Description and Architecture. A clear and comprehensive documentation about all the critical components and functions of the IT infrastructure is necessary to speed up the recovery after a disaster. The IT architecture should be described with details about the physical location of critical servers and network devices, the functionality of each component, LAN/WAN/SAN topologies, and telecommunication connections. Also, for each critical component all the information regarding their operating systems and applications should be immediately available. The plan should indicate the location where the backup copies, with software and actual configurations, are safely stored.

Responsibilities. Key roles in the organization's chart in the event of a disaster should be indicated, as long as the line of succession (e.g., if the Chief Information Officer is unable to function, his/her functions must be delegated to someone else). Aside from this, the plan describes roles and responsibilities of all the teams specifically dedicated to contain the effects of a disaster, organize the recovery of critical functions, and restore the normal operations. For each team, its members, leadership, roles, responsibilities, and coordination with other teams should be indicated.

Activation

Damage Assessment. The first duty of a disaster recovery plan is to contain the damages in the initial phase of an emergency. The top priority, especially in the event of a natural disaster, is the safety of the personnel; hence proper evacuation plans and directives must be enforced. Then the plan should state detailed procedures to determine the cause of the disaster, the extent of damages, the affected physical area, and the status of physical infrastructures and of the IT equipment. After a first inspection, a disaster recovery team should proceed to a detailed inventory, following the priorities set for the organization's assets.

Criteria for the Activation. Based on the results of the damage assessment phase, the disaster recovery coordinator could decide immediate actions like notify civil emergency personnel, the provider of the alternate facility, or the vendors for replacement items. The plan should define criteria for the activation. For example, how long the facility is estimated to be unavailable and how long until critical components of the IT infrastructure can be replaced. If the plan is to be activated, the coordinator should inform all team leaders, which in turn should activate all team members.

Recovery

Priorities. The key factor in the recovery phase is to follow priorities. Unless the disaster is confined to a single or few components, the recovery should be focused on the most critical assets and business functions. The goal of restoring as fast as possible those functions necessary for the organization business should be clearly stated and supported. Priorities have been already set during the risk analyses and the business impact analyses. The results of these two key phases of the disaster recovery planning should be reflected in primary, secondary, and tertiary recovery objectives that the disaster recovery teams should pursue.

Return to Normal Operation

Original or Alternate Site Restoration. This phase of the plan presents the activities required for restoring operations at the original or at the alternate site. Technical details may include which teams operate first and on which components, coordination activities among teams (for example, between network and system administrators, between system administrators and application administrators, and/or between personnel of the organization and personnel of the provider). Testing procedures could be also described.

Deactivation. Procedures should outline how to return to normal activity, like how to gracefully deactivate the alternate site or temporary measures put in place, and how to restore a proper backup system and the safe storage of backup data.

Appendices

Documentation. The appendices of the plan should include all the detailed documentation mentioned in the plan itself and needed during an emergency, for example, personnel contact list, vendor contact list, equipment and specifications, SLAs, IT standard operating procedures, BIA, evacuation plan, equipment inventory, and configuration data.

CONCLUSION

The scope of disaster recovery has become wider in recent years due to a change in the business functions of many enterprises. Internet connections have driven the development of new business models that require immediate recovery and continuous operations and have "zero-downtime" as their ultimate goal. While the "zero-downtime" goal is still impossible to achieve, and this should be stated clearly in each disaster recovery project, the disaster recovery area has developed new planning methodologies and techniques to match these requirements. As a consequence, the process of putting into place an effective disaster recovery plan has now sophisticated technologies to exploit but it is also more complex for its interconnections with both the IT infrastructure and the business functions of a company. An ineffective disaster recovery plan could result in severe losses when one of the many risks becomes reality. Such risks today are not only the traditional disasters like fire, floods, or sabotage, but also the "normal" failures of the IT infrastructure, such as misconfigurations, failures of applications, and security incidents, which may lead to frequent downtimes. E-business models can no longer sustain those frequent downtimes or network outages as in the past when companies could accept recovery-time of some days in the event of an IT failure.

Processes that allow achieving a better efficiency of the recovery phase in the event of a disaster, such as the risk analysis, the business impact analysis, and the innovative backup and recovery techniques, assume therefore great importance.

GLOSSARY

Alternate site A location, other than the normal facility, used to process data and conduct critical business functions in the event of a disaster.

Business continuity planning A generic term covering both disaster recovery and business resumption planning.

Critical functions Business activities that, if unavailable, can result in high costs for an organization.

Disaster Any event that can cause the inability of an organization to provide critical business functions for a certain period of time.

Disaster recovery planning The preparation of the activities and measures necessary to minimize losses and ensure the continuity of critical business functions in the event of a disaster, synonymous to contingency planning, business resumption planning, corporate contingency planning, business interruption planning, and disaster preparedness.

Disaster recovery teams A structured group of teams responsible of controlling the recovery operations in the event of a disaster.

Electronic vaulting The transfer of data to an offsite storage facility via a communication link or a different portable medium.

Facility A location containing equipment and infrastructure to perform normal business functions.

Loss The cost resulting from a disaster.

Network outage The interruption of system availability as a result of a communication failure affecting a network.

Offsite storage facility A secure and remote location where backups of hardware, software, data files, documents, or equipment are stored.

System outage An unplanned interruption in system availability resulting from operational problems or hardware/software failures.

Distance Learning (Virtual Learning)

Chris Dede, *Harvard University*

Pamela Whitehouse, *Harvard University*

INTRODUCTION: A CONCEPTUAL FRAMEWORK FOR DISTANCE EDUCATION

Understanding the likely trajectory of contemporary distance education requires envisioning today's virtual learning applications in a larger context. Organizational structures and processes for learning across distance are shaped by evolving societal needs; these include developing human skills for economic prosperity and political participation, increasing educational opportunity for disenfranchised learners, and preparing students for a technology-intensive workplace. Demographic changes and shifting student characteristics also are influential in forming the nature of distance education. The "typical" student using technology to surmount geographic barriers has shifted from a rural resident in an agricultural society seeking to understand industrialization to a huge proportion of the population using formal and informal means of education to participate in an emerging knowledge-based, global civilization. Technological evolution also molds distance education, which has incorporated successive generations of media that include lantern slides, radio, television, computers, telecommunications, and now cyberspace and ubiquitous computing. The Internet itself can be viewed as an extension of the technologies that sparked early forms of distance education over 150 years ago. Envisioning the future of virtual learning requires synthesizing all these factors, organizational, demographic, and technological, into ways sophisticated computers and telecommunications can further enable reinventing teaching, learning, and schooling.

HISTORICAL FOUNDATIONS OF MODERN DISTANCE EDUCATION

Pre-1900 Distance Education

In the 19th century, distance education in the United States was shaped by new technologies that allowed educators to overcome barriers of distance and time. These advances also altered beliefs about the purpose of education through changes in the social, political, and geographic dimensions of learning. The Progressive Era brought a shift in educational thinking from the Jeffersonian ideal of forming good citizens (Tyack, 1967) to Horace Mann's assertion that tax-supported education would provide literacy skills to enhance the employment opportunities of workers, as well as to "prepare citizens to fulfill their civic duties" (Cuban, 2001, p. 8). The roots of pre- and early 1900 distance education lie in this Progressive notion that children need education to become good citizens and contributing workers, while adults need ongoing education to improve their economic lives.

Pre-1900 forms of distance education were influenced by the need to reach learners in remote geographic locations, rural free delivery, and the birth of the Chautauqua Movement in the 1840s. This movement promoted continuing education for adults based on the ideal of lifelong learning and offered correspondence courses combined with some face-to-face meetings for adults to earn certification in certain subjects (Scott, 1999). The development and implementation of the first correspondence courses were credited to Sir Isaac Pitman of England, the inventor of shorthand. In 1840, he used the postal service in England to reach learners at a distance. Around the same time, in the United States traveling lyceum lecturers crossed the country with lantern slides, making possible national conversations between intellectuals and the citizenry. Ralph Waldo Emerson was a very popular lyceum speaker, and his talks generated many debates about the meaning of democracy (Field, 2001). A more formal version of the early American correspondence course was created by Anna Ticknor of Boston in 1873. To increase educational opportunities for women, she originated the Society to Encourage Studies at Home. The society provided courses of study for women of all social classes and served over 10,000 women over its 24-year lifespan (Nasseh, 1997; Stevens-Long & Crowell, 2002).

In 1878, John H. Vincent, co-founder of the Chautauqua Movement, created the Chautauqua Literary and Scientific Circle. This Circle offered a four-year correspondence course of readings; students who successfully completed the course were awarded a diploma. This course was open to all adults, including women and senior citizens (Scott, 1999). By 1892, the 19th-century version of the "information superhighway" (otherwise known as rural free delivery) paved the way for Pennsylvania State University to provide higher education to rural families (Banas & Emory, 1998, p. 365).

Other institutions of higher education, notably the University of Chicago and the University of Wisconsin, modeled their extension schools after the Chautauqua program (Scott, 1999).

In the pre- and early 1900s, distance education provided access to educational services for nontraditional learners and for those whose geographic or social location made continuing their education difficult. Students in remote rural areas, women, senior citizens, and others benefited from the Progressive ideals of access to education for all, as well as from the concept of lifelong learning, the founding notion of the Chautauqua movement. New technologies and services (e.g., lantern slides, railroads, rural free delivery from the postal service) provided the infrastructure to support the Progressive educational ideals of the times.

1900–1960 Distance Education

While distance education is rooted in the 19th century, the field blossomed in the 20th century. Distance educators look to technological innovations to provide new opportunities for their field, and the 20th century was rife with technological advances (Mood, 1995). During the 20th century, distance education embraced radio, television, computers, and ultimately the Internet. As the methods of delivery for distance education expanded, so did the diversity of learners seeking distance education and their reasons for enrolling in such courses. Individuals interested in learning cultural norms, becoming more capable in the workforce, or hoping to resituate themselves in their social context after wartime service became major consumers of distance education (Dymock, 1995).

As the field grew, governments discovered the potential of distance learning for spreading their messages and provided increased financial support (Sumner, 2000; Tait, 1994). Starting with the creation of the First International Council for Distance Education in the 1930s (Bunker, 1998), the formalization of distance education as a field of study established it as a valid method of education. However, only in the latter half of the 20th century did distance education gain widespread acceptance within the educational community, the result of a substantial body of research that confirmed its benefits (Nasseh, 1997).

At the start of the 20th century, distance education still relied on correspondence courses delivered primarily through the postal service. Many of these courses were delivered to their students by mail, as discussed earlier, but did not allow much interaction or individualization (Moran, 1993). Although rules for home study were established in 1926 to allow some form of governmental control, correspondence methods were not conducive to supporting learners nor were they standardized (PBS, 2002). Even the addition of motion pictures in the early years of the century failed to revolutionize this traditional pedagogy for distance education (Jeffries, 2002; Nasseh, 1997). One of the main goals of the early distance education programs was to help inculcate immigrants into the "American way of life" (Sumner, 2000), but these learners needed substantial guidance and aid. As a result, poor curricular design and lack of support were particularly problematic, and the dropout rate was high (Shea & Boser, 2001).

In the 1920s, distance education started to utilize radio for delivery of lessons (Bourke Distance Education Centre, 2002; Nasseh, 1997). In a push to widen access, speed the interaction between student and professor, and personalize the delivery of distance education, the use of radio was seen as an exciting opportunity. In the mid-1930s, an American art history course was offered by radio broadcasts (Funk, 1998), and other courses supported forming "listening groups" to enhance learning (Mood, 1995).

However, despite the rapid rise of radio technology, distance education courses were rarely if ever offered for credit in higher education (Nasseh, 1997; PBS, 2002). The education community, along with society as a whole, regarded legitimate education as only possible in conventional locales, such as classrooms (Funk, 1998). This view was clearly articulated by Harper (a designer for the Chautauqua program) in the late 1800s (Froke, 1995). He viewed the lack of face-to-face instruction to be an insurmountable problem in distance education, a view held even today.

To address this lack of teacher interaction, a modification of the correspondence course was designed in Soviet Russia in the 1930s, called the "consultation model" (Tait, 1994). As its name implies, this type of correspondence course, while primarily at distance, included periodic face-to-face meetings with instructors. However, unlike its name, the "consultations" were mostly lecture-based meetings intended to spread communist dogma. This model did offer an opportunity to put a face with the words, an issue with which today's distance education continues to grapple (Roberts, 1996).

Television was the next big advance in distance education technology. As early as 1934, the State University of Iowa used television to deliver course content (PBS, 2002). Early research into learning via television indicated mixed results, with several studies showing that it was similar to conventional instruction. Gayle Childs referred to televised distance education as an "'instrument' of delivery, not a pedagogical method" (Jeffries, 2002). Echoes of current debates about technology as a tool for learning were heard regarding the use of broadcast media in distance education (Nasseh, 1997).

Thus, the early 1900s were characterized by changes in both how distance education programs were delivered and why. New technologies such as radio and television increased the speed of delivery and personalization of distance education, and the students broadened to include those wishing to become steeped in a new culture. However, distance education was still plagued with problems and lack of acceptance by the established education community.

1960–Present Distance Education: The Rise of Computer-Based Learning

Prior to the introduction of computer technologies in the 1960s, correspondence course and independent study models of distance education posed challenges to the learning and teaching processes. This contributed to a persistent problem of credibility for the field. "Telecourses" (Verduin & Clark, 1991), developed in the 1970s, showed promise for minimizing some of these problems. Previously, television had primarily been used as an electronic blackboard and for the delivery of standardized content, through lectures intended to reach wide audiences. The development of videotape allowed educators to customize the same content for different learning environments. This medium also allowed increased flexibility; course content could be stored, delivered, and repeated at will. This minimized time-dependency, a drawback of previous televised courses. However, despite their advantages, the cost and complexity of producing telecourses made them impractical for teaching large numbers of students.

Around the same time, the "open university" concept was launched. The creation of universities open to all was driven by the need to provide alternative education for adults whose needs could not be met in the traditional classroom. The British Open University began in 1969 through video broadcasting of its weekly courses on the BBC. Over time and with the advent of new technologies, the British Open University's model of distance learning evolved into a student-centered delivery system and administrative structure separate from a campus setting. More economically practical than telecourses, this system envisioned each student as "a node in the network" (Granger, 1990, p. 189) that provides individualized instruction in a virtual classroom. The students have access to a virtual library, customizable based on their particular learning style, and to collaborative tools that encourage discourse and critical thinking (Prewitt, 1998). By encouraging a community of learners, this model overcomes some of the problem of isolation.

During the 1970s, the capability of computers to automate tasks and deliver information made them invaluable tools for many companies, thereby increasing the need for technologically competent workers. This prompted the inception of corporate training programs focused on technology literacy. In schools, word processors, spreadsheets, and database applications enhanced the productivity of educators and students, and the development of educational software offered interactive ways to deliver academic content. As early as 1960s computers were being used with adult learners at the University of Illinois through an integrated learning system called Programmed Logic for Automatic Teaching Operations (PLATO). Integrated learning systems—computer-based instructional programs—were used to distribute educational content through a local network, usually to students in the same room or building. In the 1980s, due to the rapid evolution of information technology and our increasing dependence upon computers as a society, the use of educational technologies expanded considerably. However, during these first few decades, information technologies were used more to automate traditional models of educational delivery than to develop new forms of pedagogy or to enhance learning across distance.

In contrast, during the 1990s widespread usage of the Internet transformed the nature of distance education. As discussed elsewhere in this encyclopedia, the present-day Internet traces its origins to the "ARPANET," a system developed in the late 1960s (Leiner et al., 1997). The ARPANET was initially used by instructors and researchers to share files of information. In 1972, however, e-mail capability was added, transforming computers into a medium that facilitated, direct "people to people" interaction (Weber State University, 1997). In subsequent years, the advancement of networking technologies led to the eventual development of the Internet. Increasing use of personal computers in schools, businesses, and homes helped to establish this budding network of computers. In particular, with the development of the World Wide Web (WWW) as a means of representing and accessing information, Internet use expanded exponentially.

In 1992, it is estimated that the WWW contained a mere 50 Web pages (Maddux, 2001, p. 2). During the 1990s, decreasing prices for computer technologies led to increases in personal ownership, and self-publishing resulted in an explosion of Web-based information. By 2000, the number of Web pages rose to at least one billion (Maddux, 2001). With its capability to facilitate communication between people in various geographic locations and to disseminate information quickly and relatively inexpensively, the Internet appeared well matched for distance education.

During the latter part of the 20th century, the rise of computer-mediated distance education coincided with several important demographic shifts, as well as changes in the world of work. It became less common for a person to spend most of his or her work life in one vocation or one company. Multiple career and job changes over a lifetime were becoming the norm. This increased the need for retraining programs. The citizenry was also becoming increasingly mobile, making location-dependent programs less feasible for many people. Retraining needs led a large number of older adults to seek educational opportunities, but time constraints due to work and family responsibilities made traditional, on-campus programs inaccessible. All of these factors contributed to a growing demand for distance learning programs that businesses and universities hastened to meet.

Beginning in the early 1990s, many universities began using new information technologies both to augment traditional face-to-face classes where instruction occurs in the classroom and to deliver Web-based courses, solely via the Internet. The WWW provided a plethora of resources, which could be accessed inexpensively, around the clock, and from any Internet-accessible location in the world. Course Web sites served as virtual learning "spaces," portals through which course participants gained access to course-related information and reference databases. E-mail facilitated direct, instructor-to-student and student-to-student communication. During the early period of Internet use, the level of information access and communication was unprecedented in distance education.

However, some researchers expressed concern about the efficacy of computer-mediated teaching and learning in contrast with face-to-face instruction (Nickerson, 1993; Peters, 1994). When compared with classroom-based education, some important aspects of human interaction appeared to be lacking. E-mail and Web pages did not capture the spontaneity of face-to-face conversation, the richness of group discussions, and the sense of community prevalent in well-designed classroom settings. The development of computer-mediated communication tools addressed many of these issues.

Asynchronous learning networks (ALNs) based on threaded discussion boards offered a facile way for multiple participants to engage in online conversations and to read and respond to the ideas of their classmates, unrestricted by time. Many students felt that the opportunity to review postings and to think through their own ideas before responding benefited their learning, leading to a higher quality of conversation than they customarily encountered in classroom-based dialogues. Also, the development of Web-based synchronous learning networks (SLNs) added real-time communication to the growing repertoire of distance education tools. In multiuser object-oriented systems (MOOs), multiuser domains (MUDs), and multiuser virtual environments (MUVEs), such as "Tapped In" (http://www.tappedin.org) and "Active worlds" (http://www.activeworlds.com/), learners, instructors, and colleagues were able to gather simultaneously in designated virtual spaces to discuss course-related issues and exchange information of all sorts. ALNs and SLNs proved complementary in addressing different communication preferences and in creating a sense of community among learners.

As technological media have expanded, so has the number of educational institutions and businesses offering instruction via computer and Internet technologies. Computer-mediated learning, which is not time- or location-dependent, provides educational opportunities for those whom traditional schooling might not be feasible, such as working adults, parents of young children, and those with limited mobility. In addition, the high level of autonomy and self-directedness afforded by online education, as well as relative "freedom of pace," has benefited the particular learning needs of adults (Verduin & Clark, 1991).

With the participation of many reputable universities and with increased research documenting effectiveness, distance learning is now a credible and viable mode of instruction. Though detractors exist and accreditation is still a problem for some online programs and virtual universities, the use of information technologies for distance education seems likely to continue growing and evolving, particularly as society invests in research about how to use interactive media to deliver high quality education.

Table 1 presents a timeline of distance learning and new technologies.

DISTANCE EDUCATION AT THE TURN OF THE MILLENNIUM

Socioeconomic Context

Internet-based distance education has arisen amid shifts in the nature of higher education and in socioeconomic conditions worldwide. These changes have contributed to the growth and popularity of the field. The emergence of a global, knowledge-based economy has created new demands on corporate and educational institutions. The rapid evolution of information technologies has served simultaneously to increase those demands and to offer novel ways of developing a highly educated, knowledgeable, and technologically competent citizenry.

According to Selfe (1999, pp. 45–46), growing industrialization throughout the world and "the opening of increasingly competitive global markets" posed a threat to the economic preeminence enjoyed by the U.S. since World War II. In the early 1990s, the U.S. faced rising inflation, high rates of unemployment and poverty, and a widening gap between the rich and poor. Recognizing domestic "high-technology industries [as] the most competitive in the world," the Clinton administration devoted significant resources to the enhancement of the national and global information infrastructures and the domestic computer industry, in order to create new jobs, stimulate income growth, and open new markets for U.S. businesses (Selfe, 1999, p. 51). As information technology became more powerful and less expensive, the U.S. economy hastened its shift from an emphasis on manufactured goods to services and information. In response, the 1995 Economic Report of the President identified the need for increased "investments in education and technology" to prepare a workforce capable of sustaining this new type of economy (Council of Economic Advisors, 1997, p. 7).

Changes in the economy and job market demand new skill sets. The proliferation of knowledge and information has led to "increasingly specialized subfields" (Mitchell & Dertouzos, 1997). This has created a need for workers who possess highly specialized skills and knowledge, often in emerging technology fields. At the same time, the delivery of services and the management of information across wider and more diverse markets requires broader, higher order skills, such as problem solving, project management, and communication. Since individuals today are more mobile and likely to have multiple career and job changes, these types of "soft skills," applicable across working environments, are vital (Thompson, Ganzglass, & Simon, 2000, p. 9).

A multitude of educational programs were created to respond to this demand for new and deeper skills, and corporate training became a thriving segment of the

Table 1 Timeline of Distance Learning and New Technologies

Time Period	Delivery Mechanisms	Benefits	Challenges
Pre–1900	U.S. Postal Service	Rural free delivery allowed students in remote areas to take correspondence courses	Students had to work and learn in isolation
	Railroad	Facilitated speed of mail services and transportation for people and news	Costs of travel and mail limited access
	Traveling Lecturers	Scholars and students could engage in "national" conversation on democracy	Conversation limited to mainly white, upper and middle classes
	Lantern Slides	New technology provided powerful visual aids	Limited to mainly white, upper and middle classes
1900–1960	Radio	Personalized delivery, increased speed	No person-to-person interaction, "one size fits all" content
	Television	Rapid delivery, increased access	No person-to-person interaction, "one size fits all" content
1960–Present	Videotape	Customizable content, reach wide audiences	Costly and complex to produce
	Satellite broadcasting	Wide audiences, real time	Time and place-dependent
	Computers	Rapid delivery of content and communication	Limited face-to-face interaction
	Integrated learning networks	Multiple users, standardized content	No person-to-person interaction, "one size fits all" content
	Internet	Widely accessible, inexpensive and rapid communication across distance	
	World Wide Web	Widely accessible, self-publishing, inexpensive and rapid communication	Limited face-to-face interaction
	Threaded discussion boards	Multiple users, not time dependent	Limited real-time interaction
	MOOs, MUDs, & MUVES	Multiple users, many-to-many communication, rich social interaction, real time	Some bandwidth requirements, limited face-to-face interaction

service industry. Corporations developed retraining programs, and new organizational training businesses formed, offering their services to both companies and individuals. Technology is playing an important role in the delivery of these services, which prepare the workforce for increasingly information-intensive working environments.

Developments in information and communication technologies allowed companies to establish a workforce and serve clientele in a variety of geographical regions. The Internet and Web-based communication tools provided reliable and inexpensive training solutions, to reach learners "in very large numbers, but also in very small classes, or even as individuals, anytime, anywhere" (Thompson, Ganzglass, & Simon, 2000, p. 9). Despite the slowing of the economy in the past couple of years, the need for highly trained, flexible workers remains strong. In an environment of "increased training need and lifelong learning, yet one of diminished resources," the cost effectiveness, accessibility, and adaptability of Internet-based training and education is vital (Schreiber & Berge, n.d.).

Efforts to create more efficient and effective programs, to expand business opportunities, and to recruit new employees led to the development of "corporate universities," which allow a company "to coordinate and manage programs, to train and educate its employees, customers, and suppliers" (Meister, 2001). Corporate universities, which often offer educational programs both to employees and to the general public, rely heavily on Internet technologies to deliver their services and to meet the needs of working adults, who are often constrained by time and location. In addition to creating educational institutions of their own, some businesses are partnering with traditional colleges and universities. This allows them to capitalize on existing pools of learners and infrastructures already in place to educate relatively large numbers of students. For postsecondary institutions, such partnerships create the potential to expand course offerings and career services and receive additional support for distance education initiatives.

Like businesses, colleges and universities have also been impacted by the changing economy, emerging technologies, and the demand for new job skills. These factors have combined with other trends in the field of higher education to expand the need for Internet-based, distance education. Since the end of World War II, colleges and universities have been steadily drawing larger numbers of students from remote locations (Hoxby, n.d.). Enhanced transportation and communication mechanisms have contributed to a population that is increasingly mobile. In addition, the average age of students has risen over time. The once typical 18- to 22-year-old undergrad-in-residence represents less than one-quarter of postsecondary students; colleges and universities are increasingly serving older, working adults, many of whom are part-time students (Greene, 2002).

The shifting economy and the demand for more highly skilled and knowledgeable workers has led to a trend of degree inflation: “85% percent of new jobs require education beyond high school, up from 65 percent in 1991” (Commission on Technology and Adult Learning, 2001, p. 8). This shift has brought many working adults back to school for additional education and retraining. At the same time, the average cost of college tuition “has risen rapidly since 1940,” generally at higher rates than inflation (Hoxby, n.d.).

Characteristics of Distance Education Students

All of these factors have combined to bring students with different needs to the educational market. These students are often working adults who must pay for their own schooling in the face of rising tuition costs and other substantial financial responsibilities. Rather than the traditional, liberal arts education, many seek practical, real-world skills and knowledge that can be directly applied to working environments. Some are highly mobile due to the changing job market and work-related travel, while others have limited mobility due to family responsibilities. Many have considerable time constraints. Internet-based distance education has proven successful in addressing many of the educational needs of this rapidly growing subset of students.

Both the WWW and Internet-based synchronous and asynchronous communication tools allow for the flexible delivery of course content. Learners can access course materials from virtually anywhere in the world, at any time. Unlike traditional correspondence education, students use new technologies to remain in close communication and collaboration with instructors and peers. Since geographic location does not limit participation in virtual learning environments, universities are able to recruit instructors from around the world who would otherwise be unavailable; this brings real-world skills and knowledge into the virtual classroom. In addition, the cost-effectiveness of Internet-based tools makes distance education a viable solution for those who seek education and training in a rapidly evolving job market.

How instructors can know who the students in distance education courses truly are is a topic of concern. Some instructors worry about whether an outside service may be writing the papers some students submit or taking the online tests that courses may require. Web sites exist for students to shop for a paper—for example, term-papers 4u.com promises “original” term papers that will attain good grades, hassle free. Or, one can search at EssayMart.com through over 700,000 term papers. Educators have fought back with their own Web sites; for example, Turnitin.com provides methods for detecting and dealing with plagiarism. As another illustration, Wordcheck is software that detects infringement of intellectual copyright through an extensive database (http://www.wordchecksystems.com/). Debates about how to ensure the validity of student achievements in distance education settings are likely to continue for some time.

Contemporary Delivery Mechanisms for Distance Education

How does one classify a course as distance education? Roberts (1996) suggested four criteria:

1. Teacher and student are separated physically during some portion of the educational experience.
2. There is an overseeing educational organization (this could be a university, secondary school, nonprofit, or even a corporate entity).
3. Educational technology mediates the interaction while apart.
4. Student and teacher can dialogue.

Today’s distance education courses take two forms: courses offered primarily at distance and hybrid courses, also called “distributed learning” courses, which combine face-to-face meetings with virtual experiences (Dede, Whitehouse, & Brown L’Bahy, 2002).

Historically, interactions between teacher and learner were generally unidirectional (e.g., correspondence courses, radio, and television). With the advent of computer-mediated technologies, the emphasis has shifted to interactive tools, allowing for more pedagogically sound instruction. As discussed earlier, computer-mediated communication encompasses both synchronous tools that create a virtual classroom and asynchronous tools that simulate traditional correspondence courses (Guri-Rosenblit, 1999). However, such a categorization is misleading because emerging media enable many novel forms of mediated interaction not well captured by comparisons to prior types of education. Synchronous tools allow students to work together on projects, interact with teachers, and carry on conversations. These tools include Internet-based videoconferencing, multiuser virtual environments, and virtual communities-of-practice. Asynchronous tools permit students to access coursework on their own time and place and allow for deeper reflection than “think-on-your-feet” synchronous tools. Asynchronous media include Internet technologies such as e-mail, the World Wide Web, asynchronous online conferencing systems, learning portals, and “courseware.” Also, some media (such as “groupware” collaboration tools) offer both asynchronous and synchronous options. Groups can meet simultaneously to plan, and later individuals can reenter the virtual space to access and build upon what others have previously done.

Choosing the correct tools for a course or program depends on the aims of the course and the needs of the students. “There is no ‘right’ or ‘wrong’ technology for distance education. Each medium and each technology, through which it can be delivered, has its own strengths and weaknesses" (Moore & Kearsley, 1996, p. 99). The following are illustrative examples of contemporary distance education programs; in each, the tools chosen match the needs of the organization, teacher and learner.

The Fielding Graduate Institute (http://www.fielding.edu/) is an example of a distance learning school. Several programs are offered leading to various accredited degrees. Stevens-Long & Crowell (2002) reported on the development of the Institute's Masters Program in Organizational Management. In this program, an emphasis is placed on using virtual environments, not to replicate face-to-face, but instead to create a space where students can reflect on contributions, interact, and evolve new social constructs of knowledge.

The Network for Education and Technology Services (http://www.unet.maine.edu/) was developed by the University of Maine System to increase participation in post-secondary education (in 1985, 50th in the prevalence of adult education and 47th in the percentage of matriculating high school graduates attending college). Through a tumultuous history, the UNET system has evolved into a support system for colleges within the University of Maine system offering distance education (Carchidi, 2002). One of the highlights of this program is its use of community centers throughout rural Maine to provide a place for students to access equipment and have social interactions.

After identifying potential students and desired outcomes, MCI WorldCom developed an online university (Treanor & Irwin, 2001). With increasing economic pressures and expanding world markets, the corporation's need to have training available at any time and any place increased dramatically. MCI's university utilizes a Web-based portal that allows the company to direct students to appropriate services. MCI WorldCom has tailored its tools, Web-based courses, and streaming video to the needs of the identified student population. Online training programs are discussed elsewhere in this book in more detail.

The distance learning institutions most scrutinized in terms of quality of education are for-profit distance education organizations. These organizations have dramatically increased, with enrollment up 59% in the past 10 years and the market share of four-year programs nearly tripled to 8% of the total. As a group, they are very diverse; the University of Phoenix (http://onl.uophx.edu/) is one of the largest with 75,000 students online across 15 states (Kelley, 2001). Opponents worry that quality and academic standards will become secondary to profits, but proponents suggest that these organizations are more focused on current students' needs than are traditional campuses where individualization is more difficult to achieve than it is online.

Virtual high schools offer distance education programs primarily to secondary school students (elementary programs are just beginning and are still controversial as many people consider social development to be a primary goal of elementary school). One of the pioneers in this area is the "Virtual High School" program originated by the Concord Consortium (http://www.govhs.org/website.nsf). This program currently is enrolling approximately 2000 students in 24 states in a completely asynchronous environment. The students are able to choose from a wide array of courses to enrich their local school's offerings. These courses allow students to experience different perspectives, explore areas of interest in more depth, and possibly escape from stigmas.

One of the drawbacks to distance education has been in finding a suitable replacement for science laboratory experiments. Three options have been explored: "computer simulations, videos of real laboratories and laboratory kits sent to a student" (Forinash & Wisman, 2001, p 40). While these methods decrease costs, the goal of the science lab is to offer students a chance to explore and practice scientific inquiry. Toward this goal, simulations did not allow students much choice, videos offered no options, and safety hazards of unsupervised exploration usually limited home kits. However, several new options for simulations with nearly limitless choices are currently being developed in physics and chemistry to help overcome this deficiency (Carnevale, 2002a, 2002b). Overall, the delivery methods of distance education have come a long way from the initial correspondence courses delivered by horseback. Many students are no longer absorbing information delivered from instructors in isolation, but rather are interacting across distance with teachers and fellow students, questioning, reflecting, and constructing their knowledge. Current distance education programs provide increased access for those with physical and financial limitations. In addition, those with learning styles not met by traditional education can access a wide range of options in distance education programs.

THEORETICAL UNDERSTANDINGS OF THE STRENGTHS AND LIMITS OF CURRENT DISTANCE EDUCATION

The evolution over the past century of research on distance education provides a context for understanding learning across distance. In the early years of scholarship on this topic, typical studies compared student outcomes in traditional face-to-face classrooms with outcomes in correspondence courses. This type of comparative research has sparked a continuing debate among educational researchers, educators, and policymakers, as well as much discussion over the differences between teaching at a distance and teaching in the classroom.

Typically, comparative research methodologies used to analyze face-to-face classrooms and distance learning classrooms reveal a "no significant differences" phenomenon (Russell, 1999).

Russell catalogued 335 comparative studies, and his resulting bibliography was one of the first comprehensive looks at "no significant differences" findings. For example, Crump's 1924 study of learning outcomes between correspondence and classroom students' taking the same courses found "no significant difference" between the two groups. This type of finding continued through the 1940s, when schools began using radio programs for delivery of curriculum (Woelfel & Tyler, 1945), and the 1950s when schools began using closed circuit television for delivery of curriculum (Swartout, 1959). Many present day studies repeat this finding. As illustrations, Linc & Davidson (1995) reported that there was "no significant difference between students using hypertext and those in the traditional classroom," and Navarro and Shoemaker (1999) found that, in six of eight academic variables, there was "no significant difference" between educational outcomes for students learning in the traditional classroom or learning online through computer-mediated technologies. This sort of comparative finding does not reveal much other than that student grades were similar; and, in more recent years, researchers have turned to research designs that reveal more complex and useful findings.

During the 1990s many researchers found troubling flaws in the comparative methodologies used to gauge the effectiveness of online learning. Joy and Garcia (2000) argued "learning effectiveness is a function of effective pedagogical strategies" (p. 33) and should not be measured by delivery systems. Dede, Whitehouse, & Brown-L'Bahy (2002) wrote, "Three decades of research in distance education are largely off-target because studies have typically compared a single medium (such as face-to-face) to another medium (e.g., videoconferencing) for a group. . . . Some students are empowered by each medium, others disenfranchised; the net result is mixed." Comparative studies seemed to tell only a part of the story about the power of interactive media in teaching.

Emerging technologies enable novel applications of theoretical frameworks for teaching and learning that range from constructivist principles of student-centered learning to learning styles based on cultural and affective constructs, as well as learning theories based on distributed cognition and situated learning. As one illustration, Wenger's (1998) research is founded on the assumption that social interactions are the basic process that allows people to learn; this has extended our knowledge of online communities-of-practice. Design research is an example of emerging research methodologies that combine empirical with qualitative research methods based on theories of learning and design. In 1992, design experiments were introduced by Ann Brown and Allan Collins in an effort to use formative analysis as a means to move education research out of the laboratory and into the classroom, as well as to provide a design science for education (Collins et al., in press). To provide robust research results more generalizable than those of comparative research methods, this type of scholarship measures multiple dimensions of design and learner activity in authentic contexts.

The work of Lave and Wenger (1991) in situated learning provides a framework for understanding how computer-mediated knowledge construction shapes learner experience from social, cognitive, and affective perspectives. By using multimedia and other emerging technologies to provide powerful learning experiences that build on the strengths of both distance and classroom learning, distributed learning environments offer multiple entry points for different types of learners (Dede, 1996). Roth's (2001) research in situating cognition grows from an epistemological framework that allows a multidimensional analysis of patterns of student work called "zooming." (Zooming is a research method Roth uses to identify multiple patterns of student behavior in a specific context as it occurs over time. He argues that learners are at different places in their thinking depending on how they relate to the learning environment and that it is important to use a research method that reveals these varying patterns of progress.) Lemke's (2001) analysis of multiple timescale studies of human activity utilized a synthesis of theory and method to allow sophisticated analyses across time and dimensions of behavior; this may reveal more robust findings about how people work and learn. Bielaczyc (2001) has studied developing computer supported collaborative learning communities via focusing on the social infrastructure of these communities and how the design of the tools used to support distance and classroom learning shape learner experiences and community building. Barab et al. (in press) are working to characterize distance learning in terms of the dualities of face-to-face versus online participation in a learning community. Each research method listed seeks to gain more understanding of the challenges and disadvantages of distance education.

DISTANCE/DISTRIBUTED/VIRTUAL LEARNING IN THE FUTURE

"Mixed mode" or "hybrid" courses combine the use of face-to-face teaching with synchronous and asynchronous mediated interaction. "Distributed learning" is a term used to describe such educational experiences, which are distributed across a variety of geographic settings, time, and various interactive media (Dede, Brown-L'Bahy, & Whitehouse, 2002). Within a decade, "distance education" may be an obsolete concept, as may the term "face-to-face education." Instead, all instruction may be some balance between classroom-based and distance-based learning interactions, determined by the subject matter, student population, and educational objectives. Emerging interactive media are facilitating such an evolution.

The Evolution of Interactive Media

Table 2 lists devices, media, and virtual contexts supported by sophisticated information technologies, along with the estimates of a conservative timeframe for their technological and economic feasibility (Dede, 2000). Note that many current capabilities are not yet widely used instructionally. Researchers rapidly employ new knowledge-sharing media, but pedagogical and assessment practices in schools, campuses, and organizational training settings are slow to alter.

The important issue for distance education is not the availability and affordability of sophisticated computers and telecommunications, but the ways these devices enable powerful learning situations that aid students in extracting meaning out of complexity. New forms of representation (e.g., interactive models that utilize visualization and other means of making abstractions tangible and sensory) make possible a broader, more powerful repertoire of pedagogical strategies. Also, emerging interactive media empower novel types of learning experiences; for example, interpersonal interactions across networks can lead to the formation of virtual communities.

Table 2 Devices, Media, and Virtual Contexts Grouped by Timeframe.

Functionality	Uses	Time Frame
Cognitive audit trails (automatic recording of user actions)	Support for finding patterns of suboptimal performance	Current
Intelligent tutors and coaches for restricted domains	Models of embedded expertise for greater individualization	Current
User-specific, limited-vocabulary voice recognition	Restricted natural language input	Current
High quality voice synthesis	Auditory natural language output	Current
Fusion of computers, telecommunications	Easy interconnection; universal "information appliances"	2005
Information "utilities" (synthesis of media, databases, and communications)	Access to integrated sources of data and tools for assimilation	2005
Microworlds (limited, alternate realities with user control over rules)	Experience in applying theoretical information in practical situations	2005
Semi-intelligent computational agents embedded in applications	Support for user-defined independent actions	2008
Advanced manipulatory input devices (e.g., gesture gloves with tactile feedback)	Mimetic learning which builds on real-world experience	2008
Artificial realities (immersive, multisensory virtual worlds)	Intensely motivating simulation and virtual experience	2010
"Information appliance" performance equivalent to current supercomputers	Sufficient power for simultaneous advanced functionalities	2010
Consciousness sensors (input of user biofeedback into computer)	Monitoring of mood, state of mind	2010
Artifacts with embedded semi-intelligence and wireless interconnections	Inclusion of "smart devices" in real-world settings	2010

Over the next decade, three complementary interfaces will shape how people learn (Dede, 2002):

- *The familiar "world to the desktop" interface*, providing access to distant experts and archives, enabling collaborations, mentoring relationships, and virtual communities-of-practice. This interface is evolving through initiatives such as Internet2.
- *Interfaces for "ubiquitous computing,"* in which portable wireless devices infuse virtual resources as we move through the real world. The early stages of "augmented reality" interfaces are characterized by research on the role of "smart objects" and "intelligent contexts" in learning and doing.
- *"Alice-in-Wonderland" multiuser virtual environment interfaces*, in which participants' avatars interact with computer-based agents and digital artifacts in virtual contexts. The initial stages of studies on shared virtual environments are characterized by advances in Internet games and work in virtual reality.

The following vignette illustrates how applying ubiquitous computing to embed virtual learning throughout the real world might reshape the nature of education.

> Alec and Arielle strolled through Harvard Yard on their way to the museum, to collect data for their class assignment. Each carried a handheld device (HD) that softly pulsed every time they walked past a building in the Yard. The vibration signaled that the building would share information about its architecture, history, purpose, and inhabitants, using interactive wireless data transfer. Sometimes Alec would stop and use his HD to ask questions about an interesting looking location. Today, he was in a hurry and ignored the pulses.
>
> Inside the museum, Alec and Arielle split up to work on their individual assignments. When Alec typed his research topic into the museum computer, it loaded a building map into his HD, with flashing icons showing exhibits on that subject. At each exhibit, Alec could capture a digital image on his HD, download data about the artifacts and links to related Web sites, and access alternative interpretations about the exhibit. His HD automatically supplied information about Alec's age and background to ensure that the material he received was appropriate in native language, reading level, and learning style. While the museum-supplied information was interesting, Alec always enjoyed the comments posted about each exhibit by other kids. Sometimes, he added a few remarks of his own to the ongoing discussion. Seeing a cool artifact related to Arielle's topic, Alec paused to link to her HD, sending a digital image of the exhibit and information on its location.

> Alec's favorite exhibits were those augmented by virtual environments. For example, at a panorama showing the bones found at a tar pit, Alec's HD depicted a virtual reconstruction of the dinosaurs that were trapped at that prehistoric location. In the virtual environment, he could assume the perspective of each species and walk or fly or swim through its typical habitat. Other types of exhibit-linked virtual environments enabled "time travel" to show how a particular spot on the Earth's surface had changed over the eons. For each epoch, Alec used virtual probes on his HD to collect data about temperature, air pressure, elevation, and pollutants.
>
> Walking back from the museum, Arielle and Alec shared what they had found. Both wondered what learning was like before augmented reality and ubiquitous computing, when objects and locations were mute and inert. How lifeless the world must have been!

This vision illustrates how richly interwoven real and virtual educational experiences may become as distance learning media continue to evolve.

CONCLUSION

In the long run, distributed learning can potentially conserve scarce financial resources by maximizing the educational usage of information devices (televisions, computers, telephones, video games) in homes and workplaces. In addition, distributed learning enables shifts in the pattern of society's investments in education. Less money is needed for physical infrastructure—buildings, parking lots—and more resources can go into ways of creating a virtual community for creating, sharing, and mastering knowledge.

However, in education's future, keeping a balance between virtual interaction and direct interchange is important (Dede, 1996). Technology-mediated communication and experience supplement, but do not replace, immediate involvement in real settings; thoughtful and caring participation is vital for making these new capabilities truly valuable in complementing face-to-face interactions. How a medium shapes its users, as well as its message, is a central issue in understanding the transformation of distance education into distributed learning. The telephone creates conversationalists; the book develops "imaginers," who can conjure a rich mental image from sparse symbols on a printed page. Much of television programming induces passive observers; other shows, such as Sesame Street and public affairs programs, can spark users' enthusiasm and enrich their perspectives. As we move beyond naive "information superhighway" concepts to envision the potential impacts of learning across distance, society will face powerful new interactive media capable not only of great good, but also misuse. The most significant influence on the evolution of virtual learning will not be the technical development of more powerful devices, but the professional development of wise designers, educators, and learners.

GLOSSARY

Augmented reality Real-world situations into which virtual representations are infused or superimposed.

Avatar A character within a virtual environment that is controlled directly by the user and interacts with the environment as the user's proxy.

Chat Online (Web-based), text-based, real-time communication tool.

Community of learners A group of learners, working collaboratively toward shared, educational goals.

Computational agent A character built into a software application that responds to users' actions in ways determined by its designer.

Constructivist A theory of learning based on students' building new knowledge through interpreting experiences; philosophies about constructivism have varying positions about how much instructional guidance is involved in this process.

Design experiments An emerging research method that builds theory through iterative cycles of testing in real-world settings.

Distance education/distance learning Teaching and learning across distance and time.

Distributed cognition Dispersal of intellectual functioning across physical, social, and symbolic supports.

E-learning Learning and teaching via Internet technologies.

Intelligent context An environment that responds to users' actions in ways determined by its designer.

Lyceum lecturers Intellectuals who traveled the United States over a century ago, bringing intellectual debate about democracy to everyday Americans.

Lantern slides An early version of projected slides or overheads.

Listening groups Small communities of people who gathered to listen to radio broadcasts, followed by discussions on the content.

Microworld A computer-based environment whose dynamics are based on causal factors that the user can manipulate.

Mimetic learning Learning based on copying the actions of an expert.

Multiuser virtual environment A computer application that simulates a context in which multiple participants can interact and experience simulated pheno mena.

Situated cognition The theory that knowledge is rooted in the context in which it is learned.

Situated learning A theory of learning based on students' acquiring knowledge in an authentic context with a community of participants that range from novices to experts.

Smart objects Technological tools that respond to a user's activity in ways determined by the designer.

Ubiquitous computing The infusion of smart objects and intelligent contexts throughout a real-world setting.

Web-enhanced (courses) Traditional, face-to-face cour ses that incorporate some Internet-based learning and teaching experiences.

Virtual community of practice People with similar roles who collectively use mediated interaction to share ideas about accomplishing those roles.

Virtual reality A computer interface based on multisensory immersion.

Downloading from the Internet

Kuber Maharjan, *Purdue University*

INTRODUCTION

The Internet is becoming increasingly popular. Millions of people use this technology to communicate through e-mail, conduct research and distance learning, and engage in Internet chat, teleconferencing, video conferencing, and document conferencing. They use Internet technology to exchange information via the Web. To use this technology successfully, they must understand the fundamentals of downloading from the Web.

Downloading means getting information *(files)* to your local computer *(usually a client)* from a remote computer *(usually a server)*. Conversely, *uploading* means transferring files from your local computer to a remote computer (Figure 1).

Hereafter, the term "downloading" refers to the entire process from selecting the file (or files) to be downloaded to receiving the file (or files) on the receiving computer.

Why would users want to download from the Internet? Potential users can listen to the music they like, read news or magazines, and watch movies. Because the file size of audio and video is usually very large, these types of files are usually streamed. If users download a file from the Internet this downloading results in a persistent copy residing on the user's PC. On the other hand, streamed audio or video results in a nonpersistent version. As will be discussed later, users can download files using file transfer protocol (FTP) or hypertext transfer protocol (HTTP). All downloaded materials are usually the intellectual property of the author (or authors). Therefore, users may be required to agree to their terms and conditions stipulated by the owner. Some material available for downloading may be illegal, for example, child pornography and hate literature.

Typically, users would download from the Internet to get new applications or documents and update the current ones.

DATA COMPRESSION FOR FASTER DOWNLOADS

Compression refers to converting a file to a smaller file. There are many ways to compress files to different formats without losing too much detail (images, audio, and video). Some compression techniques are lossy and some are not. In lossy data compression techniques, redundant or unnecessary information is removed, and some amount of data is lost. This enables computers and other devices to transmit the same amount of information in fewer bits. Some examples are converting from BMP or TIFF to JPG or GIF, WAV to MP3 or WMA. For example, a 100-MB (Megabyte => 2^{20} => 1,048,575 bytes) .bmp file, may be converted to a 3-MB .jpg file. Other technologies such as WinZip, UltimateZip, PKZip, JAR, and Interface de Compression Ergonomique pour Windows (ICEOWS) help compress multiple files and folders into one file. Different types of files compress to different degrees, and some of the different compression tools vary in the extent to which they can compress a file. Most text and audio/video files are highly compressible whereas program files are not. This compressed file is smaller in size and more quickly and easily downloaded. Downloaded files can be restored to the original files and folders after these technologies have been applied.

Most of these utilities allow users to view all the file names, folder names, and subfolder names, and they allow all or only selected files and/or only necessary files and/or folders to be extracted. Moreover, these technologies have other advantages: WinZip is very popular because it is easy to use; UltimateZip, ICEOWS, and JAR are free.

Connections between home computers and the Internet can vary widely in speed. Conventional dial-up modems deliver up to 56 kilobits per second (Kbps). Kbps is a transfer speed where as baud is the number of signaling events per second. In this case the bandwidth (the connection speed between a client machine and a server machine) is 56 Kbps. A dedicated phone connection such as a T-1 delivers up to 1.544 Mbps (Megabits per second, 1 Mbps = 1,000,000 bits per second). Users need to be aware of the effect their connection speed will have on the time needed to download a file. For example, a 25-MB file will take just over an hour (62 minute) at 56 Kbps, but less than 2 minute with a typical cable modem. The same 25-MB file, if compressed to 3 MB, reduces the transfer times to 7½ minute for the dial-up modem and around

Local Computer

Figure 1: Downloading and uploading.

15 second for the cable modem. Therefore, it is important to check the speed of the Internet connection and size of the file before it is downloaded. Then individuals can calculate the approximate time for downloading. Usually, once the downloading process is started, most processes will display approximate time left to download, the average transfer rate, the percentage of the completion of download, and the size of the file already transferred.

How are compressed files produced? Figure 2 illustrates creating a ZIP (compressed) file using the ICEOWS program. The author has chosen this program rather than the more popular WinZip because this program is free, efficient, and easy to use; it also supports a variety of compression formats. The same program can be used to uncompress the downloaded compressed files.

This program can be downloaded from http://www.iceows.com and installed following the instructions described in Downloading Steps. Similar programs for Macintosh (e.g., MacZip and SmartZip) and Linux (e.g., GnomeZip and kArchiveur) can be downloaded from http://tucows.com (TuCows, n.d.).

> ICEOWS is written to compress or extract easier archive files. With ICEOWS you can extract, test, read properties and comments or view files stored in ICE, ARJ, ZIP, GunZip, TAR, Microsoft CAB, RAR, ACE, MIME, Mac HQX, UUEncode, XXEncode, Base64, JAR, EAR, WAR, LHA, IMP, BZ2 files without external program. If the archive is an ICE, ARJ, or ZIP, you also can add, update, delete files stored in the archive. It integrates all of these functions in the same interface that the Windows 9x, Me, NT or XP explorer use. (http://www.iceows.com/HomePageUS.html)

Figure 3 depicts the contents of All.zip in Windows XP Explorer. As can be seen from the original sizes and compressed sizes in Figure 3, 10 BMP pictures of 4.4 MB are compressed to a 188-KB (All.zip) file. In this particular case, the compression is over 95%. This translates to a reduction in the download time of 95%.

Because data compression increases storage capacity tremendously, this technology is also widely used in backup utilities, database management systems, and other applications. While users may transfer the files in

Figure 3: Data compression example.

compressed form, it is almost certain that any application that uses the file(s) as data or as an application requires those files to be uncompressed and to remain in their full, uncompressed size. This has consequences for disk consumption. Disk usage will be based on the original, uncompressed sizes, not the compressed sizes.

SAVING AND ORGANIZING DOWNLOADED FILES/FOLDERS

When downloading applications and updates, users who do not remember the name of the original files or who have not renamed or stored the files properly may find it impossible to retrieve a downloaded file. Therefore, it is imperative that they organize their downloaded files and folders carefully in order to find them quickly and easily. When renaming a file, they should use descriptive words, so that it is easier to understand the file without uncompressing or installing software. Precise renaming will help them understand the type of the file by looking at the downloaded file name at any time.

Before downloading, individuals should verify that they have enough room to store the downloaded files. Even though users can organize the directory structure for downloaded files/folders in any fashion, they should organize them in such a way that it is easier to locate the files that they have downloaded. An example of a directory structure is shown in Figure 4.

With the introduction of the newer versions of Web browsers (Internet Explorer and Netscape Navigator), it is possible, in some cases, to open a Web site as a Web folder (Figure 5). Using this newer technology, users can treat a Web site folder as a regular folder. Once the successful connection has been made with proper authorization, users can upload/download from this site as if they were transferring files to and from local storage devices. To transfer files, users can just drag and drop. Newer folders and files can be created directly on the Web site as if users were creating files and folders in their local storage devices. Connection speed clearly determines the time necessary to accomplish download and upload tasks.

Figure 6 shows how to initiate opening a Web site as a Web folder under Internet Explorer. Netscape Navigator also supports a Web folder. After typing the URL of the Web site or selecting from the list box, the “Open as Web Folder” check box must be selected to open the Web site as a Web folder. If the particular Web site is password protected, a log-in dialog box will be presented (Figure 7). After the correct user name and the password have been entered, users will have access to Web folders as if those folders were part of their local storage (hard disk). If the Web site is not password protected, the Web folder screen will be presented automatically. Figure 8 depicts a Web folder.

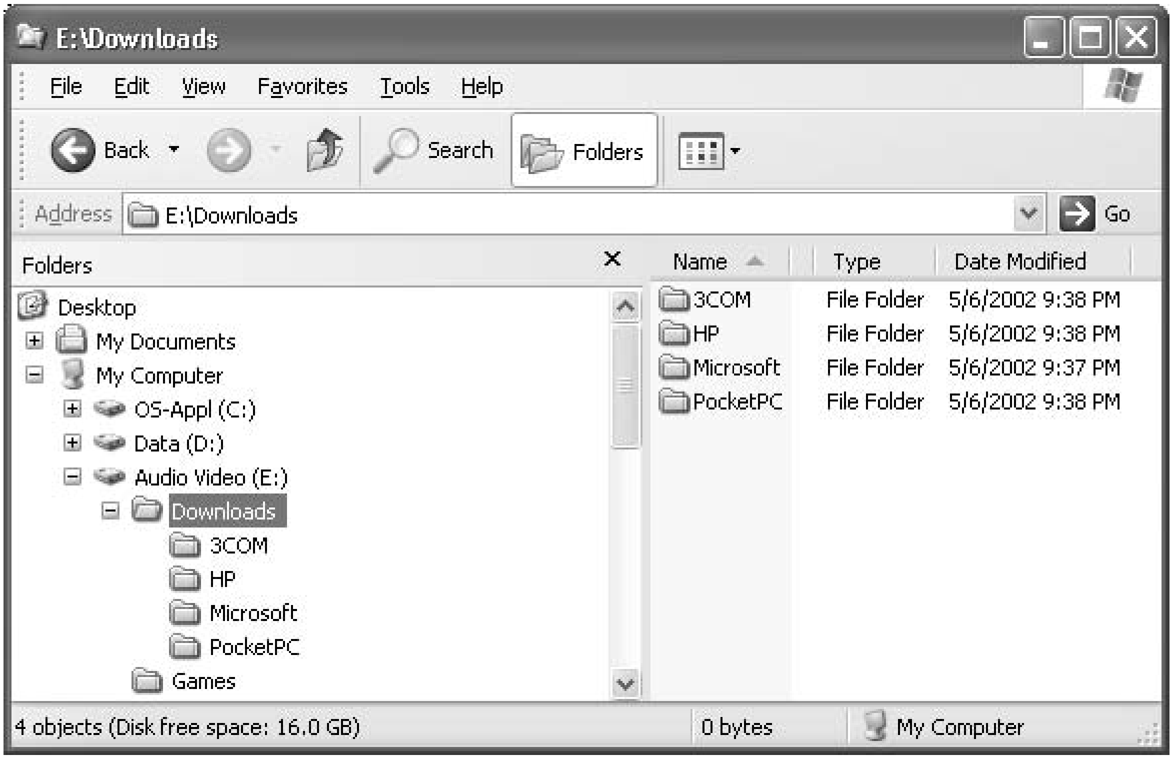
Depending upon the types of access rights assigned to Web folders and subfolders under the Web folders to specific users, authenticated users may be able to perform the following tasks:

Downloading files and folders from the Web folders—in this case, the users drag and drop as if using Windows Explorer.

Uploading files and folders to the Web folders—users also drag and drop.

Creating new folders—users right click and create a new folder.

Removing existing files and folders.



Name	Type	Date Modified

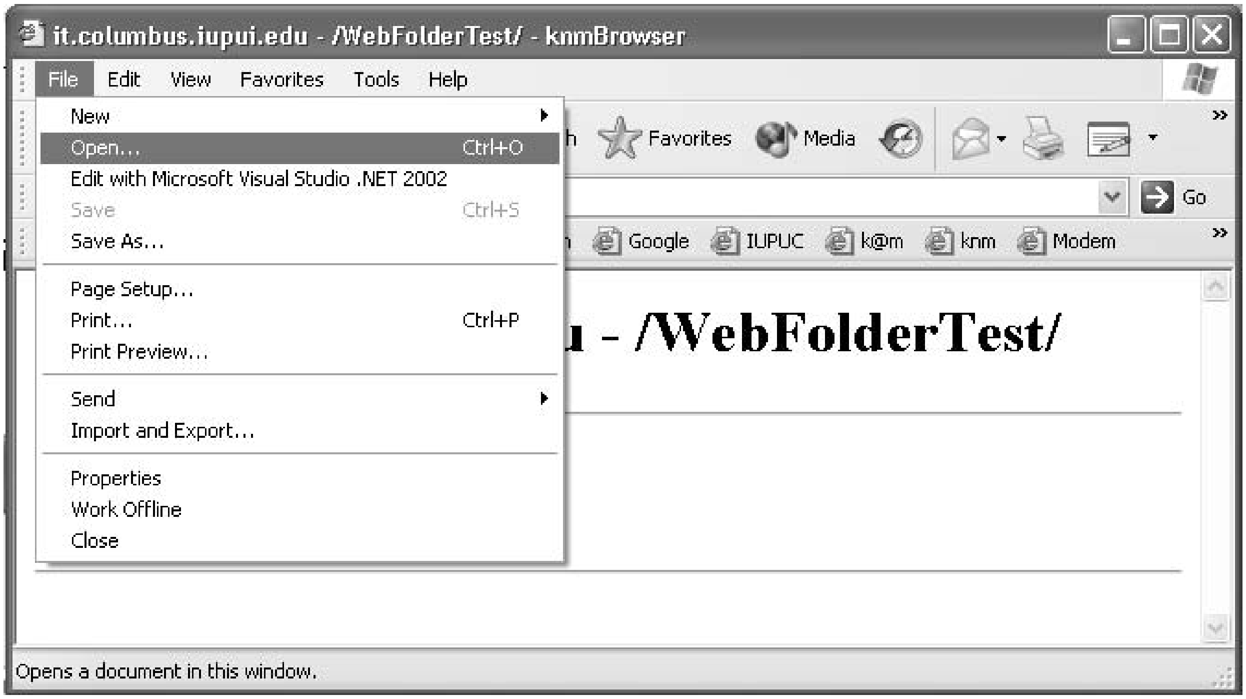
Figure 4: Organizing downloaded files and folders.

In Figure 8 individuals can see a Web folder screen under Windows XP. The author has created a new folder in a Web folder and renamed it to "CreatedFromWeb." This form of downloading and uploading greatly simplifies transferring files from the Internet to the users. Once the Web folder is opened, downloading and uploading are as simple as copying and moving files and folders around local hard drives.



Opens a document in this window.

Figure 5: Opening a Web site as a Web folder, similar to opening a Web site.

☑ Open as Web Folder

Figure 6: Opening a Web site as a Web folder.

DOWNLOADING SPEED AND TIME

Downloading time depends on many factors. The following server, network, and users' machine characteristics affect downloading:

The server: Types of server software and hardware; server software configuration; number of people downloading from the same server at the same time.

The network: Noise in communication lines; traffic conditions on the Internet.

The user's machine: Load on the client machine (CPU + memory); load on the machine's network resources.

Obviously, the larger the size of a file, the more time it takes to complete the transfer. Therefore, it is better to verify the download time before files are actually downloaded. Some sites provide multipart copying, i.e., a large file available in a small number of smaller parts that can be downloaded and recombined on the user's machine. Figure 9 demonstrates transfer speed as 188 KB per second.

Figure 7: User name and password.

LIVE UPDATES AND SMART DOWNLOADS

"Live update" allows a running application to check automatically for updates via the Internet. Live updates automate the regular downloads and installation of software. If a personal computer is connected to the Internet and the computer is configured to check for the latest updates, the personal computer will automatically download and install the latest version of software, security patches, service packs, server releases, and other updates. Many companies such as Microsoft, Symantec, Caldera, RedHat, and RealNetworks provide live updates. Microsoft provides a Web-based Windows update which automatically scans for new updates, downloads necessary updates, and installs downloaded components with the user's permission. These updates include critical updates, security updates, Windows operating system specific updates, and driver updates. This Windows update Web site also lets individuals review and install updates of their choices via the Web. This is the most efficient way to keep users' computers current with the latest updates and upgrades. Some companies will just check if users have the latest version of the software installed. If an update is available, the users will have to download and install the software on their own. An example of live update is shown in Figure 10.

This example demonstrates an easy and effective way to keep a computer current with the latest version of antivirus software updates.

Many times, if the connection is broken during downloading or uploading, the connection needs to be reestablished and the downloading process reinitiated. Usually, this means the downloading process will start from the beginning again. This occurrence is especially frustrating if a large file was being downloaded via the slower connection speed. To circumvent this inconvenience, smart downloads can be implemented. Using a smart download, a download process will resume where it left off if the connection is broken during downloading. This is particularly advantageous for users who download via noisy, slower connections. Figure 11 demonstrates the usage of a smart download.

As can be seen from Figure 11, users can pause downloading and resume it later. This is particularly helpful when downloading large files over slow dial-up connections because, if for some reason the downloading were cancelled, downloading would resume from where it left off. Unfortunately, the user depends on the server to provide this feature, and it cannot be "invoked" by a user. Not all sites provide this functionality.

TYPICAL FILES FOR DOWNLOADING

Individuals can find several types of files to download from the Internet. The following list depicts some typical types of file available for downloading:

Audio files in WAV, MP3, WMP, and RA formats.

Image files in GIF, JPG, TIFF, and BMP formats.

Video files in AVI, RM, and MPG formats.

Figure 9: Download speed (transfer rate).

Freeware/shareware/trialware/demoware software (e.g., applications, operating systems, games, utilities, device drivers, updates, and antivirus programs), flight information, stock quotes, and financial data are available for download. Users can download any type of file to any type of platform.

DOWNLOADING STEPS

This section describes the step-by-step procedure for downloading easily and efficiently. To organize the downloaded files properly, a folder should be created. This folder can be named anything—"Downloads," for example. As can be seen from Figure 4, subfolders can be created by company names, e.g., "Microsoft" and "Symantec." This enables easy access to the downloaded files in the future. Instead of naming subfolders by company name, subfolders can be organized by the type of the files as well as Operating Systems, Applications, Updates, Utilities, and AntiVirus. When connecting to an FTP server, users may be presented with a user name and a password request. Many FTP sites support anonymous FTP (a process of downloading files using file transfer protocol allowing the user to remain anonymous to the site from which the file is transferred) connections. This means users can designate the user name as "anonymous" and there is no password. Instead, as a courtesy, it is customary to send one's e-mail address as a password. If users are using a browser to connect to an FTP site, the browser handles an FTP download transparently for them. Anyone with an Internet connection can access files and folders at FTP sites that allow anonymous log-ins. This is an excellent way to disseminate information without maintaining any user names and passwords.

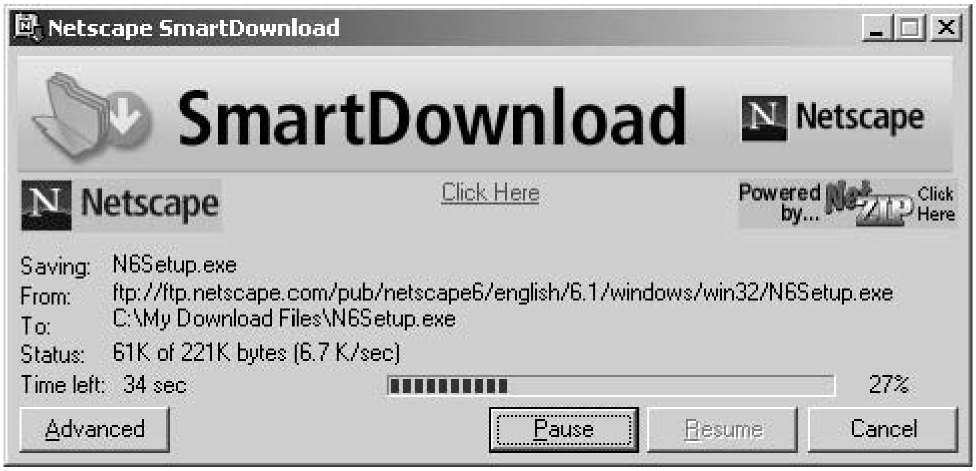
Creating a Download Folder

It is best to create a separate folder to store all the downloaded files. Depending upon the operating systems, the process of creating a directory may vary. In a Windows environment, a new directory can be created by using the following steps:

(1) Right click on "Start."
(2) Click "Explore" to open the Windows Explorer.
(3) Click on the drive letter (e.g., C:) to select the drive where the folder to receive downloaded files is to go.
(4) Right click on any blank space on the Windows explorer—a pop-up menu will open.



Saving: N6Setup.exe
From: ftp://ftp.netscape.com/pub/netscape6/english/6.1/windows/win32/N6Setup.exe
To: C:\My Download Files\N6Setup.exe
Status: 61K of 221K bytes (6.7 K/sec)
Time left: 34 sec

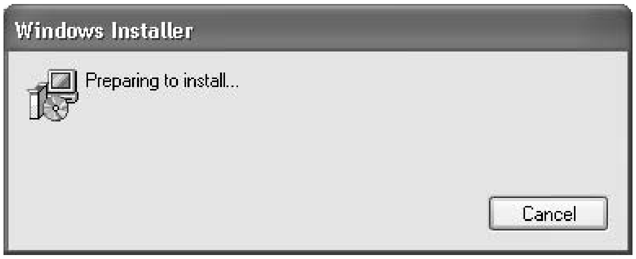
Browsing the Internet for the File

Once the directory structure has been created for receiving files and folders downloaded from the Web, it is time to browse the Internet for the files to be downloaded. Depending upon the types of files needed to be downloaded, one can start browsing Web sites such as http://download.com, http://www.webmasterfree.com, http://www.tucows.com, http://yahoo.com, or http://google.com. If users discover something that looks interesting and they decide to download, an appropriate directory structure can be created at this time as well. These sites are very well organized by category of software, e.g., operating systems, MP3 and audio, Internet, games, business, mobile, multimedia & design, Web developer, software developer, utilities & drivers, and home & desktop. Users should search for the files in the desired category. If the user is looking for a particular file from a specific company, then the best action would be to visit the company's home page and look for the necessary file. Search engines such as http://www.google.com and http://www.yahoo.com assist in finding the companies as well. Using this site, users can search for files by operating system, license type (free and free to try), size, and category. For an example, if a user is looking for freeware only and has selected "free" instead of the default "all licenses," then the http://download.com Web site will automatically filter out other types of files. Figure 12 shows the search result of a search "FTP for Windows" at http://download.com: 314 related programs, all free, are available for download.

Downloading a File Using a Browser or FTP Client Software

Once the desired file has been located, it can be downloaded using a browser or FTP client software. Most browsers support FTP in addition to HTTP. Downloading using a browser is quite simple. One should simply click on the desired file for downloading. A "file download" dialog box will be opened (Figure 13).

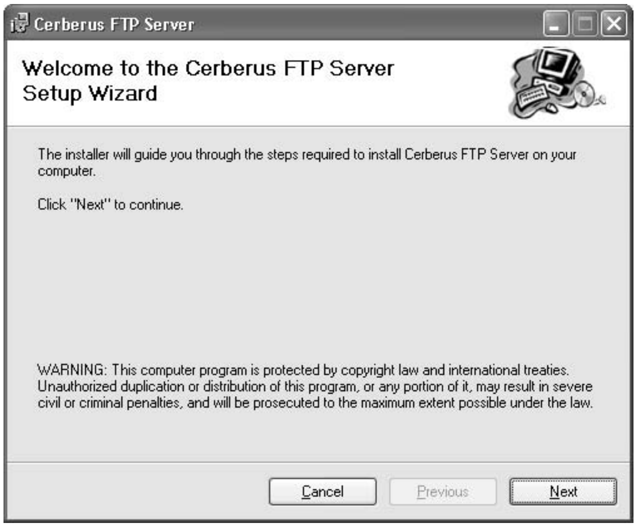
Even though users can save a file without renaming it, it is preferable to rename a file being downloaded. For example, in Figures 13 and 14 the original file cerbe171.zip is renamed to Cerberus FTP Server 171.zip and the file is being saved in the C:\Downloads\FTP Servers\ directory. Figure 9 depicts the actual transfer of the file. After some time the user may forget what cerbe171.zip is. However, Cerberus FTP Server 171.zip will provide all the information the user needs. In this case, this is FTP Server software version 1.71 from Cerberus. This way the user will always be able to find the necessary files quickly and efficiently. Once the application has been installed, users no longer need the downloaded file; however, it is wise to keep a particular release if the users need to revert to a previous version should a new one prove to be unstable.



Windows Installer

Preparing to install...

Figure 17: Windows Installer preparing to install.



Cerberus FTP Server

Welcome to the Cerberus FTP Server Setup Wizard

The installer will guide you through the steps required to install Cerberus FTP Server on your computer.

Click "Next" to continue.

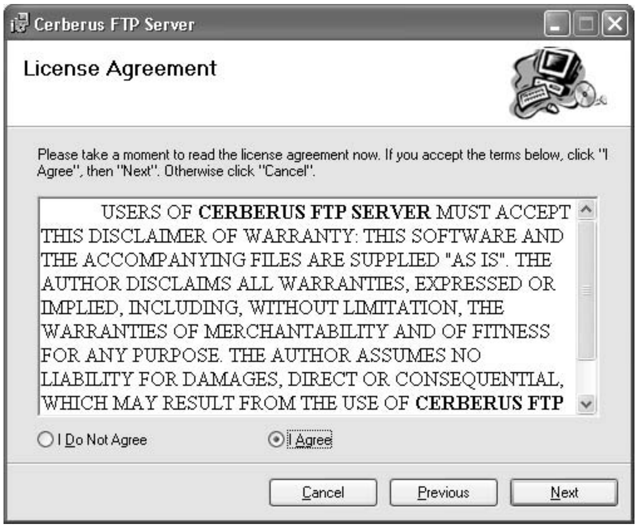
WARNING: This computer program is protected by copyright law and international treaties. Unauthorized duplication or distribution of this program, or any portion of it, may result in severe civil or criminal penalties, and will be prosecuted to the maximum extent possible under the law.

Figure 18: Setup Wizard.

Figure 15 illustrates the files and folders available for downloading. This interface is very similar to opening a Web site as a folder. To download files and folders, all the users have to do is drag and drop. The prefix "ftp://" in ftp://ftp.cdrom.com/.1/gutenberg/images/ at the address bar in Figure 15 tells the browser that the FTP protocol is being used. The browser has connected to the ftp.cdrom.com FTP server using "anonymous" as the log-in name transparently.

Preparing for Installation

Once necessary files have been downloaded, it is time to install the programs. If the downloaded file is a non-self-extracting compressed file, users should uncompress



Cerberus FTP Server

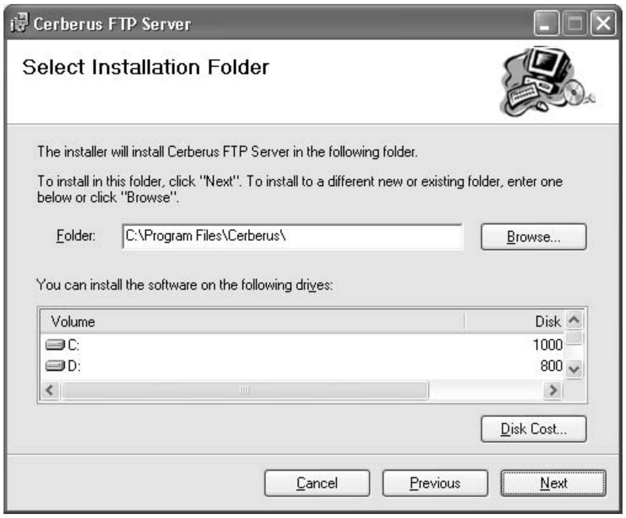
License Agreement

Please take a moment to read the license agreement now. If you accept the terms below, click "I Agree", then "Next". Otherwise click "Cancel".

USERS OF **CERBERUS FTP SERVER** MUST ACCEPT THIS DISCLAIMER OF WARRANTY: THIS SOFTWARE AND THE ACCOMPANYING FILES ARE SUPPLIED "AS IS". THE AUTHOR ASSUMES NO LIABILITY FOR DAMAGES, DIRECT OR CONSEQUENTIAL, WHICH MAY RESULT FROM THE USE OF **CERBERUS FTP**

○ I Do Not Agree ● I Agree

Figure 19: Agreeing to the License Agreement.



Select Installation Folder

The installer will install Cerberus FTP Server in the following folder.

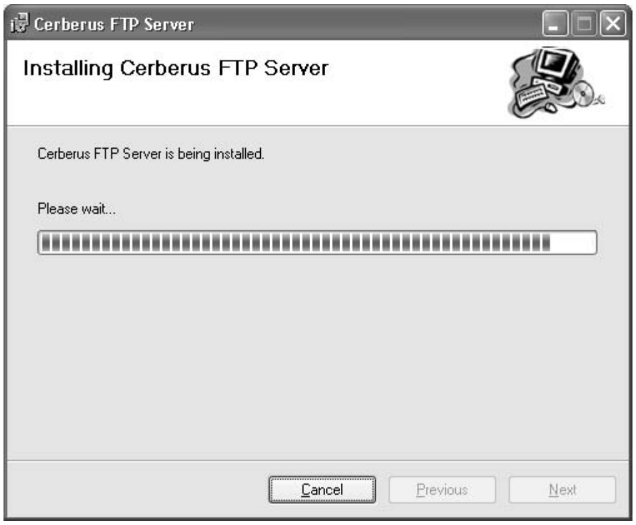
To install in this folder, click "Next". To install to a different new or existing folder, enter one below or click "Browse".

Folder: C:\Program Files\Cerberus\

You can install the software on the following drives:

Volume	Disk
C:	1000
D:	800

Figure 20: Selecting the installation folder. The default drive and folders are being selected.



Installing Cerberus FTP Server

Cerberus FTP Server is being installed.

Please wait...

Figure 22: Actual installation process.

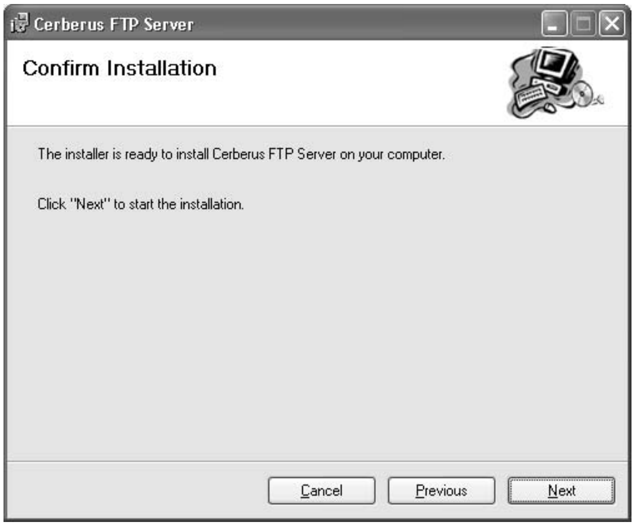
(unzip) it first. The first task is to decide where to install the program, how much space is necessary to install the downloaded software, and how much space is available. After this, the installation process is straightforward. Many times unzipping a file will automatically invoke the installation procedure, whereas in some cases, users will have to go to the folder into which the unzipped (uncompressed) files were placed and run a special program usually called setup.exe. Figure 16 depicts all uncompressed files from the Cerberus FTP Server 171.zip file in a subfolder called unzippedCereberusFTPServer171.

Opening Downloaded File

It is best to organize downloaded files as neatly as possible. This definitely takes some extra effort in the beginning, but it will save you a lot of time and anxiety later. Think of two rooms. In the first room all personal belongings are spread (stored) everywhere on the floor. The second room is very well organized with all personal belongings stored neatly by category. It is much easier to store items in the first room because all one has to do is throw one's belongings somewhere on the floor whereas in the second the room one has to think where to store before storing properly. When it is time to find one's belongings, it is very easy to find them in the second room because one knows exactly where the personal belongings are stored. The same principle applies in storing downloaded files.

Installing Downloaded File

In the final step, double click on the setup.exe file in the subfolder C:\Downloads\FTP Servers\unzipped CereberusFTPServer171. The actual installation procedures may vary from program to program but usually the installer will guide individuals through the whole installation procedure by means of the steps shown in Figures 17–24.

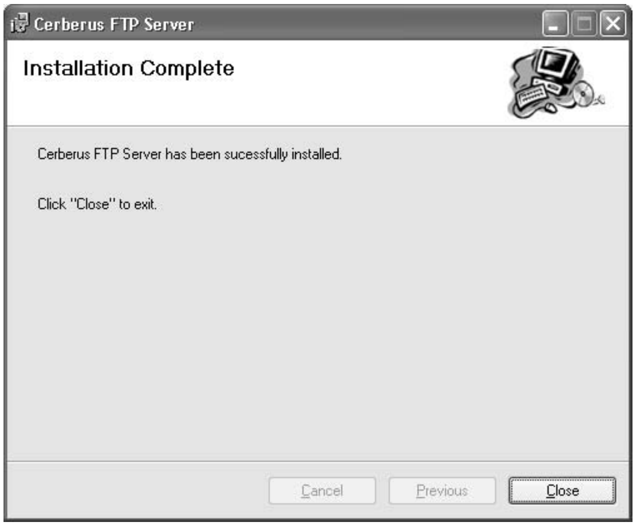


Confirm Installation

The installer is ready to install Cerberus FTP Server on your computer.

Click "Next" to start the installation.

Figure 21: Confirming the installation.



Installation Complete

Cerberus FTP Server has been sucessfully installed.

Click "Close" to exit.

Figure 23: Installation complete. Click on "Close"

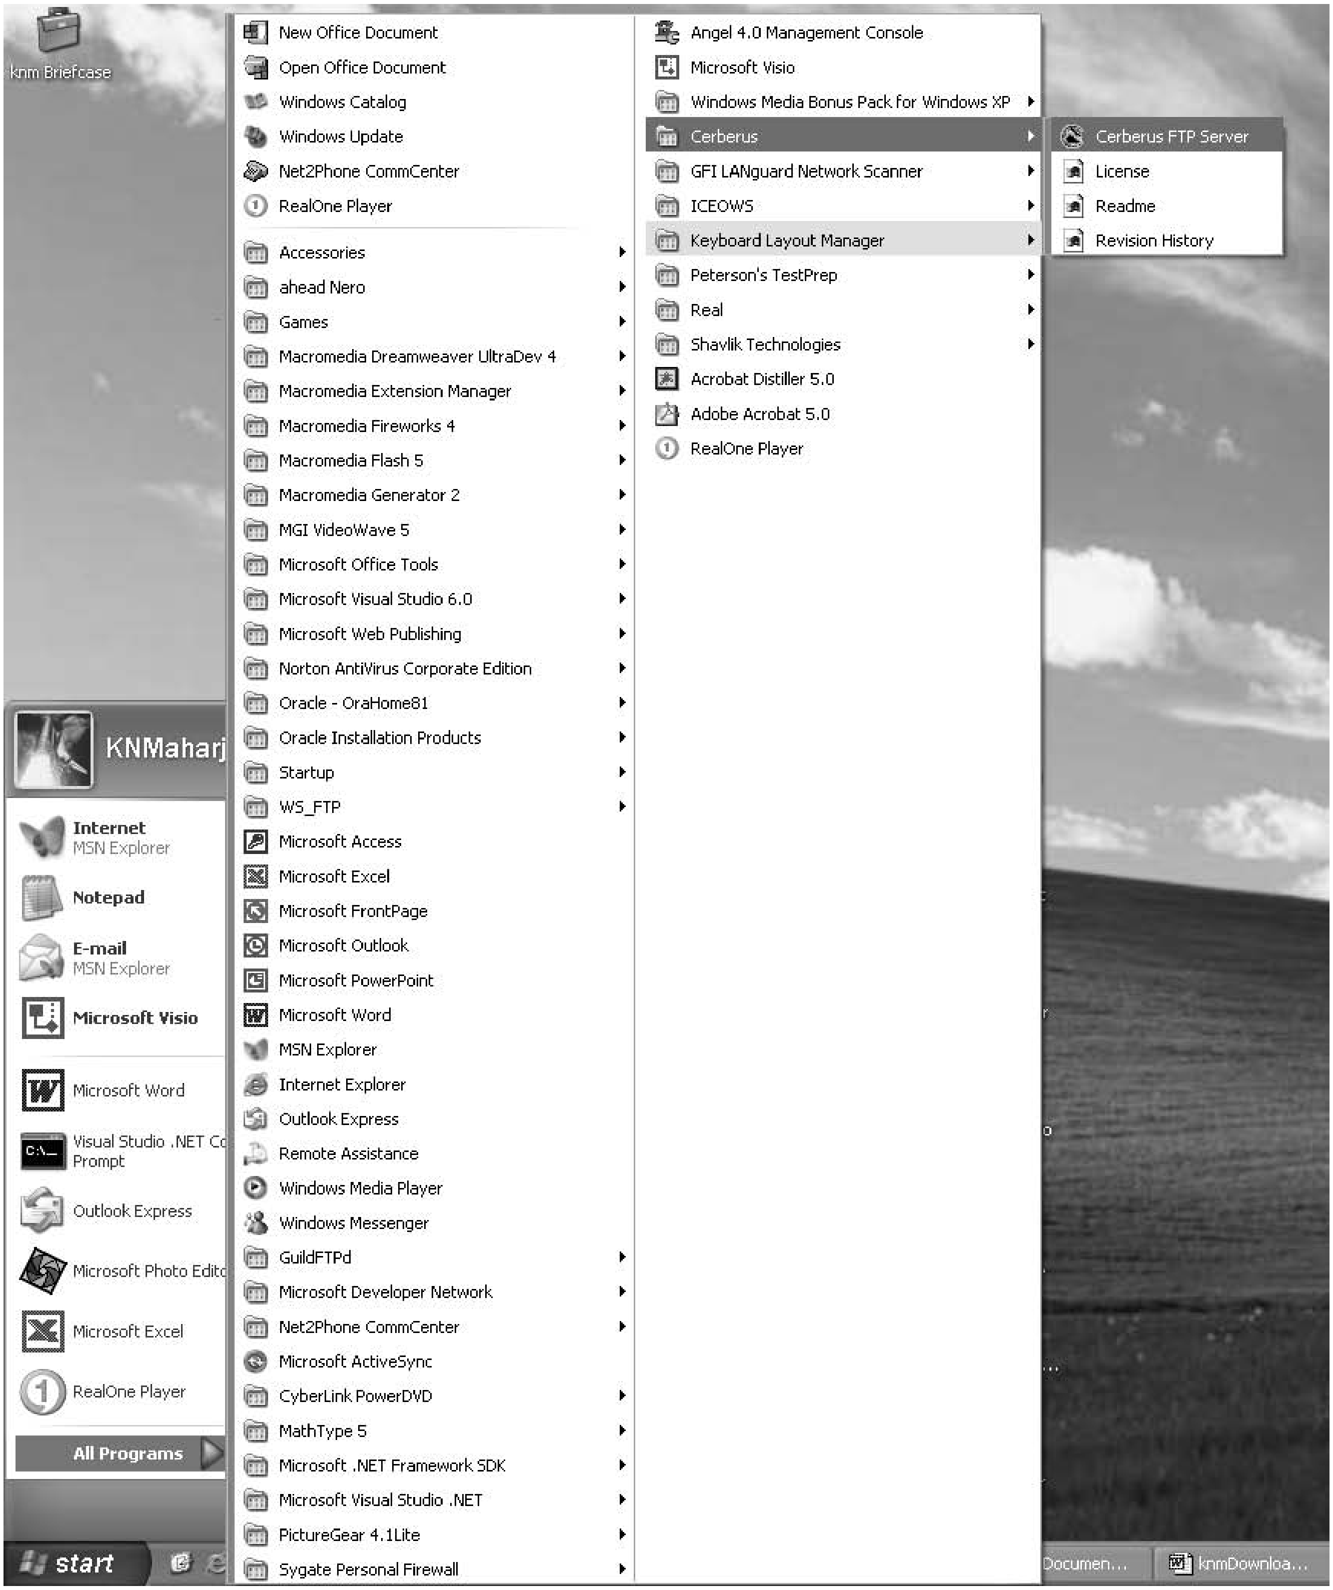


Figure 24: Invoking the program after successful installation.

Figure 25: Character-based FTP client software.

To run the recently installed program (in this example), simply click on "Start," select "Cerberus," and then select "Cerberus FTP Server." If the installer has created a shortcut on the desktop, the user can double click on the shortcut to invoke the program as well.

VARIOUS FTP CLIENT SOFTWARE PROGRAMS

If users choose to use an FTP client explicitly, rather than a Web browser, an alternative way to download files and folders is by using FTP. Before GUI-based FTP clients came over the horizon, users had to use character-based FTP client software to download files (Figure 25). For most users, this software is not user-friendly because users need to remember FTP commands to interact with it. Character-based FTP client software is distributed with today's Windows and other operating systems.

Fortunately, a number of good FTP client programs are available today, both freely and commercially. Virtually all of these software products are GUI-based (see, e.g., Figure 26). Compared to character-based FTP client software, these GUI-based programs are accessible, efficient, and intuitive. Some examples are

Freeware FTP programs: WS_FTP LE, GoZilla Free, SmartFTP, FTP Explorer, LeachFTP, Net Vampire, FTP Commander, Fictional Daemon, ES Download Resumer, HS FTPExplorer, and DLExpert.

Shareware FTP programs: Bullet Proof FTP, Internet Neighborhood, ftpNetDrive, 1stChoice FTPPro,

Figure 26: WS_FTP LE, GUI-based FTP client software.

BlackWidow, FlashFXP, LeapFTP, FTP Now, 3D-FTP, and AceFTP.

Public domain programs: llnlxftp, moxftp, and ncftp.

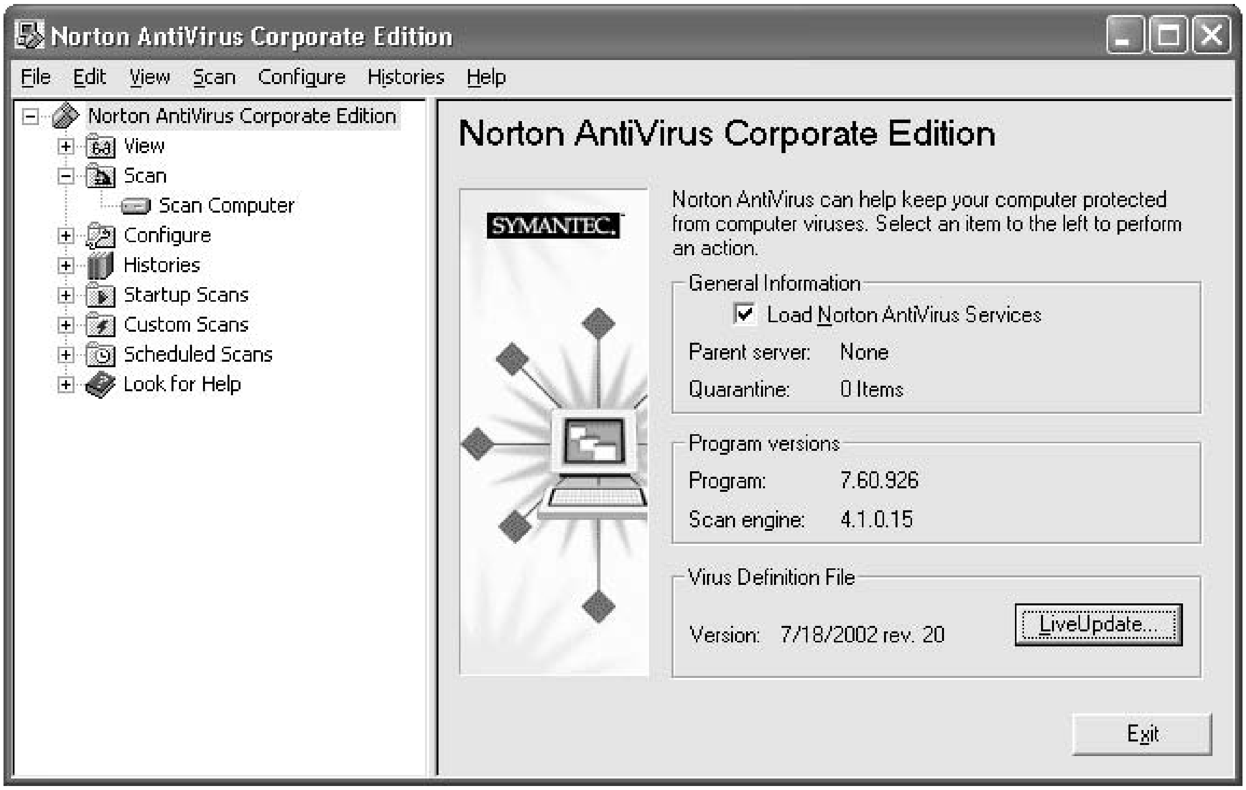
Among these programs WS_FTP LE seems to be very popular because this program is provided free of charge for a home (nonbusiness) user; a federal, state, or local government employee in the United States; and a student, faculty, or staff member at an educational institution (K-12, junior college, college, or university).

SAFETY ISSUES OF DOWNLOADING

Freely available programs are not necessarily legal or safe to download. The main concern in downloading from the Internet is the possibility of getting computer viruses via the Web. A hidden spyware/adware program may be bundled in freeware and shareware. (This type of software secretly collects user information through the user's Internet connection for advertising purposes without the user's knowledge. Usually, this software is bundled as a hidden portion of freeware or shareware and installed automatically without the users' knowledge.) Even the programs downloaded directly from popular sites may contain Trojan-horse viruses. For instance, recently:

> Two popular file-swapping sites have been unknowingly spreading a Trojan horse that sends user information such as IDs and IP addresses to a third party.
>
> The Trojan, called "W32.DIDer," is installed on a user's computer as part of the normal installation process for Grokster and LimeWire—two freeware apps that emulate Napster's file-swapping capabilities. . . .
>
> Many freeware apps have promotional software bundled with them—it helps pay the bills—but usually the promotions are simply used to flash up advertising or lure users to a website. But this promotion, called "Clicktilluwin," secretly installs a program that carries the Trojan. During the installation processes of these freeware programs, you are asked if you want to install Clicktilluwin. Regardless of whether you click yes or no, the Trojan code is installed. The code makes changes to your PC's registry so the Trojan runs each time you start Windows. The Trojan then sends information like your user ID, your IP address, and your browser preferences to a website, 2001–07.com, which has since been shut down by the ISP.
>
> Both LimeWire and Grokster have issued warnings and apologies about the Trojan. LimeWire has released a new version of its software without the Trojan.
>
> Grokster has a patch on its site at http://www.techtv.com/news/security/story/0,24195,3366715,00.html. (Worley, 2002)

These malicious viruses may be programmed to do anything from wiping out hard drives to sending information from a computer to an attacker's computer or gaining access to other computers via the compromised



Norton AntiVirus Corporate Edition

Norton AntiVirus can help keep your computer protected from computer viruses. Select an item to the left to perform an action.

General Information

☑ Load Norton AntiVirus Services

Parent server: None

Quarantine: 0 Items

Program versions

Program: 7.60.926

Scan engine: 4.1.0.15

Virus Definition File

Version: 7/18/2002 rev. 20

Figure 27: Norton AntiVirus LiveUpdate.

computer. Therefore, users must be particularly careful before downloading from the Internet.

How can the user prevent a computer from being infected? One way to prevent this is by not opening files directly by applications. For example, if the user needs to open an attached Microsoft Word file, the user first downloads the file and then runs an antivirus program to check for a possible virus on every downloaded file after downloading. Only then should the user open the downloaded document.

It is also very important that the antivirus software itself is kept current. Most antivirus software companies provide automated updates of their software and virus definitions. All the user needs to do is to make sure that he/she has scheduled a live update and the computer is connected to the Internet to keep the antivirus software updated at the scheduled day and time. Figure 27 depicts the Norton AntiVirus LiveUpdate. This antivirus software can be scheduled to check for updated programs and download updates, and install updated programs and virus definition files automatically without any user intervention.

LEGAL ASPECTS OF DOWNLOADING

When researching the Internet, users will probably find a variety of commercial software, music, movies, pictures (images), personal information, as well as access to other commercial resources and even CD Keys and Key Generator programs for specific software. These programs are usually provided by hackers and code (software) crackers. Are these legal? Downloading illegally provided commercial software is definitely not legal. The sites would be closed quickly. Were there not so many new sites emerging, it would be easier to detect and dismantle all illegal sites immediately. The users learning the fundamentals of downloading from the Web must also comprehend the ethics of downloading. Software companies around the world are losing billions of dollars every year due to software piracy.

CONCLUSION

With the advent of ubiquitous, cheap dial-up connections, ever expanding broadband connections, worldwide networking of virtually every computer, and the development of GUI-based intuitive and user-friendly software programs, downloading files and folders from the Internet has become easy and popular. Because of the simplicity of locating files on the Internet, using search engines, and the ability to download files with a few clicks, more and more users are downloading a variety of files every day. Millions of servers worldwide are providing all kinds of audio, video, image, and text files from legal to illegal and from clean to virus loaded. Therefore, before downloading files to their computers, users should really know what the implications to their computers or contents of their computers might be if virus-loaded software were downloaded. While it is very important to organize downloaded files and to scan for a virus on downloaded files, it is equally important to make sure that users are aware of the legal aspects of downloading as well.

GLOSSARY

File Extensions

.avi Audio video interleaved animation file (video for Windows).

.bmp Bit-mapped, the file format for graphics in Windows.

.csv Comma separated value format. ASCII (American standard code for information interchange. This code is used for representing English characters.) text file format with fields separated by a comma.

.doc A document created by Microsoft Word word processor. Using Internet Explorer, these documents can be viewed directly in the Web browser provided the Microsoft Word program is installed.

.exe An executable file (a computer program).

.gif Graphic interchange format, a still and an animated image file format for storing images.

.htm/html A document conforming to hyper text markup language format.

.jpg or .jpeg Joint photographic experts group, an image file format developed by Joint Motion Picture Group and extensively used in the Internet.

.mov A QuickTime video clip.

.mp3 MPEG audio layer 3 used to compress audio signals.

.mpg Video format conforming to motion picture expert group (MPEG) standard.

.png Portable network graphics, a patent-free graphics standard.

.pdf Portable document format, a popular document distribution format developed by Adobe. A specialized program such as Adobe Acrobat reader is required to read or print these types of documents.

.ra Real audio format developed by Real Networks to compress audio and music. This format supports streaming technology to deliver music and news via the Internet.

.rm Real movie format developed by Real Networks to compress video.

.sit Compressed Macintosh archive created by STUFFIT.

.tif A tagged images file format (TIFF) file, a popular file format for storing bit-mapped images on PCs and Macintosh.

.txt A file containing only ASCII text.

.wav Waveform audio file (RIFF WAVE format) for Windows.

.wma Windows Media Audio developed by Microsoft. Microsoft boasts that it is capable of compressing an MP3 file up to one-third of its size without diminishing audio quality. Using this technology up to 300 individual songs can be recorded in a regular recordable CD-ROM.

.zip A compressed file created using utilities such as WinZip, PKZip, and UltimateZip.

Terms

Anonymous FTP A process of downloading files using file transfer protocol (FTP) that allows the user to remain anonymous to the site from which the file is transferred.

ASCII American standard code for information interchange. This code is used for representing English characters.

Baud The number of signaling events per second. At lower speeds, only one bit of information (signaling event) is encoded in each electrical change. However, at higher speeds, it is possible to encode more than one bit in each electrical change.

Bandwidth A connection speed between a client machine and a server machine, usually measured in Kbps or Mbps.

Bit The smallest unit of information either 0 or 1. It stands for BInary digT.

Browser Short for Web browser, a software application used to find and display Web pages.

Byte Usually eight bits of information grouped together. This is the basic unit of data transferred during a download and is also the data unit containing one ASCII character.

Computer-based training A student learns by running special educational programs on a computer.

Client A computer running a specialized client component of client/server software to request/receive services from a server.

Cookies Information provided to a Web browser by a Web server and stored on a client computer in a text file. Next time the user visits the same Web server this information will be sent to the Web server. The main purpose of cookies is to identify users and their tastes to customize Web pages for them.

Commercial software Software which is available for a fee.

Freeware Copyrighted software provided for free. Usually, even though this software is provided for free it cannot be modified or sold.

FTP File transfer protocol developed to transfer files among networked computers.

HTML Hypertext markup language used to create documents on the World Wide Web.

HTTP Hypertext transfer protocol, the underlying protocol used by the World Wide Web.

KB Kilobyte => 2^{10} bytes => 1,024 bytes.

Kbps Kilobits per second (file transfer rate). 1 Kbps is 1,000 bits per second.

MB Megabytes => 2^{20} bytes => $1,048,576$ bytes.

Mbps Megabits per second (file transfer rate). 1 Mbps is 1,000,000 bits per second.

Modem Short for modulator–demodulator, a device that enables a computer to transmit data over telephone lines.

Public domain software This type is software is not copyrighted; therefore users can modify the software but it cannot be sold for profit.

Secure transfer The communication is encrypted to ensure that intruders cannot interpret the data being transferred.

Server A computer running a specialized server component of client/server software to provide shared services. Some examples are mail server, FTP server, and Web server.

Shareware This type of software is available to try for approximately 45 days before purchase. If one wishes to continue using the software it must be purchased.

Spyware/adware This type of software secretly collects user information through the user's Internet connection for advertising purposes without the user's knowledge. Usually, this software is bundled as a hidden portion of freeware or shareware and installed automatically without the users' knowledge. Unknown to users spyware can gather user information, e.g., e-mail addresses, passwords, and credit card numbers.

Streaming A technology that allows listening to audio or watching videos without downloading the whole file.

URL Uniform resource locator, a globally unique address of documents and other resources on the World Wide Web.

E

E-business ROI Simulations

Edwin E. Lewis, Jr., *The Johns Hopkins University*

INTRODUCTION

Since the 1980s, U.S. corporations have shown steady improvements in efficiency. This is the result of competitive pressures and the desire to optimize investor returns by executive management. As reported by the Bureau of Labor Statistics (U.S. Department of Labor, 2001), U.S. worker productivity continues to improve and the existing operational processes used by those workers continue to be optimized in most firms to support continued growth. Worldwide, corporations of other nationalities are driven by similar competitive influences originating from either local or regional firms or from international competitors, such as those in the United States. Successful firms approach competition in several different ways but in most cases, executive management responds by focusing its efforts on developing strategies that will increase revenues, reduce costs, and make improvements in existing processes. In striving to support these activities, many firms have come to the conclusion that the introduction of one or more e-business solutions into various operational areas of their organizations offers a primary means to implement these strategies.

Forrester Research predicted that corporations would spend approximately 3% of their revenues on e-business procurements in FY2002 and that this would continue to bring the financial costs of these types of systems into focus (Surmacz, 2001). This 3% investment may realistically equate to 40–60% of a firm's entire capital assets budget. Even at this funding level, not every project can be funded and there is no guarantee that those that are funded will generate the anticipated benefits. Thus, the projected benefits of capital expenditure on an e-business solution are legitimately brought under scrutiny by executive management. The most effective companies are beginning to measure a mix of business objectives, costs, and benefits to validate strategic implementation of e-business solutions. They then hold managers accountable for the results that they achieve during the implementation process and subsequent operation of the solution (Colkin, 2002).

For clarification, the term "capital investment" (or "expenditure") refers to the amount of money allocated, consumed, or used during a particular period (event horizon) to acquire or improve long-term assets such as property, plant facilities, equipment, or resources generically identified as capital assets. In this context, expenditures on research and development projects or projects of limited life would not be included in this definition. Depending on their accounting practices, some firms identify e-business solutions or larger IT systems, such as enterprise-wide systems, as capital assets because of their value to the corporation, their expected productive life, and the expenditure in capital to build, deploy, and maintain those systems. Accordingly, the purchase of these assets is referred to as capital expenditure. In all cases, the basis for any investment (expenditure of money) in capital assets must reside in sound business planning, performance, and measurable returns based on a quantifiable methodology. The challenge for any corporation's executive management becomes selecting which investment opportunity will offer the greatest benefits to the corporation over the current event horizon.

The best way to accomplish this selection between the different investment opportunities is to calculate each solution's or asset's estimated costs and benefits and then compare all available solutions to one another. This approach requires that consistent methodologies and processes for creating those estimates be developed and strictly followed. Values and risks that cannot be quantified may be considered by executive management as part of their decision-making process for determining capital expenditures, but from a quantitative valuation process, they should be excluded from the simulations and models. The cumulative results of the consistent application of valuation practices should be the identification of one or more investment opportunities that will provide the greatest returns to the corporation as compared to all other investment opportunities that are available. In general terms, this capital expenditure planning process as it relates to the procurement of capital assets is referred to herein as capital expenditure (CE) modeling or simulation.

Investments in information technology (IT), from a capital expenditure perspective, should be considered like any other capital-intensive investment by a corporation. IT investments usually have comparatively shorter life expectancies than other types of capital projects. A facility may have a useful operational life of approximately 25 years, whereas an e-business solution's hardware components may have a useful life of only 5 years. However, the intellectual property value of the developed software may be substantially longer. Often, e-business solutions require more technical labor to build and then subsequently to run the solution than other projects. Additionally, to maintain a valid operational environment, numerous upgrades to the deployed system will be required on an ongoing basis. From a commonality perspective on financial resource consumption, both IT and non-IT assets have similar process characteristics. Executive managers make the decision to invest in capital assets. The expenditure of funds is authorized and expensed and the resulting capital asset is depreciated over the life of the system or equipment.

IT investments, because of the percentage they make up of the overall capital investment budgets of most corporations, have become outcome-based with return on investment (ROI) usually being considered the key element in the decision-making process. The U.S. General Services Administration (GSA Budget 2002) Fiscal Year 2003 Budget Overview, which offered a projected $6.5B IT budget for that year, put it succinctly in their Capital Planning Guide (GSA Guide 2002), by stating that "IT projects have to clearly communicate their payoff to justify the investments. . . . " It is important to accurately predict the amount of capital expenditure required and the expected benefits that will be derived from that expenditure. To establish a standard point of analytical reference, both cost and benefit are measured in financial terms.

In addition to the cost estimates associated with an IT-based capital asset investment opportunity, estimates of its future benefit to the corporation are required. Benefits should be identified and used on the condition that they can be quantified with a level of reasonable confidence. They can range from easily identifiable cost savings, such as those brought about by staff reductions, to benefits that are much more difficult to quantify, such as projected revenue increases from a new point of sale business-to-consumer site. In these and other cases, benefits will be incurred but the amounts and duration are hard to determine. Ultimately, the simulation will need to be structured to include benefit estimations that will vary over time.

It is important to recognize that an organization's CE simulations used for e-business solution predictive or *ex ante* analysis are corporate assets of significant value. The value of a firm's simulation is directly proportional to its ability to accurately and successfully predict a specific solution's financial viability over a range of economic and environmental variables. Each firm strives to ensure that its simulation will provide better investment guidance than its competitors' simulations, giving them a true competitive advantage. As most firms recognize, once developed, tested, and validated, these simulations become, in effect, trade secrets and their dissemination is restricted as with most other intellectual property. This effectively limits the availability of complete models and simulations for download off of the Web. This fact also tends to limit the distribution of IT CE case studies based upon data obtained from operational firms.

E-business Systems

The generic term *e-business systems*, as used in this context, identifies IT systems that use Internet-based technologies to facilitate business transactions. At the highest level, the vast majority of e-business systems use Web services (essentially services provided or "served" by Web servers) to deliver content and exchange data with individual users or with other systems. This is not to say that other, non-Web enabled systems or services would not be included within an overall e-business solution. On the contrary, any solution of this type would almost always incorporate other communications systems and application services as well. However, an e-business solution cannot be classified as part of this category without a Web services component. Using this definition, most enterprise-wide systems, such as enterprise resource planning, enterprise relationship management, and customer relations management, provide some form of content delivery and systems management through a Web services interface.

This characterization is important because of the environmental and operational issues often associated with the design, development, operation, and support of systems delivering Web services. In almost every case, the time between recognizing a need and deploying an e-business solution is compressed. This results in many issues ranging from design integration to operational support problems. Often, even fundamental components of project management and IT system design are not fully examined before a project is pushed forward, investment budgets allocated, and costs expensed.

It is also important to recognize that e-business solutions are more complex than many other types of IT systems. They include component, system, and application integration activities, all of which are complex themselves and may directly affect one another. Regardless of what the various vendors would represent in their sales literature, much of the technology used within e-business solutions is often new and, accordingly, may not be mature beyond a very limited set of parameters. After examining a specific product, the analysts may agree with one another that its potential to benefit a corporation is significant. The subsequent implementation into that corporation's operational environment may identify a product's lack of maturity. Examples of this are common across the survivors of the Internet implosion. A common example was found in the initial releases of dynamic content Web server engines. Some products would work exceptionally well on Solaris platforms, whereas the same system running on an HP-UX platform would require significant tuning or patching. With other systems, the opposite was equally true. Unfortunately, the discovery process to identify and then to resolve these issues requires significant resources and time, resulting in increased costs and delays in realizing returns on the investment. E-business solutions are specifically designed to provide benefits by creating operating efficiencies, reducing costs, or increasing customer satisfaction. The three generic classes of e-business solutions are server-to-server, server-to-client, and client-to-client. It should be noted that these classes are not mutually exclusive and may be combined within the same e-business environment, resulting in a very capable system.

The challenges of the integration of e-business solutions into other systems can be significant. In most cases, effective e-business solutions include connections to one or more external systems to support data transactions. The configuration of remote systems may be unknown or uncontrollable, changing from time to time, yet functionality between the environments must be maintained and supported. This may include connections to remote systems used by other organizations or simply consist of developing code that will work with different versions of Web browsers. The number of users, operational loading, and performance parameters may change rapidly, possibly based on a market event or the effectiveness of a simple advertising campaign.

The content of an e-business solution is seldom static and requires either automatic or manual updates, often requiring different types of staff to create and then install these updates. Many of the most effective e-business solutions utilize a firm's back-office systems as a source of deliverable content. This requires connectivity to these various back-office or legacy systems, often requiring different middleware applications to support the different connections. By extension, it also requires enhanced and layered security that may not be common practice for many organizations.

Finally, adding to the complexity, most e-business solutions use a combination of technologies. Though these technologies may not be unique, the combination of them adds complexity to the solution's implementation and operation. Most IT staffs specialize in a set of standard technologies. If the designers, developers, implementers, and operators are not familiar with the technologies that are to be used in combination within this solution, design requirements will be missed, build errors will occur, and incorrect configurations will be made, adding cost and risk to the IT capital asset deployment that is an e-business solution.

E-business Solution Cost and Benefit Estimation

Mitigating the risk from these and other problems will add costs to a project. The primary means of mitigation is to allocate more time and/or skilled resources to advanced preparation and planning in the initial stages of the project. This requires the expenditure of additional labor and its associated costs in an accelerated delivery and budget conscious environment. Many firms resist these initial phase investments and accordingly, many projects fail to reach their full potential. Those organizations that fail to recognize the potential complexity of an e-business solution deployment and the need for additional planning to support it almost always incur unanticipated costs while they learn to integrate and subsequently use these systems in daily operations.

Even with the capable tools to supplement their estimating efforts, many firms simply do not accurately perform cost and benefit analyses nor do they interpret the resulting data correctly. Jupiter Research reports that most firms that perform ROI analysis on their IT projects do so with staffs that provide either an inherent bias to their analysis or that have not been properly trained to fully recognize the many aspects of this type of analysis (Mello, 2001). Staffed assigned from the Information Technology departments to perform an analysis may understand the technical details of their projects but seldom have access to information regarding the financial impacts of their projects on the company. Conversely, finance and accounting departments can determine the impacts of the expended costs and perform detailed *ex post* (or historical) evaluations of a project if the needed data is collected but seldom have complete or sufficient data for accurate *ex ante* evaluations. The key mitigation of this potential failing is training individuals in the use of the tools and methodologies that are provided to them for estimating purposes. This includes estimate preparation as well as simulation output interpretation.

The process that facilitates the collection of estimates must recognize that both the benefits and the costs contain many tangible and intangible elements. The detailed quantification of those elements is often difficult to accomplish. Intangible costs or benefits should be considered carefully before they are included as quantified values within a simulation. E-business solution analysis requires the creation of a simulation that reflects an organization's approach to business, the quantification of many variables, both known and estimated, and a use methodology that provides consistent valuations between solutions.

Simulation Design Components and Methodologies

> "One accurate measurement is worth more than
> a thousand expert opinions."
> —Admiral Grace Hopper, U.S. Navy

CE simulations utilize formulas and variable data that mimic objects, processes, and activities found in the real world. In developing a simulation, several goals for the basic design should be established first. These goals are neutrality in the simulation's formulation and structure, repeatability in its output, and reliability in its results.

1. Neutrality in the formulation and structure of a simulation refers to avoiding a bias that unduly penalizes

one variable element over another. If allowed to be introduced and exist within the simulation, such bias will always skew its results.

2. Repeatability in the output of a simulation requires a consistent and stable basis for the identification and use of variables. Variable elements will change over time, but a valid comparative analysis requires consistent use where possible.
3. Reliability in the results generated by a simulation remains one of the most critical elements of any predictive analysis. A simulation can perform flawlessly from a mathematical perspective but the subsequent results must closely reflect the actual results generated by the solution being analyzed.

The purpose of the simulation is to generate reliable and consistent results on which optimal investment decisions can be made.

Simulation Development

Once the overall goals are recognized and established, the specific approach to the simulation's design may be addressed. The basic design criteria require that the simulation be able to accurately predict each solution's financial costs and benefits while factoring into those predictions the organization's future environmental state. The recommended design concept is that the core elements of the simulation are standardized. These elements would include all base formulas, such as NPV, IRR, or ROI, and environmental factors, such as corporate interest rates or facility costs. This approach will result in any project using the simulation being subject to the same valuation formulas and environmental constraints or expectations. Solution-specific variables would remain non-standard for each analysis. Nonstandard variables would include items such as software development and hardware platform costs. With this approach, the unique aspects of each project can be measured, allowing a more efficient base for comparison purposes.

The environmental state of a firm refers to external financial and economic variables that are considered to be outside of the control of the organization. These variables impact all organizations within that same market segment or within the same organization or division within that organization. They may include items such as interest rates, inflation, and other economic factors in general. Industry-specific issues such as raw material costs or skilled labor costs within a geographic region also fall into this category. The valuation of these factors are usually the result of the corporation's financial structure and its accounting practices. These are usually incorporated into the simulations as items such as general and administrative costs and fringe benefits as applied to labor costs.

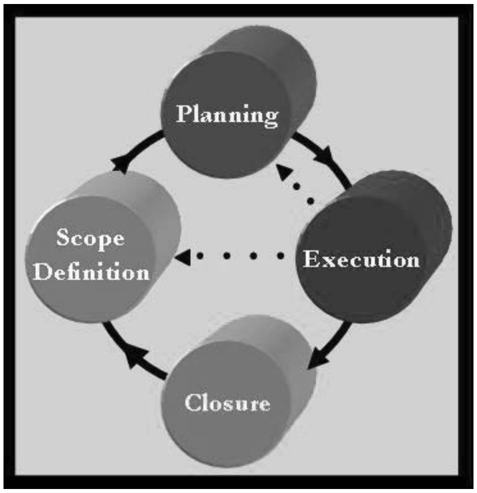

Figure 1: Project Lifecycle. (Art by Holly Robedeau.)

The simulation itself is one of several tools and processes that are used by most corporations for performing CE analysis. Estimating tools should include design engineering models that predict lines of error-free code based on developer experience and the use of processes that ensure consistent tool use in estimating each project. Though the simulation utilizes solution-specific estimates as variables, the acquisition and the quality of those variables, from a timeliness and accuracy basis, must also be addressed. Estimating processes vary from firm to firm but the most effective ones rely on a consistent methodology that is frequently validated for accuracy.

Optimally, during the final phases of a project during closeout, a "lessons learned" is also performed where errors, omissions, inaccurate estimates, and oversights are identified. The identification process is usually supplemented by an *ex post* project valuation activity that will identify these elements if performed properly. Where appropriate, the associated processes and simulation elements that were used to create the original estimates are modified to mitigate a repeat of the previous error. Training is usually associated with this type of activity to make sure the estimating teams are kept appraised of historical problems. Changes resulting from "lessons learned" analysis are designed to correct problems to an existing model and not to make core or fundamental changes to it unless absolutely necessary. They are then incorporated into the simulation or estimating process for use in subsequent modeling exercises.

Approaches to E-business Simulations

Most firms' methodologies take one of two general approaches towards developing the estimates for use in CE simulations. These are either the framework or the project-centric data acquisition methodology. A framework-based approach is structured to consider enterprise-wide projects (those that are very large in scope and affect multiple departments) and focus on process optimization to assure efficiency and reduce costs. These projects are designed to identify, reorient, and baseline departmental processes across the organization through a series of sequential steps. Initially, they seek to eliminate redundant roles and responsibilities between departments and baseline each department's responsibilities. Once completed, they will then seek to identify the technological solutions needed to optimize those recently baselined processes. A project-based approach tends to view the implementation of IT projects from a technical perspective, with a limited focus on process re-engineering beyond the processes that relate to the immediate system.

Framework-Based Financial Simulations

A framework-based financial simulation is an extension of a process developed to assess a firm's overall information technology framework architecture. This approach was created to mitigate the problems encountered as firms began to undertake the implementation of very large and complex IT projects, such as enterprise resource planning implementations. These firms discovered that the scope of those types of activities was too great to be managed within a reasonable amount of time using a normal project-based approach in most circumstances. To be successful in the implementations of these types of projects, any underlying architectural problems associated with roles, responsibilities, and processes within the various departments or organizations within a firm needed to be identified and corrected. This was followed by a comprehensive analysis of each department's business processes and their associated IT architecture. The information derived from this analysis enabled the corporation to begin the selection process of an application, or series of applications, to add efficiencies to each organization within the corporation. The Zachman Framework, developed by John Zachman in 1987, is usually considered the premier approach to this type of architectural modeling (Hay, 2000). Once an application or series of applications is selected, a further review of business processes is required to adapt to or accomodate the use of those applications; revised staffing profiles will need to be estimated and training and application support costs examined. Framework estimating uses this process as a series of data collection points and seeks to determine implementation costs and benefits using a comprehensive *ex ante* analysis methodology.

Each application and department is subjected to a cost–benefit analysis considering as many costs and benefits as are identifiable within the time available. The main problem with this approach is the collection of a very large amount of data from many sources and then preparing accurate estimates. This process is then followed by executing the project tasks against those estimates before the data change. In all cases, the data on which the estimates are based will change over time. Organizations within a firm do not stop operations while potential impacts are assessed. Baseline core competencies are subject to change for many legitimate operational reasons. The more departments, divisions, and organizations there are within a firm, the greater the geographical dispersion of those organizations, and the longer the initial assessments take, the greater the risk that overall estimated costs and benefits will become erroneous before they are compiled and an expenditure decision is made. This reality requires significant effort to be expended quickly. The implementation of an Enterprise Wide System may take more than 36 months and cost in the tens of millions of dollars. Accurate estimates to address capital allocation, cost of money and related factors are critical to the viability of the project.

Project-Based Simulations

A project-based simulation is developed to predict the operational value of a project that was created using a set project development methodology. As defined by the Gartner Group, a project methodology has four primary phases. These are the scope and requirements definition phase, the planning phase, the execution phase (which includes monitoring and managing the performance of the deliverables of the project), and project closeout. The Project Management Institute classifies project phases similarly. (see Figure 1.)

The initial data collection activities that are performed to quantify variables for use within CE simulations is usually performed during the first two phases in a project, the scope and requirements definition phase and the planning phase. In many corporate project models, detailed estimates are first prepared in the beginning of the execution phase (phase 3), which implies that the decisions relating to capital asset expenditures have already been made by management. In working with e-business solutions, the detailed estimates should be included within the first two phases of a project if at all possible, well before a decision is made and funds are obligated. As many as 50% of all IT projects overrun their initial budgets. Errors greater than 80% over the initial budget are common (Shulte, 2001). This is unacceptable by any standard and usually attributable to poor estimation in the early stages of the project when the initial funding was requested or obligated. The mitigation for this is to prepare detailed estimates during the planning stage.

The project-based simulation should have the ability to incorporate an extensive series of solution-specific variables as estimates. For accurate predictions of a solution's value to be generated by a simulation, the maximum number of variables should be identified and quantified to the fullest extent possible. Additionally, these variables should be identified to a level that documents their numerous interrelationships and interdependencies. This may be accomplished from within the simulation using mathematical permutations or by using simple raw data manipulations as a data input strategy. In support of this, the estimation methodology should deliver variable data estimates that can be used by the simulation without manipulation and that readily fit the simulation's data entry structure. This avoids translation errors when the formats of the simulation and the estimates do not match. A simple example of this is for the firm to establish a methodology where labor estimates are recorded using tenths of an hour as the measurement scale. Estimates using minutes as the measurement scale would be rejected and reworked to reflect the appropriate standard.

CE SIMULATION DESIGN ARCHITECTURE

In most corporations, capital asset projects requiring capital expenditures in amounts greater than certain monetary thresholds are subject to some form of screening. To ensure that each project is fairly reviewed in comparison to other projects, it must be remembered that all projects should be planned and estimated using a consistent set of tools and methodologies. Once the estimated costs and benefits are identified, a similarly consistent methodology should also be followed to compare opportunity to opportunity. The goal is to determine the valuation of each project so that accurate comparisons between projects can be made. The design architecture of the basic simulation is critical to this approach.

A successful design for a CE Simulation is built around a set of formulas and environmental variables that have been recognized as financial standards by the corporation. These elements are combined into a core simulation that is validated for mathematical functionality and accuracy. The design will allow the core simulation to utilize operational variables to determine specific project valuation. Once the design and resulting simulation are built, the simulation is tested and validated. Simulations that are suitable for e-business project analysis use the same base components as any other CE model but require the ability to incorporate a significantly larger number of operational variables than are required for other, non-IT projects.

Simulation Standardization

In developing a simulation, there are several aspects of the standardized formulas that must be addressed. The initial step in this process consists of identifying the values of current and future environmental variables that will affect the solution's valuation and that will be used by those formulas. By extension, this requires that the firm agree internally, across organizations and departments, on a standard approach to determining these values. The actual valuation is usually done by a group within the firm's finance or accounting department and released through them to the rest of the firm, thereby meeting these requirements. These environmental variable valuations are based upon a series of known or probable events (Arsham, 2002).

Some of the key environmental variables that many firms consider suitable for standardization include

1. **Interest Rates.** The cost of borrowing money, or the interest that could be earned by depositing money over time, is a primary financial element suitable for standardization. In that many interest rates and sources for capital that are credit- and institution-based, corporate standardization of these values is needed. As interest rates change over time, the cost of money should be identified for use over time as well.
2. **Inflation.** The annualized rise in prices that is often found in market-driven economies is of concern in any financial simulation. Inflation occurs when the demand for goods and services exceeds the available supply, increasing the price for those goods and services. Inflation may be associated with individual labor categories or commodities.
3. **Labor Rates.** There are several ways to present labor rates in any financial model. These could include using the actual rate paid to a specific employee who will do the work, using category rates (the average or weighted average rate for everyone with the same general skill set who performs similar work at a specific location for a company), or using departmental rates (the average or weighted average rate for everyone within a department, including all administrative and managerial employees).
4. **General and Administrative Costs.** Labor costs usually include some benefit costs, management costs, and HR costs, as well as a tax burden associated with each rate. These costs usually are considered to be indirect costs and may vary with location within the corporation. In larger firms, these costs are also subject to frequent changes as reorganizations and normal staffing changes occur. For these reasons, it is usually recommended that G&A costs be excluded from all *internal* analysis. However, for *external* pricing purposes, such as that used in a proposal, G&A costs are usually considered to be legitimate, reimbursable costs and should be included within these types of projections.
5. **Overhead, Facilities Costs, Material Handling, and Administrative Charges.** Depending on the firm, some or all of these elements may be charged to individual projects. In estimating costs, recognize that these are cost factors that could significantly impact a tight project budget. Additionally, these costs can change over time as a result in changes in accounting practices. It is not uncommon for these costs to be excluded from use by some simulations.

Other environmental state variables may be considered based on industry-specific standards. Additionally, the values assigned to these variables will change over time and it is imperative that this change be reflected in any simulation. This list is not meant to be inclusive of all possibilities; it represents a standard set of elements that may be recognized within most models and simulations.

Once the standard variables are identified, a set of formulas and their interrelationships within the simulation can be created. The selection of formulas will be at least partially industry-specific. For example, a firm that utilizes direct buys of imported steel for manufacturing may seek to develop simulations that include currency risk management hedges and internal rate of return calculations for estimation of its manufacturing process costs. These simulation components would provide little or no value for a consulting firm that provides accounting audits only in the United States.

For representative purposes, the following formulas should be considered for inclusion into most basic comprehensive simulations:

Net Present Value (NPV)

This calculation will present a valuation of the investment in future years:

$$\left[\left(\frac{CF1}{(1+r)^1}\right)+\left(\frac{CF2}{(1+r)^2}\right)+\left(\frac{CF3}{(1+r)^3}\right) + \cdots\cdots + \left(\frac{CFn}{(1+r)^n}\right)\right] - I = NPV$$

Solve for NPV. *CF* equals estimated cash flow, *r* equals the current investment rate, *n* equals the period over which the net present value is calculated, and *I* equates to the initial investment. n is expressed in a manner consistent with r (e.g., if r is annualized, then n is in years). If NPV > 0, then an investment can be made with a positive return expected. Conversely, if NPV < 0, then the investment should be rejected in most cases (Office of Secretary of Defense, 2000).

Internal Rate of Return

The internal rate of return (IRR) is used to measure the interest rate at which the present value of a series of investments is equal to the present value of the returns on those investments. The IRR for a particular solution is usually compared to the overall IRR for an organization or corporation.

$$\left[C0 + \left(\frac{CF1 - CST1}{(1+IRR)^1}\right) + \left(\frac{CF2 - CST2}{(1+IRR)^2}\right) + \left(\frac{CF3 - CST3}{(1+IRR)^3}\right) + \cdots\cdots + \left(\frac{CFn - CSTn}{(1+IRR)^n}\right)\right] = 0$$

Solve for *IRR*. *CF* equals estimated cash flow for that period period, and *CST* equals the estimated cost for that period. It should be noted that both cash and cost would change annually. *n* equals the period over which the *IRR* is calculated and is expressed in a manner consistent with *IRR*. (If *IRR* is annualized, then n is in years.) The results of this formula are compared to desired or expected returns for any project based on stated corporate standards (Wu, 2000). If the returns are greater, the project should be accepted. If they are less, then it should be rejected.

Payback Period

$$Payback\ Period = \frac{INV}{(CF1 + CF2 + CF3 \cdots CFn)}$$

Solve for Payback, where *INV* refers to the initial investment and CF equals estimated cash flow over time. The answer is presented as a factor of the time applied to the cash flow measurement (Wu, 2000).

Return on Investment

$$ROI = \frac{(CF1 + CF2 + CF3 \cdots CFn)}{INV}$$

Solve for ROI, where CF equals estimated cash flow over time and *INV* refers to the initial investment (Wu, 2000). ROI is presented as a percentage value either above or below the initial investment. If the ROI percentage is greater than 100%, then it is probably a financially justifiable project. If the calculated ROI is less than 100%, then the investment dollars could be better spent elsewhere.

$$0 = CF_0 \frac{CF_1}{(1+r)^1} + \frac{CF_2}{(1+r)^2} + \frac{CF_3}{(1+r)^3} + \frac{CF_n}{(1+r)^n}$$

Other formulas should not be excluded from this list and are, as with the environmental state variables, dependent on industry-specific requirements or standards. Additionally, many firms use variations of these formulas as part of their accounting and finance systems. Those formulas should be given preference over the examples offered here. The source and weighting of the values used in these formulas should also be modified as needed. It should be noted that in the formulas containing *INV* (for investment) as an operational variable, this value specifically refers to the expected funding expenditures. In most scenarios, changes to this variable will have the greatest impact to the overall results of the analysis and, by extension, the viability of the project. Additionally, this is also the one variable that can readily be managed by the corporation and the project management staff.

OPERATIONAL COST AND BENEFIT ESTIMATES

The number of operational cost estimates within an e-business solution can be significant and complex, involving many more variables than found in other capital asset projects. The installation of a Web server, as part of an overall e-business solution, must be optimized prior to use. This effort requires several specialized skills and the effort needed to be expended can be considerable. A systems administrator will need to set up the hardware, install the operating system, and then install and configure server applications. A security specialist may be needed to apply security patches to the OS and application. Additional build issues could include applying application-specific load balancing configurations, multihoming the servers, installing and configuring database and application agents, creating and installing custom code, load-testing the code, and performing session state and overall performance optimization tuning. In most cases, this is only one of many servers in any solution including application, database and special purpose devices. Similar work will need to be done with the networks, back-end system integration and content development applications, and management components.

Each of these solution components has many discreet cost estimates associated with it and often, each is unique to the solution. The identification of the discreet labor costs and all related details associated with these elements is critical to achieving accurate estimates that can be used as a basis for project comparisons. Complete and detailed estimates will lower the probability of overruns if the project is authorized and fully funded.

Benefits often prove more difficult to accurately estimate than project costs. The identification of some benefits, such as those derived from the elimination of positions that are automated by a particular solution, is straightforward. Others may require the use of their own predictive models and estimates, the creation of department specific surveys and establishing satisfaction criteria for value quantification. For a business-to-consumer (B2C) site, out-year revenue estimates may reflect significant uncertainty. A business-to-business (B2B) solution, such as those created for supply chain management purposes, may be dependent on the commitment of suppliers to continue to support the solution. For benefit estimation, a conservative approach and one that recognizes tangible benefit values first is recommended.

From strictly an analytical perspective, the quantification of savings is usually more accurate than projected revenues or the future value of customer satisfaction and good will. Though, at times, these can be reduced to a value or range of values and they are extremely important, an accurate mathematical valuation is difficult to obtain.

Benefits are as divergent as the e-business solutions from which they are derived and are always project-specific in their determination and quantification.

Regardless of the mathematical validity of a simulation and the consistent use of standard variables from project to project, the data generated by the simulation remain only as good as the operational variables that were estimated. Cost and benefit data are project-centric in their collection and presentation. They must be identified through a specific and detailed approach that is consistently used. It is generally assumed that using the same simulation in a consistent manner would be a standard practice in most organizations but, unfortunately, using different simulations for different project types is commonplace (Remenyi, 2000). This must be avoided wherever possible. The analytical approaches should always be as similar and comprehensive as possible. Projects involving IT solutions may have significantly more variables than others and, accordingly, the models used should be able to accommodate those additional variables.

Operational Cost Identification: The Framework Methodology

Framework-based estimating methodologies, used in support of division- or corporate-wide systems implementations in medium-sized to large organizations, are probably the most difficult to develop and use. A framework approach usually follows a series of general steps, each of which may be customized to support each corporate environment.

The initial step in this process involves identifying the roles and responsibilities of each department within the organization. These are examined from the perspective of each department's original charter and compared to its current activities. On review of each department, non-core functions that they are currently performing are re-assigned to the departments responsible for those functions as part of their core responsibilities. From a cost efficiency perspective, the duplication of services across departments is one of the most common problems in any organization. Departments commonly create their own internal non-core services or support infrastructure in response to their inability to receive those same services or information from the responsible department within their firm. As an example, there is usually a person in most departments whom co-workers go to for PC help instead of first calling the help desk; in other cases, management assigns someone to keep a spreadsheet to track the hours that are spent by a department on a project instead of getting that information for the accounting department. These are often referred to as "ghost" services. By creating their own support, departments meet their immediate needs but become increasingly cost and operationally inefficient over time. Creating and delivering internally provided services utilize departmental resources that should be spent on the department's core mission. With the reallocation of core roles and responsibilities as a result of a Framework analysis, revised departmental responsibilities and updated budgets are usually established to reflect the current departmental configurations of the corporation. These revised budgets are compiled and the resulting figure used as a baseline against which future project costs and benefits are compared.

At the conclusion of this initial activity, roles and responsibilities have been optimized within the existing environment. The next major step is to review the business processes of each department. Once the processes are known, comparisons between departments can be made. This activity will seek out redundant activities between departments, such as entering the same data into two different systems or performing manual transactions where automated transactions would be more efficient. As part of this comparison process, various IT solutions would be examined that will solve as many of the discovered problems as possible.

At the conclusion of the initial process assessment phase, the process of selecting an enterprise-wide system or, at a minimum, one or more e-business solutions can begin. This process includes system selection and costing. Enterprise-wide system application selection almost always requires outside expertise. Regardless of the products or modules selected, new labor, hardware, software, integration, and support costs will all be incurred by the corporation. Accordingly, the impact of the applications on each department must be identified and their costs and benefits estimated. As with all other aspects of a framework approach, these impacts must be estimated for each department and then combined into one integrated estimate package. The scope of this effort is significant in almost every respect. A detailed process and activity level analysis cannot be done without incurring significant costs over long periods of time. The combination of the departmental reviews, process reviews and application estimating often takes many months.

Some firms, looking for alternatives to lengthy data-gathering activities, attempt to use a business case analysis approach to justification for adapting large system deployments (Stien, 1999). This approach generally sets forth a series of well-founded arguments for the implementation of an integrated solution but fails to provide a sound financial basis for justifying the investment. An approach that seeks to identify the required expenditures and expected returns is more appropriate.

The reality is that, as the many elements within the overall framework assessment are identified and the magnitude of having to estimate the costs and benefits becomes known, a detailed quantification approach using internal resources is usually replaced by a more expedient approach. The solutions available are either the creation of the required estimates by the department managers or the use of an external consulting firm to perform some or all of the estimating functions.

Internally developed estimates will be prepared by department managers and their teams. The problem with this is that the level of effort is usually significant and reduces the ability of the department to perform its normal work assignments. Internal staff members seldom have the experience needed to perform process re-engineering estimating, nor do they have the key metric data needed to validate their estimates. Additionally, their assessments will reflect some inherent bias as they review their own processes. It must be recognized that if a department assumed a role or responsibility of another department, it did so to satisfy a need that was not being met elsewhere.

Facing these issues, corporations often consider experienced outside consulting firms as the preferred solution, believing that they will provide a greater level of accuracy and will be less disruptive of normal operations during the estimating phase of the activity. These firms can provide qualitative estimates using historical data obtained from previous work in firms of similar size and structure and in the same market segment. The firms that offer these types of services do so from highly specialized practices. There are only a handful of firms that have the experience and historical data to provide the level of service needed to support a large enterprise-wide system deployment. IBM Global Consulting, CSC, and EDS are leaders in this area and all have consulting practices that provide these services.

During and after their previous implementations, these consulting firms would have compiled extensive metrics on the incurred costs and actual benefits that were realized by their clients. These sets of metrics, validated by *ex post* analysis, are used as a baseline for comparative analysis on new projects. As a point of reference, the right of the consulting firm to collect metric data and use them on subsequent engagements for comparative purposes, while maintaining source confidentiality, is usually contained within the consulting firm's engagement contract. The sophisticated use of metric data for framework estimate analysis is one of the primary products offered by these types of consulting firms. They are able to provide accurate estimates because of the sophistication of their simulations and their use of these metrics. Within these parameters, the consulting firm is usually tasked with performing the framework architectural analysis and the subsequent financial analysis. This would include process re-engineering services and recommending the optimum technical solution. The general methodology that is usually followed is for the consulting firm to normalize the current implementation estimates to similar metrics that they have on file. Once this is completed, a relatively accurate set of cost and benefit assessments can be created. The level of detail will usually be less specific than that found in a project-centric simulation. The end result of this activity is that the values documented as the result of the framework analysis process can be compared to other capital asset investment opportunities. Executive management will then be in position to compare the consulting firm's solution valuation with the valuations of other capital investment opportunities.

It remains critical for the firm to select the appropriate consulting contractor and the optimal technical solution and of equal importance, to manage this effort correctly. There is a significant body of knowledge available on this process. Though using a contractor for assessment is expensive, it usually remains a cost-effective alternative to performing a predictive assessment on a department-by-department basis using internal resources. For a firm attempting to assess potential costs and benefits prior to the initiation of enterprise-wide implementation, this approach is usually the most effective.

Operational Cost Identification: The Project-Centric Methodology

Project-based estimating methodologies are commonly used for the analysis of e-business projects. They are effective in analyzing most projects and are familiar to most managers. This type of simulation seeks to accurately identify as many costs and benefits as possible for each solution. To accomplish this, several conventional project management techniques should be employed. First, the overall scope of the project is broken down into a series of work-flow processes. Each work-flow process consists of a series of sequential and interrelated work-flow elements such as

1. Designing the solution's software,
2. Building the software,
3. Testing the software, etc.

Within each of these elements, there are a series of hierarchical tasks, subtasks, and activities, with activities being the smallest work component. These are then compiled into a work list. Within each of these elements, the identification of what needs to be done to complete the overall work element, the work schedule, and the resources that are required to perform the work will need to be estimated.

A recommended methodology for managing the results of breaking down the work-flow process is the use of a work breakdown structure (WBS). A WBS is a sequential numbering of the work list that also reflects the hierarchical structure within each work flow. As a guide, each element within the WBS is single-purposed and independent (but may have dependencies for starting or stopping), and it must be of a specific duration, have clearly understood deliverables, and, if needed, be created from detailed subtask elements (Berg, 2000).

In that the resource requirements for each work-flow element within the WBS must be estimated, it is also recommended that a formal process be created to consistently document and track each estimate. This is usually done through the use of a basis of estimate (BOE) form that identifies each component of the estimate in detail. Ideally, the technical estimator will document exactly, and in great detail, what he or she will need to do to complete the work, the labor by category, and all material resources that are needed, as well as an estimated duration to complete the work within each individual WBS element. Additionally, the BOE will also include dependencies and assumptions as part of the estimating process. With this documentation, estimated costs can readily be applied to each element within the work list, simplifying the capture of the overall operational cost components. Costing should be prepared by individuals other than those who prepared the technical BOEs. This serves as a check and balance within the costing process.

Of the problems with estimating operational cost variables, beyond the ability to identify all of the work that must be done and associate a cost with those elements, is determining the ability of the current IT staff to efficiently perform the required work. If an IT department is tasked with developing an estimated 350,000 lines of custom code for a supply chain management system, several aspects of that estimate should be taken into consideration within the estimating methodology. Identifying the labor resources that will be needed for the duration of the WBS element is critical. It is intuitive that the hours needed to perform this work will not be consumed at a constant rate (level loaded) for the entire duration of the project. The loading will change over time. If there are significant costs for this work, through the use of subcontractors or expensive programmers, the understanding of how these funds will be spent is also important for efficient money management. Accordingly, the simulation should have the ability to accommodate changes in resource productivity and allocation over the duration of the WBS element.

A common solution to this is the application of a productivity curve to the estimates provided on the BOE forms. Productivity curves approximate the distribution of labor over the projected work duration of the WBS element. Depending on the methodology developed, a standard set of curves is provided to the estimators that reflect different labor loadings (bell curve, ski-jump, etc.). The estimator then selects the curve that will most realistically reflect the labor staffing profile of that specific task. This provides the simulation with a standard mathematical structure to apply time value of money principles against individual tasks. Once the project is completed, an *ex post* analysis of the task will be performed and the curve selection validated or modified for use on future projects.

Within this context is the ability of the simulation to accommodate uncertainty within the estimates that are created. Accurate estimation of software development projects is notoriously difficult. There are many methodologies that may improve the accuracy of these estimates, such as the Constructive Cost Model, or COCOMO (University Southern California, 2002), will be used to increase the accuracy of the estimates reported in the BOE. For various reasons, they are not used by many firms and their own models, if they have them, are not as accurate. The result is that software development estimates often are inaccurate by a full order of magnitude (Porter, 2002). These errors continue to plague most e-business solution development activities. If there is legitimate uncertainty regarding the work to be performed, and other reasonable alternatives to risk mitigation are not available, then a weighting process should be followed. This would only be applied after the standard estimating process was completed and would clearly identify any weighting that was applied. The application of weighting should also be subjected to several constraints and used sparingly.

The first of these requires that the basic estimates identify the minimum resources needed to perform the work. The conscious padding of estimates by including additional labor or materials to mitigate risks must be eliminated from the resource estimation process. Only estimates based on reasonable and, to the greatest extent possible, justifiable expectations of costs should be weighted. The preparation of estimates in an uncertain environment is difficult at best and may need to be performed by the team's most senior and experienced members. Blue-sky or gut-feeling estimates should be avoided if possible and should be reduced to documented values to the greatest extent possible. Though uncertainty will still exist, its parameters will be available for the *ex post* analysis. This documentation process will establish a basis for improved estimates in the future.

Second, the individuals involved in preparing the resource estimates should be involved in the subsequent weighting process. Their understanding of the risk in this aspect of the project is the greatest. Finally, management must create an environment that will allow open discussions about the estimates themselves. A perceived or real negative reflection on the estimators will nullify the productivity of these discussions and must be avoided. Once these parameters are met, weighting can be identified within the cost estimation process and added formally through a visible process within the simulation. Without visibility, subsequent metrics acquisition activities that are associated with an *ex post* analysis of the WBS element will draw incorrect conclusions.

These estimating approaches are repeated for each work-flow process within the overall scope of the project. By so doing, the operational costs within each of these discrete packages can be effectively estimated. The risk of this approach is that the intangible aspects of a deployment, such as the repercussions of process re-engineering, may not be fully addressed. For a project-centric simulation, the recommended process is to quantify the details, validate the data, and then summarize each discrete estimate to calculate the total project cost. The results of this approach are definable costs leading to the development of a known capital expenditure requirement. Again, it must be emphasized that detailed estimates should be prepared before a comparison is performed and budgets are allocated.

Project-centric data gathering and estimation should be done using internal resources whenever possible. Ideally, they should be done by the people who will actually do the work. In most firms, a methodology can readily be developed and then optimized over time. Training for the estimating staff can be developed to support this approach and the returns on that training investment are immediate when the learned techniques are applied on the next project.

Simulation Testing and Validation

The testing of a capital expenditure simulation should be done at the individual component level, at the integration level, and as a complete system. It should be subjected to the same level of comprehensive testing as any other software application. The simulation should be tested mathematically and separately validated by comparing its results with known outcomes from other projects. With each iterative enhancement of the simulation, additional testing will need to be undertaken. Each series of tests should be comprehensive. Minor errors in programming can result in the commitment of significant capital resources to a less-than-optimal project.

CONCLUSION

The use of e-business simulations for analytical purposes can provide executive management with a sound financial basis for making investment decisions and optimizing capital expenditures. To accomplish this, the simulation may utilize the standardization of certain economic variables recognized across the corporation, the consistent use of the same set of simulations on all potential projects, and a dedicated *ex ante* variable quantification process (estimation). Regardless of the use of either a framework or a project-centric estimation methodology, a formal process must be followed and the individuals responsible for these activities trained on the nuances of each. As projects are evaluated and accepted, an *ex post* evaluation of the project's estimates and the simulation's manipulation of those estimates should be performed. During this process, oversights and erroneous estimates are identified and the root causes for any problems are sought out. The simulation model and estimating approach are then modified to correct these issues, providing a more accurate tool and process the next time it is used.

The steps in establishing the parameters for building a simulation that is suitable for any capital expenditure analysis should consist of the following best practices:

1. Establish a policy of consistent use of all simulations used for capital investment analysis. Unique simulations should not be created for individual project types, such as one for e-business solution analysis.
2. Establish a methodology for identifying environmental state variables. These should reflect the overall corporate expectations of the current and future values of each variable. Do not allow environmental state variables to be calculated on a project-to-project basis.
3. Establish a methodology for the utilization of industry-specific formulas in simulations that are recognized by the firm as a basis for performing financial analysis. If the formula is not relevant to the industry, do not introduce it into the simulation.
4. Use an established methodology for the identification of predicted costs and benefits. This may be either a project-centric or a framework-based estimation methodology.
5. Include functionality within the simulation to accommodate all cost and benefit estimates to the greatest extent possible within the methodology utilized. Most e-business solutions include many variables whose valuation should be included in the cost and benefit assessments. The exclusion of variables may degrade the accuracy of the simulation.
6. Recognize that project-specific cost and benefit data collection is a complex and time-consuming task. Due diligence requires a detailed, methodical approach to estimating. Allocate time in the estimation process to allow this to be done correctly. This should be done when initial solutions are being compared, not after authorization to proceed has been received.
7. Use minimum, reasonable estimates for both costs and benefits. Do not allow individual estimators to pad their estimates independently. A structured basis for estimation should be followed.
8. Include within the simulation a capability to account for uncertainty in the quantification of costs, benefits, and outcomes. This may be done either by individually weighting estimates or by applying a weight against the outputs of the simulation.
9. Aggressively test all aspects of the base simulation. Validate the results with actual data wherever possible. For each update or modification to the simulation, the entire testing process should be repeated.

The key to all of these aspects is for the analyst and the project team to pay very close attention to the many complex and interrelated details of an e-business solution. The technology is complex and expensive in terms of the procured items and the labor needed to make them work. The technologies may be new to many IT departments, so recent past experience may not be available. Understanding of that technology, diligence, and attention to detail are the keys to making capital expenditure simulations analyzing e-business solutions work as a decision-making tool for management.

GLOSSARY

***Ex ante* evaluation** A financial analysis based on predictive information relating to a project. This type of analysis is based upon concise and detailed estimates of the costs and benefits that will be generated during the early phases of a solution's life cycle. The primary tools for this analytical process are a structured simulation and a set of processes and methodologies that are designed to generate consistent, repeatable, and reliable results that can readily be used for comparison purposes.

***Ex post* evaluation** A financial analysis using actual project data compiled during the implementation of a project and subsequent operation of the solution. The primary purpose of this type of evaluation is to validate estimates and the accuracy of predictive models.

Web servers A generic term that refers to both a configured software application that serves Web applications or services and a physical hardware device. The leading software application Web servers are Apache, Internet Information Server, and Zeus, holding 56.38%, 31.96%, and 2.26%, respectively of the reported market (Netcraft, May 2002). Hardware Web servers refer to the computers or computer appliances that host the Web server software application. The term "Web server" is usually applied contextually.

E-government

Shannon Schelin, *North Carolina State University*
G. David Garson, *North Carolina State University*

INTRODUCTION

Information technology has fundamentally altered the way we interact in today's society. The advent of personal computers, information networks, and the Internet has engendered an information revolution. E-government has developed from the information revolution as a new method of connecting with all constituents of government. Essentially, e-government consists of new channels of communication and new methods for participation between governments, citizens, employees, and businesses. Although there is widespread interest in the topic, e-government lacks a common definition. The American Society for Public Administration (ASPA) and United Nations Division for Public Economics and Public Administration (UNDPEPA) have defined e-government as "utilizing the Internet and the World Wide Web for delivering government information and services to citizens" (UN & ASPA, 2001, p. 1). Furthermore, it is often summarized as a process revolutionizing the business of government through the use of information technology (IT), particularly Web-based technologies, which improve internal and external processes, efficiencies, and service delivery.

What E-government Is and How It Is Used

E-government has evolved from the information technology revolution, particularly the proliferation of the World Wide Web. IT in government has long been acknowledged as a method for improving efficiency and communication (Kraemer & King, 1977; Norris & Kraemer, 1996). The advent of the Internet has led to developments such as electronic mail (e-mail), which have profound organizational consequences through the perceived erosion of limitations such as time and geography (Rahm, 1999). The main concerns of e-government move beyond the benefits of automating processes and employing new public ITs and concentrate more on reinventing processes to exploit fully the potential of information technology. E-government involves government to citizen (G2C), government to government (G2G), government to business (G2B), and government to employee (G2E) interactions.

According to some proponents of e-government, it is more than just a shift in communication patterns or mediums. Theoretically, e-government involves a transformation of the organizational culture of the government. According to Fountain (2002), the cultural transformation that can be achieved through e-government resides in the elimination of redundancy and duplicity of service provision. It should be noted, however, that these shifts in culture are not without difficulty. To reorient government culture successfully, data must be shared both vertically and horizontally. By creating a distributed data environment, the system will create winners and losers in terms of control over data. This battle, both political and bureaucratic, will hinder the cultural shifts associated with the apogee of e-government.

Despite the issues associated with cultural reorientation, recent authors argue that information technology facilitates new governmental structures and parameters as demanded by citizens and businesses (Heeks, 1999; Ho, 2002; Osborne & Gaebler, 1992). These demands require services that cut across traditional departmental and agency lines, which in turn require government to improve communication and interaction (Alexander & Grubbs, 1998). These new requirements, which fundamentally alter the nature of government, are made possible through the strategic use of information technology. As Fountain (2001) noted, the reinvention process requires overcoming the rigidities and limits of traditional bureaucracy. Specific objectives may include the centralization of public data and the improvement of internal processes and communications (Alexander & Grubbs, 1998). This delivery of services and information also involves the integration of government networks and databases to allow for cross-agency communication and interaction (Moon, 2002). Again, the turf issues associated with the cultural context of government may preclude some of these efforts from reaching maturation. The impact of the information era in government can be witnessed in the increasing governmental movement to Web-based information, services, and transactions, however, as evidenced by recent national surveys (International City/County Management Association [ICMA], 2002; West, 2000). Prior to looking at specific data about the expansion of e-government in the United States, it is important to examine the history of federal legislation regarding public information technology and e-government.

History of E-government at the U. S. Federal Level

The U.S. groundwork for e-government at the federal level was laid in the 1980s. The Paperwork Reduction Act of 1980 mandated an information resources management (IRM) approach to federal data, thereby establishing for the first time a single policy framework for information resource management at the federal level. The director of the Office of Management and Budget (OMB) was given responsibility for developing an IRM policy and for overseeing its implementation. A major revision of the Paperwork Reduction Act in 1995 mandated strategic planning for IRM.

At the same time this administrative structure was created, the physical Internet was being born. ARPANET, a project of the Department of Defense, had gone online in 1969, uniting some 23 defense-related military, university, and research laboratory sites by 1973. It was the funding of NSFNet by the National Science Foundation in 1986, however, that really marked the beginnings of the modern Internet. This long-haul backbone network was placed under a cooperative agreement with IBM, MCI, and Merit Network the following year and by the end of 1987 there were 10,000 Internet hosts. By 1989, there were 100,000. By the time Tim Berners-Lee developed the World Wide Web in 1992 and Mosaic software was released to surf the Web, the number of Internet hosts exceeded 1 million. One of these was the server that housed the first White House home page, launched on the Web in 1992.

Up to 1992, access to the Internet backbone was limited by the NSF's Acceptable Use Policy, which prohibited commercial traffic on the Internet. With the support of Congressman Rick Boucher (D-VA), chairman of the Science Subcommittee of the House Committee on Science, Space, and Technology, legislation was passed, and in November 1992, President Bush signed new legislation that repealed the Acceptable Use Policy, replacing it with language that permitted commercial traffic on the Internet backbone. In 1993, federal funding of the Internet ended and the Internet became a private sector entity.

With the full advent of the "Internet Age" in the early 1990s, early efforts that might be seen as part of building e-government centered on educational functions. The Information and Technology Act of 1992 sought to ensure technology development in public education, health care, and industry. It called on NSF to fund efforts to connect K–12 classrooms to the Internet. In 1993, the National Information Infrastructure Act was passed, targeting federal research and development funding to the accelerated development of high-performance computing and high-speed networking services at the university and research laboratory level.

An important part of the administrative background of e-government in the early to mid-1990s was the National Performance Review created March 3, 1993, under the leadership of Vice President Al Gore, himself a strong technology advocate. The National Performance Review reflected the Clinton administration's emphasis on IT as a tool to reform government. Its report, *Creating a Government that Works Better and Costs Less: Reengineering Through Information Technology,* was an important document of the "reinventing government" movement. This administrative movement originated with a focus on traditional forms of decentralization, devolution, and privatization. "Reinvention" advocates quickly came to see, however, that e-government was a major reform thrust facilitating and implementing their own goals of a results-oriented, client-centered, market-reliant approach to government. In 1993 the Government Information Technology Services Board was created to help implement NPR in information technology areas.

As the momentum for e-government grew, so did awareness of a major impediment: the skew of access to the Internet by the well-to-do and lack of access by America's "have-nots." The Commerce Department's 1994 report, *Falling Through the Net,* brought public attention to the issue of the "digital divide." In response, the Telecommunications Act of 1996 provided for a Universal Service Fund fee (a telephone tax, also known as the "E-rate" fund or fee), part of which was used by the Clinton administration to provide modem-based Internet access to schools, libraries, Indian reservations, and other "digital divide" target groups. By the end of the decade, however, the digital divide problem had receded because of falling hardware and software prices, making Internet access affordable to the great majority of citizens.

Some credit must also be given to another Clinton administration initiative—openness in government. The Electronic Freedom of Information Act Amendment of 1996 extended the right of citizens to view executive agency records to include access to electronic formats and online opportunities for access information.

Also in 1996 came a piece of legislation that provided the basis for centralizing in the Office of Management and Budget the authority to enforce implementation of e-government (as well as other IT practices) across the federal government. The Clinger–Cohen Act of 1996 (originally named the Information Technology Management Reform Act of 1996, an amendment to the Paperwork Reduction Act of 1980) established a chief information officer in every agency, making agencies responsible for developing an IT plan which relates IT planning with agency missions and goals. The oversight role of the director of the OMB was strengthened and later, when e-government became a priority, the existence of the chief information officer strategic planning structure was an important element facilitating e-government implementation at the federal level.

A variety of agency-centric developments extended e-government in the late 1990s. In 1997, the U.S. Department of Agriculture became the first agency to engage in e-rulemaking, soliciting Web-based comments on rules for organic foods. This initiative won the 1998 Government Technology Leadership Award and became the basis for one of the major projects of the e-government efforts of the current Bush administration (see the President's E-Government Strategy, available at http://www.whitehouse.gov/omb/inforeg/egovstrategy.pdf). The 1998 amendments to the Rehabilitation Act required federal agencies to make their IT and electronic information available to people with disabilities. The Internal Revenue Service (IRS) Restructuring and Reform Act of 1998 promoted electronic filing of tax returns, requiring the IRS to establish that all forms, instructions, publications, and other guidance are available via the Internet. It also provided for taxpayer electronic access to their accounts by 2006.

In some ways, the official "start" of federal e-government might be traced to the Government Paperwork Elimination Act of 1998, which authorized the OMB to acquire alternative ITs for use by executive agencies; support for electronic signatures; and electronic filing of employment forms, with a deadline set for most forms to be in place by October 21, 2003. The Government Paperwork Elimination Act was the legal framework for accepting electronic records and electronic signatures as legally valid and enforceable and also represented Congressional endorsement of the e-government strategy (Fletcher, 2002).

In a Presidential Memo of December 17, 1999, titled *Electronic Government,* President Clinton endorsed the concept of a federal governmentwide portal (later to be FirstGov.gov). In 2000, the President's Management Council adopted digital government as one of its top three priorities. On June 24, 2000, President Clinton made the first presidential Internet address to the nation, again calling for establishment of the FirstGov.gov portal. FirstGov.gov was launched September 22, 2000 as a Clinton management initiative. It is the official U.S. government portal, designed to be a trusted one-stop gateway to federal services for citizens, businesses, and agencies. At launch, it was a gateway to 47 million federal government Web pages. FirstGov.gov also links to state, local, District of Columbia, and tribal government pages in an attempt to provide integrated service information in particular areas, such as travel. The Office of Citizen Services and Communications, within the General Services Administration, manages FirstGov.

In Election 2000, both candidates (Gore and Bush) advocated digital government concepts. After the election, President Bush made e-government one of his central management reform themes (although opposing most "digital divide" funding advocated by Clinton and Gore). *The President's Management Agenda,* issued in August 2001, committed the Bush Administration to five major management objectives, one of which was electronic government.

In June 2001, the OMB created the position of associate director for information technology and e-government. This gave the OMB a key point of contact to give higher priority to IT initiatives, particularly the goal of creating a citizen-centric government. In essence, this position had a mandate to provide leadership to all federal IT implementation, including a special emphasis on e-government. The first incumbent was Mark Forman, who quickly took strong actions to implement e-government throughout federal agencies. On July 25, 2002, the first chief technology officer for the federal government was appointed, responsible for overseeing implementation of e-government policies. The first incumbent was Casey Coleman, heading up the General Services Administration's Office of Citizen Affairs.

The OMB issued the cornerstone document, *E-Government Strategy,* on February 17, 2002. This document set forth Bush administration e-government principles: citizen-centric, results-oriented, and market-based. It also called for increased cross-agency data sharing. Some 34 specific projects were identified for funding, including those in the "Quicksilver Initiative" announced in October 2001, as noted in Table 1.

Table 1 Overview of U.S. Federal E-government Projects

Government to Citizen (G2C)
USA Service (GSA)
EZ Tax Filing (Treasury)
Online Access for Loans (DoEd)
Recreation One Stop (Interior)
Eligibility Assistance Online (Labor)
Government to Business (G2B)
Federal Asset Sales (GSA)
Online Rulemaking Management (DOT)
Simplified and Unified Tax and Wage Reporting (Treasury)
Consolidated Health Information (HHS)
Business Compliance One Stop (SBA)
International Trade Process Streamlining (Commerce)
Government to Government (G2G)
E-Vital (SSA)
E-Grants (HHS)
Disaster Assistance and Crisis Response (FEMA)
Geospatial One Stop (Interior)
Wireless Networks (Justice)
Internal Effectiveness/Efficiency (Government to Employee (G2E))
E-Training (OPM)
Recruitment One Stop (OPM)
Enterprise HR Integration (OPM)
Integrated Acquisition (GSA)
E-Records Management (NARA)
Enterprise Case Management (Justice)

Among other recent developments in e-government at the federal level has been the implementation of e-procurement. The General Services Administration and Office of Federal Procurement Policy, with involvement from the Department of Defense, the National Aeronautics and Space Administration, and National Institutes of Health, advanced e-procurement by establishing Past Performance Information Retrieval System to give online access to past vendor performance records in 2002. Another development is the Dot Kids Implementation and Efficiency Act of 2002, passed in December 2002. This act created a new domain, like.com and like.edu. Every site designated ".kids" will be a safe zone for children and will be monitored for content, for safety, and all objectionable material will be removed.(Many civil liberties proponents have criticized this act as allowing government censorship thereby reducing transparency.)

The Electronic Government Act of 2002 was passed by Congress November 15, 2002, and signed by the president on December 16, 2002. The act was sponsored by Senator Joseph Lieberman (D-CT). It is intended to promote e-government in all federal agencies. The Electronic Government Act establishes an Office of Electronic Government within the Office of Management and Budget. The head of this office is to be appointed by the president and report to the OMB director. In essence, this formalizes the administrative setup established by the OMB in 2001 under Mark Forman. It requires regulatory agencies to publish all proposed rules on the Internet and to accept public comments via e-mail as part of "e-rulemaking." All information published in the Federal Register must now be published on the Web also. The federal courts must publish rulings and other information on the Web, and there are numerous other provisions. The Electronic Government Act makes $45 million available for e-government projects in the current fiscal year 2003 and $345 million over five years. (This compares with $5 million for Forman in fiscal year 2002).

Clearly, the legislation and mandates of the U.S. federal government indicate the importance of e-government. Other countries have even more sophisticated laws and procedures to guide e-government adoption. For example, Singapore has developed long-range strategic plans for e-government, incorporating the eCitizen Center as the one-stop shop for all G2C interactions. The United Kingdom also demonstrates one of the highest levels of executive commitment to e-government. The Office of the E-Envoy has been created to oversee the transition to e-government for all services by 2005. Many other examples from around the globe further demonstrate the shift toward e-government.

E-GOVERNMENT ADOPTION IN THE UNITED STATES

Following the detailed review of U.S. federal commitment to e-government, it is important to assess the levels of e-government adoption at the local government level, as well to illustrate usage by citizens. This description focuses on the United States; however, other sources provide more international coverage (Demchak, Friis, & La Porte, 2001; UN & ASPA, 2002). By analyzing data obtained from the 2002 E-Government Survey conducted by the International City/County Management Association, the adoption rates of e-government at the local level can be assessed. The survey was conducted to evaluate the involvement of local governments in e-government activities, including Web site development, electronic services, geographic information systems, changes associated with e-government adoption, and barriers preventing such adoption. The survey was sent to 7,844 municipal and county governments with populations over 2,500; 4,123 surveys were completed and returned, a response rate of 52.6%.

For the purposes of this analysis, the municipalities and counties have been divided into three population categories. Small jurisdictions contain less than 50,000 inhabitants, medium jurisdictions contain 50,000 to 249,999 inhabitants, and large jurisdictions contain 250,000 or more. The responding jurisdictions represent all four geographic regions: Northeast, North-Central, South, and West, as defined by the ICMA.

The presence of local government Web sites, as gathered during the ICMA survey, is significant, with 74.2% of responding counties and municipalities having an official Web site. In terms of the municipalities, 71.1% of small jurisdictions, 97.9% of medium jurisdictions, and 100% of large jurisdictions have official Web sites. Furthermore, 58.8% of small counties, 92.8% of medium counties, and 98.4% of large counties have an official Web presence. The high rate of Web presence demonstrates the movement of local governments to the e-government model; however, it is important to note that static Web presence is not sufficient for true e-government.

To better assess the required interactive component of e-government, the presence of Web-enabled transactional processes via governmental Web sites is analyzed. The ICMA survey queried respondents about several categories of transactions, including online payments of taxes, utility bills, fines/fees, form completion and submission, business license application/renewal completion and submission, online requests for records, online delivery of records, online requests for services, online registration for facility usage, online voter registration, online property registration, downloadable forms, and online communication with elected and appointed government officials. In the aggregate, few local governments are using Web-based transactions. Table 2 demonstrates the offering of transactions by municipalities, based on the population categories previously denoted.

The positive effect of size on the rate of transaction offerings is important to note. For example, only 1.8% of small municipalities offer online payment of taxes, whereas 5.3% of medium and 24.0% of large municipalities offer the same online service.

A similar trend regarding the increased offering of Web-based transactions based on population size is found in the counties. Table 3 highlights the percentage of counties offering specific transactions, by population grouping.

Although electronic transaction offerings are limited in local governments, there is an increasing citizen and business demand for such Web-based services. A national survey conducted by the Pew Research Center during September 2001 demonstrates the widespread usage of governmental Web sites and their interactive services. The 2002 Pew Internet and American Life Project indicates that 58% (68 million people) of American Internet users have accessed at least one governmental Web site (Larson & Rainie, 2002). Furthermore, 68% of Internet users indicate that government Web sites improve their interaction with at least one level of government. Approximately 63% of those surveyed have downloaded government forms, 16% have filed taxes online, and 12% have renewed automobile registrations online. The 2002 Pew Internet and American Life Project highlights the citizen interest in and use of the Internet to enhance standard interactions with government.

Although the use of the Internet by governments is increasing, there is still a significant lag time compared with private sector adoption of new technologies. Both structural inertia and risk aversion, commonplace in the public sector, foster governments that are slow to adopt and implement new technologies. The inherent tension between the need for reliability and accountability contrasted with reliance on maintaining organizational status quo leads to the increased adoption lag time in governmental organizations. For government IT adoption and implementation, the inertia that exists within the public sector means that organizations are often less willing and able to engage

Table 2 Percentage of Transactional Offerings by Municipalities, by Population Grouping

SERVICE	SMALL MUNICIPALITIES	MEDIUM MUNICIPALITIES	LARGE MUNICIPALITIES
Online payment of taxes	1.8	5.3	24.0
Online payment of utility bills	3.0	13.5	15.4
Online payment of fines and fees	2.1	12.4	23.1
Form completion and submission	7.7	16.1	33.3
Business license application and renewal completion and submission	4.4	8.0	14.8
Online requests for records	26.4	31.9	38.5
Online delivery of records	16.2	21.4	25.9
Online requests for services	31.3	41.0	44.4
Online registration for facility usage	12.1	20.3	36.0
Online voter registration	1.5	1.7	9.5
Online property registration	2.1	5.0	5.3
Downloadable forms	50.2	75.3	92.0
Online communication with elected and appointed officials	68.7	84.2	96.0

new technologies (Bretschneider, 1990). This inability to adapt to the rapidity of the information age creates a disconnect between the movement toward e-government and the need to consider all citizen requirements and needs. The most common example of this problem is demonstrated by the creation of governmental Web sites that are organized by administrative structure rather than by service orientation, which is more intuitive to constituents. To understand more fully the issues associated with e-government adoption, including challenges and benefits, it is crucial to understand the theory and typology associated with e-government.

THEORY AND TYPOLOGY OF E-GOVERNMENT

Using the theoretical frameworks of e-government of decentralization–democratization and normative–dystopian, as outlined by Garson (1999), one can begin to assess the benefits and challenges associated with e-government. The decentralization–democratization framework of e-government revolves around the progressive nature of technology and highlights governmental advances resulting from e-government. Essentially, decentralization–democratization highlights the fundamental restructuring of government interactions with its constituents through the strategic use of information technology, that is, greater efficiency, effectiveness, and increased participation. On the other hand, the normative–dystopian framework uses the high rates of conflict and failure associated with information technology applications and offers a pragmatic, even skeptical view of e-government. The normative–dystopian framework is associated with the notion that e-government is another medium for communication between constituents and the government; however, it does not support the concepts of reinvention

Table 3 Percentage of Transactional Offerings by Counties, by Population Grouping

SERVICE	SMALL COUNTIES (%)	MEDIUM COUNTIES (%)	LARGE COUNTIES (%)
Online payment of taxes	9.2	25.0	40.0
Online payment of utility bills	1.0	8.2	9.4
Online payment of fines and fees	1.9	9.2	11.1
Form completion and submission	5.6	13.6	21.1
Business license application and renewal completion and submission	1.9	5.2	16.1
Online requests for records	23.1	43.2	65.0
Online delivery of records	12.0	35.9	53.6
Online requests for services	7.6	17.9	25.9
Online registration for facility usage	6.7	10.6	21.4
Online voter registration	4.7	7.0	7.4
Online property registration	1.2	2.7	8.3
Downloadable forms	42.1	72.6	87.7
Online communication with elected and appointed officials	63.6	77.1	82.1

of government often associated with e-government. Although neither framework can be considered fully descriptive, taken together they provide a useful delineation of the theoretical literature on e-government.

Decentralization–democratization theory is the traditional view of e-government, beginning with Bozeman and Bretschneider's seminal article in 1986, which highlights the transformational, progressive nature of technology adoption in the government sector. Furthermore, Reschenthaler and Thompson (1996) contended that the power of public information technology, a prerequisite for e-government, lies in its ability to level the playing field for all sizes and types of governments. They see the basis for reengineering the business of government, refocusing its work on the needs of the citizens, and returning government to its core functions residing under the technology umbrella.

Another decentralization–democratization approach for examining the e-government model involves comparing and contrasting traditional bureaucratic design with the evolved e-government design. The traditional bureaucratic model of public service delivery (the Weberian model) focuses on specialization, departmentalization, and standardization (Ho, 2002). This traditional model has created departmental "silos" that resist functioning across agency boundaries, in the name of equitable and efficient governmental interactions. In the 1990s, however, the reinventing government movement sought to shift the core focus of government, moving from departmentalization and centralization to citizen-centric decentralization (Osborne & Gaebler, 1992).

The e-government paradigm, which emphasizes coordinated network building, external collaboration, and customer services, is slowly replacing the traditional bureaucratic paradigm and its focus on standardization, hierarchy, departmentalization, and operational cost-efficiency (Ho, 2002). In this view, the development and deployment of technology networks, shared databases, and Web-based interactions are the necessities that will facilitate seamless integration of government services. Although this shift to the e-government paradigm has not been fully realized, the Internet is a key enabler to this transformation because it provides government with the ability to use technology to impact customers directly, instead of simply reengineering internal processes (Scavo & Shi, 1999).

Decentralization–democratization proponents uses technology and e-government adoption rates as proxies for gauging the success of e-government. As the adoption and implementation rates increase, e-government technologies will enjoy increased legitimacy (Fletcher, 1999). Increasing citizen and business demand for e-government applications, which have permeated to the local government level, are central to greater adoption across all levels of government (Norris, Fletcher, & Holden, 2001). Response to the changing environment with improved service delivery, increased efficiency, and reduced costs is key to e-government success (West, 2000). Beyond the optimistic prospects of the democratization/decentralization theorists, there is a concrete reality of governmental technology and e-government failures, which are explained in the normative–dystopian framework.

Issues of privacy, security, and the digital divide fall under normative–dystopian model, which offers a critical approach to evaluating e-government. This view entertains concepts of dehumanization and isolation, resulting from the proliferation of information technology. The normative–dystopian theory addresses ethical issues that surround e-government. Recent concerns about the "digital divide," the technology gap that exists between distinct groups in the United States, highlight the issues associated with the move to e-government as a mode of service delivery, due to the potential consequences for unconnected or underserved populations. Several studies note racial, regional, educational, gender, and age disparities among Internet users and technology owners (Norris, 2001; Novotny, 1998). These gaps are of great concern for public administrators, who must serve efficiently, effectively, and equitably to fulfill their public charge.

Issues of security and privacy in the post–September 11 era are of grave concern to the majority of government constituents. In fact, the 2002 ICMA E-Government Survey indicates that 15% of the survey respondents have or will make significant changes to their existing security practices as a result of the terrorist attacks. Additionally, more than 10% indicate that they have removed information from their Web site for security reasons. Clearly, the issues of security and privacy are more salient than ever and governments must address constituent concerns if e-government is to achieve high levels of adoption and usage.

Using the normative–dystopian framework, Bovens and Zouridis (2002) examine the inherent problems associated with the shift toward an e-government paradigm. The emerging emphasis on information technologies as the medium for citizen interaction with government fundamentally alters the role of the bureaucrat. The traditional Weberian model uses street-level bureaucrats to interact with citizens and to determine the proper services and service levels to assist these citizens (Lipsky, 1980). This method allows for expertise, judgment, and practicality to be engaged in the decision-making process. In the e-government model, computer programs are used to interface with clients, assess eligibilities, and decide on proper levels of service (Boven & Zouridis, 2002). This model suggests that the street-level bureaucrats are losing their discretionary power, which can have deleterious effects on the clients. Bovens and Zouridis use the normative–dystopian framework to highlight the potential arbitrariness and threats to the legitimacy of governmental actions at the street level in the e-government model. Both frameworks for assessing e-government are valuable and valid; however, the rising citizen demand and increasing governmental use of e-government components indicate that e-government will only progress in future years.

PHASES OF E-GOVERNMENT

Several models have been developed to explain the progression of e-government (Layne & Lee, 2001; Moon, 2002). The stages or iterations of e-government do not follow a linear progression, however. Often, e-government applications are developed for utility, an ad hoc approach, instead of according to a master project plan, a systematic approach. For example, one local government may offer the ability to pay property taxes online through an application service provider but still have a basic informational Web site without interactive enhancements. Furthermore, the various models to be described offer a broad categorization of each stage or iteration. These are arranged in a continuum in which governments can be within the same stage while having diverse service capacities or functionalities.

According to the UN and ASPA (2001), there are five main stages of e-government. These five stages are precipitated by the recognition that some form of presence exists for the given locality. Stage One, the emerging Web presence, presents static information and is often considered to be "brochure-ware" (UN & ASPA, 2001, p. 16). The main goal of this stage is to provide an online dissemination of general information about the government. Often, the Stage 1 Web site visually represents the "stovepipes" that exist within agencies and does not allow for continuity across various departmental pages.

The association of the Web site denotes enhanced Web presence, Stage 2, with information on services; however, it is still organized by departments. This stage often offers e-mail as a method of two-way communication. It offers limited communication and greater information about the services of the government but is not consistent with the citizen-centric approach that has been advocated for e-government (UN & ASPA, 2001, p. 17; Layne & Lee, 2001; Moon, 2002).

Stage 3, interactive Web presence, does offer some of the citizen-centric methods as advocated by e-government proponents (UN & ASPA, 2001, p. 18). Information is presented in intuitive groupings, rather than by departmental or agency association. Often, portals are used as a single point of entry into various departments and service areas. Major groupings in the portal design might include business, new resident, seniors, children, or other standard groups. Subsequently, end users would control their Web destination based on the grouping they select. Each sublevel under the group headings offers commonly requested services, information, and assorted items of interest to the particular group. Again, specific agency or department does not designate the services and information contained within each group; they are offered as a bundle of interest to the target population. Stage 3 sites also have downloadable forms with online submissions, e-mail contact for various governmental employees, and links to other governmental Web sites.

Stage 4, transactional Web presence, allows secure online transactions (UN & ASPA, 2001, p. 19). User needs dominate the organization of this Web presence and the information presented is dynamic. Potential transaction offerings include online payments of taxes, utility bills, and fines and fees; form completion and submission; business license application and renewal completion and submission; online registration for facility usage; online voter registration; and online property registration. As evidenced by the ICMA 2002 E-Government Survey, less than 15% of responding counties and municipalities offer these services. Furthermore, only 4.6% of the respondents offer online payments.

The final stage, Stage 5, involves seamless government. This stage represents an ideal and no real example of its application is available. Stage 5 ideally involves a cross-agency, intergovernmental approach, however, that only displays one front, regardless of service area (UN & ASPA, 2001, p. 20). For example, a portal may offer a compendium of local, state, and federal government services without user recognition of what level of government provides the service. A Stage 5 site would offer vertical and horizontal integration and would require true organizational transformation with respect to administrative boundaries (UN & ASPA, 2001, p. 20).

Drawing on the UN and ASPA typology, current literature indicates that the majority of local governments are in Stage 2, with enhanced Web presence. Moon's (2002) analysis of 2000 ICMA E-Government Survey indicates that a majority of municipalities with populations over 10,000 are not offering transactional Web sites. Furthermore, based on the 2002 ICMA E-Government Survey, only 62 (1.7%) municipalities offer online payment of taxes, 113 (3.1%) offer online payment of utility bills, and 91 (2.5%) offer online payment of fines and fees. The percentages for counties are only slightly higher, with 69 (16.3%) offering online payment of taxes, 17 (4.0%) offering online payment of utility bills, and 21 (5.0%) offering online payment of fines and fees. More robust transactional services can be found at the state and federal levels of government, as would be expected.

Using Ho's (2002) methodology for assessing municipal Web sites, a different dimension of e-government typology can be discerned. He centered on three primary orientations designed to demonstrate the shift from the Weberian bureaucratic model to the e-government paradigm. The first orientation is administrative-oriented Web sites, organized along departmental lines and represents the traditional bureaucratic paradigm (p. 437). The second orientation is information-oriented, crossing departmental lines to provide a one-stop shopping experience to the user (p. 437). The final orientation is user-oriented, which categorizes information in intuitive groupings that offer end user control and rapid access to predetermined information (p. 437). This orientation also crosses traditional departmental lines in an attempt to provide an all-encompassing experience to the end user. Ho's analysis of the 55 largest municipalities' Web sites indicates that a majority has moved toward varying degrees of user-orientation (p. 438).

Further alternative approaches to defining the e-government typology use various levels of communication, applications of technology, and citizen participation in democratic forums to define its stages. One example of this approach is found in Moon's typology (2002), as adopted from Hiller and Bélanger. This framework also uses five stages but its focus is on the communications between various stakeholders, including G2G, G2E, G2C. Stage 1 involves information dissemination and uses basic Web authoring tools and bulletin boards as methods of communication (p. 426). Two-way communication, using e-mail and electronic data exchange (EDI), is found in Stage 2. Stage 3 highlights service and financial transactions, along with technologies such as EDI, electronic filing systems, digital signature, and public key infrastructure. Stage 4 centers on the concepts of vertical and horizontal integration of the technologies found in Stages 1, 2, and 3. It is similar to Stage 5 of the UN and ASPA model in its seamless outward appearance. Political participation is the mainstay of Stage 5 in Moon's typology. It involves online voting, e-democracy, and e-participation. Very few local governments have evolved to Stage 5, evidenced by the fact that only 2.1% of respondents to the 2002 ICMA E-Government Survey are using online voter registration. This alternative approach to the typology of e-government still acknowledges the importance of the user's view of e-government but extends the model to include digital civic engagement and enhanced electronic democracy.

The various models of e-government allow for broad comparisons across the various governmental Web sites, using similar benchmarking criteria. Such comparisons are useful to the extent that they can highlight the critical success factors associated with individual experiences, which can be generalized to the general population. One of these critical success factors is training for e-government. Issues of training are directly related to the need to move along the e-government continuum because training fosters greater understanding of the processes and applications, as well as provides a method of eliciting user support. By examining the current training practices of governments with regard to e-government, one can begin to understand the need to bridge e-government expansion and training to create a holistic, enterprise approach.

TRAINING FOR E-GOVERNMENT

As the information age advances, citizens expect a more responsive and accountable government. The concept of "citizens online instead of in line" enables people to have immediate access and responsiveness, while reducing personal interactions with government employees. As e-government continues to expand at all levels of government, federal, state, and local governments need to prepare their elected officials and employees to handle the multitude of changes it entails. Citizen demand for and governmental usage of e-government, as evidenced by national surveys and Web assessments (Larsen & Rainie, 2002; West, 2000), indicate that such applications will only increase in usage and importance over time. This advances the need for assessing the current state of training for e-government to determine areas of current success as well as to ascertain future direction for training.

The majority of the literature concerning training for e-government involves analysis of collegiate public administration program curricula. As early as 1988, the National Association of Schools of Public Affairs and Administration (NASPAA) added computing as a skill set for accredited master of public administration (MPA) programs (Northrop, 2003). Further calls for the incorporation of IT education came from Perry and Kraemer (1993). In 1998, Brown and Brudney completed a comprehensive examination of 106 MPA programs and found that only about 30% of the schools included in the sample offered instruction on technology planning, policy development, and evaluation, despite the NASPAA recommendation to include these in the curriculum. By 2001, Kim and Layne had conducted an empirical study of student perceptions of digital government within their institution and set forth recommendations for future training, both in the schools of public administration as well as for the leaders of the public sector.

In an attempt to highlight the importance of high-quality training opportunities for federal, state, and local government elected and appointed officials, a data set from the 2002 E-Government Survey conducted by the ICMA was analyzed. Issues of staffing and training in local government units (counties and municipalities), as well as implementation styles and challenges, were selected to measure the need for high-quality e-government training. As noted previously, this data set provides a snap shot of the current status of information technology in municipalities and counties with populations over 2500.

Although e-government adoption is the first step toward an electronically enabled government, the manner of application implementation is critical to understanding the nature of public sector information technology. As noted by various sources, staffing issues are one of the key factors in determining the success or failure of technology applications (Brown & Brudney, 1998). The existence of distinct information technology departments can be used as a proxy for the commitment of resources to information technology initiatives, including e-government. There is a large disparity between the size groupings of the jurisdictions, however. Only 28% of small municipalities have IT departments, whereas 84% of medium municipalities and 85.7% of large have such departments. In counties, 44.1% of small counties have IT departments, compared with 86.4% of medium and 98.4% of large counties. Along with the development of the chief information officer, the density of information technology departments, particularly in larger governmental units, indicates the importance of high-quality technology staff and, subsequently, their training.

Another key issue associated with preparing for e-government involves addressing those issues designated as barriers by local governments. According to the data collected via the 2002 ICMA E-Government Survey, several barriers hinder local government movement to successful e-government implementation. The lack of technology/Web staff is the most commonly cited problem, across all types and sizes of local governments. More than 45% of small municipalities, 47.8% of medium municipalities, and 44.8% of large municipalities, indicate the lack of staff is their greatest barrier. Furthermore, 40.7, 46.1, and 22.6% of small, medium, and large counties, respectively, indicate the same concern. The issue of staffing can easily be resolved through proper training. One common solution found in local governments involves the promotion of a current staff member, often a town clerk or administrative assistant, to webmaster. This promotion can be an effective solution if the skill set required to undertake such as task is already in place or can be easily leveraged through training and education.

Another commonly cited barrier to successful e-government implementation is the lack of technology and Web expertise. More than 33% of small municipalities, 28.6% of medium municipalities, and 24.1% of large municipalities indicate that this is their greatest barrier.

It also is cited as a barrier by 29.9, 25.1, and 19.4% of small, medium, and large counties. Again, increasing the training opportunities available to government employees and officials can significantly reduce this barrier.

Beyond the barriers related to e-government implementation, it is important to consider the typical development and maintenance of e-government services. More than 60% of ICMA survey respondents offering e-government services indicate that they have e-government services developed in-house by staff members. Seventy-one% of small municipalities, 45.1% of medium municipalities, and 51.7% of large municipalities have in-house development of some e-government services. Additionally, 78.4% of small counties, 32.2% of medium counties, and 33.9% of large counties developed e-government services in-house. The decreasing reliance on in-house development of services as population size increases further demonstrates the need for high-quality training opportunities for all governments, especially critical for the smaller counties and municipalities who are relying on internal staff to design and develop their interfaces with the public.

Based on a brief survey of state governmental Web sites, there is evidence that most states offer type of training, although the offerings are typically limited to technology applications and software training. Very few sites offer comprehensive e-government training with the necessary organizational, political, and technological components. As outlined by Kim and Layne (2001), there are several core components to effective digital government training for public sector officials, including an understanding of e-government infrastructure; the political, economic, and legal contexts of e-government; best practices; conceptual issues such as portals and transactions; service-related issues pertaining to Internet-based offerings; and citizen-centric government (p. 238). Additionally, training should focus on the paradigmatic shift from the bureaucratic model of government to the e-government model. This component is based on Ho's (2002) premise that the bureaucratic paradigm, emphasizing standardization, hierarchy, departmentalization, and operational cost-efficiency, is slowly being replaced by the e-government model, emphasizing coordinated network building, external collaboration, and customer services.

Clearly, the advent of the information age has fundamentally changed daily life. Additionally, the role of the Internet continues to increase in importance as penetration and digital literacy expand. Citizen and business demands mandate that government become involved in digital government initiatives, while current successful efforts increase the legitimacy for further information technology adoption (Norris, 1999). Because of the growing critical mass related to e-government, federal, state, and local governments must prepare their elected officials and employees to manage and navigate the new landscape of the e-government model. There is a paucity of research dedicated to training for e-government, as well as a lack of training opportunities. These disparities must be redressed to provide a thoughtful, high-level knowledge base, which will engender successful e-government adoption and implementation.

CONCLUSION: THE FUTURE OF E-GOVERNMENT

The march of e-government has not been without setbacks, notably in the areas of universal access and governmental openness. Presidents Bush's 2003 budget proposed to eliminate two critically important community technology programs related to diminishing the "digital divide": the Technology Opportunities Program (TOP) and the Community Technology Center (CTC) initiative. A study by Brown University's Center for Public Policy studied 1,265 federal and state Web sites and found some 6% had restricted areas requiring a password to enter, an increase reflecting post–September 11 attention to security. Likewise, the Environmental Protection Agency has removed risk management plans and other information pertaining to hazardous waste sites from its Web site, citing risk of terrorism outweighing the right of citizens to know hazardous waste risks near their homes, workplaces, and schools.

Nonetheless, the setbacks are far overshadowed by the remarkably rapid expansion of e-government. The Pew Internet and American Life Project, in the Larsen and Rainie report cited earlier, stated, "The rise of e-government has been one of the most striking developments on the Web" (Larsen & Rainie, p. 5). Because of citizen demand for things such as e-access to building permits, dog licenses, and birth certificates, the bandwagon effect for implementing e-government is strong (Moulder, 2001). There is now considerable momentum for government change along the e-government model. Governments are competing to be seen as being on the leading edge, not laggard adopters (Sprecher, 2001).

Many cities are moving away from traditional bureaucratic emphasis on standardization, departmentalization, and operational cost-efficiency, toward the "e-government" paradigm, which emphasizes coordinated network building, external collaboration, and customer services (Ho, 2002). In this way the reinventing government movement is tied to the e-government movement.

Many municipal governments have adopted e-government, but it is still at an early stage and has not obtained many of expected outcomes (cost savings, downsizing, etc.) that the rhetoric of e-government has promised (Moon, 2002). (It should be noted that this "rhetoric of e-government" promises cost savings, etc., which arguably are not realistic outcomes of e-government.) There has been general progress in online services, privacy policy statements, and standardized navigational features but much less progress in disability and foreign language access. Most agencies used Web for one-way communication with no provision for two-way interaction with citizens (West, 2001). The desire to transcend limited progress is one motivation behind the push for public–private partnerships in support of e-government initiatives (Holmes, 2001).

It is still too early to assess e-government in terms of effect on democracy. Clearly there are great hopes that e-government will provide new opportunities for widening civic engagement and participation (Milward & Snyder, 1996). In principle e-government increases the reliability and accountability of public organizations. In

Santa Monica, CA, home to Public Electronic Network (PEN), one of the first major community computing experiments, city officials were eager to participate in a community computing experiment in its first year, but by the sixth year most had ceased participation, citing lack of substance of e-forums, too much “flaming” (searing e-mail messages in which the writer attacks another participant in malicious terms), and too many personal attacks by a minority of network participants (Docter & Dutton, 1998). The Electronic Government Act of 2002 has now mandated e-rulemaking, a critical aspect of e-democracy, and there are other e-democracy experiments (e.g., all hearings and committee sessions of the Michigan Legislature are now broadcast in streaming video, live over nine channels). Although e-government may have a much less profound effect on e-democracy than it is already having in the provision of governmental e-services, at the very least new channels of two-way communication between citizens and their government are being enabled.

GLOSSARY

E-democracy A range of reforms that use the Internet to increase public participation in governmental processes, including e-voting, e-rulemaking, and various forms of two-way interaction with elected and appointed government leaders using e-mail, e-forums, e-conferencing, and other methods.

E-government A strategy for making government more efficient and effective through e-services, e-procurement, and e-democracy.

E-procurement Purchasing goods and services online by governmental agencies, including use of the Internet to submit requests for proposals, requests for bids, acceptance of bids, and the letting and monitoring of performance contracts.

E-services The provision of government services via the Internet, including provision of online information, use of online forms of all types, the ability to make payments online, online educational services, online consulting services, and online screening and referral to services which cannot themselves be rendered online.

Portals The strategy of providing one-stop, cross-agency, and cross-jurisdictional gateways to government services in a given functional area, such as student needs, small business needs, or recreational needs, or based on an aggregation of user needs, such as all state services.

Electronic Commerce and Electronic Business

Charles Steinfield, *Michigan State University*

INTRODUCTION

The term electronic commerce came into widespread use after the first graphical Web browser—Mosaic—was developed in 1993 and freely distributed around the world. Drawn by the ease of use of the browser, millions of home consumers, businesses, and educators connected to the Internet, creating the conditions for Internet-based commerce. Businesses flocked to the Internet, attracted by the ease of setting up electronic storefronts and the potential access to a global market of Internet subscribers. Sales of goods and services to consumers, often referred to as business-to-consumer (B2C) e-commerce have grown steadily each year, despite the failure in 2000 and 2001 of so many new Internet businesses (known as dot-coms because of the domain name—".com"—in their Internet address). Even more dramatic has been the extent to which businesses have adopted the Internet for supporting exchanges with other firms, such as suppliers and business customers. This is generally called business-to-business (B2B) e-commerce. Because of this rapid growth, e-commerce has become an important subject of study in its own right, and many schools now offer courses and degree programs focusing on it.

CHAPTER OVERVIEW AND THEMES

This chapter examines the development of e-commerce and its influences on the way companies work with their suppliers, market their products to customers, and compete with old and new rivals. The historical development of e-commerce suggests that it emerged as a powerful force only after a truly open and standard data network—the Internet—was coupled with easy-to-use software—the graphical Web browser. Many innovative business models evolved in an attempt to take advantage of this new platform, coupled with a host of clever new marketing strategies. E-commerce opened up new avenues for consumers as well, creating new consumer-centric markets in which their bargaining power has been enhanced. New methods of payment as well as approaches to improving the security of online transactions have been introduced as well.

Despite these developments, a key theme of the chapter is that although much has changed as a result of e-commerce, many of the expected impacts have not occurred. A review of research on several anticipated impacts highlights the need to critically assess the early hype about the effect of e-commerce on competitive strategy, market structures, B2B relationships, and prices of goods and services.

The chapter concludes with a brief summary and a look toward what the future might hold now that the dot-com era of e-commerce has passed.

DEFINING E-COMMERCE AND E-BUSINESS

Today, the term electronic (or e-) commerce most commonly refers to the process of buying and selling goods and services over the Internet. It has even found its way into popular dictionaries, and the 2000 edition of the *American Heritage Dictionary* defines e-commerce as "[c]ommerce that is transacted electronically, as over the Internet." Narrower definitions state that complete transactions, including ordering and payment, occur entirely via the Internet, while broader definitions include information exchange in support of transactions, even if the actual payment occurs outside the Internet (often called “offline” payment). More recently, the term e-business has become popular. It refers more broadly to the conduct of business over computer networks. E-business includes activities that are not purely commercial transactions, such as when two firms use the Internet to collaborate on product development or research, or a firm provides customer service online. Some (e.g., Laudon & Traver, 2001) consider e-business to include only internal applications of a firm’s computer network, and not transactions with other firms. However, today, the terms e-commerce and e-business are often used interchangeably, and we follow this practice in this chapter.

A BRIEF HISTORY OF E-COMMERCE

Long before the World Wide Web, electronic networks were used to support transactions between businesses and their various external constituents (e.g., suppliers or customers). In the 1970s, forward-thinking manufacturers and wholesalers deployed proprietary data networks and simple terminal-based remote ordering systems to business customers. In three of the most famous examples from this era, pharmacists could replenish prescription drug stocks by filling out an electronic form on a terminal provided by McKesson, hospitals could use computer terminals to order a wide range of medical supplies from American Hospital Supply, and travel agents could look up flights on a computer terminal connected to American Airlines’ Sabre system. Soon the value of computer networks to link business buyers and sellers was well established, and efforts to create standard electronic documents to support trade were occurring across many industries. These latter standards were collectively called EDI (electronic document interchange). In some industries, such as automobile manufacturing and chemical production, EDI transactions proliferated because their use was mandated by large, dominant manufacturers. However, because EDI standards were complex and the proprietary data networks on which they relied were costly to implement, especially for small businesses, the extent of EDI diffusion was limited. Unlike the Internet, these proprietary networks took substantial time, investment, and effort before any new trading partner could join.

There were precursors to consumer-based e-commerce as well. Indeed, the Home Shopping Network on cable television, in which consumers can use a standard telephone to order goods displayed on TV, certainly resembles a Web-based electronic retailing model. Even more similar, however, were the many different electronic information services, collectively known as videotex, that developed largely in Europe and the United States in the 1980s. The most successful of these systems in Europe was the French system popularly known as Minitel, named after the small terminal that initially was freely distributed to telephone subscribers. Beginning in 1983, French telephone subscribers could use their Minitels to look up a wealth of information, engage in home banking, and order a wide range of goods and services, such as tickets, groceries, and other consumer products. As with the Internet, these services, offered over a public network to which anyone could connect, used a single standard and relied extensively on graphical content. Unlike with the Internet, a clear payment model was implemented, with France Telecom (at the time, the public administration responsible for the provision of all telecommunications networks and services in France) providing a “billing and collection” service for all companies that wished to sell via the Minitel. Consumers received the bill for their Minitel use on their regular phone bill, and France Telecom, in turn, paid the various service providers. Hence, the cost of participating in the Minitel marketplace was quite low, and by the early 1990s, there were over 25,000 services available, including both consumer-oriented and B2B services. Today, even with the Internet firmly entrenched in France and with many other telecommunications operators competing with France Telecom, the Minitel survives and generates revenue.

The success of the Minitel system did not go unnoticed, and many countries tried to create similar systems, including the United States. However, American electronic information services were still based on closed, rather than open, systems, using what has been called a “walled garden” approach. That is, services such as CompuServe and America Online (which have now merged) used their own proprietary networks, and their content and services were only available to their own subscribers. Unlike the Minitel network, it was not easy for any business to “join” the electronic market without significant investment. It was not until commercial traffic was permitted on the Internet, and an easy-to-use graphical browser appeared, that a truly open electronic marketplace began to grow and e-commerce as we know it today was born.

The early years of e-commerce had all the characteristics of a gold rush, as companies flocked to the Web to set up their electronic storefronts. Lured by the rapid growth of such first movers as Amazon.com, an enormous flow of investment capital was poured into Internet start-up firms selling everything imaginable on the Web. Laudon and Traver (2001), for example, report that more than $125 billion was invested in the initial public offerings (IPOs) of Internet firms between 1996 and 2000. The birth of a new digital economy was proclaimed, characterized by a seemingly unending growth in productivity rooted in the supposedly frictionless commerce afforded by the Internet. The new Web-based businesses theoretically offered such benefits as access to a larger potential market, lower inventory and building costs, more flexibility in sourcing inputs, improved transaction automation and data mining capabilities, an ability to bypass intermediaries that added costs but little value, lower costs for adjusting prices (known as a menu costs), increased ease of bundling complementary products, 7X24 access, and no limitation on depth of information provided to potential customers (Steinfield, Mahler, & Bauer, 1999). These advantages were expected to allow Internet firms to enter new markets at a lower cost and respond rapidly to shifts in market demand. Moreover, because the Internet also lowered consumers search costs (e.g., they did not have to drive from business to business to compare prices), prices would decline and Internet firms would prosper at the expense of traditional firms.

Despite the rosy projections for e-commerce, in late 2000 and early 2001, many of the dot-com companies began to fail. Few ever made any profits, as their business approach revolved around scaling up to increase market share. This approach was based on the belief that Internet businesses would enjoy positive network externalities—implying that the more people who used a site, the more value it would have for each user. The dot-coms that could attract the most users the fastest would, thus, have an insurmountable competitive edge. In search of the required scale, Internet firms kept prices too low and quickly burned through the cash raised from venture capitalists. At the same time, the U.S. economy began to slip into a recession, and venture capitalists began to lose faith in the viability of start-ups that failed to return any profits. Stock prices, which were far too high by normal investment standards, dropped precipitously, and the venture capital community lost interest in dot-com businesses. By the end of 2001, the dot-com era was over, and according to one estimate, only about 10% of the dot-coms created since 1995 still survived (Laudon & Traver, 2001).

B2B-oriented dot-coms experienced much the same fate. Large numbers of B2B electronic marketplaces were created to help match buyers and sellers in many industries, and by early 2000, more than 750 B2B e-markets were operating worldwide (U.S. Department of Commerce, 2000). Yet most of the new dot-coms in this arena failed as well.

Despite the problems of the dot-coms, statistics on e-commerce use do show steady gains, particularly as traditional companies have moved to enhance their offerings with Internet-based sales channels. According to U.S. Census figures, even as the economy was entering a recession and the dot-coms were failing, retail e-commerce sales in the United States were growing. Total U.S. retail e-commerce sales in 2000, the first full year that the government tracked this statistic, were approximately $29 billion. In 2001, this figure had increased to $36 billion, rising to more than $11 billion in the all important fourth quarter, where holiday shopping occurs (U.S. Census, 2002). Moreover, these figures are a low estimate, because they do not include sales from online travel, financial brokers, and online ticket sales. U.S. B2B online trade has also grown, rising to an estimated $466 billion in 2001 and projected to be as high as $5.4 trillion in 2006 (Laudon & Traver, 2001).

INTERNET BUSINESS MODELS

Many innovative methods of doing business were created in the early years of e-commerce, which collectively came to be called Internet business models. Exactly what constituted a business model was the subject of much debate, as was the issue of which models were successful. Rappa (2002) defines a business model as the "method of doing business by which a company can sustain itself—that is, generate revenue. The business model spells-out how a company makes money by specifying where it is positioned in the value chain." Timmer (1998) considers a business model to include three basic components: the architecture for the product, service, and information flows; the potential benefits for the various business actors; and the sources of revenues.

A common B2C business model, for example, is a virtual merchant that operates much as a traditional retailer, only without any physical retail space. The virtual merchant acquires products from manufacturers and resells them over the Web to end consumers. Amazon.com, which sells books, CDs, videos and many other consumer products online, is the best known example of a virtual merchant. Other popular B2C models include catalogue companies and the click-and-mortar or brick-and-click retailers, which have both traditional physical stores and online channels. All these businesses typically derive revenues from the margin between the prices that suppliers charge and the prices charged to consumers. However, each adds value in different ways to attract buyers. For example, a virtual merchant (also sometimes called a digital pureplay) may be able to offer goods at lower prices because of its lower inventory holding costs and lower selling costs. On the other hand, a brick-and-click firm may use its Web site to help generate more traffic in its physical stores by offering coupons or searches of in-store inventory (Steinfield, Bouwman, & Adelaar, 2002).

Early in the e-commerce boom years, many felt that revenue from advertising would sustain e-commerce. This made some sense for content firms, such as online newspapers, magazines, radio stations, and other media-oriented companies that were accustomed to reliance on sponsors to bring down the costs for their viewers, listeners, and readers. However, one failed Internet business model, pursued somewhat by Buy.com, involved the use of advertising revenue to subsidize product sales, so that consumers could buy products at heavily discounted prices.

Another problematic business model in the B2C arena involved manufacturers of products selling directly to end consumers and bypassing wholesale and traditional retail channels. Levis, for example, attempted to sell its blue jeans directly to online shoppers. Existing retailers, however, threatened retaliation. Given the relatively small percentage of sales generated by the Internet, Levis soon gave up on the direct-sale model and now uses its Web site mainly to promote sales of Levis at traditional retail outlets or to sell online through its retailers' Web sites.

Among the more popular B2B business models was the B2B electronic hub (Kaplan & Sawhney, 2000). B2B e-hubs were established in a variety of industries by third-party market makers. Many were vertical markets such as eSteel, which attempted to create an online marketplace for all steel industry raw materials and products. These are called vertical markets because they bring together firms operating at various stages inside a particular industry value chain. Others were horizontal, such as Ariba or Grainger, which offer online catalogues that provide buyer firms with access to suppliers of a range of materials needed to operate a business. They are called horizontal markets because they focus on products needed across many different industries and bring together buyers and sellers of a wide range of maintenance, operation, and repair goods (MRO). The basic business model is oriented around the provision of an electronic brokerage service, with the market operator deriving revenue from commissions on sales, and perhaps fees charged to sellers in order to have access to the market.

Some brokerage models operated to bring consumers together, as in electronic classified services and auction services, such as eBay. These consumer-to-consumer (C2C) businesses clearly added value by attracting large numbers of buyers and sellers, increasing the chances of finding viable matches. As with B2B hubs, their revenue model usually hinged on taking a commission on sales, or charging fees to sellers.

Rappa (2002) offers a useful summary of the many business models encountered in e-commerce. His main model categories include

Brokerage: Various forms of electronic intermediaries that bring together buyers and sellers. EBay, which provides C2C auction services, is probably the most famous example of an online broker model.

Advertising: Companies that provide content in the hope of attracting enough viewers that they can sell advertising. Virtually all online newspapers and magazines that do not charge subscription fees are examples of this model.

Infomediaries: Companies that offer something of interest to consumers (normally content) in return for customer information that they can sell to third-party marketers. The *New York Times* online service uses this model.

Merchant Models: Retailers that buy goods and resell them via the Internet. Amazon is the most famous online virtual merchant. Firms that have both traditional retail outlets and online sites are using another variation of a merchant model, often called a click-and-mortar or brick-and-click model. In the same product category as Amazon we find Barnes and Noble, one of the most famous brick-and-click merchants.

Manufacturer: Producers of products that sell directly to end consumers via the Internet. Apple and Dell, for example, both sell their computers through online stores.

Affiliate: Companies that derive revenue by referring customers to other e-commerce firms, who then provide a sales commission. Many online merchants, such as Amazon, work with thousands of affiliate partners, who provide purchase opportunities in return for a small commission. In addition, firms such as BeFree help merchants establish large affiliate networks to enhance sales.

Community: Sites where the content is provided by the users themselves and revenues mainly come from advertising. ExpertCentral.com, a site that relies on volunteers to answer questions on a wide range of topics posed by online visitors, is an often-mentioned example of this type of model.

Subscription: Sites that offer access to content and services for a flat fee over some period, like traditional magazine or newspaper subscriptions. The *Wall Street Journal* operates their online paper with this model.

Utility: Sites that sell content or services on a metered, or per-use, basis. This is an evolving business model that might be used in the new approaches to software distribution.

There are many variations on each of these basic forms, with many strategies for adding value within each type. Moreover, many Internet companies represent combinations of these models, rather than existing purely within one category or another. A basic problem is that most business models emphasize the sources of revenue and are not necessarily recipes for profitable businesses. In a sense, many dot-coms following these models forgot to include a profit model. Many spent so much to scale up operations or acquire customers that they lost money on every sale. This resulted in the ironic situation that the more revenue they earned each year, the larger the total loss!

MARKETING STRATEGIES FOUND IN E-COMMERCE

Electronic commerce offers many new opportunities for firms to interact with customers. It enhances firms' abilities to offer many customer services in a cost-effective manner. Moreover, e-commerce companies have experimented with a wide range of innovative marketing strategies made possible through software, data mining, and other IT capabilities. Several of the more popular e-commerce marketing techniques are briefly highlighted below.

Personalization

An e-commerce vendor can personalize its interaction with customers, creating what some call a one-to-one marketing relationship. Personalization generally requires that the online shopper provide some information about his or her interests or preferences to the vendor. This information is then used to tailor the Web site so that it reflects these interests. Cookies are often used rather than requiring a login to identify particular customers, and each customer then receives his or her own dynamically constructed page. Yahoo and other search engines and portals were among the first to develop these techniques. More elaborate techniques use purchase histories, clickstream information, and other data to personalize e-commerce services.

Customization

Many e-commerce vendors offer customers a "build-to-order" option that allows some degree of customization of the products to suit buyer tastes. This is common for computer vendors, but other types of e-commerce companies have also used e-commerce to offer this value-added service to customers. Lands' End, for example, offers hem-to-order pants. Even Levis, in their initial foray into e-commerce, attempted a "made-to-measure" blue jeans product.

Upselling and Cross-selling

Using simple automated rules as well as more sophisticated data-mining techniques, merchants can enhance their ability to both upsell and cross-sell to customers. Upselling involves convincing customers to trade up to a more expensive option or to add a complementary product to an order. Cross-selling involves suggesting other products that customers might like that are similar to the ones in an existing order.

Collaborative Filtering

Many e-commerce sites use a data mining technique known as collaborative filtering to provide better product recommendations to customers, enabling even more powerful cross-selling. Essentially, the purchases of other customers who have similar profiles are used as a source of recommendation. Amazon was one of the first to implement such a service. Whenever a customer selects a particular book, he or she is presented with a list of related books to consider. These recommended books were purchased by other shoppers who had also bought the initial book selected by the customer.

Rich Content

Unlike products on a shelf in a traditional store, products in an e-commerce store can be accompanied by in-depth content, including product reviews, detailed specifications, tutorials, testimonials, multimedia depictions of it in use, music, and so forth.

Affiliate Programs

Vendors can use the wider Web community to help sell products. This involves more than simple reciprocal linking and can include payments to Web affiliates who refer customers who purchase products. Amazon was a pioneer in this area as well, allowing virtually anyone with a Web site to become an Amazon affiliate. For example, an author might provide a link from his or her personal Web site to the book's purchase page on Amazon. The link is coded to identify the referrer, who then earns a slight commission on any purchase originating at the referring site.

Incentive Programs

In an effort to inspire greater customer loyalty, many e-commerce sites followed the lead of airlines and offered various types of incentive marketing programs. Frequent shoppers could build up points that entitled them to discounts and other benefits. Because all transactions are automated and it is so easy to collect information via the Web, these types of programs became much more accessible to all online merchants. As with airline frequent flyer programs, these techniques create switching costs, because customers who do not return know they will lose accumulated benefits.

Direct E-mail

E-mail, the most popular application of the Internet, is a valuable e-commerce marketing tool. Companies obtain email addresses of visitors and customers and regularly send targeted letters with new product information, announcements of sales, and other promotional content.

Viral Marketing

Increasingly, companies rely on customers to help spread the word about their products and services. Such a strategy is known as viral marketing, because the marketing material is carried by customers and spread throughout a target population. Often, dissemination is accomplished by giving users access to free services or games that require the participation of others. Paypal, for example, lets its customers send payments to others for free. Recipients must open an account with Paypal in order to transfer the funds into their regular bank account. This strategy has helped increase the number of Paypal account holders, which in turn entices more merchants to accept Paypal payments. Merchants, however, do pay a fee to receive funds.

Multichannel Marketing

Brick-and click-firms and catalogue companies capitalize on the synergies that arise from the integration of traditional and online channels. Traditional retailers, for example, can provide detailed product information online, immediate pickup in a store, and extensive support after the purchase online. Traditional catalogue companies can refer to their Web sites in every printed catalogue mailed to customers. In this way, they can gain the benefit of a regular reminder to look at their merchandise, with the cost savings that accrue when customers fill out online forms instead of calling a call center.

The various marketing strategies mentioned above are by no means an exhaustive list, but they do illustrate a number of possibilities to extend and enrich relationships with customers using network-based, computer-mediated transactions.

CONSUMERS IN E-COMMERCE

Up to now, the discussion has focused on mainly on e-commerce companies. However, e-commerce also has implications for the way in which consumers interact with each other and with businesses. One of the most successful, and profitable, e-commerce businesses is eBay, which began as an auction broker for C2C transactions, providing the equivalent of a nationwide online garage sale. However, unlike real garage sales, buyers could not physically inspect merchandise, and there was no process equivalent to handing over the item in return for cash. eBay's innovative solution to this problem was to develop a feedback mechanism whereby buyers and sellers rate each other after each transaction. Buyers rate the promptness with which sellers actually delivered the purchased items, the quality of the items, how well it was packaged, the accuracy of the online description, and anything else that might help future buyers decide whether to do business with this particular seller. Sellers also rate buyers, scoring them well if they pay promptly and deal honestly. Privacy is protected because people use pseudonyms. There is an incentive to behave properly, because buyers and sellers develop a reputation (hence, these are often called reputation systems). If someone develops a bad reputation, then he or she can only return to the system under a new pseudonym, and others may be less willing to deal with someone with no reputation.

eBay relies on an auction pricing format (although buyers now have the option to click on a "buy it now" button and forego the bidding process). Unfortunately, even with the elaborate reputation system, there remains some potential for fraud. Some unscrupulous sellers, for example, may fake numerous transactions with others to build a reputation. Others may have confederates make false bids on an item in order to artificially raise prices—this practice is known as shilling. Bidders can also cheat—for example by using a confederate who makes a high bid to discourage other bidders. The fake bid is then retracted near the bidding deadline, so that the item can be acquired at a lower price. Even with a certain degree of fraud, however, eBay remains highly successful, perhaps in part due to the entertainment value associated with bidding on items.

Consumers play an important role in another well-known e-commerce service, run by Priceline.com. Priceline also uses a form of electronic brokerage, in which they match consumers' bids for various goods and services with vendors willing to accept the bid. Priceline mainly deals with travel-related services, especially airline tickets, although they attempted to expand this model to other sectors. In this way, airlines and others with perishable products have another outlet for goods and services that would otherwise go unsold. This business approach is called a reverse auction broker model and is sometimes referred to as C2B e-commerce because the consumer initiates the transaction.

PAYMENT SYSTEMS TO SUPPORT E-COMMERCE

To support complete transactions online, the e-commerce infrastructure must be capable of handling the financial settlement. Since the dawn of e-commerce, many financial and technology companies have worked to establish secure methods of electronic payment. We can group most forms of electronic payments into three broad categories: (a) closed user group systems, (b) systems that use secure transmissions of traditional payment methods, and (c) token-based systems for digital money. Each of these is briefly described below.

Closed User Groups

A closed user group approach relies on payment occurring outside of the Internet. In general, this approach is used when online shoppers have an account and are billed on some periodic basis for their usage and/or purchases. For example, an AOL subscriber has made arrangements to pay AOL via a check each month, or via his or her credit card. Any online purchases can then be appended to this regular bill. Likewise, a customer may have a private account with a vendor that offers products online. The customer then logs in with his or her account ID and password, purchases items, and receives a bill at the end of the month for all activity on the account. These are both closed groups—only members are able to make purchases, and a billing relationship is already established, so that payment happens offline.

B2B exchanges often take place within a closed user group. For example, it is common for suppliers to have long-term contracts with their buyers for prenegotiated prices. Supply-chain management systems can permit online ordering of needed supplies, whereas payment occurs through the normal offline billing and account management process.

Methods of Secure Transmission of Existing Payments

Many e-commerce vendors sell products to new customers who do not have accounts, and hence a closed user group approach would not work. Rather, the most common method of payment in e-commerce is to set up a secure transmission link to accept an existing form of payment, such as a credit card or an electronic check. One elaborate standard, known as the secure electronic transaction (SET), was developed and supported by credit card firms, including Visa and Mastercard. However, the system so far has proved to be too costly and cumbersome, and most sites simply use some variation of the original secure sockets layer (SSL) approach to enable shoppers' browsers and e-commerce servers to set up secure links. Credit card information is encrypted to prevent interception and theft as it travels over the Internet. Merchants must verify the credit card, and consumers, of course, must pay their credit card bill through normal offline means each month.

B2B payments may also occur using secure transmissions, even when the companies are not in a closed user group, as described above. Secure transmission of electronic checks, such as is offered by eCheck, has been promoted as a safe means of transferring funds between businesses. Consumers may also use e-checks for their payment needs.

Token or Digital Money Systems

One problem with credit cards is that the fees charged by credit card companies make them less viable for inexpensive purchases. Content-oriented e-commerce companies are particularly interested in better methods of low-value payment. Some music sites, for example, might find it viable to charge just a few pennies to play a song, counting on generating millions of transactions so that the total translates into real money. In these cases, one solution is to have users set up accounts and then to provide a periodic bill that aggregates usage. However, such an approach sets up a barrier to spontaneous usage. Instead, researchers have attempted to develop digital money that could reside in an electronic wallet on a hard drive, or in a mobile device. The basic idea is to have the consumer download some funds into his or her computer. This electronic cash could then be spent online, with appropriate controls, so that once handed over to a vendor, it is properly debited from the shopper. Ideally, digital money could support micropayments (even fractions of a penny), enable anonymous transactions, and prevent anyone from using the same tokens to pay more than one recipient. A famous example of an electronic cash system is the now defunct eCash from a company known as Digicash. Most of the digital money systems have not met with much success in the market (McCullagh, 2001).

One of the most successful e-commerce payment systems actually combines some elements from the above types of systems. PayPal, a payment service provider used on such services as eBay, operates somewhat like a closed user group, a credit card system, and digital money. It operates somewhat like an online bank account, from which customers can make purchases from vendors who use it. They can put funds into their accounts using a credit card or through funds transfer from their regular bank account. But PayPal is more open than other closed systems and relies on more than simple secure transmissions of card numbers. As noted earlier, account holders can send money to anyone with an e-mail address. This is an excellent example of what is called a viral marketing strategy, because anyone receiving payment by PayPal has to open up an account to actually obtain the money.

EMERGING TECHNOLOGIES

New technologies are constantly being developed for e-commerce. Some focus on enhancing the richness and vividness of the e-commerce experience, in an attempt to make it as compelling as shopping in real life. Work on virtual and 3D environments is ongoing, in anticipation of the day when consumers will have computers with fast processors and 3D video cards coupled with broadband Internet access. Early approaches have been used by clothing catalogue companies, such as Lands' End, which allow shoppers to create 3D models of themselves that can try on clothes. Each shopper can modify the shape and appearance of his or her model and then get some idea of how particular articles of clothing might look without personally trying them on. Virtual reality approaches go one step further, placing the online shopper in a synthetic environment. This is ideal for tourism, real estate walkthroughs, museum visits, and other types of products or services requiring a more experiential selling approach.

Another emerging set of technologies involves the design of software agents that act on behalf of an online shopper or vendor. One early type of agent was known as a shopping bot (short for robot), which could search out items and provide price comparisons. Agents can be programmed to perform such tasks as track and place bids at auctions, find and negotiate prices on desired items, and buy and sell stocks. Research today explores how agents behave, especially when interacting with other agents in what are called multiagent systems.

Perhaps one of the most exciting new e-commerce developments to watch is the extension of online shopping into the mobile arena. Mobile handset manufacturers such as Nokia are building cellular phones with Web browsing capability. Next-generation cellular networks support packet switching and Internet protocol traffic. New protocols, such as the wireless application protocol (WAP) and the wireless markup language (WML), enable the quick translation of Web pages into a format readable on small cellular phone and PDA screens. Once this user and network infrastructure is in place, people will no longer be tied to a desktop computer in order to surf the Internet and shop online. They are free to engage in e-commerce anytime and anyplace. Mobile, or m-, commerce is generating much interest, primarily because the global number of cellular subscribers is now more than 1 billion, which far exceeds the number of people who have computers connected to the Internet.

Many m-commerce services will be based upon the particular location of shoppers, allowing someone in a car, for example, to find the nearest vendor of a particular product. These types of services are collectively known as location-based services. In the United States, the FCC has mandated that all cellular operators be capable of determining the location of cell phone users in order to support emergency 911 services. However, there are numerous e-commerce uses of location data, and we are likely to see a wide range of services appear. Users may use their mobile device to search for available vendors in an area, receive directions from their current location to a vendor, make payments at the point-of-sale device, and receive advertisements based upon their interests when they near particular locations. Location-based services thus blend e-commerce and physical commerce in new ways, blurring the traditional online/offline distinctions of the past.

BARRIERS TO E-COMMERCE DEVELOPMENT

E-commerce has grown rapidly, but still it accounts for only a small fraction of purchases due to a number of critical barriers. Of course, there are always economic and technological barriers that can explain low e-commerce usage in many parts of the world. Obviously, e-commerce, especially when directed at consumers, has little relevance in places where there is limited computer penetration and most households do not have phone lines. Yet even in countries like the United States—where 94% of households have telephone service, two thirds of households have computers, and more than half of the population uses the Internet—only about 1% of retail trade occurs online. Among the more frequent explanations for low take-up of e-commerce are lack of trust in online vendors, security concerns, and incompatible consumer needs and desires.

Trust was largely an issue when thousands of new and unfamiliar dot-com companies flooded the Internet. Consumers were reluctant to shop at unfamiliar online stores for fear that their orders would not be fulfilled, or that they would not be able to return defective merchandise. The same problem prevents businesses from buying from unfamiliar suppliers, who have not proved that they are both trustworthy and competent to handle the business. To combat this problem, e-commerce companies often relied on trusted third parties—firms like Verisign or Trust-E—that would vouch for the legitimacy of an online vendor. Dot-com companies display the icon from these trusted third parties to help generate trust. Today, this issue is abating as e-commerce brands become better known, and as established firms move into e-commerce. However, consumers have new concerns about how e-commerce companies will use the information they collect. This is a privacy issue on its face, but it also reflects a lack of trust that online vendors will behave responsibly. Many firms now proclaim their privacy policy to help combat this issue.

A related issue is the fear that many online users have over the security of online transactions. Theft of credit card numbers and personal information are chief concerns. Secure transactions help to some extent, but these do little good when hackers find ways to break into corporate networks and steal entire databases of credit card numbers stored on servers.

Finally, for many purchases, e-commerce may not be the best approach given consumers' needs, desires, or home situations. For example, when someone needs a product immediately, they are much more likely to pick it up at a local store than wait one or more days for delivery. Some click-and-mortar firms, such as Best Buy, recognize this need and now offer in-store inventory search and pickup options for online shoppers. Other consumers see shopping as a social and entertainment activity, and a visit to the mall with friends is hardly replaceable by e-commerce. Finally, some services simply require too much of consumers to be viable. For example, in order to buy groceries, including perishable items, online, someone needs to be home at the time of delivery. This scheduling may be difficult, and to get around it, some companies attempted to use refrigerators in garages to which deliverymen had access. Yet this also requires consumers to open up their private space to strangers, and the costs of installing appliances at customer premises proved to be impractical. Moreover, not everyone had a garage, which limits the market. These are just a sampling of shopping situations where e-commerce might not be the best option.

THE ECONOMIC AND COMPETITIVE IMPACTS OF E-COMMERCE

E-commerce represents both a threat and an opportunity for most companies. It can be expensive to implement, and firms must carefully evaluate the competitive benefits they might achieve. In this section, we examine some of the competitive and economic issues raised by the advent of e-commerce.

Competitive Advantage and E-business

Information systems researchers have long recognized the fact that information technologies are important competitive weapons (Porter & Millar, 1985). Innovative IT applications and networks help firms to lower costs and allow them to offer new value-added services that serve to differentiate a company from its competitors, which are the two basic competitive strategies discussed by Porter (1985). Information technologies and networks can be deployed throughout every firm's value chain, which is the set of activities through which any company converts inputs, such as raw materials and labor, into products that can be sold to customers. E-commerce can permeate the value chain, reducing the costs of acquiring supplies, enabling firms to reach into new markets via the Internet, and supporting such value-added services as product customization and personalization of the information made available to customers.

By enabling access to distant markets without requiring expensive brick-and-mortar investments, e-commerce lowers important barriers to the entering of new markets. Moreover, because it is so easy to bundle new products over the Web, e-commerce can introduce new competitors into existing industries. Hence, one effect of e-commerce is that incumbent firms in any industry have faced new competitors that were formerly kept out by virtue of geography or other high-cost factors. New technologies may also substitute for existing ones, such as when consumers use new music formats in place of purchasing CDs at stores or online.

Yet e-commerce has another effect due to its ability to help companies pursue a differentiation strategy. Companies that gather information from customers and use it to help offer highly personalized services, or that provide incentives to keep customers returning to their Web site, create what has been called "sticky" e-commerce (Shapiro & Varian, 1999). This is when e-commerce raises customers' switching costs (the costs to move to a different supplier of a good or service), raising a new barrier that can help prevent other firms from successfully attacking a particular market. Network externalities—which create positive feedback loops, so that the larger the service, the more attractive it is—also work to make it difficult for new firms to attack established players. For example, eBay is so attractive because its large user base increases the likelihood that people will always find the specific product they are seeking. This, in turn, draws more sellers, which attracts more buyers, and so on. Smaller services have trouble competing with this dynamic. Such differentiation effects demonstrate that e-commerce does not make exchanges frictionless, and this result would not, in any case, be in the interest of merchants.

Alternative perspectives point out other reasons why new entrants may find it difficult to dislodge incumbents in any industry. Afuah and Tucci (2001) point out that incumbent firms normally possess crucial resources that new entrants may not have. These are often called complementary assets, and they include such factors as established relationships with suppliers, experience, access to retailers, powerful information systems, and strong distribution networks. Indeed, the rise of click-and-brick e-commerce shows forcefully how incumbent retailers can better capitalize on e-commerce than the new dot-coms that do not possess the required complementary assets.

There are many other potential impacts of e-commerce on the competitive dynamics of industries. In addition to the rivalry among competitors in an industry, and the potential threat from new entrants and substitute products noted above, Porter (1980) directs our attention to threats arising from elsewhere in the value chain, including suppliers and buyers. A good example of e-commerce enhancing the bargaining power of suppliers occurs when manufacturers threaten to bypass retailers to sell directly to customers. To the extent that this threat is credible, it may reduce the ability of retailers to capture more of the value when they resell products and services to end consumers. The threat of disintermediation is discussed in more detail below. Good examples of the ways that e-commerce can enhance buyer power are noted in the section above, on consumers in e-commerce. Reverse auctions such as Priceline illustrate how a market can become more buyer-centric. Other enhancements to buyer power through e-commerce occur when individual consumers band together to obtain the types of volume discounts normally only offered to larger business buyers. Third parties that organize this cobuying capability are known as buyer aggregators.

E-commerce and Transaction Costs

The primary way that e-commerce helps companies reduce costs and enable their entry into new markets is by reducing what economists call transaction costs (Williamson, 1975). Every commercial exchange, including C2B and B2B exchanges, is a transaction that can be broken into a number of discernible stages, each with its own set of costs to the participants. At the simplest level, we can consider any purchase to require an information or prepurchase phase, a purchase phase, and an after-sales, or postpurchase, phase. During the information phase, for example, buyers face search costs, while sellers have costs in supplying purchase information to buyers. During the purchase face, other costs are associated with negotiation, monitoring contracts, and actual financial settlement. Postpurchase costs include repairs, returns, and other types of customer services. When transaction costs get too high, markets become inefficient, and prices can be higher than they should be. For example, imagine a small town with one seller of some product. Without the Internet, customers in this town face high search costs (e.g., driving to another city to look in stores there) with uncertain payoff. So they pay the higher prices charged by the local monopoly provider. With the Internet, customer search costs for finding lower-priced suppliers are dramatically reduced, forcing the local monopoly seller to lower its prices. Because of this effect, many economists believe that the Internet will help reduce prices across all industries (Bakos, 1997). Indeed, it became popular to talk about the "death of distance" as a barrier to commerce due to the reduced transaction costs afforded by e-commerce. However, such an analysis overlooks many important influences on the price of any product, including the fact that online products differ in many ways from their counterparts in a store. Online products are not immediately available and cannot be touched, smelled, or otherwise physically examined, and perceived risks (e.g., ease of returns) may be higher. It further ignores the importance of established relations between buyers and sellers, a notion discussed next. Transaction cost frameworks must be extended to deal with these issues.

Market Structure and Buyer–Seller Relations

The reduction in transaction costs afforded by e-commerce is proposed to have another big economic effect, primarily at the B2B level. If transaction costs can be reduced, then market mechanisms may be used where they were not feasible before, based on an early theoretical argument proposed by Malone and colleagues (Malone, Yates, & Benjamin, 1987). For example, suppose a company needed a very specific type of input, only available from one particular supplier in its area. In the past, this company was at a disadvantage. Due to information asymmetries (the supplier knew what it cost to make the goods, but the buying company did not) and lack of alternative providers, the supplier could charge higher prices. However, the reduced search costs and greater information available on the Internet reduce these asymmetries and increase choice. Hence, firms can avoid being locked into long-term relationships and can use more spot-market buying behavior to source the inputs they need. The theoretical prediction was that such uses of e-commerce would give rise to large electronic marketplaces where businesses could buy inputs based purely on the best available offers.

Although e-commerce did result in the formation of large B2B electronic marketplaces that offered both manufacturing (vertical) inputs and commodities (horizontal) supplies, the above prediction has not been entirely supported. First, most of the third-party-developed B2B markets have failed (Laudon & Traver, 2001). Substantial empirical evidence suggests that firms are more likely to use e-commerce to increase the efficiency of transactions with trusted suppliers than to enable spot transactions with new suppliers (Steinfield, Kraut, & Plummer, 1995). Hence, they were less likely to allow new third-party firms to position themselves as profit-making intermediaries in these well-established relationships. Instead, the bulk of B2B e-commerce occurs over private industrial networks typically organized by larger buyers or sellers. Often a large company will function as the leader in a value network that encompasses firms up and down the value chain. These value networks compete with other value networks, as an extension to simple firm-to-firm competition. The B2B e-commerce links permit more than just simple buy and sell transactions—they enable collaborative e-commerce among networks of firms, allowing such activities as codesign of components and joint marketing efforts.

Intermediation and E-commerce

As noted above, e-commerce can enable producers of goods and services to bypass intermediary firms, such as wholesalers and retailers, and sell directly to end customers. This effect has come to be called disintermediation and is often anticipated because of the belief that the Internet reduces producers' transaction costs for accessing end customers. Many producers were swayed by this logic and began to sell products directly from their Web sites. For some companies, such as Dell Computer and Cisco, the direct-sale business model made a great deal of sense, and the Internet provided a cost-effective way to manage it. Most of their customers were businesses already connected to the Internet and accustomed to doing business in this way. For others, especially those selling to consumers, this approach made less sense. Sarkar and colleagues showed early on that, in fact, the Internet provided as much or more opportunity for new forms of intermediation, and that it also helped to strengthen the role of existing intermediary firms (Sarkar, Butler, & Steinfield, 1995). They argued that intermediaries' transaction costs were also reduced, and the gains they get from e-commerce may negate any advantages producers might gain. They also note that intermediaries provide many functions to both buyers and sellers, such as needs assessment and evaluation, market information, and risk reduction, which are critical for many purchases. Many subsequent analyses demonstrated the fallacy of the disintermediation hypothesis (e.g., Schmitz, 2000). Marketing theorists caution that although particular intermediaries might be eliminated, their functions cannot be, which suggests that a role remains for intermediaries even in the age of e-commerce (Stern, Ansary, & Coughlin, 1996).

Pricing and E-commerce

Because of the reduction in transaction costs, and because of access to information about prices of alternative vendors, a primary effect of e-commerce was supposed to be lower and more homogenous prices relative to traditional channels. Up to now, the evidence for lower prices is rather mixed, especially when the added costs for shipping are taken into account. Moreover, price dispersion remains high, contrary to the expectations of economists (Smith, Bailey, & Brynjolfsson, 2000). It appears that because it is so easy to change prices (referred to as menu costs), Internet companies make more changes in smaller increments in response to the market.

Another reason there is variability in prices is that e-commerce makes it easier to engage in price discrimination, whereby vendors sell the same product to different customers at different prices. The goal, of course, is to learn what each customer's willingness to pay is, and then to charge him or her that price. One way this can happen is through auction pricing, which allows customers to submit their willingness to pay in the form of bids. Another popular price discrimination approach is to charge different prices for different versions of the same product or service (e.g., a student version of software versus a professional version) (Shapiro & Varian, 1999). Sometimes e-commerce companies have tried to estimate willingness to pay based upon some aspect of online behavior. Amazon.com, for example, once angered its customers when it was revealed that the online vendor had attempted to charge higher prices to returning customers, based on the assumption that these loyal customers would be less likely to switch to other online sellers. They soon stopped this practice. Another method of price discrimination is to make assumptions about willingness to pay based upon the referring site. Thus, if a shopper arrives at an online retail site by way of a comparison shopping agent or a discount shopping site, he or she may be presented with a lower price than a shopper who had clicked on an ad in an upscale investment journal.

Collectively, the research in this area shows that e-commerce effects are not so straightforward as was once believed. Many popular notions about e-commerce effects, such as the rise of disintermediation, the death of distance, and the emergence of frictionless commerce, are now viewed as myths.

CONCLUSION

In this chapter, we have provided a broad overview of e-commerce, introduced a brief definition, and showed how the creation of a ubiquitous, easy to use, and open data network helped e-commerce emerge as a powerful force from the many precursor systems and technologies. We discussed the development of innovative business models and noted the problems that dot-coms faced when they attempted to delay profits in exchange for market share. Many powerful marketing strategies were introduced, as was the rise of consumer-centric markets. Ancillary technologies needed to enable e-commerce, such as payment systems, and emerging technologies, such as mobile commerce that will extend e-commerce, were also discussed.

A critical theme of the chapter is that e-commerce impacts are not straightforward, and claims of revolutionary changes must be carefully scrutinized. Important barriers to its development remain. Research on the competitive and economic impacts yields many findings that run counter to early expectations.

Despite these barriers and unanticipated impacts, our analysis still suggests that e-commerce will become increasingly pervasive, even without the headlines that tracked every new dot-com in the early years. There are a number of reasons for this expectation. First, as noted earlier, e-commerce usage is continuing to grow, despite the economic slowdown plaguing much of the world in 2001 and 2002. Moreover, even though IT spending is down and telecommunications firms are currently struggling, the high pace of investment throughout the 1990s means that the infrastructure is now in place to support e-commerce. The Internet backbone networks are fully capable of supporting more traffic and can accommodate the slow but steady growth in broadband access. This will, we hope, improve the responsiveness of e-commerce sites, encouraging more use. New technologies, such as the extension of e-commerce to mobile devices, will likely increase the pervasiveness of e-commerce. The dot-com bust may cause some to be pessimistic, but it can also be viewed as a normal evolutionary process at the start of a new industry. Poor business models have failed, but viable ones have survived and may prosper once the economy improves. Moreover, the entry of established companies into e-commerce is lending more legitimacy to the sector and should help overcome trust problems. These firms also have the resources and alternative sources of income to enable their e-commerce channels to develop appropriately, without reckless moves aimed at capturing market share at the expense of profits. Finally, continued B2B e-commerce development is enhancing efficiency in the supply chain, which can also carry over to B2C e-commerce. In summary, e-commerce will continue to spread throughout the economies of the world, but our analysis suggests that the economic effects will be complex and, at times, counterintuitive.

GLOSSARY

B2B electronic hub Electronic marketplaces where business buyers can acquire goods from suppliers. Vertical hubs focus on the provision of manufacturing inputs bringing together firms operating at various stages inside a particular industry value chain. Horizontal hubs focus across industries, bringing buyers and sellers of a wide range of maintenance, operation, and repair goods (MRO) to the market.

Buyer aggregation The process of organizing small buyers into a cooperative buying group in order to obtain volume discounts.

Collaborative e-commerce A form of B2B e-commerce among cooperating networks of firms that involves more than just purchases; also, such activities as the codesign of components and joint marketing efforts.

Complementary assets Resources possessed by a firm that enable it to take better advantage of innovations like e-commerce. These resources include established relationships, product know-how, existing business processes and systems, and distribution systems.

Disintermediation An effect of e-commerce whereby producing firms bypass traditional intermediaries and sell directly to end consumers.

Dot-com A name given to Internet companies because their network name ended in ".com."

EDI Electronic document interchange, a standard for transmitting business documents over computer networks.

Intermediary An entity that facilitates trade between buyers and sellers. Wholesalers and retailers are considered to be intermediaries that help manufacturers sell their products to the end consumers. Real estate agents are intermediaries who bring together home buyers and sellers.

Internet business model A generic term referring to the methods of doing business and generating revenue on the Internet.

Network externalities A term describing the benefits generated by having more people who used a service, such that the more people who use it, the more value it has for all users.

Price discrimination A pricing strategy whereby vendors sell the same product to different customers at different prices in an attempt to maximize overall revenue by matching prices to customers' willingness to pay.

Switching costs The costs a buyer faces when changing to a different supplier of a good or service.

Transaction cost Various indirect costs faced by buyers and sellers as they complete a commercial exchange, including search and information-gathering costs, monitoring and settlement costs, and after-sales and service costs.

Electronic Data Interchange (EDI)

Matthew K. McGowan, *Bradley University*

INTRODUCTION

Electronic data interchange (EDI) is the computer-to-computer exchange of business transactions in standardized formats. EDI represents a type of interorganizational information system (IOIS) because it involves an electronic link from one organization to another organization. It is also one of the earliest forms of electronic commerce. Businesses use EDI to conduct business-to-business (B2B) electronic commerce. B2B electronic commerce is the largest portion of electronic commerce. According to a recent study by the United States Census Bureau, manufacturers were the largest business users of electronic commerce, conducting 18.4% of their orders as electronic transactions in 2000. EDI allows businesses to send and receive business transactions electronically, resulting in faster processing and greater accuracy. EDI is an enabling technology for full business-to-business integration of systems. Bell Helicopter (2002) uses EDI to support many aspects of its business with suppliers, including request for quotes, shipping schedules, order status, invoices, and payments.

EDI requires (1) translation of transactions into standard EDI formats, (2) transmission of transactions to the trading partner, and (3) translation from the standard formats into the formats used by the information systems processing them. In traditional EDI, companies frequently rely on communication service providers for private network communications links with trading partners. Internet-based EDI is rapidly evolving, permitting companies to bypass private networks in favor of the Internet. Internet-based EDI has the potential to reduce communication costs but carries higher security risks than traditional EDI. Large companies may be able to provide Web-based alternatives to traditional EDI for their small trading partners that require little technical expertise or expense.

Potential disadvantages of EDI include security, transaction errors, authentication, nonrepudiation, reliance on third parties, and the costs of implementing EDI. The technical issues of implementing EDI may seem minimal to a large company with an EDI specialist, but can seem overwhelming to small companies with little technical expertise (McGowan & Madey, 1998).

Many organizations credit EDI with attainment of strategic and tactical advantages. EDI may also present organizational and administrative challenges. Companies must develop agreements with their trading partners and consider whether this information sharing will affect their bargaining power with their trading partner(s).

The following section contains a description of EDI and provides some historical perspective on its development.

WHY EDI?

Organizations have traditionally relied on paper in conducting business. Many companies developed standard forms to organize the information needed to conduct a transaction and to be sure that the information was complete. The postal service was a primary means of exchanging business documents. Innovations such as express delivery services (e.g., FedEx) and facsimile transmission allowed organizations to conduct business transactions more rapidly. Paper, however, remained the primary communications medium. When an organization receives a business document by fax or paper, someone must enter the information from the form into the appropriate information system. This step takes time and introduces opportunities for human errors.

To send a business form to a trading partner, the organization must first print the document from the information systems and then mail or fax it to the trading partner. Each organization is likely to use a different format for its forms. Because the forms do not have a standard format, it may be difficult to obtain the appropriate information from the form.

EDI, on the other hand, uses standard formats, which makes it possible to parse the information into a format for the appropriate information system to process. The business document exists electronically, so software can convert the document into a form suitable for the business application and no human intervention is required.

A company could send business documents via traditional electronic mail. That would still require human intervention and would still lack a standard format. There is the potential for using electronic mail for EDI so that no human intervention is required. A subsequent section of this article dealing with Internet-based EDI addresses that option.

HOW EDI WORKS

What follows is a discussion of how EDI operates, the alternative communications approaches for EDI, the costs of EDI, and the role of Value Added Network (VAN) providers.

Overview

Electronic data interchange uses a standard format for the exchange of business documents between two trading partners. Figure 1 illustrates an example of the EDI process. The example shows a supplier sending an advance shipping notice to a buyer. Specifically, the supplier's shipping system is sending advance shipping notices to a buyer's receiving system. In this example, the data already reside in a computer information system. The first step in the EDI process is for an application program to extract the data from the shipping system. Next, a program translates the data into the EDI standard format for an advanced shipping notice. In the third step, EDI translation software converts the extracted data into the standard format for EDI. The supplier's EDI document management software transmits the document(s) to the buyer via a communications network.

The communications network can be a private network such as a value added network (VAN) or it can be the public Internet. The buyer receives the advance shipping notice via its EDI document management software and translates the documents into a file for the appropriate application system (in this case, the receiving system), and then an application program in the receiving system loads the documents into the buyer's receiving system.

Organizations that do not have the data for EDI transactions in existing computer systems can still use EDI to exchange business transactions. Several EDI software vendors sell software that permits a company to enter data directly into the EDI software. The software then formats the EDI transactions and transmits them over the communications network. A company could even choose to print the data from an information system and rekey it into the EDI software, rather than create an extract program. Similarly, companies can receive transactions into EDI software and then print the business documents from the EDI software. People frequently refer to this form of EDI as paper-based EDI because of the paper involved with the process. However, companies do not obtain the benefits of a fully integrated system when using this technique (McGowan & Madey, 1998).

Value Added Network Services

VAN service providers can assist with many aspects of the EDI process. VAN services can include electronic

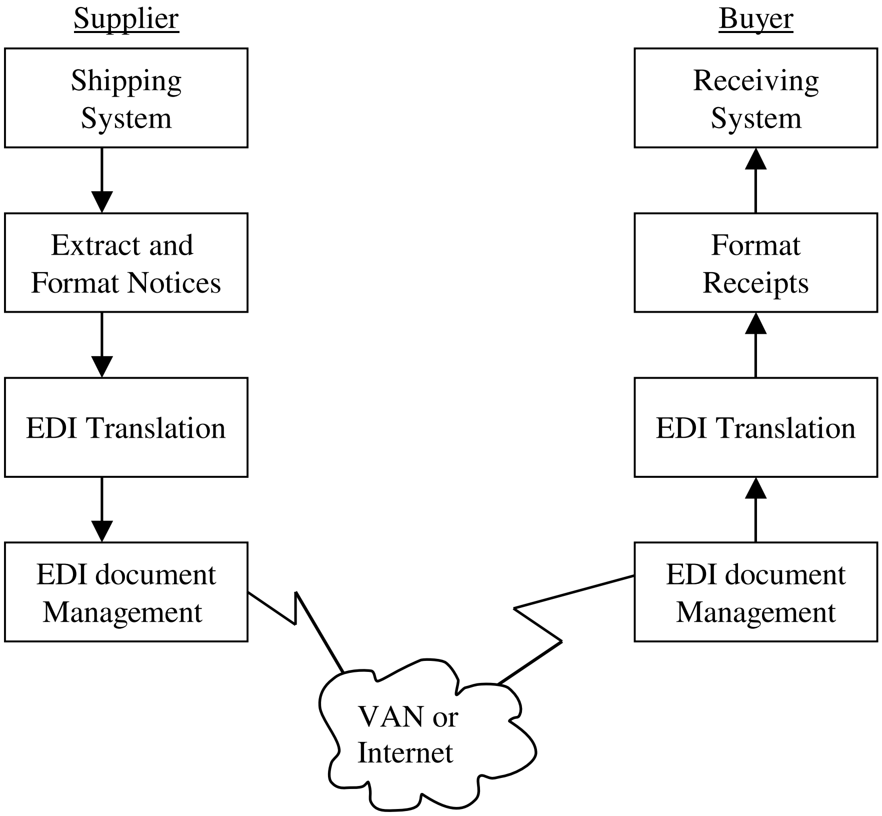

Figure 1: Steps in the EDI process.

mailboxes, connectivity, translation services, security, and an audit trail (Copeland & Hwang, 1997). The electronic mailbox feature is the most common reason for using a VAN. The VAN stores EDI documents into the company's electronic mailbox, allowing a company to retrieve the documents as desired. The VAN can also provide a service that forwards documents to the company or notifies the company if the company desires immediate notification or uses event-driven processing in its business (Copeland & Hwang, 1997).

The VAN provides connectivity to other trading partners. The VAN can store a company's documents in the electronic mailboxes of its partners, or it can forward a document to a partner's VAN (Copeland & Hwang, 1997). Thus, a company does not need to maintain a mailbox with each one of its partners' VAN providers.

VAN services can include translation of data into EDI formats. A company could provide an extract of its business data to the VAN and the VAN could translate the data into EDI documents.

A VAN provider can help with security. Security services include access control, authentication, and encryption (Copeland & Hwang, 1997). Mailbox access generally requires a user ID and password. The VAN can check that an authorized trading partner sent documents and that the documents are in a valid format. Encryption service can ensure confidentiality. VAN providers can provide private line connections or switched access to avoid potential security flaws of the Internet.

The VAN may also provide an audit trail for documents processed via EDI. The VAN can provide automatic acknowledgments to trading partners that require them. The VAN can also provide tracking information for documents (Copeland & Hwang, 1997).

Transmission Alternatives

There are three common alternatives for transmitting EDI documents: private VAN network(s) the public Internet, and direct connection to the trading partner. Traditional EDI uses a VAN network service to send the EDI documents to the trading partner. The VAN stores the EDI documents in an electronic mailbox that it manages for the trading partner. If the trading partners use different VAN providers, then the VAN provider of the sending trading partner forwards the EDI documents to the VAN provider of the receiving trading partner.

The second alternative for transmitting EDI documents is Internet-based EDI. Several techniques are available for Internet-based EDI and it is the fastest-growing form of EDI. All Internet-based EDI techniques rely on the public Internet as the communications network. A more complete discussion of this popular form of EDI will be presented later in this article.

The third alternative for transmitting EDI documents is for one trading partner to maintain a proprietary electronic mailbox system. With the proprietary system, the company maintaining the system allows its trading partners to send documents to and receive documents from the electronic mailboxes. In this case, the EDI traffic is limited to transactions involving the company hosting the proprietary system. A large company might use this approach to reduce the charges from its VAN provider.

Companies may use several of these approaches for their EDI transactions. For example, a company might use traditional EDI for some trading partners, Internet-based EDI for other trading partners, and proprietary systems for a third group of trading partners.

EDI STANDARDS

The EDI process requires that business documents be in a standard format. The first instances of EDI relied upon proprietary formats to exchange business documents. Wal-Mart and K-Mart used proprietary formats when they first implemented EDI (Choudhury, 1997). The problem with proprietary standards is that it is difficult to exchange transactions with many trading partners because of all the format conversions (Chan, 2002). Having standard formats for business documents means that all trading partners can understand the document structure and interpret it correctly.

There are two major sets of standards for EDI: the American National Standards Institute Accredited Standards Committee X12 (ANSI ASC X12, or more usually, X12) standard, and the United Nations Electronic Data Interchange For Administration, Commerce, and Transport (EDIFACT) standard.

The EDIFACT Standard

The United Nations developed EDIFACT as an international standard to help facilitate EDI for international commerce. The International Standards Organization (ISO) and the United Nations Economic Commission for Europe share responsibility for developing and maintaining the EDIFACT standard (Chan, 2002). The EDIFACT standard is essentially a combination of the X12 standard from the United States and the Trade Data Interchange (TDI) standard developed in the United Kingdom (Chan, 2002). The EDIFACT standard includes components similar to the X12 standard.

The X12 Standard

ANSI specified the development of the X12 standard to help facilitate EDI in the United States, and it is the most commonly used format in the United States. The X12 standard defines the data structure, content, syntax, and sequencing for business documents. The X12 standard specifies a type of business document as a transaction set. For example, there are transaction sets for business documents such as Purchase Order, Invoice, and Advanced Shipping Notice. There are currently more than 275 different transaction sets in the X12 standard. The standards committee assigns a name and number to each transaction set. Table 1 shows a partial list of the transaction sets. For example, an invoice document has the code of 810.

The X12 standard specifies data segments and data dictionary for each transaction set. A data segment is a group of related data elements. For example, one data segment might include the data elements related to the buyer's address, and another data segment might include the data elements related to the supplier's address. The data dictionary defines the exact content of the data elements

Table 1 Partial list of X12 Transaction Sets.

Transaction	Code
Invoice	810
Operating expense statement	819
Payment order/remittance advice	820
Customer account analysis	822
Lockbox	823
Planning schedule with release capability	830
Price/sales catalog	832
Request for quotation	840
Response to request for quotation	843
Product transfer account adjustment	844
Price authorization acknowledgment/status	845
Inventory advice	846
Response to product transfer account adjustment	849
Purchase order	850
Purchase order acknowledgment	855
Shipping notice/manifest	856
Purchase order change request	860
Receiving advice	861
Shipping Schedule	862
Report of test results	863
Purchase order change request acknowledgment	865
Product transfer and resale	867
Order status inquiry	869
Order status report	870
Functional acknowledgment	997

that comprise transaction sets. For example, the standard could specify the invoice identifier data element in the invoice transaction set as the unique identifier for an invoice.

The segment directory contains the formats and definitions for the data segments used in creating transaction sets. For example, the invoice transaction set may require an invoice identifier that may be 4 to 10 numeric characters. A loop is a repeating group of segments or segment groups that are part of a transaction. For example, an invoice transaction segment may contain loops consisting of line items for that invoice.

The X12 standard defines transmission control standards for the electronic envelope required to interchange data. Several types of transaction groups destined for the same recipient may be included in a single interchange envelope. Figure 2 illustrates an example of the X12 interchange format. In this example, one interchange envelope includes two shipping notices and one invoice grouped together for transmission to a single customer. There is a single functional header for the shipping notice documents. Each shipping notice has its own transaction set header and transaction set trailer.

Industry Conventions for Use

The X12 transaction set definitions provide users with many potential data elements that can be included in a business document. For example, the Purchase Order (number 850) transaction set defines over 160 segments of data, and each segment can have up to six data elements (dmx.com, 2002). Several industries have developed conventions to specify which segments and which data elements the industry will use in various documents. The automotive industry and airline industry have each developed a set of conventions to specify the standards of use in their respective industries. In lieu of industry conventions, larger companies may dictate to smaller trading partners what conventions to use.

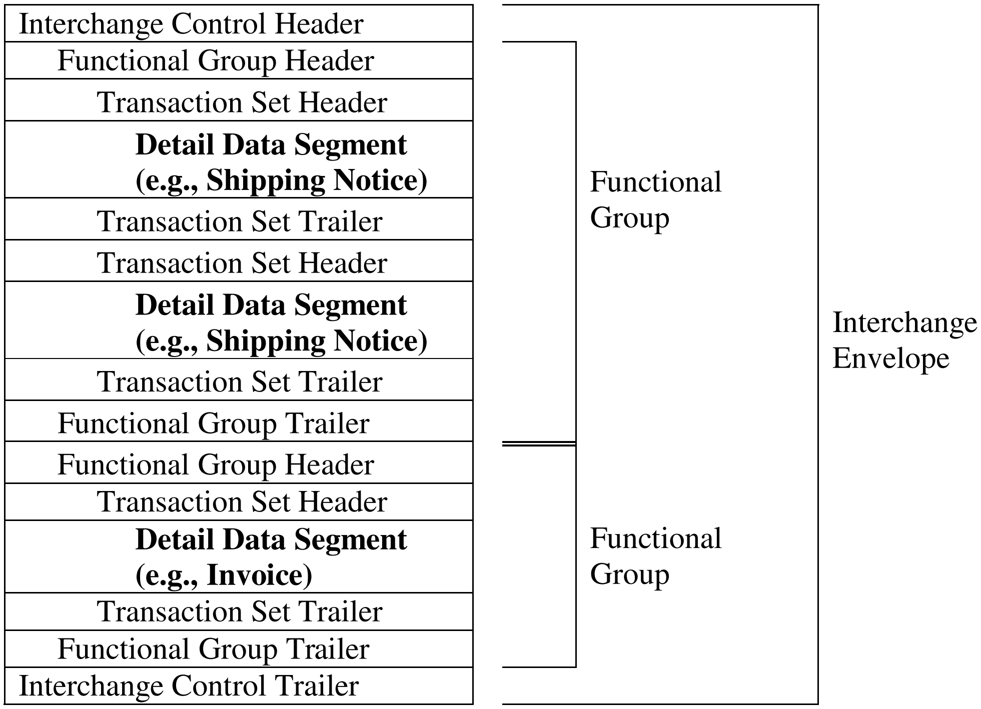

Figure 2: X12 EDI Interchange Format.

The X12 standard has been evolving. The organization responsible for managing EDI standards in the United States is the Data Interchange Standards Association, Inc. (http://www.disa.org). The organization manages both the X12 standards and the EDIFACT standards (Houser, Griffin, & Hage, 1996).

The X12 standard specifies the format and grouping of the data and transaction sets. A data interchange standard is independent of the communications media used to transmit the business documents. A company could choose to use traditional EDI via a VAN, Internet-based EDI, or a proprietary communications network using the X12 standard.

INTERNET-BASED EDI

The Internet provides an inexpensive communications network for performing EDI, so several companies have elected to use the Internet to perform EDI. There are several ways to use the Internet to conduct EDI transactions, but there is currently not a standard approach. Some of the Internet approaches allow organizations to bypass more costly VAN networks. VAN providers have responded by lowering EDI fees and by offering Internet-based services. Companies are using each of the following approaches: exchanging files of transactions using the file transfer protocol (FTP) (dmx.com, 2002); employing a VAN or related service (dmx.com); exchanging transactions via e-mail using multipurpose Internet mail extensions (MIME) (Chan, 2002); or simply using the Web as a means of entering transactions (Bell Helicopter, 2002).

Using the FTP approach to Internet-based EDI may require additional software and custom programming, but could use compression techniques to reduce bandwidth requirements (dmx.com). This usually requires creating a user id and password for each trading partner, and agreement on naming files and directories for messages (Houser et al., 1996).

VAN providers are not standing idly by while EDI moves to the Internet. Many VAN providers are emphasizing their other services while allowing their customers to use the Internet as the communications network for EDI transactions. VAN services can include encryption to secure transactions, compression to speed communications, and software services to ensure the reliable completion of the EDI process (dmx.com).

MIME is an extension of the Internet e-mail protocol that allows the Internet to carry many types of messages via e-mail (Chan, 2002). The extension supports both the X12 and EDIFACT standards for EDI, but specifies how to translate them into a MIME format that a company can send via the Internet (Chan, 2002). The EDI transactions travel via the Internet's e-mail system and the receiving end converts them from the MIME format back to the EDI standard. A company could set up various e-mail destinations for different types of transactions or based on the company submitting the transactions.

Bell Helicopter employs an Internet-based EDI technique that it classifies as Web-based EDI. Using this approach, a trading partner enters the transaction information into an online form and transmits the transaction to Bell Helicopter (2002). The approach provides Bell Helicopter with the advantages of capturing the transaction electronically. It is inexpensive to Bell Helicopter's trading partners because the trading partner only needs a Web browser connected to an Internet service provider (ISP). This approach does not require a significant level of technical expertise on the part of the trading partners. Using this approach, the trading partner does not benefit from capturing the transaction data electronically into its business system.

Many EDI software providers offer software that companies can use for Web-based EDI (Messmer, 2000). For example, one vendor's software includes a server component that includes business forms for entering transactions and another component that a trading partner can download to a Web browser. The company with the Web server software can define the forms for its trading partners to use. The trading partners can fill in the appropriate forms via their Web browsers and submit the transactions to the company for processing along with other EDI transactions.

Extensible markup language, XML, offers the potential for Internet-based EDI. XML is a language for defining documents containing data. It has advantages over HTML because it separates the structure of the data from the content and display of the data. One could define a document in XML and then use that document definition to transmit data across the Internet. It would be possible to define XML documents that contain the same data elements as X12 documents. An extension to XML, electronic business XML (ebXML) is currently under development.

Advantages and Disadvantages of Internet-Based EDI

The two major advantage of Internet-based EDI are the reduced communications costs and the widespread availability of the Internet (Chan, 2002). VAN networks typically charge fees based on usage levels whereas Internet access is typically a flat fee. Companies that have Internet connections can use the Internet for EDI and other applications.

The Web-based EDI employed by Bell Helicopter provides a way for larger trading partners to obtain the benefits of EDI without requiring a significant investment of money or technical expertise from its small trading partners. The larger organization can still process transactions in an automated way through its EDI interface.

The three primary disadvantages of Internet-based EDI are the lack of standards, security, and bandwidth and reliability of the Internet. As discussed previously, there is not a single common approach to Internet-based EDI. Because the Internet is a public network, it is inherently less secure than private networks. Lack of security of EDI transmissions is a disadvantage of Internet-based EDI. Companies can use several of the Internet approaches securely if they employ encryption techniques. The Web-based approach used by Bell Helicopter could use a secure http connection to ensure the security of EDI transactions. When using a VAN network, the VAN provider ensures adequate bandwidth and network availability (Chan, 2002). Because the Internet is a public network, there is no organization that guarantees its bandwidth and availability.

Some VAN providers are encouraging customers to use the Internet to exchange EDI transactions with the assurance that the VAN network is also available (dmx.com).

Despite the potential drawbacks of the Internet, companies are increasingly using the Internet for EDI. As more companies use the Internet, one or several standard approaches will emerge. The security of the Internet is increasing and there are already technologies available for securing transactions.

EDI IMPLEMENTATION ISSUES

Organizations that implement EDI must address the following issues: trading partner relationships, selection of one or more EDI approaches, development of an EDI infrastructure, system and business process changes, and user training. A company's relationships with its trading partners affect the ease of implementation of EDI. Some companies establish trading partner agreements that specify practices for EDI. Houser et al. (1996) suggest that these agreements be kept simple or that existing agreements be used for EDI. Industry practices may dictate what arrangements a company needs to make. It is generally easier to add EDI links with companies that are already doing business via EDI than with a company that is not using EDI. Larger companies may be able to coerce smaller trading partners to adopt EDI, but they should be aware of the costs to smaller trading partners.

The EDI process will likely mean a change in the way a company conducts business. For example, if a company is going to receive shipping notices via EDI, can the company integrate electronic documents into a business system without the need to rekey information? A company will need to maintain its current processes until its trading partners are all using EDI. Each time the company adds a partner to the EDI process requires an incremental effort. For example, the company must add the partner to a list of EDI partners, and the company should test each type of transaction with the partner.

The organization needs to plan which documents to exchange via EDI. Each additional document type requires an additional program to extract the data from or load the data to an existing system. For example, if the company decides to submit invoices via EDI, a program in the Billing System needs to extract the invoice information for translation by the EDI translation software.

Organizations that have greater levels of EDI and technical knowledge are able to implement EDI more fully than other organizations (McGowan & Madey, 1998). EDI has both technical and administrative components. Larger organizations may find that providing assistance to smaller trading partners will improve implementation. McGowan and Madey also found that organizations that made training available for EDI attained greater levels of implementation with EDI. The staff responsible for EDI needs to become familiar with the EDI software and tools.

EDI requires a significant organizational commitment. The costs (see following section) of EDI are not trivial. Top management support is necessary to ensure that resources are available for successful implementation. Organizations need an EDI champion, a person who can push the concept and overcome organizational inertia, to move forward with EDI.

Implementation Costs

The costs of EDI include the cost of data extraction and load programs, translation software, and communications costs. In-house programming staff typically develop the programs to extract data from or load data to existing systems.

Most companies purchase the software used for step two (translation to EDI format) and step three (software to manage document transmission) from an EDI software provider.

The communications costs depend on the alternative a company chooses. With traditional EDI, a VAN provider typically charges a flat monthly fee for the service and a usage fee based on the volume of transactions. A company can use Internet-based EDI either with or without the aid of a VAN. The communications costs are typically much less for Internet-based EDI than for traditional EDI.

A proprietary system requires the purchase or development of software to manage the electronic mailboxes. It also requires the hardware and network infrastructure to handle the EDI traffic load. This approach is not feasible for small companies, but large companies may find it cost-effective.

EDI Implementation and Business Strategy

Organizations should also consider how EDI applications will support the business and what type of system is appropriate for the company's competitive situation. A company may choose to implement EDI as a means of obtaining general benefits such as improved transaction efficiency, reduced errors, or lower costs. An organization could also implement EDI as a tactic in support of a specific business strategy such as just-in-time (JIT) inventory handling or as part of a continuous replenishment process (CRP).

Choudhury (1997) suggests there are three types of interorganizational information systems (IOISs), information systems shared by two or more companies: electronic dyads, electronic monopolies, and multilateral IOISs. He identifies two transaction characteristics (demand uncertainty and market variability) that influence the choice of IOIS. Because EDI is a type of IOIS, this model provides insight into an organization's choice of EDI applications. The model asserts that the selection of IOISs depends on the nature of the relationship an organization wants to implement with its suppliers/buyers.

An electronic dyad is a trading relationship in which a buyer purchases a particular product from one of a small set of suppliers. In an electronic monopoly, a buyer has one (exclusive) supplier. This situation could exist due to a market monopoly (only one supplier exists) or by choice (the buyer agrees to a sole-source supplier). A multilateral IOIS is one in which a buyer shops the entire market for each purchase. Purchasing an airline ticket through the Sabre reservation system would be an example of a multilateral IOIS. EDI is not well suited to this type of relationship because an organization addresses an EDI document to a particular trading partner. Further development of Internet-based EDI may permit this form of exchange.

Choudhury's (1997) contention is that electronic monopolies and electronic dyads both permit a greater degree of electronic integration than multilateral IOISs. He suggests that low market variability favors electronic dyads and electronic monopolies, the types of relationships well suited for EDI. For products with low volume uncertainty, the electronic dyad is the favored approach.

Iacovou, Benbasat, and Dexter (1995) make the following recommendations for EDI initiators, organizations that are encouraging small partners to use EDI, based on their study of EDI in small organizations:

Begin by developing a plan that includes small partners, even if they plan to start with large trading partners.

Assess the preparedness of each trading partner by examining resources (information technology expertise and financial ability) available and the degree to which EDI offers perceived benefits.

Provide technical and financial assistance to partners that are not ready for EDI.

Promote the benefits of EDI to the trading partner.

As a last resort, use coercive tactics, but keep in mind that the trading partners will not benefit as much from EDI when they are unmotivated, unprepared, and feel forced to implement it.

Hart and Saunders (1998) offer advice that is consistent with this. Their study found that when EDI initiators used cooperative strategies based on building trust in partner relationships, the partners were more like to have a greater volume of EDI transactions and to support a greater variety of transactions than when the firm used its power to coerce trading partners to use EDI. Both of the studies mentioned here emphasize the importance of dealing with the organizational as well as the technical issues of implementing EDI.

ELECTRONIC COMMERCE APPLICATIONS OF EDI

EDI is an effective technique for electronic commerce. Companies use EDI primarily for business-to-business (B2B) applications, the largest segment of electronic commerce. There are about 40,000 companies using EDI today (Houser et al., 1996), but the industries that lead in the use of EDI include the auto industry, the airline industry, the banking industry, and the credit card industry (Copeland & Hwang, 1997). The President of the United States, in 1993, issued an initiative to streamline the procurement process, and this is the fastest growing area of EDI (Copeland & Hwang, 1997).

One can use several dimensions to classify EDI applications. Previous sections of this chapter considered the standards (X12, EDIFACT, and proprietary) used in the application. One can also describe the different types of EDI applications based on the communications technology (VAN, proprietary network, Internet-based) used. People frequently differentiate information systems based on the business functions or processes the system serves. For example, EDI applications could include procurement, billing, logistics, payment, or other functional areas.

The following example illustrates the possible use of EDI in the procurement process. If a buyer has EDI links with multiple suppliers, the buyer could initiate an electronic Request for Quote (RFQ) to its suppliers. The RFQ would contain the same information as a paper RFQ, including product specifications, quantity required, and date needed. The suppliers who believed they could satisfy the quote would respond to the buyer with Quotations via their EDI links. The supplier would review the Quotations, select one, and initiate a Purchase Order via EDI to its selected supplier. The Purchase Order would include terms, conditions, and the information that would typically appear in a paper purchase order. The supplier would accept the Purchase Order by responding with a Purchase Order Acknowledgment via the EDI link.

BPR and CRP Applications

Organizations can implement EDI to obtain efficiencies such as improved processing speed or reduced human labor costs. However, companies achieve the greatest benefits from EDI when they implement process innovations concurrently with the implementation of EDI. Business process reengineering (BPR) and continuous replenishment process (CRP) are two types of process innovations companies pursue in conjunction with EDI implementation.

BPR involves making significant changes to organizational processes, a type of organizational change that is significantly greater than merely automating a function. For example, one could automate the Accounts Payable function by providing clerks with automated tools to enable them to match an invoice, a product receipt, and the purchase order for the product. Using BPR techniques, one could eliminate the invoice by paying the price on the purchase order for the number of units of product indicated on the product receipt. Successful BPR requires attention to organizational changes in addition to technological changes. Organizations considering the implementation of EDI should also examine the underlying processes involved to see if they should also pursue BPR.

CRP is a process innovation in which the vendor manages a retailer's inventory, replacing the typical approach in which the retailer places an order with the vendor (Lee, Clark, & Tam, 1999). This is a significant change in the inbound logistics for the retailer and a change in the traditional industry approach. Companies can use EDI to support CRP because EDI provides a way for the retailer to report inventory levels to the vendor. The vendor manages the retailer's inventory. Thus, the application of EDI is supporting a radical process change rather than simply automating the ordering process.

Lee et al. (1999) describe the use of EDI to implement a continuous replenishment process between Campbell and 31 grocery retail chains. Campbell managed the retailers' inventories, and this represented a significant change from traditional retail practices (Lee et al., 1999). Although some retail chains had previously used EDI to place orders, the retailers were responsible for managing their own inventories. The study found that the retail chains benefited from CRP and EDI because they achieved a significant increase in their inventory turns and reduced stockouts at the same time. As with other information technology investments, implementation requires attention to organizational as well as technological issues.

Internet-Based EDI Applications

The use of the Internet for EDI applications is rapidly growing. Many organizations are developing new EDI applications using the Internet, but still support traditional forms of EDI. Bell Helicopter (2002) is offering several EDI options to its suppliers as part of its electronic commerce initiative. Bell Helicopter planned a two-phase implementation. In the first phase, all suppliers would be set up to conduct business electronically. Phase two would involve the rollout of 10 types of EDI transactions. The company planned to have 1,000 suppliers active on EDI within a year. Suppliers had the option of using Internet-based EDI over the Web. For the Internet-based EDI, Bell Helicopter required suppliers to have an Internet connection and Web browser. The supplier could then enter transaction information via the Web browser for transmission to Bell Helicopter.

Wal-Mart began moving to Internet-based EDI in 1998 as part of a strategic and tactical initiative (Frook, 1998). Wal-Mart used packaged software to provide EDI services to smaller companies. The system reduced VAN costs for Wal-Mart and fit with the company's strategy to use more local suppliers. Some smaller suppliers had been unable or unwilling to absorb the expense of using VAN services. The system allows Wal-Mart's trading partners to register and download the required software through a self-service option. The system will permit small companies to automate transactions via EDI and allow verification of transmissions. Wal-Mart plans to develop a global EDI network. It has contracted with the software provider to develop foreign language versions.

Dal-Tile International Inc. implemented an Internet-based EDI system in 2001 to satisfy one of its major customers, Lowe's Companies Inc. (Greenemeier, 2001). The new system has resulted in closer coupling between the two companies. Dal-Tile implemented the EDI system to exchange documents including purchase orders and invoices, and the companies now use the system to share sales information, allowing Dal-Tile to better meet Lowe's needs. Dal-Tile did not previously obtain the sales information via EDI because of the costs associated with such a high volume of data. Dal-Tile is migrating from its traditional VAN EDI system and expects to recover its costs in the year it will take to complete the migration.

J. B. Hunt is a $2 billion trucking company that is moving its EDI away from the VAN approach to the Internet (Karpinski, 2001). J. B. Hunt links to 250 suppliers via EDI and has used traditional EDI standards. The company plans to use new formats using XML over the Internet. J. B. Hunt is concerned about the increased network management it will have to assume and is apprehensive about the change to new formats. The company will begin the conversion by moving its 12 largest customers, representing 30% of its revenues, to ensure quick payback of its $200,000 investment. Some of its customers want to stick with the managed services provided by their VAN providers. The company also plans to add delivery-tracking data to the Internet-based EDI, with an expected savings of $12,000 per week. J. B. Hunt expects the Internet-based approach to reduce the effort required to add a new partner to EDI from the current 40 hours to about 8.

An XML/EDI Application

The following is an example of an Internet-based application of XML for EDI for a book ordering application. Figure 3 illustrates how such a system might operate. The book publisher uses XML to receive orders from distributors and orders from small bookshops. A clerk at a small bookshop can access the publisher's order entry system online, and enter the appropriate information into an online form. The information is stored as an XML document and transmitted to the publisher's order processing system. The book distributor uses an automated inventory management system to automatically generate an order for transmission to the publisher. The distributor generates the order in XML format and transmits it to the publisher. The publisher can process the order from the bookshop and the order from the distributor in its order processing system.

The distributor and the publisher must use the same format in preparing the order in XML format. Figure 4 shows the XML code for a simple order document. By using the same format, the publisher will be able to read and process the order. XML requires a document type definition, but offers the advantage that one can determine whether a document is valid. For example, if the order document sent by the distributor did not include an ISBN, the publisher could not process the order.

One of the current impediments to using XML for EDI is that there are few industry standards. Various industry groups are working on developing standards. EDI standards can serve as a starting point for developing XML standards.

These applications demonstrate the value of Internet-based EDI. Large companies are able to obtain significant savings by avoiding volume-based VAN charges. The Internet-based approach makes sense for a variety of industries. It also permits small companies to meet the needs of their larger trading partners without the expense and technical expertise required for traditional EDI systems.

BENEFITS OF EDI

Organizations ascribe many benefits to the implementation of EDI. Among the benefits attributed to EDI are lower transaction costs, higher productivity, reduced cycle times, increased accuracy, reduced shipping discrepancies, and lower inventory costs (Copeland & Hwang, 1997; Raghunathan & Yeh, 2001). EDI can lower costs by eliminating paper processing. If an EDI system were fully integrated with other information systems, it could eliminate steps requiring human intervention, thus increasing productivity. EDI transactions move electronically, so EDI reduces the time needed to complete a transaction. Moving information electronically also improves accuracy because nobody has to rekey data into another system.

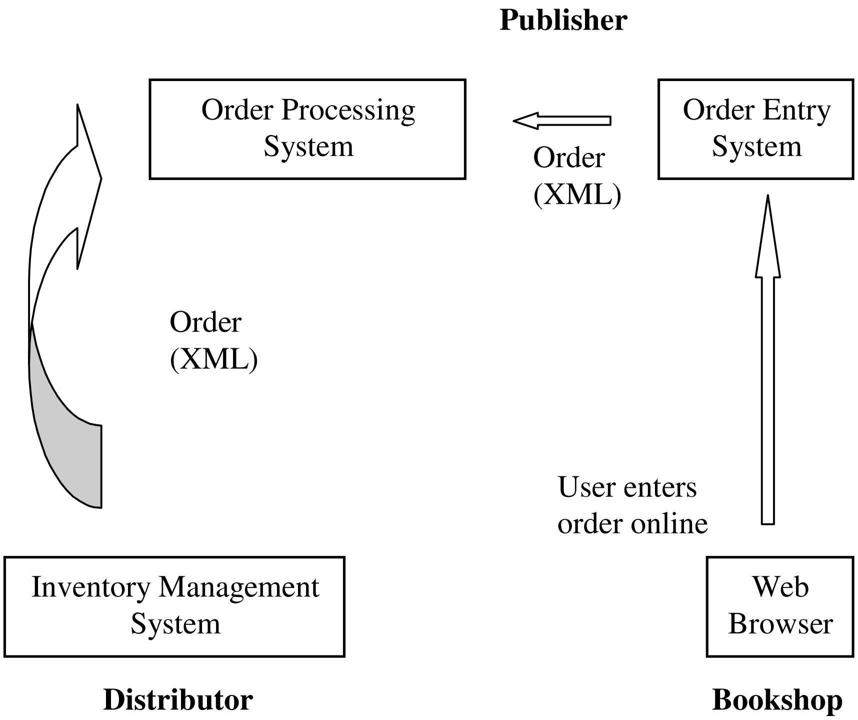

Figure 3: Book order processing using XML/EDI.

It is crucial to note that the degree of benefit, or even whether an organization obtains any benefit, is largely dependent on the specific implementation and application of EDI. If an organization does not have a high degree of automation and the EDI application lacks integration, then it will not realize the full benefit of EDI (Copeland & Hwang, 1997). A company may not obtain these benefits without business reengineering (Lee, Clark, and Tam, 1999). Lee et al. found that it is possible for the EDI initiator and its smaller trading partners to both benefit from EDI through interorganizational reengineering. Their study of the use of EDI by Campbell and 31 grocery retail chains found that the grocery chains reduced stockouts and increased inventory turns by reengineering the supply channel using EDI.

POTENTIAL DISADVANTAGES OF EDI

EDI has some potential disadvantages, particularly for smaller organizations. Interorganizational information systems projects have higher levels of risk than traditional information systems projects because of their interorganizational nature (Riggins & Mukhopadhyay, 1994). For a company initiating the EDI implementation process, the benefits depend partly on a trading partner’s implementation. The reduced control may lead to higher than expected costs and lower than expected benefits.

Although there are many potential benefits of EDI, in many cases only one trading partner obtains the benefits of implementing EDI. In particular, the trading partner that pushes for EDI is the one that realizes the benefits of EDI (Lee et al., 1999). Even for the larger trading partner, the benefits of EDI may be a long time coming. An organization implementing EDI frequently needs to maintain its traditional business procedures until all its trading partners are EDI capable. It could take years to approach 100% participation by trading partners. In the Campbell CRP case (mentioned in the Applications section), Campbell and its retailers both realized benefits from using EDI-enabled CRP, though some retailers had a learning period of over 6 months (Lee et al., 1999).

Small organizations often adopt EDI only at the insistence of larger trading partners, often their large customers. A large company may coerce its smaller trading partners into adopting EDI, and the smaller organizations may not realize any performance improvements from EDI (Lee et al., 1999).

For smaller organizations, implementing EDI may drive up the cost of doing business without commensurate benefit. The costs of doing EDI usually include translation software, the cost of VAN services, the costs associated with extraction/load programs, and the costs associated with learning the new technology. Small organizations often do not have the volume of transactions needed to make EDI cost-efficient. They act to keep from losing business to a rival, not to obtain a competitive advantage. A small business may not have much of an information infrastructure and may not integrate EDI into its business processes.

To a small business with little EDI integration, EDI means a more expensive way of doing business. A small business might decrease its data accuracy by having to key data into an EDI software package in order to send the document to its trading partner electronically. Small businesses may not possess technical expertise in using the EDI software, and may lose their traditional (paper) audit trails. They may become dependent on the EDI software vendor or VAN for conducting business. The lack of technical expertise may lead to poor security for EDI transactions; unauthorized transactions and fraud may be the result.

Organizations that are smaller than their trading partners may experience a loss of control because they have little influence on whether to use EDI and how the partners will implement EDI (Riggins & Mukhopadhyay, 1994). Smaller organizations may not understand EDI well enough to understand how they will benefit from its use. Organizations initiating EDI should consider investing resources to educate smaller trading partners on the benefits of EDI and providing technical help to smaller trading partners. This may defer the payback for an EDI investment, but may lead to greater levels of integration and better relations among trading partners.

CONCLUSIONS AND THE FUTURE OF EDI

EDI continues to grow. Many companies, particularly larger ones, can benefit from the efficiencies offered by EDI. Companies can use EDI to support JIT and CRP strategies. The benefits of EDI are not as readily accessible to smaller organizations because of the costs and learning required to implement EDI. The shift of EDI to the Internet is leading to reduced costs and greater benefits for small companies as well as large ones.

The brightest options for the growth of EDI are the Internet-based EDI opportunities. The standards committees responsible for EDIFACT and X12 have agreed to develop standards for Internet-based EDI. The most promising development is the work on electronic business XML, ebXML, a standard that extends XML for electronic business. The emerging standard has the potential to reduce costs and simplify EDI connections, particularly for small businesses. Internet-based EDI will provide the benefits of traditional EDI, but with a lower cost structure.

Organizations are likely to attain the greatest benefits when they work cooperatively with trading partners and seek to maximize value in the supply chain. Companies should look for ways to use EDI to support business strategies.

GLOSSARY

DISA (Data Interchange Standards Association) The organization responsible for the development of EDI standards in the United States.

ebXML (electronic business XML) An extension to XML designed to accommodate electronic business.

EDI Electronic data interchange, the computer-to-computer exchange of business transactions in standardized formats.

EDIFACT A set of standard formats for EDI transactions developed by a committee from the United Nations (UN).

Internet-based EDI The use of the Internet as the communications mechanism for electronic data interchange.

IOIS (interorganizational information system) An automated information system that involves information sharing between two organizations.

VAN (value added network) A company that provides a network and various other services for EDI.

X12 A set of standard formats for EDI transactions developed by the American National Standards Institute (ANSI).

XML (extensible markup language) A Web data language designed for representing data structures and data values.

Electronic Funds Transfer

Roger Gate, *IBM United Kingdom Ltd., United Kingdom*
Alec Nacamuli, *IBM United Kingdom Ltd., United Kingdom*

PAYMENTS IN THE CLASSICAL WORLD

Payment Systems

Payment systems, which guarantee the safe and efficient transfer of value between counterparties, are an essential requirement for trade and therefore a significant component of the economy's infrastructure.

Excluding cash (fiduciary money), payment systems are a set of mechanisms for the transfer of value among agents, requiring

- An instrument: e.g., check, card, electronic transfer;
- A transfer mechanism and standards: communication channels and messages;
- An audit trail of all transactions submitted and processed; and
- A legal framework and a set of procedures and rules to guarantee settlement finality, or the irrevocable discharge of obligation.

Electronic funds transfer grew up through the need to process higher volumes of transactions faster and more cost-effectively. This drove the need to exchange high volumes of data, initially between financial institutions but increasingly between banks and their customers. The need to remove the inefficiencies of handling cash and checks has driven these volume increases, relentlessly enhanced by the increasing complexity of people's lives. In Europe, payments for utility services and insurance premiums have been a big driver as both businesses and consumers saw the advantages of enhancing their cash flow and budgeting through a move to monthly rather than annual or quarterly payments.

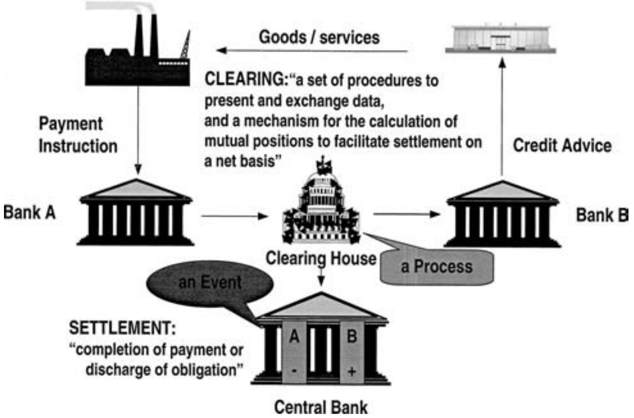
It is essential to distinguish between the information relevant to the payment and the actual transfer of value to achieve final settlement. In mature economies, the central bank always assumes responsibility for final settlement. Commercial banks hold accounts at the central bank and settlement finality (including the legal discharge of the payment obligation) takes place when the account of the payer's bank is debited by the required amount, which is credited to the beneficiary's bank, which will credit his or her account.

When large numbers of payments are involved, they are concentrated in a clearing house, which receives batches of payments for each bank, sorts them by beneficiaries' banks, sends these banks details of the payments for their customers, and calculates net positions, which are settled at the central bank. Bilateral or multilateral netting facilitates settlement by reducing a large number of obligations or positions to a much smaller number directly related to the number of participants.

In these net settlement systems, final settlement only takes place at the end of the day when all payments have been received and net positions have been calculated and transmitted to the central bank for settlement (see Figure 1). Should a receiving bank have acted on the information received and used the funds before settlement, it would have exposed itself to the risk (known as intraday risk) that the payer's bank might not be able to settle its dues at the end of the day.

For this reason, most countries now operate real time gross settlement (RTGS) payment systems for large amounts (typically above $1 million.). The payer's bank sends details of the payment directly to the central bank, which debits his account, credits the beneficiary's bank in real time, and then informs it of the irrevocable receipt of funds. These RTGS payment systems will normally account for less than 5% of the total number of payments within a country but will typically represent over 95% of the monetary value exchanged. Examples of payments exchanged over RTGS systems would include very large corporate payments and the settlement of foreign exchange and securities trades between financial institutions.

The bulk of low-value payments (e.g., salaries, pensions, and payments for utility bills, insurance premiums, and commercial invoices) are handled by automated clearing houses (ACHs). ACHs operate on a net settlement basis but the relatively low amounts involved do not pose an unacceptable risk; they will normally handle two types of electronic payments:



Goods / services
CLEARING:"a set of procedures to present and exchange data, and a mechanism for the calculation of mutual positions to facilitate settlement on a net basis"
Payment Instruction
Credit Advice
Bank A
Bank B
Clearing House
a Process
an Event
SETTLEMENT: "completion of payment or discharge of obligation"
A

+
Central Bank

Figure 1: Clearing and settlement chain.

- Credit transfers: payers instruct their banks to debit their accounts and transfer the funds to a beneficiary's bank; these include standing orders (STO), whereby the bank is instructed to pay the same amount at regular time intervals.
- Direct debits: payers authorize the beneficiary to draw funds from their accounts: these are normally used for regular payments of variable amounts, e.g., utility or telephone bills and mortgage repayments.

In most countries, corporate customers can submit payment batches (e.g., payroll) directly to an ACH, which will process them after credit authorization from the account-holding bank.

Table 1 illustrates as an example the relative numbers and values of payments handled by the U.S. and U.K. payment systems. In the U.S., the RTGS system is Fedwire and CHIPS is a large-value bank-owned real-time final settlement payments system. In the U.K., CHAPS is the RTGS system and BACS the ACH.

These RTGS systems and ACHs operate nationally for the home currency. An interesting case arose in 1999 when 12 countries of the European Union (EU) joined the European Monetary Union and created a single currency, the euro (€, EUR). A net settlement system in ECUs (the predecessor to the euro) was already in existence and was upgraded by its owner, the EBA (Euro Banking Association), to become Euro1. The European Central Bank (ECB), however, required the establishment of a cross-border RTGS system. Rather than creating a centralized new system, the ECB and the Central Banks wisely decided to interlink the existing national RTGS systems into a decentralized system known as TARGET (Trans-European Automated Real-Time Gross Settlement Express Transfer). Under pressure from the EU and the ECB, systems are currently under development for an ACH-type system for low-value transfers in euros across the EMU countries.

The systems described above relate to payments with the same currency. The explosion of international trade requires, however, the establishment of systems enabling an entity holding its bank accounts in one currency to transfer funds in a different currency. Fundamentally, currencies do not "travel." With the exception of the relatively minute amounts of foreign notes and coins required by tourists, currencies are held and settled in their home countries. International payments are normally settled through a set of procedures known as correspondent banking (see Figure 2).

Table 1 Payments in the U.S. and the U.K. (2001)

U.S.	Daily average value million ($)	% of total value	Daily average volume	% of total volume	Average payment value ($)
Fedwire (including Securities Transfers)	2,561,000	65.5%	513,000	0.7%	4,992,000
CHIPS	1,242,000	31.7%	241,000	0.3%	5,154,000
ACH	60,700	1.6%	21,300,000	27.5%	2,849
Checks	48,100	1.2%	55,335,000	71.5%	1151

U.K.	Daily average value million (£)	% of total value	Daily average volume	% of total volume	Average payment value (£)
CHAPS	333,000	96.1%	105,000	0.5%	3,171,430
BACS (ACH):	8,300	2.4%	13,600,000	66.6%	610
Checks	5,200	1.5%	6,700,000	32.9%	776

Source: Derived from data supplied by Federal Reserve Bank of New York (U.S.) and APACS Annual Review 2001 (U.K.)

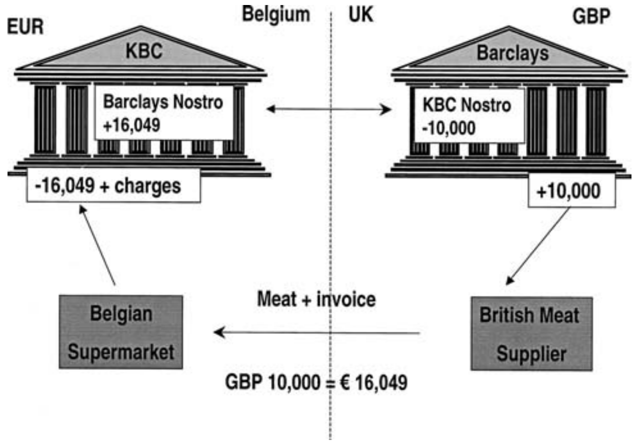

Figure 2: Correspondent banking.

Pairs of banks in each country (correspondents) open "Nostro accounts" for each other in their respective currencies. At the time of requesting the payment in a foreign currency, payers are quoted an exchange rate by their bank and the converted amount in the local currency is debited from their account and credited to the Nostro account of the correspondent bank. Payment information is sent to the correspondent bank, which debits the Nostro account of the payer's bank and credits the beneficiaries in their currency. At the end of the day, each bank sends to its correspondent a statement of the Nostro account for reconciliation.

International payments were amongst the last banking procedures to be automated, owing to differences in languages and national standards. In 1974, a consortium of banks created SWIFT (Society for Worldwide Interbank Financial Telecommunication), which has defined standards for practically every single international financial operation (payments, foreign exchange, securities trading, trade finance, etc). SWIFT operates a worldwide network that in 2001 exchanged daily, on average, 6 million transactions among 7,300 financial institutions in 196 countries, for a total value of $6 trillion. SWIFT also provides the network infrastructure for major international (e.g., TARGET, Euro1) and domestic payment systems.

Figure 3 shows the overall structure of current payment systems.

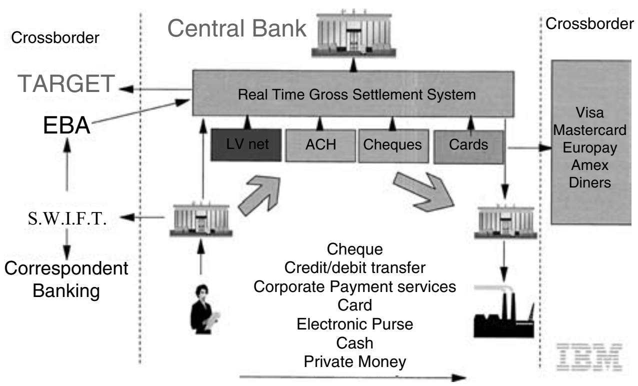

Figure 3: Overall structure of payment systems.

EDI (electronic data interchange) refers to the exchange of structured information related to business transactions. It is common to distinguish between

- Logistics EDI, which relates to the ordering, delivery, invoicing, receipt, acceptance, and possible return of goods if not satisfactory; and
- Financial EDI, which relates to the subsequent payment for these goods.

Standards are defined by various EDIFACT (electronic data interchange for finance, administration, commerce, and trade) Standardization Boards. Under the auspices of the United Nations Centre for Trade Facilitation and Electronic Business (UN/CEFACT), they define syntax and messages for specific business purposes across various economic sectors (automotive, chemical, electronics, finance, etc). Payment instructions would normally include remittance information to ease reconciliation. This remittance information can be extremely large and important when, for instance, the amount paid is less than originally invoiced because part of the consignment is being returned as a result of failing to meet agreed quality criteria. In the U.S. the American National Standards Institute (ANSI) also developed a standard for business-to-business EDI, ANSI X12. This is migrating toward the UN/EDIFACT standard and ANSI is also heavily involved in the development of an XML standard for this area, ebXML. This latter standard is sponsored by two organizations, UN/CEFACT and OASIS, a not-for-profit, global consortium that drives the development, convergence, and adoption of e-business standards. The ebXML mission is to provide an open XML-based infrastructure enabling the global use of electronic business information in an interoperable, secure, and consistent manner by all parties.

Services to Customers

Services to the retail sector are well known: direct payment of salaries into employees' accounts is now widespread and even compulsory in certain countries. Individuals pay for goods and services with checks, cards, and electronic transfers: credits, standing orders, and direct debits. Transaction details appear on statements sent for reconciliation at regular intervals. Most banks now offer Internet banking services enabling customers to initiate payments and receive balances and statements. Payments are not generally perceived as an element of competitive differentiation amongst banks in the retail sector, with the exception of credit cards. In several countries, however, regulators are intervening to force banks to improve execution times and reduce fees for payments. Specifically, the EU has introduced a regulation specifying that cross-border transfers within the Euro zone should not be charged more than domestic transfers.

Competition is more intense in the corporate sector. Large companies, seeking to optimize utilization of their funds throughout the day, require real-time notification of large amounts upon receipt. Banks have developed services enabling corporate customers to maximize the interest earned on their end-of-day balances by aggregating them. This is achieved either by transferring all funds into one concentration account (sweeping) or by offsetting the balances (pooling). Execution deadlines of payments and fees are defined by service level agreements (SLAs) negotiated between the banks and the large corporations. Most banks offer online treasury terminals to their corporate customers for payment initiation, balance and statement enquiries, reconciliation, and other financial services such as foreign exchange. These are gradually being converted to corporate banking portals.

REQUIREMENTS OF E-COMMERCE

E-commerce, although not always living up to expectations, is nevertheless changing purchasing and trading patterns.

Retail Sector

Internet shopping is becoming widely accepted, particularly for travel, groceries, books, CDs and DVDs, and electronics. Customers shopping on the Internet need to pay for goods and services purchased. Utilities and corporations are also moving to electronic bill presentment and payment (EBPP). Credit and debit cards are currently the most popular payment instrument in the B2C (business to consumer) sector, in spite of security concerns.

Cards are, however, not economical for very small payments (less than $10) known as “micropayments,” required for news, games, on-line gambling, etc. Cards are also not suited for P2P (person to person) payments required, for instance, for goods purchased between individuals through Internet auction sites.

Corporate Sector

Trading between corporations on the Internet is increasing. E-markets, where purchasers would seek goods and/or services, negotiate terms, and purchase, have not witnessed the anticipated growth but are viable in certain segments. On the other hand, the Internet has strongly contributed to facilitating commerce between corporations trading across integrated supply chains.

Looking at conventional EFT systems, ACHs are by definition cheap but require a settlement cycle of 2–3 days. RTGSs provide instant finality but at a substantial cost (typically over $20 for a retail customer). Crossborder transfers are also expensive (typically over $15 for a retail customer) and execution frequently exceeds 4 days.

New XML-based industry standards are under development and existing ones are being converted. E-commerce clearly therefore requires faster, cheaper, and above all secure electronic funds transfer systems.

SECURITY IN ELECTRONIC FUNDS TRANSFER FOR E-COMMERCE

History and Background

The changing landscape for EFT has created a number of security challenges that need to be addressed.

In the retail domain growing volume and the proliferation of new Internet payment methods linked to e-mail or prepayment schemes, some of which shift the security issues away from the financial institutions to new players, can alter the underlying security for the user.

In the business-to-business domain payments are becoming more and more embedded in the exchange of data that encompass the complete trade chain. This has brought new routes into being through which payments are initiated and therefore generated the need to create trust infrastructures that can handle these.

Also, as payment services developed, they moved from concentrating the security issues around volume and value to having to take account of the wider range of network channels that had developed, which brought with them new opportunities but also risks.

The methods and tools by which security has been achieved have therefore developed over the past three decades, starting with paper-based systems ranging from simple letters attached to magnetic tapes, and then on to the use of once-only bar code labels stuck to the covers of magnetic media such as floppy disks. As transaction data began to be transferred over networks, initially closed extranets and latterly open networks such as the Internet, new tools such as challenge and response devices that create one-time passwords, message authentication codes to ensure message integrity, and the use of cryptography for both confidentiality and nonrepudiation have been adopted.

Common tools used to deliver security through the development of these services are as follows:

Bar Code Labels

When data is transferred on magnetic media, the automated clearing house (ACH) or bank needs to know that an approved person within the correct organization has sent them. To achieve this that person would be sent a pad of once-only sticky labels, each of which was a once-only password in the form of a printed bar code that could be read by the receiving company. Additional security was managed by ensuring that the labels were kept under lock and key; the data were prepared and transferred onto the media by separate staff and once labeled the media were placed in a tamperproof carrier and sent by courier to the processing center. Risks were also mitigated by the fact that often an input report would be received and checked by a further person within the company prior to the payments actually being settled. These reports would not typically have all items shown, only summary totals, but could include a small number of items, for example those above a certain limit or random entries, which could be checked against the original input data.

It should be noted that this method does not enhance confidentiality or integrity.

Once-Only Password Calculators

As data transmission moved to networks (typically these started on closed user group X25 protocol networks, which were built to internationally recognized standards from the International Telecommunication Union (ITU), and not as open as the current Internet), there was a need to move the password to being a piece of data in itself that was not available for reuse if it was captured during the transmission. This was achieved by issuing customers with a small calculator into which a user could enter a PIN (personal identification number) and then additional data such as the date or payment file value and get back a once-only password in the form of a number that could be added to the header of the data transmission. These numbers were created in a sequence that was synchronized with the host system so that the passwords could be recognized and checked as they were used. These are also known as challenge and response devices.

IDs and Passwords

As e-banking systems based on dumb terminals and later client-based PC software began to allow payments, the logon to these systems was based on IDs and passwords. Frequently these systems asked the user to re-input the password when a specific payment or group of payments was being authorized. However, to reduce the risk in these systems, they frequently used two further tools to ensure authentication and authorization.

First, they frequently limited users to making payments against a predetermined library of beneficiaries. Each beneficiary's details, in particular the account number and bank identifier, are entered into a database by the bank against signed authorizations. This means that the user can only make payments to a subset of beneficiary accounts and does not have the ability to set up new accounts and therefore make a payment to his or her own or a collaborator's account.

Second, the user can use a message authentication code. In the simplest form, certain parts of the payment message, e.g., all or part of the amount, part of the date, and the beneficiary details reference number, known to both the sender and receiver, are added up in a certain way to create a check sum. More complex message authentication codes are created using algorithms to create a check sum made up from the whole message. In either case these calculations can be repeated by the host system and the results compared to ensure that there has been no change to the underlying message and therefore its integrity has not been compromised.

Symmetric Keys

As the demand for PC-based banking systems gathered strength, banks needed to offer free-format payment systems and thus stronger authentication and integrity checking became a requirement. Initially this was delivered using symmetric keys stored either on the PC or on a token such as a swipe card or chip card. Symmetric keys are very good for signing payments and also encrypting data for confidentiality. Messages signed or encrypted in this way can only be checked or decrypted using a copy of the same key, meaning that this had to be carefully protected by each of the parties concerned. This also meant that both parties e.g., the bank and the customer, know the key, so that it is difficult to prove nonrepudiation; i.e., either party could have signed and initiated the message.

Public Key Cryptography

Here there are actually two keys that are inextricably linked. The first is a private key that can be used to encrypt data or sign a message and the second, a public key, is the only key that can decrypt the data or check the signature. Note that the private key cannot be used to decrypt the message or check the signature in this case, because of the way in which the mathematics works. The reverse is also true if the public key is used to encrypt data, in that only the private key can be used to decrypt it. Through the use of various protocols this technology can be used to give nonrepudiation as well as strong encryption of data.

Table 2 summarizes the security characteristics of each of the methods discussed.

A final point that must not be forgotten is that most queries relating to any messages, for particular payments, always happen after the fact, sometimes after many months have passed. Therefore all systems need to have very capable and accessible audit and archive systems that can ensure that queries can be quickly and effectively sorted out. Entries to these audit systems should also be time-stamped using a certified method so that there is a

Table 2 Security methods

Security Method	Message Integrity	Message Authentication	Confidentiality	Nonrepudiation
Bar code labels	No	Authentication of data file only	No	No
Once only password calculators	No	Authentication of the data file only	No	No
ID and password	No	Authentication of the data file or communications session	No	No
Message authentication code	Yes	Provided by the ID and password	No	No
Symmetric keys	Yes	Yes	Yes if used to encrypt the data	No as both parties know the same key
Public key cryptography	Yes	Yes	Yes	Yes

clear and irrefutable sequence for the transactions that were carried out.

Trust Infrastructures Supporting New Payment Initiation Types

Throughout the development of EFT services individual payment messages and files of payments initiated by the bank customer have always been sent to the bank itself or the automated clearing house direct. In trading terms this has meant that the payment message has been created, signed, and sent to the financial institution by the buyer/payer. Also, except in limited EDI message types, the payment has often been divorced from the underlying information or trade cycle. At the same time banks have seen their traditional revenue streams decline as payments have been commoditized, reducing the prices they can charge, and new players have entered the market, taking advantage of new lower cost technologies.

Many banks therefore have recognized the need to develop services that enhance their position in the trade cycle and potentially bring them additional business opportunities. To do this a new trust model needed to be developed to allow payments and messages initiated by one bank's customers to be checked and trusted by another bank and its customers. This has been achieved by linking the development of individual public key infrastructures at banks across the world to a single trust scheme called Identrus. Other schemes such as the Global Trust Authority (GTA) have come to market, but at the time of writing Identrus is considered the most mature.

At the time of writing Identrus included 54 major banks from around the world and was actively recruiting additional members. Each bank has signed agreements that link it to the scheme and is either issuing or preparing to issue digital certificates that confirm the identity of the subscribing partner in such a way that they can be checked with certainty by any of the other banks on behalf of themselves or their customers.

Thus Identrus provides a global framework for the provision of certificate authority services, enabling financial institutions to extend their full range of services onto the Internet and become trusted third parties for e-commerce transactions. Through this they can develop new lines of businessas the Internet becomes a preferred transaction medium and their customers will have the ability to leverage a single bilateral relationship with a financial institution for all e-commerce dealings. At the same time this offers businesses and financial institutions a way to proactively manage the risk associated with e-commerce.

This form of trust has currently given rise to two new payment initiation schemes: Project Eleanor from Identrus and SWIFT e-Payments Plus from SWIFT (it should be made clear at this point that the actual settlement still occurs using the current bank settlement systems: SWIFT, CHAPS, ACH, etc.). They are both broadly similar in that they offer the ability for a payment message to be sent direct to the bank by the buyer or via the seller and the seller's bank. A range of payment types are offered ranging from a straight payment order to payments that are guaranteed by the buyer's bank or where a number of conditions are attached to payment that have to be completed by the seller and confirmed by a third party.

The first of these is a payment order, which is a revocable, unconditional electronic instruction from the buyer requesting the buyer's bank to execute a credit payment to the seller on a specific date for a specified amount. It is revocable in that the buyer can revoke the payment order up to the time the buyer's bank executes it. It is unconditional in that the seller is not required to show it has met its obligations in the underlying contract in order to receive payment.

The second type of instruction is a payment obligation, which is an irrevocable, unconditional undertaking of the buyer to pay a seller, or holder of the obligation, on a specific date for a specified amount at the buyer's bank. The payment obligation is irrevocable in that the buyer cannot revoke the obligation once it has been issued to the seller without the assent of the seller. The reimbursement arrangement for the buyer's obligation becomes effective on appropriate acknowledgement from the buyer's bank that the instruction has been accepted. The seller will have recourse against the buyer should payment not be made. The undertaking is unconditional in that the seller is not required to demonstrate that it has met its obligation in the underlying contract in order to receive payment. The rights of a payment obligation may be transferred, enabling sale and transfer of holdership in a secondary market. Furthermore, a payment obligation may also have the guarantee of the buyer's bank, in which case it becomes a "certified payment obligation."

Finally, a conditional payment may be a payment order ("conditional payment order") or a payment obligation ("conditional payment obligation") in favor of a named seller, payable at the buyer's bank upon presentation of specified electronic message(s), with a valid digital signature created by specified party(ies), to the buyer's bank, as evidence of fulfillment of preagreed conditions. The party(ies) issuing the electronic message(s) may be one or more of the following: the buyer, the seller, a third party service provider (TPSP), or a trusted service supplier (TSS). Such party(ies) must be agreed upon by at least the buyer, the seller, and the buyer's bank. The resultant payment under a conditional payment order or conditional payment obligation may be "immediate" or "deferred." Furthermore, a conditional payment obligation may have the guarantee of the buyer's bank, in which case it becomes a "certified conditional payment obligation." Table 3 summarizes the different payment types.

If we look at the first of these, a payment order using the Project Eleanor protocol from Identrus, the payment flows in a seller-initiated scenario are illustrated in Figure 4.

In the SWIFT e-Payments Plus model (see Figure 5) the main difference is that the messages are transmitted through the Internet to the SWIFT network, which carries out some of the processes prior to passing the data on to the bank. Further details can be obtained from the SWIFT Web site, http://www.swift.com.

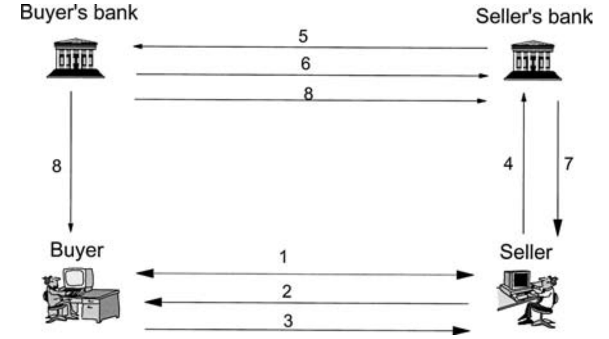
Table 3 Trusted payment types

Product	Revocable	Whose responsibility transferable on	Holdership	Payment condition
Payment order	Yes	Buyer	No	No
Payment obligation	No	Buyer	Yes	No
Certified payment obligation	No	Bank	Yes	No
Conditional payment order	Yes	Buyer	No	Yes
Conditional payment obligation	No	Buyer	Yes	Yes
Certified conditional payment obligation	No	Bank	Yes	Yes

In both cases security is provided by using the private keys generated in the process of registering for an Identrus certificate.

Summary

Security is achieved through authorization, document authentication, and signer authentication. PKI technology such as digital certificates, digital signatures, and encryption can be used to fulfill these requirements. Transaction nonrepudiation is achieved by creating a record that ensures that the agreement represented by the record cannot be disputed; this can also be achieved through the use of digital signatures. To ensure proof that a transaction was correct and properly authorized at the time, a transaction record has to be part of a reliable audit trail for internal (business audits) or external (legal, or chain-of-custody) purposes. To achieve this the transaction record needs to be capable of being archived and reconstructed with its content and context clearly defined.



1) Buyer and seller interact through seller's online system.
2) Seller software presents payment form to buyer.
3) Buyer signs payment and sends it to seller.
4) Seller appends data, signs and sends payment to seller's bank.
5) Seller's bank checks seller's signature, certificate, and that the buyer's bank is an Eleanor member. Seller's bank validates seller account details and appends data. Seller's bank signs and sends payment to buyer's bank.
6) Buyer's bank checks signature and certificate of seller's bank and that the seller's bank is an Eleanor member. Then buyer's signature and certificate are checked. Buyer's bank validates account details. Buyer's bank sends positive Service Response to seller's bank.
7) Seller's bank re-signs the Service Response and sends to seller.
8) On execution of payment, buyer's bank notifies buyer and seller's bank.

Figure 4: Identrus message flows.

B2C AND P2P E-EFT

Retail Payments

As mentioned, most banks offer Internet banking services allowing customers to initiate payments or transfer funds between their accounts.

New entrants are, however, proposing alternative schemes. The most successful is PayPal (now a subsidiary of e-Bay, the leading online auction house) which arose from the need to settle P2P payments between buyers and sellers on Internet auctions.

Customers open accounts with PayPal and register their credit card numbers and/or bank account numbers.

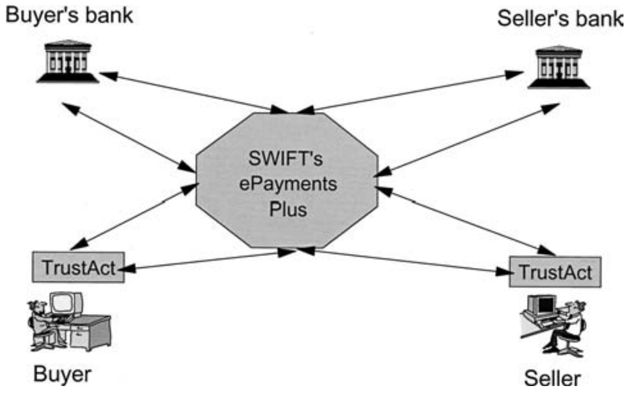


Figure 5: SWIFT e-payments plus.

The Send Money instructions on the PayPal website reads as follows: "Just enter the recipient's email address and the amount you wish to send. You can pay with a credit card or checking account. The recipient gets an email that says "You've Got Cash!" Recipients can then collect their money by clicking a link in the email that takes them to https://www.paypal.com/" (PayPal, n.d.).

Recipients are invited to open PayPal accounts. They can either transfer the funds received to their bank accounts or retain them for further purchases. Fees are significantly lower than those charged by banks and funds are immediately available. The system is viral, as recipients must open aaccounts with PayPal in order to receive the funds.

Mobile telephones appear to be a convenient solution for micropayments. Some solutions have been launched, notably PayBox in Europe and by some Scandinavian banks. Telecomm operators would appear well positioned but lack the credit assessment capabilities to enable them to safely offer services to purchase higher value goods and services. The future probably lies in alliances between banks and telcos. Various standardization bodies have been established, but progress is hampered by the lack of uniformly accepted standards.

ELECTRONIC BILL PRESENTMENT AND PAYMENT (EBPP)

EBPP is defined as the electronic presentment of bills combined with a mechanism to allow the customer to receive and pay the bill electronically. Significant cost savings would accrue to billers: printing, mailing, and in countries such as the U.S. where checks dominate, processing received checks and reconciliation.

Bills can be sent either directly to the customer's e-mail (biller-direct model) or to a consolidator, allowing customers to access all their bills at the same site. Billers now view bills as more than mere financial statements: bills are perceived as opportunities for brand reinforcement, marketing, cross-selling, and customer care. Two consolidation models are possible, with the latter therefore emerging as the favorite:

- Thick consolidation, where the full contents of the bill are presented by the consolidator, and
- Thin consolidation, where the consolidator only presents summary information with a link to the biller's site.

Two roles arise from EBPP:

- Biller service provider (BSP): e-bill extraction, publishing, hosting, and distribution; and
- Customer service provider (CSP): customer enrolment, presentation (thick or thin), customer care, payment.

EBPP has not grown as fast as originally anticipated, as customers are reluctant to pay for a process which today costs them virtually nothing. Critical mass is essential on both sides: billers are seeking to reach the maximum number of customers, whereas customers are interested in receiving the maximum number of bills online. Banks are viewed as natural providers of consolidation services, acting as both BSPs and CSPs on behalf of their corporate and retail customers. In the U.S., an example of a consolidated bill presentment and payment service is offered by CheckFree in partnership with hundreds of billing companies and a range of financial institutions across the U.S. Each time users log onto the service they are automatically directed to their MyCheckFree page, where they can view and pay new e-bills or update existing billing and payment information. Users can then pay their online bills using any ACH-enabled bank account, such as a checking or money market account, or major credit cards where accepted by the biller.

To achieve critical mass, some Scandinavian countries have implemented EBPP systems through their ACHs. The technical architecture of such a system is illustrated in Figure 6. For payment, customers are normally given the choice of paying bills by debiting their bank accounts, direct debit, or charging to credit cards.

EBPP in the B2B sector is sometimes referred to as EIPP (Electronic Invoice Presentment and Payment), but the fundamental principles are the same.

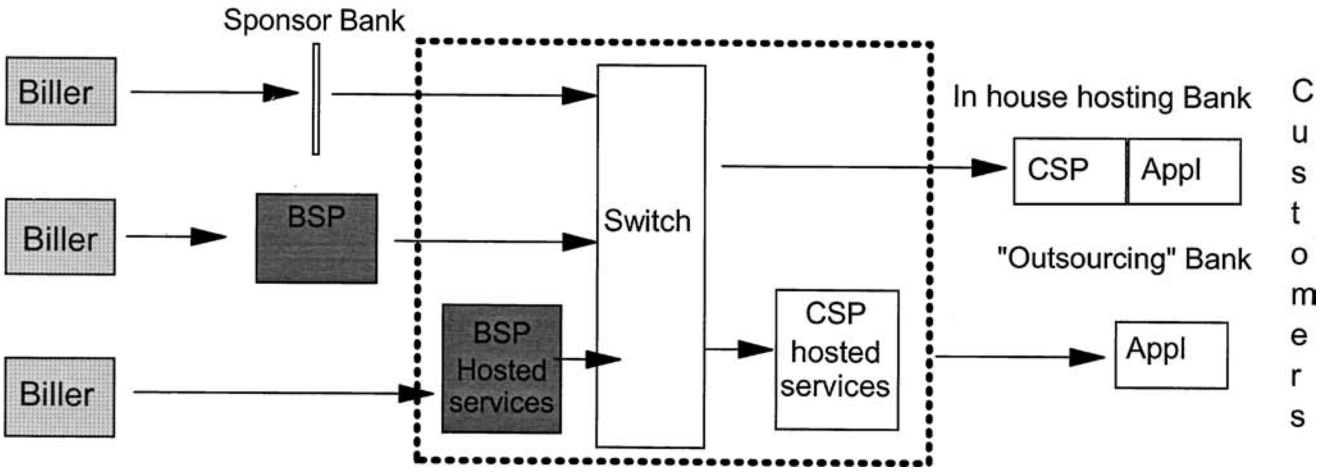

Figure 6: EBPP architecture.

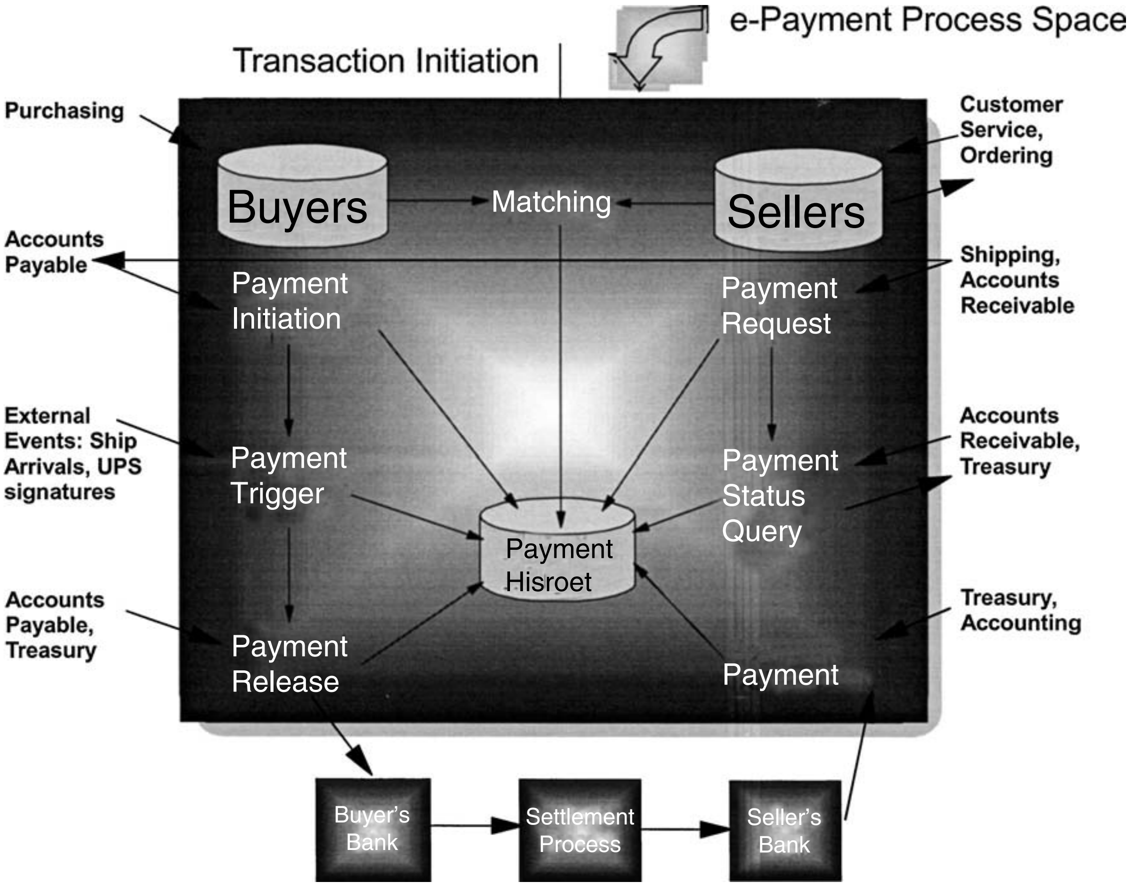

Figure 7: Basic B2B e-payment model.

B2B E-EFT

Requirements for B2B payments are more complex. The payment is one of the final steps of the complete commercial cycle and occurs upon formal acceptance of the goods or services. Purchases orders, stock control, and financials are increasingly being handled by corporate-wide ERP (enterprise resource planning) systems. Any payment solution must therefore be capable of integration with the corporation's logistic and financial processes and systems. Figure 7 illustrates the basic B2B e-payment model and the required features.

The actual transaction could be initiated by the corporation itself, as payment of an invoice presented electronically via EBPP/EIPP, or as the result of a purchase agreed to on an e-market or an integrated supply chain. E-markets and integrated supply chain systems have concentrated so far on seeking partners, negotiating terms, and sometimes logistics. To date, very few have also incorporated financial services, so payments are effected via conventional channels. Some banks are positioning themselves as providers of payment and financial services to e-markets and integrated supply chains.

FUTURE PERSPECTIVES

The systems described above do not bypass the banking system, as payments originate from and end in bank accounts and clearing and settlement take place via the conventional systems (cards or ACH). Possible exceptions could be payments charged to telephone bills, although even those are ultimately paid via the banking system. The danger for the financial institutions lies in potential disintermediation, brand substitution, and loss of customer contact. Customers are now paying through PayPal or their mobile-phone operators and their banks are one level removed.

Particularly in the B2B sector, significant opportunities exist for banks to offer classical banking services, integrated across the commercial value chain, to e-markets or clusters of corporations trading across industry supply chains: market intelligence, information and credit assessment on trading counterparties, credit, trade finance, shipping and customs clearance, escrow, factoring, invoice financing, reconciliation, treasury, etc. (see Figure 8), as well as trust services and hosting cumbersome EDI remittance information. Some banks are already offering such services to reposition themselves at the centers of commercial chains.

The technological and organizational challenge banks face is to integrate processes and IT systems, which are today siloed, into customer value propositions on user-friendly portals.

To conclude, we can predict the following:

- Major structural changes are unlikely to occur under current legal and regulatory environments,

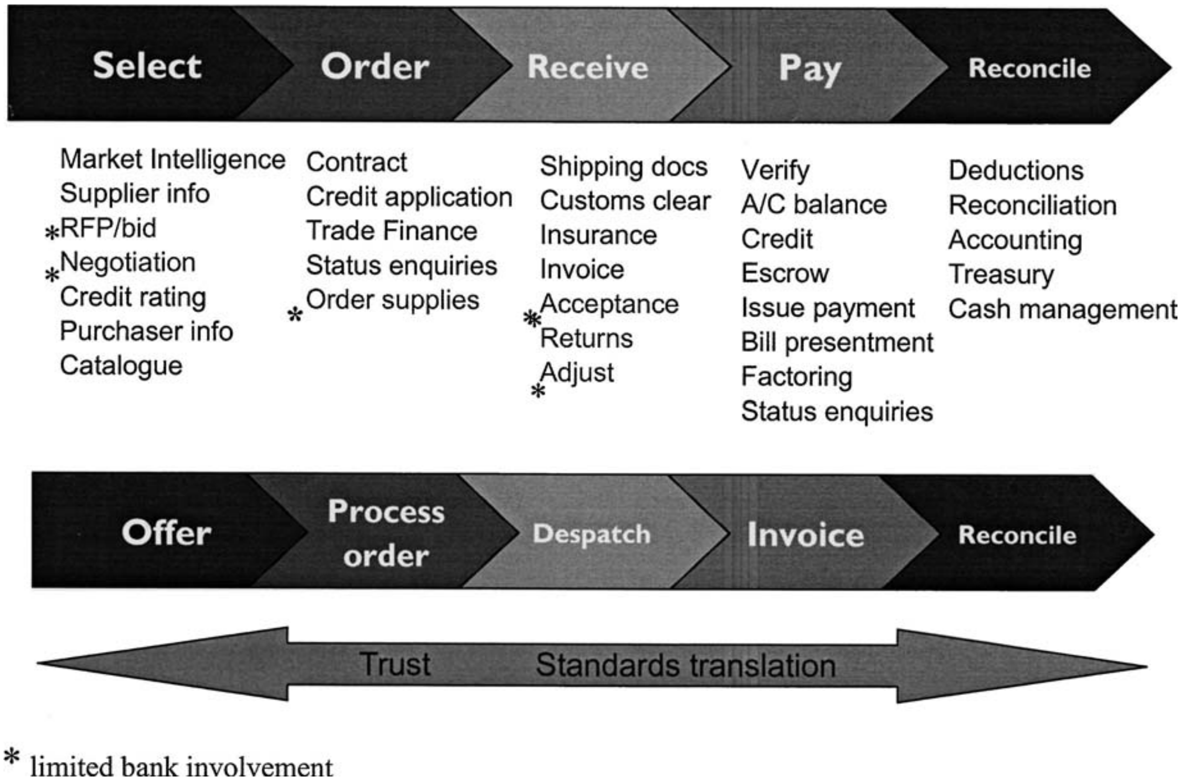

Figure 8: Opportunities for banks throughout commercial value chain.

- Service level agreements, which are commonplace in the corporate sector, will be supplemented by regulation and anticompetitive regulation in the retail sector,
- **Internet payment submission will dominate B2B within 3 years,**
- New payment systems offering speedier finality at lower cost will emerge,
- Competition will increase as banks seek alliances with telecommunication providers and e-markets, offering services to clusters of corporations across industry sectors, and
- Attention will focus on security, fraud detection, anti-money-laundering measures, and business continuity.

GLOSSARY

(Source: Bank for International Settlements Standard Red Book terms)

Automated clearing house (ACH) An electronic clearing system in which payment orders are exchanged among financial institutions, primarily via magnetic media or telecommunication networks, and handled by a data-processing center.

Batch The transmission or processing of payment orders and/or securities transfer instructions as sets at discrete intervals of time.

Correspondent banking An arrangement under which one bank (correspondent) holds deposits owned by other banks (respondents) and provides payment and other services to those respondent banks. Such arrangements may also be known as agency relationships in some domestic contexts. In international banking, balances held for a foreign respondent bank may be used to settle foreign exchange transactions. Reciprocal correspondent banking relationships may involve the use of so-called Nostro and Vostro accounts to settle foreign exchange transactions.

Discharge Release from a legal obligation imposed by contract or law.

Electronic data interchange (EDI) Electronic exchange between commercial entities (in some cases also public administrations), in a standard format, or data relating to a number of message categories, such as orders, invoices, customs documents, remittance advice, and payments. EDI messages are sent through public data transmission networks or banking system channels. Any movement of funds initiated by EDI is reflected in payment instructions flowing through the banking system. EDIFACT, a United Nations body, has established standards for electronic data interchange.

Final settlement Settlement that is irrevocable and unconditional.

Netting An agreed offsetting of positions or obligations by trading partners or participants. The netting reduces a large number of individual positions or obligations to a smaller number of obligations or positions. Netting may take several forms that have varying degrees of legal enforceability in the event of default of one of the parties.

Payment A payer's transfer of a monetary claim on a party acceptable to the payee. Typically, claims take the form of banknotes or deposit balances held at a financial institution or at a central bank.

Payment order (or payment instruction) An order or message requesting the transfer of funds (in the form of a monetary claim on a party) to the order of the payee. The order may relate either to a credit transfer or to a debit transfer.

Payment system A set of instructions, banking procedures, and, typically, interbank funds transfer systems that ensure the circulation of money.

Real-time gross settlement (RTGS) A gross settlement system in which processing or settlement take place in real time (continuously).

Settlement An act that discharges obligations with respect to funds or securities transfers between two or more parties.

S.W.I.F.T. (Society for Worldwide Interbank Financial Telecommunication) A cooperative organization created and owned by banks, which operates a network that facilitates the exchange of payment and other financial messages between financial institutions (including broker-dealers and securities companies) throughout the world. A S.W.I.F.T. payment message is an instruction to transfer funds; the exchange of funds (settlement) subsequently takes place over a payments system or through correspondent banking relationships.

Electronic Payment

Donal O'Mahony, *University of Dublin, Ireland*

INTRODUCTION

In 1994, Netscape Corporation released its first Internet browser to an Internet population that consisted of users of approximately 3 million host computers around the world. Before the term *electronic commerce* was coined, companies who had products to sell used the Web as a virtual shop window. Product brochures, specifications, and data sheets, which had hitherto been physically distributed, were put up on Web sites. Many purchasing decisions were made based on this information, but although the details of the deal may have been discussed electronically, the final order, and more importantly the payment, took place by more conventional means. By the end of 1998 (which is remembered by many as the first Christmas holiday season when on-line buying became highly significant), the Internet population had grown to around 43 million hosts worldwide. Just two years later, the number of hosts worldwide had risen to 93 million with on-line retail sales reaching over $10 billion for the holiday season and three times this for the year as a whole. Much of this took place using credit cards as the payment method and in spite of the fact that many consumers are still loath to trust the Internet as a means of effecting payment. Although many candidate systems (O'Mahony, 2001) have been offered to fill the payments gap for business-to-consumer e-commerce, not many have been adopted to any significant degree, and it may take some years before the industry converges on a standard in this area. It is really only since 1999 that companies have started to get very interested in the area of business-to-business e-commerce, and the jury is still out as to what will be the payment method of choice in this environment. In order to gain a greater understanding of what payment methods can be used across the Internet, it is useful to first examine how payment is effected in conventional commerce.

Conventional Payment Methods

The first and most obvious method of transferring value is the use of cash. This evolved from bartering of universally sought-after commodities such as salt or gold into today's system involving notes and coins issued by national governments. In most countries in the world, cash is used for some 80% of day-to-day transactions. It is very versatile in that in can be used for payment to merchants or simply from one individual to another without the need to involve a financial intermediary such as a bank. There is no need for prior trust to be established between the parties, although where this is an issue, the payee will likely examine the notes very carefully before accepting them. Very low-value transactions can be carried out, limited only by the smallest denomination on the coinage; indeed the fact that the average cash transaction in the United States is around $11 demonstrates its main realm of applicability.

It is not without its problems, however—it costs governments a significant amount of money to produce and maintain the national stock of notes and coins and increasingly this process is open to attack from counterfeiters. It can be stolen. Its anonymity makes it attractive to organized crime, and its use in large-value transactions is often associated with tax evasion. Because a given currency is tied to a particular country or region, cash is not very suited to international transactions. In spite of its problems, it is the dominant payment instrument in business-to-consumer and person-to-person low-value transactions.

When it comes to higher value transactions and also for business-to-business payments the use of the check becomes important. A check is simply an instruction to the payer's bank to transfer funds to the payee. It is fundamentally dependent on the presence of a financial intermediary, usually a bank, and unless everyone in the community shares the same bank, there must also be a clearing and settlement mechanism to connect the two banks involved.

The payment instrument can be used to transfer values of any amount, but the involvement of at least one intermediary coupled with a considerable amount of paper processing means that the transaction charges are likely be to around (U.S.) $1. Figure 1 shows the steps that need to be taken to process a check in a conventional clearing system.

The cost of this processing effectively makes checks impractical for very small transactions. Because a check is merely a promise to pay, it depends on a degree of trust being established beforehand between the two parties. Where this is lacking there may be a delay in issuing the goods or the parties may have to resort to some kind of escrow arrangement. Banks often issue check guarantee cards, which indemnify the payee against risks as long

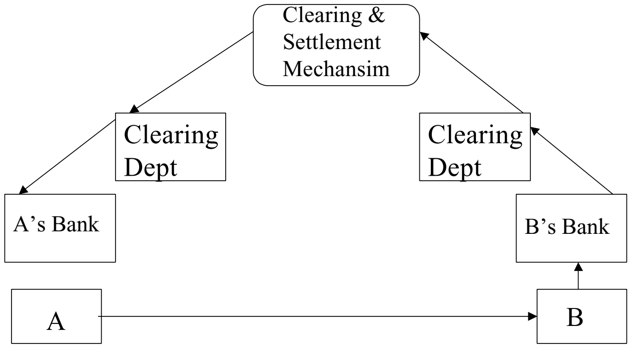

Figure 1: Check clearing process.

as the transaction size is small and some fairly rudimentary security checks are made at the time of the transfer. For larger transactions, a customer's bank will often sign the check itself, converting a simple check into a cashier's check or bank draft. Since the promise to pay is now coming from a much more trusted party, greater risks can be taken on the part of the payee to ensure that the transaction completes.

Typically all parties to a check transaction are in the same country, so no currency issues arise. Where the payer and payee are in different countries, decisions must be made about which currency to use and at what point the conversion is made. In the absence of any globally acceptable clearing and settlement authority, the major banks very often resort to correspondent banking, where special arrangements are made with a bank in the destination country to handle checks issued by them. This necessarily makes the transactions more expensive, and the need to manage risk limits the speed with which the transaction can be carried out.

To some extent, the use of a debit card is similar to an electronic version of writing a check. The source of funds is the same, as is the general flow of information. Typically, though, the debit card does some kind of authorization at the point of sale, verifying at least that the card is not stolen and possibly even verifying that sufficient funds are available.

One of the major problems in check payment is the risk associated with the "returned item" or bounced check. Even though the incidence of checks being returned is very small, the fact that it can happen at all associates high risk with a check and makes it unacceptable for many transactions, particularly where goods are delivered immediately. One way to avoid this risk is to use a credit transfer or Giro payment. Where a check represents a "pull" payment with the paper check pulling funds from the source account through the clearing network into the destination account, the Giro does the reverse. Funds are "pushed" from the source account to the destination account. The credit transfer cannot be initiated unless the funds are available, and this eliminates any risk associated with the payment.

Where the bank details of the payee are known in advance, it is possible to make electronic transfers between bank accounts using so-called automated clearing house (ACH) networks. These organizations grew out of the systems that were developed to process check clearing and are now used by consumers for recurrent payments to utilities in the form of direct debits. They are also used extensively by businesses to pay their regular suppliers and by governments to issue all manner of payments to individuals and corporations. In the United States, the system is operated by the National Electronic Payments Association and most countries in the developed world have similar systems. Indeed, it is quite common to have multiple systems of this sort operating in a single country—some operated by the central bank, and others by consortia of leading banks.

In 1999, the average value of a payment made through the ACH system was approximately $1,500 and settlement is made overnight. Where the value of the transaction is significantly larger, a different class of payment method is typically used, which is referred to as a "wire transfer." One example of this is the FEDWIRE system operated by the Federal Reserve in the United States. This offers the facility to make immediate payments with settlement performed by transferring funds between accounts maintained by the member banks with the Federal Reserve. In 1999, the average value of transactions in the FEDWIRE system was $4.3 million. It is thus used principally for major business-to-business and also business-to-government transfers. When such payments are made internationally, the messages relating to the wire transfers are typically carried on the networks of the Society for Worldwide Interbank Financial Telecommunications (SWIFT), with the settlement and risk management functions being handled by correspondent bank relationships.

Returning to retail payments, one very popular payment method that we have not yet discussed is the credit card. This payment instrument dates back to 1915, with the establishment of "shoppers' plates" aimed a simplifying payment for affluent customers of retail establishments. It has evolved over the years into an enormously popular, globally acceptable payment instrument led by two major brand names: Visa and MasterCard. One of the principal reasons for the success of these two "card associations" is that they are owned and operated by a banks from all over the world. It is these local banks that manage the relationships with the cardholders; the card associations provide the global branding and also some of the common infrastructure that link the banks that operate the system.

Credit cards are used to make payments between customers and merchants. For the system to operate, the person making the payment must become a "card holder"—that is, he or she must approach a "card issuing" bank that must open an account on his or her behalf and issue the physical card that will enable him or her to make transactions. Without appropriate restrictions, the possession of a card confers unlimited spending power on its owner. In the majority of cases, though, the card issuing bank will assign a "credit limit" to the card holder based on an examination of his or her creditworthiness. In most developed countries, this process is quite routine; indeed, customers are often bombarded by advertising from different companies offering them credit cards. In other countries, credit cards are sometimes hard to get, and in some, tight restrictions are placed on their use.

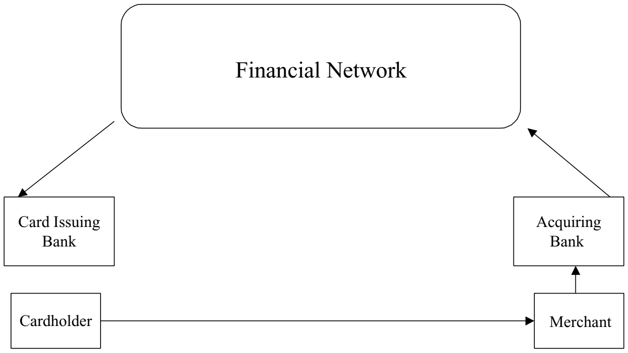

Figure 2: Information flow in a credit card transaction.

At the other side of each credit-card transaction is a "merchant." Achieving "credit card merchant" status involves opening an account with a bank that will "acquire" transactions on behalf of the business. Once the account is set up, the merchant then has the ability to charge arbitrary amounts to any credit card that has been issued anywhere in the world. Clearly, this represents a major opportunity for fraud in the short term, and acquiring banks will often subject a business to strict checks before permitting it to operate as a merchant, particularly if it intends to carry out business across the Internet. In the United States, these checks are not very stringent, but they are much more so in most European countries, and companies in some developing countries may have extreme difficulty in gaining credit-card merchant status.

Figure 2 shows the information flow when a credit card transaction is made. The cardholder presents the card details to the merchant. The merchant can authorize the transaction prior to actually making it. This is done through a connection either directly to the merchant's acquiring bank or to a technology provider acting on its behalf. The acquiring bank can authorize this transaction using a financial network that has access to the data of card-issuing banks worldwide. The transaction can have two steps—an authorization step (this is used frequently by hotels at the beginning of a guest's visit) and a later "capture" step where the previously authorized transaction is completed. Alternatively, an authorization-and-capture step can do everything in a single action.

It is, of course, not strictly necessary to make an online connection back to the source account for every credit card transaction. In situations where telecommunications facilities are not available, or where dial-up telephone connections are very expensive, the authorization step may just be a simple check of the credit card number against a periodically updated blacklist. Often merchants operate under quite complex policies to balance the risk of fraud against the cost of verifying the transaction. This may involve going through authorizations only where a transaction value exceeds a "floor limit" or carrying out an online authorization randomly for one in every 10 transactions.

One credit-card usage scenario that is interesting, because it serves as the background for Internet credit card transactions, is the so-called mail order/telephone order (MOTO) transaction. Under this scenario, merchants are allowed to accept orders by post or over the telephone with the customer simply quoting the credit card details verbally. Under this scenario—also called "card not present"—the merchant is unable to tell if the customer has the card in his or her possession. Neither can the merchant verify the signature. Some simple safeguards are put in place regarding the address to which the goods can be dispatched and in the event of the customer later disavowing the transaction, the merchant must bear the cost.

The costs involved in processing credit card transactions are considerable. Typically, these are recovered by a per-transaction levy on the merchant. The charges depend on the acquiring bank and also on the level of risk associated with the business. Typically, a merchant that has been trading profitably for years will be able to negotiate a better rate than a startup company. Any company that trades on the Internet is regarded as being "risky" and is typically subject to higher charges. Generally there is a fixed fee from around $0.10–$0.50 and a percentage of the transaction from around 1 to 5%. This effectively means that credit card transactions are not worthwhile for transactions less than $5 or $10.

The great strength of credit cards is their global acceptability. Since the processing of the transaction across the financial networks takes care of the currency conversion, merchants will receive funds in their local currency while the cardholder is levied in his. The global recognition of the two major brands and also other variants such as American Express reassures merchants that the payment will be honored. On the downside, fraud is quite easily perpetrated by rogue cardholders and rogue merchants,

Table 1 Consumer Preferences in Non-Cash Payment Methods by Country in 2000

COUNTRY	USE OF CHECKS	USE OF CREDIT TRANSFERS (GIROS)	PAYMENT CARDS	DIRECT DEBITS
U.S.	58%	4%	35%	2.2%
Netherlands	0.4%	39.7%	29.9%	29%
U.K.	26%	17.9%	36.6%	19.4%
Germany	3%	49.1%	9.6%	38.1%
Turkey (1997 figures)	6.9%	2.6%	83.9%	—
Namibia (1996 figures)	75%	14%	Not provided by local banks	9%
Angola (1996 figures)	75%	25%	Not provided by local banks	—

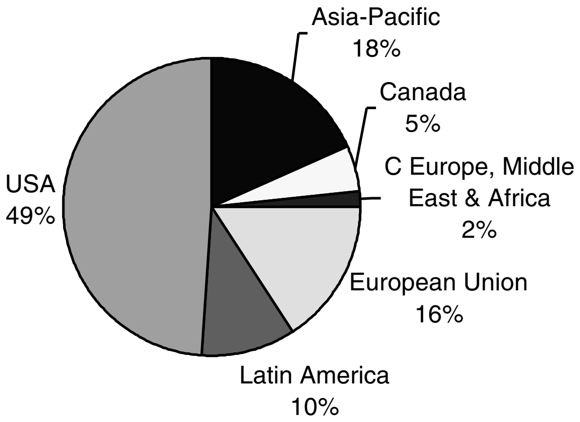

Figure 3: Geographic distribution of VISA cards issued around the world in December 1999.

particularly when the authorization process does not verify each transaction back to its source.

Geographical Variations

As Table 1 shows, the degree of adoption of different payment systems differs markedly between countries (BIS, 2001). The United States, for example, is a very heavy user of checks as a means of effecting payment. Payment cards come next in popularity, with quite infrequent usage of credit and debit transfers. It is almost the reverse in Germany, where payment card usage is extremely low compared with other developed countries and Giro credit transfers are used for more than half of the noncash transactions.

When developed countries are compared, many of the differences can be explained due to the historic evolution of payment systems over time. For example, the popularity of Giros in many European countries can be traced to the involvement of post offices in providing payment services over many years. In developing countries, the overall financial infrastructure tends to be poor. Since checks are perhaps the most basic payment instrument that a bank can offer, these tend to be available everywhere and attract widespread usage. In such countries payment cards have their use confined to particular industries (e.g., petrol stations) or they are not issued at all. Figure 3 shows how the 1 billion Visa cards that have been issued are spread throughout the globe. It can be seen that the area covered by Visa's Central Europe, Middle East and Africa division is responsible for just 2% of these. Often unusual local factors lead to a payments situation that is anomalous compared with similar countries. Turkey, for example, has embraced the use of payment cards to the almost total exclusion of other forms of payment.

ELECTRONIC PAYMENTS

In the development of e-commerce, the first transactions that took place were at a retail level, and this grew quite dramatically from just a trickle in 1995 to somewhere between $23 billion and $109 billion in 2000. Some product sectors that proved popular include books (e.g., amazon.com), apparel (Land's End, The Gap, Victoria's Secret), computer products (Dell, Gateway), and travel (Expedia, Priceline).

Credit Card Online Purchasing

In many ways, the most natural way to make a purchase over the Internet, in the absence of any alternatives, is to use a credit card. There was already a precedent set over a number of years by the catalog shopper. Business rules (the MOTO rules referred to earlier) had been developed to handle transactions where the card details were given to the merchant either on a printed order form, or over the telephone. For international shoppers, the currency problem was solved, and there were already large numbers of people worldwide who could make and accept payments without the need for any signup procedure.

When a credit card transaction is made online, the parties are exposed to the usual risks inherent in a conventional credit card transaction as well as some new risks that arise because the Internet is the medium of information transfer. These include the following:

Authenticity of the Seller: It is relatively easy for an individual to construct a credible online storefront that can appear to represent a large well-established organization. Even when the seller is authenticated, buyers who have given over their credit card details are at risk from rogue merchants who make repeat or completely bogus transactions against their accounts at a later time.

Authenticity of the Buyer: A credit card merchant has no dependable information on the identity of the persons making credit card transactions. They may have stolen the cards, or even generated valid credit card numbers at random, or they may be genuine cardholders who intend to later repudiate the transactions. Mechanisms such as cardholder address verification and the use of card verification values offer some protection against these attacks.

Security of the Information in Transit: Credit card details traveling over an unsecured Internet connection are vulnerable to capture from attackers intercepting the traffic.

Security of Information at the Merchant Site: Online merchants often capture the credit card numbers of their regular customers to ease repeat transactions. These databases are the target of attackers and there are reported cases of thieves compromising this information and using it to extort payments from merchants.

Cardholder Privacy: Archived details of online transactions form a link between a person's identity (as represented by his or her credit card) and the goods he or she purchased. Merchants can use data mining techniques to build profiles of their customers, which may represent an unwanted invasion of privacy.

Funds Availability: As with any credit card transaction, it is possible that a rogue cardholder may ultimately default on payment to the card issuer. In conventional commerce, the merchant would be indemnified against this risk, but for online transactions, the credit card companies may take a different view.

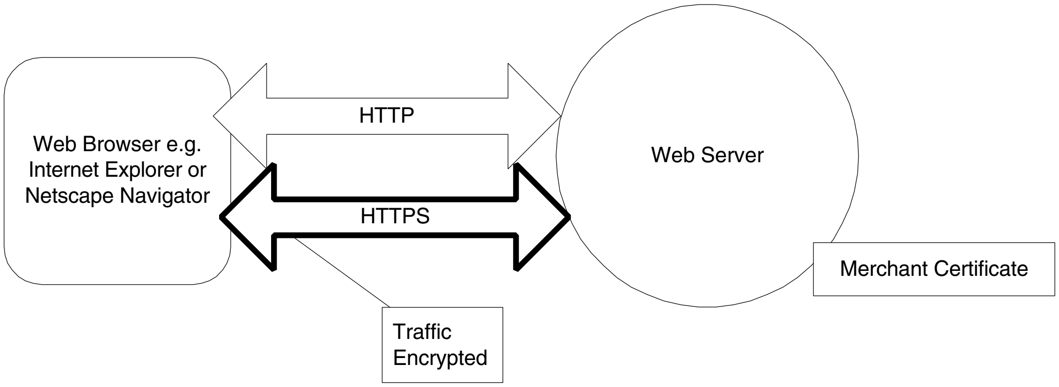

Figure 4: The secure socket layer protecting a credit card payment.

The Secure Socket Layer

The earliest Web purchases were made either by insecurely transferring the credit card details in a Web dialogue or by resorting to a separate e-mail exchange to complete the payment. The credit card companies were not happy about this method of conveying the details, and the advice they issued to consumers and merchants was not to use credit cards on the Internet until such time as new technologies had been developed to allow this to happen securely. The market largely ignored this advice and a stopgap solution was arrived at around 1995, when Netscape incorporated support into their Internet browser software for a technology standard called the secure socket layer (SSL) (Dierks, 1999).

The secure socket layer allows systems to authenticate themselves using digital signatures and X.509 Certificates. Digital signatures are produced by electronically digesting the document to be signed and producing a small unique piece of data that represents an electronic fingerprint of the document's contents. This fingerprint is then encrypted using a secret number called the private key. The encrypted fingerprint is the "digital signature" and the only person that can sign a document is the holder of the private key.

When any other party wants to verify that the signature is correct, they decrypt the document using a nonsecret number referred to as the public key. If the result matches the fingerprint of the document they accept the digital signature as genuine. In order to use this technique as the substitute for a real signature, the last thing we need is a way to associate a person's identity with a particular private key.

When people travel from one country to another, they assert their identities by producing passports. These documents provide a link between their appearances (and their handwritten signatures if necessary) and their identities (name and date of birth). They are accepted at border posts because passports are issued by national governments trusted by those officials.

The electronic counterpart of this is called an X.509 certificate. It is an electronic document that provides a link between a public key and an identity (person or company name) and is signed by an entity called a certification authority (CA) that is widely trusted.

Once we have a single CA or an international network of cooperating CAs that is widely trusted, it is possible for people to send signed digital documents such as electronic checks to each other. By including the X.509 certificate with the document, they allow the recipient to verify the signature on the document.

A merchant wishing to use SSL to protect credit card transactions must apply to a recognized X.509 certification authority to be issued a certificate. All Internet browser software comes preconfigured to trust the 20 or so most common certification authorities operating worldwide. As Figure 4 shows, a user browsing the merchant's site will interact normally until it comes to the point where the credit card details are to be transferred across the link. At this point, the user's browser will be directed to a Web page that starts with HTTPS rather than the usual HTTP. This is a signal to the browser to start a special security dialogue with the browser in which two things happen. First, the merchant proves that it represents the business to which the X.509 certificate is issued, and second, the merchant and the user agree on a session encryption key that is used to protect the credit card details and any other financially sensitive information from being intercepted by attackers as it travels across the Internet.

Thus the cardholder is afforded some protection that the merchant to whom he or she is giving the card details exists as a bona fide business, at least as of the time when the certificate was issued. Both cardholder and merchant are also protected from eavesdroppers capturing the credit card details from an insecure Internet link. There is no protection for the merchant from the card being used by someone other than the holder, and if the cardholder later denies making the transaction, there is no means of proving otherwise. The cardholder has no protection against a merchant who may retain the card details and subsequently change multiple transactions against the account. If the merchant site stores the card details online, it makes itself vulnerable to attackers breaking into the site to gain access to them.

In order to streamline the process of making credit card transactions and also to allow each individual transaction to be authorized, merchants generally equip themselves with online connections to their acquiring banks or to entities operating on their behalf. Figure 5 shows this process in action.

This process has been taken further by companies such as iTransact that operate links to the financial network

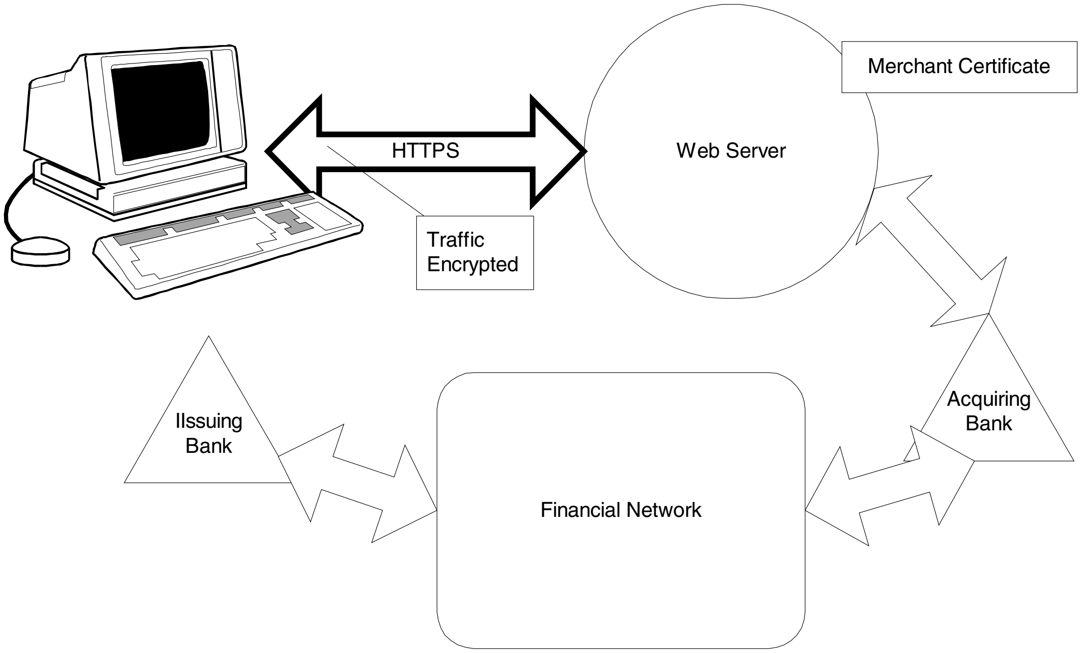

Figure 5: Online authorization of a credit card transaction.

on behalf of many hundreds of online merchants. Using their services, the B2C merchant can interact with iTransact's Web site during a purchase to authorize and complete a transaction in real time. The only requirements are that the merchant hold a merchant bank account in the United States and that the transactions be denominated in U.S. dollars. Every other component of the system, including the merchant Web site, can be located elsewhere.

Secure Electronic Transactions (SET)

Although the use of SSL, with or without online authorization, is by far the most common means of making credit card transactions, more advanced technology is available in the form of a security standard called secure electronic transactions (SET) (Mastercard, 1997). This was developed principally by the two major credit card companies, Visa and Mastercard, in 1996, but also has the support of many major technology providers and other card brands such as American Express. It is a comprehensive solution to all of the practical risks that are encountered in any credit card transaction.

Special wallet software is used by the cardholder that is partially or totally integrated into the Web browser's software. The wallet software is loaded with the card details and also with a certificate that is issued to the cardholder by the issuing bank. As shown in Figure 6, when a credit card transaction is to be made, the wallet software composes an encrypted payment request that is sent via a SET module running on the merchant's Web site and from there to an SET payment gateway run either by each acquiring bank or by the credit card company itself. The SET standard underwent a 1-year public review period and is thought to be highly secure and efficient at guarding against all anticipated risks due to stolen cards, rogue merchants, or rogue card holders.

The main problem with SET lies in its complexity. Three independent pieces of software need to be in place and working well with each other before a single transaction can be carried out, and certificates must be issued to each of the three parties to allow them to securely identify each other. Banks began to pilot SET at the beginning of 1997, but this was done mostly on a regional basis (which does not fit well with the global way in which the Internet operates), and these pilots achieved limited success in terms of persuading large populations of users and merchants to change over to the new system. As of mid-2002, SET has still achieved little market penetration and its proponents are beginning to experiment with so-called "light" versions of the standard that involve less complexity.

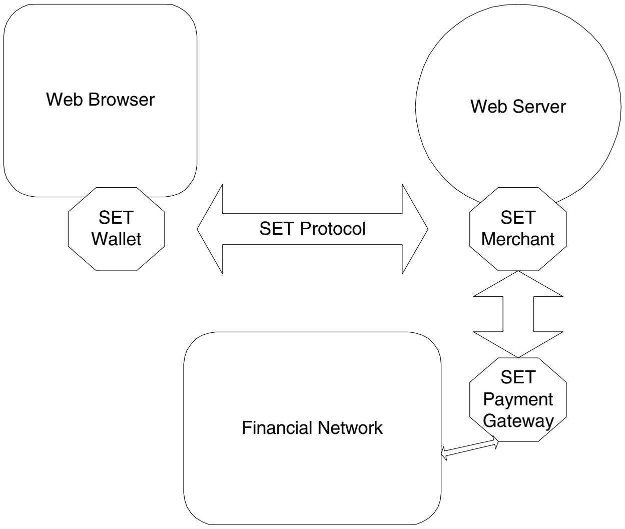

Figure 6: The secure electronic transactions protocol.

Account-Based Systems

Most of the technology involved in a credit card transaction arises because the merchant and buyer have accounts with different banks (possibly in different countries) and each transaction involves both a check for funds availability and ultimately a transfer between them. All of this can be greatly simplified if all users hold accounts with one entity. At the point when a transaction is to be made, this one entity is contacted and requested to transfer the funds from the buyer's account to the seller's account.

There are numerous system of this type available on the Internet, most of which are operated by companies that are not banks or financial institutions. Two that are worthy of mention due to their substantial customer bases are Yahoo PayDirect and PayPal. These systems all have links to conventional payment systems, e.g., bank accounts or credit cards to inject money into or withdraw it from the system, but conceptually any method can be used. Indeed some systems, e.g., PocketPass, allow the account to be primed with cash by buying a prepaid card in a store.

The difficulty these systems have in succeeding is that they essentially create a private currency that is only acceptable to people who have registered to use their services. Since, initially, very few merchants accept the currency, this makes it less attractive for buyers to sign up to use the system. This chicken-and-egg problem has caused many companies to fail in providing payment services.

Cash-Like Systems

Since cash is used for approximately 80% of the transactions that people make, one would expect that there would be a great demand for this service for electronic commerce transactions. Market reaction to some of the earlier cash-based systems (most notably eCash from Digicash BV) was less enthusiastic than expected. This company launched and deployed a software-based system that allowed individuals to make arbitrary fully anonymous transfers of value between each other in a range of currencies. E-cash was rolled out in many countries around the world in conjunction with local partners (e.g., in the United States with Wells Fargo bank and in Germany with Deutsche Bank), but in most cases was not a big success. The company has now refocused on a portfolio of payment solutions including a person-to-person transfer method.

Many other systems that claim to be cash-like are available in the market, but for the most part, these fall into the category of account-based systems, where the payment is simply a transfer between identified accounts on the provider's system.

Smart-Card-Based Systems

In conventional bank-mediated transactions, the trend for retail point-of-sale systems is away from paper-based instruments such as checks and toward electronic payment effected with a card. Most of the cards in use today are based on magnetic strip technology with some rudimentary account identifying information recorded (insecurely) on a magnetic strip on the back of the card. The banking industry is in the process of transitioning to the next generation of payment cards based on so-called smart-card or chip-card technology. Here, the plastic card has a chip mounted on its surface. When inserted into a card reader, this chip powers up and is able to have electronic dialogues with the card reader device.

The advantage is principally that the card can carry much larger amounts of information in a form that cannot be copied. The chip on the card encrypts data before sending them to the card reader, making it very difficult to break the security. Secret quantities such as cryptographic keys never leave the card. On the down side, the cards are more expensive to produce and are vulnerable to attacks from card reader hardware that has been subverted.

One application of the chip-card technology is in the realization of an electronic purse. Value is loaded into the smart card for later spending. There are two main efforts on-going in this area, the first by Mondex International and the second by a consortium led by Visa called the common electronic purse specification (CEPS). Of the two, the Mondex effort is more mature and has been in common use since 1992. The Mondex system offers a means of transferring value from one card to another. A person can transfer value from his card to that of his friend by simply inserting both cards into a hand-held value-transfer terminal. Similarly, bricks-and-mortar merchants can use a point-of-sale terminal containing a merchant card into which the buyer inserts a Mondex card to allow a transfer to take place. The Mondex card is in use in over 50 countries around the world, including several in sub-Saharan Africa. Pilot experiments have been conducted to use this system to make purchases across the Internet, but no large-scale scheme has yet been attempted.

The Visa-sponsored CEPS system is at a much earlier stage, with the CEPSCO consortium having been formed in late 1999, and early implementations are just beginning to appear. One of the difficulties of using smart-card-based payment methods for e-commerce is that each user's terminal must be equipped with a smart-card reader. Although many thought that this hardware would become part of a standard specification PC, this has not yet happened. It would seem that the prospect of smart-card-based payment methods becoming important in E-commerce is extremely unlikely for at least 2 years and possible indefinitely.

Where smart cards may play a role is in the emerging area of mobile commerce (m-commerce). Since all GSM digital phones contain smart cards (referred to as subscriber identity modules or SIMs) and there are expected to be a billion mobile phone subscribers in the world by 2002, this represents a large user base. As yet, though, it is far too early to tell what form the mobile Internet will take and whether the presence of a SIM will be influential in determining how consumers make payments in this environment.

Bank-Mediated Payments

Electronic Checks

The Financial Services Technology Consortium (FSTC) is an organization made up of the main American banks and banking technology providers formed in 1993 to enhance the competitiveness of the U.S. financial services industry

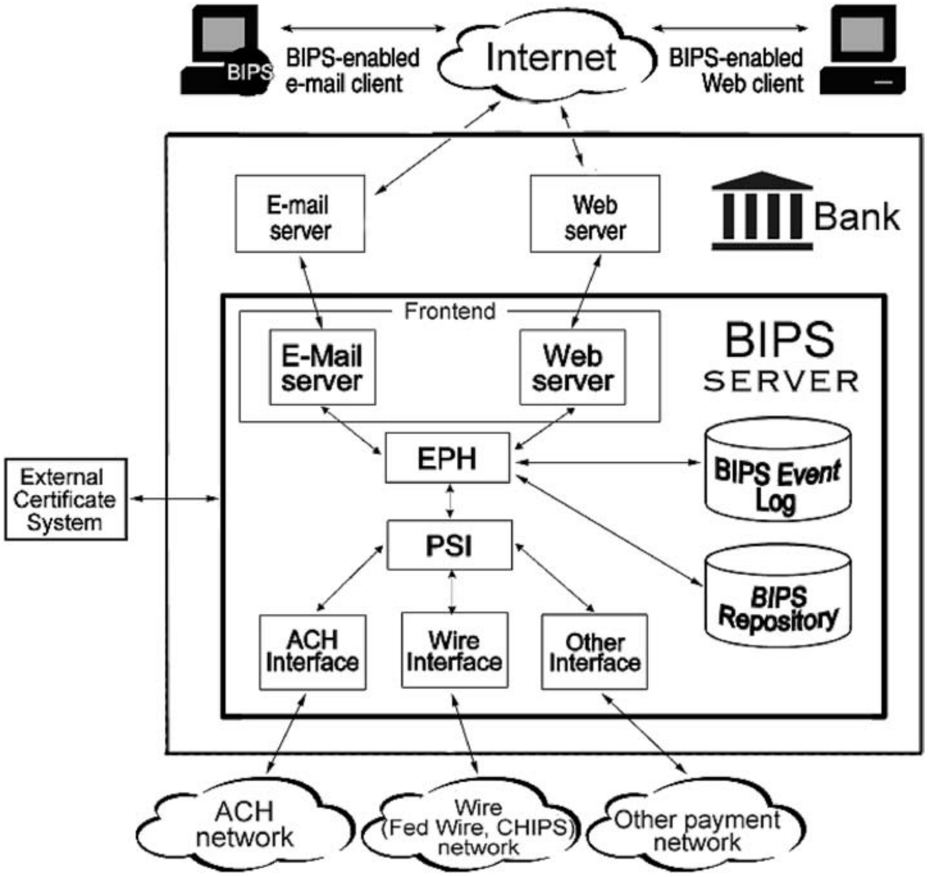

Figure 7: The bank Internet payment system (BIPS) architecture.

through the use of technology. For some years, it has been working on a specification for electronic-check-based payment (FSTC, 2001).

An electronic check is a document containing fields identical to those that might occur on a paper check, with appropriate digital signatures being added when the check is first issued by the payer and also when it is endorsed by the payee. A limited pilot using these checks was run in mid-1998, and subsequently, a new syntax for expressing the check was defined, called the financial services markup language (FSML).

Electronic checks expressed in FSML may be exchanged by trading partners in future B2B exchanges. Before these can be processed, though, the banks involved must have appropriate technological infrastructure to process them and use the information contained within to effect the required interaccount and interbank transfers. The FSTC has also laid out an architecture for upgrading a bank's existing technology to add the capability to handle electronic checks issued and transferred between organizations on the Internet.

FSTC Bank Internet Payments System (BIPS)

In 1996, the U.S. Financial Services Technology Consortium (FSTC) initiated a project to come up with a very general way to allow companies easier access to payment services. Their approach involved making as few modifications to existing U.S. banking systems as possible. Figure 7 shows how the Bank Internet Payment System (BIPS) acts as an Internet "front-end" to the existing ACH, Wires transfer, and other bank networks. Messages such as "payment requests" can be initiated by either e-mail or Web-based software. A public key infrastructure (PKI) is assumed to exist, and this component could be provided by the Identrus consortium, who are building an international PKI for banking applications.

BIPS was demonstrated in a number of projects involving the Glenview and Mellon banks in the United States in August 1998, but there has been no public progress beyond that.

Mobile Payments

In many European countries, most notably in Scandinavia, the percentage of the population who use mobile phones has exceeded 70%, and most other parts of the developed world are following the same trend, with industry estimates suggesting that there were more than 1 billion mobile phone users worldwide in April 2002.

Since each mobile phone can be viewed as a computer with network access, it makes an ideal payment instrument. In addition, GSM mobile phones are equipped with subscriber identity modules (SIM) that can be used to identify phone users and encrypt traffic between them and the network. A final plus point is that phone subscribers usually have billing arrangements with their network operators to which online purchases can be charged.

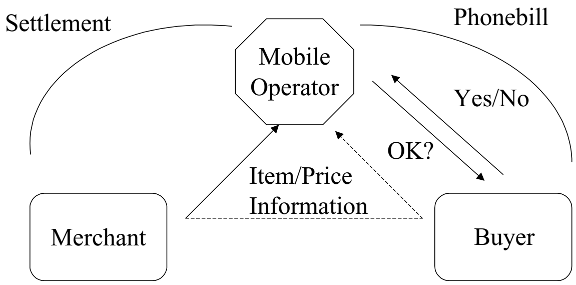

Figure 8: Making payments with a mobile phone.

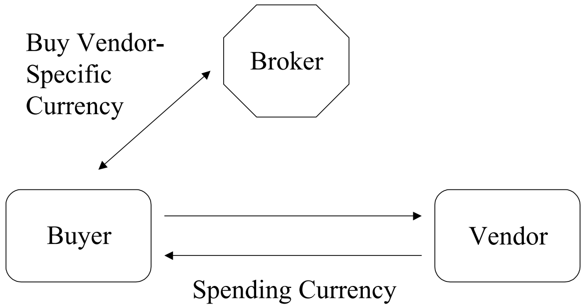

Figure 9: Typical micropayment system.

Many different payment systems that involve phone users making purchases using variations on the simple steps shown in Figure 8 are in development.

The buyer and merchant agree on the goods to be purchased and a reference to this information is conveyed to the mobile operator, possible via the buyer. The information movement can take the form of a phone call to a specially designated number or a short message or text message or may be part of a dialogue using the wireless application protocol (WAP).

In order to make the payment, the buyer is usually prompted by the mobile operator to indicate acceptance of the offer. Once again, this may be done using text messages or more elaborate dialogues, but it leverages the fact that the operator has already positively authenticated the buyer and can charge the amount of the purchase to the buyer's phone bill. The mobile operator will then perform periodic settlements with the merchant, usually deducting a percentage of the purchase price as a commission on the sale.

Micropayments

For some classes of goods and services, for example, access to information, the payment of a single once-off amount is inappropriate. In conventional commerce, this is typically handled by a subscription arrangement. Individuals subscribe to a magazine to be able to gain access to the articles published over a period of a year. While it might be interesting to sell access to a single article in a magazine, the value of such goods would be so low that it would be uneconomical to charge and collect such an amount.

Micropayments are a technology that makes such payments economical. They focus on allowing the payment of repeated very small amounts (e.g., 1 cent or less) to a single merchant. In a typical payment (called a macropayment), a buyer communicates with a seller, often using cryptographic mechanisms to secure the link or to perform authentication before a payment is made. The seller then typically communicates online to a bank or payment provider to check that funds are available and to complete the transaction. For micropayments to be economical, we must eliminate two aspects of this. First, strong cryptography cannot be used between buyer and seller, as to do so for such small transactions would mean that the seller's computer systems would be very limited in the dollars per hour of goods that they could sell. Second, we need to eliminate the online check to a third party when a transaction takes place, as there are very finite limits on the number of connections per hour that a third party's computer systems can handle.

Most micropayment systems involve a third party called a broker who issues a type of electronic currency bound to a particular vendor. Generally, this currency will be formed using lightweight cryptographic techniques and will use hash algorithms rather than more heavyweight encryption algorithms such as DES or AES.

As an example, at the beginning of the week, a buyer may make a credit card payment to purchase $20 worth of currency specific to a newspaper publisher. Throughout the week, he will then spend this currency as he browses individual articles in the newspaper. This process is shown in Figure 9.

Any unspent amounts can be redeemed at the broker. Then newspaper publisher will periodically redeem the spent micropayments at the broker and have its account credited.

In order to qualify as a micropayment, it must be possible for the vendor to check the validity of the currency without performing any very complex cryptography and without needing to contact the broker. Generally, it is impossible to do this without leaving some opportunities for fraud to occur. Micropayment systems typically allow a limited amount of fraud, but since the amounts being dealt with are small, the financial exposure is limited and worth the risk.

One well-developed micropayment was the Millicent system developed by Digital Equipment Corporation in 1995. A broker system issued a vendor-specific currency called "scrip." For each transaction, the buyer handed over the scrip and was given the appropriate change as a new "scrip" of lower value. This system underwent commercial trials in Japan in 1999, but has not progressed to wider usage. Other notable micropayments include the Payword system developed at MIT and IBM's μ3-KP.

Micropayments have yet to undergo any very large-scale deployments. One possible reason for this was the development of online advertising on the Internet. The ability for content providers to be paid tiny amounts based on page impressions for online advertising provided a solution to the problem that micropayments targeted and robbed them of their natural market. The slump that has taken place in online advertising, coupled with the fact that there are many other applications for micropayements, may see this technology deployed in the future.

CONCLUSION

In conventional commerce, many different ways of making payments have evolved, but most of these are based on the principle that the bulk of the payments occur locally. For example, a conventional check payment clears quickly when made to a merchant who shares the same bank. It is a little slower when there are two different banks operating in the same country and clears very slowly indeed when made between countries. The conventional payment method that works best globally is the credit card, and this had carried over well to the Internet, where very often the buyer and seller are very far apart. The bulk of Internet payments today are made using credit cards across a secure socket layer, which, although it protects against some of the risks involved, is still far from ideal. Many alternative technologies exist that can improve upon this, but they have proved difficult to deploy.

Many diverse payment methods exist that have characteristics similar to cash and check payment, as well as novel methods such as micropayments and payments initiated from mobile phones. While these methods often have many desirable properties that are improvements on conventional payment methods, they have yet to see broad deployment. Probably the major reason for this is the lack of locality on the Internet. It is difficult to assemble an initial population of buyers and sellers that can be persuaded to sign up for a new system and reach the critical mass required. Attempts by banks to introduce SET in particular areas failed due to this chicken-and-egg problem. Buyers will not sign up until there are a wide range of merchants using the system and merchants will not sign up unless there is a customer base that they can target.

It is likely that we will see deployments of many of the systems discussed above in the future, but it may take many years to establish a standard and it may require the backing of companies who have sufficient global presence on the Internet to reach the critical mass required within a very short period of time.

GLOSSARY

Credit cards Used by charging against the customer credit and are by far the most popular method used in electronic payment systems.

Micropayment systems Include stored financial value for online payments and are used for small payments such as pennies and fractions of pennies.

Secure socket layers Allow systems to authenticate themselves using digital signatures and X.509 Certificates.

Smart cards Include stored financial value and other important personal and financial information used for online payments.

Electronic Procurement

Robert H. Goffman, *Concordia University*

HISTORY OF E-PROCUREMENT

The concept of e-procurement has technically been around since the 1970s but in different formats and data transmission vehicles. The first electronic transactions took place through the use of punch cards and data phones that functioned as a primitive modem. A data phone transmits data one-way to prepunched cards identifying certain descriptions and quantities of the order. This system worked well with standard quantities preset by the manufacturer or supplier and usually required the merchandise to be stock items. The typical ordering consisted of maintenance type items that were regularly stocked in the supplier warehouse.

The next form of electronic procurement did not emerge until the early 1980s with the development of the facsimile machine (fax). The fax machine also provided one-way communication but offered several significant advantages over the data phone. First, it required printed material, which allowed for more detailed information than the data phone, including drawings, specifications, prices, and so on. Second, the fax did not require a computer technician to input the order and therefore was accessible to everyone. Both of these technologies had drawbacks including the following: (a) historical data was not kept electronically, (b) there was no communication assurance, (c) there was no security in place, and (d) they required manual lookups. The only way to verify receipt of the order was to follow-up with a phone call.

With the growing use of personal computers (PC) came the use of diskettes to send and receive data. A purchasing agent placed the appropriate purchasing information on a diskette and mailed it to the supplier. The supplier "read" the information, filled the order, and sent the diskette back to the buyer with the status of each item ordered. The use of diskettes provided a mechanism for maintaining historical information, increasing accuracy, and providing purchasing confirmation. Using the PC in conjunction with a fax machine further helped expedite orders. For example, a buyer could fax an order to the supplier then send a diskette with back-up detail and for tracking purposes.

This use of the PC for procurement became the foundation for electronic data interchange (EDI). As computers became more prevalent and powerful in the mid-1980s, EDI began to flourish. An EDI system is used to transfer purchase orders (POs) via electronic format from the buyer to the seller. It eliminates the necessity for double entry (data input from both the buyer and the seller) and allows additional information to be exchanged electronically, for example, forecasts of requirements, supplier shipping notification, overdue purchase orders, requests for quotations, material certifications, statistical quality analysis, and order changes and cancellations (Neef, 2001, p. 55). As EDI became an increasingly common form of procurement, technical standards were created to establish consistency among suppliers and buyers.

The Internet explosion of the mid-1990s created new strategic and technological visions in many areas. Use of the Internet and Intranet for e-procurement became a viable solution for corporations because it functioned as a powerful communication vehicle for transmitting data between buyers and sellers. The feasibility of using a full e-procurement solution increased in the public and private sectors as Internet browsers, such as Netscape and Internet Explorer, became user-friendly and the use of computers became routine.

From the late 1990s through today, the extranet has become the new strategic selling point for companies. It allows corporations to leverage their capabilities, extending volume discounts to their partners, receive additional revenue for use of internal suppliers, and offer price reductions.

INTRODUCTION TO MODERN-DAY ELECTRONIC PROCUREMENT

Today's e-procurement may be the next technological revolution for corporations, governments, and consumers worldwide. It became a technological priority for most top executives during the e-business boom era (1996–1999) and continues to be on many corporate technological agendas, even today. E-procurement has proven itself at some of the prominent corporations in the United States and also efficiently supplies the U.S. Navy. EG&G Logistics partnered with SupplyWorks to resolve the navy's problem of not having all supplies at the base's supply store when the ships came to port. With this partner solution, navy personnel now have the ability to order online while at sea through SupplyWorks' Web site using an Internet browser. The orders would be completed and delivered to the base store by EG&G ready for the personnel when they arrive.

Another prime example of an early adopter of e-procurement is General Motors (GM). GM began seeking an e-procurement solution in late 1999 and implemented its first version the following year. With a $63 billion procurement expense, GM expects substantial cost savings through the use of e-procurement. Savings would be captured through reduced prices, better analysis and information, better supplier control, and so on. It was also a logical transition as GM was already familiar with and using EDI. In early 2000, the automotive industry made a significant announcement regarding procurement. All three major U.S. manufacturers were about to embark on the creation of a single Internet-based procurement network. The purpose was to lead, control, and benefit from the significant technological advancements that were taking place.

A large part of e-procurement savings comes not from the reduced transaction costs and prices, but through strategic information and negotiations. Database management is a large part of e-procurement. "A fundamental characteristic of sourcing decisions is their uncertainty. A buyer never has complete information about all aspects of supplier performance and [its] future development" (Essig & Ulli, 2001). The goal for most e-procurement solutions is to provide more information in order to gain substantial benefit in varying ways, including cost savings, negotiating power, more accurate forecasting and analysis, reduction of uncertainty, and mitigation of risk. These are clearly reasons why GM wanted to enter into e-procurement sooner, rather than later.

With savings already being recognized by organizations such as GM and the U.S. Navy, e-procurement came to the forefront of media hype referencing how the e-business revolution would change the corporate world, and the way business is conducted fueled the fire. Industry analysts suggested the world was about to become "virtual" overnight, thus eliminating the need to visit stores or physically handle merchandise before purchasing. All shopping would occur electronically over the Internet, and companies that spent years solidifying market share would remain viable only by moving away from brick-and-mortar to selling over the Internet. Such prognostications certainly increased sales for those whose technologies facilitated Internet access. Nothing happens overnight, however, and efficient and effective use of these hyped products remained unproven. Moreover, several of the "revolutionary" products and technologies that were promoted as providing e-commerce turned out to be nonexistent or overrated. Ironically, those consumers who purchased goods over the Internet encountered a variety of problems including limited security and customer service. Through hindsight, we know that the majority of e-commerce companies still in business have survived by skillfully managing their cash flow, are well funded, and have a real product that buyers want.

There are a variety of ways in which people currently use the Internet for commerce. This chapter focuses on business-to-business (B2B) e-commerce as it specifically relates to e-procurement. This segment of Internet commerce is growing with total transaction values estimated to grow to $2.2 trillion by 2003 and $7.4 trillion by 2004 (Rybeck, 2001). Although the bursting of the technology bubble has caused companies to pull the purse strings on many new technology initiatives, most corporations continue to view e-procurement as a promising option and a part of their future.

What Is Electronic Procurement

E-procurement is a subcategory of e-commerce and supply chain management. At a basic level, it involves purchasing merchandise or services through a Web site. At a more global level, e-procurement provides an efficient, paperless solution for purchasing goods and services by allowing the end user to order an item from a computer or other internet connected device, such as a cell phone, kiosk, television top box (i.e., Microsoft's X-Box), and so on, and using an electronic payment system while storing necessary information for future analysis.

Definition

The Center for Innovation, Business, and Manufacturing (CIBM; n.d.) in Australia nicely summarizes e-procurement: "E-Procurement is the use of the Internet to connect buyers with suppliers to facilitate the purchasing of goods and services focusing on business-to-business (B2B) and business-to-government transactions (B2G)."

An alternative, more detailed definition provided by the Aberdeen Group (2002), a Boston-based consulting firm, defines e-procurement as follows: "Internet-based procurement (e-procurement) creates private, Web-based procurement markets that automate communications, transactions, and collaboration between supply chain partners." Aberdeen Group research indicates that e-procurement offers the most direct and dramatic means for organizations to reduce costs, improve productivity, and increase profits (Aberdeen Group, 2002).

Although other ways of implementing e-procurement have been available for years, use of the Internet as the electronic transmission vehicle currently is the key element that characterizes e-procurement. Prior to the current technological advances, special software and connectivity was necessary for e-procurement through the use of EDI and proprietary packages. The Internet allows for the masses to use an inexpensive, easy-to-use, procurement method through a Web browser. Today, the newer e-procurement solution methods use the Internet, eliminating the complexities of EDI and proprietary setups and software. "However, in late 2001, most observers would concede that more talk than transaction has flowed through the Internet enabled 'supply chain of the future'" (Aberdeen Group, 2001).

SUBDIVIDING E-PROCUREMENT

Some analysts further subdivide e-procurement into indirect and direct. These terms refer to the type of transaction occurring and differentiate between items bought to run a business (indirect) and those purchased to make a product (direct).

Indirect Procurement

Indirect procurement involves purchasing any item required for daily activity. Common types of indirect transactions include office supplies and equipment, travel, replacement parts, and so on. In a typical corporate environment, indirect procurement accounts for more than 60% of all purchases, typically transacted by the end user (Neef, 2001).

Indirect procurement may be further subdivided into ORM and MRO. ORM is the products and services used to facilitate daily business routines such as office supplies, travel, furniture, computers, and printers. These types of purchases usually involve high-volume, low-cost items that are purchased on an as-needed basis. MRO includes those purchases necessary to keep production running, such as replacement parts and servicing of manufacturing equipment. Ordering these products is more complex than ORM because of varying volumes, the need for regularly scheduled services, and the critical nature of the purchase.

Direct Procurement

Direct procurement is any purchase a company makes that "directly" relates to the production of the product it sells. For example, for a company manufacturing computers, direct procurement would include purchasing hard drives, memory boards, circuits, CD-ROM, and so on. Direct procurement is often a part of supply chain management (SCM). SCM is any solution that automates procurement and activities related to buying the raw materials, parts, and assemblies necessary for manufacturing finished products.

Direct procurement can be more complex than indirect procurement for MRO purchases because the company often buys materials in large volumes from a limited number of vendors through a limited number of transactions. In addition, materials may be specialized and "made to order," creating even more complexity. Direct procurement is "mission critical," and an increasing number of firms will be developing e-procurement strategies specific to such purchases. In particular, experts anticipate an increasing focus on direct procurement strategies among manufacturing firms where procurement can account for up to 60% of their total procurement expenditure (Neef, 2001).

Implementation Strategy

Because MRO solutions are much more complex than ORM implementations, many companies pursue the ORM strategy first and follow-up with the MRO and direct purchase initiatives as a second phase.

The advantages of this type of phased implementation are twofold. First, immediate financial savings can occur by implementing an e-procurement plan related to purchasing "noncontract" ORM products such as office supplies. By purchasing contracts and establishing prenegotiated discounts with preferred vendors, a company can stop the average employee from shopping anywhere and save significant money. Of course, policies preventing maverick buying must be put in place and enforced to gain the full benefit of supplier negotiated contracts. Second, the non–mission critical nature of ORM products allows an organization to "practice" or "test run" strategies without jeopardizing the heart of its business. This reduced risk provides the company with time to learn and modify its plans and activities. Furthermore, a technology solution for purchasing office supplies and equipment will most likely be easier, quicker, and more efficient than a single comprehensive e-procurement solution for all areas.

This phased implementation approach may have varying scenarios, depending on the type of organization. Risk-averse organizations may want to take small steps and prove functionality and technical capabilities before a large undertaking. In this case, one may implement a view-only catalog (to be addressed later in this chapter) for a small group of users. Once this functionality is proven, another piece may be added to the solution, and so forth until a complete e-procurement solution is established.

Although this methodology requires more time and money to implement, many companies would have greatly benefited from this approach during the e-business boom and crash. This risk-averse approach may have easily saved some companies millions of dollars by realizing that the proposed solution was not viable early in the project. With less dollars being spent on technology and a more cautious business environment, most companies are now using this phased approach to technology projects.

Combining Direct and Indirect Procurement Into a Single Entity

Most organizations have focused on e-procurement for ORM. Realizing cost savings, time savings, and increased process efficiencies, e-procurement solutions are now being considered and implemented for MRO. Industry experts are currently forecasting a consolidation among direct and indirect procurement over a long period of time. Although this merger may not happen for a decade or more, great benefits will be realized once it occurs. Procurement organizations will be streamlined, proficient, and better leveraged. The procurement area will no longer need to divide its business and resources in two. Efforts will be focused on strategic sourcing and procurement negotiations. E-procurement solutions will continue to drive or contribute to reduced product prices, increased productivity, and overall cost savings.

The consolidation of ORM and MRO procurement would be extremely difficult without an electronic solution in place. The business process, negotiations, and people are significantly different between the two entities. An e-procurement solution allows the purchasing manager to spend his or her time where it is most needed, not deciphering a person's handwriting for a particular order.

E-PROCUREMENT ARCHITECTURE

Because there are multiple entities involved in implementing a full e-procurement solution successfully, the architecture varies from company to company and depends on what part of the process an entity is responsible for (i.e., buyer, supplier). Some general basic scenarios are identified in this section, as well as technology considerations. There are also some diagrams to help understand architecture at a conceptual level.

Buy Side Scenario

The architecture for a buy side model begins with the electronic catalog. The e-catalog is a conglomerate of all products and services from all approved suppliers and is located on a company's intranet. This is where the employees will shop and order products. The e-procurement software allows for electronic order approval, creates order forms for each supplier, and routes the order to the appropriate individual supplier. See Figure 1.

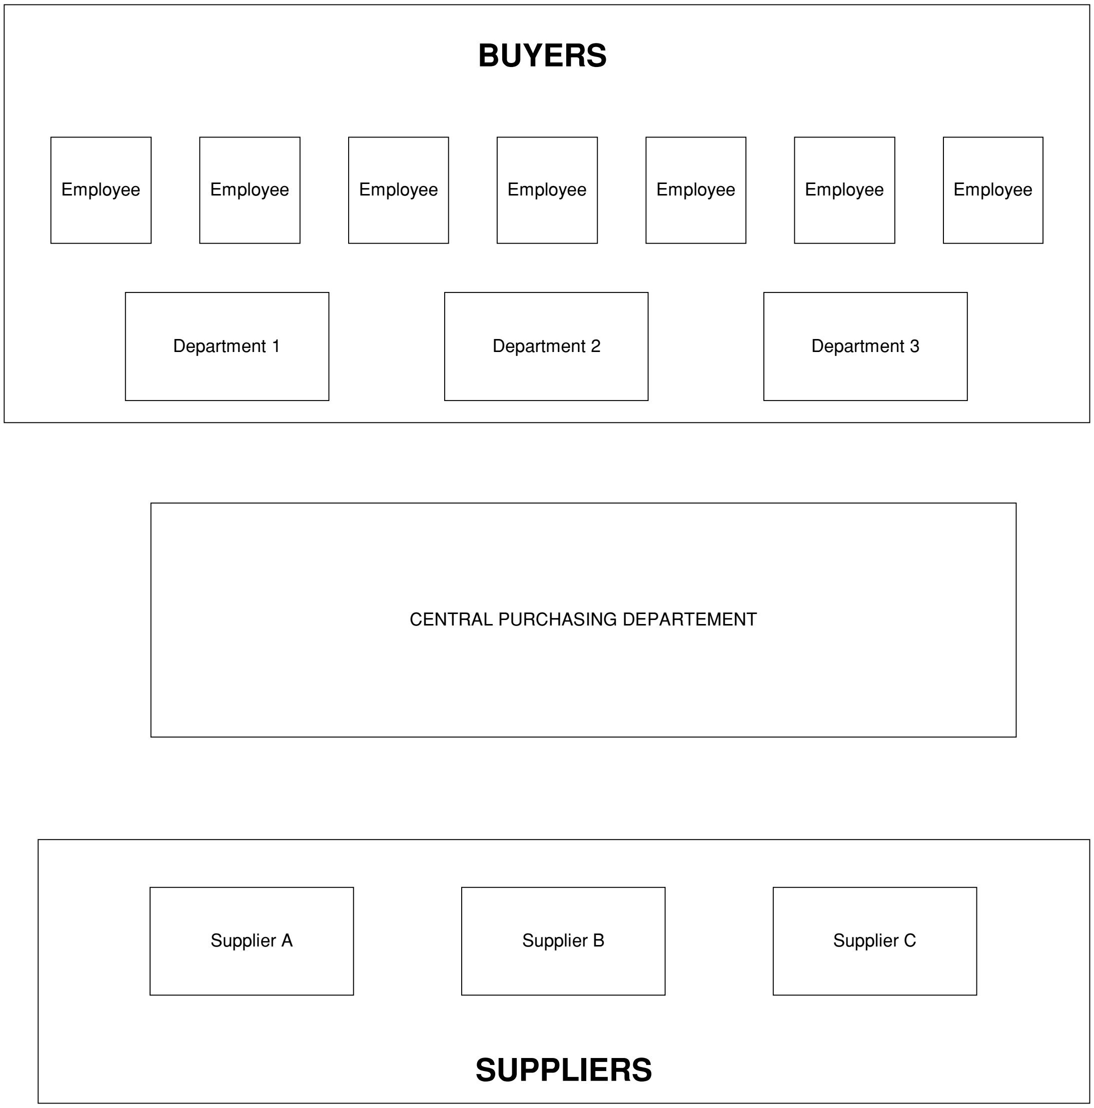

Figure 1: Procurement flow with central purchasing department.

The heart of e-procurement in the buy side model is the e-catalog. Without an easy to use, efficient, quality e-catalog, customers will not return to the intranet site. Customers will make their purchases through an alternative method, if possible.

The power behind an e-procurement solution is the software. Selecting the right vendor and software is also critical to success. The software should integrate into the current infrastructure and support the requirements gathered in the analysis. Although the buy side implementation may be complicated, the ultimate savings are worth the effort.

Sell Side Scenario

Most consumers are familiar with the sell side model. Shopping on the Internet at Web sites such as amazon.com and toysrus.com are examples of the sell side model. The suppliers offer items for sale on the Web site and receive direct orders from the consumers.

At a more complex level, suppliers integrating with large corporations may interface order processing with the client's back-office applications. Integrating supply chain management systems with e-procurement allows suppliers to replenish inventory automatically and reduce possible backlogs. More recently, suppliers have also added functionality to update the customer with real-time order status information via e-mail. See Figure 2.

Just like the buy side model, the heart of the sell side model is the e-catalog. The catalog gives the supplier visibility and drives customer business. Technically, the sell side model is usually easier to implement, but it is important to make sure that the same standards are in use at the supplier and buyer and that quality and service levels are monitored closely.

Electronic Catalogs

One of the most difficult pieces of implementing an e-procurement solution is the catalog. Establishing an effective e-catalog requires significant planning as well as search capabilities for item comparisons. In addition, maintenance of the system can become a major concern. Who will maintain the catalog? Where will the catalog be hosted? How often will the catalog be updated? What will be the process for maintaining the catalog? How are special requests handled? Most implementations focus on transaction efficiency and neglect the content management process until late in the project.

The complex and time-consuming task of developing e-catalogs has brought a new enterprise to market: content aggregators. The content aggregator works with suppliers to gather information and deliver it in a standard, searchable, user-friendly format (Intel, 2000). Some specialists in content management, aggregation, and delivery are Aspect, Requisite, and Harbinger. In addition to corporate e-procurement, many content aggregators also have e-marketplaces for their customers.

As mentioned in the buy and sell side models, the heart of e-procurement is the e-catalog. A successful solution will entice purchasers to return again and again, be easy to use, efficient, and effective. One bad experience will make it difficult to regain a customer.

Technology Considerations

Standard e-procurement architecture does not exist. Each organization most likely has a technical infrastructure already in place. E-procurement solutions will need to be integrated into current infrastructures or implemented within a larger technical solution such as an enterprise resource planning (ERP) solution.

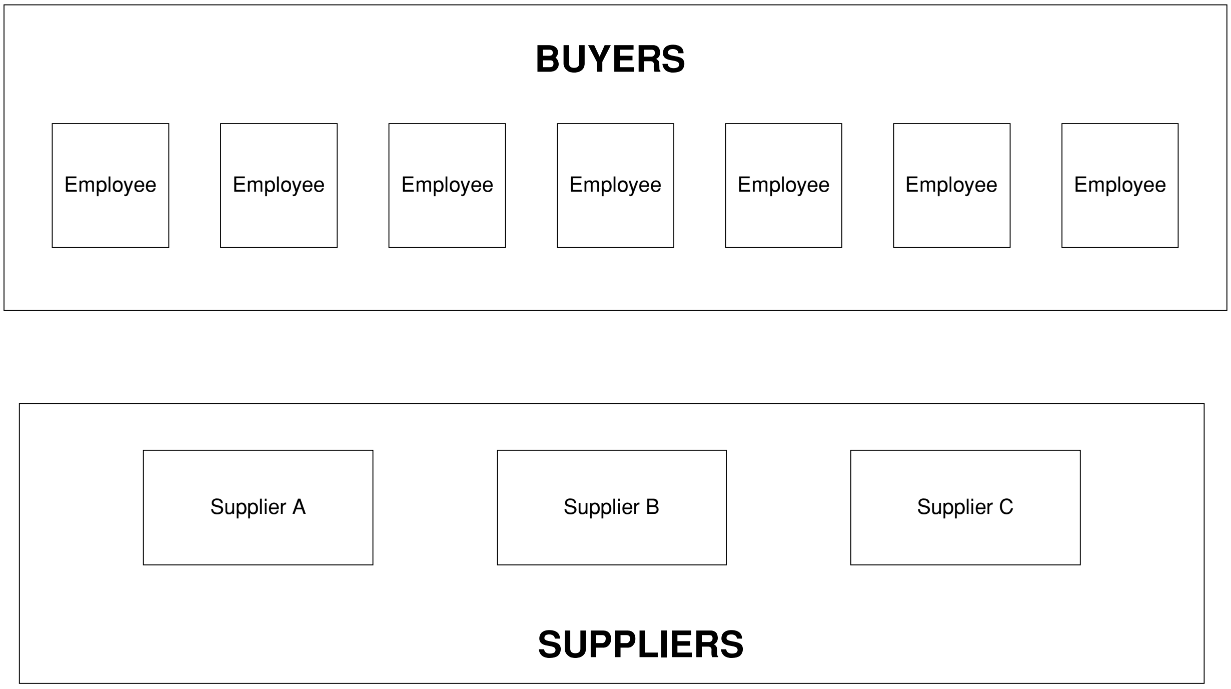

Figure 2: Procurement flow with empowered employees.

E-procurement architectures will vary from organization to organization and will certainly be different between suppliers and buyers. Because initiatives and business processes are different among suppliers and buyers, the solutions will need to adapt to current strategies.

There are some basic strategies about architecture. One will need to consider if there will be multiple vendors or a single vendor, if the solution will be integrated with other systems or set as a stand alone application, how the transmissions will take place, and whether all purchasing will take place through the electronic solution. Also, it is necessary to determine if Internet portals will be considered as a part of the solution.

When evaluating the architecture, there are several important questions to ask as well. What is the current organizational culture? Is a centralized or decentralized purchasing process in place? Should the e-procurement solution be a centralized or decentralized purchasing solution? The answers to these questions are critical to designing the e-procurement technical architecture and future business process.

To be successful, it is critical to evaluate a company's business process and what changes will take place. Make sure to have input from all stakeholders, especially the end user. This will not only help ensure success, but make the implementation much smoother and quicker.

Payment Systems

From a technical perspective, one of the most difficult pieces to implement in an e-procurement solution is the automated payment system via electronic transmission. A lack of formal standards accounts for the majority of concerns in this area. Over the past two decades, EDI has been the method for electronic transmission with standards in place. Unfortunately, only firms with deep pockets can take advantage of EDI because of the high expense and complexity entailed. In 1996, however, a newly developed standard called extensible markup language (XML) promised an affordable solution for secure transactional business data between firms via the Internet. A variety of vendors such as SWIFT and ACORD work to provide XML formats as an alternative system.

XML continues as the replacement method for EDI. In 1998, the Data Interchange Standards Association (DISA) conceded that XML as a Web-based technology would likely replace the traditional American National Standard Institute (ANSI) X12 EDI as the business-to-business standard for business data exchange. XML standards today are individually structured by industry, however, and therefore are not consistent across sectors. For example, the financial services industry uses the XML standards set by the SWIFT Cooperative, whereas the insurance industry uses XML formats set by ACORD. Even across software vendors XML standards are different. ARIBA uses cXML (Commerce XML), whereas Commerce One uses xCBL (XML Common Business Library). Although the basics of XML are intact, the standards still vary. For a financial services company to transact with an automotive company, middleware needs to translate the messages. The ultimate goal, however, is for a single standard of XML to evolve that provides standardized and predictable dictionaries of XML terms and repositories that store and manage the product descriptions (Neef, 2001).

PROCUREMENT STRUCTURE IN SUPPLY CHAIN MANAGEMENT

E-commerce is an extremely broad area that increases in scope on a daily basis. E-procurement is one area within the realm of e-commerce under SCM, a concept that encompasses all activities surrounding buyer–supplier relationships from forecasting and production planning through procurement to customer service and order management. The Supply Chain Management Group identifies the end points of SCM as the customer's customer and the supplier's supplier. Procurement is one small, but costly, piece of the supply chain. There are two market approaches to procurement: vertical and horizontal.

Vertical Markets

Vertical markets focus on one particular industry, such as financial, telecommunications, or transportation, and may cater to a core group of clientele. Many suppliers, especially in the manufacturing sector, are structured as vertical markets for niche items. Some of the leading hubs are chemdex.com, esteel.com, and neopharma.com. In addition to providing e-procurement services, vertical hubs often provide current news and other content of interest on their Web sites. Many buyers use vertical market suppliers out of necessity either because they require niche products or because of the specialized service. A vertical market supplier understands a particular industry in depth and works closely with its buyers to improve products and processes from both the buyer and supplier perspective. It is often a very close partnership. The hub provides similar services and benefits of an in-house e-procurement solution, but on a much smaller and much more limited scale. Simply stated, a vertical market hub gives the buyers direct access to member suppliers thus reducing product costs through the elimination of the middleman.

Horizontal Markets

Horizontal markets focus on broad categories that cross multiple industries such as software, electricity, or utilities. Although the majority of e-markets are structured vertically, horizontal markets are beginning to expand. Some examples of the newer horizontal markets can be found at redtagbiz.com, bidtag.com, and adauction.com. An excellent example of a horizontal supplier is an office supply store, such as Office Depot or Office Max. All companies require pens, pencils, paper, and so on. Office supply stores do not focus on any particular industry but distribute to all types of companies. Other, less tangible types of horizontal suppliers are gas and electric companies. These companies provide a basic need to everyone, regardless of the business involved.

Like the buyers and suppliers of the vertical market hubs, horizontal hubs allow direct access to suppliers therefore reducing costs. The supplier advantage of becoming a member of a hub is the increased visibility and potential for greater sales. Companies may need to use both vertical and horizontal markets. Just as indirect and direct procurement are slowly moving toward a single entity, vertical and horizontal markets will probably merge and become transparent as more companies implement e-procurement. This merger may be a decade away but is both feasible and likely.

THE PROCUREMENT PROCESS TODAY

For the majority of companies, the procurement process today is still manual and paper-driven. Supervisor and manager approvals are often required as well as a cumbersome procedure for ordering everyday items. Today there are two approaches to procurement, decentralized and centralized.

Centralized Procurement

Prior to the mid-1980s, most companies had a centralized procurement schema. All purchases had to go through a single purchasing department (Figure 3). For larger, multilocation companies, there may have been a purchasing office for each location or region, or have a single procurement department at the headquarters where all items were approved and ordered. Although many government agencies have a centralized procurement area they are beginning to realize the benefits of e-procurement and are considering electronic solutions. (See G2B: The Government and E-procurement later in the chapter.)

Although the centralized process may appear cumbersome, there are key advantages:

- Control—the organization retains purchasing knowledge and can better manage expenses.
- Contractual vendors—all vendors are contractual. Factors such as prices, quality, specifications, and service level agreements (SLA) are prenegotiated.
- Standardization—order forms, policies, and procedures are uniform across the company.
- Efficiency—orders are bought from appropriate vendors with invoicing and payment usually being centralized in the purchasing department.

The primary disadvantage to centralized procurement is time. Because of the multiple layers of approval, purchasing from an employee's perspective is often long and cumbersome. A purchasing department may delay ordering until there is enough demand or need for a particular product. Although this may help reduce cost through bulk purchasing, overall cost is higher when taking into account lost productivity, probable maverick buying by the end user, and additional effort tracking items purchased, on hold, and rejected. These disadvantages are easily eliminated through e-procurement and decentralization.

Decentralized Procurement

In the late 1980s, the paradigm began to shift toward decentralization. Companies wanted to streamline the process and possibly realize some time and cost savings through decentralized procurement (Figure 4). Although still a paper-driven process, a person or manager was now empowered to order low-cost items without approval. There are many strategies and levels of decentralization. Some companies allow invoicing and payment to become a department responsibility, whereas others leave this to the procurement department. The procurement area's responsibility ranges from duplicating orders on a shadow basis (the order is entered twice but only sent once) to complete autonomy and focus on strategic sourcing and vendor management. This responsibility depends on the need and desire for control at a corporate level.

THE E-PROCUREMENT DECISION

E-procurement solutions exist for both centralized and decentralized organizations. If the organization is centralized, all orders placed by the end user would be sent

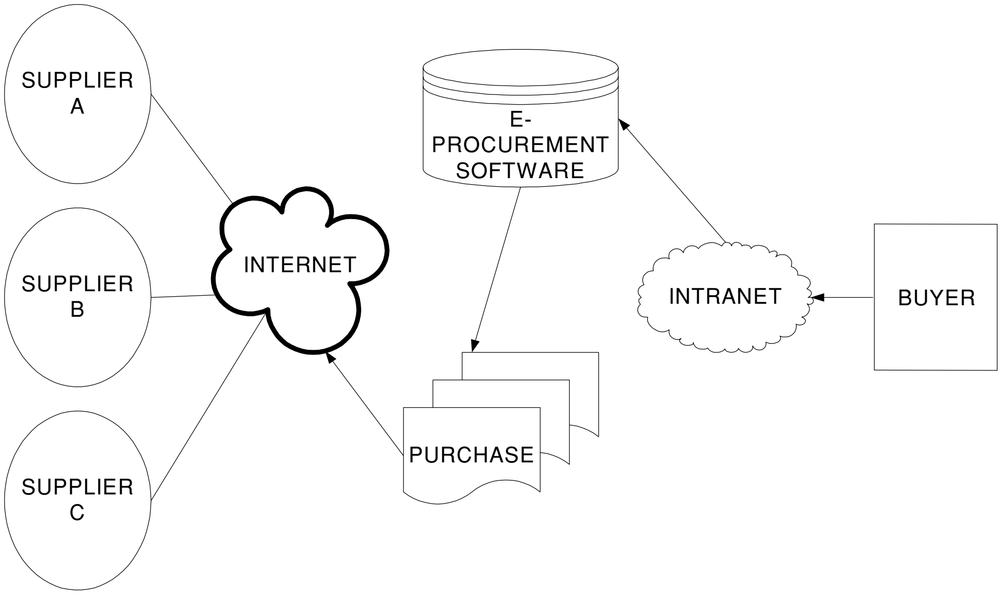

Figure 3: Generic centralized e-procurement architecture.

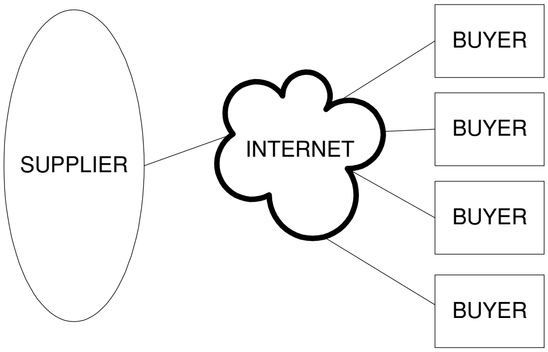

Figure 4: Generic decentralized procurement architecture (employee empowerment).

to the centralized purchasing location for review and approval. E-procurement streamlines the process, reduces cycle time, and lowers cost through use of negotiated contracts, reduced maverick buying, and process efficiencies gained. In a decentralized organization e-procurement efficiencies are gained through e-catalogs, reduced order errors, reduced cost through use of contractual suppliers, and improved productivity. Both structures can benefit by e-procurement solutions. There are several key considerations to review and analyze before deciding to design an e-procurement system.

Evaluation of E-procurement

Advantages of E-procurement

As almost every article, book, and publication on the topic notes, e-procurement benefits the bottom line in many ways. The main advantage of e-procurement is reduced costs through various avenues, including the following:

- Improved internal efficiency—productivity will increase through the use of e-catalogs and automated approval, eliminating paper catalogs and laborious, manual, paper-driven ordering and approval processes.
- Minimized maverick buying—employees will reduce or eliminate buying supplies from noncontractual vendors.
- Increased purchasing specialists bargaining power—the primary role of the purchasing specialist will no longer be order taking and "translating" but deal making. The specialist will negotiate volume discounts based on the entire company's budget. The specialist will focus on limiting the number of suppliers and ensure SLAs.
- Cut supplier costs—suppliers gain efficiencies and lower costs by reducing overhead through automating tasks previously done manually, such as order scheduling, advance shipment notice, and order acknowledgment.
- Reduce order error rate—with the inception of e-catalogs, new product and pricing information can be updated immediately, reducing order error rate. Suppliers will focus on value differentiation instead of order problems.
- Increased product visibility—the e-catalog increases vendor and product visibility by use of search engines, Web sites, electronic markets, and Intranet catalogs.
- Electronic catalogs—e-catalogs increase user productivity through reduced search time and better presentation and information. The e-catalog also substantially reduces supplier print and distribution costs.

Challenges of E-procurement

Although e-procurement has the potential to save an organization millions of dollars in a single year, the solution does not come without great challenges, including strategic, cultural, and technological obstacles. Some of the main challenges companies have encountered are the following:

- Rethinking old assumptions—Web sites must be interactive and enticing, not just content providers. Create a site that will entice users to return to it.
- Business process reengineering—current manual processes and procedures will no longer work. New business processes need to be created and implemented including the following:

  Streamlined approval process,
  Reduction in suppliers,
  Monitoring of suppliers for quality and service level,
  Negotiate discounts with suppliers,
  Use of e-catalogs and new software applications,
  Order taking,
  Inventory tracking and reporting,
  Shipping, and
  Billing and payment.

- Reinvest in technology infrastructure—servers and telecommunications will now need to handle substantial databases and Web site usage efficiently. Systems should scale in processing capability, memory, and input–output requests.

It is clear that the largest challenge when implementing an e-procurement solution is the business process. The process, policies, and procedures are re-created and affect all personnel. This is why focus on corporate culture and business process is arguably more important than the technology itself. Training is a great expense in time and money. With a new procurement process and system in place, a company will need to train all users (probably the entire company) and will need to create a rollout plan. For most companies, this means maintaining duplicate procurement processes for some period of time. Some people will continue to use the old method until trained while trained personnel will use the new system. There are of course, ways to minimize the time period and duplication, but more likely than not, some period will be required.

One other area of concern and possible challenge when making the e-procurement decision is the financial consideration. Is there a budget for the solution, does the financial analysis validate the executive decision?

Financial Considerations of E-procurement

There are many ways of performing financial analysis when determining if e-procurement is monetarily the correct solution. Some methods to consider are net present value (NPV), return on investment (ROI), and payback period (how long will it take to recoup the cost).

Since the e-business bubble began to burst in 1999, most companies are more cautious with their technology investment dollars. E-procurement solutions are expensive. Depending on the size of company, cost may be in the millions or tens of millions of dollars. This should not discourage one from undertaking an e-procurement initiative. The financial analysis will most likely demonstrate that implementing an e-procurement solution is well worth the initial investment and maintenance cost. Remember, in addition to the visible dollars saved, there are many additional savings via "soft dollars" such as increased productivity and efficiencies.

The financial consideration and budget are important considerations in addition to all other analyses previously discussed. Combining all strategic, technology, and financial considerations together, the executive team is now ready to make a decision.

Corporate Strategic Procurement Considerations

There are many reasons to pursue an e-procurement solution within a company, including the ability to find new sources, lower transaction costs, shorten cycle times, reduce prices, and provide more value added activities. Of course, successful e-procurement strategies must also take into account the need for security, training, time, money, and standardizations. Depending on the size of the organization, global, national, and local strategies may need to be considered.

Global Procurement Strategy

Procurement strategies, policies, and procedures should begin at the enterprise level of an organization. For large, international companies, this means evaluating at a global level. Executives must analyze current procurement practices and evaluate the complexity, benefits, cultural challenges, and financial impacts of how an e-procurement solution will affect the overall strategic direction. Will an e-procurement initiative affect any ongoing or planned activities? Does it make sense to implement e-procurement throughout the entire enterprise? Will all departments accept a new procurement solution readily, or will cultural impact need to be addressed? These are some questions to ask when evaluating globally.

Enterprise strategies, analysis, and decisions, are often performed by senior executives. These executives view the entity as a whole and are not involved in detailed departmental activities on a regular basis. Therefore, participants from a national, regional, and local level must be included in the final decision and plan.

Intel provides a good example of a global procurement strategy and mentions some of the difficulties with a worldwide implementation. Two challenges Intel will need to address are standards for connectivity and bandwidth. With the hundreds, if not thousands, of other customers its suppliers have, placing standards around connectivity for e-procurement will prove challenging. Although bandwidth in the United States should not be a concern, there are countries where bandwidth and infrastructure will not be able to handle the procurement solution.

Regional Procurement Strategy

Similar to the view of global procurement strategy, the personnel responsible for national or regional strategies will also evaluate at a conglomerate view. Current procurement practices at a global level are limited; however, many companies do have regional procurement centers. Evaluation and analysis of contemporary and future procurement practices will be more detailed regionally with current buyer–supplier relationships and policies and procedures for purchasing in place.

Current culture and business processes must be considered when looking to the future. Again, will employees accept e-procurement as a solution? Will the corporate culture need to change? How will the business process change? What risks will the business units endure? Although these questions are similar to those for the global evaluation, they need to be addressed and answered with a more hands-on procurement perspective.

Local Procurement Strategy

Finally, there is the local procurement strategy, often considered the office or department. Senior management often gives the directive for local strategy. Although the local strategy is predefined by regional and national levels, it is still important to include local stakeholders in the decision process. These frontline personnel will often have substantial qualitative input. They are also the final stakeholders of the end result.

Strategic Technology Considerations

Global Technology Initiatives

It is important to evaluate all projects and technology plans in conjunction with the e-procurement solution when determining an overall strategic direction. Performing a thorough analysis up front will alleviate some major headaches later. For example, if a firm is currently implementing an ERP system solution, decision makers should ensure that e-procurement integrates into the current technology plan and system. It is also important to plan for upgrades, compatibility, scalability, and possibly advanced future technologies, such as integration with personal digital assistants (PDAs).

Executives evaluating global technology initiatives often view the enterprise from a limited perspective. Senior management makes global decisions based on research, subordinate input, media hype, budget, and coordination with other technology projects. To gain a better user and benefits perspective, it is important to have regional and local personnel involved in the decision-making process and plan.

Regional Technology Initiatives

Technology projects are often initiated and implemented at the regional and local levels of an entity. Globally, there are few technology projects that benefit an entire corporation. One primary example of a global technology project is ERP, which usually spans the enterprise. Although e-procurement can certainly benefit the entire enterprise, it is often initiated within an office or region. Again, current technology and planned projects must be evaluated when considering e-procurement. One must be certain that the decision is in line with the strategic technology plan and that it will meet expectations. Once a pilot of the e-procurement solution is proven, executives may want to expand it to the entire company.

Local Technology Initiatives

Local considerations are similar to regional technology initiatives; the main difference is functionality and perspective. At the local level (offices or departments) the view is much more from an end-user perspective. This is mainly where the front-end analysis is performed. What is the current procurement process? How can the procurement process be improved? What functionality is required for an electronic solution? These are the types of questions to ask at the local level. Technology personnel are also excellent resources to identify local challenges, type of employee reception an electronic solution is likely to encounter, and type of training that may be required. It is important to include stakeholders at all levels when considering a new technology initiative.

THE DECISION—DOES E-PROCUREMENT FIT?

When evaluating the final decision, there are two critical paths of questions to ask when considering e-procurement: organizational questions and technical questions. The decision approach will most likely be made by a top-down approach. In other words, the executive management team will view the initiative at the enterprise level. The executives then work with other management at the regional and local levels to ensure that e-procurement is the right initiative. Are there higher priorities? Is there confidence in the technology? Is the organization culturally ready for a complete business process change? These are just some of the initial questions to answer when making the final decision.

Cost-cutting measures are certainly a high priority on the short list, and e-procurement is one solution to reducing tangible and intangible costs over a short period of time. The challenges are substantial in many ways, but there is usually no reward without taking a risk. If e-procurement fits into an organization, it should be embraced and installed. If your organization is not ready for e-procurement, do not endure the technological difficulties and high risk.

For Purdue University, e-procurement was a fit. After 30 years of paper, Purdue spent $4 million implementing an e-procurement solution that went live in late 1999–early 2000. Purdue's immediate expectation of savings is 7% through more favorable supplier agreements and a reduction in staff. There are many other savings and benefits that will be realized over a longer period of time, such as better information, better control of expenses, negotiating leverage through automation, and more (Ariba Solutions, 2001).

BUILD OR BUY?

The build versus buy decision should be a "no-brainer." There are many quality and proven vendors with expertise in e-procurement. Because of the extreme complexity and scale of an effective solution, using current vendors in the marketplace is highly recommended. Building a solution in-house is unlikely to keep up with the ever-changing technology environment and standards set by suppliers, buyers, and vendors. Documentation of in-house systems is usually nonexistent. Support is usually poor, but that can also be the case by choosing the "wrong" vendor.

The more difficult question to address is whether to hire a services firm for installation and integration or to use in-house personnel. Supporting commentary by both Purdue and Intel say it is difficult to predict ROI and difficult to compare the cost of outsourcing or installing in-house. The major factors involved here are expertise, personnel, and time.

Buyer Perspective

The authors of *E-Purchasing Plus* identify 10 points to consider when starting an e-procurement solution:

1. Build your team.
2. Scan the environment.
3. Obtain management support.
4. Tie e-purchasing to your broader e-business strategy.
5. Perform supply chain audit and review.
6. Promote speed and convenience.
7. Manage and improve supplier relations and performance.
8. Change, change, change.
9. Maintain a strategic focus.
10. Create a sales interface. (Giunipero & Sawchuk, 2000, p. 113)

Additional steps necessary in conjunction with these 10 items in preparing for this large, complex project are the following:

1. Establish a management environment: leadership, vision, commitment, change process.
2. Identify the customer.
3. Understand the procurement customer and needs—internal (chief executive officer, chief financial officer, engineer, maintenance) and external (suppliers).
4. Determine procurement strategies.

There are many advantages to promote when trying to gain acceptance of an e-procurement solution. Some of these include savings through reduced product prices and lowered procurement costs. These savings come through several channels, including vendor negotiations, reduced maverick buying, straight-through processing, and elimination of paperwork and extensive labor and approval processes. Another advantage is increased user satisfaction. Employees will be empowered to purchase products necessary for daily routines and enjoy other benefits such as less hassle and quicker service, response, and delivery. Multiple suppliers and catalogs may be transparent to the end user, increasing efficiency and time savings. All of these advantages lead to more productivity while reducing costs.

In addition to internal advantages, suppliers increase their benefits and should pass some of their cost savings to customers. Sales may increase, visibility with end users will improve, supplier cost will be reduced via electronic processing, errors will diminish, and an electronic payment process will reduce transaction and payment delays. These are just some of the advantages to begin promoting when considering e-procurement. Another step in gaining acceptance is to evaluate the requirements of the Web buyer and the purchasing manager.

The requirements between an individual consumer and a company using e-procurement vary somewhat. Web buyers want speed, integration, information, ease of navigation and navigation options, and a service contact person. If the system is too cumbersome or the Web site does not work efficiently, consumers will want to purchase their product elsewhere. Purchasing managers, on the other hand, want to empower the end user to purchase standard and low-cost items (indirect purchasing), training them on free navigation, electronic catalog, privacy and security, purchase limits and restricted access, search capabilities, access for authorized suppliers, and so on. The front-end or user-interface is geared toward the Web buyer and the back-end or inner workings of the system is geared toward the purchasing managers requirements. Both of these needs must be met for the solution to prove successful.

In the past, small firms have been barred from e-procurement because of cost. In today's environment, however, smaller firms may have two options: using a marketplace or possibly using a financial services firm such as their bank. With regard to the former option, more and more vertical markets are popping up on the Internet. Ventro Corp. has created marketplaces for the life sciences industry. Some of their ventures are Promedix, specializing in medical supplies; Broadlane, specializing in health care commodities; and Industria, supplying pipes, valves, and fittings. The next option is leveraging a bank or other lender. Many banks, such as Wells Fargo, Wachovia, Bank of America, MasterCard, and American Express have created alliances to help smaller firms gain cost savings through their corporate contracts. For example, Wells Fargo has a large contract with Boise Cascade as its supplier. For a small membership fee, Wells Fargo's business clients will be able to leverage the prices within the Boise Cascade/Wells Fargo Agreement and purchase via Wells Fargo. American Express gives their corporate clients discounts at various places through their contracts, such as Federal Express and Office Max. Use the card and the discount is automatically applied.

So, what's the advantage for the financial service firm? Revenue. The bank can charge a membership fee; however, the real revenue would come through loan financing. For example, if a Wachovia business customer wanted to purchase 100 computers through Wachovia's supplier, financing can be arranged immediately through the bank. In this scenario, Wachovia provides the loan and also collects the membership fee. It also creates a stronger barrier for a customer to finance elsewhere.

Supplier Perspective

As previously stated, many suppliers implement SCM systems into their organization. It makes sense to use this current system for e-procurement because it establishes direct access to suppliers and reduces costs. In addition, the SCM may have add-on modules for e-procurement or may already be integrated into the system. An alternative route is to purchase a solution that will integrate into the current infrastructure. As mentioned earlier, building a solution will take more time and money than the effort is truly worth.

E-procurement Software Specialists and ERP Vendors

The number of e-procurement specialists on the market today is still limited. Several large name companies (e.g., Ariba, Itwo, Commerce One, and ProcureNet) and a few smaller corporations (e.g., Concur Technologies, Clarus, and Trilogy) dominate the specialist market. Today many of the ERP software companies are beginning to incorporate e-procurement modules into their solutions as well. Some big names in this arena include SAP, Oracle, and Peoplesoft. Initially, e-procurement software focused on the purchase of indirect goods, but within the last year, advances have been made to include direct purchases as well. Also, some of the larger e-procurement players such as ARIBA have created portal-based communities to which companies can subscribe and participate.

Ariba, Commerce One, and Purchase Pro are known to have built-in sourcing tools that support request for quote (RFQ) and the negotiation process. Other products, Maximo and Get-It, although strong in partner information and integration capabilities, may be limited in the sourcing area. Clarus has strong RFQ and auction tools. Often a company will receive a recommendation in choosing a product through either a current relationship already in place with a supplier, consulting firm, or logistics firm.

G2B: GOVERNMENT AND E-PROCUREMENT

A predominant area for e-procurement initiatives is in government organizations, the military, universities and hospitals. It is believed that e-procurement will not only save these organizations millions of dollars a year, but also will increase efficiencies, bargaining power, and service. Many of the purchasing procedures remain manual and require approval by managers, directors, or vice presidents, depending on the request. E-procurement solutions may automate the entire process, therefore eliminating many, if not all, of the approval steps and substantially reduce process time.

One of the largest areas of government spending is the military. E-procurement initiatives are becoming common place in the defense sector, although this may be due to the suppliers rather than to initiatives among government purchasing departments. Major defense suppliers such as Lockheed Martin and General Electric (GE) are streamlining their own procurement processes and moving to e-procurement systems with defense system buyers following suit. In addition to saving costs and increasing efficiencies, e-procurement allows supplier bidding to be more competitive, thus driving the material purchase prices down.

A further result of government's move toward e-procurement has been establishment of Web portals for purchasing and contracts Some example Web sites are http://www.fedmarket.com, http://www.gsaadvantage.gov, and http://www.nigp.org. An additional benefit is increased government accessibility and availability of information for contract announcements, awards, requests for proposals, procurement announcements, and bid notices.

Although areas of the public sector are extremely interested in e-procurement solutions, especially from a cost-savings perspective, many are slow to make a decision. Often there are monetary and political considerations. Although this solution has the potential to save organizations millions of dollars per year, there is also a large upfront cost to implementing the solution. Many organizations do not have the monetary capacity or budget to consider a full e-procurement solution today.

Because e-procurement has been proven in the private sector, many public, government, and nonprofit entities are beginning to consider e-procurement as a viable cost-reduction solution and planning future budgets to incorporate e-procurement into their organization.

THE FUTURE

E-procurement has made substantial technological advances over the past few years and is expected to continue improving efficiencies and productivity in the future. Consolidation is taking place by the solution vendors and will continue over time. Ultimately, the vendors that will remain will need to provide fully scalable integrated solutions—not only for electronic procurement, but most likely for the entire supply chain management structure.

E-procurement will become more virtual in the sense that employees may be able to purchase from any Internet-connected device and have supplies delivered to any location overnight. Users will request additional functionality for e-procurement such as enhanced interfaces with internal systems, automation for time and expense, support for electronic invoicing and payment processing, and improved reporting functionality.

The e-procurement solution will integrate seamlessly into an organization's e-commerce strategy and help enhance productivity as well as increase corporate profitability. "E-Procurement offers the greatest opportunity to improve processes, increase productivity, and reduce costs across the supply chain" (Aberdeen Group, 2001).

BEST PRACTICES

Over the past two years, the Aberdeen Group affirms that e-procurement is delivering "significant and verifiable benefits." Organizations are required to rethink fundamentally their sourcing, supplier management, and procurement strategy and processes when considering e-procurement. Proven implementations have overcome these challenges and provided the beginning of e-procurement best practices. Planning a strategy for e-procurement consists of new business processes and strong management directive and includes the following:

- Setting supplier selection criteria—reduce the number of suppliers through a methodical selection criteria approach. Using a minimum number of suppliers enhances negotiating power and increases savings.
- Planning for scalability—as catalogs and electronic usage become more robust, the infrastructure must be ready to handle large volumes of data and transactions.
- Reviewing suppliers' content update strategies—accurate information is a necessity for corporate buyers. Content management is critical to success.
- Choosing compatible solutions—Use your current infrastructure. If an ERP solution is already in place, work with your vendor for compatibility.
- Increasing information technology bandwidth—higher intranet and Internet usage may put a strain on the system. Ensure high network availability by expanding bandwidth.
- Building redundancy and load balancing—redundancy and load balancing traffic will also help ensure network availability. Slow, unresponsive systems lose customers.
- Evaluating all options—perform a thorough analysis of all business and technology requirements. Evaluating suppliers, vendors, and other stakeholders will help ensure a successful implementation and solution.

When executives contemplate if or how to implement an e-procurement solution, it is extremely important to include the overall corporate strategy, culture, and architecture. The majority of system implementation failures are due to a lack of incorporation and "buy-in" from all stakeholders. Several initiatives that address this nontechnical aspect of e-procurement implementation are the following:

- Improve efficiency and reduce labor costs by eliminating the manual, paper-based processes and providing enterprise-wide, self-service procurement;
- Enforce on-contract buying; eliminate maverick buying;
- Gather accurate and meaningful data on total spending, both by supplier and type of purchase (decision support);
- Using supplier performance, select preferred suppliers for strategic sourcing;
- Move as many transactions as possible to front-line employees without undermining business rules; and
- "Smooth out" the supply chain: integrate process and systems, internally and with suppliers (Neef, 2001).

A large part of success depends on a quality communication plan with the end user. More often than not, a company implements a new system and then simply expects everyone to use it. Regardless of the technology or the successful implementation of the system, plans like this almost always result in failure because they do not meet the users' needs and expectations. The end users in these situations typically do not use the new system or change their old habits unless some form of coercion takes place, such as eliminating the original system. With regular communication, everyone remains informed about the progress and expectations, thus fostering acceptance by all parties involved with or affected by the project.

Another key to success is engaging the appropriate mission-critical resources, such as procurement managers. Obstacles to this process depend on the people involved. Many managers are wary of e-procurement systems, fearing they will lose their job or power. To mediate this type of situation, depending on the size and complexity of the organization, executives need to reassure the procurement specialists of their job security and emphasize the critical role they will play in the purchasing process. Procurement specialist will not be eliminated, but reinvented; they will no longer manage paper catalogs and mounds of paper purchasing requests and invoices. They may manage an electronic catalog and content, create and oversee purchasing policy development in regard to the new e-procurement solution, and ensure compliance with policies implemented. Their positions will be more critical, not less.

The procurement specialist is the logical choice for the "super user" of the system and will be the expert for decision support, catalog management, vendor management, service level negotiations, and so on. Ultimately, this person should be cutting costs and maintaining metrics to assure executive management that the e-procurement solution is delivering the expected success. As described earlier, efficient and effective communication between all the people involved plays a critical role in the successful implementation of a new system. It is imperative for executives to remember this human side of the business equation.

CONCLUSION

The e-business boom brought e-procurement to the forefront of technology. E-procurement continues to be on everyone's mind, especially in today's tight economy. Although the e-business boom has turned into a bust, this e-commerce solution retains some leadership in executives' minds and technology initiatives. Cost cutting is rampant in the business world, and e-procurement embraces reduced product prices, enhanced productivity, streamlined processes, and increased profitability by

- Web-enabling the workforce,
- Establishing an electronic approval process,
- Expediting supplier relationships,
- Integrating supplier and buyer software systems, and
- Transforming an organization's operational culture.

An effective e-procurement solution will

- Decrease "maverick" buying,
- Reduce prices for materials and services,
- Reduce cycle time,
- Decrease administrative tasks and costs, and
- Support strategic procurement analysis and planning.

Fortune 1000 companies that have already implemented e-procurement solutions have clearly demonstrated the benefits and cost savings gained. The average transaction price of an order has been reduced 20 to 90%. Cycle times have been reduced 20 to 70%. The number of suppliers has decreased dramatically for all companies that have implemented an electronic solution. And of course, millions of dollars have been saved.

Hesitation and cautiousness are on executives' minds as well. Over the last three years, most companies have experienced reduced revenue, reduced profits, and economic problems. Layoffs have been abundant, bankruptcies in new technology companies are the norm. This has led to less spending on technology and slower decision making. The lesson learned from the e-business boom to corporate America is to analyze the companies with whom you partner and try to use technology and solutions that have already been proven. E-procurement is still in its infancy stage and will continue to grow as economic conditions improve. It will not be the boom of the 1990s, but e-procurement will continue to prove itself as a beneficial technology in savings, efficiency, information gathering, negotiation, control, and analysis. NatSteel Electronics has demonstrated four benefits of their e-procurement solution within the first year of implementation: reduced inventories, improved ability to react to customer schedule fluctuations, increased ease of doing business with the supply base, and less procurement staff. The benefits have just begun and will be proven even further over time.

GLOSSARY

Business-to-business (B2B) Transactions that take place between business entities, not between a consumer and a business.

Centralized procurement A single person or group of people responsible for all purchases within a company.

Decentralized procurement Purchasing throughout a company; purchases may be made by individuals, departments, offices, and so on. It does not require all purchase requests be sent to a single department within a company.

Direct procurement The purchasing of materials for the manufacturing of a product.

E-business A term used for all Internet- and electronic-related business, including Web sites, supply chain management, enterprise resource planning, e-procurement.

Electronic data interchange (EDI) A standard format for exchanging business data; the format is ANSI X 12. This form of electronic exchange is most often used in purchasing transactions and information.

Electronic procurement A technological purchasing solution that has greatly reduced or eliminated paper and manual processes. A business management system that integrates all facets of the business, including planning, manufacturing, finance, sales, marketing, purchasing.

Government-to-business (G2B) Transactions that take place between public and private companies and government entities.

Horizontal market Suppliers and products that focus on broad categories crossing multiple industries such as software, office supplies, and utility markets.

Indirect procurement The purchasing of materials not necessary for the manufacturing of products; purchase of materials for day to day activities and business.

Maintenance, repair, and operations (MRO) Activities that are directly related to the manufacturing of a company's product.

Operating resource management (ORM) Activities related to daily business but not directly associated with product manufacturing.

Supply chain management (SCM) Process-oriented, integrated approach to procuring, producing, and delivering products and services to customers.

Vertical market Suppliers and products that focus on a single industry, such as financial, telecommunications, or transportation and may cater to a core group of clientele.

Extensible markup language (XML) New standard developed by the World Wide Web consortium (WC3) to replace HTML (hypertext markup language) for development of interactive Web pages.

E-mail and Instant Messaging

Jim Grubbs, *University of Illinois at Springfield*

INTRODUCTION

Although this chapter focuses on electronic or e-mail and the interactive equivalent known as instant messaging, neither technology would be as widely available as it is without the existence of an internetwork (Bucy, 2000). We know the largest of these networks as the Internet itself. For a more complete discussion, consult the entries for Internet History and Web Services: Past, Present, and Future in this encyclopedia. There really isn't a single Internet. Rather, there are a number of smaller networks that have been brought together in such a way that data routed from any point on any of these interconnected networks arrive at their destination in milliseconds. Many of the technologies and techniques discussed in this chapter existed in earlier forms long before the existence of what we now call the Internet. In those earlier days, the penetration and availability of electronic mail and instant messaging was severely limited—often to users all tied to the same computer.

The Internet has grown both in scope and in available bandwidth. Even well into the 1990s, in order to participate in an Internet-based videoconference, institutions had to shut down other communication temporarily to have available bandwidth to accommodate the video. Additional bandwidth and improved coding schemes now make those types of activities more common, if not routine. As bandwidth requirements go, individually, most e-mail and instant messages have a minimal impact on channel capacity. But as we will see, the sheer volume of such messages totals to a significant portion of network capacity.

Merging Technologies and Digital Convergence

It is becoming more and more difficult to clearly differentiate between communication devices. High-resolution display screens are used for both new television technologies and computer display purposes. The personal computer not only manipulates financial data and allows us to create text and graphic documents, but also allows us to listen to compact discs and other forms of digital music. We can watch DVDs on our PCs. The PC is capable of serving as a digital recording and editing studio. PCs now run and manage much of today's radio and television programming. DVD players can decode audio CDs as well as digital audio and video files encoded for PC use, which are not part of the DVD standard. PCs can be used to make voice phone calls using TCP/IP networks. Cellular phones can be used to exchange e-mail and browse the Web while also retaining their traditional role as a voice communication device. E-mail can be delivered to a pager; PCs and cell phones can send pages.

What makes all of this possible is that the majority of communication channels are rapidly being converted to digital data streams. Once data are in digital form, a CPU and associated circuitry can manipulate, encode, and decode them in nearly any form imaginable. Some high-resolution and high-bandwidth media require very fast processors and large amounts of memory, but the central concept remains the same. All of these media are moved from one location to another in digital form. The result is an unprecedented convergence of technologies.

Synchronous and Asynchronous Messaging

Modes of communication, whether electronic or otherwise, can be divided into two categories. When two or more individuals engage in real-time, interactive conversation, they are said to be communicating synchronously. That is, all parties have the ability to both talk and listen at the same time. The same term applies to synchronous communication among machines. For the purposes of this chapter, synchronous communication is represented by instant messaging. When we write someone a letter, or leave a message on an answering machine, we are communicating asynchronously. We send a message and trust that we will eventually receive a response, but the overall interaction is spread out over time. The Internet equivalent is electronic mail.

Each form of communication has both advantages and disadvantages. Synchronous communication is immediate. We can both ask and answer questions interactively in real or near-real time. Asynchronous communication allows us contact with others at a time of our choosing.

Impact on Society

In 2001, e-mail, in the general form that we know it today, celebrated its 30th birthday. International Data Corporation estimates that 9.8 billion messages are sent daily with the number of messages continuing to rise (Hafner, 2001). Compare that to approximately 300 million pieces of e-mail as recently as 1996 (Hafner, 2001). It is important to note that 1996 was also the year at which the number of e-mail messages first equaled and then surpassed the number of pieces of postal mail sent on a daily basis. Long before the public popularity of e-mail, there were early indicators of its importance as a communication medium. In the early 1970s, more than 75% of the data exchanged on ARPANET were e-mail, even though that was not the task for which the system was designed (Hafner, 2001). For a quick overview of e-mail statistics and milestones, see Table 1.

In the corporate world, e-mail is the new interoffice memo. E-mail is asynchronous; users send and receive messages at their convenience. E-mail also allows a user to send the same message to a group of people with ease. Though text-based messaging is very inexpensive, predictions that e-mail would replace existing forms of communication were only partially correct. There is evidence that e-mail has created entirely new levels of communication in addition to the existing levels that it enhances or has supplanted. Twenty years ago, governments predicted that there would be a significant reduction in postal workers as the result of widespread use of e-mail, but in fact, the volume of traditional mail has doubled during that time; there has also been a significant increase in postal service employment rather than a decline.

Table 1 E-mail Milestones

Year	Milestone
1971	First e-mail sent
Circa 1973	75% of ARPANET traffic was e-mail
1981	General Accounting Office predicts postal employment would be cut by two-thirds by 2000 as the result of e-mail
1982	Postal Service E-com Mail introduced (electronic computer-originated)
1983	MCI mail introduced
1985	E-com mail product discontinued by postal service
1996	300 million e-mail messages per day (average)
2001	9.8 billion e-mail messages sent each day

Source: (Hafner, 2001)

Early digital communication modes, including the Morse telegraph, long ago broke down barriers of time and space. Although most of us associate the sounds of "dots and dashes" with Morse code, the earliest form relied on the "clicking" of a simple sounder, while the spacing between the clicks allowed for decoding. The instant messaging possible via electronic communication had a number of effects on society. Standard time, for example, replaced "sun time" so that merchants and traders could conduct business without confusion; the telegraph helped trains to run on a regular schedule. In the 20th century, e-mail has had an equally profound effect on society; documents of all kinds navigate around the world through the Internet in small fractions of seconds, and without any loss in detail (Rheingold, 2000). Time, and even cost, have all but been eliminated as a factor in communication, but these advances have not come without some potentially negative effects as well.

E-mail offers a way to remain relatively anonymous, but at the same time has provided a means for words to be easily archived and retrieved years after a message is posted. Unscrupulous individuals can exploit e-mail attachments to infect distant computers with a virus or other program designed to destroy data on a personal computer or even a corporate server. It is very easy to instantly send a message to the wrong person or group, with no way to retrieve the message once the send function starts. Users are besieged with unwanted or spam messages because e-mail distribution makes it easy to distribute such communication.

Marshall McLuhan (in McLuhan & Zingrone, 1995) noted that new media at first mimic older media. E-mail, in order to gain wide public acceptance, advanced from command line, text-only messaging with few features to a form inspired by more traditional written communication. Today, we see e-mail as a versatile form of communication, but the earliest e-mail programs did not even include a "reply" function. Once e-mail achieved a look and feel similar to traditional communication, it started to explore new and innovative ways of communicating. Mail with graphics and publication-style layouts is now widely used, thanks to the inclusion of HTML parsing in e-mail clients. It is now possible to include audio and video elements in e-mail in addition to text-based messages.

In addition to asynchronous, "send and receive messages at your convenience" forms of electronic communication, a parallel application exists for synchronous or "real time" communication. Popular instant messaging programs such as America Online's Instant Messenger

(AIM), Microsoft Messenger, and Internet Relay Chat (IRC) clients allow two or more users to communicate. These applications are fast becoming multimedia capable. Even Napster and other file-sharing applications are, at their core, based on IRC-type communication.

As we have witnessed on multiple occasions, our reliance on and penchant for e-mail can cause problems when e-mail systems fail to operate as designed. For example, in the 1990s, America Online frustrated large numbers of users when their infrastructure became unable to keep up with the load demanded by their customers; smaller but equally disruptive network outages occur on a daily basis. When business depends on electronic communication, it is hard, if not impossible, to conduct business when the technology is not working.

The Impact of E-mail on Terrestrial Mail and Facsimile

Although the public was slow to embrace e-mail during the 1970s and 1980s, facsimile or fax communication grew rapidly. Facsimile technology was not new, but the means to produce machines economically made the medium attractive to a wide range of users, especially businesses. Ironically, after the introduction of the personal computer in the 1980s, businesses regularly created documents in electronic form, only to print them and then fax the printed documents to distant points. On the receiving end, if an electronic copy was required, the document had to be rekeyed. Users were slow to realize that the file could be sent directly, without the intermediate fax step.

Today's messaging technologies make it easy to integrate a variety of communication channels. Even when the recipient prefers a fax transmission, it is now an easy matter to start the document as an e-mail message with automatic translation and delivery via a fax server. Speech synthesis and speech recognition are making it possible to both send and receive e-mail messages using telephone circuits.

How Instant Messaging Has Changed Telephone and Face-to-Face Communication

Instant messaging has had multiple effects on line usage time. It is just one of several new communication modes that have changed the way we talk with each other. The rapid growth in Internet usage has actually had a positive effect on line usage time. It is more difficult to identify the percentage of that increase attributable to voice communication. Logically, much of the increase can be attributed to modem use. Demand for second and even third lines into private residences has skyrocketed as more and more households connect to the Internet. Cellular telephones and other mobile/wireless communication devices now supplement fixed-location phone service. The result has been a shortage of available telephone numbers, the splitting of area codes to create more available numbers, and more complex dialing requirements in order to accurately route traffic to more and more numbers. In 1997, Regional Bell Operating Companies (RBOCs) noted their concerns about Internet usage resulting in network congestion. Cable modems, some satellite connections, and DSL service provide full-time Internet connections without tying up the existing phone line or requiring additional phone numbers to be assigned. Additionally, home networks allow multiple computers to share a single Internet connection, further reducing the need for additional telephone lines.

As for instant messaging, there are strong indications that it has had a significant impact on the way young people, especially teenagers, communicate. America Online report that their system services more than 430 million instant messages a day (AOL Signs Messaging Allies, 2002). In 2001, the Pew Internet and American Life Project noted that three out of four online teens use instant messaging (Pew Internet and American Life, 2001). Twenty percent of these teens rate instant messaging as their primary means of communication with friends. More than a third use instant messaging to say something they would be unlikely to say by phone or in person. It is fashionable for teens to give others their screen names rather than their phone numbers. The topics of conversation are not new, but the method of communication is. Teachers also use instant messaging to stay in touch with students and to offer schoolwork help.

Instant messaging allows multiple, simultaneous, individual conversations. The Pew study found teens typically carrying on three conversations at once, known as "split attention." Researchers of online behavior question whether adults have developed or can develop the ability with the same ease as teens do. The Pew study found that less than half of adults active on the Internet have ever tried instant messaging.

Even the classroom is not immune to instant messaging. Using wireless devices, students send instant messages to friends while in class. The study found that students engaged in such behavior, along with college students who used instant messaging late into the night, got lower grades and missed more classes. Many online adults have also adapted to the instant messaging medium to keep in touch with family or, in some cases, to look for companionship. Where it was once common to make a weekly phone call to distant family, almost daily instant messaging sessions have replaced many of those conversations. Business people use instant messaging to stay in contact with team members. For example, an engineer working on a project at a customer's location can consult with other engineers at distant locations without trying to balance a telephone handset at the same time. Other businesses are offering online help and support via instant message.

Instant messaging also provides a tool for the deaf community. In the 1960s, an amateur radio operator created a program to recycle older models of teletypewriter machines (TTY) as communication devices for the deaf (Grubbs, 1988). Advances in solid-state technology allowed the creation of smaller telecommunication devices for the deaf (TDD). Such machines generally are self-contained and connect via specially designed acoustic modems to standard telephone handsets. TTY and TDD machines cannot directly connect to the Internet. As late as the 1980s, a significant portion of the deaf community resisted the switch to the text communication possibilities of the home computer. Much of the problem was one of compatibility. PCs were still a novelty, whereas the TTY/TDD network was well established. With the proliferation of PCs and the introduction of

AOL Instant Messenger in the 1995, the deaf community quickly embraced the technology. Instant messaging serves as a tool which levels the playing field for the hearing-impaired. Online, a deaf individual is perceived the same as any other user; interpreters are not required, and meetings can occur with both hearing and hearing-impaired participants without special arrangements. The types of communication most people have taken for granted are now convenient for the hearing-impaired as well. The one remaining obstacle has also recently been shattered. For example, with devices like the BlackBerry (Blackberry, 2002), e-mail and instant messaging are available in a mobile, wireless environment at a reasonable cost. The BlackBerry is a wireless handheld device with optional data and phone services. The hardware itself is less than $400—the cost of a full-featured TDD device—with an additional monthly service charge in the $20 range.

THE HISTORY OF E-MAIL

The First E-mail

Whereas "talk" or chat commands allowed synchronous communication among computer users, early pioneers saw the need for and usefulness of an asynchronous method of communicating among themselves. Ray Tomlinson, of Bolt, Beranek, and Newman, is credited with sending the first e-mail in 1971. Using the command-line programs SNDMSG and READMAIL, Tomlinson sent the first message to himself—to prove the concept. E-mail was soon adopted by his colleagues as a part of their regular communications. A number of e-mail servers and clients were soon developed.

BITNET Mail

BITNET was a network specifically designed for the communication of electronic mail. It ceased operation on December 31, 1996 (CREN History Winding Down, 2002). Though it is now primarily of historic interest, much of today's electronic messaging can be traced to the days before the Internet existed and specifically to BITNET. It began in 1981, providing the City University of New York and Yale University with a way to exchange messages. It grew to more than 500 institutional members in the United States alone. Internationally, BITNET connected with 1,400 institutions in 49 countries (CREN History and Future, 2002).

The routing and propagation of e-mail on BITNET used a concept different from that common on the Internet. Rather than an end-to-end connection being established between two distant points for direct transmission of messages between mail servers, the "store and forward" method used interim nodes connected by leased lines. In some cases, BITNET connected systems that relied on dial-up connections. Although it was based on an IBM standard, VAX, UNIX, CDC, and other computer systems could be used as long as they were capable of implementing the IBM NJE (Network Job Entry), a "store and forward" protocol.

Movement of messages from one node to the next was usually accomplished by regularly scheduled transmission and reception of messages grouped together for bulk delivery between major nodes. Especially in the early days of the system, messages could take days, even weeks, to arrive at their destination. Although BITNET itself has been supplanted by other communication means, one of the elements of the system lives on in a very impressive fashion. For ease in communicating with groups of people, LISTSERV, a mailing list server, is still widely used. Over the years, approximately 3,000 lists, covering most academic areas, have been created. As many as a thousand or more participants per list contribute to the discussions.

Today's Internet could be used for BITNET communication, but BITNET was an independent network designed to be self-sufficient. For a time, gateways allowed the exchange of electronic mail between BITNET and the Internet (NSFNET and its associated regional, state, and campus networks) and other networks.

Usenet/Newsgroups

The "User's Network" or Usenet is commonly referred to as the "newsgroups." Thousands of virtual bulletin boards are dedicated to just about every imaginable topic. There are currently eight hierarchical categories of discussion groups. See Table 2 for a list and explanation of each category.

A ninth category, called "alt," exists outside the officially defined eight general topic areas, even though it encompasses more newsgroups than any other category. It exists as a way to ensure free speech on the Usenet. In order to create a group in any of the eight main topic areas, a specific procedure must be followed. This is not the case with "alt" groups; anyone can create one. Usenet newsgroups can be particularly helpful in searching for answers to questions. An interface, such as that provided at http://www.google.com, allows anyone to search an archived database of newsgroup postings.

Newsgroup messages are created much like regular e-mail messages, though they propagate through the net in a somewhat different fashion. Network News Transfer Protocol (NNTP), developed at the University of California at Berkley, is the most common propagation mechanism, but others are used as well (Internet FAQ Archive, 2003).

Table 2 Usenet/Newsgroup Hierarchy

Usenet Hierarchy Name	Subject Matter
COM	Computer science subjects
HUMANITIES	Humanities subjects
MISC	Miscellaneous groups
NEWS	News topics
REC	Recreational subjects
SCI	Science topics
SOC	Sociological subjects
TALK	Controversial topics
ALT*	Alternative–any topic imaginable

*Not part of the official Usenet hierarchy.

Commercial E-mail

In 1983, MCI (now WorldCom) and CompuServe (now part of AOL Networks) provided the first commercial e-mail service (Hafner, 2001). A 500-character message cost 45 cents to send. Though messages were delivered electronically almost immediately, clients were not accustomed to checking for electronic mail. MCI offered a service whereby MCI employees would telephone recipients to let them know they had electronic mail and encourage them to check for it. From 1982 to 1985, the U.S. Postal Service offered a service known as electronic computer-originated mail (E-Com). Corporate clients could create messages electronically for delivery over a postal-service-controlled network (Hafner, 2001). If the recipient was not also an E-Com client, the message traveled electronically to the distant post office, where it was printed in hard copy form and delivered via standard postal mail. The advantage was that virtually all of the long-distance travel time was eliminated. This type of communication really was not new to the business world. Previously, telex messages flowed between major corporate clients. Telex machines were, in essence, teletypewriter machines connected via leased telephone circuits. Unlike e-mail, the telex machine was a dedicated device; when a message came in, the paper fed through the machine, making it obvious that one or more messages had arrived.

THE TECHNOLOGY BEHIND E-MAIL

Addressing, Routing, and Sending E-mail

The form of e-mail address familiar today dates back to a convention developed by Tomlinson for his e-mail system. He wanted a way to separate the user's name from the name of the computer to which the user was connected. The @ symbol became the separator (Hafner, 2001).

For e-mail to travel efficiently and effectively from one user to another, a central database of routing information is required. For further information, see the entries in this encyclopedia on transmission control protocol/Internet protocol (TCP/IP), digital communications, standards and protocols in data communication, Internet architecture and protocols, and public networks. E-mail is a subset of Internet traffic that relies on the TCP/IP standard. Those parts of the routing process unique to e-mail are discussed here. Internet addressing (and therefore, routing) is based on the assignment of unique IP addresses. It is possible to transmit and receive data of any sort, including e-mail, by knowing the IP address of the receiver. Early network developers soon realized that it is contrary to human nature to remember large groups of numbers. As a result, plain text "domain names" were introduced. For example, "uis.edu" is the domain name for the University of Illinois at Springfield. A domain name is independent of the route used to reach the domain.

Each domain has a set of records associated with it that help to route communication between two points on the network. One of the records is the mail or MX record. The mail server for the domain is specified in this record. Even in cases where mail is handled by a server other than the one used for other Internet communication, mail addressed to the domain is properly routed to the correct mail server. Following the convention, an e-mail address looks like this:

username@hostname.domain

The actual protocol used to exchange mail between mail servers is called the simple mail transfer protocol or SMTP (ISOC Internet Standards Programs, 2002). The server software used varies among operating systems. In Unix, sendmail is the most common SMTP server used. The SMTP protocol defines a set of rules for the exchange of messages. For example, SMTP communication begins with the HELO (hello) command; the actual exchange of the message begins with the MAIL command and ends with a QUIT command. These rules also include a method for determining the validity of the user name. Once the message has been exchanged, the received message is stored on the receiving machine's mail server until it is accessed by the user to whom it is addressed.

Receiving E-mail Using POP3

Post office protocol or POP (ISOC Internet Standards Programs, 2002) is a set of rules used by e-mail clients to both send and receive electronic messages. Its third release, POP3, is one of the most commonly used protocols for Internet e-mail. POP3 e-mail accounts are protected through the use and verification of account names and passwords. Various authentication systems are used to maintain password security. Once incoming messages have been read, they can either be deleted from the server or kept on the server. The local e-mail client can recognize previously received messages (because they have been flagged as read) and will not download them again. Passwords themselves can be encrypted and stored using DES (data encryption standard) or other schemes for protection. See the chapter on passwords in this encyclopedia for further information.

Receiving E-mail Using IMAP4

The Internet message access protocol (IMAP), developed at Stanford University in 1986, is a newer method of e-mail exchange than POP3. Like POP, IMAP is being continuously updated and is now in version 4 (ISOC Internet Standards Programs, 2002). IMAP4 includes features not found in POP3, including an enhanced "store e-mail on server" function. This feature provides functionality for users who travel, for example, and who prefer to keep all their mail on the server. It is also possible to get a list of pending messages but then only download a subset of those messages. This is especially useful when limited bandwidth is available, as is often the case with PDAs or e-mail-enabled cellular telephones.

HTML in E-mail

With the exception of e-mail attachments, which can take virtually any form, the body of an e-mail message is alphanumeric in nature. Whether one of the variations of the ASCII character set, or a specialized character set for another language, the core content of an e-mail message is alphanumeric. In an attempt to make e-mail more attractive, software developers realized that HTML code could be used to create e-mail with images and publication-type formatting. HTML is itself a text-based markup or formatting language. No special software is required to send a message with HTML in it. The situation is different on the receiving end. In the absence of an HTML interpreter, the message will appear as a plain text message that includes the HTML tags. In essence, e-mail clients that properly display HTML-encoded messages are using a simple HTML browser to interpret the HTML code and display the message as the sender intended.

On the sending end, e-mail software that allows a user to create an HTML message includes a simple HTML editor. All of this is generally transparent to the user.

Some e-mail clients implement only a small number of HTML tags. In that case, a message may properly display fonts and simple formatting commands, but be incapable of integrating graphics and more complex layouts. Put in the simplest terms, HTML-enhanced e-mail is a Web page contained in the body of an e-mail message. That is not the same thing as sending an HTML file as an attachment.

E-mail Attachments

Especially in the early days of networking, the channels used for exchange of e-mail consisted of circuits designed to exchange plain text messages. That presented a problem when binary files not encoded in plain text were exchanged. The solution was the creation of the Multipurpose Internet Mail Extensions (MIME) standard. MIME encoding of attachments is widely supported across the Internet and in e-mail clients. Regardless of the content of the attachment, MIME encoding changes everything from pure binary code to 64 alphanumeric characters:

ABCDEFGHIJKLMNOPQRSTUVWXYZ

abdefghijklmnopqrstuvwxyz0123456789 + /

The binary bits are encoded and translated into a hexadecimal code that can be represented by the characters shown above. On the receiving end, the hexadecimal-encoded text is translated back to binary. Additional instructions in the alphanumeric encoded text tell the decoder what MIME "type" the attachment is. For example, JPEG and GIF pictures have their own mime type, MPEG audio and video files have their own mime type, and so on.

Voice and Video in E-mail

Including voice or video in an e-mail message is as simple as attaching a properly encoded file containing the voice or video message. Although simple in theory, the challenge is to create a file of modest size so that it does not exceed the attachment limit on some e-mail servers. The solution to the problem is to use an encoding scheme that heavily compresses, or reduces, the total file size through a controlled reduction of redundant code. An example is Qualcomm's "Purevoice" technology. Internet e-mail users associate Qualcomm with the Eudora mail client, but their primary business is CDMA wireless (cell phone) technology. The result is a voice data stream that is very compact and requires very little bandwidth. Fidelity is limited to that of a standard voice connection.

There is another way to overcome transmission problems. Services such as AT&T WorldNet allow users to send video e-mail, but the video portion of the e-mail is never sent to the recipient. Rather, the video is stored on a video server. The text portion of the e-mail includes a URL to allow the recipient to access a streaming version of the file.

INSTANT MESSAGING

Unix "Talk"

Synchronous, "real time" communication of personal messages between computer users has been around since the first computer network was created. In the absence of an Internet or even an intranet, early implementations required that all users be hooked up to the same computer. Users accessed the central computer using "dumb" terminals. Terminals generally do not have any computing power. They are merely display and input devices connected to a central computer via hard wiring. With the development of UNIX by Bell Laboratories, the "talk" command became something of a standard for instant messaging. It was used extensively during the 1970s and beyond as a means for synchronous communication over ARPANET. In the UNIX environment, everything was done at a command line prompt. There was no graphical user interface (GUI). The talk program in UNIX was not very sophisticated. Messages from other users appeared on a terminal, interrupting whatever task the user was currently working on.

PLATO "Talk" and "Talkomatic"

The PLATO system was created on the Champaign–Urbana campus of the University of Illinois in the 1960s under the auspices of the Computer-based Education Research Laboratory (CERL). PLATO was designed specifically for computer-based education. Over time, a number of communication options were designed as part of the system. Unlike UNIX, the system included high-resolution touch-screen, graphic terminals that allowed complex graphics to appear on the screen rather than only standard ASCII characters. Talkomatic was the original chat client for PLATO. Characters were transmitted in real time as they were typed. Other talk programs generally delayed transmission until a return character was received from the keyboard. Several horizontal windows appeared on the screen—one for each participant in the chat.

Over time, the program was adapted to allow multiple communication channels, with each channel capable of handling five interactive users. The system allowed an unlimited number of users to monitor a particular channel, though an active user had the ability to "protect" the channel and allow only the active participants to see what was being exchanged. Talkomatic was constantly improved to the point of including many of the features we associate today with Internet-based instant messaging programs.

Internet Relay Chat

Internet Relay Chat or IRC is distributed, real-time communication. IRC traces its roots to the early UNIX Talk command and the associated Talker program. Talker programs are generally proprietary and run on single servers with a maximum of several hundred simultaneous users. Conversely, IRC is a multiserver, networked system capable of allowing thousands of users to use the system concurrently. IRC is an open Internet protocol invented in 1988 by a Finnish graduate student, Jarkko Oikarinen. Inspired by BITNET's Relay Chat and other existing programs, IRC became a reality in August 1988. Shortly after its introduction on Oikarinen's local campus, he asked friends at other Scandinavian universities to run IRC servers to help distribute the load. Soon after, MIT, the University of Denver, and Oregon State University joined the distributed server network As detailed later in this chapter, IRC got a boost in public awareness following the 1991 invasion by Iraq of Kuwait.

When a user starts an IRC client, he or she is connected to servers that distribute the messages. The purpose of the server is to echo the communication on a number of IRC channels. Although none of the users are directly connected, the IRC server creates the illusion that they are. Messages sent by each user are relayed to all users on the channel very quickly. By connecting distant IRC servers together over a network, the channels available on each server can be made available to all users on all active servers without the user having to take any special action. By sharing the load, both the number of channels and the number of users can grow without too great a burden on any single server. The distributed networks of servers share all of the traffic with each other. On a very busy network, there may be a delay of several seconds for messages coming from a distant server. More than a half dozen large IRC networks run simultaneously, each with dozens if not hundreds of servers. Tens of thousands of users can be accommodated at any given time.

In IRC language, a channel is a virtual meeting room. Users commonly use the term "chat rooms" interchangeably with channels. Users enter, participate, and leave channels continuously. Some client software allows a user to participate in multiple discussions on different IRC channels at the same time. Channels for just about every discussion topic and interest imaginable exist. When someone comes up with an idea for a new topic, it is a simple matter for that user to create a new channel. IRC channels are to instant messaging what LISTSERV is to e-mail.

IRC During Historic Events

During much of the 19th and 20th centuries, we relied on mass media to provide news on world events. At first, the daily newspaper was the means for disseminating dispatches from around the world. There were inherent delays. Even when events local to the newspaper were involved, there was a significant delay while a special edition of the paper was created and distributed. The advent of the telephone provided the means for virtually instant communication, but well into the 20th century it remained available only to the wealthy. The widespread availability of radio in the 1920s and 1930s provided a means for communicating information to the masses in a timely fashion. However, the content of those broadcasts was controlled by a relatively small number of individuals.

Radio amateurs ("ham operators") provided ad hoc communication networks as needed during times of disaster (Grubbs, 1988). Later citizens' band (CB) supplemented the amateur radio ranks with a large number of radio-equipped private citizens. These men and women still provide communication in disaster situations, but cellular and other wireless technologies have provided an alternative means of communication during such events. In the 1970s and beyond, the fax machine became a means of distributing information from a single source to many others in a very short period of time. The 1989 events of Tiennamin Square in China illustrated just how effective private fax machines could be at distributing information from "unofficial" channels around the world. Had the event happened just a few years later, the same information might have traveled worldwide via e-mail and IRC channels.

By 1991, the Internet was well enough established so that it began to rise as a favorite communication channel during difficult times. The 1991 invasion of Kuwait brought IRC to the public's attention. Even though traditional media outlets had been cut off, an IRC link was still operating a week later, with the result an exponential growth in IRC logins. Another event in 1993 resulted in a similar interest in IRC. As Russian lawmakers sealed themselves in Parliament, both Russian and American users relied on a specially created IRC channel to disseminate information around the world. IRC has been used in natural disasters as well. For example, when the 1994 Northridge earthquake in California knocked out many communication systems, Los Angeles Internet users established a channel to communicate with others outside the quake area (Why IRC Is Important, 2002).

Although we may never know the full extent to which Internet communication was used both in planning and in reacting to the September 11, 2001 attacks, we do know the tremendous amount of Internet traffic generated in the period shortly thereafter. IRC channels buzzed with news of the events worldwide. In all of these cases, this communication sprang up spontaneously, and for the most part, beyond government control. These events provide us with an indication of the power of the Internet itself and communication tools such as IRC.

AOL Instant Messaging

In addition to IRC servers run for the public, other proprietary chat networks exist. Perhaps the most notable is the instant messaging network available through America Online. The large user base for AOL has helped AIM to prosper. AOL subscribers automatically get the use of AOL's AIM instant messaging software. One of the unique features of AIM is that it can also be used by non-AOL subscribers. Newer versions of the Netscape browser also include AIM as part of the installation package. Interaction between members and nonmembers is seamless, as long as the nonsubscriber uses AOL's own instant messaging software. AOL members and nonmembers alike can access AOL's proprietary messaging system via a

Java-enabled Web page. The underlying software running AIM is similar to, but not compatible with, IRC standards. Early versions of the AOL instant messaging software did not allow group chats; the latest versions include group communication.

ICQ ("I Seek You")

The first release of ICQ came in November 1996. The design of the software embraced a new philosophy for locating and alerting online users for instant messaging. Current versions of the software allow not only instant messaging and chats, but also e-mail, SMS, and wireless-pager messages. File transfers and voice connections are also possible with ICQ. Although other messaging clients may be better known, ICQ has long been an innovator (*ICQ*, 2003). For additional information on audio and video transmission on the Internet, see other entries in this publication for related topics.

Microsoft Messenger and Other Instant Messaging Programs

Microsoft Messenger is that company's entry into IRC-like communication. Messenger comes packaged with an e-mail account (Hotmail) and other Microsoft products. Barnako (2002) reports that in May 2002, MSN Messenger was used by 15% of Web users, whereas AOL's Instant Messenger was used by 21% of Internet users. Like AOL's AIM, the underlying functions mimic IRC but are based on proprietary code. Yahoo Web Chat and Google Chat, as well as a number of private party software products, implement real-time chatting through Java-based clients accessed through a Web browser. This type of implementation tends to be significantly slower at distributing messages to chat members.

Interoperability Issues

Regardless of what IRC client is used, it can generally be used on any chat system that conforms to IRC published standards. Because many clients are written by hobbyists, there can be bugs. Unfortunately for the end user, proprietary systems such as AOL's AIM cannot be accessed via a standard IRC client. Similarly, an AIM user cannot directly connect with a Microsoft Messenger user. The only workaround is to run multiple chat clients simultaneously. Several software developers have developed multiprotocol clients that allow users to connect and interface with a number of different chat services through a single graphical user interface. For users of the Windows operating system, a program called Trillian allows access to Microsoft Messenger, Yahoo Messenger, and IRC using a single interface (Trillian, 2002). In the UNIX world, EveryBuddy is an example of such a client.

FUTURE TECHNOLOGIES

Although a number of messaging technologies have been introduced, particularly in the area of wireless and mobile applications, mere existence has not equaled acceptance (Grant, 2002). A 2001 study by the Yankee Group revealed that less than half those who tried wireless Web devices became regular users. The same group pegged wireless phone Web usage in the United States at the end of 2000 at 4.4 million users. In 2002, approximately half of wireless users had access to Short Message Service (SMS). Current predictions are for wireless Web usage to increase to more than 56 million users by 2005. In Europe, approximately 10 million users had access to the wireless Web in 2001 (Garcia, 2001).

The Potential of Wireless and Mobile E-mail and Instant Messaging

In the 1980s, amateur radio operators developed a form of wireless technology based on packet networking schemes to exchange e-mail messages. Admittedly, mobile operations were cumbersome, but they were possible. The same store and forward packet-based networks still operate on small LEO (low earth orbit) communication satellites and even the space shuttle. Commercially available mobile modems of the 1980s allowed laptops to connect to traditional dial-up services through mobile phone connections. The system worked, but was bulky.

In September 1999, Sprint PCS began offering wireless Web service aimed at the general consumer market. A product targeted for business users was introduced a year later. Today, virtually all mobile carriers offer some type of Web- or e-mail-like messaging service.

There are two primary obstacles to the success of devices that incorporate these features. As currently configured, data rates over wireless cellular networks are 14.4 kbps. Users accustomed to even a 56K modem find the resulting load times extremely long. Until additional bandwidth is available, there is very little providers can do to make access faster for wireless and mobile users. GSM (Global System for Mobile Communication) has the potential for bit rates up to an over-the-air bit rate of 270 kbps, although speech is still encoded at 13kbps. First launched in Japan in February 1999, NTT (Nippon Telephone and Telegraph) has developed I-mode technology—a competitor to the Wireless Application Protocol (WAP). I-mode is limited to a subset of HTML. As a result, I-mode pages do not require the type of translation server necessary with WAP. I-mode is capable of full-color presentation, is always on, and is packet-switched. Parallel voice and data networks make the "always on" feature possible. Normal HTML pages do need to be recoded with I-mode limits in mind, but the translation required is minor in comparison to that required for WAP server operation.

NTT markets the technology under the name DoCoMo—in Japanese, doco mo means "anyplace you go." In English, the acronym stands for "Do Communication Over the Mobile Network." Initially, data transfer speeds were relatively slow; however, with the introduction of a third generation (3G) network based on W-CDMA (wideband code division multiple access) technology, data rates up to 2 Mbps are possible. U.S. interests are developing and deploying GPRS (general packet radio service). GPRS is designed for data rates up to 115 kilobits per second, though it can be configured for a number of different bandwidths to accommodate a variety of services and situations.

The second challenge is associated with the input and output devices available on the typical wireless device.

Keyboards either are very tiny or require special manipulation of a numeric keypad in order to create a full range of alphanumeric characters. There is some hope for improvement here. Improving voice recognition technology can eliminate the need for routine use of a keyboard.

A 2-inch-square display screen is about average for most cell phones and other wireless devices; generally, the display is also monochromatic. Although this works well for short text messages, it is not a very effective output device for general Web content. The problem is similar to that faced by users of products such as WebTV, only worse. That is, in order to navigate most Web pages, it is necessary to scroll both horizontally and vertically in order to view the area normally available on even a small, low-resolution monitor. Wireless users are best served when the Web content is specifically formatted for a very small screen. As other electronic ventures have learned, a technology can be driven by available content; without content, the technology fails to find a home with the consumer.

The Wireless Application Protocol (WAP) allows HTML-coded Web pages to be converted on the fly to text only. All of the graphics and much of the special formatting are lost in the process. WAP does not support color. Carriers have tried to make the wireless Web somewhat more attractive by including menus of commonly used Web services known to be most compatible with WAP. Accessing sites not on the menu is still possible, but requires entering a URL using the small keypad on the device. Wireless devices also have limited memory and less computing power than larger devices, further limiting their ability to cope with richly featured Web pages. Single-purpose devices that allow both sending and receiving e-mail are also available. Research In Motion Limited of Canada has experienced success with a device known as BlackBerry (Blackberry, 2002). As of April 2001, Research In Motion had sold more than 200,000 units (Is Wireless Instant Messaging the Future of Communication? 2001). The unit includes a contact list (address book), calendar, and task list. Handspring offers devices that integrate cell phone and PDA technology with wireless Internet access. Treo and VisorPhone are two such products.

Successes in Europe, Japan, and Southeast Asia

The European and Japanese markets (as well as other areas such as the Philippines and Malaysia) have reacted more favorably to wireless and mobile applications. Carriers are aided in their attempts to attract consumers by the existence of a single transmission standard. The American open market allows competing technologies and standards. Although competition often results in new and innovative techniques, it makes it more difficult to capture the level of market share required to mass-produce devices with features and prices attractive to consumers.

Perhaps the most successful form of wireless instant messaging is a communication form well suited to the limited bandwidth and small display size (but still challenged by input device problems). In both European and Asian markets, short text messaging, more properly known as Short Message Service (SMS), has been popular for several years. SMS allows messages limited to 160 characters or less to be sent between SMS-equipped devices. Teenagers and young adults seem to have adopted the medium as their own. In some cases, SMS is only possible among customers who subscribe to the same system. Even so, in 2001 the GSM Association estimated that, each month, on an international basis, over 10 billion SMS messages were sent (Is Wireless Instant Messaging the Future of Communication? 2001). The *Wall Street Journal* reported that in May 2002, the number of SMS messages had risen to 24 billion per month (Taylor, 2002). In some areas, an SMS number has been established by police for deaf and mute persons, enabling them to take advantage of the safety of wireless communication (Taylor, 2002).

Presence Awareness

Instant messaging allows us to be aware of the presence of another person on the network. Currently, our awareness is limited in two ways. First, instant messaging software is generally a separate application; it is not integrated into the other computer tools that we use everyday. Second, we currently restrict our "presence awareness" technologies to person-to-person messaging. The future will include native instant messaging capability built directly into applications such as word processing programs, spreadsheet programs, and just about any enterprise where collaboration is useful. The possibility for generating new revenue streams exists. For example, an instant messaging client integrated into tax preparation software would allow revenue from tax preparation advice.

Today, collaborators can use a shared whiteboard product such as Microsoft's NetMeeting, but direct person-to-application messaging or application-to-person messaging can facilitate the process directly from the main application. Even machine-to-machine communication, for applications with "presence awareness," is possible.

"Session Initiation Protocol" (SIP) and "SIP for Instant Messaging and Presence Leveraging Extensions" (SIMPLE) are the protocols behind the idea (SIP Center, 2002). Interoperability (designing applications to the SIMPLE protocol) will be a key factor in the development of this technology. Lotus already incorporates "Sametime" instant messaging based on the standard.

E-mail from Your Toaster

E-mail and instant messages need not be limited to human communication or even communication between people and applications. Using "message queuing" (MQ), devices of all kinds can communicate with each other. IBM's MQSeries products, for example, allow applications on a variety of platforms to communicate with each other. The only requirement is an agreement on the content of the message (Kruczek, 1996). Communication-enabled appliances can be controlled by e-mail, issue reports on their status via e-mail or instant messages, or even communicate with each other.

Issues for E-mail and Instant Messaging

One of the challenges facing both the industry and end users is integrating convenient and accurate encryption into the client software we already use. Encryption methods such as "Pretty Good Privacy" (PGP) are available and work well, but tend to be cumbersome for users to implement. Although e-mail handles multimedia materials fairly well using the MIME format, some applications, such as Microsoft Outlook, have made alterations to the format rendering other e-mail clients unable to receive attachments under some circumstances. The areas of speech recognition and language translation also have the potential to make e-mail even more valuable. At the present time, reliable speech recognition remains elusive, and language translation, although possible, is still under development.

What's On the Horizon?

Gordon Moore, one of the founders of Intel, made an interesting observation in 1965. By plotting the capacity of microchips, he noticed an unmistakable trend: capacity was doubling every 18 to 24 months. That is, the amount of information storable on a given amount of silicon (a microchip for example) will double during the period. We now know this observation as Moore's Law. It rates escalation to a law because over the last 40 years it has been proven true over and over again. A corollary to Moore's Law is that as capacity doubles, prices halve during the same period.

George Cox, director-general of the Institute of Directors in the United Kingdom, notes that whereas it is relatively easy to predict the capacity of the technology itself, what is much less predictable is the social effects of technology. So although we can imagine and design communication devices incorporating artificial intelligence and virtual reality, what that will mean to society is nothing more than a guess.

In the immediate future, a number of technologies are ripe for deployment once the average user has access to enough bandwidth to accommodate the communication medium. We continue to see strides in coding techniques that allow many hours of full-motion video to be stored in devices that previously had trouble dealing with more than a modest number of textual data. Voice and video mail over the Internet are two technologies that will benefit from additional bandwidth. With enough available bandwidth, text-based messaging may become the exception rather than the rule.

In the wireless and mobile environment, issues of input and output will regulate growth. Voice recognition is likely to overcome the input obstacle. We already have "goggles" and small "flip down" transparent LCD screens that fit directly over the eye that may provide the necessary resolution for activities such as mobile Web browsing at the level of sophistication we have come to expect from our desktop computers and our home entertainment centers.

For the past 30 years, satellite communication has made near-zero cost connections available on a worldwide basis. They work especially well for data streams, but have an inherent delay when used for real-time voice or video communication. Until we find a way to change the physics involved, that is a limitation we are likely to have to deal with.

As is the case for roads, water, and sewer systems, we are likely to be tied to older network infrastructures for some time to come. The physical connections required for many services are expensive, with long terms for return on investment. Until the marketplace stops buying older technologies, we will still find them as part of our communication network. Wireless is not a panacea either. Electromagnetic and optical spectra, although theoretically unlimited, are limited by reality and practicality. In addition, the demand for bandwidth continues to grow at a rate that we have been unable to meet. There are environmental issues as well. We use microwaves to cook food for a reason—that part of the electromagnetic spectrum can be dangerous to the health of living things.

In the near term, expect e-mail to become more and more a relatively easy interface for the transmission of files and media streams of all sorts at the same levels of reliability and speed available today. In the instant messaging arena, expect more and more chat rooms to be netcam compatible—more videoconferencing in addition to traditional text-based instant messaging.

GLOSSARY

Asynchronous Digital communication for which there is no timing requirement. The transmitter signals the start of each.

Attachment A file associated with an e-mail message that is transmitted along with the main e-mail text.

BITNET "Because It's Time Network" began when two universities began using a leased telephone circuit for communications between accounts on their mainframe computers, eventually becoming a worldwide network. European counterpart is EARN (European Academic and Research Network) in 1982.

CDMA (code-division multiple access) Digital, cellular communication technology that uses spread-spectrum modulation techniques. Every *channel* uses the full available spectrum.

E-mail Electronically transmitted messages.

IMAP Internet message access protocol, a protocol for retrieving e-mail messages, developed in 1986 at Stanford University.

IRC Internet relay chat, a system developed by Jarkko Oikarinen in Finland in the late 1980s. IRC allows multiple participants to join in live discussions.

Instant messaging The generic term for any type of messaging system (e.g. IRC) that allows virtually instantaneous synchronous communication.

LISTSERV A commercial product marketed by L-Soft International that automatically distributes messages to a pre-determined mailing list. The term is often incorrectly used to refer to any mailing list server, including Majordomo, a freeware application.

Mime Multipurpose Internet mail extensions, a specification created in 1992 by the Internet Engineering Task Force for formatting non-ASCII character sets and non-ASCII and messages, such as graphics, audio, and video so that they can be sent over the Internet. A variation, S/MIME, supports encrypted messages.

PLATO Programmed Logic for Automated Teaching Operations. A computer assisted instruction system originally developed at the University of Illinois in the 1960s using hardware provided by Control Data Corporation.

POP (post office protocol) A protocol used to retrieve e-mail from a mail server.

SMTP (simple mail transfer protocol) A protocol for sending e-mail messages between servers.

SMS (short message service) An instant messaging system available as a feature on some digital cellular telephones.

Synchronous Communication that uses a common timing signal, that dictates when individual bits can be transmitted. In the context of this chapter, the term is equivalent to "near real time two-way communication."

TALK Command A UNIX operating system command that allows users to chat with each other.

TDD/TTY (telecommunication device for the deaf/teletypewriter) A device using a Baudot (five bit) character set that allows plain text messages to be exchanged using a low bandwidth modem over standard telephone lines. Originally developed for the deaf community.

WAP (wreless application protocol) Originally developed by Unwired Planet, Motorola, Nokia, and Ericsson to develop a standard for wireless content delivery.

E-marketplaces

Paul R. Prabhaker, *Illinois Institute of Technology*

INTRODUCTION

Gartner forecasts that the total value of goods and services transacted through the Internet, by 2004, will exceed seven trillion dollars, with 40% of transactions flowing through e-marketplaces. There are over 1400 e-marketplaces currently in existence. According to the Boston Consulting Group, total e-marketplace revenues in the U.S. will be around $9 billion by 2005, by 2004 B2B e-commerce productivity gains will amount to 1 to 2% of sales, and by 2010 these gains could increase to 6%, roughly $1 trillion (E-Commerce Times, 2001). The Gartner Group estimate supply-chain marketplaces to grow 25-35% over the next 5 years. They also believe that such marketplaces, if properly implemented, should increase ROI by 40% over a 5-year planning cycle. AMR Research estimates that investments in such e-marketplaces will increase at a compounded annual growth rate of 68% over the next 5 years. They also predict that traditional brick and mortar companies will be the primary drivers behind this investment growth. As business-to-business exchanges dominate today's e-marketplaces, this chapter will predominantly focus on B2B e-marketplaces.

An e-marketplace is an online exchange in which organizations and their communities come together to conduct commerce, access content, and collaborate to improve business performance. An e-marketplace is an Internet platform where users can surmount the barriers between countries, businesses, and computer systems (White Paper, n.d.). Simply put, an e-marketplace enables the law of supply and demand to act fully, increasing market efficiencies significantly. The e-marketplace operator acts as an enabler or, at times, a market maker. According to the Chairman and CEO of IBM, Louis Gerstner, e-marketplaces can (a) help online buyers and sellers find each other, (b) attack the inefficiencies of traditional marketplaces, and (c) play important roles in the e-business economy.

Turban (2002) suggests that all marketplaces can be defined based on a three-dimensional product–process–agent framework (see Figure 1). Using this framework, it is useful to see the coexistence of electronic commerce with traditional commerce and various forms of hybrid commerce.

The emergence of B2B e-marketplaces marks a radical change in the development of buyer–supplier relationships. In just a few short years, industry structures that had stood the test of decades of competition and untold waves of innovation are being completely redefined. Some firms have teamed up with former rivals and small new entrants, while eager third parties have announced bold plans to mediate between buyers and suppliers. In many cases, these crucial decisions were made and announced in little more than a week, driven largely by a vision of what could be and a fear of being late to the party. One thousand four hundred such e-marketplaces have thus far been launched or announced. Although some analysts predict that this number will climb to as high as 10,000, others lament that 1,400 is already 1,000+ too many (Spiegel, 2000). Whatever the final number, it is clear that competition to dominate the e-marketplace sector is heating up, as attrition and consolidation are already starting to occur in the B2B space. In the end, what matters is a firm grasp of the key factors that drive the success and failure of e-marketplaces, success being defined as creating value for e-marketplace members and

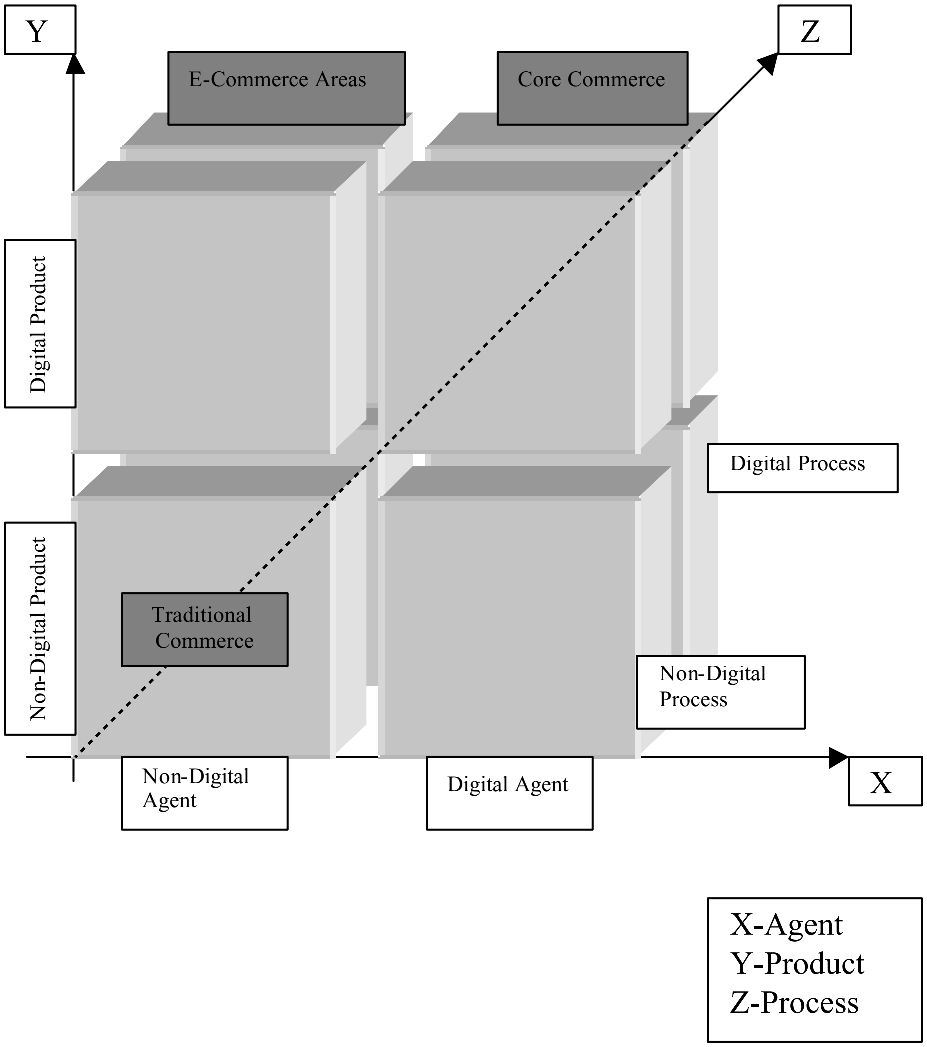

Figure 1: Integrated commerce framework.

their stakeholders on the demand side and the supply side.

The "E" Difference

A marketplace is a physical space where buyers and sellers go in order to match up with each other. This aggregation of buyers and sellers is intended to efficiently match those who have needs for products/services with those who provide the same.

A critical study of the research literature reveals that bricks-and-mortar marketplaces typically need to address five value-drivers if they wish to succeed:

Location

There have to be a sufficient number of interested buyers and sellers located within close proximity of the marketplace. Parties interested in negotiating a market transaction need to physically *go* to the marketplace.

Scale

Transaction *volume* is a key indicator of success. As larger businesses buy or sell more they are able to extract favorable concessions in a traditional marketplace—volume discounts, better credit terms, etc.

Liquidity

For marketplaces to work successfully and profitably, there has to be a defined ratio of buyers to sellers in order to sustain an optimal level of transaction volume and pricing. Physical marketplaces, particularly, have difficulty ensuring this requirement.

Market Rules

The rules regarding price setting, price discovery, negotiations, and transactions should be implemented, taking into consideration the transaction volume generated by a buyer/seller.

Business Relationships

Aside from business transactions, another type of equity is being built up in marketplaces: business relationships. As buyers and sellers repeatedly transact business in a marketplace, they become familiar with each other and before long trust starts building up. That is, transactions are consummated where the terms of the exchange go far beyond

Table 1 Benefits of E-marketplaces

Buyers' Benefits	Suppliers' Benefits
Lower processing costs	Lower costs of customer acquisition
Reduced processing cycle times	Lower costs of sales
Lower product costs through contract buying	Faster time-to-market
Enhanced supplier relationships with collaboration and supply chain management	Greater access to new buyers and markets
Greater access to new suppliers	Benefits of powerful information acquisition capabilities
Improved decision-making	Ability to personalize cost-effectively
Personalized interface	

the marketplace. The "I Win—You Lose" *negotiations* are replaced with a more comfortable and harmonious win–win *understanding*.

One of the key differentiators of an e-marketplace from a bricks-and-mortar marketplace is that the marketplace *comes* to the participants whereas with the latter they *go* to the marketplace. A direct implication of this principle is that three of the above five factors do not apply to digital marketplaces: location, scale, and business relationships. Businesses can buy and sell goods and services through an electronic marketplace regardless of whether they are large or small companies, in near or distant locations, and whether or not they have an existing relationship with the other parties. That leaves us with two critical success factors for running an e-marketplace: liquidity and market rules. A third success factor, exclusive to digital marketplaces, is the ability to connect internal business processes directly to an e-marketplace. Although this is a critical e-marketplace ability, it is also a challenge in the sense that it needs to be addressed proactively. Vertical e-marketplaces particularly leverage this capability to connect directly.

E-marketplaces and traditional marketplaces perform many functions to establish assurance and reliability. As is obviously the case, commerce, "e" or not, is based on trust. Thus, it is crucial for e-marketplaces to embed trust in their platform via concepts such as assurance and information integrity (http://www.informationintergirty.ortg). They should also have carefully thought out strategies for managing risks inherent in e-marketplaces.

Consider the industrial chemical industry. E-marketplaces have gained quick acceptance in this industry, where 65% of business is conducted through auctions on trade exchanges such as ChemConnect.com, e-Chemicals, and CheMatch.com. E-marketplaces cut through the slow and inefficient traditional system of sales visits and trade shows where business is conducted based on long-term relationships between sales reps and purchasers. Forrester expects $128 billion to flow through these chemical e-marketplaces by 2003.

Forrester predicts that between 45 and 75% of B2B e-commerce will migrate to e-marketplaces over the next few years. The largest impact will be in the computing and electronics, shipping and warehousing, and utilities industries, where Forrester predicts that more than 70% of online trade will go through e-marketplaces. In time even markets for customized products will drift to e-marketplaces. Given a sophisticated enough network, even customized products can be auctioned like commodities.

Benefits of E-marketplaces

E-marketplaces are sources of significant benefits for business organizations (see Table 1). They are used to protect market shares, add new channels, move brands online, and serve as a strategic entry point for international markets and are ubiquitously accessible means to communicate with employees (E-Marketplaces, n.d.).

A key benefit of e-marketplaces is the ability to collect buyer information and to leverage this information in the marketplace to secure an advantage. Personalization can be of great value to consumers (Häubl & Trifts, 2000) and can be used to influence them (Häubl & Murray, 2002).

Types of E-marketplace Buyers

E-marketplace users vary on many dimensions: different purposes, different approaches, and different expectations. This concept is not very different from traditional market segmentation. Customers' behavior does vary in several ways, for several reasons. To the extent that firms can understand and leverage those differences in their marketing approaches, they can benefit from marketing efficiencies. Although customers may differ on numerous dimensions—demographics, psychographics, attitudes, loyalty, etc.—it is their market behavior that ultimately matters. E-marketplace buyers can be classified into the following behavioral segments:

Baseline Buyers

These buyers are just getting started in e-marketplace procurement. Their initial objective is to reduce transaction costs associated with maintenance, repair, and operations (MRO) purchases. On average, these buyers spend $5.6 million on transaction fees, integration software, and internal staffing.

Spot Market Dabblers

These buyers use e-marketplaces to make spot purchases of direct materials to help manage inventory and avoid shortfalls. On average, these buyers spend $10.7 million on new software installation and related consultant fees.

Aggressive Spenders

These buyers tend to use the Internet and other networks to manage all their purchasing. On average, these buyers spend $22.9 million mainly on consultant fees for implementing their e-marketplace approach.

GENESIS OF E-MARKETPLACES

According to Forrester Research, over the next 5 years, business purchasers will spend from $5.4 to $22.9 billion each to integrate into business-to-business e-marketplaces. Similarly, Jupiter predicted that businesses would increase their spending on business-to-business e-marketplaces from $2.6 billion in 2000 to $137.2 billion in 2005. According to a Boston Consulting Group study, by 2004, B2B e-commerce will bring about productivity gains equivalent to 1% to 2% of sales. By 2010, that figure could grow to 6%.

Early Stages

Early e-marketplace development was characterized by attempts to set up exchange marketplaces, charging a transaction fee for matching buyers and sellers (Berryman & Heck, 2001). More than 1,000 such e-marketplaces were created for several industries. Most of the players in this phase were new entrants that defined a new way doing business. Unfortunately, most of these marketplaces failed to understand the lifeblood of such a marketplace: liquidity. In other words, a few large enterprises generate most of the volume necessary. The rest will struggle. Hence, the transaction-fee-based marketplaces have languished.

The next developmental stage of e-marketplaces had a different business model. Here, enterprises banded together into consortia with their trading partners and even competitors. Most of the players in this phase were brick-and-mortar companies that leverage from ideas in the first phase. A well-known example of this is the GM/Ford/Chrysler joint venture called Covisint. Since then over 100 similar ventures have been started in different industries. The value driver for these second-wave marketplaces was to reduce bid/ask spreads and to bring down transaction costs by matching buyers with suppliers and enabling suppliers to trade with one another to streamline and make efficient the supply-side marketplace. Unfortunately, the consortia, generally speaking, have not been very successful. Other than auctions, most other "products" in such consortia are not profitable.

E-sourcing

Sourcing provides the single greatest opportunity to reduce costs, streamline processes, and enhance overall responsiveness. It is one of the earliest stages in a supply chain. There are three reasons that e-sourcing is a crucial part of any supply chain. First, purchased products and services are the single largest expense in most organizations, accounting for 50 to 55 cents of every dollar earned in revenue. Second, reductions in procurement costs translate into a dollar-for-dollar increase in profits. By contrast, external factors such as overhead, cost of sale, and profit margins dilute improvements in other functional areas such as sales. Third, sourcing has a multiplicative effect on total costs. A 2% cost reduction in the initial sourcing cycle can yield a 14% reduction in the end cost of a new product or service

Effective sourcing has three dimensions along which investments in sourcing can pay off:

Streamlining and automating processes for the acquisition and management of *indirect* items such as office equipment and computer supplies.

Developing, monitoring, and executing supply-chain and logistics processes for management of *direct* production materials.

Designing, implementing, and nurturing the *strategic* aspects of sourcing.

70 to 80% of the total cost, quality, and structure of products are determined by the end of the sourcing and design cycles. Research across industries shows that 75% of companies believe that their ability to control the cost or quality of a product is practically nonexistent after the initial sourcing process. In the high-tech industry, about 80% of product cost is determined from and attributable to decisions made on the product designer's table. So the information to evaluate strategic sourcing options (or pursue alternative design considerations) is available well before actual sourcing is initiated.

There are different aspects to e-sourcing. Organizations can dramatically improve the processes, cycles, and results of sourcing engagements by leveraging Internet-based technologies to automate and manage the sourcing process. However, sourcing is a complex process that technology alone cannot address. Effective sourcing solutions are those that can integrate advanced negotiation technologies with sourcing methodologies and product-category intelligence and reach upstream into product design stages.

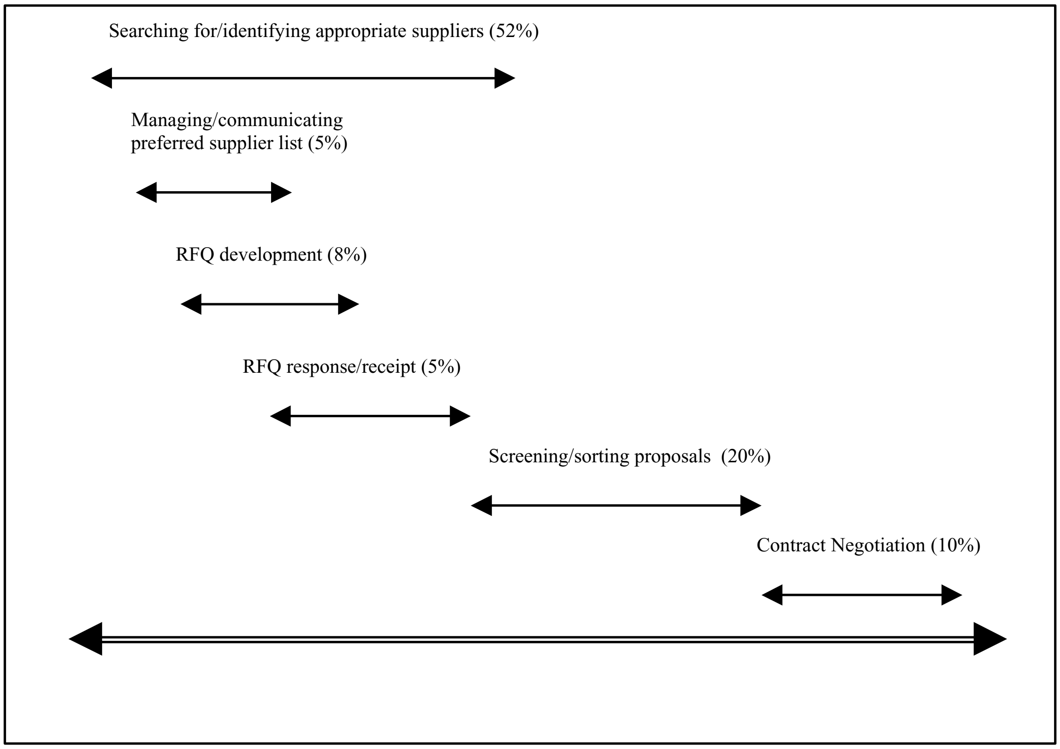
In traditional sourcing, more than half the sourcing cycle at a typical company is currently dedicated to identifying and vetting suppliers (see Figure 2). Another 20% of the total sourcing cycle involves the screening, sorting, and reviewing of supplier proposals. Traditional sourcing approaches are fundamentally electronic data interchanges (EDI) intended to automate a variety of related documentation. Unfortunately, EDI has high set-up and operational costs and burdens that make it ill affordable to a majority of players and lacks the functionality for online negotiation.

There are several benefits of e-sourcing:

Identifying, qualifying, and negotiating with an increased number of suppliers, creating more competitive bidding environments;

Negotiating an average 5% to 20% unit price reduction;

Shortening sourcing cycles by an average of 25% to 30%;



Searching for/identifying appropriate suppliers (52%)
Managing/communicating preferred supplier list (5%)
RFQ development (8%)
RFQ response/receipt (5%)
Screening/sorting proposals (20%)
Contract Negotiation (10%)

Average sourcing cycle = 3.3 months to 4.2 months

Figure 2: Typical sourcing cycle.

Reducing time-to-market cycles by 10% to 15%;

Lowering process costs for sourcing engagements;

Improving quality levels for the goods and services being sourced;

Increasing access to technology and service innovations through improved collaboration;

Applying strategic sourcing to a broader range of products and services; and

Promoting knowledge-sharing and standardization of sourcing best practices across the enterprise.

E-procurement

E-marketplaces have their roots in e-procurement and evolved as a consistent response to the myopic "buy-side/sell-side" mentality (see Figure 3). The latter approach emphasized the efficiency of each side, sometimes at the cost of inefficiencies on the other side. E-marketplaces revolutionize the exchange concept of a market. A marketplace is not just a place to execute an exchange transaction between two parties; it is a place where multiple parties with an integrated set of goals follow commonly agreed-to procedures, where the exchange transaction itself is an incidental matter. The singular focus on transactions by early e-marketplaces brought unsustainable success to them. Later entrants leveraged from the lessons that emerged. The key here is the integrated, collaborative platform that the marketplace provides. E-marketplaces, therefore, provide their value-add in the platform of integrated market operations. The type of collaboration encouraged in a properly run e-marketplace moves away

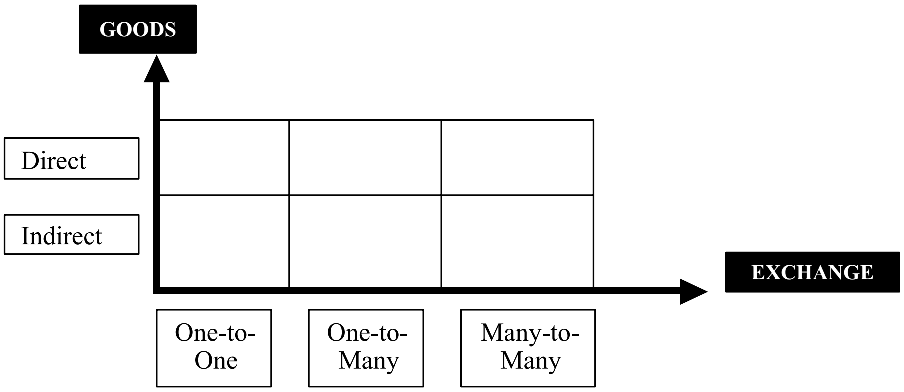


Figure 3: E-procurement to e-marketplaces.

from emphasizing cost and delivery to innovation and reward. In other words, the market partners do not try to eke out more concessions from each other but work together to elevate the success of the entire supply chain (White Paper, n.d.).

E-procurement enabled buyers and sellers to automate their interactions and collaboration. Purchasing processes are linked to back-office enterprise systems. As buyers and sellers integrated their functions, the supply chain became more transparent. According to *Logistics Magazine*, e-procurement can cut distribution costs below the typical 8% of sales. The Aberdeen Group claims to have evidence that processing costs are reduced from $107 to $30 and product costs are reduced by from a minimum of 5% to a maximum of 20%. At the same time, the procurement cycle can be trimmed from typically 7.3 days to 2 days. Ariba, often regarded as the pioneer of e-procurement software, advocates purchase order transaction cost reduction from $150 to $25 for most large U.S. corporations.

Despite these impressive gains, it became increasingly clear that e-procurement is only part of the solution, for two reasons. First, e-procurement applications are more commonly applied to indirect goods—such as office equipment, stationery supplies, and repair services—when such goods account for less than one-third of manufacturing expenses. Only a limited amount of items that a corporation has a need for can be bought through an e-procurement channel. The challenge to e-procurement vendors to extend their solution into the direct materials territory was insurmountable in most cases, because such a shift required domain expertise in the industries served. Second, e-procurement is a one-buyer/one-seller model, whereas most companies do business with multiple vendors and vice versa.

The many-to-many model was quickly accepted in the B2B world, as the benefits were obvious: enabling more buyers and sellers to interact, making it possible for multiple systems to connect, and eliminating the need to implement multiple platforms to link multiple partners.

The many-to-many e-marketplace functions as a central online market where buyers and sellers can share information, initiate transactions, integrate supply-chain goals, and collaborate. The value of an e-marketplace increases as the quantity and quality of its buyers and sellers also increase.

Ultimately, e-marketplaces are not about transactions or collaboration; they are about a platform of *trust*. Raisch (2001) suggests that e-marketplaces will evolve beyond transactional platforms, and even beyond knowledge exchange platforms, to *value trust networks*. Trust between parties, when interlinked, forms a trust network. Such trust networks, it is suggested, could become a critical platform for creating online value. Trust is a complex construct, based on familiarity, integrity, security, and privacy (Prabhaker, 2000).

E-MARKETPLACE CASES

There are several e-marketplace successes, just as there are several e-marketplace failures. Let us look at some e-marketplace cases to understand their uniqueness and patterns for success.

TradeWeb

A description of TradeWeb, paraphrased from their Web site, is as follows:

> TradeWeb is the world's leading online trading network for fixed-income securities. TradeWeb offers a complete spectrum of services. You can view the largest fixed-income markets in real time via TradeWeb's premier Market Data. You get unprecedented depth and breadth of information as well as tight bid and offer indications. TradeWeb's dealer-to-customer platform provides the deepest pool of liquidity for fixed-income products. Today, the network delivers the market-making power of 18 of the world's leading primary dealers to over 1,000 of the largest buy-side institutions. Since inception in 1998, more than $10 trillion in bond trades have been executed over the TradeWeb network. More than $40 billion in securities change hands through TradeWeb every business day. Get live, executable prices from multiple dealers and markets in seconds.

TradeWeb is an online bond exchange. TradeWeb enables a bond buyer to request quotes from multiple brokers simultaneously. Prices pop up in 10 seconds and are updated a million times a day (Weinberg, 2001). The fund manager clicks on the most appealing offer and receives confirmation a second later. Compare this online exchange process to the manual offline process it is replacing: bond buyers had to call several brokers for prices, the brokers called their trading desks who relayed the information to the brokers, and the brokers then passed the price information back to the investors. The offline process often took so long that the prices quoted were not current by the time the investors received them! The icing on the cake here is that the cost of asking and receiving price quotes decreases dramatically thanks to online exchanges.

What makes a TradeWeb type of online e-marketplace so effective?

One key seems to be that successful e-marketplaces limit themselves to the role of an efficient online platform for buyers and sellers to collaborate *without trying to make a market by themselves*. Those e-marketplaces that tried to do the latter by creating disruptive Internet marketplaces generally failed as they discovered that an essential requirement for such disruptive business models to succeed was to garner buy-in from archrivals within an industry. In other words, disruptive technologies need to be funded by top players within an industry. On hindsight, it is easy to see why such archrivals hesitated to feed their trade secrets into a common technology, disruptive or not. As an example, consider Dial-A-Truck Inc., which is in the business of electronically matching rigs with cargo. Rival sites with the same business goal were unsuccessful, as they threatened to eliminate brokers, who for decades had matched trucks with cargo. Dial-A-Truck Services, on the other hand, gives truckers, customers, and brokers a quick and easy way to pair up.

Can e-marketplaces succeed by being industry neutral? Yes, as long as they can find a way to generate liquidity by leveraging their process infrastructure. Thus, the second key seems to be the ability and willingness of e-marketplaces to provide process improvement services. For instance, Toys "R" Us uses amazon.com's infrastructure to sell toys online. Instead of trying to put brick and mortar retailers out of business, amazon.com may be better off using their online process infrastructure to serve as the retailers' Web distributor.

Transora

A single point of connectivity. The leading global e-marketplace for the consumer packaged goods industry, Transora offers an integrated array of collaborative solutions to eliminate inefficiencies throughout the supply chain to deliver breakthrough value.

Transora is an e-marketplace for consumer packaged goods (CPG) companies. It is a successful example of a public marketplace funded by specific partner organizations. In the case of Transora, investors include Campbell Soup Company, Bristol-Myers Squibb, Kraft Foods, Procter & Gamble, Coca-Cola, and Unilever. Funding from partner companies has exceeded $250 million. Such a financial tie-in with an e-marketplace creates a strong incentive to use the e-marketplace often. Transora has used the money raised to make their marketplace more valuable by adding community, content, marketing tools, and supply-chain services.

ChemConnect

ChemConnect is the leading online chemical and plastics global marketplace. Their mission, paraphrased from their Web site, is as follows:

> We know your industry and the challenges you face when buying and selling chemicals and plastics, and we've developed solutions to meet those challenges. Now you can access reliable market information, reduce costs, and increase efficiencies—all of which helps you compete on the worldwide market.

Two giant online exchanges in the chemical industry, ChemConnect and CheMatch, have merged, resulting in a one-stop, $4+ billion chemicals and plastics e-marketplace (Harreld, 2002). The new ChemConnect offers a comprehensive solution including online auctions, a commodity spot and futures exchange, and an electronics communication hub for the automatic transfer of transaction data. ChemConnect has successfully launched a subscription-based revenue model in addition to transaction fees.

FreeMarkets

FreeMarkets' mission, paraphrased from their Web site, is as follows:

> FreeMarkets is the leading global provider of sourcing software and service solutions. Our sourcing software and service solutions help suppliers to win new business and buying organizations to dramatically improve their sourcing process and identify immediate and ongoing savings. Our flexible portfolio of sourcing software and service solutions provide companies with all of the tools they need to dramatically improve their sourcing process and identify fast, measurable savings by conducting strategic sourcing online. Through our sourcing software and service solutions, organizations can identify high-quality, global suppliers, create and distribute detailed Requests for Quotation (RFQ), and structure and execute effective online markets for a wide range of goods and services. The world's leading and largest companies have used FreeMarkets to source more than $35 billion in goods and services, and identify savings of over $7 billion to date

The revenue model for FreeMarkets is simple: 1% to 3% of the value of what clients source. Ultimately, FreeMarkets lets customers decide how to use its technology, either in public auctions or in private auctions. Then it implants itself deep into a client's infrastructure to make it work. FreeMarkets charges buyers based on volume. FreeMarkets' revenue model is based primarily on auction value and consulting services. The auctions are private or public for new, used, or surplus goods. The consulting services are for identifying the buying or auctioning needs of clients. Businesses will want to study the pricing models carefully: what works for one industry may not work for another.

Covisint

> Covisint is the central hub where OEMs and Suppliers of all sizes come together to do business in a single business environment using the same tools and user interface. Covisint's online tools will enable your company to compress planning cycles and enhance supply chain planning. In doing this, it allows you to directly increase efficiency and asset utilization, while ultimately realizing greater profits and shareholder valuations.

Covisint is one of the most famous examples of a public e-marketplace. The intention is to create a supply chain management arena for the entire auto industry, worldwide. Their trading partners include

ArvinMeritor
DaimlerChrysler
Delphi
Faurecia
Ford Supplier Portal
Freudenberg
General Motors
JCI
Nissan

Peugeot

Renault ("Covisint will save (Renault) $280 per car in reduced inventories and faster lead times"—Renault CEO Louis Schweitzer)

Siemens Automotive

Tower Automotive

Yazaki NA

The ambitions, however, may or may not be realized. Different automakers, such as Volkswagen and BMW, are choosing to create private e-marketplaces. Covisint has been a classic case study of the economic benefits of a large-scale public marketplace vs. the downside of consortium limitations of such a marketplace. Thus, a large industrial marketplace may not be assured of success over a company's customized private marketplace.

E-marketplace Case Analysis: PetrochemNext.com

PetrochemNext.com is an online gateway to the world of plastics. The exchange is designed to answer the commerce, content, and community needs of manufacturers, consumers, end-users, distributors, dealers, and others—in short, people whose world revolves around plastics. The portal enables users to buy and sell plastics online in the real-time and dynamic marketplace, access updated technical and commercial information about plastics, and interact with members of the plastics community.

Corporate Profile

Internet ExchangeNext.com Ltd. and the Indian plastics community collectively own PetrochemNext with a strong partnership base and equity participation by leading manufacturers, distributors, dealers, and processors.

PetrochemNext has partnered with five leading manufacturers for an ample supply of polyethylene, polypropylene, PVC, polystyrene, polyamides, ABS, and thermoplastic polyester through the online marketplace.

Internet ExchangeNext.com Limited (EXCHANGE NEXT) is established to help e-enable the businesses in the Indian manufacturing and services sectors. EXCHANGENEXT is currently setting up infrastructure for end-to-end, e-commerce solutions in the business-to-business arena. The company also hosts and supports other Indian e-marketplaces such as papernext.com, steelnext.com, brokerfirstoffice.com, and brokernext office.com.

The exchange was developed by Internextexchange.com with hardware and e-commerce support from IBM, Web hosting by Reliance Infocom, online payment gateway and net banking with HDFC Bank, and customized software for order management system from Tally.

Activities:

PetrochemNext follows an offline accreditation process to select its trading members, who can trade on multiple trading floors in the online marketplace. The trading floors offered currently are as follows:

Offer To Sell In the Offer to Sell section of the marketplace, sellers can create sale offers of specific products at fixed prices with well-defined terms and conditions targeted at the trading community. The products can be catalog products if they are already listed in the marketplace catalog or noncatalog products if not listed. The seller organization can benefit from the combined purchasing power of multiple buyers across the country, receive direct orders placed through this mechanism, and ensure that complete and accurate data are available to the buyers, thereby maximizing sales.

Buy In the Buy section of the marketplace, buyers can easily and quickly locate sellers by searching through offers, communicate with sellers, make informed purchase decisions, and create purchase orders. This electronic purchasing solution is the fastest and most effective way of doing business online, saving time and money.

Auctions Sellers can create Auctions in the marketplace by specifying the type of auction, the minimum auction quantity, reserve price for the product, if any, and other bid control rules. The buyers can browse through the auctions listed, bid in the auctions, and avail themselves of the best bargains in the market.

Open Cry Auctions This type of auction is similar to the public meeting model. All bids under an open cry auction are available for everyone to see. These auctions work well in situations where the prospective buyers are able to bid in the auction without traversing a geographical distance and want to submit counter bids quickly. On PetrochemNext, however, open cry auctions can be conducted for an extended period of time, giving buyers more time to react and submit bids. Anonymity is maintained throughout the auction.

Reverse Auctions Buyers can create Reverse Auctions in the marketplace by specifying the type of auction, the minimum auction quantity, the opening bid price and starting price for the product, if any, and other bid control rules. The buyers can browse through the auctions listed, bid in the auctions, and avail themselves of the best bargains in the market.

Reverse Open Cry Auction This type of auction is similar to the public meeting model. All bids under an open cry auction are available for everyone to see. These auctions work well in situations where the prospective sellers are able to bid in the auction without traversing a geographical distance and want to submit counter bids quickly. On PetrochemNext.com, however, open cry auctions can be conducted for an extended period of time, giving sellers more time to react and submit bids. Anonymity is maintained throughout the auction.

Revenue Model

Transaction Fees. The buyer organization that requests an e-procurement auction is charged a transaction fee of 1% of auction value or Rs.10,000 per auction [about $200], whichever is higher. This covers hosting the e-procurement auction on the buyer's behalf, training his or her invited suppliers for participation in each reverse auction event, providing him or her with a view of the live auction status, and finally sending him or her an analysis at the end of the auction.

The participating suppliers are not charged a fee.

CHARACTERISTICS OF SUCCESSFUL E-MARKETPLACES

Markets are about power; the most powerful customers set the terms of trade. Powerful buyers can moderate the pace of the market and drive down prices. The marketplaces can facilitate this. Some marketplace make collaboration easier and allow suppliers to demonstrate their value-added. E-marketplaces can support both competitive and collaborative activities. E-marketplaces also increase market visibility, making poor performance visible—transparency.

Given the above, there are specific rules that need to be considered in identifying characteristics of successful e-marketplaces. First, markets will only support one to three e-marketplaces within any given industry segment. Second, e-marketplaces will need to bridge the gap between falling transaction fees and rising demand for collaborative services. Third, unfortunately, collaborative services, such as supply-chain forecasting and demand planning tools, are difficult and expensive to implement. Fourth, sellers particularly will be looking for ways to ensure that e-marketplaces do not commoditize their products.

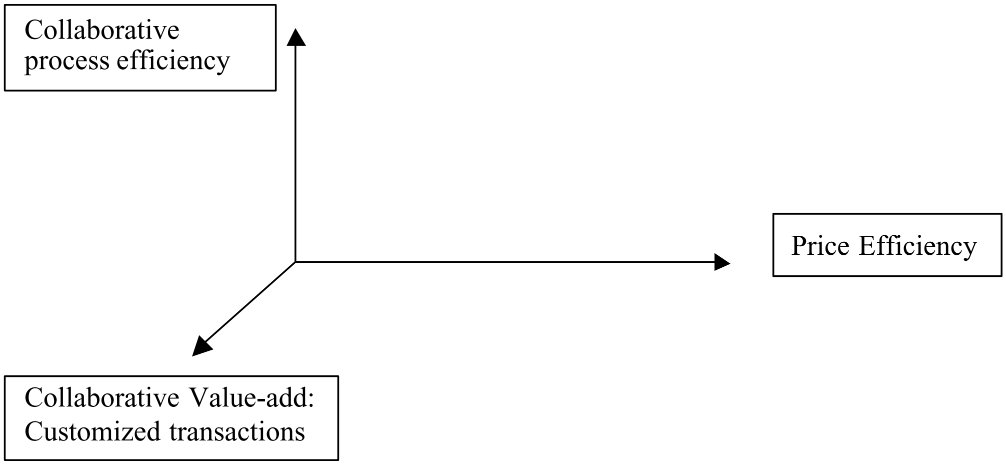
Careful examination of successful e-marketplaces reveals the following common characteristics:

1. Liquidity: Large aggregation of buyers and suppliers with multiple static and dynamic pricing mechanisms
2. Transparency
3. Customized transactions
4. Collaboration
5. End-to-end functionality: Catalog, price discovery (auction, fixed, quote, negotiated), requisition, ordering, status, shipment, insurance, logistics, tax computation, bill presentment, bill payment, report, and reconciliation
6. Open technology standards: For implementation of the marketplace itself; especially standard technology and open interfaces for integration with systems of other parties (buyers, suppliers, banks, logistics, escrow, catalog/content providers, etc).

All six characteristics have a direct bearing on market efficiencies. For example, greater price transparency will lead to a lower price via increased efficiencies in processing price information. However, more efficient integration between buyers and sellers will require collaboration and open technology standards. Similarly, customized transactions provide a value of their own.

So what sets the successful e-marketplaces apart from those that are not? The extent to which they leverage the above characteristics. These characteristics in reality define the market space for e-marketplaces (see Figure 4).

E-marketplaces have been largely buyer-incentivized and buyer-driven. In that sense they polarize the model of a marketplace. The value proposition of e-marketplaces to suppliers has so far been weak. True e-marketplaces should go beyond merely squeezing suppliers' prices to reducing costs and assets for all participants in the supply chain. Successful e-marketplaces need to embrace a business model that calls for going beyond simplistic transaction-only trading networks to providing a collaborative environment linking multiple trading networks, individual buyers, suppliers, and service providers.



Collaborative process efficiency
Price Efficiency
Collaborative Value-add: Customized transactions

Figure 4: E-marketplace space.

Successful e-marketplaces generally exhibit a key capability to deal with known e-marketplace pitfalls, such as the following:

E-marketplaces that fail to deliver a balance of benefits to suppliers and buyers will find it difficult to generate the threshold liquidity to survive.

E-marketplaces that do not contribute to an enhanced relationship between business partners will not deliver enduring value.

E-marketplace implementations that are based on closed or proprietary architecture limit a company's ability to link with other participants, thus reducing the overall capabilities it can provide and value it can deliver.

E-marketplace fraud is a key issue. Auction fraud accounts for nearly 43% of all online fraud. Nondeliverable merchandise and nonpayment accounted for 20.3% of complaints and Nigerian letter fraud made up nearly 15.5% of complaints. More than 49,000 complaints were filed with the Internet Fraud Complaint Center in 2001.

E-marketplace Guiding Principles

Based on research on the prevailing business models, ownership structures, marketing tactics, service offerings, and strategic positions in the e-marketplace arena, we can define a set of guiding principles to help e-marketplaces and their participants develop successful B2B strategies. First, e-marketplaces are all about industry transformation and collaboration across the value chain and extended enterprise. Second, as a follow-up, lower product prices get attention but are not where the real value lies. Third, e-marketplaces must deliver value to the core businesses of member organizations. Without delivering core value to all participants (win-win for all), the e-marketplace will ultimately lose. Fourth, e-marketplaces replace inventory with information. Integration and technology "plumbing" will help deliver the value promised by e-marketplaces. Without appropriate technology foundations, e-marketplaces will never be able to replace inventory with information. Fifth, the capabilities required to operate and use e-marketplaces require implementation and integration of many technology components across a variety of business processes and functions. This means multiple technology vendors integrated with people and processes. Finally, each company will need to leverage multiple e-marketplaces of different types and will need to participate in other forms of B2B. This will allow companies to maximize benefits across the goods they purchase, processes, and geographies.

Based on the above principles, there are five critical principles that e-marketplaces and participant companies can use to help guide their strategies and tactics:

Operating Structure and Ownership Long-term success will require that e-marketplaces attract and retain a critical mass of transactions. This will require that the e-marketplace offer value and a level playing field to all participants. Third-party e-marketplaces offer participants a neutral trade environment. However, in industries where power is concentrated in the hands of large brick-and-mortar organizations, brick-and-mortar-led consortia may have the market-making power to reach critical mass and beat neutral third parties. For brick-and-mortar consortia to succeed, new mechanisms will be needed to guarantee a fair environment to all participants.

Governance Long-term success will hinge on how well governance structures can guide and regulate e-marketplace management—balancing the interests of shareholders, members, and outside interests (e.g., the U.S. Federal Trade Commission [FTC]).

Scale The e-marketplace will only succeed if it can maintain transaction volumes that satisfy scale considerations for buyers, suppliers, and intermediaries alike. It must provide buyers with leverage, geographic coverage, and, in some cases, a broad array of available products. It must provide sellers with sufficient economic scale to offset the resources invested and intermediaries with sufficient reason to play.

Regulatory Compliance The e-marketplace must walk the fine line of maximizing benefits and leverage to its members and owners without attracting FTC scrutiny that would hobble implementation efforts.

Technology Enabling capabilities beyond simple transaction matching requires that the buyers, the sellers, and the e-marketplace itself build robust, interconnected systems that span a number of processes, systems, enterprises, and industries. E-marketplaces that support deep integration with their members and can help their members implement and integrate technology will have a competitive advantage, and will become "sticky."

These five principles can help companies looking for guidance in e-marketplace selection separate the eventual winners from the inevitable losers. It is important to note, however, that each e-marketplace is a fragile ecosystem—made up of buyers, sellers, and various intermediaries. As such, the success of each e-marketplace is dependent on the success of each of its participants.

TAXONOMY OF E-MARKETPLACES

E-marketplaces may be classified based on their market-sector coverage, vertical or horizontal. They can also be classified by who has access to their services, private parties or the public. Thus, vertical e-marketplaces may be public or private, and so may horizontal ones.

Vertical E-marketplace

Vertical e-marketplaces strive to provide a particular market sector with a network platform for an automated, Internet-based transaction model for made-to-order products.

Advantages for participants include

Better supply-chain management,

Online strategic sourcing,

Reduced costs,

Enhanced vendor relationships, and

Improved inventory management of raw and finished goods.

Examples

Covisint (Automobile industry)
WorldWide Retail Exchange (WWRE) (Retail industry)
GlobalNet (GNX) (Retail industry)
Transora (Consumer Packaged Goods [CPG] industry)

Horizontal E-marketplace

Horizontal e-marketplaces strive to provide customers with a generic platform for pan-industry products and value-added services.

There are several products and services that are essential for the efficient production and delivery of goods across industries. Examples of such pan-industry products would range from stationery products to logistics services, payment services, etc. Example: Ariba for MRO products.

Private E-marketplace

Private e-marketplaces strive to provide benefits for specific supply-chains/consortia/enterprises.

These e-marketplaces include e-procurement and e-distribution modules. They enable the consortia/enterprises to deliver the right products in the right quantity to the right customer at the right time. To that extent private marketplaces need to be treated as separate e-businesses by the participants: that is, the participants need to invest, nurture, and grow these as though they were in-house business units.

Public E-marketplace

Public e-marketplaces strive to provide benefits for any and all interested enterprises/supply-chains/consortia.

Public e-marketplaces are stand-alone marketplaces that are distinct profit-making entities. Their business models revolve around their ability to leverage online technologies in delivering value to buyers and sellers in their exchange transactions, processes, and collaborations.

Another way to classify e-marketplaces is to look at their functions:

Procurement Marketplaces

Aggregate suppliers and allow customers to search/compare offerings of different vendors (e.g., bCentral's Buy & Sell page).

RFQ/RFP Matchmaking

Here, buyers submit their need specifications through a request for quote (RFQ) or request for proposal (RFP); interested vendors then submit a quote/proposal for the work.

Auctions

These are demand-based exchanges allowing buyers to bid against each other for items offered. The final selling price is usually determined by the highest bid received for the item.

Barter Exchanges

These are e-marketplaces where businesses trade their products and services. No money exchanges hands.

Trading Networks

Trading networks, or trade exchanges, are a basic type of e-marketplace focused on reducing purchasing costs. A unique characteristic of trade exchanges is the bid/ask pricing mechanism. They are designed to squeeze procurement benefits from *processes* and *trading partners*.

Hybrid E-marketplaces

Hybrid e-marketplaces are an integrated, customized solution for enterprises that need the efficiency of e-marketplaces and would also like an enhanced brand-building customer experience.

Benefits of Hybrid E-marketplaces

Protect premium brand: Achieved by controlling what products are sold through private and public exchanges and dictating the business rules for each type of transaction

Increase market share: The ability to differentiate between public e-marketplace customers and private exchange customers enables effective market segmentation. A carefully implemented segmentation strategy will usually result in an increase in market share.

Increase revenue: Reaching more customers with more personalized offerings results in an increase in revenue and profits.

Reduce system costs: A single integrated interface for channel management and personalization reduces administrative costs

VALUE-ADD DIMENSIONS OF E-MARKETPLACES

E-marketplaces generally add value along multiple dimensions. First, they leverage network effects. Essentially, more connections mean more value, and better connections mean more value. The value creation domain here is based on inter-firm relationships. Consumer information that was maintained by companies with their own computers now resides in giant databanks accessed by globally networked computers (Kakalik & Wright, 1996). Second, e-marketplaces create and deliver value-add services. Successful e-marketplaces present more than transaction services; they also provide business services that complement transactions. For instance, firms combine data from their warranty-card databases with credit-bureau files to dramatically improve their insights into consumers' lifestyles (Scott & Shermach, 1998). Services such as credit services, payment services, taxation, shipping, and documentation would be such value-add services. More importantly, e-marketplaces consolidate all these business services into one site so buyers and sellers can use a single site for transactions and *all* business services they require. Third, they provide a collaborative infrastructure capability. As e-marketplaces evolve, many back-office applications migrate to the Web site. Organizations transfer responsibility for processes, such as business intelligence, product planning, and promotional activities, to the e-marketplace. By moving this workload to the e-marketplace organizations are better able to collaborate with their sellers and buyers, jointly managing their shared supply chains across multiple platforms without the need to implement additional applications. Finally, time saving and reduction of inventory-carrying costs are the greatest benefits of digital marketplaces. Online auctions, a form of e-marketplace, have cut down procurement time from about 2 months to a matter of hours for Sprint. Process efficiencies are improved both outbound and inbound. In its first reverse auction, Sprint received 250 bids in the very first hour! Such gains, however, come only for those prepared to capitalize on them. For instance, companies need to be able to link data generated online with back-office systems such as purchasing, inventory, and accounting. Otherwise, information must be updated and entered again, eliminating any gains form digital marketplaces.

E-marketplaces Add Value to Supply Chains Along Three Dimensions

Clearly, improved collaborative communications is a key, as it results in better market efficiencies. What is Web-based collaboration? It is more than just managing inventories and maintaining communications; it is a Web-centric relationship management system characterized by multiple network computing systems and communities of people. See Figure 5.

E-marketplace Benefits

A different perspective on e-marketplace value-add is seen if we look at different *levels* of value rather than different *recipients* of value. Electronic marketplaces result in certain direct value-adds that are denoted first-order. If managed properly, these value-adds should lead to measurable results that are second-order benefits. Beyond this, if the value-adds are combined with other capabilities they can result in competitive advantages, which are called third-order benefits.

First-order benefits:

Improved supply-chain visibility,
Reduced inventory costs,
Reduced procurement costs,
Improved order and approval processes,
Reduced transaction costs, and
Relationship management [or perhaps this should be in second order].

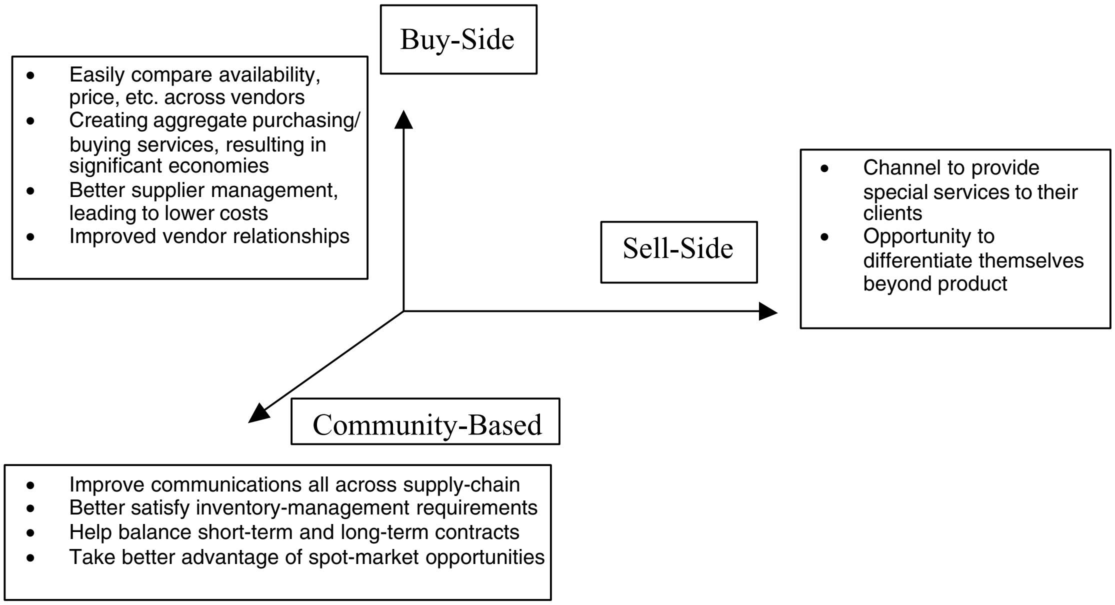
Second-order benefits:

Improved asset utilization,
Better capacity planning and utilization,
Higher labor productivity,
Increased economies of scale,
Decrease in product development times,
Increased market share,
Higher profitability, and
Reduced time to market.

Third-order benefits:

Higher service levels,
Easier product customization,
Increased customer loyalty, and
Lower marketing costs.

E-marketplaces are realizing that they need to offer more than efficient commerce capabilities to succeed in



Buy-Side
• Easily compare availability, price, etc. across vendors
• Creating aggregate purchasing/ buying services, resulting in significant economies
• Better supplier management, leading to lower costs
• Improved vendor relationships
Sell-Side
• Channel to provide special services to their clients
• Opportunity to differentiate themselves beyond product
Community-Based
• Improve communications all across supply-chain
• Better satisfy inventory-management requirements
• Help balance short-term and long-term contracts
• Take better advantage of spot-market opportunities

Figure 5: E-marketplace value-add space.

the tough competitive environment: they need to offer genuine value through those capabilities. Additionally, these values have to be realized from the perspective of all participants, not just buyers. Horizontal capabilities include personalization, communities of interest, portal capabilities, and the capability to handle RFQs and RFPs. The value in these capabilities is not just transaction support but also the ability to embed the role of e-marketplaces more deeply in the trading partners' relationships with each other. Vertical capabilities, on the other hand, include add-on services that let the marketplace control the end-to-end trading cycle. Such services focus on settlement, fulfillment, and returns processing. Companies in specific industries, such as banking, financial services, insurance, and shipping, all have a vested interest in getting their piece of e-marketplace trade.

For instance, consider settlement services:

E-marketplaces need credit validation services to verify that buyers have sufficient funds available to back their purchases. Also, in certain cases there is a need to create escrow accounts to hold goods until funds are actually received.

Trading partners need lines of credit for operating capital and to expand their businesses. E-marketplaces could extend lines of credit to buyers in order to settle the buyers' accounts while charging the buyers interest or fees. Timely settlement for a fee!

Consider fulfillment and returns processing services:

Many low-tech trading partners do not have the infrastructures needed to handle these functions. E-marketplaces can take on more responsibility for delivery and returns. Insurance can also play a role here.

Invoicing, bill presentation, and payment are key services for marketplaces. As buyers and sellers use a marketplace for trade, it is logical that they use the same marketplace as a conduit for these services.

Key: the vertical services apply not just to new marketplace entrants but also to brick-and-mortar companies that are adding e-marketplaces to expand their businesses. *The challenge for any marketplace is in integrating all of these services into its offerings.*

CONCLUSION

E-marketplaces are powerful vehicles to achieve a competitive advantage in today's fiercely competitive industry sectors. Unfortunately, many e-marketplaces have missed the point. The focus, incorrectly, is on transactional efficiency, instead of on improving business processes to unlock additional value. E-marketplace-enabled information sharing and collaboration are the keys to this value. Also, effective e-marketplaces recognize that individual managers and individual companies make buy/sell decisions, not entire industries. Thus, attempting to transform the procurement practices of entire industries utilizing e-marketplaces generally is not successful.

Electronic marketplace exchanges are here to stay because they make great business sense (Oliver, 2001). Based on sensible business models, e-marketplaces can add game-breaking capabilities to a firm's competitive arsenal. Both vendor and customer firms stand to benefit from good e-marketplaces. Misused, such e-marketplaces can put the same vendors and customer firms in a deep competitive hole. This makes a strong case for carefully harnessing the power of e-marketplaces.

FUTURE ASPECTS OF E-MARKETPLACES

It is important to bear in mind the foundational aspect of e-marketplaces: those that are able to create a network effect—delivering greater value as increasing numbers of participants join and collaborate online—will outlast others.

Gains that result from increased transactional efficiency alone will not be sufficient to convert buyers and sellers to buy into the concept of e-marketplace. True gains from marketplaces will result not from trading but from better access to information. In other words, collaboration based on sharing of information over the Web seems to be the real value of e-marketplaces. For example, supply and demand forecasts, inventory level reports, and effect of price on demand are some ways to leverage collaboration on line.

Also, based on the same hindsight, it is possible to arrive at some key conclusions. The e-marketplace field is enormous and continually expanding. Many players will appear but many more will disappear, as value-creation and industry transformation become the central focus of e-marketplaces. The first conclusion is that *fewer, larger e-marketplaces will be required to realize significant value.*

The multi-trillion-dollar projections from a variety of industry analysts indicate that B2B is just beginning to hit its stride. E-marketplaces and B2B participants should adopt a strategic, long-term view. E-marketplaces are an outcome of the interest in jointly managed supply chains, resulting in greater service integration and more collaboration. The second conclusion, therefore, is that, increasingly, *competition is between supply chains rather than between corporations*. Guly (1998) suggests that this new economy has new rules. In the traditional economy *value* typically was a result of scarcity, whereas in the new digital economy value comes from plenitude. This important observation points to the foundation for business strategies of the future. Managing supply and demand for products is not as important as managing networked relationships of products, probably owned by different companies.

Operational efficiency is the primary driver for e-marketplace development. Hence, the third conclusions is that *companies must wrap a business process around the initiative rather than adopting it as a technology, or the initiative will not be successful*. One of the most enduring lessons from the rise and fall of dot-com mania is that the rules of business have not changed much at all. Initially, the corporate motivation for participating in e-marketplaces will be to save money. However, as a final conclusion, *corporations should treat their participation in e-marketplaces as a strategic asset and suppliers must prepare themselves for new rules in these dynamic marketplaces.*

APPENDIX: E-MARKETPLACE ASSESSMENT TOOLS

E-marketplace Orientation Index

Should we "e" our marketplace? Although e-marketplaces have significant benefits, not all companies are endowed with the market/organizational environment to reap the full rewards e-marketplaces. Here is a quick and easy way to compute an (index) of e-marketplace orientation:

Score the business on a scale of 1 to 5 on each of the following items:

Target Customer: Who Are the Customers?

E-marketplaces can be designed to cater to business-to-business, business-to-customer, business-to-consumer, or a variety of hybrid models. Consumer-based goods and services tend to be sold directly through the Web, rather than through e-marketplaces. Auction sites are obvious exceptions.

[1 = individual consumers; 2 = consumer groups; 3 = individual customers (resellers); 4 = business customers (resellers); 5 = business customers (value-add resellers)]

Market Coverage: Where Are the Customers?

The more homogenous and local the market, the better brick-and-mortar marketplaces work. The more fragmented and distant the market, the better e-marketplaces work.

[1 = local + homogenous clusters; 2 = local + fragmented market; 3 = regional/national + fragmented market; 4 = distant/international + homogenous clusters; 5 = distant/international + fragmented markets]

Buying Process: How Do the Customers Buy?

The more customers are accustomed to using technologies in their buying process the more natural the fit with e-marketplaces.

[1 = see actual product + buy onsite; 2 = see actual product + buy through telephone/fax; 3 = catalog purchases; 4 = shop offline+ buy online; 5 = shop and buy online]

Market Growth Trend: Is the Market Expected to Grow?

The adaptation to an online marketplace can be stressful on existing business practices and processes. At best, an online marketplace will add, requiring more human and financial resources. This extra resource demand makes sense if the market is in a growth mode.

[1 = declining market; 2 = flat market; 3 = slow growth; 4 = stable growth; 5 = fast growing market]

Organizational Stress: Cost of Adapting to E-marketplaces?

Many other business functions will be affected—not just those that reap the immediate reward of e-marketplaces. Given this situation, it is important to evaluate the cost of the organizational stress generated by participating in e-marketplaces.

[1 = internal stress nearly impossible to deal with; 2 = very difficult in the short term; 3 = can find a way to adapt; 4 = pretty easy; 5 = no stress due to e-marketplaces]

Disintermediation Reactions to E-marketplaces by Vendors/Suppliers?

The impact of e-marketplaces on existing business relationships with vendors/suppliers/customers/business partners can be painful; this would call for an adjustment not just internal to the firm but also by external parties. How these external parties choose to adapt to the realities of e-marketplaces can either make or break participation in such online marketplaces.

[1 = existing vendor relationships cannot be changed; 2 = existing vendor relationships can be changed at great cost; 3 = mandated change; 4 = fairly easy as vendors see long-term benefits; 5 = vendors share in e-marketplace gains]

Interpreting the E-marketplace Orientation Index Score

A score of 1 through 10: E-marketplaces are *not* a natural fit.

A score of 11 through 20: Will realize e-marketplace gains in the long run.

A score of 21 through 30: E-marketplaces are a natural fit. Implement immediately.

E-marketplace Screening Grid

Which e-marketplace is the right one for a business? Address the following five questions to systematically define the ideal e-marketplace for a given business's needs and circumstances:

1. What Types of Businesses Participate in the E-marketplace?

Check out the neighborhood. What companies participate? What types of items do they sell? How successfully? How many buyers? First-time/repeat customers?

2. How Do Customers Buy?

Some e-marketplaces just connect buyers and sellers; others offer all sorts of support services and manage the entire exchange process. What do the customers in this exchange expect?

3. What Will It Cost?

Fee structures and add-on charges for e-marketplace participation vary substantially. What is the breakdown of costs?

4. How Are the E-marketplace Vendors and Customers Evaluated in a Particular Exchange?

What vendor screening criteria does the site use? What customer credit risk evaluation criteria does the site use? Are these criteria consistent with the business philosophy?

5. Who Controls the Presentation of Products on the Exchange?

e-marketplaces have their own policies and standards on product presentations. Ideally, the company should retain maximum control over presentation of its products.

E-marketplace Evaluative Framework

How do we estimate the value-add of an e-marketplace to our business? Score the e-marketplace on the following criteria (Microsoft bCentral) to evaluate an exchange's capabilities and offerings.

1. Easy Product Updates

E-marketplaces should make it easy to update product catalogs, implement special promotions, discounts, etc.

2. Back-End Integration

E-marketplaces that can be integrated into back-office functions (accounting, inventory, etc.) can reduce costs and improve efficiency.

3. Reports

Versatility in reporting options provides a significant advantage in forming marketing and sales strategies. Such reports allow useful information—e.g., location of best customers, buying habits of different customers, identifying product bestsellers—to be gathered and sent to the right person at the right time.

4. Transaction Support:

What level of support does the exchange offer? Credit card payment, shipping options? Customers are increasingly expecting such transaction support services.

GLOSSARY

Brick-and-mortar marketplace A traditional marketplace where the buyers and sellers meet to do business.

B2B (business-to-business) Selling products or providing services to other businesses.

Consortium An association or a combination of businesses, financial institutions, or investors for the purpose of engaging in a joint venture.

E-marketplace An on-line exchange in which organizations and their communities come together to conduct commerce, access content, and collaborate to improve business performance.

E-procurement Procurement through fully automated, Internet-based self service systems that streamline the transactional purchasing process between the buying organization and its suppliers.

E-sourcing Strategic sourcing using Internet tools.

EDI (electronic data interchange) The transfer of data between different entities using electronic networks, such as the Internet. This transfer can occur both within and between organizational entities.

Fragmentation A market condition characterized by many uncoordinated buyers or suppliers. Fragmented markets are inefficient and costly to reach. Fragmentation also exists within large purchasing organizations when procurements are made in smaller, uncoordinated batches, resulting in higher prices.

OEM (original equipment manufacturer) A company that purchases products or other complex components, often for specific applications, from vendors and then adds original technology, hardware or software, and sells the aggregated products/systems.

RFQ (request for quotation) An invitation for suppliers to bid on clearly specified products or services. Exchange technology can combine multiple RFQs to produce lower bids and increase sales efficiency.

ROI (return on investment) The income that an investment provides in a year.

Strategic sourcing A disciplined approach used to optimize sourcing decisions for goods and services.

Supply chain The total sequence of business processes, within single or multiple enterprise environments, which enable customer demand for a product or service to be satisfied.

Encryption

Ari Juels, *RSA Laboratories*

INTRODUCTION

Encryption is the procedure of rendering a message into a concealed form so that it is decipherable exclusively by a particular recipient or recipients. The message in its original state is known as a *plaintext* (or *cleartext*); in its encrypted form, it is known as a *ciphertext*. Historically, the aim of encryption has been to enable two parties to exchange messages confidentially, even in the presence of an eavesdropper capable of intercepting most or all of their communications. The use of encryption has been confined chiefly to diplomatic and military circles in the past, but its scope in everyday life has broadened enormously in recent years. Thanks to the rise of the Internet, it is estimated that over half a billion personal computers are equipped today with strong encryption capabilities in their Web browsing software. This includes nearly every new computer sold today.

Active users of the Internet employ encryption on a regular basis. When accepting credit card information or processing other financial transactions, most Web servers initiate encryption sessions with clients. The form of encryption used to support sessions of this kind on the Web is very strong—so strong that it is generally believed to be effectively unbreakable by even the most powerful existing computers. In most browsers, the appearance of an icon representing a closed padlock on the bottom of the screen indicates the use of encryption in a protocol known as SSL (secure sockets layer). By clicking on this padlock, a user can learn detailed information about the encryption session, much of which is explained in further depth in this chapter.

For the reader interested in a cursory introduction to encryption, without much of the detail provided in this chapter, it is possible to read the following sections as a more-or-less self-contained exposition: Some Basics, Symmetric-Key Encryption Today, the opening paragraphs of Public-Key Cryptography, The RSA Cryptosystem, and How Public-Key Encryption Is Used.

Some Basics

The science of constructing encryption algorithms and related systems is known as *cryptography*. That of analyzing and attempting to find weaknesses in encryption algorithms is called *cryptanalysis*. Together, the two complementary sciences are known as *cryptology*. Cryptologists like to explain their ideas in terms of a small troupe of fictional characters. Traditionally, Alice and Bob are the names assigned to the fictional parties wishing to exchange confidential messages with one another. The hypothetical eavesdropper on their communication is called Eve. We follow this nomenclature in our explanations in this chapter.

The operational basis of an encryption algorithm, or cipher, is a piece of information known as a key. A key serves as input to the encryption process that Alice and Bob have agreed to use. The encryption process consists of a series of instructions on how Alice, for instance, should convert a plaintext into a ciphertext. The key serves as a parameter guiding the instructions. The reverse process, whereby Bob converts a ciphertext back into a plaintext, is also guided by a key, one that may or may not be the same as Alice's. The security of traditional ciphers, that is, the privacy of the messages they encrypt, depends upon a shared key that is kept secret. For example, in one form of folklore encryption, Alice and Bob each have copies of the same edition of a particular novel. They share the identity of this novel as a secret between them. Alice encrypts a plaintext by finding a random example of each letter of her message in the novel. She writes down the page, line, and ordinal position of each of these letters in turn. The result of this process constitutes the ciphertext. Bob, of course, can reverse the process and obtain the original plaintext by referring to his copy of the shared novel. In this case, the novel itself serves as a key—one that is quite long, of course, running as it usually does to hundreds of pages. In the forms of cryptography used on computers today, the key is much shorter, typically the equivalent in length of several words or sentences.

Symmetric-Key Encryption: Introduction

When Alice and Bob make use of the same key for encryption and decryption, as in our example involving the novel, this is referred to as symmetric or symmetric-key encryption. Let us consider another folklore cipher, in which each letter of a message is replaced with another letter according to a fixed set of random, predetermined assignments. For example, the message, "MEET ME UNDER THE BRIDGE" might be encrypted as:

ZKKO ZK BWIKQ OPK UQMIFK.

This form of encryption is known as a substitution cipher. It is in fact quite easy for a skilled cryptanalyst to break. (Edgar Allen Poe, for instance, challenged readers of a newspaper in 1839 to submit English-language ciphertexts produced by letter substitution. He published the plaintexts of many such challenge ciphertexts in subsequent numbers of the newspaper.) Knowing, for example, that 'e' is the most common letter in the English language, one would be tempted—quite correctly—to identify the letter 'K', which appears most frequently in the above ciphertext, with the letter 'E' in the plaintext. More sophisticated cryptanalytic techniques for attacking substitution ciphers focus on the frequency statistics not just for single letters, but also for letter pairs and triples.

Knowing that their cipher is subject to cryptanalytic attacks of this kind, Alice and Bob might be tempted to use a different, perhaps more complex cipher, and to hide from Eve not just their key, but also the workings of the cipher. This is equivalent in effect to making the choice of the cipher a part of the key itself. An important principle enunciated by the 19th century cryptologist Kerckhoffs discourages this approach. Adhered to by contemporary cryptologists, this principle may be stated as follows: The security of a cipher should reside in the key alone, not in the secrecy of the process of encryption. The motivations behind Kerckhoffs principle are several. First of all, widespread use of a good cipher requires that its workings be divulged in some form. Even if a cipher is only disseminated through software, for example, the underlying instructions can be reverse-engineered. Thus, it is fair to assume that an attacker can learn the mechanics of the cipher. Moreover, despite the oft-demonstrated inventiveness of the cryptographic community, there is time enough to devise and refine only a limited number of basic techniques for strong new ciphers. A poorly designed cipher, even when its workings are hidden from view, is vulnerable to attack by means of an arsenal of analytic techniques refined by the cryptanalytic community over many years. These techniques are roughly analogous in spirit to the idea that leads to the discovery of the letter 'E' in the example ciphertext above, but rely on more sophisticated forms of statistical analysis.

The basic unit of information in the computer and the fundamental unit for the encoding of digital messages is not the letter, but the bit. For this reason, contemporary symmetric-key ciphers operate through the manipulation of numerical units, rather than lexicographic units. One of the earliest ciphers designed from this perspective is known as the one-time pad. Invented during World War I, the one-time pad is also of interest as the only cipher whose security is provable in the strictest mathematical sense. Formal understanding of its properties emerged in 1948–1949, with the publication of seminal work by Claude Shannon. (The security analysis of other ciphers, as we shall explain, has a strong, but less rigorous mathematical basis.)

A one-time pad is a key shared by Alice and Bob consisting of a perfectly random string of bits as long as the message that Alice wishes to transmit to Bob. To encrypt her message, Alice aligns the pad with the message so that there is a one-to-one correspondence between the bits in both. Where the pad contains a '1', Alice flips the corresponding bit in her plaintext. She leaves the other bits of the plaintext unchanged. This simple process yields the ciphertext. As may be proven mathematically—and perhaps grasped intuitively—this ciphertext is indistinguishable to Eve from a completely random string. Indeed, from her perspective, it is a completely random string. This is to say that Eve can learn no information at all from the ciphertext, no matter how powerful her cryptanalytic capabilities. Apart from its requirement of perfect randomness, though, the one-time pad carries another strong caveat. The term "one-time" refers to the fact that if Alice uses the same key to encrypt more than one message, she loses the security properties of the cipher. This makes the one-time pad impractical for most purposes, as it requires that Alice and Bob generate, exchange, and store many random bits in advance of their communications. Nonetheless, the one-time pad has seen practical use. For example, the "hot-line" established between the United States and Soviet Union in the wake of the Cuban missile crisis employed a one-time pad system to ensure confidentiality, with tapes containing random keying material exchanged via the embassies of the two countries.

Symmetric-Key Encryption Today

The symmetric-key ciphers in common use today are designed to employ relatively short keys, typically 128 bits in length. Moreover, these ciphers retain their security properties even when individual keys are used to encrypt many messages over long periods of time. Indeed, a well-designed symmetric-key cipher should permit only one effective avenue of attack, described by cryptographers as exhaustive search or brute force. By this, it is meant that an attacker familiar with the cipher makes random guesses at the key until successful. If Eve wishes to mount a brute-force attack against a ciphertext sent by Alice to Bob, she will repeatedly guess their shared key and try to decrypt the message, until she obtains the correct plaintext.

Given use of a 128-bit-long key, Eve will on average have to make well more than a trillion trillion trillion guesses before she is successful! This is more, for example, than the total number of atoms composing all of the human beings in the world. The most powerful computers available today could not be expected to mount a successful brute-force attack against a well-designed cipher employing a key of this length, even over the course of many years. It should be observed that the difficulty of breaking a key doubles for every additional bit in length. Thus, for instance, a 128-bit key is not twice as hard to break as a 64-bit key, but over a million trillion times harder.

The first widely embraced cipher employing the strong design principles in use today was the Data Encryption Standard or DES (pronounced "dehz"). Developed at

IBM, the DES cipher was published as a federal standard in 1976 by what is now the National Institute of Standards (NIST) of the United States government. DES and security-enhanced variants are still widely deployed, particularly in the banking industry. DES employs a 56-bit key, operating on a basic unit of encryption consisting of a 64-bit block. This is to say that in order to encrypt a long message using DES, Alice first subdivides the message into 64-bit (i.e., eight-byte) blocks, each of which she enciphers individually. Ciphers that operate in this fashion are referred to as block ciphers.

Brute-force attack on a 56-bit key requires substantial computational effort, very likely beyond the reach of most organizations at the time of invention of DES. Today, however, such capability is attainable with networks of ordinary workstations. This was first demonstrated in 1997 when a successful attack was mounted against a DES-encrypted ciphertext by a network of thousands of computers over the course of 39 days, and subsequently duplicated by a single, special-purpose computer in less than a day. Earlier concerns about the strength of DES had already prompted many organizations to employ a strengthened version involving application of DES operations not once, but three times to each input block, and using up to three distinct DES keys. Known as triple-DES, this enhanced version offers considerably stronger security than DES, with what may be viewed as an effective key strength of up to 112 bits.

With DES in its basic form approaching the end of its serviceable lifetime, the cryptographic community began in 1999 to lend its efforts to the development of a new standard cipher to serve as a successor. The Advanced Encryption Standard or AES (pronounced letter by letter) emerged as the result of an open competition conducted by NIST. After a period of rigorous scrutiny by the research community and government agencies, a cipher known as Rijndael (of which one recognized pronunciation is "Rhine dahl") was selected as the AES. Designed by two Belgian researchers, Joan Daemen and Vincent Rijmen, the AES promises to see widespread deployment in the United States and internationally in coming years. Rijndael is a block cipher designed to accommodate key lengths of 128, 196, or 256 bits and operate on data blocks of 128, 196, or 256 in any of the nine possible combinations. Rijndael, like many contemporary symmetric-key ciphers, is capable of very fast encryption—substantially faster than triple-DES. On a Pentium III running at 1 GHz, implementations of AES with 128-bit keys are capable of achieving an encryption speed of 50 megabytes per second. The code sizes for such implementations can be less than one kilobyte. The size of a basic ciphertext yielded by AES, as with any block cipher, is roughly the size of the plaintext. A little extra space—less than the block size—may also be needed to accommodate the fact the plaintext generally cannot be divided into data blocks of exactly the right size. See the NIST AES Web site for further information and links (National Institute of Standards and Technology, 2002).

Another symmetric-key cipher deserving discussion is RC4. Known as a stream cipher, RC4 does not operate by encrypting individual blocks of data. Rather, the only input to RC4 is a key, typically 128 bits in length. The output of this cipher is a string of random-looking bits. This string may be made as long as desired by the user. In order to encrypt a message for Bob, Alice inputs a shared key to RC4 and generates a string as long as the message. Although not a one-time pad, this string is used by Alice to encrypt the message in exactly the same manner as a one-time pad, i.e., using the same system of bit alignment and flipping. Additionally, the output string of RC4 for a particular key has the "one-time" restriction, which is to say that the string can be safely used for encryption only once. The fact that RC4 can generate a string of arbitrary length, however, means that different portions of the string can be used for different messages. Also, encipherment under RC4 is naturally capable of yielding a ciphertext identical in length to the plaintext.

This said, the output string of RC4 on a given key is not in fact a one-time pad, because it is not fully random. This may be seen in the fact that Alice and Bob know the process that generated the string, because they know their shared input key to RC4. In particular, they can write down a short set of instructions describing to someone else how to generate exactly the same output string from RC4. If k denotes their shared key, these instructions would simply say, "Give the key k as input to RC4." They could not do this in the case of a truly random string. Suppose, for instance, that Alice and Bob generated a shared random string, i.e., a one-time pad, by flipping a coin many times. If they gave the instructions "Flip a coin" to Carol, it is almost certain that Carol, in following the same instructions, would generate a very different-looking string. Obviously, though, RC4 is much more convenient for Alice and Bob to use than a one-time pad, because it only requires of them that they share a key of, say, 128 bits in length. For all intents and purposes, this is true no matter how long the messages they wish to encrypt.

The security of the RC4 cipher comes from the fact that from the perspective of Eve, who does not know the key, the output of RC4 is indistinguishable from a one-time pad. This is to say that if Alice were to give an RC4 output string to Eve (rather than using it for encipherment), and were also to give Eve a truly random string of the same length, Eve would not be able to tell the difference. Thus, as far as Eve is concerned, when Alice and Bob encrypt their messages using RC4, they might as well be using a one-time pad. This, at any rate, is a rough expression of the conclusion that cryptanalysts have arrived at after many years of statistical study of the RC4 cipher. They express this belief by describing the output of RC4 as being pseudo-random. Strong block ciphers like AES are also believed to possess this property of pseudo-randomness, but in a different form.

RC4 is of particular interest because it is one of the most commonly used ciphers in the world and included in the software in nearly every new PC sold today. It is generally a component of the SSL encryption system used for secure credit-card transactions on the Internet. In other words, the closed padlock on a browser screen mentioned earlier in this chapter indicates that the RC4 cipher is being used. RC4 was designed by Ron Rivest, one of the co-inventors of the RSA cryptosystem, which we discuss later in this chapter. The letters "RC" stand for "Ron's

Code," and the number '4' denotes Rivest's fourth cipher design. The design principal for RC4, like that of most symmetric ciphers, is a delicate sequencing of a few very basic mathematical instructions. In RC4, the operations are the swapping of integer elements in a small array representing a permutation and addition of small integers (in fact, modular addition, an operation explained later in this chapter). Others of Rivest's suite of cipher designs are also in common use, namely RC2, which forms the basis of many e-mail encryption programs, and also RC5. Apart from DES, triple-DES, AES, and the RC series, there are a number of other popular ciphers used in various systems today. These include IDEA, CAST-128, and Blowfish, to name just a few.

More on the Security of Symmetric-Key Encryption

As already explained, cryptologists know of a complete mathematical proof of security only for the one-time pad. For DES, triple-DES, AES, RC4, and kindred ciphers, cryptographers have no such security proofs. Strong proof for these ciphers is not possible; belief in their security, however, rests on fairly well-explored mathematical foundations.

Shortly after the publication of DES, two cryptologists named Eli Biham and Adi Shamir developed a technique called differential cryptanalysis. Roughly speaking, differential cryptanalysis involves statistical analysis of a cipher based on the way particular bits change (or do not change) in output ciphertexts when bits in certain positions are flipped in input plaintexts. The technique of differential cryptanalysis helped to confirm the strength of DES and to inform the design of later ciphers.(Some time after the academic development of differential cryptanalysis, it was publicly revealed that the technique had already been familiar to the government intelligence community, and had indeed helped guide the design of DES.) Subsequently developed cryptanalytic techniques have further enhanced the collection of tools available to the cryptanalyst, influencing new cipher designs in the process.

We have thus far been describing Eve as a passive eavesdropper, attempting to decipher the messages sent between Alice to Bob by harvesting and analyzing the ciphertexts they exchange. In fact, cryptologists also consider a range of active attacks that Eve might mount. By active attacks, we mean ways in which Eve might try to tamper with or otherwise influence what messages Alice and Bob exchange, in the hope of learning additional information. For example, if Alice encrypts all of her e-mail, then Eve might send a note containing a petition to Alice, and ask Alice to forward it to her friends. If Alice sends the petition to Bob while Eve is eavesdropping, then Eve learns a ciphertext for which she herself has selected the corresponding plaintext. In other words, Eve is able to perform active experimentation on the cipher. If Alice and Bob use a cipher that is poorly designed, then Eve may be able to gain information about their key in this way, or about messages they have exchanged with one another. This type of attack is known as a chosen-plaintext attack. It is an example of one of the types of active attack against which cryptographers must ensure that their cipher designs are resistant.

Even if a cipher is well designed, however, it must still be used with great care. Consider another example. Suppose that Alice and Bob always use a strong block cipher such as AES with a random 128-bit key to encrypt their communications. They perform encryption simply by dividing their messages into blocks and encrypting each block individually under their key. But suppose further that Eve knows that Alice and Bob exchange stock tips, and that these regularly take the form of simple buy and sell orders. Eve might then pass some stock tips to Alice, such as "Buy ABC, Inc." and "Sell DEF Corp.," and suggest that these be forwarded to Bob. If Eve eavesdrops while these stock tips are forwarded, then she learns what the corresponding ciphertexts look like. Thus, if Alice later sends the message "Buy ABC, Inc." to Bob, Eve will be able to recognize the ciphertext and identify the corresponding buy or sell order. In other words, even though Alice and Bob are using a very strong cipher, Eve will be able to identify (and effectively, to decrypt) any of a small set of target messages!

The way that Alice and Bob use a block cipher is known as a mode of operation. The naïve example we just described is known as electronic code book (ECB) mode, a form whose use is avoided today in part because of the problem we have just described. To prevent Eve from learning what particular ciphertexts look like, Alice may adopt a mode of operation that involves the introduction of random bits into the message. One popular mode of operation today is known as cipher-block-chaining (CBC) mode. In this system, Alice divides her plaintext into blocks and inserts some freshly generated random bits at the beginning to serve as the first block. Alice then employs a principle of "chaining" in which the encryption of one block is affected by the encryption of the previous one, thereby causing the randomness in the first block to propagate through the ciphertext. Although the architectural motivations behind this mode are somewhat complex, its basic impact on message privacy is easy to understand. The fact that Alice introduces randomness into her ciphertexts means that the same plaintext is not encrypted twice the same way, and thus that Eve cannot trick Alice in order to recognize the stock tips or other plaintexts that Alice encrypts.

Encryption and Passwords

Symmetric-key ciphers are used not only to protect communications, but also commonly to protect files against unauthorized access. Many users rely on encryption software to protect files on their hard drives against exposure to hackers or to protect sensitive data in case of laptop theft. For these purposes, it is common for the user to employ a password. The encryption software converts this password into a key for use with a standard symmetric-key cipher such as AES. Because users typically employ passwords consisting of or closely related to words in their native languages, there is generally less randomness in the key generated by a password than in a randomly generated symmetric key. One well-known means for a hacker to attack password-encrypted files in a particular encryption system, therefore, is to compile a large lexicon of common passwords. The hacker converts each entry in the lexicon into a symmetric key in the same manner as the encryption system and then uses each such key in a brute-force attack against individual users employing that system. This is known as a dictionary attack. One way to reduce vulnerability to dictionary attacks is to use salt. This is a random string of bits generated for each password individually and combined with the password in the generation of a symmetric key. The use of salt renders dictionary attacks more difficult, as it effectively forces an attacker to recompile the base lexicon for each target password. It should be understood nevertheless that salt is a limited countermeasure, and does not compensate for poor selection of passwords.

Passwords are, of course, also the most common way for users to authenticate when logging into accounts over the Internet. In this context, however, the password is typically not used as an encryption key. Instead, the server to which the user is attempting to connect checks processed password information against a database entry for the requested account.

A Brief Historical Note

Although the history of cryptology is an exciting subject of study in its own right, it is also intimately associated with the birth of the digital computer. During WWII, the efforts of British signals intelligence to break the German Enigma cipher led to the development of mechanical devices known as “bombes,” so called because of the ticking sounds they made in testing possible cipher keys. The “bombes” and the later generation of Colossus machines arising from these efforts were important precursors of the modern computer. Moreover, the man overseeing the immensely successful Enigma break was Alan Turing, a progenitor of the field of computer science.

PUBLIC-KEY CRYPTOGRAPHY

Many years of research have led to the widespread deployment of strong symmetric-key ciphers capable of high encryption speeds. One might be tempted to believe that the basic problem of private communications has been solved and that the science of cryptology has run its course. Even if a symmetric-key cipher is unbreakable, however, there remains a fundamental problem. We have assumed in our discussion that Alice and Bob share knowledge of a secret key. The question is: How do they obtain this key to begin with?

If Alice and Bob can meet face to face, in the absence of the eavesdropper Eve, then they may generate their shared key by repeatedly flipping a coin, or Alice may simply hand Bob a key written on a piece of paper or stored on a floppy disk. What if Alice and Bob wish to communicate privately over the Internet, however, without ever meeting? Alternatively, what if a commercial site on the Web wishes to enable any customer, new or old, to submit an order and credit card number securely from anywhere in the world? The administrator of the Web site cannot possibly hope to communicate keys in private to all customers before they log in. To simplify the formidable difficulties that secure key distribution can pose, cryptographers have devised a form of mathematical magic known as public-key encryption or cryptography (also known as asymmetric-key cryptography, in contrast to symmetric-key cryptography). Using public-key cryptography, Alice and Bob can send each other encrypted messages securely, even if they have never met, and even if Eve has eavesdropped on all of their communications!

In a public-key cryptosystem, Alice possesses not one, but two keys. The first is known as her public key. Alice makes this key known to everyone; she may publish it on her Web page, in Internet directories, or in any other public place. Her second, mathematically related key is known as a private key. Alice keeps this key secret. She does not divulge it to anyone else, even people she wishes to communicate with privately. Together, the public key and private key are referred to as a key pair. Bob sends a private message to Alice by performing a computation using her public key, and perhaps a private key of his own as well.

Public-key cryptography is a powerful tool—indeed, one whose feasibility may at first seem counterintuitive. Even if Eve knows Alice and Bob’s public keys, it is possible for Alice and Bob to communicate privately using public-key cryptography. Moreover, with public-key cryptography, not only Bob, but Carol or any other party can achieve private communication with Alice over a public communication medium like the Internet.

Diffie–Hellman Key Exchange

Public-key encryption was the brainchild of Ralph Merkle, who in 1974 conceived a plausible, but somewhat impractical initial scheme. The idea saw its first practical form in 1976 in a seminal paper by Whitfield Diffie and Martin Hellman entitled “New Directions in Cryptography.” Diffie and Hellman proposed a system in which Alice can combine her private key with the public key of Bob, and vice versa, such that each of them obtains the same secret key. Eve cannot figure out this secret key, even with knowledge of the public keys of both Alice and Bob. This system has come to be known as Diffie–Hellman key exchange, abbreviated D–H.

D–H exploits a form of mathematics known as modular arithmetic. Modular arithmetic is a way of restricting the outcome of basic mathematical operations to a set of integers with an upper bound. It is familiar to many schoolchildren as “clock arithmetic.” Consider a clock on military time, by which hours are measured only in the range from zero to twenty-three, with zero corresponding to midnight and twenty-three to 11 o’clock at night. In this system, an advance of 25 hours on 3 o’clock brings us not to 28 o’clock, for example, but full circle to 4 o’clock (because $25 + 3 = 28$ and $28 - 24 = 4$). Similarly, an advance of 55 hours on 1 o’clock brings us to 8 o’clock (because $55 + 1 = 56$ and $56 - (2 \times 24) = 8$). In this case, the number 24, an upper bound on operations involving the measurement of hours, is referred to as a modulus. When a calculation involving hours on a clock yields a large number, we subtract the number 24 until we obtain an integer between 0 and 23, a process known as modular reduction. This idea can be extended to moduli of different sizes. For example, in the modulus 10, the sum of 5 and 7 would not be 12, which is larger than 10, but 2, because modular reduction yields $12 - 10 = 2$. We say that an arithmetic operation is modular when modular reduction is applied to its result. For example, modular multiplication is simply ordinary multiplication followed by modular reduction. We write mod p to denote reduction under modulus p. Thus, for example, it is easily seen that $3 \times 4 \bmod 10 = 2$.

Diffie and Hellman proposed a public-key cryptosystem based on modular multiplication, or more precisely, on modular exponentiation, i.e., the repeated application of modular multiplication. Their scheme depends for its security on the use of a modulus that is a very large number. In the systems used today, the modulus is typically an integer that is 1024 bits in length, i.e., a little more than 300 decimal digits. It is also generally prime, which is to say that apart from the number one, it is not divisible by any smaller integers. There are some additional, technical restrictions on the form of the modulus that we shall not explore here.

The security of D–H is based on the following idea. Suppose that p is a large modulus and g is an integer less than p (again, with some additional technical restrictions). Suppose that Alice selects a random integer a, also less than p. She then computes the integer $y = g^a \bmod p$ and gives the integers p, g, and y to Eve. It is believed by cryptologists that with this information alone, it is infeasible for Eve to figure out the value a. The task of figuring out a is known as the discrete logarithm problem, one that has been the subject of many years of study by mathematicians and cryptographers. Although the security of D–H is not directly based on the discrete logarithm problem, it is very closely related.

In D–H, the values p and g are standard, public values. They may be conveyed in some widely distributed piece of software, such as a browser. Alice selects a random integer a less than p as her private key and computes $y_{\text{Alice}} = g^a \bmod p$ as her public key, i.e., the key that she publishes. Bob similarly selects a random integer b, also less than p, as his own private key, and computes $y_{\text{Bob}} = g^b \bmod p$ as his public key. Using her secret key a, Alice can take the public key y_{Bob} and compute a value $k = (y_{\text{Bob}})^a \bmod p$. Bob, similarly, can compute exactly the same value k using y_{Alice} in combination with his own private key b. In particular, it is also the case that $k = (y_{\text{Alice}})^b \bmod p$ (thanks to the commutative properties of modular exponentiation). Eve, however, cannot figure out the secret k. This, at least, is the belief of cryptologists, based on the idea that Eve knows neither of the private keys a or b and on the difficulty of the discrete logarithm problem. Thus, if Alice and Bob employ the secret k as the basis for private communication using a symmetric-key cipher like AES, Eve will be unable to eavesdrop successfully on their communications. This is a capsule summary of the idea behind the Diffie–Hellman cryptosystem. There are other details involved in making D–H a secure, workable system, which we gloss over in this description. We also note in passing that an attractive feature of D–H is the fact that variants may be implemented over algebraic structures known as elliptic curves. This results in more compact key lengths and faster running times.

D–H is used, among other places, in some versions of PGP (Pretty Good Privacy), a popular piece of encryption software used to secure Internet communications such as e-mail, and available as freeware in some versions.

The RSA Cryptosystem

A year after the publication of Diffie and Hellman's key exchange system, three faculty members at M.I.T. proposed a new public-key cryptosystem. This cryptosystem is called RSA after its three inventors, Ronald Rivest, Adi Shamir, and Leonard Adleman. RSA is now the most widely deployed cryptosystem in the world (see RSA Laboratories, 2002).

Use of the RSA cryptosystem for encryption is very similar to that of D–H. One superficial difference is that in the RSA cryptosystem, Bob can send an encrypted message to Alice without having a public key of his own. In particular, Bob can encrypt a message directly under Alice's public key in such a way that Alice can decrypt the ciphertext using her private key. (Similar functionality can be achieved with D–H by having Bob generate a temporary key pair on the fly and using this as the basis for encryption of a message for Alice.) There are two rather more important differences between the two cryptosystems. The first lies in the speed of their respective operations. In RSA, encryption is a very fast operation; it generally requires less computational effort than a D–H key exchange. Decryption, however, is several times slower for RSA than key exchange in D–H. Another important difference between the two is a feature present in RSA, but absent in D–H (although realized in later variants). RSA can also be used to perform digital signing, an operation not covered in this chapter, but of central importance in cryptography.

The RSA system employs modular arithmetic, the same type of mathematical basis as for Diffie–Hellman key exchange. In D–H, the modulus is a published value that may be used by any party to construct his or her key pair. In RSA, however, every party uses a different modulus, published as part of his or her public key. Thus, if Bob wishes to encrypt a message for Alice, he uses a modulus N_{Alice} unique to the public key of Alice; if he wants to encrypt a message for Carol, he uses a different modulus, N_{Carol}. The reason for the use of different moduli is the fact that the value of the modulus in the RSA cryptosystem relates directly to that of the private key.

A modulus N in the RSA cryptosystem has a special form. It is the product of two large prime integers, generally denoted by p and q. In other words, $N = p \times q$. The pair of primes p and q are treated as private values in the RSA cryptosystem; they are used to compute the private key for the modulus N. Thus the security of RSA is related very closely to the difficulty of determining the secret primes p and q given knowledge of the modulus N. This is known as the problem of factoring and is believed to be extremely difficult when p and q are large. In typical systems today, p and q are chosen to be primes of about 512 bits in length, so that N is an integer of about 1024 bits, the same length as generally selected for a Diffie–Hellman modulus. Factoring is the only effective method known for attacking RSA when the cryptosystem is used properly.

Among its many other uses, the RSA cryptosystem (along with RC4) is used as the basis for SSL, the encryption system in most Web browsers today, and also in some versions of PGP (Pretty Good Privacy) software.

More Technical Detail on RSA

We now describe in more mathematical detail how the RSA cryptosystem works. Unable as we are to delve further into the underlying mathematics, we provide only prescriptive formulae, without explaining the rationale behind them. For further information, the reader is directed to, e.g., (Menezes, van Oorschot, & Vanstone, S. A., 1996).

To compute her public key, Alice selects two random primes, p_{Alice} and q_{Alice}, both of roughly equal length in bits, e.g., 512 bits long. The product $N_{\text{Alice}} = p_{\text{Alice}} \times q_{\text{Alice}}$ is the modulus used by Alice in her public key. She also selects a small odd integer e_{Alice}; generally, this value is more or less standardized in a given system, the integer 65535 being a common choice. An additional restriction on e_{Alice} is that it must not have a factor in common with $p_{\text{Alice}} - 1$ or $q_{\text{Alice}} - 1$, a criterion considered in the selection of primes. Together, the pair of values $(e_{\text{Alice}}, N_{\text{Alice}})$ constitutes Alice's public key. Her private key is computed as follows. Let $\Phi(N_{\text{Alice}}) = (p_{\text{Alice}} - 1) \times (q_{\text{Alice}} - 1)$. Alice computes her private key, generally denoted by d_{Alice}, in such a way that $e_{\text{Alice}} d_{\text{Alice}} = 1 \bmod \Phi(N_{\text{Alice}})$. The bit-length of the private key d_{Alice} here is typically quite close to that of N_{Alice}.

A message in the RSA cryptosystem consists of a positive integer m less than N_{Alice}. To encrypt m, Bob computes the ciphertext $c = m^{e_{Alice}} \bmod N_{\text{Alice}}$. As a technical restriction required to achieve good security, the plaintext m is formatted so as to be about equal in length to the modulus, resulting in a ciphertext that is similarly so. To decrypt the ciphertext, Alice applies her private key and computes $m = c^{d_{Alice}} \bmod N_{\text{Alice}}$.

An Example

Let us consider a small example to provide some flavor of how the RSA cryptosystem works. For illustrative purposes, we consider integers much smaller than those needed for true, secure use of RSA. Suppose that p_{Alice} and q_{Alice} are 5 and 11 respectively. Then $N_{\text{Alice}} = 5 \times 11 = 55$. Observe that $e_{\text{Alice}} = 3$ does not divide $p_{\text{Alice}} - 1$ or $q_{\text{Alice}} - 1$. Thus, Alice can use $(e_{\text{Alice}}, N_{\text{Alice}}) = (3, 55)$ as her public key. A valid private key for Alice is $d_{\text{Alice}} = 27$, because $\Phi(N_{\text{Alice}}) = (p_{\text{Alice}} - 1) \times (q_{Alice} - 1) = (5 - 1) \times (10 - 1) = 40$, and $e_{\text{Alice}} \times 27 = 81 = 1 \bmod 40$.

To encrypt the message $m = 7$, Bob computes the ciphertext $c = 7^3 \bmod 55 = 343 \bmod 55 = 13$. Alice decrypts the ciphertext $c = 13$ by computing $13^{27} \bmod 55$. Using a pocket calculator, the reader can easily verify that the result of this decryption operation is indeed the original plaintext $m = 7$.

The security of RSA requires some special, technical restrictions on the value of m. In fact, as the RSA cryptosystem is generally employed, the message m itself encodes the key for a symmetric-key cryptosystem such as AES. Public-key cryptosystems are generally used in conjunction with symmetric-key cryptosystems, as we discuss below.

With a 1024-bit RSA modulus, a Pentium III running at 1 GHz can perform roughly 40 RSA decryption operations per second, and about 600 encryption operations per second under the public exponent $e = 65535$. (These speeds, of course, depend critically on the particular software implementation.)

As explained above, the security of the RSA cryptosystem is closely related to the difficulty of factoring the product of two large primes. Security guidelines for RSA thus depend upon advances in the factoring problem made by researchers, as well as the cost and availability of computing power to a potential attacker. According to guidelines issued in 2001 by NIST, 1024-bit RSA moduli may be used to secure data whose privacy needs to be assured until the year 2015. For more sensitive data, a 2048-bit RSA modulus is recommended instead. Although there is substantial debate and uncertainty among cryptographers as to the exact ongoing security level afforded by RSA, there is general agreement as to the rough accuracy of these predictive guidelines. To avoid a common misconception, it should be emphasized that the mathematical basis for the RSA cryptosystem means that the recommended modulus lengths, and thus the public and private keys, are substantially longer than the 128- to 256-bit key lengths prescribed for symmetric-key ciphers.

How Public-Key Encryption Is Used

Encryption of a large quantity of data is generally much slower using a public-key cryptosystem than using a symmetric-key cipher. On the other hand, public-key encryption offers an elegant approach to the problem of distributing keys that is unavailable in symmetric-key ciphers. It is common in practice, therefore, to combine the two types of encryption systems in order to obtain the best properties of both. This is achieved by use of a simple principle known as enveloping. Enveloping involves use of a public-key cryptosystem such as RSA as a vehicle for transporting a secret key, which is itself then used for encryption with a symmetric-key cipher. To send a megabyte-long file to Alice, for example, Bob might select a random 128-bit RC4 key k and encrypt the file under k. He would then send this ciphertext of the file to Alice, along with an RSA encryption of k under Alice's public key. In effect, enveloping is a way of making a public-key cryptosystem faster.

As with symmetric-key ciphers, cryptologists aim to design public-key cryptosystems to withstand a wide range of possible attacks, involving some very strong ones in which, e.g., Eve can persuade Alice to decrypt a range of ciphertexts that Eve herself selects. Like symmetric-key block ciphers, when used in a naïve manner, RSA has a limitation in that encryption of the same plaintext always yields the same ciphertext. Prior to encryption under RSA, therefore, it is common practice to subject a message to a special type of formatting that involves the addition of random bits, plus some additional processing. Loosely speaking, this addition of randomness serves much the same purpose as in the case of cipher-block chaining for symmetric-key block ciphers, as described above. Other aspects of the formatting process permit the RSA cryptosystem to withstand other forms of attack, and to do so with guarantees that are subject to rigorous mathematical justification.

Most public-key encryption systems have an additional advantage over symmetric-key systems, in that they permit a flexible approach to distributed storage of the private key, known as secret sharing. This is a way of mathematically splitting a private key into a number of elements known as shares. To achieve a decryption operation, each of these shares may be applied individually to a ciphertext, without the need to assemble the shares themselves in a single place. Thus, a cryptosystem can be set up so that compromise of any one share does not expose the full decryption key itself. For example, Alice can divide her private key into, say, three shares, keeping one for herself and giving one each to her friends Bob and Carol. To decrypt a ciphertext, Alice can ask Bob and Carol to apply their shares and to send her the result. Alice can then complete the decryption with her own share, without Bob or Carol seeing the resulting plaintext. If an attacker breaks into Alice's computer and obtains her share, the attacker will still be unable to decrypt ciphertexts directed to Alice (without also obtaining the assistance of Bob and Carol). The system can even be set up so that decryption is possible given particular sets of shares. Thus, for example, Alice might be able to achieve decryption of her ciphertexts even if Bob or Carol is on vacation.

Despite its great flexibility, public-key cryptography does not directly address all of the challenges of key distribution. For example, we have said that Alice can safely disseminate her public key as widely as she likes, publishing it in Internet directories and so forth. But when Bob obtains a copy of Alice's public key, how does he really know it belongs to Alice, and is not, for example, a spurious key published by Eve to entrap him? To solve problems of this kind, we appeal to a public-key infrastructure (PKI), as explained in detail in the chapter on that topic. Another issue worth mentioning—and a pitfall for many system designers—is the problem of finding an appropriate source of randomness for generating keys. Good generation of random bits is the cornerstone of cryptographic security and requires careful attention.

A final problem that encryption alone does not solve is that of message integrity. When Bob sends a message to Alice encrypted using, e.g., RC4, he may be reasonably well assured of the privacy of his communication if he uses the cipher correctly. When Alice receives his message, however, how does she know that Eve has not tampered with the message en route, by changing a few bits or words? Indeed, how does she even know that Bob is the one who sent the message? For this type of assurance, some additional cryptographic apparatus is required in the form of a message authentication code or a digital signature. These are techniques for applying a key to a message to obtain an unforgeable "fingerprint" that shows evidence of any tampering.

CONCLUSION: FURTHER READING

Two broad and accessible introductions to the field of cryptology are *Applied Cryptography*, by Bruce Schneier (2002a), and the online compendium *Frequently Asked Questions About Today's Cryptography* (RSA Laboratories, 2002). A more detailed technical treatment of cryptographic techniques and concepts, along with an extensive bibliography, may be found in the excellent *Handbook of Applied Cryptography*, by Alfred J. Menezes, Paul C. van Oorschot, and Scott A. Vanstone (Menezes *et al.*, 1996). Detailed information on the AES algorithm (Rijndael) is available in *The Design of Rijndael*, by Joan Daeman and Vincent Rijmen (2002).

Readers interested in the practical application of cryptography in real-world systems may wish to consult *Network Security: Private Communication in a Public World*, by Charles Kaufman, Radia Perlman, and Mike Speciner (2002), and *Cryptography and Network Security: Principles and Practice*, by William Stallings (1998). Also of interest to such readers may be Bruce Schneier's *Secrets and Lies* (Schneier, 2002b), which offers some caveats regarding the limitations of cryptography.

A good introductory textbook of a more academic flavor is *Cryptography: Theory and Practice*, by Douglas Stinson (2002). For information on the foundational mathematics and theory of cryptology, an important work is *Foundations of Cryptography: Basic Tools*, the first in an evolving series of volumes by Oded Goldreich (2000). For a historical overview of cryptology, the classic text is *The Codebreakers*, by David Kahn (1996). More up-to-date, although less exhaustive, is *The Science of Secrecy from Ancient Egypt to Quantum Cryptography*, by Simon Singh (2000).

Cryptologists continue to devote effort to the development of new symmetric ciphers and public-key cryptosystems, as well as the improvement of existing ones. Although encryption is the fountainhead of contemporary cryptology, it is by no means the only focus of the field. As is the case with many branches of science, cutting-edge inventions in cryptology often lie dormant for years or decades before their widespread use. The scope of cryptologic research today extends beyond the problems of message privacy and integrity to the goal of achieving fair play in electronic environments in a much broader sense. Secure electronic voting, on-line privacy protection, and digital rights management are just a few of the many areas where researchers in cryptography have made strides in recent years. At the frontiers of cryptology are ideas involving the use of quantum mechanics and even DNA for attacking ciphers. Many cryptologists are members of the International Association for Cryptologic Research (IACR), whose home page (IACR, 2002) lists publications and conferences devoted to advanced current research in cryptography and cryptanalysis.

GLOSSARY

AES The Advanced Encryption Standard, a symmetric-key cipher known as Rijndael, serving as successor to DES.

Asymmetric In the context of encryption, a type of cryptographic system in which a participant publishes an encryption key and keeps private a separate decryption key. These keys are respectively referred to as public and private. RSA and D–H are examples of asymmetric systems. *Asymmetric* is synonymous with *public-key*.

Ciphertext The data conveying an encrypted message.

Cryptanalysis The science of analyzing weaknesses in cryptographic systems.

Cryptography The science of constructing mathematical systems for securing data.

Cryptology The combination of the complementary sciences of cryptography and cryptanalysis.

Cryptosystem A complete system of encryption and decryption, typically used to describe a public-key cryptographic system.

Decryption The process of obtaining a readable message (a *plaintext*) from an encrypted transformation of the message (a *ciphertext*).

DES The Data Encryption Standard, an existing form of symmetric cipher in wide use today, often in a strengthened variant known as triple DES.

Diffie–Hellman (D–H) A public-key cryptosystem used to exchange a secret (symmetric) key.

Encryption The process of rendering a message (a *plaintext*) into a data string (a *ciphertext*) with the aim of transmitting it privately in a potentially hostile environment.

Enveloping A method for using a symmetric-key cipher in combination with a public-key cryptosystem to exploit simultaneously the advantages of the two respective systems.

Key A short data string parameterizing the operations within a cipher or cryptosystem, and whose distribution determines relationships of privacy and integrity among communicating parties.

Key pair The combination of a public and private key.

Plaintext A message in readable form, prior to encryption or subsequent to successful decryption.

Private key In an asymmetric or public-key cryptosystem, the key that a communicating party holds privately and uses for decryption or completion of a key exchange.

Public key In an asymmetric or public-key cryptosystem, the key that a communicating party disseminates publicly.

Public-key In the context of encryption, a type of cryptographic system in which a participant publishes an encryption key and keeps private a separate decryption key. These keys are respectively referred to as public and private. RSA and D–H are examples of public-key systems. *Public-key* is synonymous with *asymmetric*.

RC4 A symmetric-key cipher of the type known as a stream cipher. Used widely in the SSL (secure sockets layer) protocol.

RSA A public-key cryptosystem in very wide use today, as in the SSL (secure sockets layer) protocol. RSA can also be used to create and verify digital signatures.

Symmetric A type of cryptographic system in which communicating parties employ shared secret keys. The term is also used to refer to the keys employed in such a system.

Enhanced TV

Jim Krause, *Indiana University*

INTRODUCTION TO ENHANCED TV

Background

For years film and television producers have been operating within the framework of broadcast. In the broadcast model, a signal is sent out from one or more points to reach a great number of installed receivers. Viewing is a passive experience, with options limited to changing channels or switching off the set. Through technological advances, the medium has evolved, providing more numerous channels and methods of delivery, higher quality sound and images, and the addition of embedded information to the video signal. Just recently the paradigm of one-way communication has begun to crumble as broadcasters and cable companies experiment with and implement two-way or interactive communication. Interactive television allows viewers to customize their television experience. They can choose what programs or information to watch and when to watch it and have the ability to use chat and e-mail, order products, and make financial transactions.

Enhanced TV bridges the gap between the historical broadcast model and interactive communication.

eTV or iTV?

In 1977 Warner Cable launched the first interactive television system by introducing Qube to some 30,000 viewers in Columbus, Ohio. Viewers using the experimental system could select TV programs, participate in live polls, and purchase pay-per-view movies. Despite attempts to expand service into Cincinnati and Dallas, Qube ultimately closed down due to prohibitively high system expense. About the time of Qube's demise, the 1984 Cable Act was accelerating the growth of cable. By the end of the decade cable reached into more than 50 million homes. Digital cable and digital broadcast satellite growth continued strongly through the end of the 20th century. Perhaps due to the concurrent growth of the Internet, unsuccessful early implementation, and a shaky investment history, interactive television had acquired, at least to some, a bad reputation.

Some view enhanced television as a subset of interactive television (iTV). Others consider it as a more favorable term for interactive television, clean of any stigma that may have been attached to it. Regardless, iTV is an umbrella term that can apply to a broad range of services relying on two-way communication between the viewer and content provider (CRTC, 2002). Enhanced television shares some key features with interactive television, such as a software interface and the ability in some systems for the user to transmit data, so it's easy to see why the two are sometimes confused. To clarify, a fundamental precept behind interactive television is that the user can influence the content or storyline. Enhanced TV is primarily concerned with augmenting the content of programming, not shaping it.

This chapter addresses the following:

What is enhanced television?

What infrastructure supports enhanced television?

What is the impact of enhanced television?

What business models can be applied to enhanced television?

Definitions

Microsoft sums it up: "Enhanced TV is any programming that enables consumers to interact directly with the show they're watching" (Microsoft TV, 2002). As enhanced television can describe a broad scope of interactive technologies, two subcategories can be defined. The first is rooted in the historical broadcast model while the second refers to a system of two-way communication. Both systems require set-top-boxes or other decoding devices.

1. "Basic" enhanced TV/one-way interactive—This system offers the viewer metadata, which is additional

information augmenting the program's content. While there is no return path or back channel, viewers can view additional data or make selections that display information on the program itself or regarding selected items. Programming enhanced in this manner can be transmitted over analog or digital means, as the information can be delivered via the vertical blanking interval (VBI) of the television signal.

2. "Interactive" enhanced TV/two-way interactive—A key component of this system, which is popular in the UK, is a return path or back channel. Viewers' selections and potentially other data (answers to questions, credit card numbers, etc.) can be sent back to the place of signal origination, or to anywhere else connected to the network: marketing agencies, advertisers, or content providers. As in the first category, content providers can use analog or digital transmission, delivering additional information in the VBI, but there must be some method of a return path.

Subsets and variations of each of these two types of enhanced television will be explored later in this chapter.

Convergence Factor

The convergence of broadcast, cable, telephone, satellite and Internet-based applications presents a dizzying array of new opportunities to broadcasters, cable companies, and viewers. Once considered television providers, satellite and cable companies are now dishing out broadband Internet service. Telco/IP networks can provide television programming. Microsoft, the company that dominates the PC software industry, is deeply entrenched in television and cable networks and manufactures set-top-boxes and the software that resides inside. People can listen to the radio and watch TV on computers, and surf the Web on TVs.

Users have grown accustomed to and are demanding more information and more data. Since the introduction of the Internet, Web surfers have learned to click a link to find out more, to order products, to download files, or to play games and interact with others. From Web browsing, users have grown accustomed to clicking a link to trigger pop-up video clips and instantly jump to a new URL. In this manner, enhanced television can be interpreted as an outgrowth of the Internet, even though its roots are planted firmly in the blue glow of the family TV set. Formerly WebTV, Microsoft MSN TV's set-top-box offers users complete access to the Internet through their television sets. The lines are becoming blurred between different types of media. Users can receive cable broadcasts on the same lines that supply broadband Internet connections.

MTV: The Proverbial Yardstick

In 1981, MTV was in the spotlight and music videos became the latest novelty. Just watching Michael Jackson's moonwalk and videos from bands like the Police used to be entertainment. Now some 20 years later, viewers need more to keep them tuned in. MTV has reduced the amount of time dedicated to music videos and resorted to varied programming lineup including news, reality and game shows, documentaries, and even wrestling. CMT, VH1, and MTV augment their music videos with additional information. Through programs like *Pop-Up Video*, viewers learn that the waitress in a music video would later become a famous actress or that the red guitar once belonged to a Beatle. Some may find it interesting that VH1's popular series of documentaries, *Behind the Music*, provides viewers with information on popular musicians whose careers were fueled in part by being featured on MTV. The tendency to insert additional information into program content is becoming more popular with other networks as well. On the American Movie Classics (AMC) program *DVD-TV*, movies are offered with facts and trivia, presented at the bottom of the screen, related to the talent or production. The programming on CNN Headline News and CNBC networks resembles an enhanced television display. The primary image is squeezed into a corner, while weather reports, stock quotes, and news bulletins border the edges. So even without interactive set-top-boxes, stations are trying to squeeze as much varied and additional information as possible into their programming.

APPLICATIONS OF ENHANCED TV

Definitions aside, the real question is what can it do. What does enhanced TV look like? Program providers can provide enhanced content through single- or dual-screen applications. Methods of the specific relationships program providers can have with their audience have also been identified. Technically, one can categorize types of enhanced services according to the method of delivery, the corresponding interface and equipment required, and the means (if any) of returning information from the viewer.

Two- and Single-Screen Applications

Two-screen systems refer to a TV and the monitor of a computer connected to the Internet (see Figure 1). Single-screen systems rely on set-top-boxes or other decoders that can superimpose information directly on top of a television display. A major advantage of two-screen systems is that there is a huge base of potential users—households with televisions and computers with Internet access in the same room. People who surf the Web while watching TV are sometimes called "telewebbers" (Davis, 2000). In April of 2001 estimates counted approximately 20 million households with PCs in the same room as television sets (Zdnet News, 2001). One year later, *USA Today* estimates showed between 30 and 40 million people watch TV and view the Web simultaneously, compared to approximately 10 million homes with interactive-capable satellite or cable service (*USA Today*, 2002).

Two-Screen Systems

In lieu of superimposing additional information over the TV broadcasts, which can only be accessed by viewers with service plans and set-top-boxes or other decoders, broadcasters can provide time synchronous, program-related content over the Internet. (Truly dedicated enhanced content providers do both!) This provides broadcasters with a relatively straightforward manner in

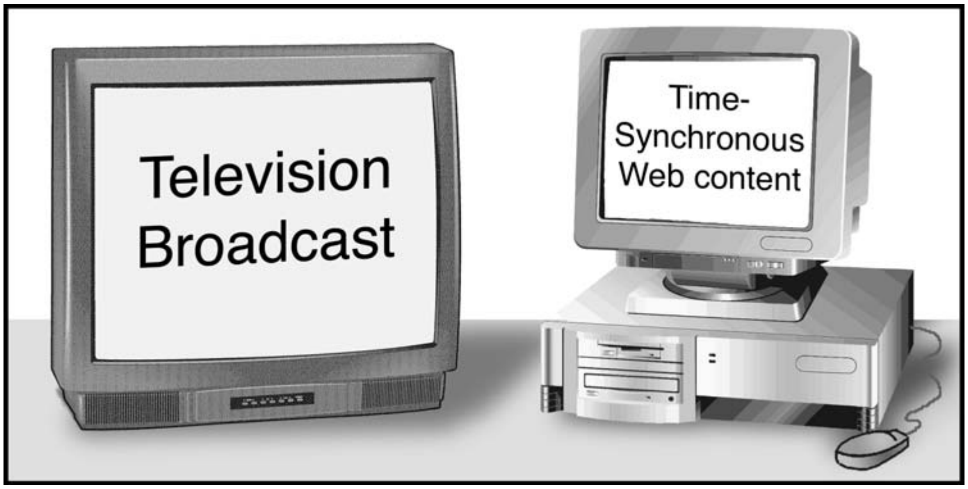

Figure 1: Two-screen application. From http://www.ttop.com. Copyright by Tabletop Productions. Reprinted with permission.

which to reach and maintain their viewers' interest in the programming outside of or even during the broadcast.

Although offering little or no embedded metadata in its programming, ABC touts its enhanced television programs on the company's Web site. Viewers watching shows like *Alias*, *Who Wants to Be a Millionaire?*, and *Sunday Night Football* can find a number of interesting ways to play along with their favorite shows. ABC's eTV Web site offers viewers a chance to participate in polls, answer trivia questions, build fantasy football teams, play interactive games, and even win prizes.

Web Strategies. In a study of enhanced television Web sites, three strategic models have been identified according to intended target audiences and strategic functions (Ha, 2002): "welcome all," "fans-friendly," and "hello." "Welcome all" Web sites are targeted equally to viewers and nonviewers. Web visitors can find general information on services and the station's programming. The "fans-friendly" model is targeted specifically to TV viewers. Web visitors who may have just wandered by might feel like they're missing out on something or a bit disoriented. "Hello" model Web sites are geared toward those with no knowledge of the station's programming.

ABC's eTV Web site could fit the "fans-friendly" model. It offers little information regarding the station's nonenhanced television programming, but offers direct links to upcoming interactive events. New users can register, and a tour button that promises to show how users can interact with their favorite programs is prominently displayed.

Single-Screen Systems

CBS was one of the first networks to bring single-screen interactive content to prime time shows. Viewers of *C.S.I.* (*Crime Scene Investigation*) with either MSN TV or Ultimate TV boxes can view case files, visit the crime lab, see short bios on the characters, and even track clues to help solve the case. *Survivor Africa* lets viewers see the voting statistics, contestant bios, and information on game challenges and history.

Single-screen systems require the use of set-top-boxes or computers with decoder cards. The additional data are superimposed over the television signal, or in some cases, the program signal is reduced in size to make room for the other content. Single-screen two-way systems also allow users to access related Web pages without entering a URL. Through what is sometimes called TV or channel hyperlinking, viewers can be easily redirected to Web sites or be provided with additional on-screen information. The latest crop of multimedia PCs from Hewlett–Packard and Sony feature tuner cards, providing access to enhanced broadcasts without a set-top-box. Because of the limited size of television and video monitors, and the fact that interfaces share the screen with the program content, the design must be simple, yet aesthetically pleasing.

Wink. Wink users can shop and view additional sports, weather, and news information through cable networks including Discovery, TLC, TechTV, The Weather Channel, ESPN, CNN, CNN Headline News, ABC, NBC, CNBC, FOX, CNBC, TBS Superstation, TNT, USA Network, and E! Entertainment. To use Wink, viewers first must register their credit card and profile into the system. Wink transmits its data using the VBI. Because of the limited amount of room available in the VBI, Wink's pop-up displays tend to be simple and straightforward. When viewers see the Wink logo on their screen, they can click their remotes to display on-screen information and interactive content. Wink TV reaches more than five millions homes and is available on DirectTV and a number of cable systems including Comcast, AT&T, Charter, Time Warner, Rogers, and Adelphia. For two samples of Wink screenshots, see Figure 2.

Types of Relationships

The types of relationships viewers have with enhanced television content can be categorized into four areas (Hurst, 2000): fan-based, game-based, information-based, and programming-based. Fan-based relationships focus on the viewers' desire to get closer to the star. Game-based enhanced content tries to recreate the fun and excitement

Figure 2: Wink screenshots from http://www.wink.ocm. Copyright by Wink Communications. Reprinted with permission.

of the particular game. For instance, viewers can play along with *Jeopardy* or *Who Wants to be a Millionaire?* ABC's enhanced TV Web site gives sports fans the ability to assemble their own fantasy teams and call plays during the televised games. Information-based refers to the viewers' need for extended content, often in the areas of news, weather, and sports. Programming-based interactivity delivers programs customized for the viewer's personal tastes. This is achieved through personalized custom channel selections and personal video recorders, allowing the user to record programming so that they can play it back whenever they desire, without commercial interruption.

MODELS OF ENHANCED TV

In order to implement enhanced TV, a basic system with certain components must be in place: an interactive TV software application, a means of introducing additional content into the application, and a method of delivering content to eTV-enabled receivers or set-top devices. The following are operational models of a few of the more common types of enhanced TV systems, along with the basic system requirements.

System Design

Methods of Propagation

Because program metadata can be packaged within the vertical blanking interval, one-way, interactive enhanced content can be delivered to the viewer in digital or analog form through cable, terrestrial on-air broadcast, the Internet, and satellite. The return channel can use any form of Internet connectivity including cable, DSL, telephone service, and even satellite uplinking.

Terrestrial

Broadcasters in the United States are in the process of upgrading to DTV transmission. The new digital standards will allow for increased resolution, HDTV, and expanded data transmission content. At first glance, terrestrial-based digital broadcasting's main obstacle is the obvious lack of a return channel. Although this doesn't affect one-way enhanced analog or digital broadcasts, it presents an impediment to two-way interactivity. Still, terrestrial broadcasters have a few options. Alternative return channels can be routed through Telco/IP systems, as demonstrated by the satellite industry, as well as wireless return channels, providing the right equipment is in place.

After success with its digital terrestrial broadcasting standard, the European consortium DVB (see the following section Setting Future Standards: Development Communities) has been working to establish a wireless return channel. This new standard has been outlined by DVB-RCT (Digital Video Broadcast Return Channel Terrestrial), which provides a return channel for DVB-T (Faria, 2002).

Satellite

In the mid 1990s, satellite digital broadcast systems (DBS) first became available to the public. At the time of this chapter (December 2002), DirecTV and DISH Network are the largest digital satellite providers with nearly 20 million installed systems. Their digital systems provide one-way digital interactivity and two-way interactivity employed through land-based return channels. If a customer orders a pay-per-view (PPV) through DISH Network, the set-top-box (STB) uses the telephone line to bill the user's account. Hughes Network Systems developed a system allowing users to download data from a satellite and upload over a telephone modem. Their newer development, DirecPC, is a two-way system allowing downloading and uploading from a satellite. Starband is another company offering bidirectional satellite networking.

Cable

The Cable Act of 1984 helped deregulate the industry and gave a strong boost to cable growth. The 1990s saw many cable companies upgrading their systems to two-way digital networks, capable of supporting a wide range of services. According to the National Cable and Telecommunications Association (NCTA, n.d.), in 2001 digital cable service and cable modems were available to more than 65 million homes. Digital cable households can receive standard cable, digital cable, telecommunications services, and high-speed Internet access. Internet users tired of slow dial-up connections have increasingly turned to digital cable for its "always on" broadband Internet service. The scope of two-way interactivity varies with the cable distributor as well as the geographic location.

Telco/IP Systems

In addition to terrestrial, cable, and satellite, IP systems are a viable means to bring television into a household and provide users a means to receive interactive content. While telephone companies have a long history of providing Internet connectivity through dial-up connections, they have only recently begun to offer broadband service at rates comparable to cable. IP television providers across the globe have been experimenting with delivering programs and other full motion video. Broadband IP networks have been designed from the ground up to support two-way communication and potentially offer a higher degree of interactivity. This two-way communication can pose a problem in the flow of communication over such networks. When demand is high, the whole network can slow down.

Setting Future Standards: Development Communities

There is a necessity for individuals, organizations, and industries with shared interests to form alliances. These can be viewed as communities in that they have organizational structure, establish self-imposed guidelines, provide a means of sharing information and interaction through forums, electronic newsletters, and conferences, and exist to protect the interests of their membership. The growth of interactive programming is particularly significant, as it affects an unprecedented wide range of industries. The careers and livelihoods of telephone technicians, software developers, computer companies, cable companies, video producers, and screenwriters will all be affected by the growth of interactive television.

Interactive digital broadcasters from around the globe participate in industry-led consortiums to ensure open standards and a means of sharing development information. These cross-industry alliances minimize investment risk and help create agreed-upon standards.

AFI

The American Film Institute serves film, television, and video artists and is dedicated to "preserving the art of the moving image" (http://www.afi.com). In 1998 The AFI began sponsoring a series of enhanced television workshops with the purpose of exploring the best ways of developing effective interactive programming compatible with the new and emerging technologies. Their ongoing workshops provide television producers a means to showcase their work and stimulate creation of working prototypes.

ITVT

Tracy Swedlow's InteractiveTV Today is a Web-based organization featuring a number of resources for iTV developers. ITVT's Web site, http://www.itvt.com, provides a newsletter, journal articles, an online glossary, and screenshots of a number of enhanced and interactive television examples.

ATVEF

The Advanced Television Enhancement Forum (ATVEF) seeks to create a unified pathway for interactive content developers ensuring widespread compatibility throughout cable, terrestrial, satellite, and local distribution networks, regardless of the distribution path. ATVEF's enhanced content specification outlines the infrastructure supporting one- and two-way interactivity. To minimize the need for developing new technologies, the ATVEF specification supports existing Web standards such as HTML, CSS, and JavaScript. The specification also allows the sharing of data between digital and analog systems, as well as networks with no video at all (ATVEF, 2002). In order to work with varying video networks standards, the ATVEF specification requires IP bindings developed for each protocol. Content specifications provide a means to incorporate HTML and TV content. The organization offers membership and news and provides technical documents from their Web site at http://www.atvef.com.

ATSC

The Advanced Television Systems Committee was formed in 1982 as a not-for-profit, cross industry organization seeking to develop voluntary standards (ATSC, n.d.). The FCC has worked closely with the organization and adopted ATSC-developed standards for the changeover to digital transmission, which is taking place across the country. Their DTV standard has also been adopted in Canada.

SMPTE

The Society of Motion Picture and Television Engineers (SMPTE) is the leading technical society of the film and video industry. Formed in 1916, SMPTE functions to establish industry standards, enhance education through seminars, communicate the latest developments in technology, and promote networking and interaction (SMPTE, 2002). SMPTE has recently created a new standard, SMPTE DDE-1, a compliant version of ATVEF 1.1r26.

DVB

Mainly composed of members from the European television, broadcast, and data industries, Digital Video Broadcasting (DVB) is an industry-led consortium focused on developing global standards for digital television and broadcast (DVB, 2002). Through various working groups, DVB facilitates the development of open standards and widespread interoperability and has already successfully implemented a series of technical standards for digital broadcast. The DVB-MHP (multimedia home platform) standard defines a layer allowing third-party applications to interface with a variety of decoding devices including STBs, integrated TV sets, and multimedia PCs (Jones, 2002). The DVB-MHP (multimedia home platform) begun in 1997 has been adopted by ETSI, the European Telecommunications Standards Institute. The DVD-MHP version 1.0.1 specifies Java as the application environment for both enhanced and interactive broadcasts and has recently been adopted by a U.S. company, CableLabs. The set-top-box manufacturer will begin selling units following the DVB-MHP specification.

Middleware

Middleware is software and hardware that helps applications work together. In the case of enhanced TV, companies like OpenTV, Liberate, and Microsoft TV create systems that support the set-top-box applications, ensuring they interface with the data systems back at the point of origination. Middleware typically provides subscriber definitions, channel assignments, packages and pricing, video asset and metadata management, and transactions and billing interfaces (Hawley, 2002). Middleware providers develop the software and interfaces that allow users to select programming and products, connect to the Internet, and make secure transactions. Current ATVEF standards support program development through a number of third parties using readily available Web development tools.

Other companies create software that users interface with through using their remote controls and set-top-boxes. Examples include the Wink interface, an interactive program guide (IPG), or the video-on-demand (VOD) interface. With ACTV's HyperTV, content creators can develop synchronized Web sites to add interactivity to programs or advertising materials targeting viewers with compatible single-screen decoding devices. HyperTV has been used to develop material for TBS, MTV2, TNT, TV Land, and Starz/Encore. The Disney Company is another interactive developer, which developed the Internet-enhanced broadcasts of ABC's *Monday Night Football*, *Who Wants to be a Millionaire?*, and ESPN's *Sunday Night Football* (Rudnick, 2000).

Set-Top-Boxes (STB)

The set-top-box is a small computer that runs software allowing users to interact with their distribution networks. It receives and decodes signals and displays them on the television monitor. STBs for one-way systems can access embedded information and superimpose it on the TV screen. Two-way systems send information back to the broadcaster. As mentioned previously, computers with the right configurations can perform the functions of a set-top-box. Digital cable STBs contain a cable modem, and can send information back to the head-end through the cable distribution network.

Satellite networks use specialized set-top-boxes that incorporate an integrated receiver decoder (IRD). IRDs receive and descramble satellite signals. Most installed satellite set-top-boxes for both analog and digital systems require a connection to a telephone line, which serves as a return channel. Users' responses to polls, interactivity with game shows, or catalog purchases are sent back through the return channel to the source of origination. The STB keeps track of PPV movies or VOD, and then transmits the information back to the satellite distributor in order to process billing information. Some nonsatellite systems, such as MSN TV (formerly WebTV), employ the same technique, using a phone line as the means to send return data. Some of the next generation of STBs will likely be able to use alternate means of sending return data through a LAN or other Internet connection.

Cable distribution companies tend to provide STBs to subscribers at no initial cost, subsidizing the expense through monthly service fees. The choice of STBs is usually limited to assure compatibility and to keep costs down. Digital satellite providers tend to sell STB/IRDs separately, offering a range of choices.

Personal Video Recorders (PVRs)

Some set-top-boxes act as personal video recorders capable of recording, time-shifting, and playing back broadcasts. TiVo and ReplayTV are popular stand-alone STB personal video recorders. DirecTV viewers can use Microsoft's UltimateTV set-top-box, which provides PVR functions. The units contain tuners and large hard drives, some capable of holding several days' worth of programming. They are capable of not only recording and playing back, but in time shifting programming. For example, you could set one to record a three-hour game and then start watching the game an hour after it started. As illustrated by stringent copy-protection schemes on videos and DVDs and recent legal action shutting down NAPSTER's streaming audio Web site, a certain stigma associated with digital recording exists. Many in the broadcast industry are fiercely opposed to the notion of PVRs, equating their use as stealing. Similarly, they also oppose features such as ReplayTV's commercial skip function. This hasn't prevented the sales of PVRs, and satellite companies appear to be encouraging their use. Half of the STB/IRDs on DISH Network's Web site contained integrated PVRs (DISH Network, 2002). Perhaps it dawned on satellite companies that it provides a way to sell more of their own programming. While PVR manufacturers are being taken to court, Nielson Media Research has signed an agreement to begin tracking their use.

Spam Television

There are dangers to PVR users. In what was labeled a marketing experiment in the UK, BBC and TiVo programmed PVRs to record the TV show *Dossa and Joe*. Viewers were not able to delete the program for a week and the action generated hundreds of complaints. In the United States, TiVo PVRs automatically recorded promos for a Sheryl Crow album and advertisements for Best Buy. TiVo characterized their action as an innovative way for broadcasters to deliver content to their machines and even promised that viewers could expect more in the future.

IMPACT OF ENHANCED TELEVISION

Impact on Broadcasters

Enhancing TV shows with interactive content is a major undertaking for content producers. Regardless of their feelings for the Internet, broadcast and cable networks along with the larger broadcast stations cannot ignore the necessity of providing Web content corresponding to their programming. Every major network is pursuing some form of two-way enhanced television. Development is expensive and time-consuming. It can take nearly six weeks to develop the interactive content for an episode of *C.S.I.* (Pinsker, 2001). Developers must work closely with the show's producers while ensuring they adhere to the technical constraints of the particular platform they are developing for. Content must be compatible with a wide range of STBs and middleware architecture to reach the largest audience possible. Traditional teams involved in the various stages of production must reorganize and learn new skills in order to create interactive content. Broadcasters developing interactive content using Wink must receive specialized training and certification to use the proprietary development tools. On the whole, broadcasters are in the process of investing billions of dollars into new technologies.

Programming

How is programming affected? Ideally, interactive content is not appended as an afterthought, but carefully integrated into the design of the program. Content creation must be rethought from the ground up and addressed in the early phases of production. Broadcasters are faced with the challenge of developing enhanced content for a wide range of programming including news, sports, and episodic and entertainment programming. TV producers are looking for innovative ways to enhance both new and old programming. At the American Film Institute eTV Workshop, production teams demonstrated enhanced versions of *I Love Lucy*, *Sesame Street*, and *P.O.V*.

According to the BBC, the information needs to be obviously beneficial and relevant. Viewers respond more frequently when alerted that interactive content is available. The information should be in small doses and straightforward (BBC, 2002).

Usage of Enhanced Television

Content providers used to be broken down into broadcast networks, broadcast stations, and cable networks. With the rise of multicasting cable and satellite, this distinction has become somewhat blurred.

Broadcast TV Networks

All of the broadcast networks (ABC, CBS, NBC, PBS, and FOX) provide some degree of enhanced programming

Table 1 FCC Licensed Broadcast Stations—December 2001

UHF	Commercial TV	740
VHF	Commercial TV	576
UHF	Educational TV	254
VHF	Educational TV	125
Total		1,695

From *Broadcast station totals* by FCC (retrieved December 12, 2002, from http://www.fcc.gov/mb/audio/totals/bt011231.html). Copyright 2001 by the Federal Communications Commission. Reprinted with permission.

through either single- or dual-screen applications. It has come to be generally accepted that broadcasters who ignore new distribution opportunities such as enhanced television are likely to lose audience members.

Broadcast TV Stations

According to FCC (2001) as of December 31, 2001, there were 1,695 terrestrial television broadcasters in the United States, consisting of commercial and educational UHF and VHF stations (see Table 1). While enhanced television can take place over existing analog transmission towers through the VBI, digital broadcasting's increased bandwidth opens up a realm of additional data opportunities. As of November 2002, 354 stations were broadcasting digitally in the United States.

Cable TV Networks

Cable networks are uniquely positioned to take advantage of cable's existing infrastructure and, since the debut of Qube, have been at the forefront of exploring interactive programming and applications. CNN, TV Land, The Food Network, Turner Classic Movies, and the USA Network have been early adopters of developing and delivering enhanced programming. The FCC's Ninth Annual Report on Competition in Video Markets, released December 31, 2002 (FCC, 2002), reported that as of June 2002, multichannel video program distributors were reaching nearly 69 million households through cable.

Satellite TV Providers

The FCC's Ninth Annual Report also showed that direct broadcast satellite service grew quicker than cable from nearly 16 million households in June 2001 to approximately 18 million households in June 2002. This figure represents more than 20% of all the multichannel video program distributor subscribers. Major satellite providers include DISH Network and DirecTV. As illustrated by DirecTV's channel lineup, a growing number are offering eTV programming (see Table 2).

Impact on Users

The widespread growth of enhanced and interactive television along with its established acceptance in the UK is a testament to the fact that viewers use and enjoy the new features. Ideally, interactive television provides the best that both television and the Internet offer, combined into an integrated, interactive experience. As demonstrated by WebTV, set-top-boxes can effectively combine the two media and even provide users a way to save money by purchasing only one device.

Table 2 DirecTV's Listing of Stations Offering Enhanced Television

Network	Channel	Availability
Bloomberg Television	353	All day
CBS	Varies	Select programming
CNBC	355	All day
CNN	202	All day
Discovery Channel	278	Select programming

Personalized TV Experience

One of the promises of eTV is a truly personalized television experience. Using electronic program guides and personal video recorders, viewers can customize the programming they receive, deciding what to watch and when to watch it. With PVRs much of the enhanced content is available for later use, as the information is embedded into a portion of the video signal.

Privacy

While viewers interact with enhanced TV programs, middleware and STB application developers are quietly recording what they watch. For advertisers it provides a wealth of personalized data and a means to deliver targeted, personalized advertising (Chester, Goldman, Larson, & Banisar, 2001). Well within the capabilities of existing eTV system architecture, data profiling systems can record what is being watched and what Web sites are visited along with the time of day and duration. It is chilling to some to consider that marketing agencies can collect personalized data on viewers who are doing nothing more than watching TV.

IMPACT ON E-COMMERCE

Before the dawn of cable, satellite, and the Internet, there was broadcast television. Early business models of broadcasting were simple, centered on advertising revenues. Stations gave programming to the public for free, while charging sponsors for advertising. The greater the number of viewers, the more they could charge the advertisers. Fifty years later, new technologies have lured viewer's eyeballs to other media. Today, traditional broadcasting is just one player in a cacophony of content providers, competing with cable networks, pay-per-view, video-on-demand, superstations, video rentals, satellite distribution, gaming computers, and the Internet, all vying for the viewers' attentions. If viewers could trace the signal path from the source to their TV sets, they would be surprised at the number of unseen entities, including distribution networks, middleware providers, and STB application developers involved in delivering their programming and supporting the interactive exchange of information. These entities are indirectly funded through the viewer's consumer and media purchases, and subscription fees. Sorting out the stakeholders and tallying the comparative rate structures is a complex task, and return on future investment is in good part based of speculation. One thing is clear: the historic broadcast model supported by advertising revenue is woefully ill suited for enhanced television.

Investment in emerging and untested technologies requires an enormous amount of capital and a great deal of faith. Millions of dollars have been invested into software and hardware to support enhanced and interactive television. Stakeholders can be broadly categorized into content creators, broadcasters, distribution networks, and infrastructure developers. Each sector has its own customers, its own means of generating revenue, and concerns over the economic viability of enhanced television.

Business Models

While traditional broadcast and Internet models still have some relevance, the new technologies coupled with current economic conditions have forced investors to take a hard look at the prospects of interactive television. There are four business models that can be applied to interactive television (CRTC, 2002): advertising, pay-per-use, subscription, and t-commerce.

Advertising

While television broadcasters acknowledge that they may lose viewers by exposing their audience to other forms of electronic media, for most, the potential benefits and promise of interactive advertising outweigh any concerns. Similarly, concerns of viewers zapping commercials with personal video recorders are minimized by the numerous possibilities of alternate and contextual ad placement in interactive programming. Banner-type ads can be placed in EPGs, a central and frequently visited location in the viewer's personalized TV experience. Clicking on the ad could draw the viewer to the sponsor's Internet site or to a "walled garden." Walled gardens are a series of Web pages contextually related to the jumping-off point. They let viewers explore additional information and purchase products and services. Another advertising opportunity so readily used by Wink is the on-screen icon, which signals the viewers that additional information is available. Clicking on the appropriate button on the viewer's remote provides additional on-screen information on the product. If there is Internet connectivity the user could visit a dedicated advertising location (DAL) to make purchases or explore an accompanying walled garden.

Pay per Use (PPU)

Video-on-demand and pay-per-view movies and events are well-established examples of the pay-per-use model. Lesser known but gaining attention is the area of pay-per-play. The well-established video rental business provides a ripe market for potential PPU customers. As consumers become accustomed to the ease of purchasing movies and games through their set-top-boxes, satellite and cable distributors are likely to see their PPU revenues soar. Using alternate distribution networks to purchase video-on-demand, games, and other programs could result in a decline in the video rental business from $11 billion in 2000 to $5.9 billion in 2010 (Renaud, 2002).

Pay per Play

PC gamers have been participating in network battles for years, recently joined by X-Box and Playstation users. Digital broadcasters are just catching on that there is a growing market of fun-seeking users who enjoy the interactive features that iTV provides. Similar to VOD and PPV, pay per play lets users buy whenever the impulse strikes. Sky Active's customers can access pay-per-play games with a few clicks on the remote. Users can participate in betting and sports games and play versions of *Space Invaders* and *Who Wants to Be a Millionaire?*. Two Way TV, an iTV developer, has even announced an adult play-per-play application called *Sex Games*.

Subscription

Users of broadband, cable, satellite, and any other distribution service pay periodic subscription fees. In most broadcast distribution systems, the payment interval is monthly, but daily and weekly time periods may also be used. Other subscription fees can include cost of auxiliary services and program packages, along with hardware such as cable modems and decoding equipment. An advantage of the subscription model is that distributors are not directly dependent upon advertising revenue.

T-commerce

Purchasing goods or making financial transactions through interactive television services is known as t-commerce. While viewers can order products, food, and even place bets, middleware and application companies are tracking the traffic. As C. J. Fredrickson, Director of ATVEF, states

> By tracking local consumer "remote click" activity, local operators/affiliates would have the ability to sell information to advertisers and national programmers, such as demographic data based on actual consumer activity. By accumulating this data, local operators would have a new revenue source providing more specific and immediate information on consumer television habits and activity than has ever been available. (Fredrickson, 1999)

Internet Models

Internet TV should lead to greater efficiencies in five areas (Waterman, 2001): (1) reduced delivery costs and capacity constraints, (2) more efficient interactivity, (3) more efficient advertising and sponsorship, (4) more efficient direct pricing and bundling, and (5) lower costs of copying and sharing. While his study focused solely on Internet propagated television, points (2), (3), and (4) should resonate with enhanced television proponents, especially considering that the Internet is quickly becoming an established provider of television content. A key idea behind enhanced TV is the concept of interactivity, providing opportunities for highly targeted television advertising and sponsorship. The Internet can cater to specialized niche markets providing advertisers with extremely focused sponsorship opportunities. Would a marine supply company rather purchase advertising on a cable network seen by millions or a boating webcasting site seen by thousands? Just as cable and satellite distributors can provide bundles of program packages, the Internet offers equally, if not more customizable options.

CONCLUSION

Navigating through the ever-changing and broadening network of interactive programming has been initially confusing for both the industry and consumers. While some U.S. companies have scaled back, most are moving ahead with plans to develop and/or expand their enhanced television services, and overseas the use of interactive TV services is going strong. European communities have been leading the world in delivering interactive television content and advertising. Researchers have projected that by 2005, TVs will surpass PCs in e-commerce revenues (E-Commerce Times, 2000). In November 2002, AOL launched its first interactive TV service on Sky Active in Europe, bringing instant messaging, e-mail, news, weather, and sports to more than 6 million homes. Research data optimistically suggests that enhanced TV will continue to grow and gain acceptability among consumers in the United States, reaching 65 million users by 2006 (Bird, 2002).

Little is understood at this time of the impact that the changeover to digital broadcasting will have on the growth of enhanced television. According to the FCC, by 2006 TV stations should relinquish the analog spectrum, broadcasting only in digital. Considering digital broadcasts as a string of bits, broadcasters must decide how to most effectively use their limited resources and allotted bandwidth. Expanded enhanced features and television content will likely be vying for the same bandwidth required by HDTV. While the industry stumbles with implementing the changeover and consumers balk at the high price of DTV equipment, the low cost and existing infrastructure of enhanced TV could easily fuel acceptance. Considering the widespread acceptance of iTV in the UK and the wealth of opportunities that convergent media offer to advertisers and consumers through interactive content, it appears likely that enhanced TV will make strong inroads in the near future.

GLOSSARY

Advanced Television Enhancement Forum (ATVEF) A not-for-profit coalition establishing industry standard protocols for enhanced programming.

Back channel (a.k.a. return channel) The physical path that the return signal can take from the set-top-box back to the broadcaster through which interactive TV users can transmit information back to the point of origination.

Bandwidth The amount of data that can be sent through a signal path.

DTV (digital TV) A system of transmitting and receiving digital television.

DVB (Digital Video Broadcast Forum) An organization seeking to establish technical standards for digital television and responsible for DVB-RCC (digital video broadcasting return channel through cable) and DVB-RCT (digital video broadcasting return channel through terrestrial).

Integrated receiver/decoder (IRD) Used to decode signals downloaded from satellite receivers.

Interactive program guide (IPG) An electronic display that can be customized to list available and favorite channels, program names, and program descriptions.

Interactive television (iTV) An umbrella term referring to a range of interactive television services.

IP (Internet protocol) A means of sending packets of information over Internet networks.

MPEG-2 (Moving Picture Experts Group) A version of the MPEG video file format used to deliver digital video.

Megahertz (MHz) A measure of frequency equal to one million cycles per second.

Metadata In the digital television context, data about the programming, such as start and stop times, titles, and information on the upcoming show.

Pay per view (PPV) A service available through cable and satellite distributors that allows viewers to purchase programs, such as movies or sporting events.

Personal video recorder (PVR) A device that allows the user to record, store, and playback video such as television broadcasts from a hard drive.

Set-top-box (STB) A device used with televisions allowing users access to enhanced and sometimes proprietary features such as digital channels, video-on-demand, and Internet access.

T-commerce Monetary transactions made over the television.

Vertical blanking interval (VBI) The time it takes for the electron beam to jump from the bottom of a frame to the top of the next. This invisible portion of the television signal can be used to carry data such as teletext, closed captioning, and even HTML documents for set-top-boxes.

Video-on-demand (VOD) A service that uses server technology to allow users to purchase and watch programs of their choice.

Enterprise Resource Planning (ERP)

Zinovy Radovilsky, *California State University, Hayward*

INTRODUCTION TO ERP

Definition of ERP

Few recently introduced software applications have had such a profound impact on business as enterprise resource planning (ERP). ERP systems experienced significant growth in sales in the last decade of the 20th century. From 1990 to 2000, the ERP sales have grown from $1 billion to almost $30 billion. In 2004 the enterprise applications market will reach, according to some forecasts (AMR Research Center—Press Center [AMR], 2000), $78 billion. ERP systems will continue to be one of the largest, fastest-growing, and most influential players in the IT field well into the new millennium.

Enterprise Resource Planning (ERP) is defined as an integrated computer-based system that manages internal and external organization resources. These resources include tangible assets, financial resources, materials, and human resources. At the same time, ERP is an application and software architecture that facilitates information flows between various business functions inside and outside an organization and, as such, is an enterprise-wide information system. Using a centralized database and operating on a common computing platform, ERP consolidates all business operations into a uniform system environment.

The word “enterprise” in the ERP name represents the fact that this system integrates and automates processes within an entire organization regardless of the organization’s nature. In fact, ERP systems have been implemented in manufacturing, distribution, transportation, education, healthcare, banking, and other industries. The word “resource” in the ERP name reflects the system’s intention to rationalize the usage of an organization’s resources. Finally, the word “planning” describes one of the main functions of resource management, i.e., planning resources through a variety of business processes.

Introduced in the early 1990s, the term “ERP” does not reflect the real capabilities of the system it represents. First, ERP systems provide not only planning but also other management functions such as organizing, controlling, scheduling, reporting, and analyzing business processes. Second, a traditional approach to ERP considers it a “back-end” computerized system for managing the internal resources of an organization. However, the ERP has crossed the boundaries of being just a system for planning internal resources. It may often contain “front-end” applications of managing customers and improving customer satisfaction—customer relationship management (CRM); collaborating with suppliers through applications of supply chain management (SCM); and utilizing business-to-business (B2B) e-commerce. As such, this integrated system combines external (front-end) and internal (back-end) business applications and should be defined as an extended enterprise management system or extended ERP system (see Figure 1).

As the original term “ERP” does not fully describe existing integrated solutions, many ERP software vendors avoid using this term to represent their extended enterprise management systems. For example, these systems are called “Total Integrated Solutions,” “E-Business Platform,” “E-Business Suite,” etc. Regardless, the term “ERP” or “ERP system” continues to be the most popular term to describe a suite of integrated applications of an extended enterprise management system.

Brief History of ERP Evolution

ERP systems have more than a 30-year history of evolution. Understanding this evolution is important for comprehending current ERP systems and seeing perspectives of their future development. The idea of integrating and automating business processes utilizing computer programs was first introduced in the late 1960s–early 1970s with the development of *material requirements planning (MRP).* This coincided with the time when manufacturing companies started to extensively employ computers, specifically mainframes and minicomputers, in business and management decisions. MRP is an integrated computer-based system for calculating material and delivery schedules. It combines inventory management, materials planning, capacity planning, purchasing,

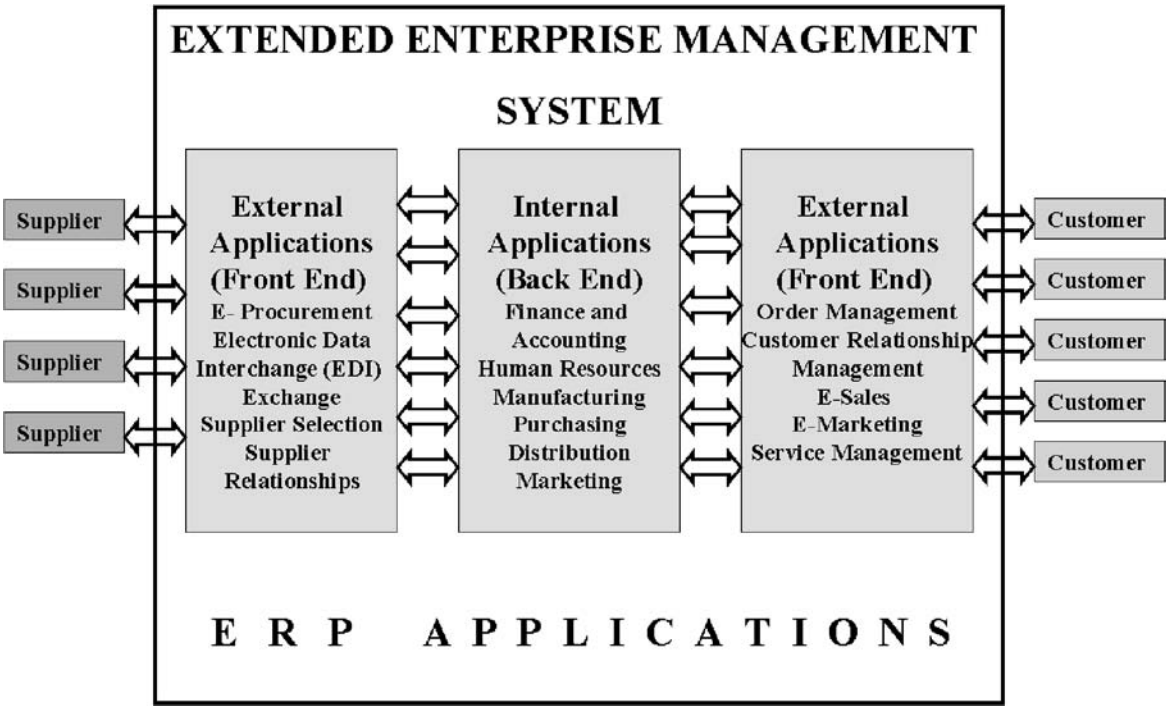

Figure 1: General ERP structure.

and distribution. Later MRP systems also generated purchase orders to suppliers and work schedules for internal production.

The next major step in the evolution of ERP was the development in the early to mid-1980s of a new breed of integrated systems: *manufacturing resource planning (MRP II).* This system fully integrated materials and capacity planning with distribution planning, sale ordering, marketing, finance/accounting, and human resources. Besides planning material and capacity resources, MRP II integrated inventory with financial/accounting transactions, sales orders with materials planning and accounting/finance transactions, marketing and sales analysis with demand forecasting, etc. All inputs and outputs, analysis, and reporting were based on one centralized database system. MRP II was very popular and widely utilized by a variety of large and midsize companies that employed predominately mainframe and minicomputer technology.

Modern ERP systems were established in the early 1990s. This coincided with the proliferation of personal computers, which replaced the old mainframe capabilities with the new client-server technology. Considered as an advanced MRP II system, modern ERP has several major differences from MRPII systems: utilization of the client-server technology and its ability to run on personal computers (clients) and powerful servers utilizing multiple operating platforms (Unix, NT, etc.); advent of ERP into nonmanufacturing companies ("enterprise" rather than "manufacturing" resource planning); and integration of MRP II applications with new business processes like supply chain management and customer relationship management. In the mid- and late 1990s, a large number of companies converted their existing computer systems to ERP due to the Y2K problem. Rather than spending a substantial amount of money on fixing this problem in the existing systems, companies preferred to implement modern ERP systems that were Y2K compliant.

The latest evolution of ERP systems started at the end of the 1990s with the introduction of Internet-enabled ERP systems. This introduction correlated again with major changes in IT systems that were signified by the Internet and e-commerce revolution. The new systems were characterized by Internet-enabled ERP architecture; new front-end e-commerce solutions; easy access to the system by employees, customers, and suppliers; collaborative planning and scheduling; and optimized operations, finance, and marketing decisions.

ERP and E-commerce

The majority of modern ERP systems are fully Internet-enabled systems. This means that communication between a server where an ERP system is installed and many clients (end-user PCs) is done through the Internet.

An ERP system may comprise three main tiers: clients, applications server, and database server (see Figure 2). Clients are end-users that connect to the system via Internet browsers. An applications server incorporates a Web server, forms, system tools, and a variety of ERP programs. A database server includes a relational database with ERP records. Some ERP systems have been developed with separate applications and Web servers, which would define them as four-tier systems (clients, Web server, applications server, and database server).

ERP systems are considered to be a backbone of e-commerce solutions. Successful utilization of the "front-end" e-commerce solutions is unimaginable without

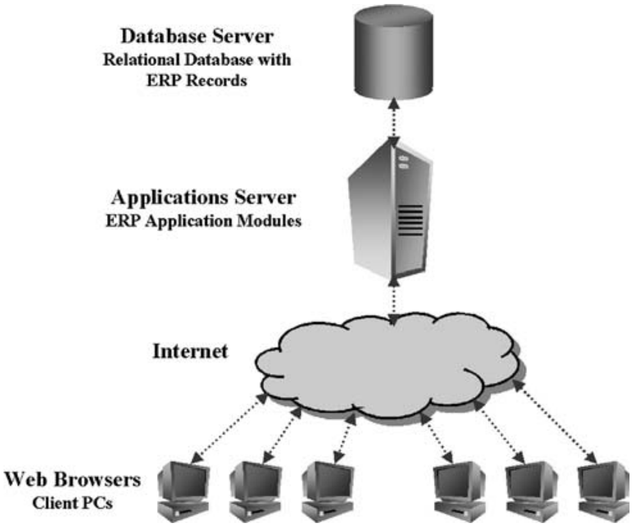

Figure 2: Typical architecture of Internet-enabled ERP systems.

strong support by and cooperation with the internal "back-end" computer systems. In fact, many ERP vendors combine ERP applications and e-commerce solutions in one integrated computer system.

PRINCIPLES, FEATURES, AND APPLICATIONS OF ERP

Main ERP Principles

In many respects, ERP is a result of modern organizations' efforts in designing management information systems. Various processes of an organization have to be linked together so that whenever a change in an external or internal process takes place, the company is able to adjust all other related processes immediately and effectively. ERP systems enable this to happen, not only at the information systems level but also at the applications level, by utilizing certain principles and features. The two main ERP principles are integration and automation.

ERP integration is based upon these items:

- A single database system operating on a common computing platform. All ERP applications would input data and retrieve information from the same database and all employees would have the same point of access to get necessary information
- An integrated set of commonly designed business applications including manufacturing, distribution, marketing, accounting, finance, and human resources. This set consolidates all business processes into a uniform system environment
- Integration between internal company applications and external applications for accessing customers and suppliers.

ERP automation represents the ability of an ERP system to automatically process business transactions and information between different processes and functions inside an organization, as well as between this organization and its customers and suppliers. The elements of ERP automation are as follows:

- Automated business transactions. For example, these can include calculation of production and material schedules, demand forecasts, inventory levels, and production costs.
- Automatic information sharing between numerous organization functions. Data created in one application become available to other related applications. For example, a new employee input made in a human resources module may be available in other applications like purchasing and marketing, which utilize this employee information.
- Automated recording, monitoring, and reporting of the data generated in ERP.

ERP Features

One of the most important ERP features is that it is a *process-driven system*. In contrast to individual and function-driven computer applications in marketing, finance, or operations, an ERP system integrates these functions into a variety of computer-based processes. They represent real business processes that companies apply to managing resources, working with customers and suppliers, etc. In general, an ERP system may include a variety of business processes such as

- order fulfillment
- production planning and scheduling
- capacity planning
- outsourcing materials from suppliers (purchasing)
- shipping products to the customers
- product costing, payments, and receipts
- managing customers
- selecting and managing suppliers.

Some of these processes are interrelated and dependent on one another (see Figure 3). Integrating these business processes into a company's ERP system provides the necessary environment for running the company in real time with all functions being interoperable in the system.

Other features of ERP systems include

- A *relational database* that integrates all data inputs, transactions, and outputs of ERP systems. This can substantially reduce or even eliminate inaccuracy and inconsistency of records that might have existed in separate individual databases. The Oracle database is the most popular relational database used in ERP systems.
- *Company-wide access to information* from a relational database. Transactions that are taking place in each ERP-driven business process may be visible, in principle, to anyone in an organization. In practice, however, the level of an employee's visibility of and access to ERP processes depends on the employee's role (responsibilities) in the company.
- *Multiple simultaneous accesses* to the ERP system by many users and in various locations. This feature may

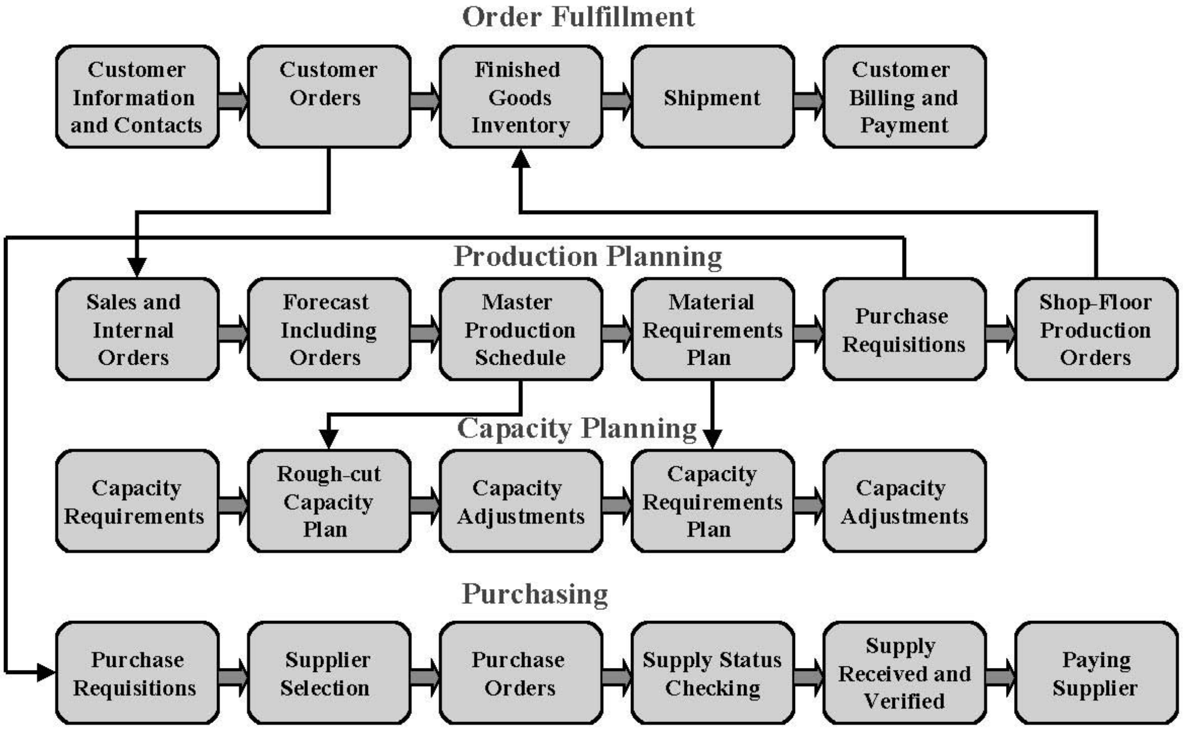

Figure 3: ERP processes and their integration.

be used by a company that has multiple domestic and international locations/divisions and wants to integrate all business functions into one computer system. This feature also enables fast and reliable information sharing between different parts of the company.

- *Scalability*, which means that an ERP system provides adequate capabilities in the situation where the total number of users of the system is growing. This may be due to the company's expansion or to its merger with or acquisition of another company. A scalable ERP system should also accommodate a growing number of users and applications without jeopardizing the speed of transactions or the performance of the entire system.
- *Internet-based architecture* of ERP systems. From a technical standpoint, ERP systems should be flexible enough to run on *various implementation platforms* and operating systems, like Unix, Linux, and NT.

ERP Applications and Their Integration

ERP integrates a great variety of business applications. Their titles, components, and capabilities may vary between different ERP software packages. However, traditionally, an ERP system is composed of *manufacturing and distribution*, *financial, human resource management (HRM),* and *marketing and sales* groups of applications. In addition, an extended ERP system may include *supply chain management (SCM)* and *customer relationship management (CRM)* groups of applications. In many modern systems, the *manufacturing and distribution* applications are tightly associated with, and sometimes become inseparable from, the SCM applications. Thus, they may be considered as one combined ERP group. The same is true for the *marketing, sales, and CRM* group.

Within each group, ERP applications may be clustered into three main categories. The first category—*core applications*—is composed of traditional "back-end" business applications existing in current and old versions of the ERP software. The second category—*applications enhancements*—is a set of additional applications that are used to analyze, improve, and optimize business decisions and processes in each ERP group. The third category—*e-commerce solutions*—is composed of various applications of B2B e-commerce. These groups and categories of ERP applications are presented in Table 1.

The SCM group of applications is associated with planning and scheduling material and information flows from suppliers to a manufacturing/service organization; scheduling, executing, monitoring, and reporting production plans in this organization; and distributing final products to the customers. The applications' enhancements in the SCM group include *manufacturing* and *supply chain intelligence* applications that provide a variety of analyses and data reports on purchasing, supplier scheduling and supplier performance, production results, distribution schedules, and other functions. Besides, this category contains applications of *advanced planning and scheduling (APS)* that enable to create optimized production schedules, taking into account material and capacity constraints. Also, the SCM group integrates a number of B2B e-commerce applications including

- *e-procurement,* which provides capabilities for outsourcing material, labor, and other resources online (online purchasing)

Table 1 Major Groups of ERP Applications

Groups of Applications	Applications' Categories		
	Core Applications	**Applications Enhancements**	**E-commerce Applications**
SCM Group: Manufacturing, Distribution, Supply Chain Management	Inventory Supply Chain Planning Materials Requirements Planning Capacity Requirements Planning Shop Floor Management Warehouse Management Purchasing Quality Management Product Development Management	Manufacturing Intelligence (Analytics) Advanced Planning and Scheduling Supply Chain Intelligence (Analytics) Supplier Relationship Management	E-procurement E-supplier Portals Private Exchange Online Auction Collaborative Commerce (C-commerce) E-design Mobile Supply Chain Commerce
Financials Group: Accounting, Finance	General Ledger Accounts Receivable Accounts Payable Asset Management Cash Management Activity Based Costing Budgeting Property Management Treasury Management	Financial Intelligence (Analytics) Balance Scorecard	E-expenses E-receivables E-payment
HRM Group: Human Resource Management	Personnel Administration Payroll Employee Benefits and Compensations Time Management Training Administration	HR Intelligence (Analytics) Organizational Development	Self-Service Human Resources E-recruitment E-learning HR-centric Web Portal Information Collaboration Mobile Commerce
CRM Group: Marketing, Sales, Customer Relationship Management	Order Management Product Configurator Order Fulfillment Customer Management Service Management Marketing Sales Filed Customer Service	Marketing Intelligence (Analytics) Service Intelligence (Analytics) Advanced Demand Management Customer Interaction Center (Call Center)	E-marketing E-selling E-fulfillment E-service Mobile Sales

- *private exchange,* which is an electronic marketplace that invites suppliers and customers to do trading online
- *collaborative commerce (c-commerce),* which enables buyers and sellers to collaborate on demand forecasting and synchronize plans based on the dynamic exchange of information
- *mobile commerce (m-commerce),* which extends the supply chain management system to all the members of the network with wireless communications regardless of where they are.

Financials are another major group of ERP applications. They include core accounting and financial applications, as well as applications enhancements and e-commerce solutions (see Table 1). Financial intelligence applications are used to analyze and optimize market forecasts, credit risk of new contracts, cash flow and liquidity, financial portfolio, and market risk. Also, financial intelligence applications monitor and track financial performance and measure key financial indicators. The Financials group also contains several B2B e-commerce applications (see Table 1). For example, E-receivables (E-payment) is a secure online application that allows customers to review account information, pay bills, transfer funds, and dispute invoices online.

The HRM group of applications is composed of core applications, modern analytical tools (*HR intelligence/analytics*), and a variety of HRM e-commerce applications (see Table 1). Examples of HRM e-commerce applications are

- *self-service human resources,* which allow line managers and employees to update and use HR information through interfaces personalized to their roles

- *e-recruitment,* which is a set of comprehensive recruitment tools and services that are integrated with a network of recruitment service providers.

The CRM group of applications includes a set of core, enhancements, and e-commerce applications related to customer interactions with the company, managing customer demands, and improving customer satisfaction (see Table 1). Among e-commerce CRM solutions are

- *e-marketing,* which enables implementation and execution of personalized, real-time mass marketing over the Internet
- *e-selling,* which provides comprehensive capabilities for selling products and services over the Internet
- *e-service,* which offers customers and business partners online access to dedicated information such as product catalog and pricing solutions.

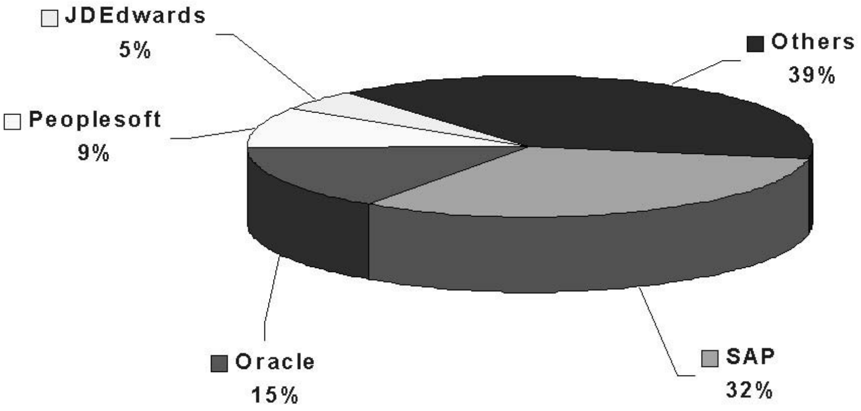
Major ERP Vendors

The number of software companies that develop ERP software runs in the hundreds. Many of these companies provide limited ERP functionality as market niche players; others focus on some vertical markets (industries). However, a relatively large segment of these companies provide comprehensive solutions to their customers. The largest and most popular ERP vendors are SAP, Oracle, and PeopleSoft. These three companies have around 56% of the global ERP market share (see Figure 4).

SAP (www.mysap.com) is the largest ERP vendor in the world (Top 100 Software Vendors, 2001). The most famous SAP system, SAP R/3, includes all common groups of the ERP applications. SAP is specifically popular with large manufacturing companies that run its manufacturing, distribution, and supply-chain applications. Realizing that its R/3 architecture could not meet the challenges of e-commerce in the late 1990s, SAP started implementing an Internet-based solution. For that, SAP launched its totally redesigned, Internet-based solution—mySAP.com. It is a broad undertaking by SAP to extend its back-office suite to the Web. This site is a single entry point for a range of front-end, back-end, and e-commerce ERP applications. The SAP software has been implemented in a variety of companies (predominately, large companies) including IBM, Hewlett–Packard, Philips, Siemens, Chevron, and many others.

Oracle Corporation (http://www.oracle.com) is the second largest ERP vendor. Oracle was the first company to offer a fully integrated, Internet-enabled suite of business applications—E-Business Suite. This system runs entirely on the Internet, supporting e-business across the SCM, Financial, Human Resources, and CRM groups. However, Oracle's Financials and Customer Relationship Management groups of applications are considered to be the company's most popular among the customers. Oracle's E-Business Suite, along with SAP, is also commonly used by large and mid-size manufacturing and service companies. These include Cisco, Sun Microsystems, Applied Materials, Visa International, Alcoa, Xerox, and many others.

PeopleSoft, Inc. (http://www.peoplesoft.com) is also one of the largest ERP vendors. Just like Oracle ERP, the latest version of the PeopleSoft ERP system is on the Internet and represents a full set of Web-based groups of applications. Both Oracle and PeopleSoft put every aspect of a client's business, from supply chain management to sales, on the Internet. However, PeopleSoft considers its ERP system to be the only pure HTML-based solution in the industry. PeopleSoft's applications do not require Java downloads (as Oracle does) to run the browser and are fully accessible from a host of mobile devices such as PDAs and cell phones. However, Oracle claims that Java is typically included in a Web browser and its E-Business Suite is accessible from mobile devices where it makes sense. PeopleSoft customers include a variety of business companies, universities, and government organizations.



Total Revenue, 2000

Source: AMR Research, 2001

Figure 4: Top ERP vendors.

Among the most famous PeopleSoft customers are 3Com Corporation, Sprint, Hewlett–Packard, Analog Devices, and British Telecom.

Besides SAP, Oracle, and PeopleSoft, there are many other quite popular ERP vendors including J.D. Edwards (http://www.jdedwards.com), Invensys Software Systems (http://www.invensys.com), and Siebel Systems (http://www.siebel.com).

ERP BENEFITS, ISSUES, AND APPLICATIONS SERVICE PROVIDERS

ERP Benefits

The rapid growth and proliferation of ERP systems in the past 10 years indicated the great importance of these systems to businesses. In general, the implementation of an ERP system should increase the reliability of a company's information; provide full access to this information at any point of time; automate a variety of tasks and processes in different organizational functions; improve forecasting, planning, scheduling, and reporting; and facilitate external collaboration with customers and suppliers. These improvements may lead to a shorter order-to-market time; lower inventory levels; more efficient and effective management of resources; and, as a result, major cost savings and increased return on investments (ROI). A publication at *CIO Magazine* (The ABCs of ERP, 2002) suggests that the median annual savings from a newly implemented ERP system are approximately $1.6 million.

A survey conducted by Mabert, Soni, and Venkataramanan (2001) showed that 70% of companies that implemented ERP felt that their systems have been successful or very successful. This survey also found that important improvements due to the ERP implementation are associated with (in a descending order of importance)

- quickened information response time and increased interaction across the enterprise
- reduced order cycle
- decreased financial close cycle
- improved interaction with customers
- improved on-time delivery
- improved interaction with suppliers
- lowered inventory levels
- improved cash management
- reduced direct operating costs.

The same survey also recognized that areas benefiting the most from ERP were availability and quality of information and integration of business operations/processes, as well as the three functional areas of inventory management, financial management, and supplier management and procurement.

ERP Issues

Despite the benefits, ERP systems still remain the most complicated, time-consuming, and costly computer-based systems. Implementation time and software cost depend on the company's size, number of implemented applications (modules), and level of planning and preparation of the implementation process.

A survey conducted by Mabert et al. (2001) showed that the ERP implementation time for a large or mid-size company could vary from 23 to 35 months, on the average. The average implementation cost for a large or mid-size company could be around $20 million, and smaller firms may spend up to $12 million (Willis, Willis-Brown, & McMillan, 2001; Mabert et al., 2001). A substantial portion of companies, while implementing ERP, had major cost overruns exceeding the original estimated budget by an average of 60% (Mabert et al., 2001).

Implementation is only one element of the total cost of ownership (TCO) of an ERP system. In general, TCO includes software license fees, hardware cost, installation and implementation fees (consulting, additional personnel, training, testing, etc.), cost of maintenance, and customer support. The average TCO of an ERP system could run up to $85 million, but for some large organizations could reach $400 million (The ABCs of ERP, 2002). According to one study (Cliffe, 1999), more than 65% of executives believed that ERP implementation had at least a moderate probability of hurting their companies. In several cases, documented in the literature sources, a long and inefficient implementation led to substantial drawbacks in the companies' performance, loss of sales and customers, and strained relationships with suppliers. Among numerous companies that experienced costly problems with their ERP implementations were W.L. Gore and Associates (with PeopleSoft) and Whirlpool, Hershey Foods, Allied Waste Industries, and Volkswagen (all with SAP).

Analysis of ERP implementation practices revealed the following major issues that companies need to deal with while implementing an ERP system:

- ERP is a complex and rather rigid system that may require a company to redesign its business processes. The top ERP systems are based on the best business practices, and a company must accept the assumptions inherent in those systems. This pushes the company toward generic processes established in ERP. Thus, the company needs to ensure that adopting generic processes does not sacrifice its production results, customer service, and competitive advantage.
- Successful ERP implementation is nearly impossible without thorough preparation and efficient management of the implementation process. These require strong executive commitment and involvement in the ERP implementation process from start to finish; an empowered implementation team that needs to define objectives, outcomes, and implementation strategy; clearly developed education and training strategies; and full communication of ERP plans to the company's employees.
- ERP systems require virtually a life-changing experience for everyone involved. A company that implements ERP and its employees need to overcome traditional conservatism in utilizing a previously unknown computer system, which has new input forms, output reports, functionality, etc. Thus, extensive and consistent training of

all involved employees becomes a critically important element of a successful ERP implementation.

ERP Solutions for Industries and Small-Size Companies

A top-ranked ERP system, being a time- and money-consuming system, may not be suitable for implementation in small and mid-size companies. Also, a standard ERP system, which is developed with generalized business processes and applications, may not be appropriate for certain industries. To address these issues, the leading ERP vendors provide a host of solutions that include

- customizing ERP systems for individual industries
- developing ERP solutions for small and mid-size companies
- lowering applications costs by selling individual modules
- providing hosting solutions using applications service providers (ASP).

For example, SAP established customized solutions for 21 different industries, among which are aerospace and defense, automotive, banking, chemical, consumer products, engineering and construction, financial services, and healthcare. Each industry-related ERP system contains industry-specific applications, for example, *profit management* and *risk management* applications for banks or *healthcare e-business applications* for the healthcare industry. Besides, an industry-related system may also include standardized ERP applications like accounting/finance, CRM, human resources, and others relevant to that industry.

Oracle has introduced, along with its well-known E-Business Suite, an integrated set of applications for small- and mid-size companies—Small Business Suite. This system consists of only a few ERP applications limited in capabilities, like *accounting, sales force automation, customer support management, employee expanses, time and billing, payroll, online bill payment, Web store,* and *customer care*. Due to the relatively small number of applications and their limited capabilities, the TCO of the Small Business Suite is lower than that of a general ERP system.

Another way of lowering TCO is to acquire a group of applications rather than the entire system. Analysis of ERP implementation showed that companies tend to utilize only a subset of the applications available in a standard ERP system. A survey conducted by Mabert, Soni, and Venkataramanan (2000) showed that the most frequently implemented ERP applications are financial accounting, materials management, production planning, order entry, purchasing, financial control, and distribution/logistics. Thus, selling these modules individually or in an integrated package may reduce customer TCO and shorten the implementation cycle.

Applications Service Providers (ASPs)

Due to the complexity and costs of ERPs, ERP hosting/outsourcing became a popular option for small and mid-size companies that lack the capital and resources to do in-house implementation. An applications service provider (ASP) is an organization that hosts, manages, maintains, and monitors computer applications on behalf of its customers. An ASP assumes responsibility for the underlying delivery mechanisms, which include networking infrastructure and hardware requirements. An ASP may also be responsible for application maintenance and upgrades, training, technical support, and overall systems management. Typically, an ASP charges an end-user organization a fixed monthly fee based on the application usage and services rendered. These services may include hardware installation, customer support, maintenance, and upgrade.

Many companies outsourcing ERP-related applications evidenced benefits from ASPs. Research of the Aberdeen Group (2001) suggested that hosted solutions could be implemented 23% faster and at 60% lower cost than in-house ERP systems. Research conducted by the author identified the following important benefits of outsourcing enterprise applications through an ASP versus implementing them in-house (the benefits are presented in descending order of their importance):

- *Various cost savings/cost reductions, which improve companies' return on investments (ROI)*. These reduced costs include costs of additional IT staff to manage implementation, maintenance, and support of the applications; expenses of creating, running, and maintaining a complex infrastructure; cost of installing and running servers and other hardware; and cost of software upgrades/updates.
- *Companies can concentrate on their core competencies.* Outsourcing complex ERP systems allows companies to focus on their core strategic activities and achieve greater competitive differentiation in their principal business areas.
- *Fast implementation schedule.* According to various researches, the average time to implement outsourcing solutions is around 6 months, which is at least four to six times lower than the average time for implementing an ERP system in-house.
- *Investment risk reduction.* The ASP model reduces companies' risk of making huge investments in the software implementation and purchasing soon-to-be obsolete software.
- *Regular software upgrades/updates.* In many cases, ASP companies are responsible for the timely upgrade of their software according to customer suggestions and requests.

While selecting an ASP company, customers should consider a combination of factors representing major aspects of the ASP model. Based upon several research reports and information from the ASP-related Web sites, the author identified important factors that customers need to look into while selecting the ASP. These factors are presented below in descending order of their importance to customers:

- *Guaranteed delivery (reliability of vendor).* Customers would need to get a reliable ASP that provided service

Table 2 Main Steps and Elements of ERP Implementation

Steps	Elements
Phase 1. Preparation and Selection of ERP	- Form ERP selection and implementation team - Develop ERP vision (needs, objective, outcomes) - Identify the implementation model (one-vendor solution, best-of-breed solution, outsourcing, etc.) - Develop selection criteria - Establish ERP software candidate list (four to six candidates) - Create Request for Proposal (RFP), and send it to the prospective candidates - Review their responses and identify three-four finalists - Request the finalists to demonstrate their packages - Select the winner and negotiate the contract - Justify the investment
Phase 2. Installation and Implementation	- Organize the implementation project - Define the performance measures for the new system - Create the initial detailed implementation project plan - Educate the project team - Assess integrity of the existing database - Install new or upgrade existing hardware - Install the software; perform the computer room pilot - Educate the ERP users - Define and refine procedures for the new system - Ensure integrity and accuracy of the data - Bring the fist module/product/plant live; refine and adjust. Repeat the same for other modules/products/plants - Improve continually

virtually all the time, with uptime of at least 99% and guaranteed access 24 hours a day and 7 days a week.

- *Quick implementation time*. The implementation cycle time should be no more than 6–9 months.
- *Vendor's reputation*. Customers should select a well-referenced vendor that has a successful track record of implementations, excellent customer service, and maintenance.
- *Financial stability of ASP*. An ASP's financial position is very critical to supporting the ongoing business so that it can provide services over the long term. Therefore, a customer, prior to making its final ASP decision, needs to fully investigate the ASP's financial performance and results.
- *Scalability*. ASPs should offer services that scale as quickly as a company develops.
- *Cost of ASP*. Customers should look for low-cost solutions with a fixed fee structure at compatible rates.
- *Appropriate security*. Customers would need to get ASPs that provide layered data security and backup service. Moreover, only authorized escorted personnel should have access to the data center.
- *Expertise with applications*. ASPs must have extended experience with and expertise in implementing and maintaining applications it hosts.
- *Professional services*. It is preferable to have an ASP company that is a niche player and focuses on a specific market segment. ASPs should have an ability to integrate with existing systems and provide some application customization.
- *Regular updates*. Customers would need to select an ASP that frequently enhances its software with regular updates.

ERP SELECTION AND IMPLEMENTATION

The selection and implementation of an ERP system consists of several major steps that prepare a framework for successful implementation, identify an ERP software vendor and applications to be implemented, and install and implement the software. As described by Langenwalter (2000), the main steps and their elements are presented in Table 2.

One of the critical elements in the first step is to develop a company's ERP vision. The vision should include objectives, needs, and expectations for implementing such a system, as well as an implementation model. Today, companies utilize several implementation models. One of them is a single integrated ERP system from an ERP software vendor, i.e., a "one-vendor" system. Another model is associated with a combination of the "best of breed" applications. For example, a company might decide to select SCM applications from SAP, HR from PeopleSoft, and Financials from Oracle. In this case, separate subsystem solutions are interfaced and not integrated (Harrelson, 2001). The third model might represent an outsourcing of ERP solutions through ASP. To choose a specific implementation model, a company needs to take into consideration a variety of factors including size of the company, industry the company belongs to,

Table 3 ERP Implementation Measurements

Group of Measurements	Possible Indicators
Financial results	- Cost savings - Return on investments - Financial payback - Total cost of ownership
Process improvement results	- Order fulfillment time - Procure-to-pay time - Inventory level - Production/service quality
Customers and supplier satisfaction	- Simultaneous number of customers in the system - Number of customer complaints - Relationship with suppliers
Systems results	- Availability of information - Reliability of information - System response time

ability to integrate various applications, and projected investments.

Selection of the best ERP vendor should be based on the following criteria:

- *Features and functionality*—the capabilities that ERP software has to fulfill the company's needs; the multiplicity of features and applications that the vendor can provide
- *Estimated total cost of ownership (TCO)* as defined in ERP Issues
- *Provided service and support*—quality and timeliness of a vendor's product installation, service availability, customer service, business consulting, and system integration
- *Financial viability* of the vendor to provide long-term service for the company (vendor's revenues, growth margins, earnings per share, fundamentals ratios, etc.)
- *Technical execution*—ability of the vendor to meet industry milestones (R&D capabilities in comparison to those of other vendors).

To monitor and analyze implementation processes and results, a company needs to put in place a system of ERP implementation measurements. This system should describe financial results of implementing ERP, process and system improvements, customer and supplier satisfaction, and technical/system performance results. Possible measurements of ERP implementation are presented in Table 3.

CONCLUSION: THE FUTURE OF ERP

In more than 30 years of evolution, ERP systems have undertaken a significant transformation from function-specific applications to fully integrated process-driven systems. These systems operate over the Internet and contain both back-end and front-end capabilities. Being one of the main enterprise-based computer architecture and business application, ERP systems have been experiencing a dramatic growth in sales for the past 10–12 years, and, according to various forecasts (AMR, 2000; Data Analysis Group, 2000), will continue to grow in the future.

The further development of ERP systems is associated with the following trends:

- Full integration of e-commerce solutions into ERP systems
- Substantial increase in the number of collaborative ERP tools and applications
- Future development of analytical and business intelligence tools imbedded into ERP
- An open ERP architecture environment that makes it possible to connect the system with other internal and external customer and supplier applications.

In lieu of these trends, The Gartner Group (Genovese, Bond, Zrimsek, & Frey, 2001) has introduced and described a new ERP paradigm shift—ERP II. According to Gartner, "ERP II is an application and deployment strategy that expands out from ERP functions to achieve integration of an enterprise's key domain-specific, internal and external collaborative, operational and financial processes." A cornerstone of ERP II is open architecture of its components. That means that the monolithic systems of the past will have to change. ERP II will be more componentized, and, thus, companies will open their systems up to other companies, suppliers, and customers. This would further irradiate the "inward looking" nature of core ERP systems and the "one vendor owns everything" ERP model. According to the ERP II concept, core ERP systems have to be redefined and extended to embrace the Internet, new virtual supply chain models, CRM systems, and the B2B e-commerce models. With ERP II, the role of ERP systems expands from an attempt to optimize enterprise resources to a focus on "exposing the information involving those resources to other enterprises within a community of interest."

The Gartner Group's research (Genovese et al., 2001) predicts that by 2005 40% of ERP II vendors will offer native integration of between 60% and 80% of enterprise-centric commerce processes, depending on domain. Also, by 2005 less than 50% of enterprises will rely on a single vendor to enable more than 80% of their enterprise-centric commerce processes.

GLOSSARY

Applications service provider (ASP) Organization that hosts, manages, maintains, and monitors computer applications on behalf of its customers.

B2B (business-to-business) e-commerce Use of computer networks, primarily the Internet, to buy and sell products, services, information, and communications between business organizations.

Customer relationship management (CRM) Set of applications related to customer interactions with a company, managing customers' demands and orders, and improving customer satisfaction.

Enterprise resource planning (ERP) Integrated computer-based system that manages internal and external organization's resources; application and software architecture that facilitates information flows between various business functions inside and outside an organization.

ERP II Application and deployment strategy that expands out from ERP functions to achieve integration of an enterprise's key domain-specific, internal and external collaborative, operational, and financial processes.

Manufacturing resource planning (MRP II) Integrated computer-based system that combines materials and capacity planning with distribution planning, sale ordering, marketing, finance/accounting, and human resources.

Material requirements planning (MRP) Integrated computer-based system for calculating material and delivery schedules; combines inventory management, materials planning, capacity planning, purchasing, and distribution.

Process-driven system ERP feature of integrating business functions into a variety of processes, which are computerized versions of real business processes that companies apply to managing resources, working with customers and suppliers, etc.

Scalability ERP feature of providing adequate capabilities when the total number of users of a system is growing due to a company's expansion or its merger with or acquisition of another company.

Supply chain management (SCM) System of principles, methods, and applications of planning and scheduling material and information flows from suppliers to a manufacturing/service organization; scheduling, executing, monitoring, and reporting production plans in this organization; and distributing final products to the customers.

Total cost of ownership (TCO) Total cost of owning a computer-based system; includes software license fees, hardware cost, installation and implementation fees (consulting, additional personnel, training, testing, etc.), cost of maintenance, and customer support.

Y2K problem Derived from presenting a year as a two-digit number in software; for example "00" could stand for "1900" or "2000." This can cause failures in arithmetic, comparisons, sorting, and input/output to databases or files when date-related data are manipulated. This problem potentially exists in old computer-based systems.

E-systems for the Support of Manufacturing Operations

Robert H. Lowson, *University of East Anglia, United Kingdom*

INTRODUCTION

In five years, the "e" will disappear from the term e-manufacturing as there will no longer be anything new or mystical about "e-manufacturing." However, despite being increasingly evident in management literature, the subject has received little clarification concerning its full meaning, application, potential and challenges—something this chapter hopes to rectify.

This chapter offers five distinct, yet interconnected themes. First, an in-depth analysis of e-manufacturing covers its background, the concept, the potential, and the implications for manufacturing of being able to produce at disparate sites, often globally. Linked to this, the second part evaluates the strategic choices possible when using a global production strategy. The third section further develops the strategic argument by assessing how an e-manufacturing strategy can be formulated. A number of steps are considered and a direct link is then formed to the penultimate section: competitive advantage from e-manufacturing. Finally, empirical evidence for the application of e-manufacturing is given in the form of a small case study.

THE CONTRIBUTION OF E-MANUFACTURING

Before turning to the contribution of e-manufacturing, a word of caution is necessary. The Internet is an extremely important new technology that has received much attention through the latter part of the 20th and the early 21st centuries. However, as Porter (2001) points out, it is perhaps time to take stock and develop a clearer view. As he suggests: to move away from the rhetoric about "Internet industries" and "e-business strategies," and a "new economy." To see the Internet for what it is: "an enabling technology—a powerful set of tools that can be used wisely or unwisely in any industry and as part of almost any strategy." However, technology and the Internet, in particular, do provide a better opportunity to establish operational effectiveness than previous generations of information technologies.

The Internet per se will rarely provide a competitive advantage. The creation of true economic value (the gap between price and cost to produce) will always be the bottom line in terms of survival or failure. Sustainable competitive advantage can only be achieved by operating at lower cost, by commanding a premium price, or doing both. These cost and price advantages can be achieved in two ways: First, *operational effectiveness* (doing the same things as your competitors but doing them better); and second, *strategic positioning* (doing things differently from competitors in a way that delivers a unique type of value to customers). Best practice in terms of operational effectiveness includes better technologies, superior inputs, better-trained employees, more effective management structure, and a clearly articulated operations strategy that links business policy to operational activity.

The Internet can affect operational effectiveness. A powerful tool, but, according to Porter, "simply improving operational effectiveness does not provide competitive advantage . . . this can only be done by achieving and sustaining higher levels of operational effectiveness than competitors." Best practice tends to be copied quickly! As it becomes harder to sustain operational advantages, strategic positioning becomes all the more important. This goes far beyond the pursuit of best practice (the quest of the operations strategy). Strategic positioning involves the highly integrated configuration of a tailored value chain, the series of primary activities required to produce and deliver a product or service: inbound logistics, operations, outbound logistics, marketing and sales, and after-sales services—the first three also being the province of the operations strategy.

According to this viewpoint, the Internet is ostensibly a powerful new technology to aid operational effectiveness, but in reality, is just another way of doing business and not a business strategy in itself. It is,

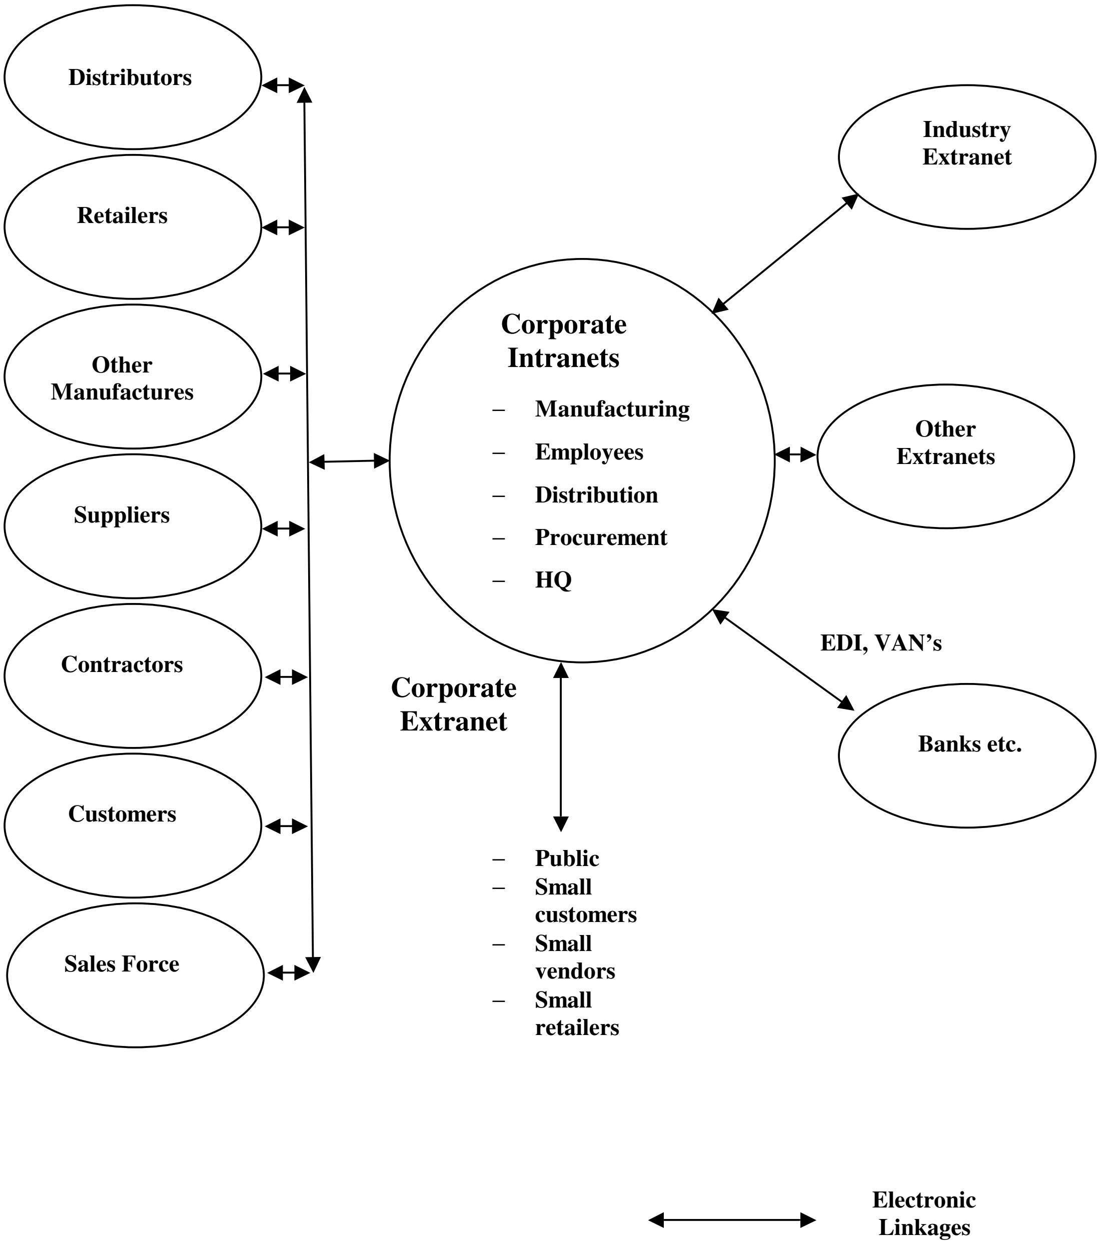

Figure 1: The networked model.

nevertheless, an operational management resource that can be advantageously exploited as part of an operations strategy.

The Background to E-manufacturing

Electronic commerce can change mass production systems to demand-driven and customized, just-in-time manufacturing. Furthermore, production can now be integrated with finance, marketing, and other functional systems, as well as with business partners and customers. Using Web-based enterprise resource planning (ERP) systems, orders are taken from customers and directed to designers (using computer-aided design) and/or to the production floor, within seconds. Production cycle times can be cut by 50% or more in many cases, especially when manufacturing is completed in a country different from the design and engineering location. Companies like IBM, General Motors, General Electric, and Boeing are assembling products for which the components are manufactured in many locations. Sub-assemblers gather materials and parts from their vendors, and may use one or more tiers of supply manufacturers. A whole disparate production system is capable of being electronically coordinated from one central location. Using electronic bidding, assemblers acquire subassemblies 15–20% cheaper and 80% faster. In addition, such systems are flexible and adaptable, allowing fast changes with minimum cost. Further, costly inventories that are part of a mass-production era can be minimized. As can be see in Figure 1, firms today can combine the Internet, intranets, and extranets in an integrated whole. The manufacturing enterprise in this figure is part of a number of extranets. Apart from its own, there may be connections to banks and other financial institutions using secured electronic data interchange (EDI) across a value- added network (VAN). VAN-based EDI systems can also link the organization with its suppliers and other business partners; meanwhile, Internet-based EDI is used with smaller firms.

E-manufacturing is highly dynamic in nature, but will typically include certain critical systems, technologies, and software, e.g., computer-aided design, manufacture, and engineering; remote failure effects analysis; manufacturing resource planning and enterprise resource planning; just-in-time; outsourcing; vendor-managed inventory, and e-supply chains.

There are numerous interpretations of the e-manufacturing concept, some more specific than others. E-manufacturing is the application of open, flexible, reconfigurable communications and computing technologies to manufacturing practices and the movement and storage of products. In its highest form, it is a seamless integration of e-business components that can coordinate distributed manufacturing operations as a single entity, matching demand to supply—"cybermanufacturing" (Toussaint & Cheng, 2002). It should be noted that there are differences between e-manufacturing, e-supply chain, and e-logistics. The following perspectives are adopted in this chapter:

E-manufacturing—Electronically mediated data/information exchanges and the information communication technology systems that support them. To facilitate the operation, enhancement, reengineering, and integration of the range of production processes, both within an organization and externally (both supply and demand sides), takes place. Physical manufacturing is local, regional, or international with the global sharing of knowledge using the Internet. E-supply chains and e-logistics are the interfaces to manufacturing.

E-supply chain—Supply chain management, part of a wider supply network, that coordinates the flow of materials both up- and downstream. Equally important are the information streams involved. Once these flows are enhanced by an electronic means of communication, then the e-supply chain is evident.

E-logistics—Logistics deals with microissues (such as transportation) that take place after production; in other words, the demand side. Information flows are vital and if electronic means are provided to support them, e-logistics becomes available.

The remote monitoring and maintenance of a production process seems to have instigated the birth of e-manufacturing. Today, adherents suggest (Pires, 2001) that it encompasses a new business model. Web-based customer order systems activate procurement and manufacture processes by digitizing the raw data and information associated with the production life cycle; these include computer-aided design, digital quality control, remote maintenance, and real-time shop floor information and control systems.

The E-manufacturing Concept

E-manufacturing can have two applications: tactical and strategic. In the former, the Internet is used to monitor processes on the manufacturing floor and other material handling to ensure optimal operation. This monitoring can be undertaken on a remote basis, providing basic information regarding work in process, inventory, and other problem diagnostics. At a strategic level, however, the impact of e-manufacturing is likely to be more profound. Here, e-based systems across a supply network provide electronically transmitted knowledge to design products, transmit orders and enable order management, procure components and materials, link planning and scheduling, and allow for the testing and validation of finished products. It is business process visibility of capacity, processing, and inventories, from raw material to finished goods, and the collaboration involved, that is likely to bring the greatest strategic benefits. Yet, the transformation from full internal integration to supply chain and customer integration is far from easy. Merely overlaying Internet technology upon existing processes will not suffice.

In a fully implemented e-manufacturing scenario, the strategic benefits offer real opportunities for competitive advantage in linking disparate, world-wide production sites and supply networks in a coordinated move closer to mass customization and the individualization of goods; see Figure 2. In this figure, e-manufacturing can be visualized as a hub activity. Using electronic data/information flows, the e-business structure is linked to integrated product development and moves closer to mass customization (including intelligent products and technologies). It seems clear that e-manufacturing has immense potential for opening a number of new markets.

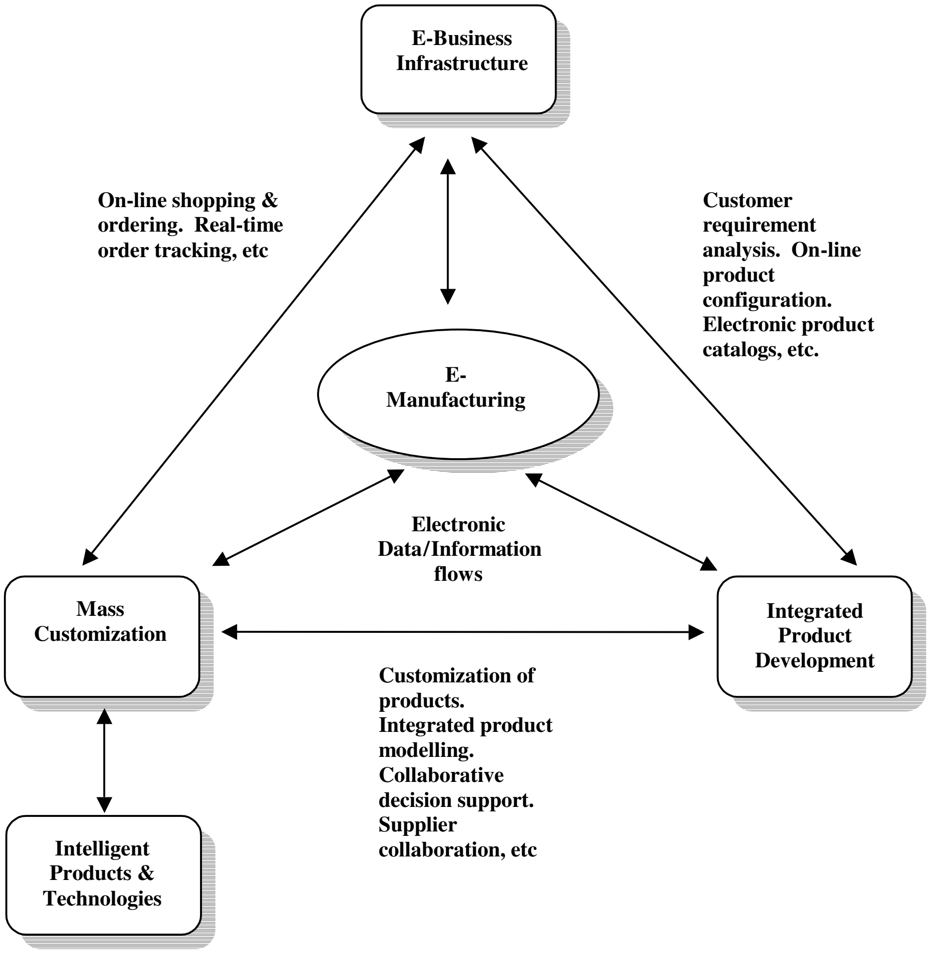
E-manufacturing Market Potential

> E-commerce has been mismanaged at the manufacturing level. People have figured out all kinds of ways for customers to order instantly. But they haven't figured out a way to actually know in advance, on a real time basis, whether or not they will be able to satisfy those orders. (T. Murrell, personal communication, July 15, 2002)

It is conceivable that the emergence of factory-to-business (F2B), business-to-business (B2B), and factory-to-consumer (F2C) models may alleviate the dire problems described in the quote above in providing the missing "e-fulfillment link," as seen in Figure 3. The figure show the conceptual position of a firm locating its physical operations globally and serving its customers (using F2B, B2B, and F2C) using e-manufacturing. Other linkage mechanisms between product and the customer will be found in the appropriate operations strategy such as, for example, supply chain management (SCM), vendor-managed inventory (VMI), and efficient consumer response (ECR) (Lowson, 2002a). These strategies are themselves enhanced by various internet applications.

Manufacturing and Production for E-business

It is now possible to examine the nature of manufacturing in an e-business environment. The process can be defined



E-Business Infrastructure
On-line shopping & ordering. Real-time order tracking, etc
Customer requirement analysis. On-line product configuration. Electronic product catalogs, etc.
E-Manufacturing
Electronic Data/Information flows
Mass Customization
Integrated Product Development
Customization of products. Integrated product modelling. Collaborative decision support. Supplier collaboration, etc
Intelligent Products & Technologies

Figure 2: The e-manufacturing model.

as follows: “The management of the internal and external systems, resources and technologies that create and deliver the firm’s primary products.”

This definition expands the manufacturing concept beyond just internal processes. It can encompass other activities such as purchasing, distribution, and product and process design. Further, in an e-business setting, there will also be external managerial responsibilities at a supply network level, covering the interconnections between external firms.

E-business can revolutionize many elements of production management due to its effective time, resource, and cost reduction. This is mainly achieved through improved communication and dissemination of economically valuable data and information by improving visibility and integration of supply chains and effectively replacing the need for inventory with real-time information (Van Hoek, 2001).

Such improvements provide opportunities for e-manufacturing to further increase economic efficiencies by matching output to demand and facilitating the exchange of information and goods and services—a move closer to the perfect market.

E-manufacturing Strategy

In order to understand the organizational context of e-manufacturing and an e-manufacturing strategy, the infrastructure of the modern organization is viewed as consisting of four conceptual levels:

1. *Business model*—Definition of a general, long-term business strategy;
2. *Operations strategy*—Decisions made regarding the medium- to long-term operational or manufacturing aspects of providing certain products and services;
3. *Operational management*—The tactical processes necessary to implement both the above strategies and provide products and services; and
4. *Information system (IS) and information technology (IT) architecture*—The supporting information and technology necessary in an e-business setting (often there might also be distinct IS and IT strategies).

The role of the operations strategy and operational management (levels 2 and 3) is to execute or implement the general business strategy and effectively use the tools and information flows involved in level 4. An e-business must also seek to understand how to take advantage of new operational and IS/IT capabilities to migrate to more effective business models. The challenge for an e-manufacturing strategy is to translate these business models into activity.

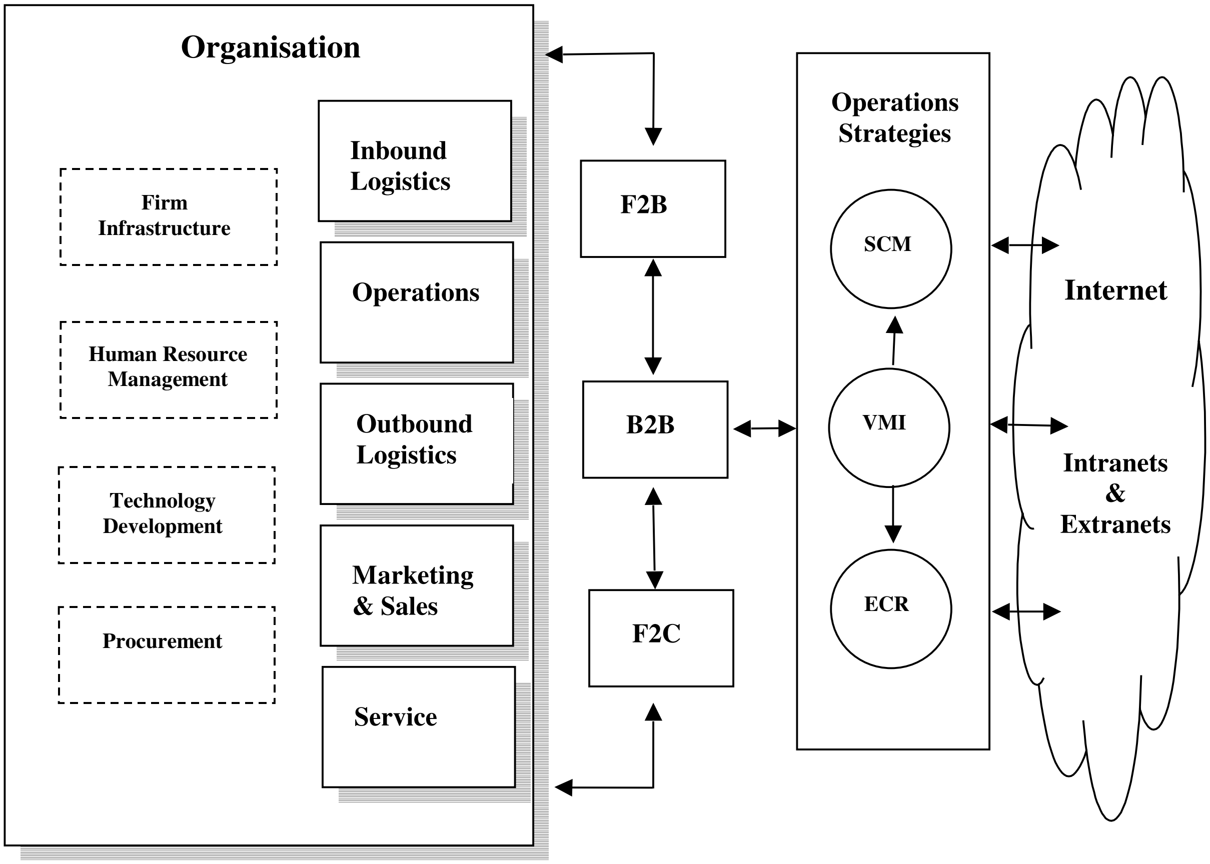


Figure 3: F2B, B2B, and F2C: A 3-tier model.

An operations strategy (in this case one for e-manufacturing) is concerned with both the internal and external decisions necessary to translate the business vision. The subsequent business model will be a fluid collection of business activities—each one focusing on a limited number of competencies in order to create value.

The Components of an E-manufacturing Strategy

The potential of e-manufacturing is of a strategic nature and a functional operations strategy will be of concern to most organizations. The possible components of such a strategy can be viewed as a pattern of medium- and long-term decisions. Recent empirical research (Lowson, 2002b) has identified the components of an e-manufacturing strategy as being selected and blended to represent both the resource-based and market-driven views of policy making. (We acknowledge the role of strategic management may not always be rational and planned. Some strategies will be logical and of a breakthrough nature; others will be adaptive, emergent and incremental.) In the case of the former, companies are seen as a collection of resources, rather than holding purely market positions. The market-driven view of strategy formulation, meanwhile, argues that it is not just the industry that is important, but where the organization wants to compete and the nature of the competition.

Previous empirical work (see Lowson, 2002c) has indicated that operations strategies (including those appertaining to production or e-manufacturing) contain various components. These can be conceptualized as core competencies, capabilities, and processes; strategic network relationships; resources; technologies; and key tactical activities to support a particular strategy or positioning. We will return to these components as part of the case study to examine their application in an e-business setting.

E-manufacturing—The Opportunities

An e-manufacturing enterprise will have a number of revenue-enhancing opportunities that will need to be considered in any e-manufacturing strategy.

Direct Sales to Customers. This allows more members of the supply network to have direct contact with the customer in channels not previously open or controlled by intermediaries (a retailer or wholesaler, for example).

Twenty-Four-Hour Access from Any Location. Accessibility, in theory, could be 24 hr a day and 7 days a week for the placement of orders. However, unlike a retailer, the goods are not always provided straight away. Similarly, geographic location is no barrier to accessing e-services, but e-fulfillment may not always be feasible.

Aggregating Information. Sales can be increased by offering information regarding a large selection of products and services that do not have to be held in inventory (a corresponding variety provided by a retailer would entail having a large stock-holding).

Personalization and Customization. The Internet offers the potential to use customer's personal information to intelligently guide each buying experience and increase sales. At an F2B level it is possible to establish customer-specific sites to personalize the buying experience.

Speeding Up Time to Market. Increased revenues are available by introducing new products much faster than using physical channels. A new product can be made available as soon as the first unit is produced.

Flexible Pricing. An e-business can alter prices by changing one entry in a database. Prices can be adjusted rapidly to reflect inventory and demand preferences.

Price and Service Discrimination. Prices can also be altered to reflect the buying power of individuals. Prices can be adjusted for each microsegment and even by individual customer—rather than having a single price for all.

Efficient Funds Transfer. The payment collection cycle can be much shorter for an e-business—this can substantially improve cash flows and possibly increase revenue.

Shipping Time and E-fulfillment. This is still a potential disadvantage for an e-business. For example, physically buying a pair of jeans allows the customer to touch and try on the goods. After payment the customer leaves with her purchase. For an e-business, shipment takes time (unless we are dealing with services and goods that can be downloaded from to a computer). Shipping costs are also a common cause of concern with many consumers abandoning the online "shopping cart" when they add the cost of shipping.

Centralized Inventory. The ability to stock goods in one location rather than spread over numerous scattered locations allows the firm to keep substantially lower amounts by avoiding duplication.

Reduced Facilities Cost. This benefit is obtained by avoiding the need for stores and other outlets in expensive prime locations.

Self-sourcing. Consumers often can do work of the business. For example, delivery services encourage the customer to track their own deliveries, purchase tickets online, and pay bills and set up banking facilities online. These advantages may be the single most important feature of the Internet.

Job Specialization and Scheduling. This allows companies to centralize operations, giving rise to opportunities of greater task specialization. For service firms especially, this is a valuable benefit as it allows a high degree of customization to be retained in the front-end of the service, but this is supported behind the scenes by standardized tasks and processes that can utilize economies of scale through high-volume transactions. The Internet alleviates the fundamental tradeoff between customization and efficiency, especially when applying technology to 24-hr, 7-days-a-week services.

Other Positive Cost Impacts. Cost reduction opportunities include reduced product handling and shorter supply networks, postponement of product differentiation until the order is placed, decreasing delivery cost and time (downloaded goods), reduced physical processing costs, reduced inventory costs, and improved supply chain coordination arising from better information flows.

E-manufacturing—Pitfalls and Challenges

Just as certain opportunities will exist for an e-manufacturing system, there will also be limitations. The operations strategy seeks to minimize and mitigate the following:

Technology. An e-business and its e-manufacturing strategy will live or die by its technological choices. The flexibility brought by information technology will also have a price in terms of the necessary development and maintenance. Often, firms will not possess the expertise necessary in these areas and will either have to outsource or hire the human resources necessary. This can result in higher costs and loss of control. In addition, according to Moore's law, computing power doubles every 18 to 24 months. To keep pace, investment in new technology is both necessary and substantial.

Trust and Security. These remain major concerns for many businesses contemplating an e-manufacturing strategy. The former is fundamental to the proper functioning of e-manufacturing interfaces between firms. Information systems in particular must remain open to enquiry and use by a number of parties to an intranet or extranet. The term "network security" is regarded by many as a contradiction in terms. The use of e-manufacturing increases an organization's visibility on the Internet and more exposure and availability of the product increases turnover and profit. However, it also opens the operation to a wide number of security threats that must be identified and planned for using the necessary security devices.

Increased Shipping. Rather than delivering one shipment to a store for customers to purchase, e-manufacturing must ensure that each individual purchase is delivered. For tangible goods, this has high-cost implications that cannot be avoided—especially if the products are fragile or large.

Accountability/Legality. Accountability for the sale of controlled items is always a problem with the anonymity of the Internet. It is difficult to ensure that items such as liquor or prescription drugs do not fall into the wrong hands. Similar problems arise regarding copyright of music and other intellectual property.

Communication Barriers. Despite the customized Web pages of Amazon and Dell, for example, there is still a barrier to communication without two-way or face-to-face interaction.

Other Negative Cost Impacts. Higher costs are likely in the following: inbound and outbound transportation costs as the e-business will tend to aggregate inventory at a central location rather than at a number of geographic points; increased handling costs if customer participation is reduced (groceries, for example, where some tasks are performed by the customer in store); and, a large initial investment in information infrastructure.

E-manufacturing and the Small- to Medium-Sized Enterprise (SME)

In many developed nations, SMEs make up a large proportion of the manufacturing base. As such, the transformation to a form of e-manufacturing may well be inevitable as customer demand increases for faster delivery and instant access to order schedules. Additionally, when there is a large power imbalance between SME supplier and a larger customer organization these pressures will be exacerbated.

As we shall see later, cost savings are just one of the benefits of e-manufacturing and other electronic processes in "back-end" operations. SMEs need to embrace the latest technologies in order to penetrate nontraditional markets and remain flexible, responsive, and competitive, challenges made more onerous by globalization, liberalization, and technological advancement.

For many firms, including SMEs, the plant floor is often the weakest link in the supply system and this is likely to be the largest gain of e-manufacturing. However, the costs of the necessary technologies may well be prohibitive. Unfortunately, some of the cheaper systems available will be those that fail to integrate with other organizational processes and the supply chain, dissipating the benefits of e-manufacturing.

GLOBALIZATION OF AN E-MANUFACTURING STRATEGY

Although e-manufacturing can be localized, distributed e-manufacturing brings with it certain operations strategic considerations, one of which is location. Theoretically, under such a system, disparate production sites can be controlled from a central location. Yet, there remain a number of other necessary strategic considerations.

Now, even small- and medium-sized manufacturers can source and trade on a global basis. Advanced forms of information communication technology and the Internet have made feasible operations and the selling and buying of products on a global basis. New markets are available in corners of the world previously unthinkable; even micro-organizations can realize benefits from utilizing (often through outsourcing) international resources for both labor and materials.

International competition is a complex arena for any firm. As Meredith and Shafer (2002) suggest, organizations now operate in domestic, exporter, and international markets at the same time. Global firms, joint ventures, partial ownership, strategic alliances, outsourced production and services, build and assemble offshore agreements, foreign suppliers of parts, reimporting manufacturing arrangements, and now e-manufacturing are all commonplace. However, despite global production being used to reduce direct costs, it exacts a heavy price in terms of coordination and flexibility.

Meredith and Shafer suggest that global coordination consists of many elements. An accurate information provision is required in the supply chain to minimize the cost of errors as well as those associated with storage and inventory holding. Indeed, as global coordination becomes more of a problematic issue, many firms will seek to establish closer "sole-source" arrangements with a smaller, "preferred" supply base.

Growth in world trade and the extension of operational activities beyond the boundaries of the firm has clear implications for competitiveness and the dimensions of a manufacturing strategy. Operations have a crucial role to play in international competitiveness. Strategic operations decisions regarding such issues as the responsiveness and flexibility of domestic supply compared with outsourcing to less flexible, low-cost, low-wage producers offshore; the appropriate locations for international facilities; the output capacity of plants; and the labor–technology tradeoffs in each location are necessary. There are six primary characteristics of the transformation system that are crucial when making such decisions (these have been adapted from the work of Meredith and Shafer, 2002):

Efficiency or "doing the thing right"—Measured as output per unit of input. The problem comes in making meaningful comparisons and choosing the right measures for these inputs and outputs.

Effectiveness or "doing the right thing"—Are the right sets of outputs being produced? Are we focused on the right task?

Capacity—The maximum rate of output attainable. Here, a balance must be struck between capacity and efficiency.

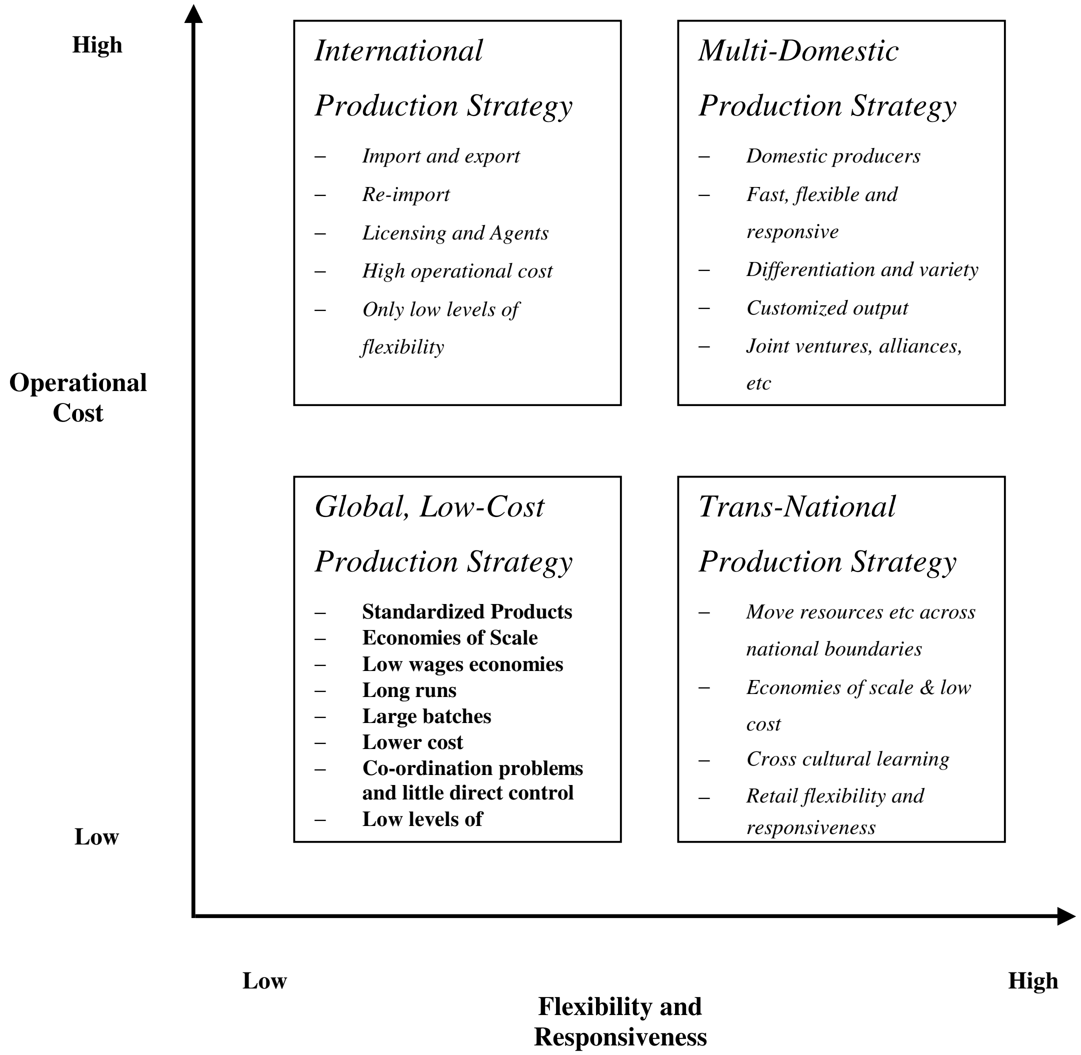
Quality—Are the quality levels of the output right and can they be consistently attained?

Response time—How quickly can the output be produced? Or preferably, can the output levels be set to respond to the exact nature of "real-time" demand?

Flexibility—Can the transformation system produce different outputs? How easily? How fast? What levels of customization are possible?

The Right Choice of a Manufacturing Strategy for E-manufacturing

The choice of production strategy will reflect two diametrically opposed variables: the levels of cost reduction necessary, and the levels of flexibility and responsiveness required (Lowson, 2001). Figure 4 demonstrates the manufacturing strategies that might be applied—depending upon the objectives of the enterprise. The matrix in Figure 4 details the two variables. The vertical axis shows the operational cost of a particular manufacturing strategy. The horizontal axis displays the degree of flexibility and responsiveness. The implications for each international strategy are critical for both trade and competitive edge. The various types of strategy can be examined together with their advantages and disadvantages in terms of flexibility, responsiveness, and cost.



High
Operational Cost
Low
International Production Strategy
– Import and export
– Re-import
– Licensing and Agents
– High operational cost
– Only low levels of flexibility
Multi-Domestic Production Strategy
– Domestic producers
– Fast, flexible and responsive
– Differentiation and variety
– Customized output
– Joint ventures, alliances, etc
Global, Low-Cost Production Strategy
– Standardized Products
– Economies of Scale
– Low wages economies
– Long runs
– Large batches
– Lower cost
– Co-ordination problems and little direct control
– Low levels of
Trans-National Production Strategy
– Move resources etc across national boundaries
– Economies of scale & low cost
– Cross cultural learning
– Retail flexibility and responsiveness
Low
High
Flexibility and Responsiveness

Figure 4: Cost and flexibility considerations in choosing a global production strategy. From Hill & Jones, 1998, and from Hitt et al., 1999.

International Production Strategy

Here, the domestic enterprise imports and exports goods and components from its home country to another—a strategy relying upon the granting of licenses and agents abroad. In this instance, the firm operates in high cost, but also low-responsiveness mode. It is the least advantageous, with low local responsiveness or flexibility and little cost advantage as the transformation processes are some distance from the market. However, as an international manufacturing strategy, it is sometimes the easiest to establish with little change in existing operations and risk exposure.

Multidomestic Production Strategy

In this instance manufacturing decisions are decentralized and taken in each particular country concerned. Organizationally the firms involved are usually strategic business units, subsidiaries, franchises, outsourcing partners, or joint ventures with suppliers. Local producers in local markets maximize response and flexibility and encourage differentiation and variety—often high degrees of mass customization to accommodate local tastes are also an option. Control and coordination are also easier using this strategy as the firm is not just exporting a product but also managing the processes. There are, however, cost disadvantages using this multilocal approach, although flexibility and responsiveness increase with closer ties to the market. The advantages and disadvantages of this type of production strategy can also be applied to sourcing from domestic vendors rather than offshore.

Global, Low-Cost Production Strategy

This strategy is applied to standardized products and processes that can be produced in bulk (often in advance of a sales season) by large manufacturers operating in low-wage economies such as Asia. Economies of scale and low cost are possible due to long runs and size of operations. Coordination is often a problem as control over the numerous offshore suppliers can be difficult; there is also a degree of instability in these arrangements. The strategy also lacks responsiveness and flexibility to changes in demand.

Transnational Production Strategy

This strategy seeks to achieve the best of both worlds. It exploits economies of scale and learning, as well as pressure for responsiveness, by recognizing that core competencies, capabilities, or processes do not just reside in the domestic or "home" country. The strategy is transnational as it moves people, processes, material, and ideas that transgress national boundaries. These firms then pursue differentiation, low cost, and response simultaneously. We can think of such firms as "world" companies whose country of origin is unimportant as they possess an independent network of world-wide operations. Key activities are neither centralized nor decentralized; instead the resources and activities are dispersed, but specialized, so as to be both efficient and flexible (Bartlett & Ghoshal, 1992). In fact these firms are, as Toffler (1994) suggests, "stateless."

In summary, global production strategies increase the challenges and opportunities for most organizations. Many domestic firms have chosen to develop internationally for strategic reasons such as cost and supply network improvement. However, there are also problems in terms of providing sufficiently flexible and responsive operations that can provide the variety of goods increasingly in demand.

FORMULATING AN E-MANUFACTURING STRATEGY

A production or manufacturing strategy will direct the translation of competitive and market aspirations into tangible goods. In other words, having ascertained the value sought and the various order qualifiers and winners, it is necessary to arrive at an operations strategy that will make decisions about various product groups that will be made and delivered.

Developing an E-manufacturing Strategy

The manufacturing strategy cannot be designed in a vacuum. It requires the input of customer needs and requirements as well as resource and capability considerations. The subsequent strategic vision will have to be aligned to the wider business strategy in making decisions about the target market, product groups, and core operational competencies. We must also remember that these decisions are strategic and they will involve radical "step" changes. To create a distinctive or core competence Skinner (1996) suggests that "tinkering with the current system" and just adding new technologies is not enough. In a complex and dynamic commercial environment, new techniques must be replaced by "a whole new product realization system that is different and better than any offered by a competitor."

A strategy for the manufacture of goods is directly concerned with the transformation of raw materials and/or components into products. Often these physical transformations will take place as part of a function (operations or manufacturing) and the operations strategy in this case is at a functional level. The type of strategic decisions to be made can be summarized under the following categories (Harrison, 1993):

How are the various product transformation processes defined?

How are these transformational systems linked?

What are the basic operational principles (processes and infrastructure) for each transformation system?

How is the actual transformation carried out?

What are the quantitative limits of the transformational process?

Where is the process located?

How are the processes physically organized?

Who owns the transformation system?

How are the design attributes arrived at?

How is quality controlled and improved?

How are the informational needs of operations met?

How are human resource needs met?

Hill (2000) provides an important and explicit framework for a manufacturing strategy that reflects the close association between manufacturing and corporate decisions. His approach in developing a strategy places a strong emphasis upon strategic integration, in particular, the links between manufacturing and marketing essential in an e-business environment. In Figure 5 (adapted from Harrison, 1993) we can see how these various steps form a strategic framework that provides a close association between strategic thinking and various choices necessary. The various steps are now described in more detail:

Step 1—Corporate Objectives

The objectives for the business are the basis for establishing clear, strategic, directions with an awareness and willingness to succeed. The directions also define the boundaries and parameters against which the various inputs can be measured and established—a coherent corporate plan. Of course, these objectives will vary from one enterprise to another and will mirror the economy, markets, opportunities, and preferences involved in the situation. These broad objectives may include growth aims, survival, profit expected, return on investment, and other financial measures. However, they can also reflect other concerns such as environmental resource issues and employee policies.

Step 2—Strategic Positioning

Any commercial enterprise will need to adopt a particular strategic positioning that will underpin both its corporate objectives (Step 1) and marketing strategy (Step 3). We can immediately see the difficulty of a linear approach in this. Positioning can be conceptual (variety-based, need-based, and access-based—or a combination of all three); or practical (based upon cost, quality, flexibility, response, etc). This positioning involves a set of decisions that will take into account strategic priorities but will also dictate the operational activities that will be necessary to achieve these priorities.

Step 3—Marketing Strategy

The marketing strategy is just one of the many functional strategies the organization may choose to adopt. These

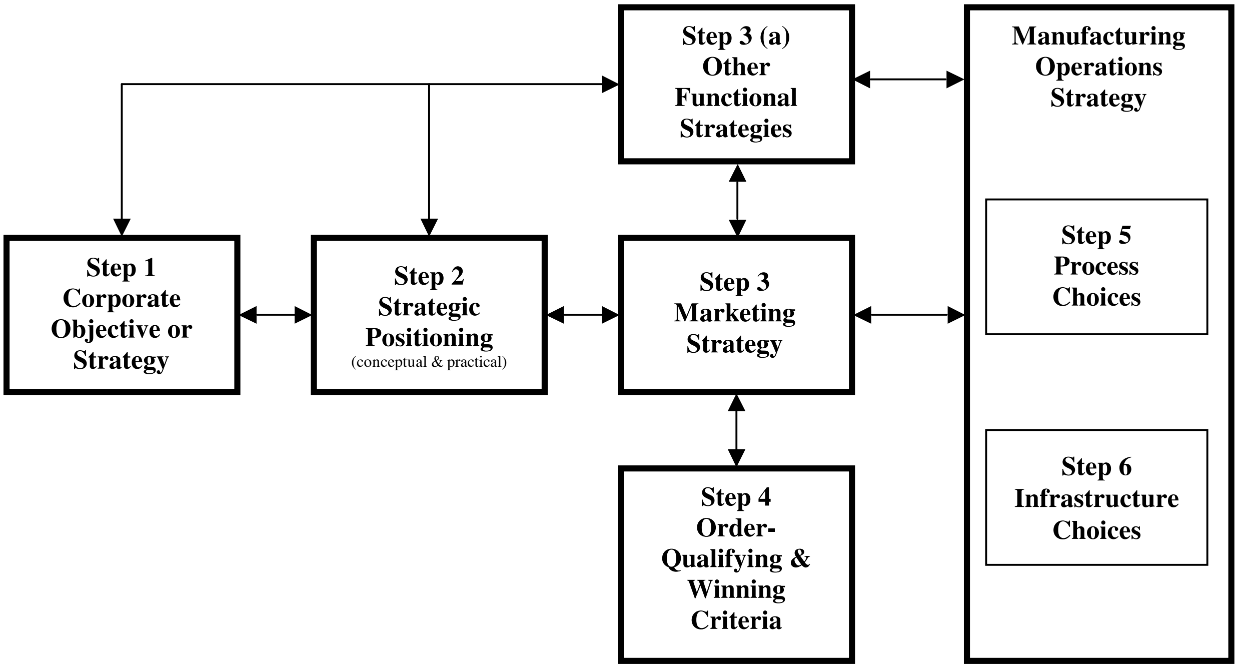


Figure 5: Manufacturing strategy framework.

include, for example, the operations or production strategy, financial strategy, human resource management strategy, and information systems and information technology strategy.

The marketing strategy will include the following:

Marketing planning and control, i.e., establishing the target markets for various product groups;

Analysis of product markets to estimate value sought, trends, buying behavior, and competitive activity; and

Identification of target markets and agreeing on objectives for each, both short and long term, and the action plans necessary.

In addition, the marketing plan will need to establish levels of support and the various resources necessary to meet objectives. The output of the marketing strategy will determine and identify product markets and segments; the range, mix, and volumes of products involved; the various product attributes necessary to satisfy value demands; and the overall marketing strategy for the various target markets (for example, a leader, aggressive competitor, new player, or follower).

Step 3(a)—Other Functional Strategies

In parallel to the marketing strategy, other functional strategies will need to be developed (too often, strategic planning fails to take this into account sufficiently early in the process). These functional strategies will cover a number of areas, but for our purposes, the manufacturing strategy is most important. Here, it will be important that the strategy both supports the corporate and marketing strategies and be compatible with other functional strategies. The various decisions about, and strategic management of, core competencies and processes, technologies, resources, and key tactical activities used in the organization and its supply network must reflect the value demanded by a customer/consumer, as well as the strategic priorities of marketing and the business as a whole. The resultant production strategy blends the various components into a fusion or strategic architecture with various levels of emphasis. This approach allows each strategy to be customized and to fit the requirements of not only the marketing strategy, but also the target markets for each product or customer group (Lowson, 2002a).

Step 4—How Products Qualify and Win Orders in the Market

The task of the manufacturing strategy is twofold. First, it is to meet the criteria necessary to qualify for the market through operational effectiveness (*performing similar activities better than rivals*). Second, it is to win orders and sustainable competitive advantage through differentiation from competitors (*performing activities different from rivals' or performing similar activities in different ways*). The qualifying criteria are the essential features of a product while order- winning criteria provide the basis for customer choice between alternative offerings. The following are some of the possible customer choice criteria that, in differing circumstances, or product life-cycle stages, may be associated with either market qualification or order-winning: total price, specified product or service attributes, quality of the product, design and design flexibility, delivery arrangements, delivery performance, volume and mix flexibility, speed of quotation service, product features, after-sales support, and the stability of continuing customer support.

The decisions in this step are strategic and need to be taken at a cross-functional level. They are not the prerogative of one function, as there will be many conflicting perspectives of a firm's products and markets. This underlines the strong link necessary between corporate marketing proposals and commitments and the manufacturing processes and infrastructure necessary to support them.

Step 5—Manufacturing Strategy (Process Choice)

There will be number of alternative processes available to make particular products. In making such choices, the key considerations will include volume, degree of customization, mix, complexity in the production process, and the necessary order-winning criteria. However, each type of choice involves both current and future tradeoffs, often between cost and variety.

Process choice relates to the basic mode of operation of a system, e.g., producing one-off projects designed for a specific customer, at one extreme, and continuous production, of say, petroleum or chemicals, at the other. The process choice will involve decisions regarding the use of alternative processes, the tradeoffs embodied in the process choice, the role of inventory in the process configuration, decisions on whether to "make" internally or "buy" parts or components externally, and capacity decisions (size, timing, location).

Step 6—Manufacturing Strategy (Infrastructure Choice)

This concerns the non-process features within the production strategy, and can include the procedures, systems controls, compensation systems, work-structuring systems, and organizational issues within manufacturing. Infrastructure choices include the necessary support needed for the operations function, planning, and control systems; quality assurance, management, and control systems; manufacturing systems engineering, data, and information requirements; clerical and informational procedures; compensation agreements; and work and organizational structures.

COMPETITIVE ADVANTAGE FROM AN E-MANUFACTURING STRATEGY

A summary of the advantages of e-manufacturing and its potential for a strategic competitiveness can now be offered. There are a number of unique opportunities offered by e-manufacturing:

Customized design—Customers can electronically transmit requirements to remote locations and become closely involved in the design of individualized goods. The final product can be quickly manufactured and distributed.

Greater product customization—As described above, it is a major advantage in terms of manufacturing to order unique goods, at relatively low cost.

Alliances—Organizations can use electronic linkages (see Figure 1) to form alliances and rapidly bring on-stream new products using advanced manufacturing techniques such as quick response and agile and virtual manufacturing.

New and modified products—The formation of strategic alliances takes advantage of brief windows of opportunity in the market. The blending of core competencies in such alliances, even on a virtual plane, has substantial implications for reducing time in product life cycles.

Increased market share—SMEs, for example, can more easily advertise their capabilities using computer networks and tender for work on projects required by other firms as part of an outsourcing strategy.

Technological applications—Software system brokers can connect users to sophisticated manufacturing tools for a temporary access to technology normally too expensive to acquire.

Procurement—Intelligent procurement systems can facilitate and speed parts procurement, billing, and payment transactions. This will reduce cost, improve accuracy, and meet customer needs in a timely manner. The ability to link efficient procurement strategies and the business workflow together with robust technological implementation will differentiate market leaders.

Production processes—E-manufacturing also accommodates swift changes in product designs, product lines, and the processes necessary.

Cost reduction—It now seems widely accepted that e-enabled production facilities have the strategic potential to reduce costs and improve efficiency. A new generation of Internet-compatible equipment will make it possible to use monitoring systems to identify cost-effective locations for large orders and ensure seamless flow of information from the factory floor.

Product information—Packaging information, providing access to manufacture and product information, and informational e-tools are becoming critical differentiators in the customer's purchase decision.

Consumer contact—Perhaps one of major advantages of e-manufacturing will be its ability to bring the consumer closer to the producer. In recent years, retailers have held power due to their closeness to the customer and ability to capture and manipulate customer data (mainly using point-of-sale scanning systems). This not only gives information regarding preferences, it also allows more accurate replenishment and re-estimation and reorder systems. The advent of e-manufacturing establishes a direct information link between the consumer and manufacturer without any retail intervention.

This chapter concludes with an empirical case study, which gives some indication as to the application of the Internet and the potential of e-manufacturing.

CASE STUDY APPLICATION

Pentwyn Splicers—E-manufacturing for the Small- to Medium-Sized Enterprise

> Just a year ago, the small engineering firm Pentwyn Splicers was on the edge of bankruptcy. Now it is turning itself around thanks to innovation, the Internet and e-manufacturing.

> Hard work, new product ranges and the development of an acclaimed Internet site have lifted export sales by more than a fifth since its black days. Turnover, helped by fresh markets in Thailand, Korea, Poland and Indonesia, has reached $600,000 at the company, which makes devices known as splicers for the textiles industry. Last year the website won the final of the ISI/InterForum E-Commerce award. Johnson (1999)

The pneumatic splicers made by this company allow weavers to join two separate lengths of yarn without tying knots, which introduce ugly lumps into the fabric and potentially jam up looms. These simple yet innovative products have given Pentwyn, an SME employing 12 staff, a way of surviving the huge slump in the textile sector. However, the firm also had to develop new markets, and the Internet and e-manufacturing proved the solution.

Pentwyn wanted to improve its customers' experience by providing better quality, faster information on its products, and a better response to orders. It needed to reach new markets in a cost-effective manner. The company also had to cut costs, particularly the cost of traveling to service customers and the costs of developing new products.

The firm incurred some cost in hardware and software and the investment time and resources in setting up a Web site and its e-manufacturing function was considerable. It was estimated that approximately 300 hours over a 12-month period were devoted to this (many by specialist engineers and designers). The company introduced e-mail to aid communication with agents and customers and established a Web site to market its products to new customers. Having Internet access also allowed it to source its business needs online.

Pentwyn increased export turnover by 20% in its first year of introducing these new technologies into the business. Its Web presence has enabled it to sell to new customers and markets it could never previously reach (Poland and Thailand, for example). It has improved the speed of communications with customers and is now able to send high-resolution video stills of products and full-technical manuals by e-mail, at much reduced cost.

By using the Internet as a market communications device, prospective customers can seek information and send an e-mail to which the company responds product photographs attachments. For example, a firm in Estonia recently sent samples of their yarn and the company responded immediately by e-mail, attaching photos of splicers joining the ends together. The company also delivers manuals and product updates electronically to clients: "It saves massive printing costs," according to Graham Waters, Managing Director (Waters, personal communication, June 15, 2000). Orders received automatically trigger production planning and the sourcing of materials. Customers can also track the progress of the order in production at a distance and even make some last-minute adjustments to volume or mix. For larger accounts, Pentwyn allows electronic access to inventory levels to provide automatic replenishment orders (as part of their vendor-managed inventory system), which in turn prompts further production scheduling. In addition, customers and suppliers also participate in Internet-based product design support systems.

More than 25% of Pentwyn's new business can be tracked directly to the introduction of the Internet. It made a 10% saving in cycle-time necessary for product development by sourcing materials from new suppliers discovered via the Internet. Online searches have also cut the cost of foreign travel. Overall, the firm estimates that the move toward e-business and e-manufacturing has enabled a cost saving in the region of 10–15%. Further research conducted with the firm demonstrated that the introduction of e-manufacturing had substantially reduced product development time and the levels of inventory and work-in-progress. It was estimated by the managing director that these moves would result in a further 15% saving in both direct and indirect cost.

In the future, the company plans to set up a password-protected extranet for agents and existing customers to improve the level of service that can be offered. It also hopes to translate its online manuals and price lists into French, German, Spanish, and Italian. According to Waters,

> We have a simple vision of the future. We want our web presence to be like a bookshop. We want visitors to stay for ten minutes and browse, not be pressurized and not threatened by hard sell. The real revelation to us is the progress achieved through e-mail communication and website development. The quality of our responses, and their speed, has transformed relationships with customers and our agents. E-manufacturing also offers great opportunities to all small manufacturing companies to transform their approach to business, and the quality of their service. We have found it an ideal medium to equip us to expand in a global market by allowing customers a direct input into producing customized goods and services. But, firms cannot just rely on the technology alone. Their operational systems, and as we have now learned, operations strategies, have to also be developed to support e-commerce. (Waters, personal communication, June 15, 2000)

It is possible to summarize the main components of Pentwyn's e-manufacturing strategy using the building blocks introduced in the previous sections.

Core Competencies, Capabilities, and Processes

These can be further subdivided as follows:

Process-Based (Derived from Transformation Activities). For Pentwyn, the main transformation involved in their e-manufacturing systems concerned information. The core competence they developed involved producing information regarding products and services accessible on an international basis, seeking information from potential customers and suppliers globally, and then matching the two streams by providing business opportunities. In addition, the automatic conversion of this information into signals that triggered production, call-offs from inventory, supplier scheduling, and replenishment activities could all be shared with major customers and suppliers.

System- or Coordination-Based (across the Entire Operation System). The information transformation described above had to be coordinated across their current operations to manufacture for new customers or source from new suppliers. The ability to link and manage the various data streams to control manufacturing schedules, raw material supply, inventory levels, and order processing is of key importance in an e-manufacturing environment.

Organization-Based (across the Entire Organization). For an e-business, organizational structures, processes, and procedures will need to radically change. First, competencies and processes will have to reflect a new tempo of immediate operation. With a faster, more flexible, "real–time" response, Pentwyn had to develop the ability to process information and react to demand across the whole organization much faster than before. In addition, their domain of operation became global and much larger. This involved developing new capabilities and competencies in what was now an outward-facing firm.

Network-Based (Covering the Whole Supply Network). As indicated above, the ability to manage a wider network of operations (both suppliers and customers) quickly became a core necessity for Pentwyn, as did the integration tasks involved in developing a supply network. In an e-business and e-manufacturing domain, greater reliance is placed upon external relationships.

Resources (Individual Resources and Their Unique Combination)

Tangible. Clearly the technologies used by Pentwyn in their e-manufacturing strategy proved vital. These included ISDN lines, CAD software, integrated numerically controlled machinery, sufficiently powerful stand-alone PCs, Internet access, e-mail, video-conferencing facilities, and membership of an electronic trading system. Other enabling techniques and implementation issues included Java programming, 3D modeling and simulations, open computing, and interactive design.

Intangible. The various communication and information systems developed for coordination became an important contributor to Pentwyn's success. They had to develop new business systems for a new method of trading. Thus, the skills in developing new management structures became fundamental.

Human. Specialized skills had to be quickly developed to take advantage of the e-manufacturing opportunities. Knowledge, motivation, and training all played an important part in providing a unique resource combination, capable of utilizing the e-business environment.

Technologies

Over and above resource technologies used, as with any e-business, future technological process development and application will be vital. The innovation and know-how to apply technological advances to new products and processes becomes as important as the technology itself.

The Key Tactical Activities

These are the necessary tactical activities vital to Pentwyn in supporting their business strategy and strategic positioning. Although not strategic in themselves, e-manufacturing decisions had to be made regarding the future of these aspects, e.g., fast and effective sourcing, shared product design, higher quality levels despite speed of response, information system integration, close communication and working partnerships with suppliers and customers, and supply system integration.

The various building blocks of any manufacturing strategy will need to be fused into a particular strategic architecture that reflects the importance placed upon some elements vis-à-vis others. In so doing, individual strategies are developed with a unique emphasis that reflects the commercial situation (Lowson, 2002a).

CONCLUSION AND FURTHER RESEARCH

It is clear that e-manufacturing has huge potential with benefits extending beyond the ability to monitor production systems at a distance. The strategic implications are perhaps most noteworthy in providing a clear route to increased flexibility and responsiveness as well as the ultimate goal of mass customization and product individualization. However, the full benefits of e-manufacturing require high degrees of coordination; both internally and externally. At present, many organizations struggle with these implications. Often, production and supply chain processes and information communication systems lack the integration necessary to take full advantage of the e-manufacturing potential.

It is suggested this lack of integration poses one of the most fruitful areas for future research. In addition to the technical barriers, many of which can be surmounted, the main challenge remains cultural. The true potential of e-manufacturing cannot be achieved without an open culture of shared communication between organizations in a supply network. This enables the coordination not only of production processes, but also of other equally important aspects of order fulfillment. Unfortunately, many firms, and indeed whole industries, still struggle with this concept despite so-called "preferred" supplier agreements, alliances, and partnerships. Competition may now be at supply chain level, but the very fact that a competitive ethos still persists between enterprises at different nodes of a supply system poses an immense barrier to full e-manufacturing deployment.

GLOSSARY

E-manufacturing Electronically mediated data/information exchanges, and the information communication technology systems that support them, to facilitate the operation, enhancement, reengineering, and integration of the range of *production* processes, both within an organization and externally (up- and downstream).

E-business All electronically mediated information exchanges, both within an organization and with external stakeholders, supporting the range of business processes.

Flexible response The ability to satisfy demand in all its many forms.

Manufacturing strategy Patterns of decisions that shape the long-term capabilities of the organization to provide products and the contribution to the overall corporate or business strategy.

Supply network An interconnection of organizations using different processes and activities to add value.

Extensible Markup Language (XML)

Rich Dorfman, *WebFeats! and Waukesha County Technical College*

WHAT IS XML?

XML (extensible markup language) is a text-based, human- and machine-readable language used for sharing data over the Web, intranets, and extranets. XML is platform- and language-independent, making XML to data what Java is to platform-neutrality and .NET is to language-neutrality. XML is the *lingua franca* of data.

XML is three things:

XML is a core language, defined in a World Wide Web Consortium (W3C) Recommendation (World Wide Web Consortium, 2000), that is used to organize data in a hierarchical structure.

XML is a family of technologies. W3C has issued Recommendations and Working Drafts for several languages that are often used in conjunction with the core language to accomplish frequently demanded tasks.

XML is a standard that defines syntactic and semantic rules for creating XML-based languages. XML-based languages are also known as *dialects* or *grammars* of XML.

Figure 1 shows the XML core language, other languages in the XML family of technologies, and some of the XML-based languages that are built upon them.

The XML core language is similar to HTML in syntax but different with regard to functionality. XML is a markup language because it uses tags to give structure to data. XML is extensible because it enables users to create their own collections of tags, as opposed to HTML, which has a fixed set of tags.

The core language has found and continues to find an ever-increasing range of applications, often in conjunction with other XML dialects. Some of the more popular uses of the XML core language include the following:

Displaying data in a browser or other user agent.

Specifying configuration information for stand-alone applications and servers.

Sharing data between different applications, platforms, and companies.

In this chapter we focus primarily on the XML core language, but bear in mind that its syntax and semantics form the basis of all other XML-derived langu ages.

The XML family of technologies arose as W3C continued to build upon its original XML Recommendation. Some of the members of the XML family of technologies include the following XML dialects:

XSL (XML stylesheet language), a native XML replacement for CSS, is used for rendering XML documents in accordance with a style sheet.

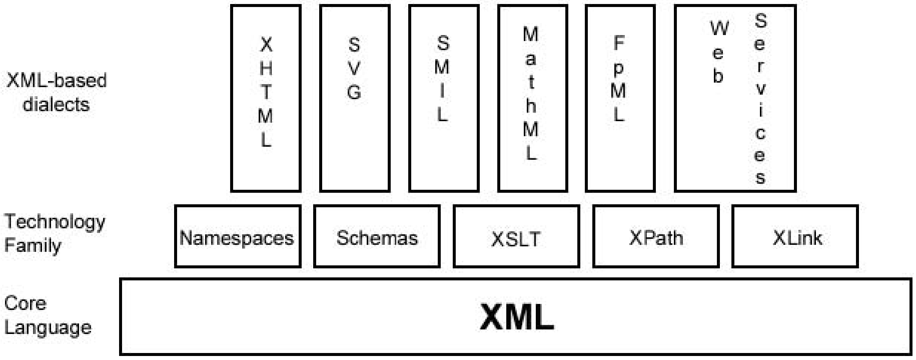

Figure 1: The XML pyramid.

XSLT (XSL transformations), and its companion XPath, are used to transform XML into another format, e.g., XHTML or SVG, for the purpose of presentation.

XLink and XML Base describe a standard way to add hyperlinks to an XML file.

XPointer is a syntax for pointing to parts of an XML document. An XPointer is similar to a URL but instead of pointing to a Web address, it points to pieces of data inside an XML file.

XML Namespaces provide a means to avoid name conflicts when using multiple XML documents within an application.

XML Schemas 1 and 2 help developers precisely define data structures to be used in multiple XML documents. A native XML replacement for DTDs, XML schemas are used to ensure the integrity of shared data.

While W3C has created several XML-based languages, independent companies, industry groups, and academicians have also been active in creating their own specialized grammars. Some examples of XML-based languages include the following dialects:

XHTML (extensible hypertext markup language) features the semantics of HTML 4.01 using the syntax of XML.

MathML (mathematical markup language) provides a grammar for easy rendering of mathematical symbols and equations.

CML (chemical markup language) is an XML vocabulary for representing and drawing molecular information.

MusicML defines a language for rendering sheet music.

FpML (financial products markup language) is a standard metalanguage for describing swaps and derivatives.

HOW DOES XML WORK?

To understand how XML works, we first compare and contrast it to HTML. Next we look at a simple XML example. Finally we discuss XML parsers, the magic that makes it all work.

XML Is Like HTML, Only Different

To understand how XML works, it is helpful to compare it to a language that is familiar to many of us—hypertext markup language (HTML).

HTML consists of tags, or *elements,* that we use to surround blocks of text in an .html file. These tags provide formatting information. When we load an .html file into a Web browser, the browser displays, or *renders,* our text in the format specified by the tags. This bit of magic is made possible by a *parser*—all Web browsers contain their own parsers, or rendering engines, that interpres HTML tags and translates tag formatting information into a graphical display.

HTML tags may also include *attributes* and, if included, each attribute is assigned a *value*. For example, the HTML code fragment `<p align="center">This is a paragraph.</p>` declares that the text "This is a paragraph." is to be formatted as a single paragraph horizontally centered in the browser window. `"<p>"` is the paragraph tag, `"align"` an attribute, and `"center"` its value. The closing `</p>` tag delimits the text enclosed by the tags.

XML uses a similar syntax that includes elements, attributes, and values. But whereas HTML is used for *displaying* information, XML is used to *organize* data in a hierarchical structure. Whereas HTML has a fixed and finite set of tags, XML lets us create whatever tags we wish as long as we conform to its semantic and syntactic rules. Table 1 summarizes similarities and differences between HTML and XML.

A Simple XML Document

Listing 1 shows a simple XML document that structures a company's employee and payroll data. Line numbers appear for reference only and are not part of the actual file.

Listing 1: File payroll.xml.

```
<?xml version="1.0"?>
<!-- payroll.xml -a simple XML file -->

<payroll company="Acme">
  <employee id="23">
     <first_name>John</first_name>
     <last_name>Doe</last_name>
     <salary>$34,000</salary>
  </employee>
  <employee id="24">
     <first_name>Jane</first_name>
     <last_name>Smith</last_name>
```

Table 1 Comparison of HTML vs. XML

FEATURE	HTML	XML
Uses	Used to format text, images and other media for rendering and display in a browser or other user agent	Used to organize data in an hierarchical structure
Has tags (elements), attributes and values	Yes	Yes
Has a fixed, finite set of tags	Yes	No
Has a strictly enforced set of semantic and syntactic rules	No, laxly enforced to varying degree depending on browser	Yes
Can be created in a text editor	Yes, HTML files are plain text	Yes, XML files are plain text
Is contained within a file	Yes, HTML code resides in an.htm or.html file.	Yes, XML code resides in a.xml file but may additionally exist only temporarily as a structure in memory

```
13     <salary>$42,000</salary>
14   </employee>
15 </payroll>
```

Line 1 is the *XML declaration*. Technically, XML documents do not need to start with the XML declaration, but W3C recommends it (Holzner, 2001).

Line 2 is a *comment*. Note that XML uses the same syntax for comments as HTML.

Line 3 is blank, or *white space*. It is included simply to make the code more readable.

Line 4 is the *root element*. The root element is the first element in an XML document and contains all the other elements nested between its start and end tags. The root element may include an *attribute*. Here, the attribute "company" has the value "Acme."

Line 5 begins an element ("employee") that contains an attribute-value pair (id="23"). Note that in the strict XML hierarchy, there are parent–child relationships between all elements. Here, <payroll> is the parent, <employee> the child.

Lines 6–8 contain three more elements, all children of <employee>.

Line 9 closes the <employee> element begun on Line 5.

Lines 10–14 describe another employee of the company. More employees could easily be added by following the same structure.

Line 15 closes the <payroll> root element begun on Line 4 and ends the document.

So now that we have an XML file, what good does it do us? The short answer is, "none." The longer answer is, "plenty, given the right tools to further process the file or format it for display." Our simple XML file is in fact a *data source that is accessible programmatically*. We can query, manipulate, and display XML data using any of several programming languages, in conjunction with an *XML processor*, or parser—the application that reads and interprets our XML.

Parsers

We could of course write code ourselves to parse the contents of an XML file—after all, it is just a text file. However, there is no need to reinvent the wheel, as free parsers are readily available for download. Most likely, we one or more parsers came with software that is installed on our systems.

Parsers have the intelligence to read, write, and manipulate data in XML files, but they have one limitation—they cannot read our minds. To tell a parser what to do, we use an API (application programming interface). Many parsers come complete with their own API tools. Alternately, we might use one company's parser while accessing it via an API from a different party.

We will discuss parsers in more detail later in this chapter. First we need to take a look at *well-formed* and *valid* XML documents—the language's syntax and semantics.

CREATING WELL-FORMED XML DOCUMENTS

What Are Well-Formed XML Documents?

Definition: XML with correct syntax is well-formed XML.

Parsers check XML documents for well-formedness. If a document is not well formed, the parser discontinues processing and returns an error message that indicates where the malformed syntax occurred.

Rules for Well-Formed XML

A well-formed XML document must conform to W3C semantic and syntactic rules (W3C, 2000). The following rules specify the conditions an XML document must conform to to be considered well formed.

Semantics

W3C specifies that a well-formed XML document has three parts: a prolog (which can be empty), a root element, and various miscellaneous components.

The Prolog. The prolog comes at the very beginning of an XML document. The prolog can contain an XML declaration, processing instructions, a document type definition (DTD), and comments. A document does not absolutely require a prolog to be considered well formed, but W3C recommends including at least an XML declaration. If an

XML declaration is included, it must appear on the very first line.

An XML declaration looks like this:

```
<?xml version="1.0"?>
```

To date, the version attribute is always equal to "1.0," although W3C issued a Candidate Recommendation of the XML 1.1 specification in October 2002 and expects to issue a finalized Recommendation in 2003.

Other optional attributes of the XML declaration include the following:

Encoding—specifies the character set used in the document. Defaults to UTF-8. A document may also use Unicode sets such as UCF-2 and UCF-4 or ISO character sets such as ISO-8859–1 (Latin-1/West European).

Standalone—specifies whether the document requires an external file. Setting standalone to "yes" means that the XML document does not require an external DTD or schema or any other external file. We would set this to "no" if you were referencing an external DTD or schema file. DTDs and schemas are discussed in the next section of this chapter.

Besides the XML declaration, the prolog may contain additional *processing instruction*s. Processing instruction tags start with `<?` and end with `?>`. Processing instructions are directives to the *XML processor,* or parser—the application that reads and interprets our XML. Any processing instructions that we use must be understood by our parser; they are not built into the XML Recommendation. Here is an example of a commonly used processing instruction that links a stylesheet to the XML document. It is understood by parsers in both Internet Explorer 5 and Netscape 6:

```
<?xml-stylesheet type="text/css"
  href="myStyle.css"?>
```

The prolog may contain three more things: *comments* and *white space,* which are discussed in Syntax, below, and the *document type definition (DTD),* which is discussed in the next section of this chapter.

The Root Element. The first element that comes after the prolog is known as the root element. All XML documents must have root elements.

The root element consists of a tag pair and includes everything between its starting tag and its ending tag. All other elements in the XML document are nested between the starting and ending tags of the root element. In the simple XML example shown at the beginning of this chapter, `<payroll>` is the starting tag of the root element and `</payroll>` is the ending tag. It's like saying, "This document is a payroll."

Miscellaneous Parts. Optional miscellaneous elements in an XML document may consist of comments, processing instructions, and white space.

We have already met processing instructions in the prolog. There are other processing instructions that may be used anywhere in an XML document. Again, the constraint is that the processing instruction must be understood by the parser.

Syntax

W3C specifies that a well-formed XML document must conform to the following syntax rules.

Tags are delimited by "greater than" and "less than" brackets.

Element tags start with < and end with >.

Elements consist of a starting tag, an ending tag, and everything in between.

Just as the root element must have a closing tag, so too must all other elements. The closing tag consists of the name of the opening tag, prefixed with a slash ("/"). Attributes, if present in the opening tag, are not repeated in the closing tag. For example,

```
<employee id="24">
   <salary>$42,000</salary>
</employee>
```

If the element does not contain text or other elements, we may abbreviate the closing tag by simply adding a slash ("/") before the closing bracket in our element. For example,

```
<payroll>
   <employee id="24" />
   <employee id="807" />
</payroll>
```

Here, `<employee id="24"/>` is a so-called *empty* element, as is `<employee id="807"/>`.

Elements must be properly nested.

In the strict XML hierarchy, there are parent–child relationships between all elements. The root element may contain one or more child elements. Each child element, in turn, may act as parent to its own children. Child elements must be correctly nested within their parent elements. For example, in HTML we can get away with this:

```
<b>
   <i>This text is bold and italic</b>
</i>
```

But XML requires that we close child elements before closing their parents:

```
<b>
   <i>This text is bold and italic</i>
</b>
```

XML tags are case sensitive. Whereas `<employee></employee>` is well-formed, `<EMPLOYEE></employee>` and `<Employee></eMPLOYEE>` are not.

Attribute values must be enclosed in quotation marks. `<employee id="24"/>` is well-formed, but `<employee id=24/>` is not.

Comments in XML. The syntax for writing comments in XML is the same as that used in HTML. For example,

```
<!-- payroll.xml - a simple XML file -->
```

XML preserves white space within elements.

HTML ignores white space. An HTML statement such as

```
<p>Hello.        How are you?</p>
```

looks like this when rendered by a browser:

Hello. How are you?

XML parsers, however, preserve the element's white space:

Hello.   How are you?

On the other hand, parsers ignore the use of vertical and horizontal white space between elements to make code more readable. For example, in

```
<payroll>
   <employee id="24"/>
   <employee id="807"/>
</payroll>
```

XML converts CR/LF to LF.

In Windows applications, a new line of text is stored as two characters: CR LF (carriage return, line feed). In Unix applications, a new line is stored as a single LF character. Some applications use only a CR character to store a new line. In XML, a new line is always stored as LF.

Only five entity references are predefined.

Like HTML, XML uses *entities,* or escape sequences, to allow us to use special characters within XML elements. For example, say we need to use a numerical relationship within an element, such as

```
<relationship value="a > b">
```

We are trying to say, "a is greater than b," but we run into a problem because XML parsers interpret the "greater than" symbol (">") as the end of an element. Instead, we have to use the following entity reference:

```
<relationship value="a &> b">
```

Here, `"&>"` is the entity reference for the "greater than" symbol.

In XML, entity references always start with an ampersand (`"&"`) and end with a semicolon (`";"`). The W3C spec defines, and XML parsers recognize, only the following five entity references:

```
&amp;     The & character.
&lt;      The < character.
&gt;      The > character.
&apos;    The ' character.
&quot;    The " character.
```

If we wish to use any other entity references, we must define them in a DTD or Schema.

Data contained within XML elements are either CDATA or PCDATA.

PCDATA (parsed character data) are just normal, everyday data, such as the "$34,000" in `<salary>$34,000 </salary>`. Data contained within element tags are always considered PCDATA unless specifically declared as CDATA. PCDATA are text that will be parsed by a parser—any tags inside the text will be treated as markup and entities will be expanded.

CDATA (character data) are text that will NOT be parsed by a parser. Tags inside the text will NOT be treated as markup and entities will not be expanded. CDATA are typically used for large blocks of text. Their syntax looks like this:

```
<employee>
<![CDATA[
   This is an unparsed character data area.
     Because it's
   not parsed, I can include < and > symbols
     without having
   to worry about the parser mistaking those
     symbols for markup.
]]>
</employee>
```

CREATING VALID XML DOCUMENTS

What Are Valid XML Documents?

Definition: Well-formed XML validated against a DTD or schema is valid XML.

Definition: Both DTDs and schemas define the tags and attributes that are permissible within an XML document.

Besides checking to ensure that documents are well formed, parsers may also check to ensure that documents are valid. A "valid" XML document is a "well formed" XML document that also conforms to the rules of a document type definition (DTD) or XML schema. If a validating parser finds a validation error in an XML document, processing is halted.

In Java programming, classes are used as "templates" to create instances of objects. Think of a DTD or schema as a class and the conforming XML document as an object that is an instance of the "class" defined by the DTD or schema.

Why do we need to check for document validity? Isn't being well formed enough? In fact, valid XML is not necessary for many XML applications. The main reason for using a DTD or schema is to share data. If we wanted to share payroll data with another company, we would make sure our individual payroll.xml files referenced a common DTD to ensure that our accounting records followed the same format.

Valid XML Using a Document Type Definition (DTD)

Along with defining the tags and attributes that are permissible within an XML document, a DTD defines the document structure: what order tags should appear in and which tags can appear inside other tags. The DTD may also define entities we wish to use apart from the five entities predefined in the W3C XML spec. DTDs are specified within the W3C XML Recommendation (W3C, 2000).

A DTD can be declared within an XML document or as a reference to an external document. Normally we will reference an external DTD, as the whole point of using a DTD is to ensure that our data structure matches the structure of someone with whom we are sharing the data.

Simple XML Document with External DTD

Listing 2 shows our simple XML document modified to reference an external DTD document. Line 4 is the document type declaration used to reference the external file. The document type declaration must appear after an XML declaration but before the document's root tag. We will be taking a closer look at this declaration's syntax in the section on *Using XML to Share Data,* below.

Listing 2: File payroll2.xml—reference to external DTD.

```
 1 <?xml version="1.0" standalone="no"?>
 2 <!-- payroll2.xml -simple XML file
     that references external DTD -->
 3
 4 <!DOCTYPE payroll SYSTEM "C:\WINDOWS\
     Desktop\payroll.dtd">
 5
 6 <payroll company="Acme">
 7   <employee id="23">
 8      <first_name>John</first_name>
 9      <last_name>Doe</last_name>
10      <salary>$34,000</salary>
11   </employee>
12   <employee id="24">
13      <first_name>Jane</first_name>
14      <last_name>Smith</last_name>
15      <salary>$42,000</salary>
16   </employee>
17 </payroll>
```

Listing 3 shows the DTD referenced in payroll2.xml. External DTD file names use the ".dtd" extension. Note that payroll2.dtd is not a well-formed XML document. We will see later that schemas *are* well formed and valid XML and thus confer the benefits of parsability.

Listing 3: DTD for payroll2.xml.

```
 1 <?xml version="1.0"?>
 2 <!-- payroll2.dtd -the DTD for
     payroll2.xml -->
 3
 4 <!ELEMENT payroll (employee+)>
 5 <!ATTLIST payroll
 6   company CDATA #REQUIRED
 7 >
 8 <!ELEMENT employee (first_name,
     last_name, salary)>
 9 <!ATTLIST employee
10   id CDATA #REQUIRED
11 >
12 <!ELEMENT first_name (#PCDATA)>
13 <!ELEMENT last_name (#PCDATA)>
14 <!ELEMENT salary (#PCDATA)>
```

A DTD may include three types of declarations:

```
Element declaration:      <!ELEMENT>
Attribute declaration:    <!ATTLIST>
Entity declaration:       <!ENTITY>
```

For validity, every element, attribute, and nonstandard entity used in an XML document must be declared in its DTD.

An element declaration has the following syntax:

```
<!ELEMENT tagName elementContent>
```

As an example, look at Line 4 of Listing 3:

```
<!ELEMENT payroll (employee+)>
```

The tagName is `payroll`. The `payroll` root element must contain one or more `employee` elements (`employee+`).

An attribute declaration has the following syntax:

```
<!ATTLIST tagName attributeName valueType
  defaultValue>
```

As an example, look at Lines 5–7 of Listing 3:

```
<!ATTLIST payroll company CDATA #REQUIRED
```

The attributeName is `company`. As you can see in Listing 2, the `payroll` root element contains the `company` attribute, whose value is, in this case, "Acme." The "Acme" value is of type `CDATA`, or character data. The attribute does not have a default value but it is a `#REQUIRED` attribute.

An entity declaration has the following syntax:

```
<!ENTITY entityName "entityValue">
```

Listing 3 does not declare any entities, but here is an example of how they work:

DTD example:

```
<!ENTITY writer "Donald Duck.">
<!ENTITY copyright "Copyright W3Schools.">
```

XML example:

```
<author>&writer;&copyright;</author>
```

Simple XML Document with Internal DTD

Listing 4 shows the simple XML document, modified to include the DTD internally.

Listing 4: File payroll3.xml - DTD included internally.

```
<?xml version="1.0" standalone="yes"?>
<!-- payroll3.xml - simple XML file
  that includes internal DTD -->

<!DOCTYPE payroll [
   <!ELEMENT payroll (employee+)>
   <!ATTLIST payroll
     company CDATA #REQUIRED
   >
   <!ELEMENT employee (first_name,
     last_name, salary)>
   <!ATTLIST employee
     id CDATA #REQUIRED
   >
   <!ELEMENT first_name (#PCDATA)>
   <!ELEMENT last_name (#PCDATA)>
   <!ELEMENT salary (#PCDATA)>
]>

<payroll company="Acme">
  <employee id="23">
     <first_name>John</first_name>
     <last_name>Doe</last_name>
     <salary>$34,000</salary>
  </employee>
  <employee id="24">
     <first_name>Jane</first_name>
     <last_name>Smith</last_name>
     <salary>$42,000</salary>
  </employee>
</payroll>
```

Listing 4 has exactly the same functionality as the code shown in Listings 2 and 3. The only thing that is different is the syntax used to include the DTD internally.

Valid XML Using a Schema

XML schemas are an alternative to DTDs that are specified in a W3C Recommendation (World Wide Web Consortium (W3C), 2001). The schema specification addresses several shortcomings of DTDs (Lee, 2001), including the following:

A DTD is not a well-formed XML document, so XML parsers do not process it easily.

DTDs do not support data typing, so all content is treated as strings.

Schemas are well-formed XML documents that support data typing. The XML schema language is referred to as XML Schema Definition (XSD). Before the W3C's XSD was approved as a Recommendation, Microsoft implemented an interim solution to XSD—the XDR (XML-Data Reduced) schema language. XDR is supported in many Microsoft products such as the BizTalk server, Office 2000, Internet Explorer 5, and the SQL Server. Microsoft's parser, MSXML release 4, supports both the XSD and XDR languages. MSXML3, however, supports only XDR (Lee, 2001).

The purpose of an XML schema is to define the legal building blocks of an XML document, just like a DTD (Refsnes Data, 2002). An XML schema

defines elements that can appear in a document

defines attributes that can appear in a document

defines default and fixed values for elements and attributes

defines which elements are child elements and the order and number of child elements

defines whether an element is empty or can include text

defines data types for elements and attributes.

A detailed discussion of the XSD language is beyond the scope of this chapter, but we present below an example of an XSD schema and its XML document, along with a brief explanation.

Simple XML Document that References an External Schema

Listing 5 shows our simple XML document, which has been modified to reference an external XSD schema document, and Listing 6 shows the referenced schema file payroll4.xsd.

Listing 5: File payroll4.xml - reference to external Schema.

```
<?xml version="1.0" standalone="no"?>
<!-- payroll4.xml -simple XML file that
  references external Schema -->

<payroll company="Acme"
  xmlns:xsi="http://www.w3.org/2001/
    XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="C:\
    WINDOWS\Desktop\payroll4.xsd">
    <employee id="23">
       <first_name>John</first_name>
       <last_name>Doe</last_name>
       <salary>$34,000</salary>
  </employee>
  <employee id="24">
     <first_name>Jane</first_name>
     <last_name>Smith</last_name>
     <salary>$42,000</salary>
  </employee>
</payroll>
```

Listing 6: Schema for payroll4.xml.

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- payroll4.xsd -the Schema for
  payroll4.xml -->

<xs:schema
 xmlns:xs="http://www.w3.org/2001/
   XMLSchema"
 elementFormDefault="qualified">

<xs:element name="payroll">
<xs:complexType>
```

```
10
11 <xs:sequence>
12       <xs:element name="employee"
           maxOccurs="unbounded">
13       <xs:complexType>
14
15       <xs:sequence>
16          <xs:element name="first_name">
17             <xs:simpleType>
18             <xs:restriction base=
                 "xs:string"/>
19             </xs:simpleType>
20          </xs:element>
21          <xs:element name="last_name">
22             <xs:simpleType>
23             <xs:restriction base=
                 "xs:string"/>
24             </xs:simpleType>
25          </xs:element>
26          <xs:element name="salary">
27             <xs:simpleType>
28             <xs:restriction base=
                 "xs:string"/>
29             </xs:simpleType>
30          </xs:element>
31       </xs:sequence>
32
33       <xs:attribute name="id"
           use="required">
34          <xs:simpleType>
35          <xs:restriction base=
              "xs:integer">
36             <xs:minInclusive value="0"/>
37             <xs:maxInclusive
                 value="100"/>
38          </xs:restriction>
39          </xs:simpleType>
40       </xs:attribute>
41
42       </xs:complexType>
43       </xs:element>
44 </xs:sequence>
45
46 <xs:attribute name="company"
     type="xs:string" use="required"/>
47
48 </xs:complexType>
49 </xs:element>
50
51 </xs:schema>
```

In Listing 5, the XSD reference takes the form of two attributes within the root element, as shown in lines 4–6. The XSD reference makes use of XML namespaces. We will be taking a closer look at XML namespaces in the section on *Using XML to Share Data*, below.

Listing 6 shows the XSD file referenced in payroll4.xml. External schema files use the ".xsd" extension. For validity, every element, attribute, and nonstandard entity used in an XML document must be declared in its schema.

Lines 4–6 compose the *root element*. The `<schema>` tag is the root element of every XML schema. Here, `<xs:schema>` specifies that the `"xs:"` prefix is to be used as a label for all succeeding tags in order to refer to the referenced namespace.

The remaining lines in the file specify elements and attributes to be used in payroll4.xml. The XML schema spec defines two types of elements: simple and complex. A simple element is an XML element that can contain only text. A complex element is an XML element that contains other elements and/or attributes.

PARSERS AND THEIR APIS

An XML parser is software that reads (and sometimes writes) an XML file and makes its data available for sharing, display, or further processing. In order to access parser methods and tell the parser what to do, we use an API (application programming interface).

XML parsers come in two flavors. *Nonvalidating parsers* only check that an XML document is well formed and do not check for validity against a DTD or schema. *Validating parsers* not only check for well-formedness but also verify that an XML document conforms to a DTD or schema.

APIs are available in most modern programming languages. It is possible to interface with parsers using Visual Basic, Java, ASP, Python, PHP4, Perl, JavaScript, etc. Of the available APIs, most implement methods that lcan process XML files in one or both of two ways: DOM (XML document object model) or SAX (simple API for XML).

Popular Parsers

The following validating parsers are the ones in most widespread use today:

Xerces—The Apache Software Foundation's open-source Java parser.

XML4J—IBM's XML Parser for Java. Free Java parser based on Xerces.

Oracle XML Parser—Available as a free standalone and also shipped with Oracle's RDBMS products, this parser supports Java, C, C++, and PL/SQL using industry-standard DOM and SAX interfaces.

XML::Parser—Larry Walls' perl-based parser based on James Clark's *expat*.

Microsoft Parsers—Microsoft has introduced several parsers, each more conformant to emerging XML standards than the last. Microsoft shipped Internet Explorer 4.0 with version 1.0 of the MSXML parser. Later products, including Office 2000, IE 5 and 5.5, Windows 2000, and BizTalk Server, were bundled with later versions of MSXML. Microsoft's current parser offerings include the following:

MSXML 3.0—A Component Object Model (COM) parser implemented via the file Msxml3.dll. Initial Web release: November 2000. Features complete implementation of XSLT and XPath W3C specs, improved SAX2, DOM, and namespace support.

MSXML 4.0 (Microsoft XML Core Services)—Another COM object-implemented parser (Msxml4.dll) that features DOM–SAX integration and complete support for XSD schemas. Initial Web release: October 2001.

System.Xml—The "assembly" that provides XML functionality for the .NET platform.

Many more parsers, both validating and nonvalidating, are available. Ken Sall has compiled an extensive list (Sall, 2000).

Which Parser Should We Use?

In practice, the parser we use will be determined by our development platform. If we plan to serve XML documents via a Perl-based CGI, then our choice will most likely be XML::Parser. For projects hosted by a Java application server, we will wind up with Xerces or XML4J or a similar Java parser. Reading and writing XML based on data in an Oracle database management system? Then stick with Oracle XML Parser. Building an end-to-end Microsoft solution? Use MSXML or System.Xml (Simpson, 2000).

DOM and SAX—The Standard API Models

Though APIs may implement many methods to facilitate parsing, two models have become standard: DOM (document object model) and SAX (simple API for XML). All current parsers support one or both of these models in their APIs.

DOM is a *tree-based API*. Tree-based APIs map XML documents into internal tree structures and then allow applications to navigate those trees. The Document Object Model (DOM) working group at the World-Wide Web Consortium (W3C) maintains a recommended tree-based API and there are many such APIs from other sources.

DOM's tree-like representation of XML documents are stored in memory, providing random access to the contents of an entire document. A DOM tree is composed of *nodes*. All nodes in the tree are contained within a root node that corresponds to the document's root element. All other elements in the XML document are also represented as nodes, as are data contained within the elements. Figure 2 shows how Microsoft's MSXML parser implements its built-in DOM API.

With DOM, much of the work of XML processing requires navigating the tree structure to find or modify data. DOM is useful when we need to create or modify a document in memory, read a document from an XML source file, or maintain ongoing random access to various parts of the XML document. The downside to DOM is that it puts a great strain on system memory, especially for large XML documents. For example, using DOM, a 100 kilobyte (KB) XML document can produce a tree that occupies up to 1 megabyte (MB) of memory.

SAX is an *event-based API*. Event-based APIs report parsing events (such as the start and end of elements) directly to the application rather than building internal trees. SAX was originally a Java-only API developed collaboratively by members of the XML-DEV mailing list, led by David Megginson. The API, now available in many languages, is supported by most parsers and has become a *de facto* API standard. The current version, SAX2, was released in May 2000.

SAX is designed for reading, not writing, XML documents. DOM is a better choice for modifying XML documents and saving changed documents to memory. SAX's advantages are that it uses much less memory than DOM and can locate specific pieces of data much faster than DOM.

SAX processes documents serially and generates events as it finds specific symbols in the XML document. In our application, we then implement handlers to deal with the events of interest to us, much as Java applications must handle events generated by a graphical user interface.

To understand how event-based processing works, consider this example. We have an XML document that contains stock prices:

```
<?xml version="1.0"?>
<stocks>
   <company>
       <symbol>IBM</symbol>
       <price>72.50</price>
   </company>
   <company>
      <symbol>CSCO</symbol>
      <price>13.05</price>
   </company>
</stocks>
```

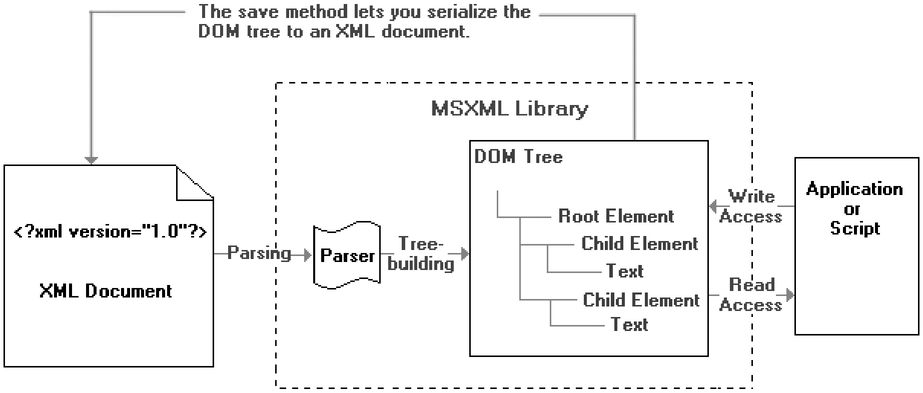

Figure 2: The DOM model. Source: Microsoft Corporation (2002a). © 2002 Microsoft Corporation. Reprinted with permission from Microsoft Corporation.

An event-based SAX interface would parse the above document and generate the following events:

```
start stocks
start element: stocks
start element: company
start element: symbol
characters: IBM
end element: symbol
start element: price
characters: 72.50
end element: price
end element: company
start element: company
start element: symbol
characters: CSCO
end element: symbol
start element: price
characters: 13.05
end element: price
end element: company
end element: stocks
end stocks
```

Now say that we are writing an application, and in our app we wish to locate the stock price of Cisco Systems (CSCO). Using the SAX interface, our app would have an easy time and be very efficient. The app's pseudocode might look something like this:

```
If event = "start element: symbol" Then
   If characters = "CSCO" Then
      For element: price
         Get characters
Stop parsing
```

A Parsing Example Using MSXML, ASP, and DOM

To get a feel for how parsing and APIs work, study the code below. This example uses Microsoft's MSXML parser running on a Windows 2000 server. IIS 5.0 processes the VBScript code in the ASP file. The VBScript code uses MSXML's built-in DOM API to traverse the XML document and dynamically generate HTML for display in a browser.

Our task is to generate an HTML page that shows Acme Corporation's organization chart. All organization data are contained in the file org_chart.xml, as shown in Listing 7. Listing 8, org_chart.asp, shows the VBScript code that uses DOM API to parse the XML document and generate HTML. Finally, Figure 3 shows the results of an HTTP request to the IIS Web server for the file org_chart.asp, as rendered in a browser.

```
<% Option Explicit %>

<html><head><title>Acme Organization Chart</title></head>
<body>
<h1>Acme Organization Chart</h1>

<%
Dim xmlObject, fileString, xmlDoc

Set xmlObject = Server.CreateObject("Microsoft.XMLDOM") 'Fire up MS XML Parser
xmlObject.async = false
fileString = Server.MapPath("org_chart.xml") 'Map a path to the XML file
xmlObject.Load(fileString)
Set xmlDoc = xmlObject

Dim deptNodes, deptItems, deptSubItems
Dim deptName, deptItemName, deptSubItemName
Dim i, j, k

Set deptNodes = xmlDoc.selectNodes("//department")
Response.Write "<ol>" & vbCrLf

For i = 0 To (deptNodes.length - 1)
  deptName = deptNodes(i).getAttribute("name")
  Response.Write "<li>" & deptName & vbCrLf ' deptLevel0
  If deptNodes(i).hasChildNodes Then
     Response.Write "<ol type = 'a'>" & vbCrLf
     Set deptItems = deptNodes(i).selectNodes ("department_sub1")
     For j = 0 To (deptItems.length - 1)
         deptItemName = deptItems(j).getAttribute ("name")
         Response.Write "<li>" & deptItemName & vbCrLf
         If deptItems(j).hasChildNodes Then
              Response.Write "<ol type='i'>" & vbCrLf
              Set deptSubItems = deptItems(j).selectNodes("department_sub2")
              For k = 0 To (deptSubItems.length - 1)
                  deptSubItemName = deptSubItems(k).getAttribute("name")
                  Response.Write "<li>" & deptSubItemName & vbCrLf
              Next
              Response.Write "</ol>" & vbCrLf
              Set deptSubItems = Nothing
         End If
     Next
     Response.Write "</ol>" & vbCrLf
     Set deptItems = Nothing
  End If
Next

Response.Write "</ol>" & vbCrLf
Set deptNodes = Nothing
Set xmlDoc = Nothing
Set xmlObject = Nothing
%>

</body>
</html>
```

In Listing 8, Lines 8–14 start the parser, load the XML document, and build the DOM tree. In Line 11, the parser's `async` attribute is set to "false" to make sure that all the XML data are loaded before any other processing takes place. Lines 16–46 then call DOM API methods to traverse the tree and generate HTML for display in the requesting browser.

USING XML TO SHARE DATA

In order to communicate, computers need to agree on the rules that govern the exchange of information. For example, we store Web page information in HTML files but we need a set of rules—the hypertext transfer protocol (HTTP)—to transfer the page information from server to client.

So too, if we wish to share XML data between different platforms, applications, and companies, it is crucial that the different systems involved agree on the structure of data within the XML document. For example, if our computer always writes company name information to the third field of a record and another computer always looks for employee salary information in the third field, it's just not going to work. In order to accurately extract and use shared data, the computers have to agree on the type of information to be contained within each field.

This definition of data structure, familiar to database programmers, is known as a schema. To share information using XML, we do the same thing. We define a common data structure using either a DTD or an XML schema.

Once we agree on a common data structure, it does not matter which mechanism we use to exchange XML files. Our computer may request XML-structured data from another using a database query, RPC, DCOM, CORBA, or Web service. As long as the XML data on each end of the request meets validation criteria defined in a common DTD or schema, then our computer will have no problem using the data.

If it's just two people sharing data, then one might write a DTD and e-mail it to the other. The computers would then each reference a local copy of the agreed DTD to validate and exchange XML data. If all the companies in our industry wish to share data, then it's a bit more involved. We have to get all of the companies to agree on a common data structure for the exchange of information—an industry-standard DTD or schema.

Industry-Standard DTDs and Schemas

Those familiar with EDI (electronic data interchange) may be aware of the years of struggle required to hammer out standard industry guidelines. This issue remains the biggest challenge to using XML to exchange data. The rewards for coming to agreement are much lower cost, clearer implementation, and cross-platform interoperability. Progress has been made in several industries.

Early adopters of DTDs and schemas for XML data interchange include the financial services, energy/utilities, and healthcare sectors. To determine the state of DTD/schema development in a given sector, check with industry groups for the most current information in the field. Or have a look at the XML.org Industry Registry at http://www.xml.org/xml/registry.jsp, which maintains a repository of hundreds of industry-standard schemas and DTDs.

Referencing DTDs in Code

If we have agreed with our trading partner(s) on a DTD to use, then it is time to reference the DTD in our code. We do this by using the `<!DOCTYPE>` tag within our XML document (refer to the section on *Creating Valid XML Documents*, above). The `<!DOCTYPE>` tag may take one of the following four forms:

```
<!DOCTYPE rootElement SYSTEM "URI/URL">
<!DOCTYPE rootElement PUBLIC "URI/URL">
<!DOCTYPE rootElement PUBLIC
  "FormalPublicIdentifier">
<!DOCTYPE rootElement PUBLIC
  "FormalPublicIdentifier" "URI/URL">
```

In the first form, the `SYSTEM` keyword means that the DTD is stored locally on our system. As an example, consider the `<!DOCTYPE>` tag in List 2 in the *Creating Valid XML Documents* section:

```
<!DOCTYPE payroll SYSTEM "C:\WINDOWS\
  Desktop\payroll.dtd">
```

Here, the URL points to the path on the local file system where the payroll.dtd document resides.

The remaining three forms of the `<!DOCTYPE>` tag all use the PUBLIC keyword to indicate that the DTD is stored remotely somewhere on the Internet. We could modify the above `SYSTEM` example to access a publicly available version of the DTD as follows:

```
<!DOCTYPE payroll PUBLIC "http://www.
  web-feats.com/dtds/payroll.dtd">
```

The disadvantage of using a `PUBLIC` copy of the DTD is that looking up resources on the Internet is time-consuming and slows down the application every time the document is parsed. Once we agree on a standard DTD with our trading partner(s), it's common to copy the DTD and reference it via the local file system. The downside to this approach is that it ties the reference to a specific file, on a specific file system, in a specific location—if we move the application to a different server, we need to modify the DTD URL. Java programmers avoid this problem by packaging all required classes, XML files, and DTDs into a single JAR file and then including the JAR in their CLASSPATH.

Probably the best-known example of the third form, using a `PUBLIC DTD` with a "formal public identifier," is the following:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.0
  Transitional//EN">
```

This is the document type declaration used in an HTML 4.0 document. Here, `HTML` is the `rootElement;`

the root tag of every HTML document is `<HTML>`. `PUBLIC` means the DTD is available somewhere on the Internet. `"-//W3C//DTD HTML 4.0 Transitional//EN"` is the formal public identifier.

The formal public identifier (FPI) system is a carryover from SGML (simplified general markup language), the standardized language from which XML is derived. Public identifier fields are separated by `"//."` Here is what all the fields in the above FPI mean:

`"-//W3C//DTD HTML 4.0 Transitional//EN"`—the dash (`"-"`) indicates that the DTD is not a standard. Use a plus sign (`"+"`) if the DTD has been approved by a standards body such as ISO.

`"-//W3C//DTD HTML 4.0 Transitional//EN"`—W3C is the name of the owner who maintains the DTD.

`"-//W3C//DTD HTML 4.0 Transitional//EN"`—DTD is the document type; HTML 4.0 Transitional is a label that describes the document.

`"-//W3C//DTD HTML 4.0 Transitional//EN"`—two-letter abbreviation for the language of the documents to which the DTD applies. EN stands for English.

For our application to use a DTD referenced by an FPI, the FPI must be converted to an Internet-accessible URL. Our parser must have the ability to do this conversion. The parser must have what is known as an *entity resolver* in order to resolve the FPI into its actual URL.

The formal public identifier system has always been unwieldy and problem-laden. We are better off directly accessing `PUBLIC` DTDs by explicitly referencing their URLs, as in the previous document type declaration form. Better still, use a local copy of the DTD.

Finally, the fourth form of document type declaration uses both an FPI and a URL. For example:

```
<!DOCTYPE payroll PUBLIC "-//WebFeats//
  DTD Payroll//EN"
"http://www.web-feats.com/dtds/payroll.dtd">
```

Here, if the parser cannot resolve the URL of the DTD from the public identifier, it uses the URL as specified (Castro, 2001).

Referencing Schemas in Your Code

If we have agreed with our trading partner(s) on an XML schema to use, then we need to reference that schema in our code. We do this by adding attributes to the root element of our XML document.

If we are referencing a copy of the schema on the local file system, two attributes are added to the root element of our XML document. As an example, consider the root element in Listing 5 in the *Creating Valid XML Documents* section:

```
<payroll company="Acme"
   xmlns:xsi="http://www.w3.org/2001/
     XMLSchema-instance"
   xsi:noNamespaceSchemaLocation="C:\
     WINDOWS\Desktop\payroll4.xsd"
>
```

Here, `xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"` tells the validating parser that the `"xsi"` (XML schema instance) syntax we are using is defined in the W3C *namespace* `"http://www.w3.org/2001/XMLSchema-instance."` The parser does not actually access this W3C URL.

The `xsi:noNamespaceSchemaLocation="C:\WINDOWS\Desktop\payroll4.xsd"` fragment tells the parser to validate against an instance of the XML Schema `"payroll4.xsd"` that lives on the local file system along the path `"C:\WINDOWS\Desktop\payroll4.xsd."`

If we wished to access a publicly available version of the schema via the Internet from a *qualified XML namespace,* we would modify the above root element as follows:

```
<payroll company="Acme"
xmlns:xsi="http://www.w3.org/2001/
  XMLSchema-instance"
xmlns="http://www.web-feats.com/2002/
  Payroll"
xsi:schemaLocation="http://www.web-feats.
  com/2002/Payroll payroll4.xsd"
>
```

Again, `xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"` tells the parser that the syntax we are using is defined in the W3C namespace.

The fragment `xmlns="http://www.web-feats.com/2002/Payroll"` tells the parser the *qualified XML namespace* of the schema it will be using for validation; all of the elements used in the XML document are defined in the "http://www.web-feats.com/2002/Payroll" namespace.

Finally, `xsi:schemaLocation="http://www.web-feats.com/2002/Payroll payroll4.xsd"` is the Internet URL and file name that the parser has to access to fetch the payroll4.xsd that is to be validated against.

XML namespaces are defined in a W3C Recommendation (World Wide Web Consortium, 1999). They provide a means of avoiding element name conflicts when an XML document references additional, external XML documents. That is, the external XML schema that we are referencing is itself a well-formed XML document. Because we define your own tag names in XML, we need to ensure that if the schema uses any of the same tag names that we have defined, the parser can differentiate between the two different tags that have the same name. By prefixing tags from each document with prefixes for different namespaces, we avoid any potential conflicts.

Well-Formed, Valid with DTD, or Valid with Schema?—XML Design Considerations

When should we use a schema or DTD? When is well-formed XML sufficient?

In general, if we are not sharing our data with another application, platform, or company, then well-formed XML is sufficient. When our application's only goal is to use

XML to generate HTML for display in a browser, valid XML is usually not required. In fact, many browsers do not even have validating parsers. A DTD or schema adds a layer of processing between the point when a user clicks and when he or she sees the Web page. If there is no need to share data, we are better off avoiding the additional overhead of a DTD or schema.

When our application needs to share data with another party, the choice between using a DTD or schema comes down to these considerations:

Is there a standard DTD or schema available for our industry? If a standard already exists that is sufficient for our needs, then we should go with it. If a DTD is available, we should use the DTD. If an industry standard schema exists, we should use the schema.

If our organization only plans to use XML to share data internally, then consider these points in deciding between a DTD or schema:

Skill level of the programmers—XML schemas are more complex than DTDs.

Extensibility—Some day we may wish to share information outside of the organization. XML schemas are becoming the data definition language of choice as the standard has solidified.

Data types—If our application would benefit from set data types within the XML structure, then XML schema is a better choice. XML schema has support for data types, whereas DTDs view all data as strings.

Parsability—If our application would benefit from machine processing of the data structure, then XML schema is a better choice. XML schemas are well-formed XML documents and can be processed by parsers. DTDs are not well-formed XML.

USING XML IN THE BROWSER

There are five ways to view XML files in a browser:

Process XML on server and dynamically generate HTML for display in a browser.

Format an XML document for display using a cascading style sheet (CSS).

Format an XML document for display using XSL and/or XSLT.

Format an XML document for display using HTML and Microsoft data islands.

View XML source code or data structure.

Because of varying levels of XML implementation and conformance in different browsers and different browser versions, most XML processing today is done on the server. The server then dynamically generates HTML for display in the browser. We saw an example of this using VBScript, ASP, DOM, and MSXML in the section on Parsers and Their APIs, above. When processing XML on the server, we can programmatically control the generated HTML to target specific user agents (mobile devices or specific browser types) or specific locales (customized pages for French, German, English, etc., audiences).

When we have control over the browser to be used for viewing, as in developing for corporate intranets, it can be useful to have the browser itself directly format XML for display. In this section we will look at direct browser XML formatting using CSS and Microsoft data islands. XSL and XSLT are discussed in another chapter in this encyclopedia. We will also look at displaying XML source code in the browser. But first, we will look at XML-compatible browsers.

XML-Compatible Browsers

Newer browsers support parsing of XML documents to varying degrees. For the most part, XML-capable browsers do not check for XML validity but only for well-formedness. Some browsers, however, provide validating parsers and also may provide support for XSL and XSLT.

Although we generally use server-side processing to dynamically generate HTML for display in a browser, the following browsers are XML-capable:

Microsoft Browsers

Internet Explorer 4.x—Limited XML support.

Internet Explorer 5.x—Supports most of the international standards for XML 1.0, XSL and DOM.

Microsoft Internet Explorer 6.x—Conforms very well to the latest World Wide Web XSLT Recommendation.

Mozilla Browsers (parser based on James Clark's expat)

Netscape 6—Limited XML support.

Netscape 7 and Seamonkey 1.0—Support standards for XML 1.0 and DOM. Direct support for other XML languages, such as MathML (mathematical equations) and SVG (two dimensional vector diagrams).

Opera (versions 4.0 and higher)—XML support added May 2000.

Jumbo 3.0—A "molecular browser and toolkit." Jumbo was created to support the Chemical Markup Language (CML). Requires Java Runtime Environment 1.3.1 or later.

Viewing XML Source Code in a Browser

If we load an XML file into Internet Explorer, the browser renders it as a tree structure (see Figure 4). To view the XML source code, right-click on the page and select "View Source."

If we load an XML file into Seamonkey or Netscape 6 or 7, the browser parses the file and displays unformatted data (see Figure 5). To view the XML source code, right-click on the page and select "View Page Source."

Using Cascading Style Sheets to Format XML Data for Display in a Browser

Using cascading style sheets (CSS) to display XML data in a browser not only is dependent upon the browser's XML implementation; but also is subject to varying degrees of browser CSS support. Here we look at an

16
17 first_name {
18 }
19
20 salary {
21   position: absolute;
22   left: 200px;
23 }
```

Lines 3–7 set font properties for the entire document—because <payroll> is the root element of the XML file, all its child nodes inherit these settings.

Lines 9–11 define each employee as a CSS *block*. This is necessary to display name and salary information on the same line; otherwise, each name and salary element would be treated as a separate block and each block would be rendered on a new line.

Lines 13–15 show how the last_name element's font-weight property overides the value inherited from the payroll element.

Lines 17–18 show that even though no properties are declared for the first_name element, font properties are inherited from the payroll element.

Lines 20–23 show use of absolute positioning to place the salary figures in their own column.

Figure 6 shows how payroll5.xml is rendered when loaded in IE 5.5. Figure 7 shows the file when loaded

in Netscape 7—note the misformatting. This is due to Netscape's implementation of CSS absolute positioning.

Using Microsoft Data Islands to Display XML Data in Internet Explorer

Internet Explorer lets us bind HTML tags to an XML data source included in the page as a "data island." Microsoft has proposed that data islands be included in the XML Recommendation, but so far W3C has not taken any action. Internet Explorer 5.0 and later are the only browsers that support data islands (Microsoft Corporation, 2002b).

Listing 11 shows an HTML file that uses data islands to parse and display data from the simple XML file "payroll.xml" (refer to Listing 1). IE identifies the `<xml>` tag as a data island. (There can be no <xml> tag within the referenced XML document.)

Listing 11: File payroll.htm.

```

USING XML CONFIGURATION FILES

A strong case could be made that configuration files are the most common use of XML today. They are certainly the most visible use of XML. Java application servers and .NET both depend on XML configuration files. Unix administrators are writing many of their config files in XML. Windows applications that previously used INI files or the Windows Registry now use XML configuration files.

Recent versions of RealNetworks RealAudio player use XML configuration files to store channels and tuner information—look at the channels.xml and tuner.xml files. In recent versions of Adobe Acrobat Readert the RdrENU.xml file is used to store version and update information.

The advantage of using XML configuration files over using Windows INI files, the Windows Registry, or Unix text files is that if we are writing an application for deployment on more than one platform, we can use the single XML config file everywhere rather than writing a different version of the config file for each platform.

Consider the following example, which stores an application's window position and most recently used file history (TurboPower Software Company, 2002):

```
<softapp>
  <mainwindow>
    <state size="normal" x="100" y="100">
    <MRUFile>
      <file>c:\bloat.txt</file>
      <file>d:\clients\wile\memo20010208.
        txt</file>
      <file>d:\rec\castlerock.txt</file>
      <file>c:\autoexec.bat</file>
    </MRUFile>
  </mainwindow>
</softapp>
```

Besides the widespread use of XML configuration files in Java application servers and .NET, more and more products are being built around XML. Table 2 shows some products that are noteworthy for their use of XML, either in configuration files or as an integral part of the product framework.

XML AND DATABASES

If we have XML, what do you need a database for? Isn't XML a programmatically accessible data source?

Bourret (2002a) answers,

> XML provides many of the things found in databases: storage (XML documents), schemas (DTDs, XML schema languages), query languages (XQuery, XPath, XQL, XML-QL, QUILT, etc.), programming interfaces (SAX, DOM, JDOM), and so on. On the minus side, it lacks many of the things found in real databases: efficient storage, indexes, security, transactions and data integrity, multiuser access, triggers, queries across multiple documents, and so on.

In real life, the need to use XML with databases arises for one of two reasons:

We need to access data from a "legacy" RDBMS (relational database management system); or

We need a repository for our XML documents; we need to "persist" XML data for long-term storage and retrieval.

To see where the first case may arise, consider this scenario. We are resellers of widgets. As orders come in from our customers, we need to order the widgets from our supplier. Orders come in to our company through our accounting software and are stored in a RDBMS. Our supplier, however, has provided us with a DTD and wishes to receive all our orders in XML format. So we must write an application that queries our RDBMS, extracts order information, and translates the orders to a valid XML format for sharing with our supplier. Our application is a *datacentric* use of XML—XML is used as a transport mechanism for data intended for machine consumption.

Contrast the preceding scenario with the following *document-centric* use of XML. Our Web site sells widgets to customers in England, France, and Germany. For each widget in our inventory, we have three XML documents, one for each of our target markets. England.xml contains a product description in English and a price in pounds. France.xml naturally contains the description in French

Table 2 Noteworthy XML Products

Product/Company	Description	URL
Ant/Apache Software Foundation	Ant is a Java-based build tool. All buildfiles generated by Ant take the form of standard XML documents	jakarta.apache.org/ant
Outlook 2002/Microsoft	Outlook 2002 lets you create and customize your own views. Each view is defined as an XML schema	msdn.microsoft.com/library/default.asp?url=/library/en-us/dnout2k2/html/odc_xmlviewdef.asp
Cocoon/Apache Software Foundation	Cocoon is an XML publishing framework that provides separation of content, logic and style	xml.apache.org/cocoon
BizTalk Server/Microsoft	BizTalk is an XML-based framework designed to facilitate electronic commerce over the Web	www.microsoft.com/biztalk

   <employee id="23">
      <first_name>John</first_name>
      <last_name>Smith</last_name>
      <salary>$34,000</salary>
   </employee>
         .
         .
         .
</Payroll>
```

Figure 9: SQL-to-XML using Java, Xerces, and Cloudscape.

and price in francs, whereas Germany.xml uses German marks. When a visitor to our Web site clicks a link for his or her preferred locale, he or she is rewarded by seeing all our glorious widgets described in his or her native tongue. So our Web application, upon user locale selection, must retrieve appropriate XML documents for each widget in our inventory. Our application then transforms XML data into HTML for viewing in a browser—document-centric XML is generally intended for human consumption.

The datacentric case utilizes a RDBMS. For the document-centric case, we may achieve best performance by using a NXD (native XML database).

XML AND RDBMS

In order to translate data between an RDBMS and XML, we must map the schema used in the RDBMS to the schema of our XML document. This is not a trivial task. Relational data mappings can be error-prone, inflexible, and time-consuming and, unless very carefully constructed, they can slow down our application's throughput.

To address the mapping problem, database vendors have developed tools that assist in converting XML documents to relational tables, and vice versa (Dayen, 2001).

Vendor Mapping Solutions

Oracle provides an XML SQL utility (XSU) that models XML document elements as a collection of nested tables. To go the other way, from SQL to XML, XSU constructs an XML document by using a one-to-one association between a table and a nested element.

IBM DB2 XML Extender provides new data types to store XML documents in DB2 databases and new functions to work with these structured documents. Managed by DB2, these documents are stored as character data or external files. Retrieval functions enable us to retrieve complete documents or individual elements.

Microsoft's SQL server extends SQL-92 with the FOR XML structure to provide SQL-to-XML mapping. For XML-to-SQL mapping, Microsoft has extended ADO by introducing the OPENXML row set.

An Example: SQL-to-XML Using Java, Xerces, and Cloudscape

Open source tools also provide methods for SQL-to-XML and XML-to-SQL mapping and data extraction. This example shows how to use Java JDBC classes to query a table in a Cloudscape database. The Xerces parser is invoked to construct a DOM tree that corresponds to the query result set. The Xerces serializer is then called to write the DOM tree to a flat file.

Figure 9 graphically depicts the process. The Payroll table in Acme's database is queried and Xerces builds the DOM tree and writes it to a file. Listing 12 shows the Java source code. Listing 13 shows the XML document that gets written to the flat file.

Listing 12: File SQLtoXML.java.

```
import java.sql.*;                 //JDBC Classes
import java.io.*;                  //Java IO classes for serialization
import org.w3c.dom.*;              //W3C DOM API classes
import org.apache.xerces.dom.*;    //Xerces DOM parser classes
import org.apache.xml.serialize.*; //Xerces classes for serialization

public class SQLtoXML {

//Declare database connection parameters

    <last_name>Smith</last_name>
    <salary>$42,000</salary>
  </employee>
</Payroll>
```

XML AND NXD

Native XML databases (NXDs) are optimized for storage and retrieval of XML documents—documents go in and documents come out. Documents are the fundamental unit of storage, similarly to the way in which rows in a table are the fundamental unit of storage in a RDBMS. NXD's main benefit arises in document-centric XML usage—we do not have to worry about mapping our XML to some other data structure; we just insert data as XML and retrieve them as XML.

The NXD storage model is able to locate documents based on their content—elements, attributes, PCDATA, and element order. To facilitate location and retrieval of documents, NXDs support one or more *query languages*. XPath is the current NXD query language of choice but XQuery, a more database-oriented language, is currently under development. Several vendors have begun to release prototype XQuery implementations for use with their databases (Staken, 2001). XQL and a number of other languages are also used for querying XML documents.

To improve the performance of queries, NXDs support *document collections*. The notion of a document collection is similar to the concept of a table in a relational database. Where a RDBMS table is a collection of rows, an NXD document collection is a collection of XML documents that share common characteristics. For example, our company may store all XML documents related to sales orders in one collection, all XML documents related to product manuals in another collection, and so on. We can then query and manipulate a document collection as a set.

To do updates on documents, most NXDs currently require that we retrieve a document, change it using our favorite API, and then return it to the database. A few products, however, have built-in support for XML:DB XUpdate, an update language that facilitates easy, direct modifications to documents stored in a database.

Like other modern data management systems, most NXDs provide support for transactions, rollbacks, security, and concurrent access (Sholtz, 2002).

Table 3 A Sampling of Current NXD Products

Product	Company	License	URL

ozone	Ozone	Open Source	ozone-db.org
Xindice	Apache Software Foundation	Open Source	xml.apache.org/xindice

NXD Vendors

Two of the more mature native XML databases products are Software AG's Tamino and Ipedo's Ipedo XML Database. Oracle's XML DB is a feature of Oracle9*i* Database and provides native XML storage and retrieval technology. The Apache Software Foundation's Xindice is a promising open source NXD.

Table 3 lists several vendors' NXDs. Many more NXDs are available. Ronald Bourret maintains an extensive list (Bourret, 2002b).

Using NXDs

Writing code to store, query, and retrieve documents from a NXD depends on the NXD product and the API methods it exposes. Although NXD code samples are beyond the scope of this chapter, many excellent resources appear on the Web, including the following:

XML Querying: XPath and XQuery (Obasanjo, 2001)—Good introduction to the two leading NXD query languages.

Apache Xindice (Apache Software Foundation, 2002)—Download the latest release. Untar/unzip and refer to the /java/examples directory for examples using Java, XPath, and the *XML:DB API*.

XML Tech Center—Sample Corner (Oracle, 2002)—Oracle-centric code for using both Oracle's NXD-like product (Oracle9*i* XML) and their standard RDBMS product.

USEFUL TOOLS

Any text editor is sufficient for writing XML. Many vendors, however, have created custom XML editing tools. These tools can be a real productivity enhancer, as many of them incorporate some or all of the following features:

XML editing and validation

Schema editing and validation

XSL editing and transformation

Automatic DTD generation from XML document and vice versa

Automatic Schema generation from XML document and vice versa

IDE workspace with multiple document views and context-sensitive property inspectors.

Table 4 shows a few of the more popular XML editors. Many more authoring tools are available. Ken Sall maintains an extensive list (Sall, 2002).

THE FUTURE

What lies in the future for XML? Start studying now; one of the topics below is sure to become the Next Big Thing.

Web Services

Web services are an XML-based means of invoking methods and programs across a distributed computing environment. We are talking about application-to-application communication. Previously this role was filled by such diverse communications protocols as COM, CORBA, DCOM, and RMI. The problem with these protocols is that they are not easily interoperable—COM can only call COM, CORBA can only call CORBA. It is not easy for an application running on a Windows desktop to call an application running on an IBM mainframe.

Web services solve this problem. Surprise, a standard that all competing camps agree upon! Think of Web

Table 4 XML Editors

Product	Company	License	URL
XML Spy	Altova	Commercial	www.xmlspy.com
XMetaL	Corel/SoftQuad	Commercial	www.xmetal.com
xmlPro	Vervet Logic	Commercial	www.vervet.com
XMLwriter	Wattle Software	Commercial	www.xmlwriter.net
XML Notepad	Microsoft	Freeware	msdn.microsoft.com/xml/notepad/intro.asp

services as RMI with a marketing department. Web services let developers invoke services running on local and remote resources using a platform-independent range of client applications.

Consider this example. An insurance company has agents preparing quotations from headquarters, branch offices, and remote dialup connections. To prepare the quotations, software being run by the agents needs to access actuarial tables. If the tables are included within each locally installed software package, then every time the tables change, all 6,000 agents in the company must be sent CD-ROMs with the new data. The Web services solution? Host the actuarial tables (the business rules) at one central location and have all the distributed applications request data from the central repository. That way, when the rules change, all clients immediately have access to the latest data. The general principles are (a) encapsulate the business rules, (b) provide methods to access them, and (c) make the methods accessible over the intranet or Internet.

The Web services solution is implemented using three XML-based languages:

WSDL (Web services definition language)
SOAP (simple object access protocol)
UDDI (Universal description, discovery, and integration).

A WSDL document exposes the methods of the application being offered as a Web service. The location (URI) of the WSDL is registered in a UDDI repository and accessed via a UDDI request. SOAP provides the messaging protocol used in the client-to-UDDI-to-WSDL-to-service communication.

Several companies already offer free usage of public UDDI repositories. For example, IBM maintains a registry at https://uddi.ibm.com/ubr/registry.html, Microsoft at http://uddi.microsoft.com/default.aspx, and Oracle at http://otn.oracle.com/tech/webservices/htdocs/uddi/content.html.

It is not necessary to use a public UDDI repository. Tools are readily available that let companies create their own private UDDI registries hosted on the company intranets. In fact, this author, for one, sees intranets as the primary consumer of Web services. Web services that are offered over the public Internet suffer from the Scylla and Charybdis of latency and security concerns.

ebXML

ebXML (electronic business extensible markup language) is a joint initiative of the United Nations (UN/CEFACT) and OASIS, whose goal is to create a single global electronic market.

To facilitate global commerce, the ebXML business process specification provides a standard framework for defining business transactions. The current version of ebXML supports binary collaboration (business between two parties). Future versions will support business collaboration among multiple parties (Siddalingalah, 2001).

ebXML draws upon ideas similar to Web services. To interact with a trading partner, a company first accesses an ebXML registry to determine business rules both parties can agree on to govern the transaction. Current proposals call for using UDDI and SOAP to access the ebXML registry.

ebXML is not so much a new specification as a codification of existing standards and business practices. Whereas ebXML hopes to succeed EDI (electronic data interchange), official descriptions tend to emphasize learning from EDI rather than throwing it out. The ebXML specifications tend to incorporate what businesses do anyway, rather than trying to get companies to do business differently. The ebXML initiative clearly holds an embrace-existing-standards-and-methods attitude (Mertz, 2001).

VoiceXML

VoiceXML is a server-side technology for creating voice interfaces. It uses speech recognition or touchtone keypads for input and prerecorded audio or text-to-speech synthesis for output.

One popular application of VoiceXML is the voice portal, a telephone service where callers dial a phone number to retrieve information such as stock quotes, sports scores, or weather reports. Other possible applications include voice-enabled intranets, contact centers and notification services, and more exotic applications such as speech-controlled home appliances (Rehor, 2001).

Although voice-based technologies are likely to see continued development, conflicting standards may impede the acceptance of VoiceXML. VoxML, introduced by Motorola in September 1998, is a more mature technology than VoiceXML but contains less advanced features. Microsoft is active in SALT, another voice XML technology introduced in 2002.

Because “voice browser” technology requires extensive server-side architecture, companies that have invested in their own implementation schemes may be unlikely to abandon them.

GLOSSARY

Data-centric Type of application that uses XML as a transport mechanism for data intended for machine consumption.

Dialect Any XML-based language that conforms to W3C’s syntactic and semantic rules. Usually designed to address one particular class of data, such as musical or chemical notation. Also known as a *grammar*.

Document-centric Type of application characterized by the display of XML data for human consumption.

DOM (Document Object Model) An API (Application Programming Interface) that maps an XML document into an internal tree structure.

DTD (document type definition) Used to check the *validity* of an XML document; defines the order tags should appear in and which tags can appear inside what other tags. May also define *entities*.

Element The basic unit of data storage in an XML document. An element consists of a start tag, an end tag, and everything between the start and end tags.

Entity An “escape sequence” that starts with an ampersand (“&”) and ends with a semicolon (“;”). Entities provide a shorthand notation for special characters, words, or phrases that may be used within an XML document.

Grammar See dialect.

Namespace A means to avoid element name conflicts when more than one XML document is referenced within a single application.

Parser The application that reads and interprets XML. Also known as an *XML processor*. Parsers reject XML documents that are not *well-formed* and may also check for *validity*.

SAX (simple API for XML) An API (application programming interface) that reports parsing events (such as the start and end of elements) directly to the application rather than building an internal tree.

Schema Like a DTD, a schema is used to check the *validity* of an XML document. Unlike DTDs, schemas are well-formed XML documents that support data typing.

Valid Well-formed XML that is validated against a DTD or schema is valid XML.

Well-formed XML with correct syntax is well-formed XML.

XML (extensible markup language) A text-based, human- and machine-readable language used for sharing data over Web, intranets, and extranets.

XML processor See parser.

XML, XML EVERYWHERE, BUT NOT A DROP OF COMPATIBILITY

If we both store our data as XML, we should be compatible with each other, right? Unfortunately, no. The XML Recommendation specifies how XML documents are formed, but not how the data they contain should be organized. Consider, for example, the many valid ways to store a date:

```
<date>February 26, 2002</date>  <!-- American standard     -->
<date>26 February 2002</date>   <!--  European standard    -->
<date month="February" day="26" year="2002"/>  <!-- no ambiguity -->
<date>                          <!-- reasonable alternative   -->
   <month>Feb</month>             <!--  which also eliminates  -->
   <day>26</day>                  <!--  ambiguity but now uses -->
   <year>2002</year>              <!--  an abbreviation for the  -->
</date>                         <!-- month name             -->
<date>2/26/02</date>            <!-- common American abbreviation -->
<date>26.2.2002</date>          <!-- common European abbreviation -->
<date>2002-02-26</date>         <!-- ISO 8601 format, standard used -->
                                <!--    in XML Schemas          -->
<date>37313</date>              <!-- serial number  -->
```

The simple solution, of course, is for everyone to agree to express dates in the same format. As the flower girl cum socialite mused in *My Fair Lady,* "Wouldn't it be loverly?" But as the auctioneer cum Mafioso chirped in *Mickey Blue Eyes,* "Fughedaboudit!"

The problem is not that people disdain compatibility, it's that XML allows each of us to wrap our data in any tags that make sense to us alone. There are no standards for tag names. So even though Company A may really want its inventory system to automatically communicate with Company B's order processing system, and even though Company A's sending program can generate XML output and Company B's receiving program can take XML input, the two may still not be able to communicate. Both may be Y2K compliant, but if Company A's program represents the year number in an element (`<year>2002</year>`) and Company B's program expects an attribute on a `date` tag (`year="2002"`), well, "never the twain shall meet." The analogy here is that if you ask for a "hoagie" in a town where such sandwiches are known as "grinders," "heroes," or "subs," you'll very likely go hungry. "But this is no big deal," you say. "All one has to do is write a simple C++ or Java program to convert one data format to another." I fear that such programs are not as simple as they may at first appear, and of course the more complex the conversion, the more complex the conversion program. XML data are fairly easy to create and maintain, while C++ and Java programs are not. It would be nice if we had an

Figure 1: The Internet Explorer default rendition of XML data. (This file is adapted from one developed by Mary Stehlin in an XML class taught by the author at McKessonHBOC, Inc., in Alpharetta, GA, May 2000.)

XML-based solution to convert XML data from one format to another. This is precisely what XML stylesheet language *transformation* (XSLT) is for.

A "stylesheet language" may seem a strange moniker for a protocol that converts one data format to another, but the name is historical. XSLT is a component of the extensible stylesheet language (XSL), which was originally conceived as a native XML replacement for cascading style sheets (CSS), just as the schema was conceived as a native XML replacement for document type definitions (DTDs). The XSLT part of XSL is an extremely powerful and efficient method for viewing XML data in a variety of formats. It does this by essentially transforming XML into HTML. A few examples will make this readily apparent.

Formatting XML-based Web Pages

If one brings up XML data in Internet Explorer, one sees a nice tree-structured rendition such as that in Figure 1. Microsoft has cleverly made this display interactive,

Figure 2: The same data formatted with XSL.

allowing the user to expand and contract subtrees by clicking the + and − prefixes. This is nice for developers, but rather awkward for regular folks who are interested in the data per se, not its XML representation.

A relatively few lines of XSL can transform these data into the user-friendly format shown in Figure 2. In this example, XSL was used to generate the entire HTML page being displayed, but one could just as easily use XSL to format just part of the page. Thus dynamic data stored in XML format can be integrated with dynamic or static data stored in other Web-friendly formats to produce pages that not only look good, but also allow more sophisticated processing because the data have semantics (expressed in XML tags) rather than just formatting information (expressed in HTML tags).

(For readers who want to dive right into code, listings for this and the examples in Figures 3 and 4 are provided in the Appendix. Also note that the Internet Explorer XSL Engine will not apply XSL formatting to an XML file that contains a schema reference on the root node!)

Generating Reports from XML Data

If one looks carefully at Figures 1 and 2, one will notice that "Mootsie" appears as the fourth cat in Figure 1, yet is listed second in Figure 2. This is an indication that XSL can do more than just format data: It can also rearrange it. Rearrangement is another simple type of transformation (Cagle, 2000a). XSL can also *filter* XML data, that is, extract selected elements whose values match a given *pattern*

and, if so desired, juxtapose their data values with those of other selected elements. Such “filtering” is similar to “selecting” data from relational databases with SQL queries that incorporate `WHERE` clauses. Furthermore, XSL can *sort* data on the values of any XML element, allowing data to be presented in an order that makes sense for the purpose at hand.

These types of basic transformations are the essence of generating reports, that is, presenting different views of the same data for different purposes or different audiences. Figure 3 shows the cats in order of their birth dates. Figure 4 shows only the two female cats and presents just their IDs, names, and number of kittens. Each of these reports was generated from the same XML file by applying a different XSL file to its contents.

Resolving Differences Between Disparate XML Data

The DOB data in the Cats XML file is stored in ISO 8601 format, an international standard that defines a method for writing dates and times unambiguously (W3C, 1997). The date part of the standard specifies that a four-digit year be followed by a two-digit month (with a leading zero if necessary) and a two-digit day (again possibly with a leading zero). Hyphens separate the three data items, making `YYYY-MM-DD` the common abbreviation for this format. In addition to being unambiguous, dates expressed in ISO 8601 format have the distinct advantage of being alphabetically sortable. That is, a simple alphanumeric sort will correctly put “2002-01-31” before “2002-02-01,” while the same sort would incorrectly put “January 31, 2002” after “February 1, 2002” and “31.01.2002” after “01.02.2002.”

When a programmer is confronted with the need to compare dates stored in the many formats shown at the beginning of this chapter, one approach is to convert all dates to ISO 8601 format and then do the required comparison (see Figure 5). XSLT provides the capability to do this and similar conversions with relatively few lines of code and surprising execution speed. (Code to do this is presented in the final example of this chapter.) Using XSLT for this task allows a programmer to stay within the XML paradigm, eliminating the need to write functions in other, more general purpose languages.

Communicating Between Applications

The first two sample XSL applications discussed above transform XML into HTML. The third transforms data from one form of XML to another. XSL can actually be used to transform XML data into virtually any text-based format, thus making it an invaluable partner to XML in situations where one application must exchange data with another (Cagle, 2000b).

Consider, for example, the relationships between various components in a multitiered Web application (see Figure 6). A customer might browse product descriptions and prices online using HTML generated from XML. When the customer places the order, that same XML

might be processed by another XSL file to generate an SQL query that determines product availability. The accounting department will need the same information in a form compatible with its invoice-generating program, and XSL might provide that in a comma-delimited data stream. The shipping department may require yet another form to generate pick lists and mailing labels. Once again, XSL might be used to perform the required transformation.

WHAT XSL IS AND IS NOT

"Decorating" vs. "Transforming" (CSS vs. XSL)

At first glance, XSL may appear to be for XML what CSS is for HTML. Alternatively, a cursory comparison of CSS and XSL might lead one to reasonably—but erroneously—conclude that XSL is a "better" type of CSS. Indeed, one can apply CSS to an XML document to achieve some of the capabilities we have demonstrated with XSL. For example, Figure 7 shows the Cats XML file with CSS attributes applied. However, Table 1 explains the real differences between CSS and XSL. Thus XSL is not a better type of CSS. It is really a different technology with capabilities for manipulating XML data, while CSS is still as valuable as ever for controlling the appearance of generated HTML elements.

XSL as an XML Document

Any discussion of what XSL is and is not will reveal different opinions based on how one uses this technology. However, one issue is not open to debate: XSL structure. An XSL document is first and foremost an XML document, and as such it must conform to all the syntactic and semantic rules for XML documents. This means that if one includes HTML constructs in an XSL file (a common practice), they must be well-formed. All start tags must have end tags or be self-closing (end with `/>` rather than just `>`). Thus one cannot use HTML tags such as `<br>` and `<img>` in an XSL file without their corresponding end tags, `</br>` and `</img>`, which almost never appear in standard HTML. Shortcuts are allowed, such as `<br/>`. (The author has found that `<br/>` [without any spaces] is sometimes interpreted as `<br><br>` by browsers. `<br />` [with a space between the `r` and the `/]` seems to be reliably interpreted as a single `<br>` tag.) One also cannot use entity references such as `&nbsp;`, because XSL has only five predefined entity references: `&lt;`, `&gt;`, `&amp;`, `&apos;`, and `&quot;`. (For `&nbsp;`, you can use `&#160;`.) Finally, if generating HTML, one must be more careful with white space characters, because these are significant in XML while typically insignificant in HTML. These types of issues become moot if one works in XHTML, which is a version of HTML that conforms to XML standards, thus requiring all documents to be well-formed in the XML sense.

The characteristic that clearly distinguishes XSL documents from all other XML documents is their *namespace*. The most recent XSL namespace is http://www.w3.org/1999/XSL/Transform (W3C, 1999), but one may see some older books and papers using a previous version, http://www.w3.org/TR/WD-xsl. 5 (including version 5.5) only supports the older version unless one adds a plug-in. Internet Explorer 6.0 supports the newer version, which is more complete and more closely conforms to the W3C Recommendation. The many various versions of all browsers, including Netscape and Mozilla, provide widely varying built-in levels of support for XSL.

The XSL Processing Model

Purists will state that XSL is a *pattern-matching* language, not a *programming* language. Indeed, it would be quite cumbersome to do many general purpose programming tasks in XSL. There are, however, a number of programming constructs built into XSL, such as `if` constructs, `choose` constructs (analogous to `switch` or `select` in other languages), sorting, iteration, recursive descent, and numerous others as well as pattern matching.

The overall strategy, however, is *declarative* rather than procedural or functional. This means that you "specify how you want the result to look rather than saying how it should be transformed" (Anderson et al., 2000, p. 375). An XSL *engine*—software that applies an XSL file to an XML file—first loads an XML source document and an XSL stylesheet into memory (see Figure 8). Internally, each of these documents is represented as a multibranching tree.

The XSL engine then begins processing the stylesheet tree at its root node. The output specifications in this node may cause other stylesheet nodes to be applied to the source tree in turn. Those may be applied to the whole source tree, selected subtrees, or collections of source tree nodes. Each stylesheet node specifies how the transformation result for some part of the source tree is to look. As shown in Figure 8, applying stylesheet specifications to a source tree results in the XSL engine generating a *result tree*. That result tree can then be output in any of a number of formats, of which text, HTML, and XML itself are the most common.

XSL APPLICATION INFRASTRUCTURE

The Minimal XSL Document

As mentioned above, an XSL document is first and foremost an XML document. Thus all XSL document files begin with the standard XML *processing instruction:*

```
<?xml version="1.0" ?>
```

(As of February 16, 2003, there is only one officially accepted version of XML, so the version number is always 1.0. The W3C Recommendation for XML Version 1.1 is currently under review.)

The *root element* of an XSL document is always `stylesheet`. This element name comes from the XSL namespace, so it must be preceded by a *namespace prefix* (W3C, 1999) followed by a colon. By convention, most people use `xsl` as the namespace prefix, declared with an `xmlns` attribute on this root element (see below). In addition, the stylesheet element requires a `version` attribute, which (like XML itself) is currently 1.0. Thus the minimum well-formed and valid XSL document that uses the most recent XSL namespace (as of July 2002) must contain the following three lines:

Table 1 Capabilities of CSS vs. XSL

CSS	XSL
CSS controls the formatting properties of elements, their so-called "decorations"	XSL "transforms" an XML tree into a new tree
CSS cannot reorder elements, generate text, or perform calculations	XSL can do all of these
CSS cannot access XML attributes	XSL has full control over XML attributes, just as it does over elements
CSS can only render a node's value once	XSL can use a node's value as many times as desired and in as many contexts as needed

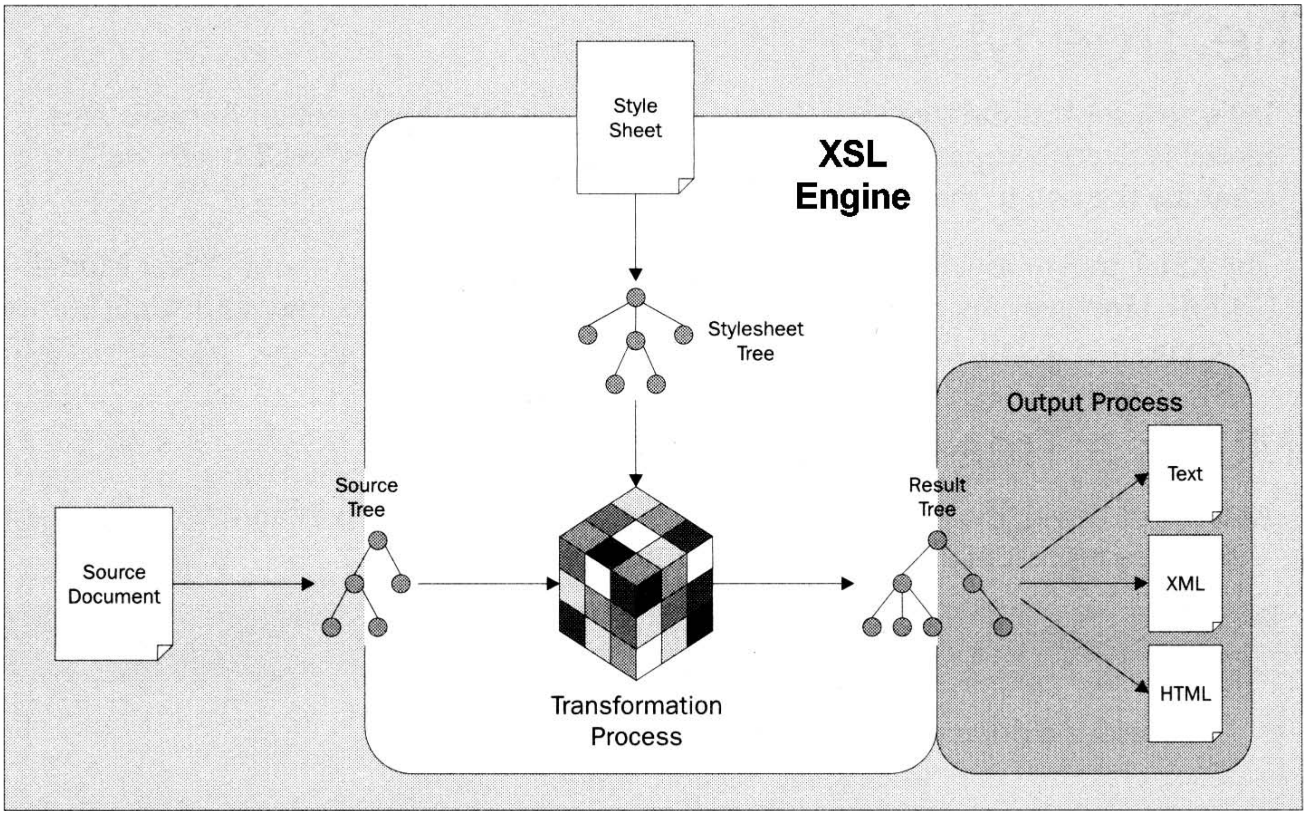

Figure 8: The XSL processing model (Kay, 2000, p. 49). (Copyright © 2000, Wrox Press, Ltd. All rights reserved. Used with permission.)

```
<?xml version="1.0" ?>

  "http://www.w3.org/1999/XSL/Transform"
    version="1.0">
    ...
</xsl:stylesheet>
```

XSL Templates

The abstract stylesheet nodes referred to in the discussion of the XSL processing model above are specified using XSL *templates,* which are introduced by the `xsl:template tag`. These can be thought of as pieces of output that get generated—or further specifications that get processed—when the XSL engine state causes those templates to be applied. Each template is differentiated by a *match condition* that identifies the *context* in which it is applied. (Templates with identical match conditions may optionally be differentiated by *modes*.)

The XSL engine starts its processing with the template whose match condition specifies the XSL document's root context. The `template` tag for this node is

```
<xsl:template match="/">
    ...
</xsl:template>
```

It is important to realize that the XSL document root context is *not* the XML document root node. One should think of the XSL root context as an abstract context *just above* the XML root node, as represented in Figure 9. This template is equivalent to the `main` function in a C or C++ or Java program: it is where processing begins. The output specified here is typically code that "frames" output that will be generated by other templates. For an XSL document designed to generate HTML, this means that this "main" template typically contains at least the opening and closing `<html>` and `</html>` tags, most of the output for the `head` section, and the `body` tags. A simple XSL file structured in this way is shown in Listing 1.

If you try to bring up this file in Internet Explorer Version 6.0, you will get the XML tree display shown in Figure 10. This is because an XSL file *is an XML file,* and without *applying* it to an XML file via an XSL *engine,* it is no different than any other XML file.

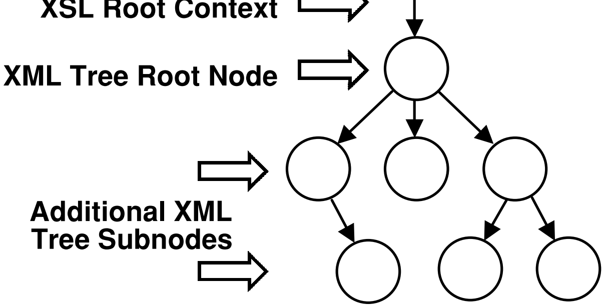

Figure 9: The XSL root context vs. the XML root node.

```

Choosing an XSL Engine

When it comes to selecting an XSL engine, there are many choices. We will follow the lead of most other books on this subject by using the XSL engine built into Internet Explorer 6.0 (Microsoft, 2002), because that makes it easy to see our results. As mentioned earlier, the XSL engine in Internet Explorer 6.0 conforms quite well to the latest World Wide Web XSL Recommendation, but the one in previous versions of Internet Explorer does not.

However, one should realize that there are numerous other high quality XSL engines available and several ways to link an XML file to an XSL file using these engines. The choice of which engine and which technique to use depends largely on where one is using XSL (on the client side, the server side, or in a stand-alone application) and the format of one's XML and XSL documents (files on disk or data structures in memory). We cannot explore all the possibilities in this chapter, but it is worth mentioning that the differences in browser versions at the time of this writing make applying XSL on the client side extremely unreliable.

Most of today's XSL processing that generates HTML Web pages is therefore done on the server side. A popular XSL engine that integrates very smoothly with Java Web servers is the Xalan-Java engine, which is available free of charge from the Apache Software Foundation (Apache, 2002). In this chapter we will work with the client-side Internet Explorer engine, but the appendix provides listings of small programs to apply XSL files to XML files on the server side. These programs include a small, self-contained JavaServer Page that demonstrates using hard-coded XML and XSL file names and an analogous Java Servlet that processes XML and XSL file names supplied by an HTML form.

Applying an XSL File to an XML File

To link an XSL file to an XML file, one can include a processing instruction in the XML file that specifies the relative path to the XSL file to be applied:

```
<?xml-stylesheet type="text/xsl"
 href="hello.xsl" ?>
```

Hello, XSL!

Figure 11: File `hello.xsl` applied to XML file `hello.xml`.

Since the simple XSL file in Listing 1 makes no reference to the elements in any XML file that may link to it, we can create a minimal XML file that includes only this processing instruction and some arbitrary root tag required to make the XML document well formed. Bringing up the XML file shown in Listing 2 in Internet Explorer Version 6.0 generates the output shown in Figure 11.

Listing 2: Minimal XML file that links to an XSL file.

```
 1 <?xml version="1.0"?>
 2 <!--
 3   hello.xml - minimal version including
 4     xml-stylesheet processing instruction
 5   updated by JMH on April 11, 2002
 6 -->
 7 <?xml-stylesheet type="text/xsl"
 8   href="hello.xsl" ?>
 9 <hello>
10 </hello>
```

Inserting the `xml-stylesheet` processing instruction in an XML file as done at line 7 in Listing 2 is equivalent to hard-coding the link. Microsoft JScript (their extended version of JavaScript) provides the ability to load XML and XSL files dynamically and apply one to the other under program control. This technique allows XML data styled with XSL to be seamlessly integrated into HTML pages. The minimal code to accomplish this is shown in Listing 3. (One could, of course, read the file names into variables and apply them dynamically, but they are shown hard-coded in Listing 3 for simplicity.) Of course, JScript is only one way to apply XSL to be applied to XML dynamically. The appendix includes code to do so through a JavaServer Page and a Java Servlet, and other techniques are possible as well.

EXTRACTING XML DATA

We're now ready to explore the code that gives XSL technology its real power. This code centers around the `xsl:template` element we have already seen, but with considerably more complexity. A large portion of that complexity resides in XPath, the language used to express the crucial *patterns* that appear in the `match` and `test` attributes of XSL elements. Like XSLT, XPath is an integral part of XSL. Of course, entire books have been written about XSLT and XPath (see, for example, the *XSLT Programmer's Reference* by Michael Kay, 2000), but the scope of this chapter is considerably less ambitious. It strives only to give a feel for the types of things one can do with some of the basic XSLT elements, how XPath is used to apply those elements to selected parts of the XML tree, and how one should think of an XSL document as a whole.

We'll use the XML file in Listing 4 for the examples in this section. This file contains information on the titles and authors of four of the chapters in the *Internet Encyclopedia* using a variety of XML structures. These structures allow us to demonstrate how XSL can address each piece of data by applying different XSL files to this XML document. Most of the transformations in the remainder of this chapter were generated under program control using the minimal JScript code shown previously in Listing 3, which explains why there is no `xml-stylesheet` processing instruction hard-coded in the `book.xml` file shown.

Extracting Single Data Items

Extracting Data Stored in Element Nodes

The main way to extract data from an XML document is via the `xsl:value-of` element, and the heart of that element is the `select` attribute which specifies the data to be extracted. The value of the `select` attribute is an XSL *pattern*. The syntax of that pattern is an XPath *expression,* which defines a *collection* of XML nodes for processing by XSLT. Let's replace line 14 in Listing 1 with

```
<xsl:value-of select="book/chapter/
  affiliation/department" />
```

The result is the single string:

```
    Information Technology
```

To understand why, consider the following points:

Listing 3: Minimal JScript code to apply an XSL file to an XML file.

```
<html>

```

- This `xsl:value` instruction is being executed within the `xsl:template` element whose match attribute is `"/"`. Therefore, as shown previously in Figure 9, the context of this template is the XSL root context, just above the XML root node.
- To "descend into" the XML document, we must therefore first reference the XML root node, `book`.
- To descend further into the document, we refer to the nodes in the order in which they appear in the XML source tree, separating successive tree levels with forward slashes (/). This is basic XPath syntax. The pattern is most easily read from right to left: we are looking for a `department` node that has an `affiliation` node as its parent, a `chapter` node as its grandparent, and a `book` node as its great-grandparent.
- When, as in this case, the XSL pattern references a node whose only child is an unnamed text node (that is, an element whose DTD specification is `<!ELEMENT` *elementName* `(#PCDATA)>`), the `xsl:value-of` element returns the text stored in that node. Thus in this case we get the text "Information Technology."
- Note that in this example the text of only the first node that matches the XPath specification in the `select` attribute is returned. (We will see how to reference groups of nodes a little later.)

Extracting Data Stored in Attribute Nodes

To extract data stored in attributes, we use the @ sign:

```
<p><i>Chapter Title:</i>&#160;
   <xsl:value-of
     select="book/chapter/@title"/>
</p>
```

Reading the pattern from right to left: we are looking for the text stored in an attribute node named `title` that is a child of a `chapter` node which is in turn a child of a `book` node. We've added some additional HTML code to this group of instructions to show further how XSL output can be wrapped in formatting text. The resultant output is:

```
   Chapter Title: Cascading Stylesheets (CSS)
```

Extracting Text Data in Mixed Content Nodes

Look at the structure of the data stored inside the `affiliation` tags in Listing 4. This type of structure is called *mixed content* because it includes both text and subelements. The DTD code for this structure is

```
<!ELEMENT affiliation
  (#PCDATA | department | e-mail)*>
<!ELEMENT department (#PCDATA)>
<!ELEMENT e-mail (#PCDATA)>
```

If we try to extract the text data stored in the `affiliation` node that begins on line 10 in Listing 4 with the statement,

```
<xsl:value-of
  select="book/chapter/affiliation" />
```

the result is all of the text in all of the subelements:

```
   University of Montana Information
     Technology pratter@cs.umt.edu
```

To get only the text at the first level of the `affiliation` node, we use another XPath feature called a *location path* (W3C, 2001). In this case we want to use the `text()` location path, which selects all the text node children of the context node. In the problem at hand, the context node is `affiliation`. So to get just its text, we use the statement:

```
   <xsl:value-of select="book/chapter/
     affiliation/text()" />.
```

This gives us just the text we desire:

```
    University of Montana
```

We have now seen how to extract data from elements that contain only text, attribute values, and nodes that contain mixed content. These are the three most common situations for any *single* piece of data. Let's now see how to extract sets of data.

Extracting Sets of Data Items

Iteration

One way to extract sets of data is to use the `xsl:for-each` instruction. Like the `xsl:value-of` instruction, `xsl:for-each` has a `select` attribute, but this time the attribute is interpreted as a *node set expression* that selects all the XML data items that match its XPath expression. The `xsl:for-each` instruction then applies the template between its start and end tags to each node in the set.

Java Server Pages (JSP)
JavaScript
Extensible Stylesheet Language (XSL)
Extensible Markup Language (XML)

Figure 12: Result of applying the XSL iteration construct in Listing 5 to the XML file in Listing 4.

Consider the code in Listing 5. The `xsl:for-each` instruction appears at line 13, and its XPath specification (reading right to left) selects all of the `chapter` elements that are children of `book` elements. This listing also formats the XSL output as an HTML table, a common practice with tabular data. Applying the XSL file in Listing 5 to `book.xml` in Listing 4 results in the display shown in Figure 12.

Listing 5: XSL iteration with the xsl:for-each instruction.

```
 1 <?xml version="1.0" ?>
 2 <!--
 3   book2.xsl
 4   updated by JMH on April 15, 2002
 5 -->
 6 <xsl:stylesheet xmlns:xsl=
 7   "http://www.w3.org/1999/XSL/Transform"
 8  version="1.0">
 9 <xsl:template match="/">
10   <html>
11     <body>
12       <table border="1">
13           <xsl:for-each
14             select="book chapter">
15              <tr>
16              <td>&#160;<xsl:value-of
17                select="@title" />&#160;</td>
18              </tr>
19           </xsl:for-each>
20       </table>
21     </body>
22   </html>
23 </xsl:template>
24 </xsl:stylesheet>
```

This example also demonstrates the important concept of *node context changes*. Note that the XPath expression in the `xsl:value-of` instruction's `select` attribute (line 16 in Listing 5) is `"@title,"` not `"book/chapter/@title"` as in the example we looked at for extracting data stored in attribute nodes:

```
<p><i>Chapter Title:</i>&#160;
   <xsl:value-of
     select="book/chapter/@title"/>
</p>
```

The difference here is that the `xsl:for-each` instruction *changes the context* of the instructions inside its start and end tags to the node specified in its `select` attribute. Thus line 16 is executed in the context of a `book/chapter` node. Saying it another way, line 16 is executed on a `book/chapter` *subtree*. We extract the text in the `title` attribute by referring to the XPath *relative to* the current context. Since we're already at `book/chapter`, we only have to go down one more level to `@title`. Understanding context changes is crucial to understanding the preferred way of extracting sets of data items: using recursive descent.

Recursive Descent

There is nothing wrong with iteration, but it is generally thought of as a procedural construct. Since XSL is declarative by nature, creating additional templates and applying them under certain conditions is more in keeping with XSL's overall design philosophy. Templates can be applied recursively as one descends into the XML source tree. Thus this technique is a form of *recursive descent*.

The XSL instruction used to apply templates is aptly named `xsl:apply-templates`. Like the `xsl:for-each` instruction, `xsl:apply-templates` uses a `select` attribute to specify a set of nodes to which matching templates should be applied.

To change the code in Listing 5 from iteration to recursive descent, we first replace lines 13–19 with the single statement:

```
<xsl:apply-templates
  select="book/chapter" />
```

We then define a new template:

```
<xsl:template match="chapter">
  <tr>
    <td>&#160;<xsl:value-of select=
      "@title" />&#160;</td>
  </tr>
</xsl:template>
```

Note that the value of the match attribute is not only another XSL pattern, but also note that the context of this pattern is somewhat "free floating" and does not include the full XPath expression in the xsl:apply-templates select attribute. In this example, match="chapter" will cause this template to be called *whenever* the context is "chapter," which it is when we specifically descend into the XML document's book node and select all the chapter nodes. The output generated by the xsl:apply-templates and xsl:template instructions is exactly the same as that in Figure 12.

If chapters had subchapters that were also identified with chapter tags, we could do a true recursive descent into the source tree to find all the chapter nodes by changing the xsl:apply-templates instruction's select attribute as follows:

```
<xsl:apply-templates select="//chapter"/>
```

Again reading right to left, this expression tells the XSL engine to select "all chapter nodes that are children of any other node." Since the selection is made recursively, all chapter nodes in the following structure would be processed:

```
<chapter title="Extensible Stylesheet Language (XSL)">
  <author last="Heines" first="Jesse" middle="M." />
  <title>Associate Professor</title>
  <affiliation>University of Massachusetts Lowell
     <department>Computer Science </department>
     <e-mail>heines@cs.uml.edu</e-mail>
  </affiliation>
  <chapter title="XML, XML Everywhere, But Not a Drop of Compatibility" />
  <chapter title="What XSL Is and Is Not" />
  <chapter title="XSL Application Infrastructure" />
  <chapter title="Extracting XML Data" />
</chapter>
```

Filtering

One last variation before we move on: the ability to simulate queries into the XML data by *filtering* the set of extracted data items. To do this, one adds a Boolean expression enclosed within square brackets to an XPath. (Such expressions are more precisely called *predicate expressions* and are an integral part of XPath.) For example

```
<xsl:apply-templates select=
  "book/chapter[not(author/@middle)]"/>
```

returns the set of all chapter nodes that are children of book nodes and whose child author nodes do *not* include a middle attribute. (For our sample XML file, this statement would select the nodes for **Frederick Pratter**, **Constantine Roussos**, and **John Ulmer**.)

It is easy to see that such filters can quickly get very complex. The standard Boolean =, !=, and, or, and not operators exist in XPath, as well as numerous functions such as contains and starts-with for strings. When working with strings, remember that an XSL document is an XML document, so single quotation marks must be included inside double quotation marks, or vice versa, because there is no escape character like "\" in C/C++/Java.

This feature provides some of the capabilities of a WHERE clause in SQL queries. For example,

```
<xsl:apply-templates
      select="book/chapter[starts-with
        (author/@first,'J')]"/>
```

returns the set of all chapter nodes that are children of book nodes and the value of the first name attribute of the child author node begins with the letter J. (For our sample XML file, this statement would select the nodes for **Jesse Heines** and **John Ulmer**.)

Sorting Transformations

Once one knows how to refer to each type of data in an XML source using XPath expressions and iterate over sets of nodes or recurse into the XML tree, one has full access to the XML data and can use XSL to transform it in a myriad of ways. Let's look at sorting as an example. This is accomplished by adding xsl:sort instructions as children of either the xsl:for-each or xsl:apply-templates instructions.

The xsl:sort element has three main attributes:

- select specifies the data on which to sort
- data-type is typically either "text" or "number"
- order is either "ascending" or "descending"

If one includes multiple xsl:sort instructions, the first is taken as the primary sort key, the second as the secondary sort key, etc.

The code in Listing 6 generates a table showing the five chapters sorted primarily on the authors' last names and secondarily on their first names. The output is shown in Figure 13.

Listing 6: Sorting data.

```
 1 <?xml version="1.0" ?>
 2 <!--
 3   book3.xsl
 4   updated by JMH on April 15, 2002 at 11:49 AM
 5 -->
 6 <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0">
 7
 8 <xsl:template match="/">
 9   <html>
10     <body>
11       <table border="1">
12         <xsl:apply-templates select="book/chapter">
13            <xsl:sort select="author/@last" data-type="text" order="ascending" />
14            <xsl:sort select="author/@first" data-type="text" order="ascending" />
15         </xsl:apply-templates>
16       </table>
17     </body>
18   </html>
19 </xsl:template>
20
21 <xsl:template match="chapter">
22   <tr>
23      <xsl:apply-templates select="author" />
24      <td>&#160;<xsl:value-of select="@title" />&#160;</td>
25   </tr>
26 </xsl:template>
27
28 <xsl:template match="author">
29    <td nowrap="">
30     &#160;<xsl:value-of select="@last" />,
31     <xsl:value-of select="@first" /> &#32;
32     <xsl:value-of select="@middle" />&#160;
33     </td>
34 </xsl:template>
35
36 </xsl:stylesheet>
```

Note the following points about this code.

Lines 13 and 14: The XPath in the `xsl:sort` instructions' `select` attribute is relative to the context specified in the enclosing `xsl:apply-templates` instruction.

Line 23: We have chosen to create a new template to handle `author` elements. Once again, note the context in the `select` attribute at line 23 and how the context changes in the template at lines 28–34.

Line 29: Remember once again that an XSL document is an XML document, so we cannot use the standard HTML `<td nowrap>` construct because every attribute must have a value. Thus we have set the value to something. An empty string will do just fine: `<td nowrap="">`. (In XHTML, the `td` element has no `nowrap` attribute. In that case, you must use CSS to achieve the same result: `<td style="white-space: nowrap">`.)

Lines 30–32: If we put nothing at the end of line 31, the authors' first and middle names will be run together. In line 24 we used `&#160;`, the XSL equivalent of `&nbsp;`, to get the extra aesthetically pleasing spaces before and after the text in each cell of our table. But if we use `&#160;` at the end of line 31, we get two spaces instead of one. Thus we have used `&#32;`, which is the standard ASCII space character.

CONTROLLING XSL PROCESSING ENGINE FLOW

Calling Templates with Parameters

The `xsl:for-each` and `xsl:apply-templates` instructions certainly provide some degree of flow control within the XSL processing engine. Further control can be achieved with the `xsl:call-template` instruction, which allows XSL templates to be called by name just like standard subroutines. In a nutshell, the syntax is

```
<xsl:call-template name="templateName" />
```

Rather than the `match` attribute we saw in templates called by `xsl:apply-templates`, templates called by name have a `name` attribute:

Heines, Jesse M.	Extensible Stylesheet Language (XSL)
Pratter, Frederick	Java Server Pages (JSP)
Roussos, Constantine	JavaScript
Ulmer, John	Extensible Markup Language (XML)

Figure 13: Result of applying the XSL sort construct in Listing 6 to the XML file in Listing 4.

```
<xsl:template name="templateName">
  instructions to execute when this template is called
</xsl:template>
```

Another important difference between *applying* and *calling* templates is that in the former the node context changes, as we just saw, while in the latter it does not.

There is also a *parameter* construct that allows templates to be called with values that can be further used to control program flow. This construct can be used with `xsl:apply-templates`, but it is more commonly found with `xsl:call-template`:

```
<xsl:call-template name=" templateName">
  <xsl:with-param name=" parameterName"
    select=" pattern" />
</xsl:call-template>

<xsl:template name=" templateName">
  <xsl:param name=" parameterName" />
    <!-- name must match that used above -->
      instructions to execute when this template is
        called, parameter can be referenced using
        $parameterName
</xsl:template>
```

Examples of these constructs appear in the code for the next major section.

One can therefore see that even though no one would claim that XSL is a general purpose programming language, it is a rich set of instructions that provides many of the basic features of a declarative programming language, coupled with exceptional abilities to manipulate XML data.

Conditional Execution

One of the basic flow control features in any language is the Boolean `if` construct that provides conditional instruction execution. XSL does indeed have an `xsl:if` instruction. Its basic format is

```
<xsl:if test="Boolean expression">
   instructions to execute if the test of the enclosing
     xsl:if is true
 </xsl:if>.
```

This instruction is not as heavily used as one might expect, however, because it has no “else” clause. People therefore tend to use the XSL equivalent of the C/C++/Java `switch` statement: the `xsl:choose` instruction. The basic format of this instruction is

```
<xsl:choose>
  <xsl:when test="Boolean expression">
    instructions to execute if the test of the enclosing
    xsl:when is true
  </xsl:when>
  ... any number of additional xsl:when elements
    may be included here...
  <xsl:otherwise>
    instructions to execute if no other Boolean
      expressions in this xsl:choose are true
  </xsl:otherwise>
</xsl:choose>
```

As you surely suspect by now, the Boolean expressions include XPath expressions, which can, in turn, include Boolean operators and numerous functions. The following sample `xsl:choose` construct outputs **Dear Ms. (*last name*):** if the current context node’s first attribute contains the string “Elizabeth;” otherwise it outputs **Dear Mr. (*last name*):**. Note the use of single and double quotation marks in the `test` attribute of the first `xsl:when` element.

```
<xsl:choose>
  <xsl:when test="@first='Elizabeth'">
     Dear Ms. <xsl:value-of select="@last"
       />:
  </xsl:when>
  <xsl:otherwise>
     Dear Mr. <xsl:value-of select="@last"
       />:
     </xsl:otherwise>
</xsl:choose>
```

One note of clarification to C/C++/Java programmers: Each case (xsl:when or xsl:otherwise) is mutually exclusive. That is, each case ends with an implicit break statement (in C/C++/Java terms), and processing exits the xsl:choose structure as soon as any case is completed. It is therefore critical that tests be sequenced from the most specific to the most general, with xsl:otherwise (if present) as the last case in the sequence.

MAKING DATA IN XML DOCUMENTS COMPATIBLE

To put everything together that we've seen so far, we return to the problem introduced at the beginning of this chapter: incompatibility of date formats. The XML file in Listing 7 has six person elements, each with a birth date specified in one of three different formats: in attributes (line 6), in subelements (lines 10–14), or as text (line 17). (Having different date formats in the same XML file is certainly contrived for this demonstration, but it is common to have different formats in different files, as discussed at the beginning of this chapter.) The XSL file in Listing 8 determines how the birth date for each person is stored and executes the required instructions to transform each into ISO 8601 format. The table resulting from the transformation is shown in Figure 14. Comments on specific XSL techniques follow the listings.

Listing 7: XML file containing birth dates in various formats.

```
 1 <?xml version="1.0"?>
 2 <!-- birthdates.xml
 3   updated by JMH on April 15, 2002 -->
 4 <family>
 5   <person id="Dad">
 6     <birthdate month="November" day="28"
 7       year="1916" />
 8   </person>
 9   <person id="Mom">
10     <birthdate>
11       <month>December</month>
12       <day>13</day>
13       <year>1918</year>
14     </birthdate>
15   </person>
16   <person id="Judy">
17     <birthdate>1/14/42</birthdate>
18   </person>
19   <person id="Carol">

      <!-- output day, prefixing with "0" if it's expressed in one digit -->
        <xsl:if test="$strDay &lt; 10">0</xsl:if>
        <xsl:value-of select="number($strDay)" />
    </xsl:when>

    <!-- handle default case -->
    <xsl:otherwise>
      unknown
    </xsl:otherwise>

  </xsl:choose>
</xsl:template>

 <xsl:template name="month">
   <xsl:param name="monthName"/>
   <xsl:choose>
     <xsl:when test="$monthName='January'">01</xsl:when>
     <xsl:when test="$monthName='February'">02</xsl:when>
     <xsl:when test="$monthName='March'">03</xsl:when>
     <xsl:when test="$monthName='April'">04</xsl:when>
     <xsl:when test="$monthName='May'">05</xsl:when>
     <xsl:when test="$monthName='June'">06</xsl:when>
```

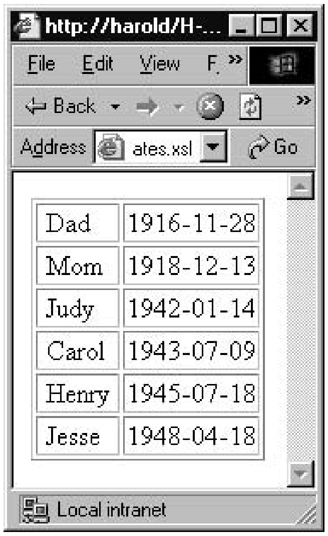
```
118       <xsl:when test="$monthName='July'">07</xsl:when>
119       <xsl:when test="$monthName='August'">08</xsl:when>
120       <xsl:when test="$monthName='September'">09</xsl:when>
121       <xsl:when test="$monthName='October'">10</xsl:when>
122       <xsl:when test="$monthName='November'">11</xsl:when>
123       <xsl:when test="$monthName='December'">12</xsl:when>
124     </xsl:choose>
125   </xsl:template>
126
127   </xsl:stylesheet>
```

The heart of this transformation is in the template that begins on line 58. This template is executed in the context of a `birthdate` node, which exists for each `person` regardless of the birth date's format.

At line 62 we test for the existence of a `month` attribute associated with the `birthdate` node. If such an attribute exists, we assume that the birth date is stored in attributes and proceed accordingly. We extract the value of the `year` attribute and add it to the generated output at line 63. ISO 8601 format specifies that the year value be followed by a hyphen (`YYYY-MM-DD`). However, adding that hyphen at the end of line 63 generates an extra space in the output, so we follow it with a tag that we know HTML processors will ignore: `<null/>`. This dummy tag is immediately followed by another tag at line 64, so no additional spaces are generated.

At line 64 we call the template named `month`, passing it parameter `monthName` with the value extracted from the `month` attribute (line 65). The template named `month` that begins at line 109 transforms month name strings into numbers to conform to ISO 8601 format. Line 67 tests the value of the `day` attribute to see if it is numerically less than 10. If so, this line outputs a 0 to add a leading 0 to the day number to conform to ISO 8601 format.

Line 72 tests for the existence of a `month` subelement in the `birthdate` context. If it exists, we assume that the birth date is stored in subelements and proceed accordingly. The code here is very similar to that in the previous case, except that we extract data from elements rather than from attributes, so no @ signs appear in the `select` and `test` attributes of the various instructions.



Dad	1916-11-28
Mom	1918-12-13
Judy	1942-01-14
Carol	1943-07-09
Henry	1945-07-18
Jesse	1948-04-18

Figure 14: Birthdates transformed to ISO 8601 format.

Line 82 tests whether the text in a `birthdate` element contains a forward slash (`"/"`). If it does, we assume that the birth date is stored in the common American month/day/year format. We then use the XPath string functions `substring-before` and `substring-after` to isolate each of the numbers delineated by the slashes and transform them appropriately to conform to ISO 8601 format.

The template that begins at line 109 is essentially one large `xsl:choose` instruction. Line 110 accepts the `monthName` parameter passed to this template via the `xsl:with-param` instructions at lines 65 and 75. We then use that parameter in the `xsl:when` test attributes by preceding its name with a dollar sign ($). We check for each of the 12 month names in turn and add the corresponding month number (with a leading 0 if necessary) to the output when one of the Boolean tests is true.

Thus the disparate date formats are all made compatible with one another. Of course, one could add additional cases to the `birthdate` template that begins at line 58 to handle all of the variations presented at the beginning of this chapter. (Serial dates require computing a unique day number, where January 1, 1900, is defined as day 1.)

The previous example is fine for generating HTML output as we have been doing throughout this chapter, but many applications that use XML and XSL have no interest at all in generating HTML. Instead, they want to take an XML file in one format and convert it to an equivalent XML file in another format. That is, they would want to convert the file in Listing 7 to a new file with all dates in the same format. The XSL file in Listing 9 does precisely this, generating the output in Listing 10.

XSL FORMATTING OBJECTS

The third component of XSL is the set of *formatting objects* (XSL-FO) that can be used to render output in sophisticated formats such as PostScript, Portable Document Format (PDF), and even Java (using the Abstract Windowing Toolkit for screen display). Use of these formatting objects is a direct extension of the concepts and techniques presented in this chapter, applied using the `http://www.w3.org/1999/XSL/Format` namespace. This namespace provides tags similar to, but considerably more sophisticated than, those found in CSS. To include the XSL-FO namespace in an XSL file, simply add it to the `xsl:stylesheet` tag:

```
<xsl:stylesheet version="1.0"
      xmlns:xsl=
       "http://www.w3.org/1999/XSL/Transform"
      xmlns:fo=
       "http://www.w3.org/1999/XSL/Format">
```

The full set of XSL-FO tags and allowable attributes is truly immense. One "short reference" that merely lists them all is 26 pages long! Thus this chapter can only address the basic structure of an XSL file that uses the XSL-FO namespace. For detailed discussion of XSL-FO, please see the *W3C Recommendation for XSL Version 1.0* (W3C, 2001).

Listing 9: XSL file to generate a new XML file with birth dates in various formats converted to ISO 8601 format.

  <person id="Jesse" birthdate=
    "1948-04-18"/>
</family>
```

XSL formatting objects specify page layout using a hierarchical system of *pages*, *flows*, and *blocks*. Further refinements of the hierarchy include *rectangles*, *borders*, and *spaces*. Full discussion of these topics is beyond the scope of this chapter, but basically one may think of a simple printed document as having a *master layout* that is broken down into *page sequences* that contain *flows* that are composed of *blocks*.

Formatting Static Text

As a first example, consider the code in Listing 11, which is adapted from one of the examples provided with the transformation engine used to render the examples in this section: the Formatting Objects Processor (FOP) from the Apache Group. (This software can be downloaded free of charge from http://xml.apache.org/fop/.) The adapted example renders a version of the abstract for this chapter in Portable Document Format, which can be viewed in the popular Adobe Acrobat Reader as shown in Figure 15. (The explanation of this code that follows is drawn largely from the comments embedded in the original example.)

Listing 11: Simple XSL-FO to render the abstract for this chapter.

```
<?xml version="1.0" encoding="utf-8"?>

```

```
32               text-align="center"   padding-top="0pt">
33           The Extensible Stylesheet Language (XSL)
34         </fo:block>
35
36         <!-- subtitle -->
37         <fo:block font-size="14pt"     line-height="20pt"
38                   font-family="Times"  space-after.optimum="12pt"
39                   font-weight="bold"   padding-top="0pt">
40            Abstract
41       </fo:block>
42
43       <!-- first paragraph -->
44       <fo:block font-size="12pt"     line-height="15pt"         text-indent="25pt"
45                 font-family="Times"  space-after.optimum="12pt" text-align="justify">
46         XSL - the Extensible Stylesheet Language - is an XML-based technology for
47         transforming XML documents from one form to another. It uses a declarative
48         programming paradigm and a specific XML namespace that gives programmers full
49         access to all XML components - elements, attributes, and text - and the ability
50         to manipulate them in ways that go far beyond the capabilities of Cascading
51         Style Sheets (CSS).  XSL can be used to control the rendition of XML data,
52         selectively filter the data items selected for transformation, convert data from
53         various incompatible forms into a single, standard form, or implement just about
54         any other operation that one might want to perform on XML data without changing
55         the original XML source. Various parts of XSL are now industry standards (known
56         as World Wide Web Consortium "Recommendations"), and are therefore highly usable
57         even in today's ever-changing Web environment.
58       </fo:block>
59
60       <!-- second paragraph -->
61       <fo:block font-size="12pt"     line-height="15pt"         text-indent="25pt"
62                 font-family="Times"  space-after.optimum="12pt" text-align="justify">
63         This chapter presents the basic concepts and techniques used in XSL. It
64         provides a variety of examples of XSL Transformations (XSLT), XPath Expressions
65         (the language used to refer to collections of XML nodes for processing by XSLT),
66         and XSL Formatting Objects (XSL FO).
67       </fo:block>
68
69      </fo:flow>
70    </fo:page-sequence>
71 </fo:root>
```

We see from line 1 that this is an XML file, but it does not use the XSL transformation engine. Therefore, only the XSL-FO namespace is specified on the fo:root element in line 9. (The next example will use both namespaces as just discussed.)

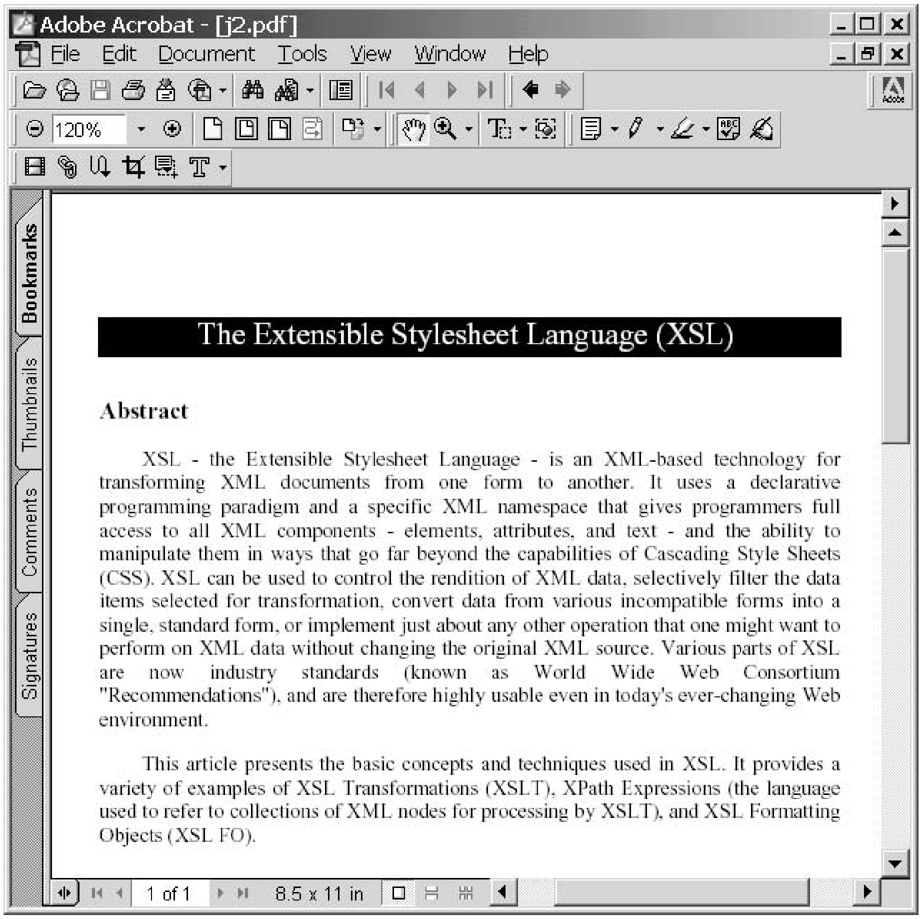
The fo:root element must contain one and only one fo:layout-master-set element (line 12), which in turn contains one or more page master elements that specify sets of *master layout* parameters. In this example, there is only one fo:simple-page-master element that defines the layout for all pages. If there were multiple page layouts, they would be differentiated by their master-name attributes (line 13).

A document's content is organized into one or more *page sequences*. Each fo:page-sequence element (line 23) has a master-reference attribute whose value corresponds to the master-name attribute of one of the previously defined page master elements (line 13).

Page sequences contain *flows*, which can be positioned in one of five regions: the page header or footer, the left or right margin, or the body. The fo:flow tag at line 26 begins the definition of a body flow.

Actual content is then contained within *blocks* that contain text and formatting instructions. There are four blocks in this example. The first block, which begins at line 29, displays the overall title centered in 18-point white type on a black background (72 points = 1 inch). The text for this block appears on line 33. The second block, which begins at line 37, displays a subtitle left-justified in bold 14-point type. The text for this block appears on line 40.

The format of the two paragraphs is defined at lines 44–45 and 61–62. The first line of each paragraph is indented 25 points and their text is justified (all text in all lines except the first is aligned at both the left and right margins).



The Extensible Stylesheet Language (XSL)

Abstract

XSL - the Extensible Stylesheet Language - is an XML-based technology for transforming XML documents from one form to another. It uses a declarative programming paradigm and a specific XML namespace that gives programmers full access to all XML components - elements, attributes, and text - and the ability to manipulate them in ways that go far beyond the capabilities of Cascading Style Sheets (CSS). XSL can be used to control the rendition of XML data, selectively filter the data items selected for transformation, convert data from various incompatible forms into a single, standard form, or implement just about any other operation that one might want to perform on XML data without changing the original XML source. Various parts of XSL are now industry standards (known as World Wide Web Consortium "Recommendations"), and are therefore highly usable even in today's ever-changing Web environment.

This article presents the basic concepts and techniques used in XSL. It provides a variety of examples of XSL Transformations (XSLT), XPath Expressions (the language used to refer to collections of XML nodes for processing by XSLT), and XSL Formatting Objects (XSL FO).

Figure 15: PDF rendering of the XSL-FO file in Listing 11.

Formatting Text from an XML Document

The real power of XSL formatting objects, of course, comes into play when they are combined with XSL transformations to format text read dynamically from XML files. The basic structure of the XSL file is the same as that shown for static text in the first example, but the XSL-FO tags are now embedded within XSLT tags that control flow and pull data from an XML file. That may sound more like alphabet soup than computer programming, but the example that follows is intended to clarify how these technologies fit together.

This example uses the XML file in Listing 12, which is an excerpt from the glossary for this chapter. The corresponding XSL file is in Listing 13.

First, we see the presence of both namespaces defined in the `xsl:stylesheet` element at lines 81–83. Lines 85–87 are the standard top level "main" template, which simply passes processing on to the XML document's root element, `article`.

The template that matches XML element `article` begins at line 89. It contains the `fo:root` element (line 90) and defines the *master layout* using an `fo:layout-`

159   </xsl:template>
160
161   </xsl:stylesheet>
```

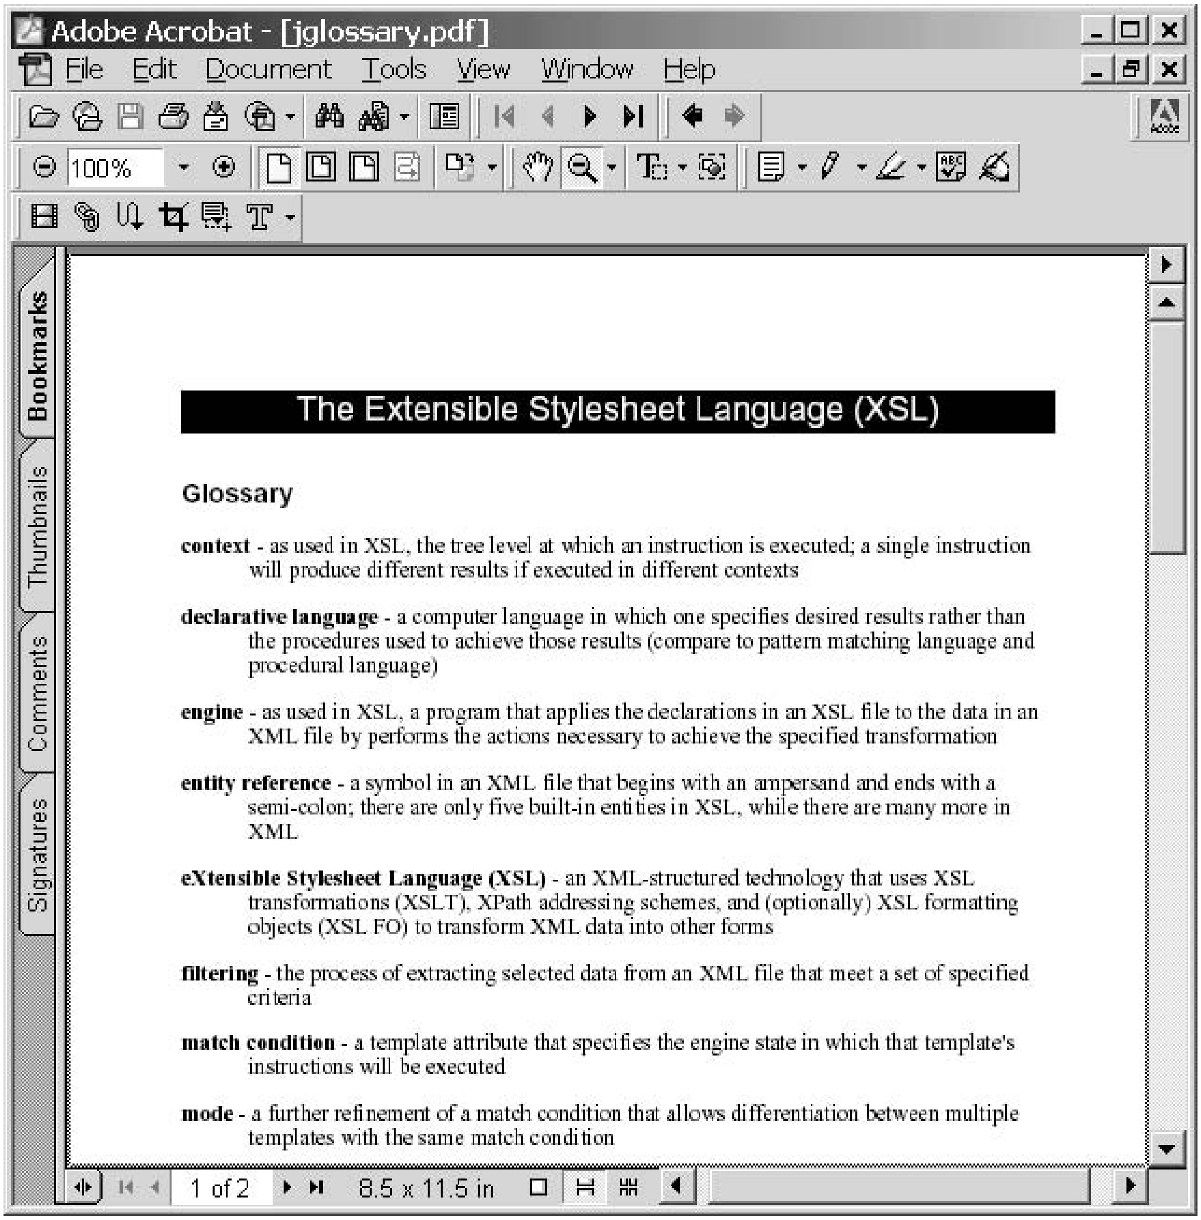
`master-set` element (lines 92–100). The *page sequence* begins at line 102. It starts a *flow* at line 104 and creates the first *block* at lines 106–111. Note, however, the one major difference between this example and the previous example: line 110 does not contain static text. Rather, line 110 inserts the text contained in the `title` child element of the XML `article` element using an `xsl:value-of` instruction. Line 114 then descends into the XML tree by applying the appropriate template that matches all the `section` child elements.

That template begins at line 123. It creates a new block at lines 125–129. Here again, at line 128, we use an `xsl:value-of` instruction to pull the text content to be rendered from the XML file rather than hard-coding it as static text in the XSL file. Note, however, that the `title` element here refers to a child of the XML `section` element, which is not the same as the `title` referred to at line 111. Refer back to lines 9 and 11 of the XML file in Listing 12 to see that `title` elements appear at two different levels. The recursive descent structure of the XSL processing engine ensures that we are referred to the right element at each level.

Next, controlled by the `xsl:if` instruction at line 132 to make sure that the section we're currently processing is a glossary, the `xsl:apply-templates` instruction at line 133 initiates processing of all glossary entries. Here's where the real fun begins!

Each `entry` element in the XML file has two child elements: `term` and `definition` (see lines 13 and 14 in Listing 12). Before displaying each term, the `entry` template begins a *block* (line 139 in Listing 13), which in this case is essentially a paragraph. Thus a line break occurs and the formatting instructions for that block are applied. All of the blocks in this layout have `space-after.optimum` set to 12 points (1/6 of an inch), essentially leaving a blank line between glossary entries. Line 142 then initiates processing of the `entry` element's `term` child element.

In the `term` template we see an `fo:inline` tag at line 148. This tag begins the definition of a section of text similar to a block, but `inline` indicates that no line break is to occur. The `fo:inline` tag is analogous to an HTML `<span>` tag: It delineates a section that has its own formatting but that is not separated from its surrounding elements by white space. Here the font weight is set to



The Extensible Stylesheet Language (XSL)

Glossary

context - as used in XSL, the tree level at which an instruction is executed; a single instruction will produce different results if executed in different contexts

declarative language - a computer language in which one specifies desired results rather than the procedures used to achieve those results (compare to pattern matching language and procedural language)

engine - as used in XSL, a program that applies the declarations in an XSL file to the data in an XML file by performs the actions necessary to achieve the specified transformation

entity reference - a symbol in an XML file that begins with an ampersand and ends with a semi-colon; there are only five built-in entities in XSL, while there are many more in XML

eXtensible Stylesheet Language (XSL) - an XML-structured technology that uses XSL transformations (XSLT), XPath addressing schemes, and (optionally) XSL formatting objects (XSL FO) to transform XML data into other forms

filtering - the process of extracting selected data from an XML file that meet a set of specified criteria

match condition - a template attribute that specifies the engine state in which that template's instructions will be executed

mode - a further refinement of a match condition that allows differentiation between multiple templates with the same match condition

Figure 16: Glossary transformed to PDF format using XSL-FO.

bold, and then the xsl:value-of instruction is used to insert the text of the current XML term element.

Line 150 continues processing by applying the definition template to the current term's sibling definition element. In that template (lines 155–159), the fo:inline tag is used to return the font weight to normal (not bold), and then a hyphen is rendered followed by the content of the XML definition element.

In addition to the finely tuned formatting control provided by XSL-FO tags and attributes, XSL-FO engines are now beginning to appear that can render those formats in a variety of ways. Figures 16–18 show the glossary excerpt we have been discussing rendered in PDF, PostScript, and Java AWT formats, respectively. All of these renderings were created from the same XML and XSL files using the FOP processing engine. To produce the different outputs, only the output specification parameter passed to the FOP program was changed.

WHERE TO GO FROM HERE

Hundreds—if not thousands—of pages would of course be needed to cover all the features of XSL and its XSLT, XPath, and XSL-FO subcomponents, but hopefully this chapter has given you enough information to grasp the essence of these powerful Web technologies. The References section provides pointers to further reference material and Web sites where you can not only learn about XSL, but also download the software discussed in this chapter to use XSL on your own systems.

  // as parameters from an HTML form or via some other such technique.
  String strXMLfilename = "hello.xml" ;  // replace with your XML file name
  String strXSLfilename = "hello.xsl" ;  // replace with your XSL file name

  // We need to construct a full path to the XML and XSL files, including the
  // "http://" protocol specification, server name, and server port number (if
  // it's not the default of 80). The following code accomplishes this.
  String strFullPath = "http://" + request.getServerName() ;
  if ( request.getServerPort() != 80 )
    strFullPath += ":" + request.getServerPort() ;

  // We then add the full path to this JSP and finally strip off this JSP's file
  // name and extension that follow the last forward slash (/).
  strFullPath += request.getRequestURI() ;
  strFullPath = strFullPath.substring( 0, strFullPath.lastIndexOf( "/" ) + 1 );

  // We append the XML and XSL file names to the full path to pass them to our
  // ApplyXSL method, which applies the XSL file to the XML file and returns the
  // result as a string. Printing that String shows the result in the browser.
  out.println( ApplyXSL( strFullPath + strXMLfilename,
                         strFullPath  + strXSLfilename ) );
%>
</body>
</html>

GLOSSARY

Context As used in XSL, the tree level at which an instruction is executed; a single instruction will produce different results if executed in different contexts.

Declarative language A computer language in which one specifies desired results rather than the procedures used to achieve those results (compare to *pattern matching language* and *procedural language*).

Engine As used in XSL, a program that applies the declarations in an XSL file to the data in an XML file by performing the actions necessary to achieve the specified transformation.

Entity reference A symbol in an XML file that begins with an ampersand and ends with a semi-colon; there are only five built-in entities in XSL, while there are many more in XML.

Extensible stylesheet language (XSL) An XML-structured technology that uses XSL transformations (XSLT), XPath addressing schemes, and (optionally) XSL formatting objects (XSL-FO) to transform XML data into other forms.

Filtering The process of extracting selected data from an XML file that meet a set of specified criteria.

Match condition A template attribute that specifies the engine state in which that template's instructions will be executed.

Mode A further refinement of a match condition that allows differentiation between multiple templates with the same match condition.

Namespace A collection of externally predefined words that are used in an XML document as element types and attribute names; the namespace is specified as a uniform resource identifier, which for XSL is `http://www.w3.org/1999/XSL/Transform`.

Namespace prefix A user-chosen name used to refer to the namespace to which an XML tag name belongs.

Node As used in XSL, an object in an XML tree that has zero or one parent and zero or more children; the abstract representation of an XML tag or attribute or text content.

Pattern matching language A language for specifying constraints ("patterns") under which actions are to take place (compare to *declarative language* and *procedural language*).

Procedural language A computer language in which one specifies the precise steps required to achieve a desired result (compare to *declarative language* and *pattern matching language*).

Processing instruction A command in an XML file that specifies file attributes such as the version number or stylesheet link; a processing instruction is not part of the XML data.

Recursive descent The process of visiting each node in a tree or subtree by recursively tracing the links to each node's child to traverse the entire tree structure.

Root element The "top" element of a tree that has no parent node.

Style An attribute of a visible element such as its color, size, font type, etc., or any other characteristic appropriate for some other type of element (compare to *transformation*).

Stylesheet A collection of specifications that define how information is presented; stylesheets can define how text data is rendered on a screen, how words are pronounced, etc.

Template A collection of instructions that specify the desired result of a transformation in a specific context and (optionally) mode.

Transformation The process of generating a new form of data from another form (compare to *style*).

XPath The expression language used to refer to collections of XML nodes for processing by XSLT.

XSL formatting objects (XSL-FO) An XML namespace that defines a language for transforming XML data into a formatted presentation.

XSL transformations (XSLT) The language used by XSL to transform XML data into other forms.

Extranets

Stephen W. Thorpe, *Neumann College*

INTRODUCTION

The Internet is a wide-area network that consists of thousands of organizational networks worldwide. The Internet became popular in the 1990s with the advent of the “World Wide Web.” The Web provides information stored on servers that are connected to the Internet. Web browsers, such as Netscape Navigator and Microsoft Internet Explorer, provide interfaces to interpret and display the Web pages. Documents accessible on the Web contain hyperlinks to move from one document to another. The benefits of the Internet include the ability to discover information more quickly and in larger volumes as well as increased opportunities for communication with individuals and groups. It is hard to imagine an organization today that does not have access to the Internet or does not maintain its own organizational Web site. In the early days of the Internet, an organizational presence on the Web provided a competitive advantage. Today, an organization’s presence on the Web is an essential part of doing business.

The benefits of Internet technology and Web browsing led to the creation of organizational networks that provide restricted access for internal employees. The internal networks became known as “intranets,” private enterprise networks that use the Internet and Web technologies for information gathering and distribution within the organization. By converting old applications or writing new applications for use on an intranet, organizations can eliminate dependence on a particular operating system/platform. The intranet has also become an effective communication vehicle to share information within the organization. The intranet provides easy access to internal information that can be published by departments within the organization. Other applications supported by the intranet include employee access to legacy systems, Web sites for human resources, payroll information, and even training programs. Intranets support collaborative processes between departments, such as scheduling, messaging, and discussion groups (Lloyd & Boyle, 1998). Intranets can also empower customer support center staff with intranet knowledge management systems that result in improved customer satisfaction (Phaltankar, 2000). Through the use of intranets, organizations have reduced costs while also increasing employee productivity.

The intranet is typically protected from the public Internet by a firewall, a device that acts as a gatekeeper between the organizational intranet and the outside Internet. The firewall permits internal employees to access the public Internet, but it prevents outside users (the public) from accessing the internal resources of the organization.

A natural extension of the intranet would allow selected external entities to access internal organizational resources. An “extranet” provides a collaborative network that uses Internet technologies to extend intranet applications and services to selected external organizations, thereby creating a community of interest beyond the walls of the organization. In addition, providing remote access to the intranet permits employees who are off site to access intranet services; for example, employees working from home could access intranet resources through the deployment of an extranet. The extranet is typically not available to the general public but rather it is limited to “strategic partners.” These strategic partners may include suppliers, vendors, customers, or other organizations involved in collaborative research and development. Bringing suppliers, partners, and even customers into the information loop is critical to developing a company’s quick response and strategic movement as it adapts to an evolving market environment (Baker, 2000). Figure 1 depicts an organizational extranet.

STRATEGIC USES OF EXTRANETS

The role and importance of extranets appear to be increasing. In a 1999 study by Forrester Research of 50 large manufacturers who had implemented extranets, 80% of the interviewees said they expected to extend extranet access to all of their business partners within two years (Orlov, 1999). While over two-thirds of those surveyed were already providing marketing and product specifications through their extranets, virtually all of the executives interviewed expected to expand their extranets to include online sales and sharing of inventory information. The manufacturers also anticipated a 32% reduction

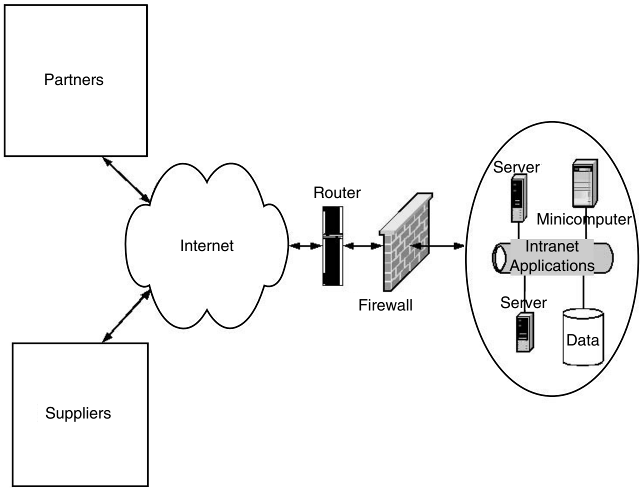

Figure 1: Organizational extranet.

in support costs and a 17% increase in sales from their extranet applications.

Extranets provide several strategic advantages for organizations to extend their intranet applications to their business partners: business-to-business e-commerce, collaboration for research and development, and internal efficiency. Throughout the following section, several examples of extranets will be described to illustrate the application of extranets. The illustrations are intentionally drawn from a variety of industries to demonstrate the ubiquity of extranet deployment in business.

Business-to-Business E-commerce

Business-to-business (B2B) e-commerce has taken off in recent years through the maturity of the Internet and the Web. Extranets provide a means to share existing intranet content for real-time communication between business partners. The extranet also provides external organizations with access to internal databases and legacy systems without necessarily connecting to the full intranet of the organization. Among the advantages of e-commerce, the extranet can be an effective tool in customer relationship management, supply chain management, and the electronic exchange of business transactions.

Customer Relationship Management (CRM)

Customer relationship management involves integrating the customer service processes with a business, such as sales, marketing, customer service, and support. The idea behind CRM is to adapt business processes to a "customer-centric" business strategy. The deployment of an extranet achieves CRM strategies by providing customers with 24-hours-a-day, seven-days-a-week access to internal information without the involvement of business personnel. For example, extranets can support business-to-business transactions, such as sales, while also providing information resources for products and services. Several customer service components of an organization could potentially be deployed through an extranet.

In the health care industry, Humana has developed an extranet application for physicians, consumers, employers, and brokers that may well transform the company and establish it as a technology leader in health care (Lewis, 2001b). The extranet site, Emphesys.com, provides a customer-centric approach toward delivering information in real time for various organizational constituencies. The extranet offers Web portals for doctors, patients, and others to share real-time data as well as to access information from a medical database. The extranet includes links for doctors to access the National Institutes of Health and other research resources. In addition, physician offices will have online access to patient data ranging from claims status to prescription histories. For health care plan members, the extranet application provides information regarding Humana's various health plans and allows individuals to review their medical records and prescription data. The extranet application will permit members to enroll in the health care plan of their choice and provide expedited plan authorization. Efficiencies are gained through the extranet, which will provide a member's enrollment eligibility information to doctors within four hours, compared to two or more weeks that had been necessary before the extranet.

Even small organizations can deploy extranets to improve customer access to internal information. The law offices of Dinsmore & Shohl established a subsidiary organization, DinsNet Technologies, to offer electronic services for clients and lawyers (Baker, 2000). Because of a number of cases that were document intensive, the law office began scanning the documents to make them available in electronic format. The DinsNet case management services extranet allows clients to access documents as well as billing statements and provides for immediate client/attorney interaction and document sharing. The extranet provides enhanced flexibility for communication with clients who are not physically near the law offices.

Supply Chain Management

Supply chain management involves the integration of business processes and technology to optimize information and product flows among the business partners within the supply chain, from suppliers to internal logistics, distribution, and customers. By providing suppliers with access to organization inventory systems through an extranet, the organization can implement "just-in-time" inventory replenishment policies. This provides a cost savings since the inventory is not maintained by the organization, but rather by the supplier. Extranets also provide the possibility to outsource the function of inventory management to suppliers.

For example, Coors Brewing Company, which has always been challenged to forecast product demand, has deployed an extranet application that allows over 1,000 distributors to order beer, access promotional information that might impact sales, and communicate with other distributors (Moozakis, 2001). The extranet allows distributors to populate a database with forecasts that Coors can then aggregate to make its own demand projections. The extranet provides basic ordering applications and will provide market analysis for distributors to understand better their regional demand. Other features planned for the extranet include inventory management and shipping applications that will connect to Coors' enterprise resource planning system.

Cisco Systems, a networking equipment maker, has deployed an extranet that links their component suppliers, distributors, and manufacturers to form a virtual, just-in-time supply chain (Koch, 2000). When a customer order arrives, typically through Cisco's Web site, a series of electronic messages are sent through the extranet to their business partners to produce the requested equipment. Contract manufacturers are able to access the supply chain process through Cisco's extranet that links to their manufacturing execution systems. On the other hand, Cisco has access to the contractor's assembly line and, when the equipment is ready, a connection is established for Cisco to complete product testing through their automated testing software. When testing is completed satisfactorily, Cisco releases the customer name and shipping address so the contractor can complete distribution to the customer. Through this innovative use of extranet applications, Cisco reduces or eliminates entirely the need for inventory space and paper invoices.

Electronic Data Interchange (EDI)

Extranets provide an economical method for the exchange of business transactions between organizations. To gain efficiencies in business-to-business transactions, large organizations adopted strategies for electronic data interchange to conduct business transactions through private, long-distance networks. Electronic data interchange is a computer-to-computer exchange of business information in a standard electronic format between business partners. These networks, however, required propriety protocols and were expensive to implement. The high cost of investing in private networks and the hardware and software for EDI was prohibitive for smaller organizations that could not realize the benefits of this technology.

Unlike traditional EDI systems that required private networking solutions, the extranet uses the public Internet to exchange transactional data. By eliminating the costs of private networking technologies, an extranet provides an economical alternative for medium and smaller companies to exchange transactional data with other businesses (Pfaffenberger, 1998; Salamone, 2000). Because the extranet uses the public Internet and TCP/IP protocols, it provides an open platform that is not limited to only participants who use the same protocols, Internet service providers, or operating systems (Anderson, 1997).

Collaboration with Business Partners

Communication up and down the supply chain with business partners is typically handled by telephone, fax, or e-mail. The extranet, however, provides the ability to get all parts of the business community working together and communicating in a way that is more timely and effective (Meyer, 2000). By putting employees, customers, and strategic partners in closer contact, extranets promote real-time collaborative efforts and expedite the time to market for products. Because everyone involved in a project can see proposed changes in real time, the extranet can also support many more iterations of the design process as compared to traditional techniques (Pfaffenberger, 1998).

Marshall Industries, an electronics distributor, developed an extranet that facilitates the flow of information to its hundreds of suppliers, systems integrators, and value-added resellers who can get point-of-sales reports at any time as well as real-time inventory access (Anderson, 1997). The extranet application, PartnerNet, provides both suppliers and customers with the ability to create customized information views from their corporate intranet. When new information is available, PartnerNet notifies the registered user.

One of the critical steps in designing an extranet is defining the differences and levels of access needed by business partners who might need to access the extranet. Marshall Industries recognized the differences among individual partners and does not provide equal access to their extranet for all members. A sales representative, for example, may be restricted to information regarding assigned accounts. A manager-level representative, however, may be provided access to regional-level sales activity for that manager's region, but the representative would not be provided with information from other regions.

The McCann Worldgroup is a marketing communications agency that uses collaboration software for internal and external communications to provide employees and clients with more effective ways to share work in progress (Maddox, 2001). The portal product, McWisdom, is both an intranet for internal communications and an extranet for client collaboration. By logging onto the secure area of the McCann Web site, employees as well as clients can review media plans, status reports on ad campaigns, and reports on campaign performance. The portal also provides clients with personalized views of projects in development.

Caterpillar, a manufacturer of heavy equipment, has developed extranets to facilitate collaboration between engineers and suppliers. The collaboration includes sharing and marking up design drawings and allowing suppliers to conduct their own simulations and testing. Through these efforts, Caterpiller has shrunk its product development cycle from as long as eight years to 39 months (Hills, 1998).

Internal Efficiencies

The use of an extranet can simplify workflow and create internal efficiencies. By allowing authorized employees to access supplier extranets, for example, organizations can simplify processes for ordering supplies and products (Ling & Yen, 2001). The Dell Computer Premier Dell.com Web site provides a useful example of how organizations can gain internal efficiencies through extranet applications. Litton PRC, a global systems integrator, began planning for an electronic purchasing system in 1999 (for more information, see http://www.dell.com/us/en/casestudies). Prior to this time, Litton PRC's procurement system was paper-based and required purchase requisitions from their worldwide offices to be reviewed by the main headquarters. On average, this paper-based system required 16.2 days to get the purchase requisition to the Purchasing office and up to as many as 17 approvals. Once the extranet application was implemented, the time required for Litton PRC to purchase Dell computers dropped to an average of 1.9 days from the time of creating a requisition order to delivery.

The use of extranets also provides internal efficiencies in the distribution of corporate information to external partners. Conoco, the nation's number five oil refiner, developed a partner-focused B2B Internet initiative to deliver invoices, credit card settlement, and electronic funds transfer information to its 5,000-plus wholesale and retail marketers (Lewis, 2001a). Prior to deploying the extranet, Conoco relied on faxes and other methods to distribute accounting data to marketers. The extranet application provides more timely feedback of information to their business partners.

The Ketchum extranet speeds up interoffice communications and provides an efficient method to help employees learn about new client businesses (Clark, 2001). Ketchum, a public relations firm, introduced MyKGN in March 2000, which allows employees to do research and work with customers online. In the past, research was done on a piecemeal basis. With the extranet, employees are able to research subject databases quickly and efficiently, while also working with clients in real time on such things as press releases and company logos. Ketchum has deployed over 400 collaborative client sites that are using MyKGN, and estimates that its extranet application saves 90 minutes a week per employee. By 2003, Ketchum may realize up to $5.6 million in cash flow and productivity benefits (Clark, 2001).

Organizations can realize internal efficiencies by enabling customers or suppliers to search internal business databases to find and order products, check pricing and availability, and find product documentation without the intervention of employees within the organization. Beyond the benefits of providing faster access to information for customers, extranet applications relieve some of the demands on customer support service personnel (Pfaffenberger, 1998). SunLife Financial, for example, recently deployed an extranet to attract insurance brokers to do business with them rather than their competitors. They hope the extranet will provide a competitive advantage while also holding down costs by allowing insurance brokers to obtain information without having to contact SunLife's call center. By making information available through the extranet, SunLife expects to be able to expand their business without having to increase call center resources (Messmer, 2000).

PLANNING AND IMPLEMENTING AN ORGANIZATIONAL EXTRANET

Planning and implementing an extranet require careful coordination between the organization and its business partners to identify the best business opportunities for an extranet, as well as an assessment of the potential risks to the organization once an extranet is implemented (Szuprowicz, 1998). Important issues to consider in building an extranet include defining the purpose and intended audience of the extranet, determining the return on investment, developing a content management strategy, and security. Of these issues, clearly security of internal information that will be shared over the public Internet is a critical concern. However, defining the purpose and applications for the extranet is also critical if the extranet is to provide the organization with a competitive advantage. In addition, outsourcing the development of the extranet is a possibility for those organizations that do not have the time or expertise to invest in design, implementation, and management of an extranet.

Defining the Purpose for an Extranet

Developing an extranet involves a shift in management philosophy since traditionally internal corporate information was intended to remain internal. Changing the management philosophy will likely meet with cultural barriers among employees who may not be eager to share internal data with outside organizations (Harreld, 2000). People who controlled information in the past may feel threatened by an extranet approach that eliminates information silos and potentially the power bases of some individuals. It is a management imperative to anticipate and resolve internal opposition in order for the development and implementation of an extranet to be successful; in fact, failing to recognize and address resistance is one reason for extranet failure (Pfaffenberger, 1998; Szuprowicz, 1998).

In deciding to implement an extranet, the organization must have a clear purpose in mind, which in part requires a determination of the target audience. With extranet applications, the target audience is typically an established business partner with whom the organization is looking to make doing business easier, faster, and more economical. Without a clear understanding of the purpose and audience for the extranet, content developers will be unable to create a satisfactory site.

While extranet design will be specific to the organization and its business opportunities, extranets tend to fall into three general categories: publishing, collaboration, or transactional (Pfaffenberger, 1998; Szuprowicz, 1998). Publishing extranets are intended to make internal documents available to external users. These documents might include technical documentation, training materials, specifications, or research data. Publishing extranets rely on servers and scripts to database applications for document retrieval. The primary focus of a publishing extranet is cost reduction by eliminating paper, mailing and faxing expenses, and even reducing customer service center expenses (Szuprowicz, 1998).

Collaboration extranets are designed to provide interaction between internal employees and external partners. The focus of collaboration extranets is to reduce the time to market of products by accelerating the product design cycle. The extranet examples cited earlier from the McCann Worldgroup and Ketchum facilitate communication between employees and clients in planning, designing, and reviewing marketing strategies in real time (Clark, 2001; Maddox, 2001). These extranets are more complex than publishing extranets since they must enable two-way interaction with outside users in addition to document sharing.

The most advanced extranets are transactional in nature and facilitate electronic commerce. These extranets are designed to support online transaction processing (for example, sales) and typically provide EDI services through the public Internet. Transactional extranets are complex to design and implement and require more extensive security.

Inasmuch as the design of an extranet includes both an analysis of the business processes and the technical logistics, individuals who possess an understanding of the business as well as technical experts will need to work together to define the extranet applications, who will be invited to participate from the outside, and how the extranet will be deployed. Failure of extranet projects is often attributed to insufficient involvement of both business and technical people working together on the extranet project design (Covill, 1998).

Determining the Return on Investment

Early estimates from marketing surveys have indicated that the return on investment (ROI) for extranets can be high, especially if the extranet is integrated into business processes where the focus is on cost reduction (Pfaffenberger, 1998). However, managers are often challenged to present cost justifications for new capital projects, especially in the areas of information technology. An extranet application is likely to be no exception.

Return on investment is one method to justify investments in information technology and to determine the priorities for project implementation. The ROI formula compares the benefits of a potential project with its related costs. The formula seems very simple; however, determining the benefits and costs of new technology deployment is not so straightforward. The cost of new hardware and software will be obvious, but estimating the indirect costs and potential savings of an extranet will likely be more of an art than a science.

Bort and Felix (1997) defined types of extranet costs in several broad areas, including equipment, security, development, training, management, support, and taxes. While the extranet might utilize existing networking hardware, such as internal LANs or the Internet gateway, major hardware expenses will likely be required in the areas of additional servers, firewalls, and routers. Defining the purpose for an extranet will inform decision making regarding the hardware needed for the project. For example, a low capacity publishing-type extranet will require less expensive server and firewall protection than a transactional extranet that may require virtual private networking (VPN) security for transmission of sensitive data.

Software for the extranet site must also be considered. While hypertext markup language and more recently extensible markup language might be useful for small-scale extranets, larger and more complex extranets will likely require an investment in content management software.

Consideration must also be given to personnel needs in the deployment of an extranet. Additional personnel may be required to design the extranet application, or to manage the content of the extranet site. Even if existing personnel will be assigned responsibility for management of the extranet, some cost will be incurred for the time current employees will not be available for other projects.

On the benefits side, extranets typically do not generate revenue, but rather they provide organizations with the opportunity to reduce costs. It should be noted, however, that if an extranet is part of an organization's e-commerce strategy, then some portion of the revenue generation should be attributed to the deployment of the extranet (Bort & Felix, 1997).

Some of the potential cost savings for the organization can be estimated in terms of reduced paper costs and improved process efficiencies (Pfaffenberger, 1998). Additional savings could be expected and should be estimated in the following areas where extranets can reduce:

customer service costs by providing customers with direct access to information resources and thereby reduce the demand for customer service personnel;

phone, fax, mail, and shipping costs;

time and cost for product procurement;

training costs; and

any private network charges by using the public Internet and VPN technologies rather than private solutions for EDI.

Additional benefits from extranets, such as customer relationship management and access to information, are even more difficult to measure. An extranet for customers is one way to develop a tighter linkage and potentially gain a competitive advantage. Enhanced communication and access to information in real time are additional benefits within the organization that can result in internal efficiencies. Moreover, organizations may see additional benefits in terms of increased customer loyalty, improved image, and even customer recognition for improved service (Ling & Yen, 2001).

Content Management Strategy

Once the purpose for an extranet is established, developing and managing content on the extranet become priorities. Unlike intranets where content is often developed in a distributed fashion for internal use, content on an extranet is shared with strategic partners and customers outside of the organization. Because of this outside access, the content must be presented in a useable form, and links to resources must be operable. If information on an extranet site is incomplete, outdated, or missing, the organization's credibility and possibly sales will be lost (Reimers, 2001).

The importance of content management cannot be overemphasized. Failures of extranet sites can often be traced to insufficient content management and extranet site development. Successful extranets ensure that their sites offer valuable content and functionality so the users can find what they are looking for quickly. In addition, the extranet site must be fast and reliable.

Selecting products and services for developing and managing the content of an extranet site is a real challenge because of the evolving state of technology. Software tools will be required for Web authoring and content management of the extranet site, database integration tools, auditing tools, and performance evaluation tools. Forrester

Research, in their rankings of content management vendors in March 2001, suggested three questions that should be asked in selecting content management software (Wilkoff, 2001). First, the dominant content source should be identified since this source will require high integration with the content management application. Second, content managers should be determined. Identifying the right content management software will depend on whether the content is going to be managed by a centralized information technology department or delegated to nontechnical business users. Finally, the audience of the content should be identified. If the target audience consists of consumers, then they will require greater performance than typical extranet users. If the target audience of the extranet is buyers, on the other hand, then they will likely require personalization of content. (For listings of vendors and products, see Bort & Felix, 1997; Loshin, 1997; Szuprowicz, 1998.)

In developing extranet applications, consideration should be given to how much of the intranet content will be mirrored on the extranet site. Duplication of extensive databases and applications on an extranet can create problems with synchronizing the data stored on the intranet behind the firewall versus the data provided on the extranet. For this reason, organizations may consider providing trusted partners with direct access to selected intranet servers, although this is more often the exception than the rule because of obvious security concerns.

Security of the Extranet

Security is a critical aspect of extranet development, which extends to both the organization and its partners (Phaltankar, 2000). Security issues must be considered through the design, implementation, and management of any extranet applications (Loshin, 1997). Developing a security plan for an extranet application should begin with a risk assessment to identify the potential sources of threat to the network, how likely these threats are to occur, and the investment (cost) in security that will be required. The level of security investment will vary depending on the nature of the extranet application, the threats of intrusion, and the sensitivity of the information shared on the extranet. Extranet security should consider authentication and access control, privacy, and data integrity (Meyer, 2000).

Access Control

Access control provides or denies access to the network and is usually implemented through deployment of a firewall. A firewall alone, however, is not a sufficient security strategy. Providing confidentiality of information while it is in transit over the public Internet can occur through encryption strategies. User authentication can take place in part at the firewall, but it is usually handled by the application service. User control, however, is almost always handled by the application service (Meyer, 2000).

Authentication

Authentication defines the external population that is permitted to access the extranet and ensures that the external interaction with the extranet is coming from an authorized sourse. Assigning account names and passwords to extranet users is the typical method for implementing authentication. The identity of an extranet user is then confirmed when they present both the account name and password to the host application. Static passwords are not only the simplest way to control access, but also the least secure (Covill, 1998; Szuprowicz, 1998). Moreover, the password if transmitted over the Internet in text (versus encrypted) can be compromised by a password "sniffing" application. A security policy can resolve this potential security breach by using one-time only passwords that expire once a user has been authenticated or encrypting the password before transmission over the Internet (Phaltankar, 2000).

Other forms of authentication are available depending on the level of security required for the extranet. Source address authentication, for example, would authenticate an extranet user based on the IP address of their Internet connection (Phaltankar, 2000; Wack, Cutler, & Pole, 2001). This technique is typically used on intranets to restrict access based on those IP addresses that are internal to an organization. This method of authentication could be sufficient for small-scale extranets with few external organizations where the static IP addresses are known. This technique would not be ideal for global access to an extranet where the IP address of the user is unknown in advance.

Other forms of authentication include tokens, digital signatures, or smartcards to establish the identity of users (Loshin, 1997; Phaltankar, 2000; Pfaffenberger, 1998). Token authentication schemes typically involve two levels of authentication. The first requirement is a personal identification number (PIN), while the second form of authentication is a number displayed on the token card. For example, the SecurID card from Security Dynamics displays a unique number every 60 seconds, which in combination with the user's PIN forms a unique password. The advantage of using tokens or other authentication schemes is that authentication requires two pieces of information: something from the card and something from the user. Without both the card and the valid PIN, authentication will not occur. Of course these additional techniques require additional investments in hardware and software to manage user accounts and for password synchronization between the extranet server and the user's token card (Phaltankar, 2000).

Privacy

Privacy of communication with the extranet and exchange of data are typically implemented through an encryption technique. Encryption is the process of scrambling data before transmission over the public Internet. Several techniques are available, such as the public and private-key cryptography systems developed by RSA (see http://www.rsasecurity.com).

Exchanging information over the public Internet encounters the risk of alteration during transmission. While encryption is an effective strategy to protect the confidentiality of information during transmission, it does not prevent interception and alteration or guarantee that the data packets are received intact.

Data Integrity

Data integrity provides the assurance that the data transmitted over the public Internet are not modified in any way. Data integrity can be implemented by cryptographic checksums and hashing (Phaltankar, 2000). Hash functions create a fixed-size hash value that is a compressed, nonreadable form of a variable-length data message. One-way hash functions are preferred because the hash value cannot be reversed to reconstruct the original message (Covill, 1998). If the same hash value is not generated by the receiver when the data are received, the integrity of the data packet becomes questionable.

For most applications requiring privacy, encryption techniques such as a secure sockets layer (SSL) connection will provide sufficient data privacy and integrity. Virtually all Web browsers recognize the SSL protocol, among others, for data encryption. An organization can provide its business partners with access to an internal application via SSL and password authentication, similar to the way e-commerce Web sites currently interact with consumers (Wilson, 2001).

For sensitive applications or the exchange of strategic data, organizations may require additional security precautions, such as the creation of virtual private networks.

Virtual Private Network

A virtual private network is a technique of implementing secure connections over the public Internet through encryption and authentication schemes. VPNs can also be used to provide secure access to organizational networks for employees who are remote from the organization or perhaps telecommuting. The creation of private networks is also possible through leased lines, X.25 packet-oriented public data networks, or other private IP networks that are available from major service providers. The use of VPNs is becoming increasingly popular because of the cost savings over implementing private networks or remote access facilities, such as modem pools (Pfaffenberger, 1998; Salamone, 2000).

VPNs require firewalls that support VPN technologies. The VPN adds additional protection for the confidentiality and integrity of data transmitted over the Internet by using additional protocols and encryption. The VPN creates a “tunnel” through the Internet that establishes a secured connection from the user site to the extranet. Different protocols are available for implementing a VPN. One popular set of protocols is known as IPSec, the Internet security protocol (Wack, et al., 2001). Other current VPN protocols include point-to-point tunneling protocol, which is a Microsoft standard, and the layer 2 tunneling protocol.

The state of VPN technology and standards for communication protocols are still evolving. The disadvantage of implementing a VPN solution is that it almost always requires the same vendor hardware and software product on both ends of the connection, from the organization hosting the extranet and its business partners. It may not be possible, therefore, to require an organization’s partners to use one particular vendor’s VPN application (Wilson, 2001).

In addition to these security mechanisms, the placement of the extranet within the organizational network can affect security. Early implementations of extranets provided direct access to intranet servers to select outside parties. More recently, a “middle ground” between the public Internet and the internal intranet has become the home of the extranet. This middle ground, called the demilitarized zone (DMZ), is a physical space between the public Internet and the firewall of the intranet (Wack et al., 2001). By placing the extranet in the DMZ, the intranet is protected from potential security breaches by outside parties, both from business partners and potential hackers. Figure 2 depicts an organizational extranet within the DMZ. The DMZ is also used for public access servers, and again restricts the intranet to internal access. One potential disadvantage to this approach is mirroring content from the intranet onto the physically separate extranet that will require synchronization between the servers. The advantage of enhanced security of the intranet, however, would seem to outweigh the disadvantage of synchronization.

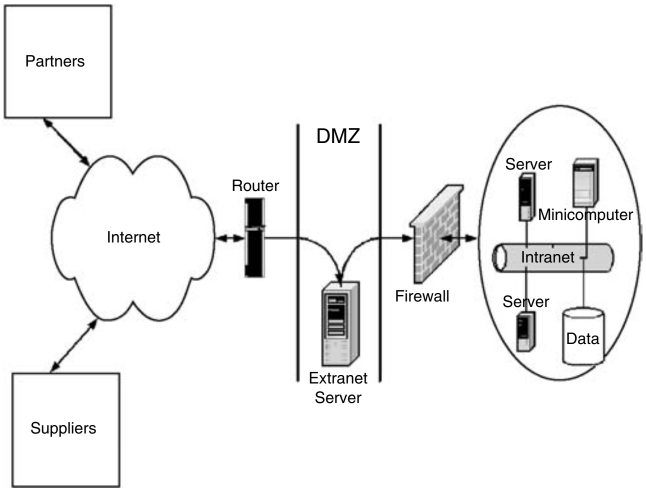

Figure 2: Organizational extranet within the DMZ.

Beyond the security of using the public Internet for business transactions, establishing business partnerships involves careful planning as well. Information technology professionals can design security systems to protect intranet resources from hackers on the public Internet. However, with extranets, the greater security threat may well be from within—disgruntled employees or business partners who have access to internal information (Marcinkowski, 2001). An organization’s extranet partners may come and go, and therefore consideration must be given to guarding against potential misuse of internal information. Moreover, the security of the extranet may be compromised by insufficient security at the partner’s site; that is, a security breach at a partner’s site also exposes the organization’s internal resources made available on the extranet (Schwartz, 2000). Weiler (2001) suggested several steps to safeguarding internal resources:

verifying the security of internal systems before exposing them to extranet partners;

developing contracts between business partners that address expectations, process, hiring background checks, and security administration;

developing human resources notification systems for events such as employee termination;

examining security administration systems; and

planning strategies based on risk management and emerging business requirements rather than on technology.

Outsourcing the Extranet

For organizations that do not have the internal expertise, the time, or the interest to develop and manage an extranet application, extranet service providers may provide a solution (Harreld, 2000). Outsourcing the extranet design, implementation, and management provides the organization with the expertise needed to deploy an extranet while freeing the organization to focus on content management concerns.

Several organizations provide outsourcing resources and technology for deployment of organizational extranets (see, for example, Szuprowicz, 1998). These services typically include extranet development, integration of existing intranets, facilities management, and security. Larger Internet service providers now provide extranet hosting services.

AVOIDING FAILURE IN EXTRANET DEPLOYMENT

Several reasons have been identified for the potential failure of extranet development and implementation (Pfaffenberger, 1998). Because the organization is exposed to external clients, suppliers, or partners through the deployment of an extranet, serious consideration is needed to minimize the potential for a failed extranet.

Potential reasons for extranet failure include:

Selecting technology for the extranet that is not compatible with organizational standards and expertise. If the extranet is going to be managed by internal personnel, then hardware and software decisions need to be mindful of the expertise of existing personnel.

Designing an extranet in the absence of a well-focused plan.

Anticipating potential resistance within the organization and reacting accordingly.

Failing to plan for increased demand and additional capacity. In planning for an extranet, the server architecture should be scalable so additional capacity can be provided as demand for services increases.

Excluding critical stakeholders in the planning process. The success of an extranet will be determined by its usefulness. This includes understanding the needs of business partners who will be accessing the extranet, such as suppliers or customers. A cross-organizational team is ideal for defining the services of an extranet.

Failing to plan and establish content standards and guidelines. Extranets are created for external audiences and therefore makes content guidelines more critical than for internal networks. The organization's image and credibility are at stake if the content provided on the extranet site is not current, reliable, and useful to the external audiences. In a 1999 study of 30 business-to-business sites by Forrester Research, each of the sites failed basic tests of value, ease, and reliability (Sonderegger, 1999). Major problems included missing content, limited functionality, and frequent errors. Planning content for an extranet should be designed with customers, not companies, in mind using a scenario-centered design methodology.

Neglecting to identify who is responsible for the extranet. Extranets are likely to span departmental functions and boundaries and therefore some department will need to be assigned the responsibility for extranet management and coordination of content. In addition, managing the content of an extranet is a time consuming task. As much as 70 to 80% of an extranet's recurring costs are attributable to content management (Pfaffenberger, 1998).

CONCLUSION

Extranets can fundamentally change how organizations share internal resources and interact with outside suppliers, customers, and strategic business partners. The implementation of an extranet can be effective in developing tighter linkages in supply chain management and customer relationship management. The current trends suggest an increasing movement toward developing these linkages through extranet applications. Extranets provide a cost effective means to improve collaboration and decrease the time to market for new products. Moreover, extranets can increase internal efficiencies within the organization. As the extranet examples have shown, applications for extranet deployment are not isolated to one type of industry. Extranets can be effective in seizing a competitive advantage in virtually any type of industry.

The implementation of an extranet solution for any business requires careful planning and a shift in business and management philosophy. Moreover, opening the corporate intranet requires careful assessment of security precautions, defining the external audiences who should have access, and establishing policies for content management.

GLOSSARY

Electronic data interchange A computer-to-computer exchange of business information in a standard electronic format between business partners.

Extranet A collaborative network that uses Internet technology to extend intranet application and services to selected entities external to the organization, such as suppliers, customers, or other businesses that share common goals.

Firewall A device that protects internal networks from unauthorized access from external sources, typically the Internet.

Internet A global network of interconnected networks, providing connection for private and public networks in one cohesive unit.

Intranet A private enterprise network that uses the Internet and Web technologies for information gathering and distribution within the organization.

Virtual private network A technique of implementing secure connections over the public Internet through encryption and authentication schemes.

Feasibility of Global E-business Projects

Peter Raven, *Seattle University*
C. Patrick Fleenor, *Seattle University*

INTRODUCTION

Businesses realized the commercial value of the Internet shortly after the introduction of the World Wide Web in about 1994 in Switzerland. The graphics capabilities of the Web encouraged many people, even those without technical skills, to utilize the Internet. As a result, the Internet has grown more rapidly than any other commercialized media technology, including radio and television. As the number of people accessing the Internet has grown, the Internet has become a global phenomenon. But why should an e-business consider expanding globally? In a phrase, "that's where the money is!"

A Web site oriented to North Americans reaches only 4% of the world's population and 20% of the global economy. The U.S. share of the global Internet population will decrease from 36% in 2001 to about 24% in 2005 (Dunlap, 2001). Half of all online revenue will come from outside the United States by 2004. Clearly, e-business opportunities will increasingly be global. Unfortunately, two-thirds of U.S. firms are not prepared to do business in the global online market space.

There are many compelling reasons to consider global e-business, not the least of which is the very rapid rate of growth in online populations overseas, some of which have doubled in the past year (Dunlap, 2001). Global markets are often used to hedge economic conditions. For example, while the U.S. may be in an economic slump, other countries may be growing, allowing companies to maintain or even increase sales. Often, the first company into a new foreign market may realize a competitive advantage. Beating competitors to lucrative overseas markets has far-reaching implications in developing new markets and being able to sustain current markets. Progressive firms are increasingly interested in globalizing, but the nuances of conducting global e-business often escape them. Doing global business on the Internet provides many opportunities for product differentiation, creating new forms of complex transactions, simplifying routine purchases, and many other possibilities (Leamer & Storper, 2001). This chapter explores the feasibility of global e-business projects and focuses on global strategies for commercially using the Internet. To answer the title's implied question, is it feasible to develop global e-business? The answer is a resounding *yes*, but it is not always easy or straightforward.

BACKGROUND

In this section we examine the growth of e-business and e-business models to help build a framework for developing global strategies. Although the terms e-business and e-commerce are often used interchangeably, we define *e-business* as all the activities a firm can use on the Internet to facilitate business and *e-commerce* as strictly transactions via a Web site. E-business activities include information dissemination and collection, advertising, promotion, communication, transactions (e-commerce), and many other processes.

Growth of E-business

E-business has grown with the Web. With more than half a billion people online (Table 1), many businesses think it imperative to incorporate the Internet into their strategies. Once a firm is on the Internet, it also has a global presence, but merely having a global presence does not imply that it is ready for global e-business!

Planning for an effective global e-business requires companies to incorporate global Internet strategies. There is considerable anecdotal evidence to illustrate the problems of not developing a good Internet strategy. Neglecting to plan for foreign visitors is one of the more obvious. Evidence from Web site logs suggests that about a third of all visitors to U.S. e-business sites are from overseas (Gutzman, 2000). Ignoring these foreign visitors results in lost business. Further, some Internet firms have even been given a solid order from overseas customers, but have lacked the knowledge to fulfill it, resulting in lost

Table 1 Global Online Population ("Educated guess" as of May 2002)

	February 2002	May 2002
World Total	544.2 million	580.78 million
Africa	4.15	6.31

sales and perhaps ill will. Good business practices are especially critical for success in global markets.

Internet Business Models

Several business models exist on the Internet, but four dominate: Business-to-consumer (B2C), business-to-business (B2B), consumer-to-consumer (C2C), and business-to-government or government-to-business.

Business-to-consumer models have the most public visibility and are what most people consider as business on the Internet. B2C models are essentially online storefronts, but there are many variations, ranging from strictly informational sites all the way to highly interactive and personalized transactional sites. Although statistics of Internet usage are suspect due to different measures, the numbers provide some insight. In the U.S., 84% of Internet users have purchased something online (NUA, 2002b). Even though B2C e-commerce is only about 1% of all retailing, 49% of Internet users bought online in 2001 and spending online has increased threefold since 1999, probably due to increased consumer confidence and perceived convenience. Interestingly, consumers express considerably more trust in some institutions than others. A national survey of Internet users revealed that 68% of them trusted information from small businesses almost always or most of the time, but only 32% held that much confidence in large corporations (Princeton Survey Research Associates, 2002).

Business-to-business e-commerce dwarfs that of B2C. B2B models range from procurement (including electronic data interchange) to supply chain management (SCM) to customer relationship management (CRM). B2B models include both informational and transactional activities between businesses. International Data Corporation (IDC) forecasts global B2B revenues to climb from (in U.S. dollars) $282 billion in 2000 to $4.3 trillion in 2005, a compound annual growth rate (CAGR) of 73% (IDC, 2002). The potential for growth is evident by estimates that online e-commerce was only about 2% of all U.S. B2B trade in 2001 and that only 11% of U.S. companies have fully implemented e-business strategies (Cyberatlas, 2002).

While most B2B transactions occur in the U.S., B2B e-businesses in Western Europe and the Asia–Pacific region are expected to grow rapidly. For example, B2B e-commerce was about $9.2 billion in Asia in 1999, but it is expected be $1 trillion in 2004 (Lewis, 2000). IDC predicts the B2B market in the Asia–Pacific region (excluding Japan) to grow at an exceptional rate over the next few years to about $500 billion by 2005, as online access improves and firms become increasingly interconnected (IDC, 2001). Cyberatlas (2002) predicts a CAGR of 68% from 2001 to 2005 in the U.S., Western Europe at 91%, and the Asia–Pacific region at 109%. As can be seen, B2B e-business is expected to be the focus of most of the rapid growth of global e-business in the near future.

Consumer-to-consumer e-business is most evident in the U.S. in auction sites such as eBay and barter sites such as SwapVillage. The size of this market is difficult to measure, since some goods are exchanged, rather than purchased; thus figures reported underestimate the true value of this activity. However, eBayis considered the largest C2C site with 2001 sales of $748.8 million and a growth rate of almost 74% in 2001 (Hoover's Online, 2002). This model has increasingly been adopted in some European countries where auctions are already common and require few new consumer behaviors.

Business-to-government or *government-to-business* is also a growing trend. Many governments encourage the use of the Internet for both internal government communications and between businesses and consumers. The United States took an early lead in this direction during the Clinton Administration with that administration's framework for global e-commerce making government agencies accessible on the Internet (Clinton & Gore, 1997). As an example, the U.S. Internal Revenue Service encourages the filing of income taxes electronically. Taxes may be paid by credit card and refunds deposited directly into a bank account. Finland and Singapore are other countries where a number of government services are available online, with some transactions permitted.

Companies select strategies for their Internet presence—from "pure play," where a company only has an Internet presence, to a "bricks and clicks" model, where a company has both an online and an offline presence. Firms may mix a bricks and clicks model in one market and a pure play in other global markets, depending on whether they already have a physical presence in the market and on their strategy for the market. Our discussion will focus primarily on online B2C and B2B models, with either pure play or bricks and clicks strategies assumed, as these are most important internationally. While there are obvious differences between B2C and B2B, there are also many similarities and many companies employ both models. Manufacturing firms, for example, may use B2B in their SCM and B2C in e-tailing products to final consumers. Therefore, we consider B2B and B2C jointly.

Factors Influencing Global E-business Strategy

Despite the great promise of the Internet for equalization across countries and markets, e-business has not yet fulfilled that promise. Indicators identifying new markets for e-commerce are not well established, but some have gained greater acceptance than others. However, these indicators may not provide the specificity needed to accurately identify potential markets for individual firms. For example, the U.S. has had a tremendous growth in e-commerce due to a homogeneous language and good infrastructure, and because it is a large country (Krück & Papenbrock, 2000). Although most regions of the world do not benefit from all of these important factors, other issues may suggest e-business potential.

Not all countries are equally well connected to the Internet and firms utilize the Internet to different degrees within countries and between countries. Industry Canada, for example, proposed a model adopted by the United Nations Conference on Trade and Development as a starting point for assessing e-business readiness of a country (UNCTAD, 2001). Included in the model are

Readiness of its people, businesses, economy, and infrastructure to undertake e-commerce—of primary interest for countries in early stages of e-business activity.

Intensity with which information and communication technologies are used within a country—of interest for countries where e-business is becoming more prevalent.

Impact of e-business on national economies and business activities—of interest for countries where e-business is well developed.

This model provides an initial, broad screening device that firms can use to understand the current level of e-business of a country before examining the potential more closely.

Many factors influence Internet usage and global e-commerce, just as they do any international trade initiative. Some factors are common to both offline and online market development, but those specific to the Internet include personal computer (PC) penetration, telecommunications infrastructure, and political, economic, and cultural issues related to the Internet and specific to each country. For example, Rasmusson (2000) suggests that wealth, education levels, telecom infrastructure, and PC penetration influence Internet usage in Europe. Ebusinessforum.com (2001b) publishes a ranking of countries based on their "e-readiness." This site is enlightening in that it weights countries on six categories.

Connectivity (30%): adequacy of telecommunications and Internet infrastructure, including fixed and mobile services, affordability, and availability.

Business environment (20%): expected attractiveness of the business environment in the next five years.

E-commerce consumer and business adoption (20%): including payment and logistics systems.

Legal and regulatory environment (15%): including a legal framework involving e-business, support for legal transactions, and digital signatures.

Supporting e-services (10%): intermediaries, portals, Web hosting firms, application service providers, and others.

Social and cultural infrastructure (5%): education, literacy, entrepreneurship, risk-taking, and proclivity for business innovation.

That study concluded that active government support is often needed to assure affordable Internet access. In this regard, large countries do not necessarily have an advantage over smaller countries. For example, India and China both have large populations and, while Internet usage is growing rapidly, these countries suffer from poverty, illiteracy, and poor information and communications technology (ICT) infrastructure. On the other hand, wealthy countries do not always have an advantage over less wealthy countries. More important to e-business readiness, it seems, is a country's embracing of high tech industries and broadband connectivity.

Many of the measures used by E-businessforum.com and others are obvious, but it is necessary to discuss in greater detail PC penetration, infrastructure, and regulatory issues.

PC Penetration

The degree to which personal computers have been adopted is frequently used as a key indicator of e-commerce readiness. PC penetration is highly correlated with income level (Rabe, 2001). For e-commerce to succeed, some threshold level of income is necessary, not only to purchase a PC and products online, but also to access the Internet. PCs are the dominant means of connection and likely to be so for some time. GartnerG2 predicts that in Europe, even with its high penetration of interactive TV and wireless connections, 73% of online shopping will still be done on PCs by 2005 (Regan, 2002b). As might be expected, PC penetration varies widely around the world. In Asia, for example, it ranges from 17/1000 in Thailand to 217/1000 in Singapore (Polster & Trinh, 2000). In the U.S. PC penetration is about 60% of households, with more than 70% in some U.S. cities (Scarborough Research, 2000). However, PC penetration is not a complete measure of Internet access, as office and home computers could be shared, Internet cafes may be popular, and wireless devices can be used.

Infrastructure

Internet transactions require a modern telecommunications infrastructure. Some countries have sophisticated telecommunications systems, which facilitate Internet connectivity. Others, however, have neglected or have been unable to build the necessary systems. Data describing the level of Internet use in a country is often questioned because the estimates vary considerably and may have been published for political or other purposes. Several indicators of telecommunications infrastructure exist to help companies realistically evaluate connectivity. When taken together, they provide a fair indication of current and potential Internet use in particular: telephone penetration, cost of connection, number of Internet service providers (ISPs), and level of broadband usage. Telephone penetration is a reasonable indicator of Internet connectivity because much of the world connects to the Internet through regular telephone lines. Related to telephone penetration is the cost of being connected through telephone lines (WTM, 2001a; Rabe, 2001). Except for Finland and Denmark, European countries pay much higher connection fees than in the U.S., where the average is $25 per month for unlimited access. ISP charges in France average $45 a month and in Germany $68 for just 20 hours. To reduce connection costs, some European ISPs offer free services, taking a portion of the telecommunications fees. These prices are due partly to telephone monopolies and price gouging (Singh, Jayashankar, & Singh, 2001). In addition, many telephone systems charge a toll per unit time of usage. The combination of connection charges and use charges tends to inhibit the usage of the Internet in many countries and, by extension, reduces e-commerce activity. Crispin (2000) indicates that government policies can also severely hinder e-business. In Thailand for example, all long distance telephone and Internet connections pass through the Communications Authority of Thailand (CAT), a monopoly resulting in limited choices, high fees, and historically poor service.

The number of ISPs provides an indication of the extent of commercial Internet use in a country. Presumably, the greater the number of ISPs, the more people within a country utilize the Internet.

Broadband facilitates Internet connectivity, but broadband infrastructure varies a great deal globally. Singapore, Hong Kong, and South Korea are broadly wired for broadband (McKinsey, 2001). South Korea is now the world's leading broadband market with 40% of households connected to the Internet, half by broadband (Dodgson, 2001). Broadband is not yet very common in Europe, but it is growing in popularity.

Economic, Regulatory, and Cultural Influences

The society within which businesses operate influences how business functions and performs. Some social aspects relevant to e-business include the following.

Economic influences are probably the most generalizable because they impact all businesses to some extent. A recession affects both offline and online businesses. The feasibility of e-business is necessarily influenced by the economic conditions in a target country. Economic trends, infrastructure development, income levels, and many other factors influence a country's potential for e-business. For example, the recent economic downturn in Asia has affected all businesses.

Regulation of the Internet is generally not well developed, with most countries either leaving the Internet alone or just contemplating regulations. The European Union (EU) has been the most active in regulating Internet activities, primarily in privacy issues. In May 2001, the European Commission prepared an eEurope action plan with three main objectives: to provide inexpensive, fast, and secure online access; to invest in IT and information society skills; and to promote the use of the Internet (Ebusinessforum.com, 2001a). Recently, a Norwegian was imprisoned for posting racist and anti-Semitic propaganda on a Web site (Seattle Post-Intelligencer, 2000).

The integrity of the institutional environment, especially the "rule of law," is important for the development of e-business (Oxley & Yeung, 2001). Businesses and consumers need to be confident that a firm will deliver satisfactory performance and that there is legal recourse if it does not. While physical infrastructure is most important for explaining *variations* in Internet use, the Oxley and Yeung (2001) data support that e-commerce *activity* depends primarily on the rule of law, and secondarily on the availability of payment methods, such as credit cards. In countries without a strong rule of law tradition, personal relationships become more important and customers are often leery of dealing with faceless strangers over the Internet. In such societies, close-knit trading communities developed to strengthen discipline through informal sanctions. E-commerce is not likely to flourish in its present state in such an environment.

Regulating access to the Internet occurs in several countries. Some countries make a concerted effort to protect their citizens and/or political regimes from accessing the full Internet. China has been very concerned about isolating the country from the rest of the network. Chinese users are encouraged to use the Internet, but access to overseas sites is strictly controlled and the information users post online is closely monitored (Economist, 2001). Singapore, Saudi Arabia, Syria, and the United Arab Emirates filter and censor Internet content. South Korea bans gambling sites. In Iran it is illegal for children to use the Internet and access providers must filter any immoral and anti-Iranian material. In our view, attempts at broad control will ultimately fail. Several countries still attempt to control access to television broadcasts, but the advent of satellite TV has made full control nearly impossible. Internet access will undoubtedly follow a similar development.

Culture and sensitivity to cultural differences play critical roles in successful international business. Understanding how the Web fits into a country's culture is necessary to forming successful customer relations (Rasmusson, 2000). Sites targeting foreign consumers should appear friendly to them, which often requires translating the site into the local language. Eighty percent of Web content is now delivered in English, but almost half of current users do not read English or they prefer to use their own languages. As more non-English speakers go online, translating sites into local languages becomes increasingly important for assuring customer satisfaction. Different languages and cultural values compound the complexity of e-business overseas. An even bigger barrier may be the attitude of business and government entities (Singh, Jayashankar, & Singh, 2001). For example, many European CEOs understand the power of the Internet, but fail to fully exploit it. They see the Internet more as a tool for improving existing business models, rather than a revolutionary device requiring a completely different mindset. In the end, they may be proved right, but this attitude perhaps partially accounts for the uneven acceptance and use of the Internet in industrial Europe.

In addition to language and attitudes, other cultural behaviors such as risk aversion and lifestyle differences may impact success on the Web (Singh et al., 2001). The use of Hofstede's (1980) cultural dimensions can help e-businesses better understand their customers. For example, cultures rating high on uncertainty avoidance and low on individualism are likely to be difficult markets for introducing consumer e-business.

In a recent empirical study, Lynch and Beck (2001) profile Internet buyers in 20 countries in major regions of the world. Their study compares two views of global Internet customers: (1) that there is essentially a world culture of Internet users allowing for standardization of Internet offerings and (2) that there are cultural differences between local markets, suggesting that standardization is infrequently promising (i.e., the standardize/customize dilemma). Their findings indicate that North American Internet users were unique among respondents in that they had a greater affinity for the Internet, less fear of it, enjoyed shopping more on it, and typically looked for branded products. The authors concluded that building a standardized Web site based on North American preferences would not be advisable because of profound cultural differences. Asians, for example, like to shop and look for brands, but have the least favorable attitudes toward the Internet and low intentions to purchase on it. While these differences were noted, the authors also found few differences between countries in a particular region (North America, Europe, and Asia/Pacific).

Global Internet Law

There are no political or natural boundaries applicable to the Internet; so a crime or action committed in cyberspace is not clearly limited to one country or region of the world. In addition, the open infrastructure of the Internet has led to a number of laws in various jurisdictions. The communication and exchange of information cannot be centralized or monopolized on the Internet, as is possible in traditional communication systems. For example, less than a dozen U.S. corporations own and operate 90% of the mass media controlling almost all of America's newspapers, magazines, TV and radio stations, books, records, movies, videos, wire services, and photo agencies (Bagdikian, 1997). The Internet is much more fragmented and loosely controlled by many organizations, including businesses, governmental organizations, individuals, nongovernment organizations, associations, and many others. Nevertheless, countries and international organizations are developing legal frameworks to ensure an efficient and fair use of the available information.

The Internet and its cross-border activities challenge the traditional state-based precepts of private international law. The range of actual and potential disputes affects many aspects in the private and public arenas. Specifically regarding international business, these disputes include e-commerce, taxation, freedom of expression and other human rights, jurisdiction, privacy and data security, and intellectual property rights. The necessity for providing a framework for reliable Internet legislation, adjudication, and enforcement is crucial for global trading. States need to agree on identification of new crimes, jurisdictional rights, and criminal liabilities regarding communications on the Internet. For a basis, states may use legal models of the law of the sea and/or outer space regulations, which deal with similar issues.

Federal governments can regulate a large portion of the Internet, but international e-commerce relies more on international agreements and treaties for legal basis. A variety of mechanisms exist in the international legal systems that provide continuing frameworks for preparatory works in treaty negotiation. The Hague Conference on Private International Law, the International Telecommunication Union, the World Trade Organization, the World Intellectual Property Organization, and other United Nations organizations have permanent secretariats which maintain evolving agendas referring to possibilities for negotiation of new treaties. For example, The Hague Conference on Private International Law attempted in 1999 to establish common grounds for jurisdiction and applicable law arising out of electronic commerce and Internet transactions (The Hague Conference, 1999).

Global Internet law deals with three different issues created by the Internet: first, the Internet facilitates the negotiations of treaty-based systems; second, it alters the balance of interests that shapes the political dynamics determining the content of international law; and third, the Internet's global character challenges traditional state-based precepts of private international law. One of the main reasons is the low economic barrier that allows for access and participation of more people in the discussion of policymaking. Consequently, weaker groups in the political arena can easily mobilize people across national borders. The Internet drastically reduces search costs, thereby making it possible for groups advocating for international legislation to communicate, organize, and bring political pressure to bear. Nongovernmental organizations can easily direct their activities and coordinate through e-mail and the Web. In addition, the Internet aids in detecting violations and mobilizes sanctions on the violators (Perritt, 2000).

The issues are less problematic for e-commerce because the governing law is usually the respective commercial contracts law of a nation. B2B has been fairly easy to deal with, but B2C and C2C have created enormous legal challenges. Private individuals constitute a free-rider problem because they are interested in acquiring information for little or no cost and they cannot effectively be prevented from doing so. Two of the most obvious examples are Napster.com and Morpheus.com, which allowed Web users to download free copies of copyright-protected works. On the other hand, businesses, including e-businesses, have contractual obligations toward each other as there is usually an exchange of some value between the parties. The contract issues are different for private individuals—they do not usually enter into legal contracts with businesses with specified terms and obligations online.

The United States and the European Union represent two different approaches for regulating the Internet. The EU has enacted tough privacy legislation for data collected through the Internet. The EU prohibits data on EU citizens from leaving the EU to countries that do not have privacy standards for Internet data equal to those of the EU—the emphasis here is on individual privacy. In contrast, U.S. privacy policy is not as comprehensive, as the U.S. targets specific areas only when considered needed. U.S. Internet privacy policy is market-oriented. Firms can buy and sell data collected from cookies and mouse clicks to other firms and regulate their conduct themselves. In order to bridge these different privacy approaches and facilitate U.S. organizations' compliance with the EU directive, the U.S. Department of Commerce, in consultation with the European Commission, developed a "safe harbor" framework (U.S. Department of Commerce, 2002). The Safe Harbor framework sets out seven principles in order to be eligible for doing business in the EU. These principles include

Notice: providing notice to individuals that data are being collected and how the information will be used.

Choice: individuals must be given the opportunity to "opt out" and choose not to have their personal information disclosed to a third party.

Onward transfer: to disclose information to a third party, organizations must subscribe to the choice and notice principles.

Access: individuals are to have access to their personal information and the ability to amend incorrect information.

Security: organizations must take reasonable precautions with personal information.

Data integrity: personal information must be relevant and reliable.

Enforcement: recourse and other mechanisms for complaints and verification must be in place.

Firms complying with Safe Harbor are theoretically eligible to transmit data from the EU to their U.S. offices, as well as to receive other legal benefits.

Since the terrorist attacks of September 11, 2001, privacy issues have changed somewhat. The EU has considered making cyber attacks punishable as a terrorist offense. Germany has reduced restraints on government interception of communications. Canada and Australia have introduced laws to redefine terrorist activity and grant powers of surveillance to security agencies if terrorist activity is suspected. Singapore introduced a model data protection code in February 2002 and many other countries have initiated specific anti-terrorism measures. In addition, the worldwide economic slowdown and terrorism anxiety have increased the demand for Web conferencing technologies. As business people travel less, communication is increasingly through electronic means (Geralds, 2002). This, of course, has important implications for global e-businesses. Firms that have geared up for Internet communications and transactions with their global subsidiaries, branches, suppliers, and customers should be at a competitive advantage over their rivals who cling to traditional communication and transaction methods.

Regional Growth of E-business

In this section we examine regional variations in the growth of e-business and examine the critical e-business issues in each region. Our examination of regions is not exhaustive, but, rather, illustrative of regional variations in e-business. By 2005, nearly one billion people (15% of the world population) will be using the Internet (Ecommerce, 2001a). With more than 100 million new users on the Web each year, the Internet will become widespread and not dominated by a single region. However, there are numerous regional differences, many of which will likely persist. We begin with the birthplace of the Internet, the United States and North America.

North America

Growth of Internet use in the U.S. continues, but at a somewhat slower rate than in the past few years. PC penetration and Internet connectivity are in the mature phase of their life cycles, as indicated by their use by large percentages of the population and decreasing rates of Internet growth. In 2000, 54 million U.S. households (51%) had one or more computers and 80% of households (44 million) with computers had at least one member using the Internet at home (Newburger, 2001).

The future for Internet usage is encouraging, though, as 90% of school-age children have access to a computer, either at home or in school, and weekly use has increased (Newburger, 2001). In addition, children increasingly turn on their computers, rather than radios or televisions, to get news and information. Women, minorities, retirees, the less affluent, and the less educated have all increased their usage of the Internet in the past few years (Pastore, 2001).

The Internet is increasingly an important part of the B2B market in the U.S. A recent study found that 45% of large U.S. companies spending $100 million or more per year on supplies used the Internet in the fourth quarter of 2001. This was up sharply from the previous quarter at 28% (Regan, 2002a). Most U.S. corporate executives (53%) see the Internet as either "very important" or "critical" and 87% indicated it was "important" to their purchasing and cost-savings plans in 2002.

Western Europe

The number of Internet users in Western Europe has now overtaken that of the United States (Upton, 2002). Western Europe contributes about 29.8% of global Internet users, while the U.S. has 29.2%. However, Western Europe lags the U.S. in e-commerce revenue—25.7% of the total versus 43.7%. Internet use has grown rapidly in Europe, but somewhat differently from the U.S. Differences in telecommunications charges, landline availability, and other factors caused Western Europe to lag behind North America in Internet usage, especially e-commerce (Greenberg and Spiegel, 2000). Further, there is a reluctance to buy online because of perceived risk of credit card fraud and a mistrust of online shops. Western Europe is characterized by different cultures and languages that have inhibited uniform growth in technological advances. There is also a disparity in Internet connectivity. Connectivity is greatest in the north and progressively diminishes as one travels further south. As a result, the Nordic countries are considerably ahead of other European countries, particularly southern European countries, and even the U.S., in e-business.

Nevertheless, in their e-Europe Initiative of 1999 EU governments stress the need for every European citizen to be online as soon as possible (Liff, 2000). Importantly, the EU has recognized the potential of the Internet to be socially inclusive, building consumer trust and social cohesion (eEurope, 2002). As the e-Europe Initiative progresses through different stages of development, both governments and consumers will be encouraged to utilize the Internet for e-business and other activities. The advent of the euro as common currency in most of the EU will remove even more barriers to e-business (Grant, 2002).

Nordic countries lead Europe in Internet connectivity and Internet usage there is growing, as is online purchasing. Scandinavian countries are the most wired nations in the world. They are also relatively homogeneous markets, making them ideal for a number of marketing initiatives, including call and customer service centers. Digital signatures are legally acceptable, indicating a readiness for e-contracts. While there are individual variations, foreign firms doing business in these countries are expected to pay value added taxes, unless the level of business is below some threshold, when it becomes the obligation of the consumer.

Finland is, of course, the home of Nokia, a world-class marketer of wireless phones and appliances, and the Finnish government encourages the use of Internet commercial activities, including the issuing of national e-identification cards to facilitate online commerce. In a country of about 5.2 million people, 42% of households had PCs in 1999 and 2.2 million were online in 2000 (Ebusinessforum.com, 2002). About 70% of the population in 2000 had cell phones and the number of cell phones has surpassed the number of fixed telephone lines. By 2003 it is estimated that more mobile phones than PCs will be connected to the Internet.

The infrastructure in Finland is in place for e-business, but Finns seem reluctant to shop online. Jupiter Communications expected only 36.8% of the population to purchase online in 2002. Most businesses with more than 20 employees had Internet access in 1999 and about 52% of Finnish firms ordered goods and services online. Thus, this country is poised for e-business growth and online volume has increased considerably with monthly turnover of B2C e-commerce estimated at (in Finnish Markkaa) 113 million in February 2000 (Ebusinessforum.com, 2002). B2B e-commerce is estimated to be at least 10 times that amount.

Mobile commerce (m-commerce) is attracting much interest and its potential is very large due to the expected rapid growth in mobile phone use in the next few years. In a recent move to capitalize on the global growth of mobile phones and the huge potential for m-commerce, Nokia will license its source code controlling such functions as mobile Web browsing and the popular short messaging software to a consortium of mobile phone manufacturers and operators (Brewin, 2001). The mobile software components will initially include multimedia messaging, digital rights management for music and video, subscriber authentication, and XHTML for Web browsing. The authentication software is seen as being able to jump-start m-commerce.

Sweden is the largest of the Scandinavian markets and has taken the lead in IT technology evolution (Yorgey, 2001). Relatively low telecommunications costs, a high GNP/capita, and favorable social policies drive this technology evolution. In this country of almost 9 million, 71% of the population is online and 60% of the population uses cell phones (Ebusinessforum.com, 2002). B2B e-commerce is growing, especially in the music and steel industries. Sweden is a mature Internet market with most of the purchasing options found in the U.S. B2B, B2C, and C2C are typical business models, but the Swedes are also launching consumer driven and alternative pricing sites, including “group shopping” sites where vendors drop the price after a critical mass of buyers request it.

Norway has considerable wealth generated by its offshore petroleum and gas resources. Norway is well wired and e-commerce has taken off with little hindering it (Ebusinessforum.com, 2002). With 500,000 installed lines, Norway has the highest rate of integrated services digital network penetration in world. E-commerce spending is expected to reach $4.7 billion in 2002 because online consumers can buy everything from food to books to electricity on the Internet. As is typical in Nordic countries, online banking is available through even the smaller banks as well as Internet-only banks. In the B2B area, Norwegian businesses readily use the Internet for procurement, logistics, and data transmission. The government is planning to allow firms to pay taxes, fees, and customs duties electronically. The oil industry utilizes e-commerce extensively in online auctioning for procurement, providing management information, and integrated systems through third-party service providers (Kingsley, 2000). M-commerce is, of course, taking off rapidly.

With the largest population of any country in Europe, Germany is an important market, but e-commerce represents a relatively small part of its economy. However, with 1.4 million Internet hosts in 1998, 25% of the population owning a PC, and 10% able to access the Internet, the Internet future appears bright. E-commerce spending is expected to reach $62.8 billion in 2002, about twice that of 2001 (Ebusinessforum.com, 2002). The German government continues to liberalize the Internet and telecommunications sectors and to implement EU directives (Lubben & Karenfort, 2001). Many of the regulations are designed to enhance consumer confidence in e-commerce. For example, the Distance Selling Act applies to all contracts between sellers and consumers by distance communication, including the Internet. It gives consumers the right to withdraw from such a contract for a period of time if the seller does not provide sufficient details about the product/service and consumers’ legal rights. However, Germany has strict regulations regarding offline and online store hours.

Although France has had online capabilities for about two decades through the state-run Minitel system, their Internet capabilities have not kept pace. The Minitel service is quite expensive and does not connect easily to the Internet, so it is of limited e-business value. Only 12% of the French population is connected to the Internet, but these people are avid users, primarily of chat programs. One of the factors inhibiting commercial use of the Internet is the cost of connection, which can run from $2.50–$4.00 per hour, not including ISP charges. Europeans in general, and the French in particular, are somewhat reluctant to purchase online because of fear of credit card fraud (Greenberg & Spiegel, 2000).

The U.K. is more similar to the U.S. than with its European neighbors in its use of ICT for e-business. Regulations in the U.K. and Sweden tend to be lighter than in other European countries, facilitating Internet shopping (Ecommerce, 2001b). The British have taken to the Internet, both consumers and businesses, and are much more likely to use credit cards for payment than other Europeans.

Southern European countries, such as Spain, Portugal, and Italy, lag behind their northern neighbors, but there are encouraging signs even here. These countries have seen some of the highest rates of average growth in Internet usage in Europe and the IDC believes that they will reach levels comparable to the more advanced European countries in coming years (Skipper-Pedersen, 2001).

European Internet penetration seems to have plateaued at about 38% in December 2001 (Ebusiness-forum, 2002). The slower uptake of ICT by consumers is partly a result of persistent high costs of computer connections, even though dialup costs are decreasing since the telecommunications markets have been opening up. Broadband costs are significant, running €45–€60 per month. B2C e-commerce is developing more slowly than predicted, leaving some doubt if the EU will meet its objective of making it "the world's most dynamic knowledge based economy" by 2010. In 2002, Germany is expected to dominate e-commerce sales with $20 billion, followed by the UK at $9 billion, and France with less than $4 billion (Regan, 2002b). However, European online purchasing habits differ between countries. Swedes, the Swiss, Spaniards, and Italians prefer to buy with cash, the French with checks, and Germans, Swiss, and Austrians want an invoice option to pay. Only the British include credit cards among their top three payment methods.

Asia–Pacific Region

Asians seem to adopt technology long before adapting it to e-business. One study found that small- and medium-sized enterprises (SMEs) face a number of barriers in adopting e-commerce in Asia. One of the most important barriers is the low use of e-commerce by consumers and companies within Asia–Pacific Economic Cooperation (APEC) countries, particularly the less developed member nations. This inhibits SMEs from selling online to consumers and conducting e-commerce with other companies (PWC, 2000).

The Boston Consulting Group estimates that Asian B2C revenues more than doubled in 2000 and will grow by more than 100% per year, led by the banking and finance industry (Peng, 2002). There is an average of only 0.01 PCs/person in Asia, compared to 0.40 in the U.S. As a result, average online retail spending is quite low, but there is wide variance. For example, on average, Indonesians annually spend $0.01/person online, Indians $0.03, Thais $0.20, and Malays $0.50. Even though the affluent societies of Taiwan, Singapore, and Hong Kong are very well connected to the Internet, people there would rather shop in malls, where they can touch and compare products, as shopping is considered a pastime. Asians are also wary of using credit cards online. To reduce this concern, VISA now offers a "Verified by VISA Program" using personalized passwords to serve as additional verification.

Despite these issues, there is substantial opportunity for e-business in Asia, especially in China and South Korea. Although business portals have difficulty generating revenue, e-commerce revenue is expected to grow to more than $16 billion over the next few years (China Daily, 2002). Firms have found creative ways of overcoming the lack of credit card penetration. For example, Jiangsu Province is testing a new "cyber-notary" system to reduce the risks of identity theft in Internet bidding (Ji, 2002). Dell Computers is allowing customers to pay on delivery or through banks (Einhorn, 2001). Dell sees China as a country with 1.3 billion people and less than 10% PC penetration, but closer to 30% penetration in wealthier cities. Dell's strategy is to reduce the price of computers to the point where 85% of the Chinese urban population can afford one.

South Korea makes a concerted effort to increase connectivity and now it has the highest broadband penetration in the world, with more than half of South Korea's 15 million households having broadband and 60% of the population with cell phones. The Seoul suburb of Seongnam plans to be the world's first digital city (Ihlwan, 2002). Broadband connections there are expected to do away with cash and credit cards. Citizens will be able to pay for purchases at every store via digital cell phones.

Japan is noted as the Asian leader in technological innovations and for its high penetration of NTT DoCoMo's i-mode, a cell phone messaging system, but less so for its Internet connectivity. Despite the high levels of mobile phone penetration, most Japanese connect to the Internet via PCs (75%). Internet penetration remains under 20% in Japan and will likely remain below the level of other countries in the region, such as Singapore (41% penetration), Australia (32%), Taiwan (29%), Hong Kong (22.6%), and South Korea (21.2%) (Cheung, 2001c). However, Internet penetration in Japan is projected to grow to 29% by 2004, with e-commerce revenues growing proportionately. B2B e-business has the potential to modify traditional Japanese business practices, especially the inefficient and expensive distribution system through disintermediation. Credit cards are not widely used in Japan, but innovative ways around that are sometimes used. For example, the local convenience store sometimes acts as Internet kiosk, cash payment collector, and pickup point for products ordered online. Japan's share of e-commerce revenues for 2000 were 70% of Asia–Pacific's total e-commerce market and will likely fall to 60% in 2004, as the rest of Asia catches up. Japan's B2C e-commerce revenues are expected to climb to $24 billion and B2B to more than $180 billion by the end of 2004. A survey conducted jointly by Accenture, the Japan Ministry of Economy Trade and Industry (METI), and the Electronic Commerce Promotion Council of Japan (ECOM), is even more optimistic, projecting Japan's B2B market to grow to $955 billion and the B2C market to $115 billion by the end of 2005 (Cheung, 2001b).

Much of the projected growth in Japan and Asia will be fueled by m-commerce because the Asian cellular market is one of the most advanced in the world. In many Asian countries, poor telecommunications infrastructure and expensive telephone connectivity have driven the move to wireless. With the use of 3G services in Japan and elsewhere, m-commerce will likely grow rapidly. Japan and South Korea will probably take the lead in this area (Cheung, 2001a). The ARC group predicted that Japan alone will account for 25% of world wireless subscribers by 2003, and Asia (including Japan) for more than 39%.

Other Areas

Many other areas of the world are not yet ready for e-business or are just getting started. Due to insufficient infrastructure to support widespread B2C e-business and a small market because of low discretionary income, e-business in these areas will undoubtedly start as B2B.

However, it is premature to dismiss B2C entirely, as its potential is growing.

In Latin America, for example, e-commerce revenues are expected to grow to $67 billion by 2005, mostly in B2B e-commerce (Ecommerce, 2001c). Brazil dominates Latin America with almost 4 million Internet users, or 40% of this region's total. PC penetration is low—from 3% in Peru to 10% in Argentina. Because of fixed line infrastructure limitations, Latin America is increasingly turning to wireless connections. By 2005, more than 50 million Internet users in Latin America will access the Net via mobile devices.

Africa and the Middle East have low PC and Internet penetration levels. However, even in these countries the use of the Internet is growing, primarily in the B2B area. Unfortunately, the struggle to reach sustainability has eluded many e-businesses. In South Africa, for example, the 2.4 million users are probably insufficient to support many e-businesses (Ebusinessforum.com, 2002). In both Egypt and Saudi Arabia, Internet penetration is very low and costly and many people use Internet cafes to access the Internet. Internet cafes allow information exchange, but tend to inhibit e-commerce per se, as transactions are less convenient compared to using individually owned PCs. While there is potential for growth in these countries, it will be slow. The use of mobile phones, however, has grown much faster.

Eastern European countries, especially Hungary, the Czech Republic, and Poland are much brighter spots in the growing Internet market space. Generally higher levels of education, acceptance of technology, and growing economies in these countries suggest that businesses and consumers in these countries will be receptive to e-business. A potential impediment in these countries, as elsewhere, is concern about data security. A national sample of American Internet users revealed that 65% worry a lot or somewhat that someone might obtain their credit card number and misuse the information (Princeton Survey Research Associates, 2002). While many companies are attracted to the Eastern European markets because of proximity to the EU and lower prices, these markets are still evolving and the B2B market is underdeveloped (Drummondi, 2001).

Global E-business Strategies

Merely having a Web site does not constitute a global strategy. Substantial effort is required in planning and executing a successful global e-business strategy. We now focus on advice for prospective e-entrepreneurs.

Business Models

Some firms, especially those with a bricks and clicks model, use their Web site primarily as an informational brochure (*brochureware*), describing the firm and its products and services. They expect interested customers to go to a physical store or contact the firm via e-mail or telephone to request more information. This has some appeal as an international strategy because it is relatively low risk. There are drawbacks, though, because a visitor to the site can easily click somewhere else. Beyond brochureware, an advanced step includes interactivity, personalization, and data collection about visitors. This increases the "stickiness" (length of stay) of a site, increases return visitors, and provides valuable information about a visitor's online behavior. A further stage is transactional, where customers order and pay for the product/service online. This stage involves two-way communication between the customer and the company. Any of these stages may be appropriate for a particular international market, but the most appropriate Web site will depend on the market, the product/service, and the goals and objectives of the firm. In global e-business, the challenges are in communicating with the right customers, focusing on their needs, providing efficient fulfillment, and ensuring secure payments.

Setting Goals and Objectives

Almost anyone can put up a static Web site for little cost, but designing an appropriate e-business site requires setting goals and objectives for the site and skill in its execution. The investment in developing an interactive, sophisticated, transactional site is usually very high, as are the risks of doing the job poorly. In addition, the countries on which a firm is focused, as well as the target segment within those countries, must be clearly identified before a site is launched. Misidentifying the target market may well misposition the Web site and the product, and thus reduce revenue.

Goals and objectives help determine the type of site, whether simple brochureware or more complex interactive and transactional sites. For example, an informational site designed to complement offline stores should describe products, the firm, retail locations, and contact information. Measuring the success of such a site can be as simple as counting the number of e-mails or phone calls generated in a period of time. However, an objective of increasing sales through a Web site requires an appropriately sophisticated transactional site. Metrics can determine number of pages downloaded, click-throughs, sales per unique visitor, or other appropriate measures. Data may be collected anytime a visitor clicks on a Web site, but many firms do not complete the process by analyzing the data and utilizing that information in their online strategies. The analysis of these metrics is crucial to successful e-commerce. Learning which pages are downloaded, which ads are seen, site stickiness, etc., provides invaluable information to aid e-businesses in developing appropriate online strategies for their target markets.

Consumer Behavior, Relations, and Culture

Understanding a customer's culture and their online behaviors are crucial for effective global e-business. Country culture and consumer behavior are related. Web site design must respect the target culture. This may be as simple as providing a language option or as complex as avoiding culturally sensitive issues. For example, certain products are offensive to some cultures, such as pork or alcohol in Islamic cultures. Colors mean different things to other cultures, such as white representing death and mourning to Muslims and Chinese. The number "four" symbolizes funerals to Japanese and Chinese, so items packaged in fours or the display of four objects should be modified for sites targeting the Japanese. Cultural nuances and symbols are difficult to understand and predict for nonnatives, so one should have a sample of the target audience and culture preview and screen the site for culturally sensitive items and correct language translation before launch.

Consumer behavior online differs in some respects from more traditional purchasing activity. Theorists believe many consumers go through a mental process in purchasing products, especially expensive products or those with a high social cost (e.g., image). This decision-making process occurs both offline and online, but is instructive in developing appropriate Web sites. The purchase decision process consists of searching for ways to solve a perceived problem (e.g., how should I resolve my need to get to work on time?), analyzing the choices (e.g., public transportation, buying a car), determining prospective solutions (e.g., Honda, Toyota), and then making the purchase (e.g., based on price, performance, service, perceived value). Focusing on each of the steps in the purchase process can facilitate online purchasing. If international consumers are in the information-gathering stage, a firm's site should focus on providing information to help make the purchase decision. Different cultures may focus on different data in making the decision, which complicates this process, but makes research very important. For example, purchasing an automobile may involve an information search on the engineering and technical aspects of the vehicle in one culture, but the options or image of the vehicle in another. The importance of providing the right information is that your competitors are just a mouse click away.

B2B consumer behavior is less variable than in B2C transactions. Businesses typically purchase on well-defined specifications, easily disseminated via a Web site or e-mail. However, people in different cultures require different levels of human contact. People in high context countries (e.g., Asians, Latin Americans), for example, may require personal phone calls, e-mail, or even personal visits in order to maintain the desired relationships.

Adapting to Cultures

A major value of the Internet lies in its community building. A company with an Internet presence and global strategy makes the commitment to participate in this increasingly global community. Still, assuming that the whole online world is now part of a company's market is unrealistic; thus it is important to specifically identify those markets the firm wishes to, and is able to, service well. It is important to establish partners in target countries in order to serve the market more specifically. In this way, adapting the site to a market's needs becomes easier. For example, target country partners will be able to identify culturally sensitive issues to avoid on a Web site, language nuances that may not be obvious, and specific needs of target customers.

Global Customer Relationship Management

CRM refers to the visible front-end operations that create and maintain customer satisfaction. Offline, it includes such activities as keeping in touch with customers through customer service representatives, maintaining store relationships, and so forth. Online, CRM requires presenting a consistent image and following up inquiries with e-mail and customer satisfaction inquiries. CRM can be integrated with back-end operations such as supply chain management to help the entire supply chain focus on customer needs and expectations creating strong synergy (Strauss & Frost, 2001).

CRM requires understanding the lifetime value of a customer, because it is much less expensive in the long term to retain a good customer than to acquire a new one. As a result, firms invest in keeping good, profitable customers and "firing" less profitable customers. Globally, this translates into managing the costs of acquiring new customers and retaining current customers. In their well-known study, Peppers and Rogers (1996) found that it costs about five times as much to acquire new customers as to retain current customers. The ratio internationally is probably much higher. Consequently, it is critically important to maintain good customer relationships with global customers.

The Global Internet Marketing Mix

The impact of a global Internet strategy on the marketing mix is significant. One of the key advantages for global Internet marketers is the ability to provide mass customization, which refers to the ability to electronically customize some or all of the marketing mix to suit a target market. This allows firms to present a customized offering much less expensively than with traditional methods.

Product Strategies

Products and services acceptable to domestic Internet markets are generally appropriate for global Internet markets. Some consumer products require adaptation for specific markets, but others can be marketed as is. B2B e-marketing can be very efficient in that nonstandardized products can use the Internet to expedite the customization process. Customization is facilitated by allowing design specifications and product modifications to be changed in real time, with approval likely to be much faster than that of traditional methods. Likewise, online auctions and trade exchange sites, such as the Online Technology Exchange and the Chemical Industry Data Exchange, facilitate the important processes of procurement by providing information on offerings and by bringing providers and suitable customers together.

Electronic products are especially well suited for global Internet marketing because the Internet audience already has a higher proportion of technology savvy users and the products require little or no customizing. Consequently, online marketing of electronic hardware has become one of the mainstays of e-commerce. Software is easily marketed on the Web because of the high involvement of users and the opportunity for users to sample the product online, purchase it online, and even have it delivered online.

Distribution and Fulfillment Strategies. The discussion of distribution and fulfillment in e-business is essentially one of electrons vs. atoms, as distribution functions include not only physical distribution of a physical product, but also the locale where the product is offered for sale (Web site or physical store), transfer of information, payments, breaking bulk, assembly, warehousing, etc.

Fulfillment refers to how an order is completed and is directly related to distribution. Distribution and fulfillment strategies are significantly more complex in supplying international markets, requiring well-organized strategies. Distribution encompasses the value chain from manufacturer/producer to the final consumer, but the entire value chain, including the supply chain, should be considered as a whole. Due to the complexity of overseas shipping, especially documentation, many e-commerce firms use third party logistics providers. Firms such as Fed Ex, Airborne Express, and UPS can provide a complete logistical solution for overseas deliveries, but costs must be able to be supported by customers, while the firm maintains profit margins. Price escalation due to high delivery costs may reduce the global marketability of a product on one hand, but on the other may be insignificant compared to the basic cost of a product or the unavailability of substitutes.

One of the promises of the Internet has been disintermediation, in which intermediaries are eliminated from the distribution system, reducing the length of the distribution channel (Leamer & Storper, 2001). The Internet allows customers to buy direct from manufacturers or to eliminate one or more intermediaries. This potentially reduces costs to the consumer, but the functions provided by intermediaries must still be performed, sometimes by the customer. For products or services not requiring physical distribution, such as consultation or software downloads, disintermediation may result in lower costs to the firm and lower prices to consumers. However, for firms with both an online and offline (physical or bricks and mortar) presence, there are good strategic reasons for maintaining similar retail prices online and offline, such as reducing consumer confusion and discontent, and maintaining customer loyalty. For example, if prices are cheaper on the Web site than in the physical retail store, business may be cannibalized from the retail store. Customers may also feel confused and even cheated if there are large discrepancies in price between physical and virtual stores.

Disintermediation sometimes leads to reintermediation. Reintermediation occurs when distribution channels, which have been disintermediated, are reformed in new and unique ways to provide value added services. For example, reintermediated services include auto-locating services, information and e-commerce services in real estate and home services that combine multivendor information, comparison shopping, and sometimes ties to local retailers (Hanson, 2000). Reintermediation strategies could provide much needed innovative services in global markets.

Fulfillment issues are often glossed over in favor of developing glitzy, interactive Web sites. In a bricks and mortar retail outlet, this function is unseen and largely taken for granted by consumers. Stores already have the product in stock, or will order it, and delivery is a behind the scenes issue. For an online retailer, however, fulfillment issues are critical and force companies to examine their entire value chain (Sowinski, 2001). Better integration between supply and demand chains helps to resolve exceptions such as backorders, returns, and incorrect orders, while improving delivery times and customer satisfaction. Fulfillment issues are thus critical for several reasons: first, they lead to consumer satisfaction or dissatisfaction; second, they influence a firm's profitability; and third, they affect returns.

Customer satisfaction is directly related to fulfillment. Of course the product/service must meet customer expectations, but it must also be delivered when and where the customer wants it and in a satisfactory condition. Integrating customer service functions is crucial to online success; poor customer service is detrimental in a global retail marketplace where competition is only a mouse click away (Chow, 2000). E-commerce customers expect speed and quality of delivery. Meeting, and exceeding, customer expectations results in customer satisfaction, repeat business, loyal customers, and profit (Saenz, 2001). However, B2B and B2C firms must solve different fulfillment problems.

B2B customers typically order few items, but in high volume. B2C customers order a variety of items in low volume, such that the frequency of B2C smaller orders can be astronomical and overwhelm even well designed fulfillment systems (Saenz, 2001). The basic fulfillment functions of picking, packaging, and returns are common to both B2B and B2C, but B2C systems must accommodate large numbers of small orders. Efficient fulfillment operations return large dividends in profit and in customer satisfaction, but many e-businesses are ill equipped to perform this function well themselves and, instead, rely on third party providers.

Outsourcing fulfillment makes sense for many e-businesses, but at what point should an e-business consider this option? Aichlmayr (2000) recommended that e-businesses with fewer than 1000 orders per day build their own fulfillment infrastructure. Firms with more than 10,000 orders/day will likely want to exercise greater control by keeping the fulfillment function in-house. E-businesses handling between 1000 and 10,000 orders/day are often better off outsourcing fulfillment with firms such as PFSweb Fulfillment Services, Omni Fulfillment, Connextions Fulfillment Center, i2 Technologies, and many others.

There are several types of third party providers for firms to consider (Aichlmayr, 2000): "Physical Infrastructure Providers" perform warehousing, delivery, and returns functions; "Technology Providers" supply technological infrastructure to trading partners, including order management and virtual supply chain; and "Integrators" provide both technological and physical infrastructure, such as shopping cart technology, credit card processing, tax and freight calculations, and order tracking. Global e-businesses may desire distribution facilities in their major global markets to assure optimum fulfillment and customer satisfaction.

Unfortunately, not all customers are satisfied, and they return their purchases. Traditional retailers (bricks and mortar stores) expect about 10% of purchases to be returned, but e-tailers get about 30% returns on average (Saenz, 2001). For an e-business with a large volume of small orders, returns can seriously affect the bottom line. Global e-businesses can be impacted to an even greater extent than domestic businesses. Part of the problem appears to be communication. Forrester Research indicates that 85% of e-businesses have no automated, real-time connection with any of their business applications.

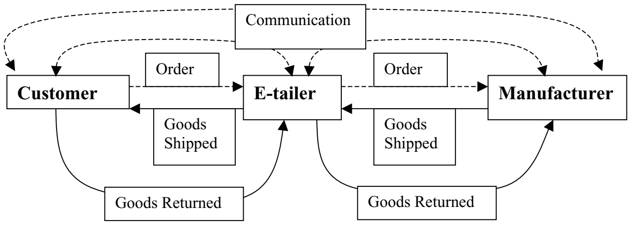

Figure 1: E-commerce fulfillment model.

Further, a Jupiter Communications study showed 42% of Web sites never responded to customer inquiries, took more than five days to do so, or did not offer e-mail responses to problems (Chow, 2000). Clearly, the level of customer service has not kept pace with the growth of e-business. Handling customer inquiries and returns is a critical activity for global e-businesses. Outsourcing this function has been effective for many firms, including Pharmacia & Upjohn, IBM, Hewlett-Packard, Dell, Nokia, Lancome, Tyco International, Sony On-Line Entertainment, and others.

A simplistic model of e-commerce fulfillment is shown in Figure 1 to conceptually illustrate the process. Dashed lines indicate the flow of communications and solid lines the flow of goods/services. The model becomes significantly more complex as the number of intermediaries increases and as customers, retailers, and manufacturers are separated by political and geographic boundaries. For example, while ordering and communications are quite straightforward and very rapid over the Internet, the shipping of physical goods and even some services will be much less so. E-businesses need to consider customs, duties, and logistics as goods are shipped to customers. They also need to manage a returns policy that will meet customer needs without incurring excessive costs. As indicated earlier, outsourcing may facilitate all of these functions.

The increase of B2C e-commerce domestically and internationally will challenge fulfillment operations. One area of fulfillment often overlooked, but capable of having long-term effects on profitability, especially internationally, is packaging. Jupiter Communications reports that 27% of e-tailers spend more than 10% of their revenues on fulfillment, more than half related to packaging (Hogan, 2001). Fewer than 62% of Internet orders are shipped using best practices, and problems include high costs and high rates of return due to broken or damaged products. Consumers are also concerned about the size of package, wanting packages close in size to the actual product. Designing packaging that is effective in protecting the product while reducing material and handling costs, including returns, is challenging, but obviously important. In addition, packaging must not create a bottleneck to rapid delivery.

Pricing Strategies. Internet pricing strategies take on new complexity in international markets. Price floors must take into consideration various influences to price escalation, including transportation, tariffs, duties, and increased channel length. Price ceilings reflect cultural and economic issues and the ability to pay. But, pricing is also strategic, so prices must also reflect competition, demand, perceived value, and a host of other factors. These issues are present in offline international marketing as well, but what makes Internet marketing unique is the ability of customers to rapidly search the Web for competitive prices.

Web scanning is facilitated by use of shopping agents or bots, which scour the Internet, researching products by price and other parameters determined by the bot manager. This requires Internet marketers to continually scan the market space for competitor price changes. This is a significant issue in the EU, where the euro is now the common currency for most member countries. Price transparency and the ability to rapidly search for competitive prices make pricing strategy considerably more important today than in the past.

The Internet allows for real-time pricing, which permits price changes to occur instantaneously (Arend, 2002), emphasizing the need for tracking competitor prices. For example, a marketer pricing a product in France can rapidly determine if competition is changing prices to compete, permitting the marketer to immediately adjust prices on their Web site. Price changes in the past often took considerable time to implement because price schedules had to be changed, catalogs printed, and various channel members informed. The Internet allows all of this to be done very rapidly.

The Internet also facilitates yield/capacity management, sometimes referred to as “perishable asset revenue management.” These practices are most often used in industries with a great deal of volatility in purchases, such as airlines and hotels. The Internet allows the rapid change of prices to help ensure that airplanes fly at or near capacity and that hotels, resorts, and restaurants are filled on weekends and other off-peak times. In the airline industry, tickets purchased online are often less expensive than those purchased through travel agents and e-tickets are even less. Besides reducing transaction costs, the Internet facilitates yield management technology and information dissemination, allowing lower fares through an Internet purchase.

Communication and Promotional Strategies

Advertising and promotion via the Internet are common in the U.S. and can be very effective. Interactivity makes the Internet an important advertising vehicle, as it provides advertisers opportunities to identify customers, differentiate them, and customize purchase and post-purchase service and offerings (Roberts & Ko, 2001). Customers benefit by having greater and quicker access to companies through e-mail, discussion groups, direct ordering, and links to further information. As with offline advertising, online advertising must be sensitive to cultural, language, and consumer behavior differences. Hall’s “silent languages” provide an example. High context/collectivist cultures (e.g., Asians, Latin Americans) use indirect modes of communication and favor emotional appeals reflecting the needs of the group. On the other hand, low context/individualistic cultures, such as North Americans and Scandinavians, use direct modes of communication and seem to prefer high content messages. Which strategy an e-business should use will, of course, depend on the market on which they focus. Web sites designed for Scandinavians would probably not be effective for Latin Americans.

Probably the best-known approach to understanding cultural values in the business literature is the theory of national culture proposed by Geert Hofstede. Hofstede identified four main value dimensions affecting cultures, power distance, uncertainty avoidance, individualism, and masculinity, later adding a fifth, long-term orientation, which better explained Chinese cultural values (Hofstede, 1980, 1991, 1994). National culture is considered the most important influence on international business and Hofstede's work over the years has demonstrated the usefulness of the five value dimensions in a number of cross-national studies that can be generalized to international e-business. For example, cultures low on individualism and high on power distance (e.g., many Asian and Latin American countries) should respond to Web sites emphasizing collectiveness and hierarchy. People in these countries would not respond in the same way to sites emphasizing individualism and egalitarianism, as would Nordic Europeans and North Americans.

Web advertising is growing at a faster rate outside the U.S., but the U.S. is still the dominant Web advertising market (Halprin, 2000). Online advertising in Europe is different from the U.S. due to lower levels of Internet use and broadband penetration, as well as language, culture, and market issues. Because Internet usage is growing rapidly in Europe, online advertising is expected to grow from $901 million in 2000 to $6.4 billion in 2005. Germany is expected to be the largest online advertising market in Europe, followed by the U.K. and the Scandinavian countries, as a group.

Online advertising is also rapidly increasing in Asia, from about $465 million in 2000 to nearly $4 billion by the end of 2004, or about 12.1% of world total (Cheung, 2000). Still, online advertising remains a relatively unproven and distrusted concept in Asia, primarily because of relatively low PC penetration and a lack of credible, consistent data on Web traffic volume. Click-through rates on banners are low. Wireless advertising, on the other hand, is expected to grow strongly, especially in Japan, China, and South Korea.

Unfortunately, little work has been done on estimating the value of Internet advertising internationally, but assuming most domestic online advertising issues apply to global online advertising, we can make some generalizations. First, the Internet allows for very focused communications through e-mail. This is similar to direct marketing, but much more effective because it can be more focused and is relatively inexpensive. Focus is enhanced by e-mail addresses generated by opt-in requests from users. These are exactly the people who will react to the ads and information. E-mail costs about 1/100th that of regular direct mail in the U.S. (Gartner, 2002) and is undoubtedly even less expensive to overseas customers.

Personalized opt-in e-mail generates about 6–7% click-through, compared to 1% for generic e-mail and direct mail. Besides being less expensive and more effective than direct mail, e-mail marketing campaigns can be measured more quickly and easily than traditional direct mail. E-mail campaigns should be attractive for global marketers with the ability to focus on those customers more likely to purchase. E-mail, of course, should be in the language of the customer, correctly translated from the home language, and should have contact information so customers can respond. Banner ads have been shown effective at improving a brand's image and attitude toward a brand, but less effective in inducing purchasing behavior. This is not surprising, as Internet users are familiar with banner ads and less likely to click-through than they were when banner ads were relatively new. However, in some global markets banner ads may be new and exciting and quite effective at creating awareness of a product category and brand.

CONCLUSION

In our examination of the feasibility for global e-business activities we found not only many similarities between regions, but also major differences. North America, especially the United States, has entered a mature phase of e-business. Many other countries are just developing their e-business infrastructure and technology to compete in an increasingly global and technological world. Europe and the Asia–Pacific regions are growing in their e-business capabilities faster than any others and, therefore, appear to be prime areas for e-business market development. Most other areas of the world are growing in Internet connectivity and are potential e-business markets in the near future, primarily for B2B e-business.

Firms considering global e-business must recognize that e-business in foreign markets is likely to be different than domestic e-business. First and foremost is the language issue. Even if a foreign target audience understands English, it may be important to have its home language available on your site, making users feel welcome and signal that you are truly interested in serving them. Other important cultural factors to consider include symbols with specific cultural meanings. We discussed colors and numbers as being symbolic, but there are many more, as well.

Other cultures also have different ways of doing business. Those impacting e-business are the use of credit cards and other e-payment options. It is very important for both parties that credit information be secure. If customers are reluctant to use credit cards, we must find other ways for convenient payment. Innovative ways of serving global customers are likely to encourage not only more sales, but also stronger customer loyalty.

Fulfillment is critical for satisfying customers and for the bottom line. B2C e-businesses can outsource this function if they are not prepared to handle the volume of business a successful global strategy can attain. In any case, long-term profitability and brand image may well rest on this important process. Providing the quality of product or service demanded by the global market space is no longer sufficient—it must also get to its proper destination in the expected time, in the expected condition, and at the expected price, while still providing a profit to the firm. This is not always an easy task.

As with any global effort, proper and timely communication will diminish problems. The Internet facilitates routine communication, but does not substitute for face-to-face communication desired by many cultures, where personal relationships can last and be profitable for a long time.

The outlook for global e-business is encouraging. It will not look exactly like it has in the U.S., but it is growing and will continue to grow. Wireless connectivity in many parts of Europe, Asia, Latin America, and other regions will change the nature of B2C e-business, and probably B2B business, as well. E-business firms that have well-developed business models and a thorough understanding of global markets will be leaders in the new global e-economy.

ACKNOWLEDGMENT

The authors gratefully acknowledge the Institute for Global e-Business and Innovation at Seattle University for its assistance on this project, especially Research Assistants Claudia Zeibe and Tan Chee Ming.

GLOSSARY

Banner ad Rectangular space on a Web site that is paid for by an advertiser.

Bricks and Clicks Retail stores with both online and offline selling.

Broadband High bandwidth necessary for transmission of multimedia content over the Web.

B2B Business to business—marketing of products to businesses and institutions.

B2C Business to consumer—marketing of products to end consumers.

Brochureware Information on a Web site describing a firm's products and services and the firm itself.

Click-through Determined when a Web user clicks on a banner ad that is hyperlinked to the advertiser's site.

CRM Customer relationship management—process of identifying, attracting, differentiating, and retaining customers using digital processes and integration of customer information.

E-business All electronic activities conducted by a business.

E-commerce Buying and selling online.

ICT Information and communications technology.

ISP Internet service provider—a firm with a network of servers, routers, and modems attached to the Internet. It is used by subscribers to connect to the Internet.

Shopping agents (Bots) programs used to allow consumers to scan the Web to compare prices, features, retail locations, etc., of products.

File Types

Jennifer Lagier, *Hartnell College*

INTRODUCTION

Each time an individual searches the Internet, the inquiry results in the retrieval of information in the form of a file. This file may be displayed, downloaded, or executed and may exist in the form of a Web page, image, document, data, software program, or multimedia, such as digitized movies or sounds. The organization of the file is called its format. The choice of file format depends on the kind of information being transmitted and the way it will be used (Hofstetter, 1998).

File formats and their associated file name extensions provide clues about what the file contains—a software program, information that has been compressed, text, image, sound, video, animation, or data. To view, play back, execute, manipulate, interpret, or alter the contents of the file requires different software tools or specific hardware configurations for different file types (Hofstetter, 1998; Ackerman & Hartman, 2001).

Files may interact to produce a displayable Web page, or they may be stored on a Web server and made accessible from a Web page that contains hyperlinks coded to retrieve the requested file. Sometimes files are transferred to and from Web servers using special software designed for this purpose. File transfer software permits the uploading or downloading of files from the Internet without requiring the user to actually open the file.

Some Web pages work together with special script or program files stored on the Web server. Some examples are JavaScript (JS) files, active server pages (ASP), PHP (personal home page) script files, common gateway interface (CGI) files, and cascading style sheet (CSS) files. By themselves, these files are of little use, as they contain formatting or program instructions, not actual Web content. However, when used in conjunction with hypertext markup language (HTML), these separate files can (a) retrieve data from an online database, then create Web pages on the fly to display search results or store and modify information; (b) interact with other programs to perform a variety of online actions; or (c) determine the display characteristics of one or multiple Web pages (http://www.whatis.com).

Text format files include HTML files and document files that can be downloaded or retrieved and displayed. The most common text file types encountered on the Internet are plain text, rich text, and word processing files (Miller, 1997). These files may be identified by their file name extensions: .txt for plain or ASCII text, .rtf for rich text, and .doc or .wps for word processing files. Some text files may be compressed and saved in this format or as an image to save space or retain formatting characteristics.

Data files usually consist of files created by spreadsheet programs. In addition, some Web sites make use of various database programs to create data files. These files are saved in a nontext format that can be translated and displayed by the software programs that originally created them. Newer versions of spreadsheet programs often contain filters that permit the interchange of files created by multiple software programs (Ackerman & Hartman, 2001).

To reduce the time required to download from the Internet and to conserve Web server space, larger files are frequently compressed to create small file sizes. Compressed files must be extracted before they can be used. Some compressed files have been saved as self-extracting executable files. Others require the use of file compression programs to uncompress the file (Ackerman & Hartman, 2001). Some common file name extensions for compressed files are .zip, .gz, .hqx, .sit, and .tar.

The software program used to create these images frequently determines graphic file formats. The most common formats found on the Internet include GIF and JPG or JPEG. The Web browser can display images in these formats without the use of additional software (Miller, 1997). Graphic images stored in bitmapped (.bmp) or tagged image formats (.tif or .tiff) can be downloaded from the Internet, but to be displayed, they require the use of other software programs (Miller, 1997; Ackerman & Hartman, 2001).

Audio files require the use of a computer equipped with a sound card and speakers, as well as media player software to convert the file into sound. Recent versions of Netscape Navigator (7.0) and Microsoft Internet Explorer (6.00) come with the necessary software components to deal with most common audio files. Older versions of browsers may require helper applications to allow the computer and browser to access the appropriate program or action to make use of the file. Some audio files, such as RealAudio and MP3 formats, require use of additional media players or software programs to convert these files into sound (Ackerman & Hartman, 2001). Common file name extensions for audio files include .wav, .au, .snd, .ra, .ram, .aif, .aiff, .aifc, .mid, .midi, and .mp3.

Common multimedia file formats include MPG or MPEG (Moving Picture Expert Group), MOV or QT (QuickTime), RM or RAM (RealVideo), DCR, DIR, and DXR (Shockwave). Multimedia files permit the simultaneous viewing of digitized video accompanied by sound. As with audio files, multimedia files frequently require player applications for conversion to motion and sound.

Server-side files are files saved in a format that allows them to interact with HTML pages. Some of the more common formats include ASP, CGI, JS, and CSS. Files of these formats are stored on a Web server and function in a way that determines the formatting and display characteristics of Web pages. ASP and CGI scripts interact with information from databases, such as online catalogs, archives, and digital library collections.

Although the Internet provides users with a wealth of information, much of which can be downloaded and saved, it is important to consider copyright restrictions that may limit or prohibit copying or distributing files. Copyright laws of the United States, the Universal Copyright Convention, and the Berne Union protect Web pages and their contents (Ackerman & Hartman, 2001).

TEXT FILES

There are four different text formats most commonly available on the Internet: plain text, rich text, hypertext, and word processor files (Hofstetter, 1998). All browsers can display plain text, or ASCII, files. ASCII (American Standard Code for Information Interchange) is the most commonly used text format for Internet or computer files. Text files contain characters that can be viewed or printed, but they do not include formatting, such as special font faces, or styles, such as bold or italics. Files of this type usually have the file name extension .txt (Ackerman & Hartman, 2001).

Hypertext files contain text that has been surrounded with special HTML codes. The HTML coding defines how text will be displayed on the page (font face, font size, font color) as well as whether or not the text will appear in bold, italics, or underlined. HTML coding also permits text to function as a trigger or link that takes the user to another Web site, Web page, or place within the same Web page. Hypertext links can also launch various actions or activate multimedia files. Hypertext files have either .htm or .html file name extensions (Hofstetter, 1998). The World Wide Web Consortium (W3C) maintains a Web site that provides information about HTML standards and specifications (http://www.w3.org/MarkUp/).

Such word processors as Microsoft Word and WordPerfect create files that contain proprietary formatting. The format codes within a word processor file determine font face, font size, margins, borders, headings, footers, and pagination (Hofstetter, 1998). Word processing files have file names that may end in a variety of extensions, such as .doc (Word document file), .wpd (WordPerfect document file), or .rtf (rich text format). Unlike text and hypertext documents that can be opened and read by Web browser software, a browser cannot display word processor files. These files require helper applications in order to be opened and have their contents displayed. Rich text format files contain text that can be translated by multiple word processing programs (Ackerman & Hartman, 2001).

PostScript is a file format invented by Adobe Systems. These files contain text, but they are usually not in a readable form. They contain commands that a printer or display device interprets—commands relating to formatting, fonts, font size, and images within the file (Ackerman & Hartman, 2001). A PostScript file usually has a file name extension of .ps.

Although PostScript is recognized as the industry standard for printing and imaging, portable document format (PDF) files, also invented by Adobe, are more widely used for Internet document exchange (http://www.whatis.com; Miller, 1997). Adobe Acrobat creates PDF files by converting word processor or printed documents into bitmap images. Although the software to create PDF files is not free, Adobe Acrobat Reader software, used to view PDF files, is available as a free download from the Adobe Web site, (http://www.adobe.com/products/acrobat/readstep2.html).

Text files in a variety of formats are used to provide online documentation, product order forms, registration forms, college catalogs, course handouts, newsletters, research articles, dissertations, publications, brochures, and more. If document layout and print formatting are unimportant, ASCII text files provide a simple method of sharing files on the Internet. Word processor text files are an appropriate choice for those working on collaborative projects, editing and augmenting each other's work. Hypertext files are well suited for online course content, interactive Web-based tutorials, online catalogs, forms, or lists of hypertext links. Portable document files duplicate desktop publishing formats, allowing users to view publications exactly as they were designed to appear in print versions. These files may be accessed by using a free downloadable reader and do not require any specialized application programs to open, print, or view.

NUMERICAL DATA FILES

Spreadsheet programs, such as Microsoft Excel and Lotus 1-2-3, produce files containing data represented in a nontext format. Excel files have extensions of .xls. Lotus 1-2-3 files have extensions of either .wks or .wk1. As with word processor files, spreadsheet files need to be opened by the program used to create them. Newer versions of spreadsheet programs contain translation filters that can open and display data with any of the file extensions listed (Ackerman & Hartman, 2001). In addition, Excel software allows files to be saved in HTML format, creating Web pages suitable for viewing on the World Wide Web. Data files are most often used to share or display statistical information, such as census data, mortgage rates, interest tables, and demographic breakdowns.

COMPRESSED FILES

Files are often compressed to save space on a server and to permit transfer that is more rapid over the Internet. One or more files can be packed into a single file. Once the user has downloaded a compressed file, the file will need to be unzipped or extracted to view, display, or use it. Users may download application software from the Internet to perform this function (Ackerman & Hartman, 2001).

Self-extracting archives are compressed files containing multiple application files or a set of data packed into a single file. After downloading a file to the computer's hard drive, the user must launch the archive file, which then unpacks the files and stores them on the computer. Many software companies now distribute application programs over the Internet using self-extracting archives (Hofstetter, 1998). Examples of self-extracting software programs may be found at CNET's http://download.com (Hofstetter, 2001).

A significant number of the files accessed through anonymous file transfer protocols (FTPs) are stored in a compressed format (Ackerman & Hartman, 2001). The most common compressed or archived files are those with extensions of .zip, .gz, .hqx, .sit, or .tar. Shareware programs that work with compressed files are available from http://www.pkware.com, http://www.stuffit.com/expander/index.html, and http://www.winzip.com.

IMAGE FILES

Graphic image files may be stored in a variety of formats. Most Web browsers can display images stored in GIF (graphics interchange format) or JPEG (Joint Photographic Expert Group) format. Files with images in these formats have file name extensions of either .gif, .jpeg, or .jpg.

Tagged image file format (TIF or TIFF) is used to store and exchange high-quality bitmap images. Some browsers are unable to display TIFF files, necessitating the use of software applications that can either display or convert TIFF files to a format such as GIF or JPG, which can be viewed with any browser.

PNG (portable network graphics) is a new standard currently being developed by W3C. The new PNG format would provide a patent-free image file format that would replace GIF and TIFF format files.

BMP (Windows bitmap) images are composed of a grid broken into small squares called pixels. Each pixel contains color and location information. Because each BMP graphic contains a specific number of pixels, magnification can produce image distortion.

GIF

CompuServe Information Services introduced the GIF image format. GIFs were designed to be a platform-independent format designed for slow modem speed transfers (http://www.wdvl.com). GIFs are 8-bit compressed images that can be displayed without any loss of original graphic information. This process is known as lossless compression. GIF files are limited to a palette of 256 colors and are considered one of the standard image formats found on the Internet. A GIF file is encoded in binary as opposed to ASCII, or text, format. Binary files require the use of a software program to interpret their content. Transparent GIFs allow a background image color to be designated as "see through," allowing the illusion of images that float over a Web page's background color, texture, or graphics. Transparent GIFs may also be used to represent type fonts and blank spaces. GIF files can be in GIF 87a or GIF 89a format. The latter permits creation of an interleaved, or animated, image (http://www.whatis.com).

Animated GIFs

An animated GIF appears on a Web page as a moving image. Animated GIFS are created from a series of unique images saved within a single file in GIF 89a format. The animation displays a sequence of images that appear in a specific order. An animated GIF can display its sequenced images once and then stop, or it can loop endlessly (http://www.whatis.com).

JPEG

JPG, or JPEG, images are compressed 24-bit files that can contain over 16 million colors. JPGs are used to display digitized photographs, full color, and naturalistic grayscale images (http://www.wdvl.com). The JPG format allows a range of compression qualities. The greater the compression ratio, the lower the display quality of the image and the smaller the file size. As with the GIF format, JPG is one of the standard Internet image formats (http://www.whatis.com).

PNG

Currently, the W3C is working on a new graphics format called PNG (portable network graphics). This format will handle images containing up to 48 bits of color information per pixel and will eventually replace the older GIF format. As with GIF, PNG image files are lossless, yet will permit compression rates 10%–30% more compressed than the GIF format.

An Internet committee designed the PNG format to provide a patent-free alternative to the GIF. Unlike the GIF format, PNG files not only support transparency, they also allow a range of transparency values. PNG also supports interlacing, gamma correction (the ability to tune the brightness of an image to correspond with specific monitor displays), and the ability to save in true-color, browser safe, or gray-scale formats (http://www.whatis.com).

Mapped Images

Mapped images contain an invisible layer of hyperlinks over the image. By moving the cursor over the image and clicking on various spots within the image, the user triggers the link (Weinman, 1999). Links may retrieve external Web sites, Web pages, places within the same or another Web page, images, or other types of files, such as digitized videos or sound files.

AUDIO FILES

In order to hear sound files from the Internet, the user needs to have a computer equipped with a sound card, speakers, or headphones, as well as a plug-in or helper application that works in conjunction with the Web browser software. When the Web browser encounters a sound file with a WAV, MIDI, NeXT/Sun, MP3, or audio interchange format, it downloads the entire file onto the hard drive of the computer. Depending on the file size and speed of the Internet connection, this may take several minutes. Once the download is completed, the helper application is launched. The Windows Media Player is an example of a helper application that might be used to play back audio files.

The Web browser then loads the sound file into the application. The application plays the sound. A plug-in performs the same function as a helper application only it does so inside the browser window rather than by starting up another software application (Burns, 1999).

Rather than downloading an entire audio file before activating playback, streaming audio downloads a portion of the sound file into a buffer, then continues downloading as playback proceeds. Information is transmitted from the Internet to the user's workstation in a steady, continuous stream. Because many users do not have high-speed Internet connections, streaming technologies are becoming an increasingly popular way to deliver online multimedia (Ackermann & Hartman, 2001; Hofstetter, 2001).

Sound files transmitted over the Internet often have one of the following formats:

Waveform audio format (WAV), a standard format for computers using Microsoft Windows (file names end with .wav).

NeXT/Sun format (file names end with .au or .snd).

RealAudio format (file names end with .ra or .ram).

Audio interchange format (file names end with .aif, .aiff, or .aifc).

Musical instrument digital interface (file names end with .mid or .midi).

MP3 format (a compression system for music files that does not diminish sound quality).

WAV

Microsoft created the WAV audio file format, which has become accepted as the standard PC audio file format. Both PC and Macintosh computers can use WAV files. The WAV file contains raw audio in an uncompressed format, as well as information about the file's number of tracks (mono or stereo), sample rate, and bit depth (http://www.whatis.com).

A waveform audio digitizer can be used to record sound. The waveform describes a unique sound's frequency, amplitude, and harmonic content. A waveform audio digitizer captures sound by sampling a waveform thousands of times per second, then storing the samples within a file format suitable for Internet transmission (Hofstetter, 2001).

AU/SND

NeXT and Sun computers produce sound files in a unique format. The audio file names usually end with the extensions .au or .snd. Audio files with extensions of .snd do not have file headers to indicate different sampling rates and compression formats, thus allowing variable recording and playback rates. Audio files with names ending in .au extensions are recorded and played back at a standard rate. Audio files produced by NeXT and Sun workstations provide a larger dynamic range than normal 8-bit samples, approximately equivalent to 12-bit samples (Hofstetter, 1998).

RA/RAM

RealAudio refers to continuous or streaming sound technology developed by Progressive Networks' RealAudio. RealAudio sound files are stored in a special format optimized for real-time transmission over the Internet and can be recognized by their file name extensions of either .ra or .ram. This is the format used for Internet radio broadcasts. Unlike other sound files, which must be completely downloaded before playback can occur, RealAudio files are downloaded and played simultaneously. RealAudio files must be played through a RealAudio player. The RealOnePlayer is able to read the file stream as it is coming in and begin playing it long before the rest of the file arrives, thus providing continuous, or streaming, audio (Hofstetter, 1998). RealOnePlayer is available as a free download from http://www.real.com.

AIF/AIFF/AIFC

Audio interchange file format (AIF, AIFF, or AIFC) is the format used to create audio files on Macintosh computers. Sound files with the extension of .aifc indicate a Macintosh-produced audio that has been compressed. When used on a PC, these files usually have the file name extension .aif (Hofstetter, 1998).

An AIFF file contains the raw audio data, channel information (monophonic or stereophonic), bit depth, and sample rate. AIFF files do not support data compression, so files in this format are usually large. Files with the extension .aifc indicate a compressed version of the AIFF format. The AIFC format supports compression ratios as high as 6:1 (http://www.whatis.com; Hofstetter, 1998).

MID/MIDI

The musical instrument digital interface (.mid or .midi) audio file format was designed to enable the recording and playing back of music on digital synthesizers supported by many makers of personal computer sound cards (http://www.whatis.com). Unlike other audio formats, MIDI does not directly record the actual sound. Instead, MIDI records information about how the audio file is produced. The information includes note-ons, note-offs, key velocity, pitch bend, and other methods of controlling a synthesizer (Hofstetter, 1998).

The sound waves produced are those already stored in a wavetable in the receiving instrument or sound card. Codes within the MIDI file tell the sound card within the computer when to turn notes on and off, what volume to use, and what instrument should make the sound. MIDI files require little bandwidth to transmit, making them a popular format for transmitting audio over the Internet (Hofstetter, 1998).

MP3

MPEG-1 audio layer-3 (MP3) compresses high-quality sound sequences into digital audio format. MP3 provides small file sizes (about one twelfth the size of the original file size) while retaining original sound quality. This results in compact audio files that download quickly without degradation of sound.

MP3 files require the use of a player, available for download from the Internet. There are multiple Web sites that provide access to MP3 music files, making them available for download. Two good sources for additional information about MP3 technology are http://MPEG.org and http://MP3.com (Hofstetter, 2001).

MULTIMEDIA FILES

Multimedia files allow the user to view digitized video and simultaneously hear accompanying sound. Some popular multimedia formats include AVI (audio/video interleave, created by Microsoft); QuickTime (created by Apple Computer); MPEG (Moving Picture Expert Group, the name of the ISO standards committee that created this format); RM or RAM (RealVideo, created by RealNetworks, Inc.); and macromedia shockwave files (Hofstetter, 1998).

AVI

The audio/video interleaved (AVI) format has been designed to conform to the Microsoft Windows resource interchange file format (RIFF) specification. AVI format files contain both sound and video. Within each file, audio frames are interleaved with video. Audio takes priority during playback, thus playing the sound track without interruption. The computer displays as many video frames as it can process during the audio playback, skipping those for which it has run out of time. This can result in the appearance of choppy motion. AVI files have a file name extension of .avi and require a special player that can be downloaded from the Internet if not included with the user's browser software (Hofstetter, 1998).

MOV/QT

QuickTime stores sound, text, animation, and video in a single file with file name extensions of .qt, .mov, or .moov. Both PCs and Macintosh computers support the QuickTime format. QuickTime files are viewed using a QuickTime player. The player may be included with browser software or downloaded from the Internet and allows the user to view and control brief multimedia sequences. (http://www.whatis.com).

MPG/MPEG/MPE

Multimedia files in MPEG format have file name extensions of .mpg, .mpe, or .mpeg. The MPEG format creates high-quality digitized video that requires the use of a MPEG player or other software program to view. There are a number of free players available for download from the Web (Hofstetter, 1998).

MPEG compresses video by eliminating redundant data in blocks of screen pixels and stores only the changes from one frame to another, instead of each entire frame. The video information is then encoded using a technique called delta-frame encoding, or DCT (Hofstetter, 1998).

There are three versions of MPEG: MPEG-1, which is a noninterlaced version used for CD-ROM playback; MPEG-2, an interlaced version designed for all-digital TV transmission; and MPEG-4, a low-bandwidth MPEG version for transmission over mobile and wireless networks as well as the Internet (Hofstetter, 2001). A fourth version, MPEG-3, was originally developed to accommodate high-definition television transmissions but was made unnecessary by the development of MPEG-2.

RM

RealVideo, created by Progressive Networks, conforms to the proposed industry standard real-time streaming protocol (RTSP) and delivers full-motion streaming video over the Internet. Streaming video may be defined as an uninterrupted sequence of moving images that have been compressed and are then transmitted over the World Wide Web. RealVideo files have file name extensions of .rm or .ram. As with streaming audio, streaming video transmissions are downloaded and displayed by the viewer as they arrive. Download and playback occur simultaneously. The user needs a player to view the video and hear the audio sound track. Players can be downloaded from the Internet if not included as part of the user's browser software (http://www.whatis.com; Hofstetter, 1998). A free RealONE media player, available from http://www.real.com, is one example of a downloadable media player.

Shockwave

Shockwave files are animations created by Macromedia's Director, Authorware, or Flash programs and included as Web page objects. These files usually have file name extensions of .dcr, .dir, or .dxr and are invoked by HTML code referencing the appropriate object file name. Shockwave supports audio and video. It runs on Windows as well as Macintosh computers. As with MPEG and QuickTime animations, Shockwave requires the use of a plug-in and player application to display and hear the files it creates (http://www.whatis.com; Hofstetter, 1998). A free Shockwave player is available for download from http://sdc.shockwave.com/shockwave/download/.

SERVER-SIDE FILES

The file types discussed earlier within this chapter reside on a Web server and are downloaded to the user's computer when accessed through the Internet. In contrast, server-side files not only reside on the Web server, they also perform some action while working from this location. Unlike other Internet file types, server-side files do not have to be downloaded to the computer user's hard drive to be used. Instead, they interact with user input, create a Web page on the fly, and then return a customized display.

Some types of server-side files interact with Web pages or a combination of Web pages, and database applications are stored on the Web server. Once connected to the Internet, the user accesses a Web page through the browser software application (Netscape, Microsoft Internet Explorer, or others). HTML coding within the Web page provides a path or map to the Web server directory where the server-side file is stored. This file is accessed and an action is performed. The action depends on the type of server-side file and the instructions it contains. It may generate a new HTML page, send information to or from an HTML form page, display an alert, take the user to a new URL (uniform resource locator, or Internet address), open a new browser window, or dictate the way Web page text is formatted and displayed.

Examples of some common server-side files include ASP or CGI, PHP, JS, and CSS.

Active Server Pages

An ASP makes use of scripting technology to create dynamic, interactive Web pages. The ASP contains HTML to define the Web page layout and embedded programming code written in a scripting language, such as visual basic script, Perlscript, or JS (Gladwin, 2001; Langley, 2001). These scripts are processed on a Microsoft Web server. As a result of this action, a Web page is created on the fly based on the user's request and data accessed from a database. This page is displayed in the browser (http://www.whatis.com).

ASP allows developers to create Web pages that may be used to interact with databases or other applications. Online forms, Web pages that contain such dynamic information as news reports and stock market data, often make use of ASP. Once the browser requests a file from the Web server, an embedded script runs, pulling up a file with an .asp extension from the Web server. The requested information is returned to the browser in the form of a customized Web page (Langley, 2001; Gladwin, 2001).

Common Gateway Interface

CGI is a standardized procedure for transmitting information between a Web server and a script. The CGI script is usually written in a programming language, such as Perl. When a user types information into a Web page form, this input is transmitted to the Web server, where it is routed through the CGI to an application program that, in turn, processes the data. The program responds to the user's input by displaying an existing Web page in the browser, generating a custom Web page on the fly, or retrieving and displaying an image or multimedia file (Hayes, 1999; Castro, 2000).

Some examples of CGI scripts used in conjunction with Web pages to retrieve database information, then return this data within the format of a Web page created on the fly, include search engines or directories, online registration forms, online order forms, and electronic full-text databases (http://www.whatis.com).

PHP

Like ASP, PHP is a script language and interpreter used primarily on Linux Web servers. The PHP script is embedded within a Web page among the HTML codes. Before the page is sent to a user who has requested it, the Web server invokes PHP to interpret and then perform the actions called for in the PHP script. An HTML file that includes a PHP script usually possesses a file name extension of .php, .php3, or .phtml (http://www.whatis.com).

JavaScript

JS is a program that can be included in HTML coding on a Web page, or as a separate script file stored on a Web server and invoked by a line of code embedded as a part of the HTML coding. JS allows the creation of interactive Web pages, validation of online forms, dynamic HTML, and the creation of customized HTML pages on the fly (Negrino & Smith, 2001).

A server-side JS file is coded as a separate text file, saved with a file extension of .js, and stored on the Web server. A corresponding line of HTML code that tells the browser the URL of the .js file is embedded in the Web page's HTML coding. When that Web page is accessed, the JS file is retrieved from the server and runs inside the Web browser (Negrino & Smith, 2001).

Cascading Style Sheets

Like JS, CSS coding can either be included in a Web page's HTML coding or saved as a separate text file that is stored on the Web server and invoked by a line of HTML code within a Web page. A server-side CSS is saved with a file name extension of .css. A style sheet allows Web page designers to specify the look and format of Web pages; set font face, style, size, and color; and define precise positioning of such elements as images or text, or both (Burns, 1999).

FINDING AND DOWNLOADING FILES FROM THE INTERNET

Some search utilities, such as Google (http://www.google.com/), Alta Vista (http://www.altavista.com/), and HotBot (http://hotbot.lycos.com/), provide the ability to limit searches according to format (images, video, MP3, audio, etc.). Users may use these utilities and other tools to find files in a specific format. FTP archives are another source of various Internet files. Some general-purpose FTP archives include the following resources: the University of Illinois at Urbana-Champaign UIArchive, http://uiarchive.uiuc.edu/; the Washington University in St. Louis Wuarchive, http://wuarchive.wustl.edu/; the University of Vassa, Finland, Garbo Anonymous FTP Archive, http://garbo.uwasa.fi/; and the Monash University Monash Nihongo FTP Archive, http://ftp.monash.edu.au/pub/nihongo/00INDEX.html.

Saving Internet Files

Text within a Web page may be saved by using the browser's Save As function. Once the Web page is displayed in the browser, the user chooses File and then Save As and then selects Save As Type: Text (Figures 1 and 2).

To save an image found on the Internet, place the mouse cursor directly on the image and right click (PC) or click (Macintosh). Choose Save Image As, rename or accept the existing file name, and indicate the directory location where you wish to save the file (Figures 3 and 4) (Ackermann & Hartman, 2001).

Files may also be exchanged over the Internet using file transfer protocol (FTP) software. Unlike HTTP (hypertext transfer protocol), FTP allows files to be transferred over the Internet from a Web server to the hard drive of the user's computer without first retrieving and then opening the file. Using FTP software configured to access the host computer's address, a user can locate and transfer one or multiple files. When the user knows the exact name and location of a file, FTP can be a quick and efficient way to copy files from one computer to another (Ackermann & Hartman, 2001).

What is FTP?

The name FTP is an acronym for file transfer protocol. Downloading is what it is called when a user copies a file from someone else's (however remote) computer to his/her own. When the user sends a file from his/her computer to someone else's, this is defined as uploading the file.

In FTP terminology, the user's computer is called the local host and the other computer is called the remote host. It does not matter where the two computers are located, how they are connected, or even whether they use the same operating system. Using FTP, the two computers can, through the Internet, exchange files.

Anonymous FTP

Collections of files are made available for public downloading by storing them in a public FTP directory located

on an FTP server. Anonymous FTP is a facility that lets users log onto remote hosts and download files by using the user identification (log-on) of anonymous. By using a log-on of anonymous, the need to supply a regular password is eliminated. Instead, the user supplies his or her e-mail address (Figure 5) (Lehnert, 1998).

Transferring Files

All FTP clients work more or less the same way. The screen display window is be divided into two sections, one on the left and one on the right. The left section displays information about the directory structure and files on the local computer. The right section shows the

names of the directories and files on the remote computer (Figure 6).

The general process of accessing anonymous FTP resources involves the following steps:

1. Establish a connection to the remote host.
2. Navigate to the directory on the remote host that contains the desired file.
3. Set the desired transfer options. Usually an ASCII transfer is used for text files. A binary transfer is used to transfer software or graphic image files. This transfer mode simply moves the file without attempting to open or change it.
4. Select the file to be transferred.
5. Designate the desired directory on the local computer in which to store the transferred file.
6. Initiate the file transfer (Hofstetter, 1998; Ackermann & Hartman, 2001).

Downloading Files and Software

At times, users may wish to download extremely large files or entire software programs. To reduce the cost and space of storage and download time, large files are frequently stored in a compressed format. Such files should be treated as binary files (i.e., files that require translation by a software program or hardware processor). The problem is that getting the file transferred from the remote host to the user's local computer is only half the process. Once it is there, the user will need to extract or unzip the file to make it usable (Ackermann & Hartman, 2001).

When using FTP, the user may want to move an entire directory or collection of directories. At this time, there is no standard command or effective means of accomplishing this in a single step. Instead, the most common practice is to move multiple files from an FTP archive or back up a selection of files into an aggregate file, which then can be moved (Ackermann & Hartman, 2001).

Although current technology makes it possible for users to easily download files from the Internet and save them on the hard drives of their own computers, it is important to observe copyright restrictions. Only the individual or entity that retains ownership can grant the right to copy or distribute materials, including those found on the World Wide Web. Detailed information describing copyright restrictions and fair use doctrine is provided elsewhere in this encyclopedia.

GLOSSARY

Active server pages A Web or HTML page that includes an embedded program called a script. A Microsoft Web server processes the script, creating a Web page on the fly.

Bitmap A graphic that is pixel based, defining display space and color for each pixel within an image. Both GIF and JPG files contain bitmaps.

Browser or Web browser Software that permits the user to traverse the Internet, navigating between Web sites, accessing and downloading files. Examples include Microsoft Internet Explorer and Netscape Navigator.

Cascading style sheets Specify the look and format of Web pages; set font face, style, size, and color; and define precise positioning of images or text, or both. Style sheet coding can be included within a Web page's HTML coding, or it can be a stored on the Web server as a separate file.

Common gateway interface (CGI) A server-side script that transmits information between a Web page and an application program. Search engines and online forms use CGI scripts to communicate with the server, returning information to the user by means of Web pages created on the fly.

File name extension A two- to four-character string that is appended to a file name following a period. The file name extension can be used to associate a software program with the file. For example, a file name of *article.txt* indicates this file is in text format.

Format A preestablished layout for information. All data is stored in some format. A program that recognizes that format will be able to retrieve, read, and process the stored information.

FTP (File Transfer Protocol) The method used to transfer files over the Internet.

GIF (Graphics Interchange Format) The most commonly used image format on the Web.

Helper application A program that works in conjunction with the Web browser to activate and play a multimedia file. Two examples of helper applications are RealPlayer or QuickTime.

HTML (Hypertext Markup Language) The markup code used within a text format file to create Web page files.

Hypertext Text on a Web page that has been linked to another Web page, a location in the current Web page, or an image, audio, video, or multimedia file. Clicking on the hypertext activates the resource to which it is connected. Hypertext files have file name extensions of .htm or .html.

JavaScript A scripting language developed by Netscape Communications that adds interactivity to Web pages and supports dynamic HTML or DHTML. Examples include alerts, pop-up windows, image swapping, and scrolling text banners.

JPG or JPEG (Joint Photographic Experts Group) File format used for full-color images on the Internet.

MID or MIDI (Musical Instrument Digital Interface) File format used to transmit music files over the Internet.

MPG or MPEG (Motion Pictures Expert Group) File format for digital video files named after the ISO (International Organization for Standardization) standards committee. There are four versions of MPEG. MPEG-1 is designed for playback from CD-ROMS. MPEG-2 is used for all-digital, broadcast-quality television transmission. MPEG-3 was to be used for high-definition TV but the development of MPEG-2 made it unnecessary. MPEG-4 permits the transmission of movies using wireless or mobile communications.

MP3 A method and format for compressing audio files.

PHP A script language and interpreter used primarily on Linux Web servers.

Plug-in A software application used in conjunction with a Web browser to view or display certain file formats. Examples of plug-ins include Shockwave and Adobe Acrobat Reader.

Streaming media Sound or video transmitted over the Internet in such a way that a portion of the file downloads into a buffer and then starts playing as the remainder of the file is downloaded. Download and playback occur simultaneously in an uninterrupted stream.

Text file A file containing readable characters with no formatting commands such as underlining, bold face, or italics. The file name extension for a text file is .txt.

URL (Uniform Resource Locator, or Internet address) Examples are http://www.google.com and ftp://ibiblio.org/pub/docs/books/gutenberg/.

Firewalls

James E. Goldman, *Purdue University*

INTRODUCTION

When an organization or individual links to the Internet, a two-way access point out of and in to their information systems is created. To prevent unauthorized activities between the Internet and the private network, a specialized hardware, software, or software–hardware combination known as a firewall is often deployed.

Firewall software often runs on a dedicated server between the Internet and the protected network. Firmware-based firewalls and single-purpose dedicated firewall appliances are situated in a similar location on a network and provide similar functionality to the software-based firewall. All network traffic entering the firewall is examined, and possibly filtered, to ensure that only authorized activities take place. This process may be limited to verifying authorized access requested files or services, or it may delve more deeply into content, location, time, date, day of week, participants, or other criteria of interest. Firewalls usually provide a layer of isolation between the inside, sometimes referred to as the "clean" network, and the outside or "dirty" network. They are also used, although less frequently, to separate multiple subnetworks so as to control interactions between them.

A common underlying assumption in such a design scenario is that all of the threats come from the outside network or the Internet, but many modern firewalls provide protection against insiders acting inappropriately and against accidental harm that could result from internal configuration errors, viruses, or experimental implementations. Research consistently indicates that 70–80% of malicious activity originates from insiders who would normally have access to systems both inside and outside of the firewall. In addition, outside threats may be able to circumvent the firewall entirely if dial-up modem access remains uncontrolled or unmonitored, if radio-LANs (local area networks) or similar wireless technology is used, or if other methods can be used to co-opt an insider, to subvert the integrity of systems within the firewall, or to otherwise bypass the firewall as a route for communications. Incorrectly implemented firewalls can exacerbate this situation by creating new, and sometimes undetected, security holes or by creating such an impediment to legitimate uses that insiders subvert its mechanisms intentionally. It is often said that an incorrectly configured and maintained firewall is worse than no firewall at all because it gives a false sense of security.

Advantages

When properly configured and monitored, firewalls can be an effective way to protect network and information resources. Firewalls are often used to reduce the costs associated with protecting larger numbers of computers that are located inside it. Firewalls provide a control point that can be used for other protective purposes.

Disadvantages

- Firewalls can be complex devices with complicated rule sets.
- Firewalls must be configured, managed, and monitored by properly trained personnel
- A misconfigured firewall gives the illusion of security.
- Even a properly configured firewall is not sufficient or complete as a perimeter security solution.
- The processing of packets by a firewall inevitably introduces latency which, in some cases, can be significant.
- Firewalls often interfere with network applications that may expect direct connections to end user workstations such as Voice over Internet Protocol (IP) phones and VPNs (virtual private networks) as well as some collaborative tools such as instant messenger, and video and audio conferencing software.

FIREWALL BASICS

A given firewall may, but does not necessarily, offer any or all of the following functions.

Address Filtering

This function can, and perhaps should, be performed by a device other than the firewall, such as a border router. Based on address filter tables containing allowed or disallowed individual or groups (subnets) or addresses, address filtering blocks all traffic that contains either disallowed source or destination addresses. Address filtering by itself may not provide adequate protection because it is too large a granularity for some protective requirements.

Port Filtering

Port filtering goes beyond address filtering, examining to which function or program a given packet applies. For example, file transfer protocol (FTP) typically uses ports 20 and 21, inbound electronic mail (simple mail transfer protocol; SMTP) typically uses port 25, and inbound nonencrypted Web traffic (hypertext transfer protocol; HTTP) typically uses port 80. Attacks are often targeted and designed for specific ports. Port filtering can be used to ensure that all ports are disabled except those that must remain open and active to support programs and protocols required by the owners of the inside network. Static port filtering leaves authorized ports open to all traffic all the time, whereas dynamic port filtering opens and closes portions of protocols associated with authorized ports over time as required for the specifics of the protocols.

Domain Filtering

Domain filtering applies to outbound traffic headed through the firewall to the Internet. Domain filtering can block traffic with domains that are not authorized for communications or can be designed to permit exchanges only with authorized "outside" domains.

Network Address Translation

When organizations connect to the Internet, the addresses they send out must be globally unique. In most cases, an organization's Internet service provider specifies these globally unique addresses. Most organizations have relatively few globally unique public addresses compared with the actual number of network nodes on their entire network.

The Internet Assigned Numbers Authority has set aside the following private address ranges for use by private networks:

10.0.0.0 to 10.255.255.255
172.16.0.0 to 172. 31.255.255
192.168.0.0 to 192.168.255.255

Traffic using any of these "private" addresses must remain on the organization's private network to interoperate properly with the rest of the Internet. Because anyone is welcome to use these address ranges, they are not globally unique and therefore cannot be used reliably over the Internet. Computers on a network using the private IP address space can still send and receive traffic to and from the Internet by using network address translation (NAT). An added benefit of NAT is that the organization's private network is not as readily visible from the Internet.

All of the workstations on a private network can share a single or small number of globally unique assigned public IP address(es) because NAT mechanism maintains a table that provides for translation between internal addresses and ports and external addresses and ports. These addresses and port numbers are generally configured so as to not to conflict with commonly assigned transmission control protocol (TCP) port numbers. The combination of the shared public IP address and a port number that is translated into internal address and port numbers via the translation table allows computers on the private network to communicate with the Internet through the firewall. NAT can also run on routers, dedicated servers, or other similar devices, and "gateway" computers often provide a similar function.

Data Inspection

The primary role of many firewalls is to inspect the data passing through it using a set of rules that define what is and is not allowed through the firewall and then to act appropriately on packets that meet required criteria. The various types of firewalls, described in the next section, differ primarily in what portions of the overall data packet are inspected, the types of inspections that can be done, and what sorts of actions are taken with respect to that data. Among the data elements that are commonly inspected are the following:

- IP address
- TCP port number
- User Datagram Protocol port number
- Data field contents
- Contents of specific protocol payloads, such as HTTP, to filter out certain classes of traffic (e.g., streaming video, voice, music, etc.), access requests to restricted Web sites, information with specific markings (e.g., proprietary information), content with certain words or page names

Virus Scanning and Intrusion Detection

Some firewalls also offer functionality such as virus scanning and intrusion detection. Advantages of such firewalls include the following:

- "One-stop shopping" for a wide range of requirements,
- Reduced overhead from centralization of services, and
- Reduced training and maintenance.

Disadvantages include the following:

- Increased processing load requirements,
- Single point of failure for security devices,
- Increased device complexity, and
- Potential for reduced performance over custom subsolutions.

FIREWALL TYPES

Another difficulty with firewalls is that there are no standards for firewall functionality, architecture, or interoperability. As a result, users must often be aware of how firewalls work to use them, and owners must be aware of these issues to evaluate potential firewall technology purchases. Firewall functionality and architectures are explained in the next few sections.

Bastion Host

Many firewalls, whether software or hardware based, include a bastion host—a specially hardened server or a trusted system designed so that the functionality of the device cannot be compromised by attacking vulnerabilities in the underlying operating system or software over which its software runs. Specifically, the bastion host employs a secure version of the operating system with the most recent patches, security updates, and minimum number of applications to avoid known and unknown vulnerabilities.

Packet Filtering Firewalls

Every packet of data on the Internet can be identified by a source address normally associated with the computer that issued the message and the destination address normally associated with the computer to which the message is bound. These addresses are included in a portion of the packet called the header.

A packet filter can be used to examine the source and destination address of every packet. Network access devices known as routers are among the commonly used devices capable of filtering data packets. Filter tables are lists of addresses with data packets and embedded messages that are either allowed or prohibited from proceeding through the firewall. Filter tables may also limit the access of certain IP addresses to certain services and subservices. This is how anonymous FTP users are restricted to only certain information resources. It takes time for a firewall server to examine the addresses of each packet and compare those addresses to filter table entries. This filtering time introduces latency to the overall transmission time and may create a bottleneck to high volumes of traffic. A filtering program that only examines source and destination addresses and determines access based on the entries in a filter table is known as a port-level filter or network-level filter or packet filter. Hardware implementations of such filters are often used to provide low latency and high throughput.

Packet filter gateways can be implemented on routers. This means that an existing piece of technology can be used for dual purposes. Maintaining filter tables and access rules on multiple routers is not a simple task, and packet filtering of this sort is limited in what it can accomplish because it only examines certain areas of each packet. Dedicated packet-filtering firewalls are usually easier to configure and require less in-depth knowledge of protocols to be filtered or examined. One easy way that many packet filters can be defeated by attackers is a technique known as IP spoofing. Because these simple packet filters make all filtering decisions based on IP source and destination addresses, an attacker can often create a packet designed to appear to come from an authorized or trusted IP address, which will then pass through such a firewall unimpeded.

Application Gateways

Application-level filters, sometimes called assured pipelines, application gateways, or proxy servers, go beyond port-level filters in their attempts to control packet flows. Whereas port-level filters determine the legitimacy of the IP addresses and ports within packets, application-level filters are intended to provide increased assurance of the validity of packet content in context. Application-level filters typically examine the entire request for data rather than just the source and destination addresses. Controlled files can be marked as such, and application-level filters can be designed to prevent those files from being transferred, even within packets authorized by port-level filters. Of course, this increased level of scrutiny comes at the cost of a slower or more expensive firewall.

Certain application-level protocols commands that are typically used for probing or attacking systems can be identified, trapped, and removed. For example, SMTP is an e-mail interoperability protocol that is a member of the TCP/IP family and used widely over the Internet. It is often used to mask attacks or intrusions. Multipurpose internet mail extension (MIME) is another method that is often used to hide or encapsulate malicious code such as Java applets or ActiveX components. Other application protocols that may require monitoring include but are not limited to World Wide Web protocols such as HTTP, telnet, ftp, gopher, and Real Audio. Each of these application protocols may require its own proxy, and each application-specific proxy must be designed to be intimately familiar with the commands within each application that will need to be trapped and examined. For example an SMTP proxy should be able to filter SMTP packets according to e-mail content, message length, and type of attachments. A given application gateway may not include proxies for all potential application layer protocols.

Circuit-Level Proxies

Circuit-level proxies or circuit-level gateways provide proxy services for transport layer protocols such as TCP. Socks, an example of such a proxy server, creates proxy data channels to application servers on behalf of the application client. Socks uniquely identifies and keeps track of individual connections between the client and server ends of an application communication over a network. Like other proxy servers, both a client and server portion of the Socks proxy are required to create the Socks tunnel. Some Web browsers have the client portion of Socks included, whereas the server portion can be added as an additional application to a server functioning as a proxy server. The Socks server would be located inside an organization's firewall and can block or allow connection requests, based on the requested Internet destination, TCP port ID, or user identification. Once Socks approves and establishes the connection through the proxy server, it does not care which protocols flow through the established connection. This is in contrast to other more protocol-specific proxies such as Web proxy, which only allows HTTP to be transported, or WinSock Proxy, which only allows Windows application protocols to be transported.

Because all data goes through Socks, it can audit, screen, and filter all traffic in between the application client and server. Socks can control traffic by disabling or enabling communication according to TCP port numbers. Socks4 allowed outgoing firewall applications, whereas Socks5 supports both incoming and outgoing firewall applications, as well as authentication.

The key negative characteristic of Socks is that applications must be "socksified" to communicate with the Socks protocol and server. In the case of Socks4, this meant that local applications had to be recompiled using a Socks library that replaced its normal library functions. However, with Socks5, a launcher is employed which avoids "socksification" and recompilation of client programs that in most cases do not natively support Socks. Socks5 also uses a private routing table and hides internal network addresses from outside networks.

Application gateways are concerned with what services or applications a message is requesting in addition to who is making that request. Connections between requesting clients and service providing servers are only created after the application gateway is satisfied as to the legitimacy of the request. Even once the legitimacy of the request has been established, only proxy clients and servers actually communicate with each other. A gateway firewall does not allow actual internal IP addresses or names to be transported to the external nonsecure network, except as this information is contained within content that the proxy does not control. To the external network, the proxy application on the firewall appears to be the actual source or destination, as the case may be.

Trusted Gateway

A trusted gateway or trusted application gateway seeks to relieve all the reliance on the application gateway for all communication, both inbound and outbound. In a trusted gateway, certain applications are identified as trusted and are able to bypass the application gateway entirely and are able to establish connections directly rather than be executed by proxy. In this way, outside users can access information servers and Web servers without tying up the proxy applications on the application gateway. These servers are typically placed in a demilitarized zone (DMZ) so that any failures in the application servers will grant only limited additional access to other systems.

Proxies are also capable of approving or denying connections based on directionality. Users may be allowed to upload but not download files. Some application-level gateways have the ability to encrypt communications over these established connections. The level of difficulty associated with configuring application-level gateways versus router-based packet filters is debatable. Router-based gateways tend to require a more intimate knowledge of protocol behavior, whereas application-level gateways deal predominantly at the application layer of the protocol stack. Proxies tend to introduce increased latency compared with port-level filtering. The key weaknesses of an application-level gateway is their inability to detect embedded malicious code such as Trojan horse programs or macro viruses and the requirement of more complex and resource intensive operation than lower level filters.

Stateful Firewalls

Rather than simply examining packets individually without the context of previously transmitted packets from the same source, a stateful firewall stores information about past activities and uses this information to test future packets attempting to pass through. Stateful firewalls typically review the same packet information as normal simple packet filtering firewalls such as source address, destination address, protocol, port, and flags; however, they also record this information in a connection state table before sending the packet on. This table will have an entry for each valid connection established over a particular reference frame.

Some stateful firewalls keep sequence number information to validate packets even further, so as to protect against some session hijacking attacks. As each packet arrives to a stateful firewall, it is checked against the connection table to determine whether it is part of an existing connection. The source address, destination address, source port, and destination port of the new packet must match the table entry. If the communication has already been authorized, there is no need to authorize it again and the packet is passed. If a packet can be confirmed to belong to an established connection, it is much less costly to send it on its way based on the connection table rather than reexamine the entire firewall rule set. This makes a stateful firewall faster then a simple packet filtering firewall for certain types of traffic patterns, since the packet filtering firewall treats each connection as a new connection. Additionally, because there is a 'history' in the state tables, flags can be analyzed to ensure the proper sequence as in the TCP connection handshake, and the stateful firewall can drop or return packets that are clearly not a genuine response to a request.

As a result, stateful firewalls are better able to prevent some sorts of session hijacking and man-in-the-middle attacks. Session hijacking is very similar to IP spoofing, described earlier, except that it hijacks the session by sending forged acknowledgment (ACK) packets so that the victimized computer still thinks it is talking to the legitimate intended recipient of the session. A man-in-the-middle attack could be seen as two simultaneous session hijackings. In this scenario, the hacker hijacks both sides of the session and keeps both sides active and appearing to talk directly to each other when, in fact, the man-in-the middle is examining and potentially modifying any packet that flows in either direction of the session.

Internal Firewalls

Not all threats to a network are perpetrated from the Internet by anonymous attackers, and firewalls are not a stand-alone, technology-based quick fix for network security. In response to the reality that most losses due to computer crime involve someone with inside access, internal

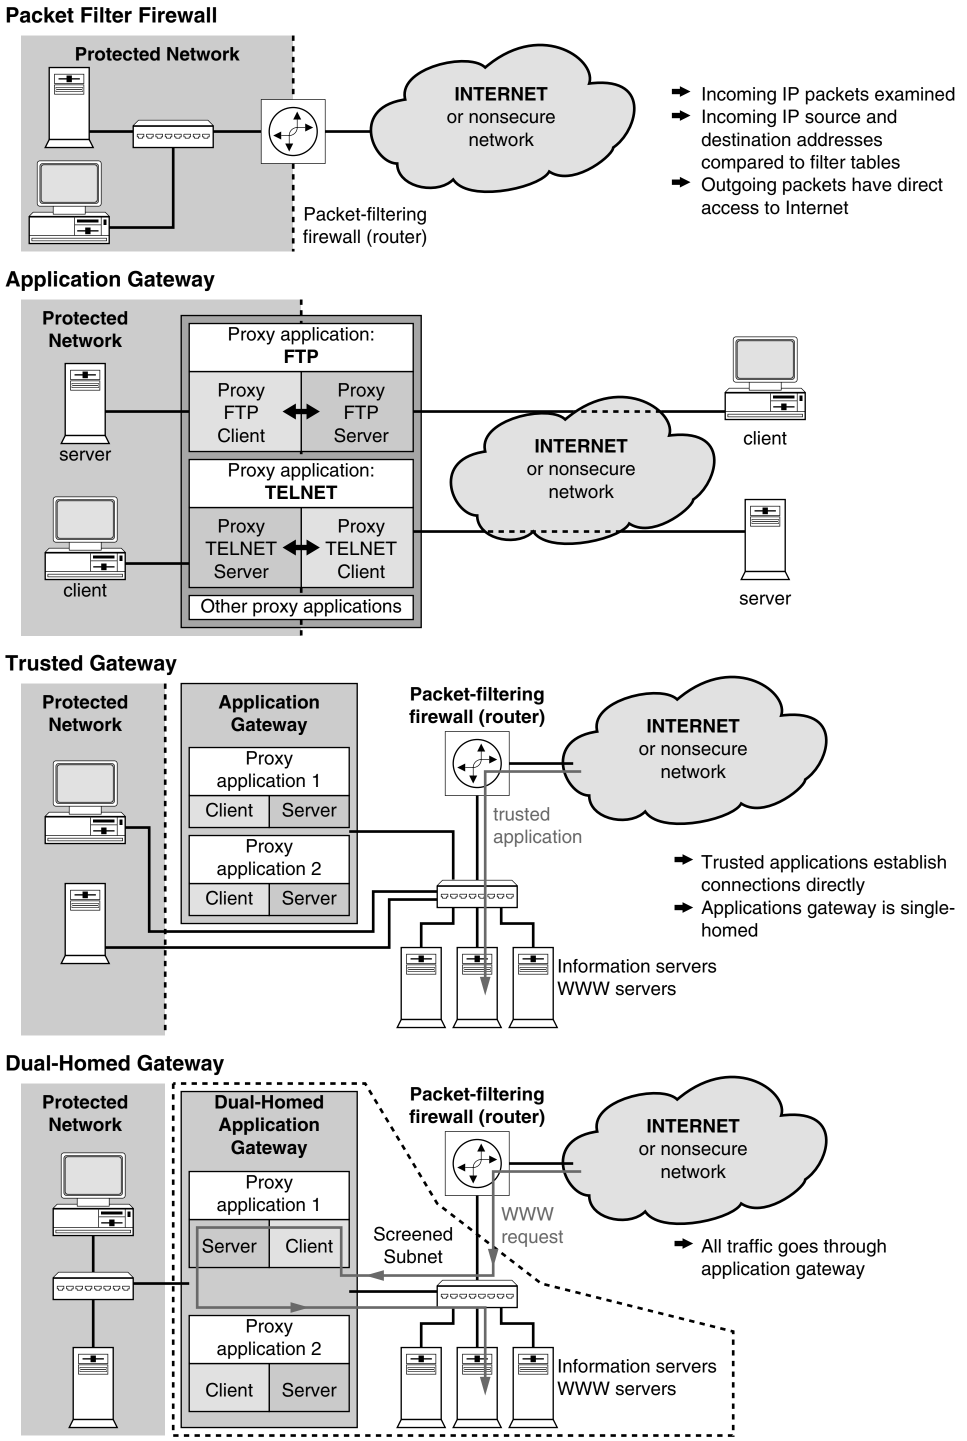

Figure 1: Firewall types.

firewalls have been applied with increasing frequency. Internal firewalls include filters that work on the data link, network, and application layers to examine communications that occur only within internal networks. Internal firewalls also act as access control mechanisms, denying access to applications for which a user does not have specific access approval. To ensure the confidentiality and integrity of private information, encryption and authentication may also be supported by firewalls, even during internal communications. Figure 1 illustrates some of the aforementioned types of firewalls.

ENTERPRISE FIREWALL ARCHITECTURES

The previous section described different approaches to firewall architecture on an individual basis, but key decisions remain to be made regarding the number and location of these firewalls in relation to the Internet and a corporation's public and private information resources. Each of the alternative enterprise firewall architectures explored in this section attempt to segregate three distinct networks or risk domains:

1. The Internet: contains legitimate customers and business partners as well as hackers
2. The DMZ, otherwise known as the screened subnet, neutral zone, or external private network: contains Web servers and mail servers
3. The internal private network, otherwise known as the secure network or intranet: contains valuable corporate information

Packet Filtering Routers

Packet filtering routers or border routers are often the first device that faces the Internet from an organization network perspective. These packet filtering routers first remove all types of traffic that should not even be passed to the firewalls. This process is typically fast and inexpensive because it involves only simple processes that are implemented in relatively low-cost hardware. Examples of removed packets include packet fragments, packets with abnormally set flags, time to live (TTL), abnormal packet length, or Internet control message protocol (ICMP) packets, all of which could potentially be used for attacks or to exploit known vulnerabilities and packet from or to unauthorized addresses and ports.

Dual-Homed Host Firewalls

In a dual-homed gateway or dual-homed host firewalls scenario, the application gateway is physically connected to the private secure network and the packet filtering router is connected to the nonsecure network or the Internet. Between the application gateway and the packet filter router is an area known as the screened subnet or DMZ. Also attached to this screened subnet are information servers, Web servers, or other servers that the company may wish to make available to outside users. All outside traffic still goes through the application gateway first, however, and then to the information servers. TCP/IP forwarding is disabled, and access to the private network is only available through one of the installed proxies. Remote logins, if they are allowed at all, may only allowed to a gateway host.

Screened Host Firewalls

An alternative to the dual-homed gateway that seeks to relieve the reliance on the application gateway for all communication, both inbound and outbound, is known as a trusted gateway, screened host firewall, or trusted application gateway. In a trusted gateway, certain applications are identified as trusted and are able to bypass the application gateway entirely and establish connections directly rather than by proxy. In this way, outside users can access information and Web servers without tying up the proxy applications on the application gateway.

Screened Subnet Firewall (DMZ)

Rather than using only the packet filtering router as the front door to the DMZ, a second firewall is added behind the packet filtering router to further inspect all traffic bound to or from the DMZ. The initial application gateway or firewall still protects the perimeter between the DMZ and the Intranet or secure internal network. The DMZ still contains mail, Web, and often e-commerce servers.

Multitiered DMZ

As e-commerce and e-business have proliferated, the need for e-commerce servers to access more and more secure information from database and transaction servers within the secure intranet has increased proportionately. As a result, the number of connections allowed through firewalls into the most secure areas of corporate networks has increased dramatically. In response to this phenomenon, the model of a multitiered DMZ has developed. Such a scenario really builds on the screened subnet firewall (DMZ) architecture by adding additional tiers to the DMZ, each protected from other tiers by additional firewalls. Typically, the first tier of the DMZ closest to the Internet would contain only the presentation or Web portion of the e-commerce application running on Web servers.

A firewall would separate that first tier of the DMZ from the second tier that would house the business logic and application portions of the e-commerce application typically running on transaction servers. This firewall would have rules defined to only allow packets from certain applications on certain servers with certain types of requests through from the first tier DMZ to the second-tier DMZ. The third (most secure) tier of the DMZ is similarly protected from the second tier by a separate firewall. The servers in the third-tier DMZ would be database servers and should contain only the data necessary to complete requested e-commerce transactions. Finally, as in the screened subnet firewall architecture, a firewall would separate the third-tier DMZ from the intranet, or most secure corporate network. Figure 2 illustrates some of the aforementioned enterprise firewall architectures.

FIREWALL FUNCTIONALITY AND TECHNOLOGY ANALYSIS

Commercially available firewalls usually employ either packet filtering or proxies as firewall architecture and add an easy-to-use graphical user interface (GUI) to ease the configuration and implementation tasks. Some firewalls even use industry standard Web browsers as their GUIs. Several certifying bodies are available to certify various aspects of firewall technology. As an example, one certifying body certifies the following:

- That firewalls meet the minimum requirements for reliable protection
- That firewalls perform as advertised
- That Internet applications perform as expected through the firewall

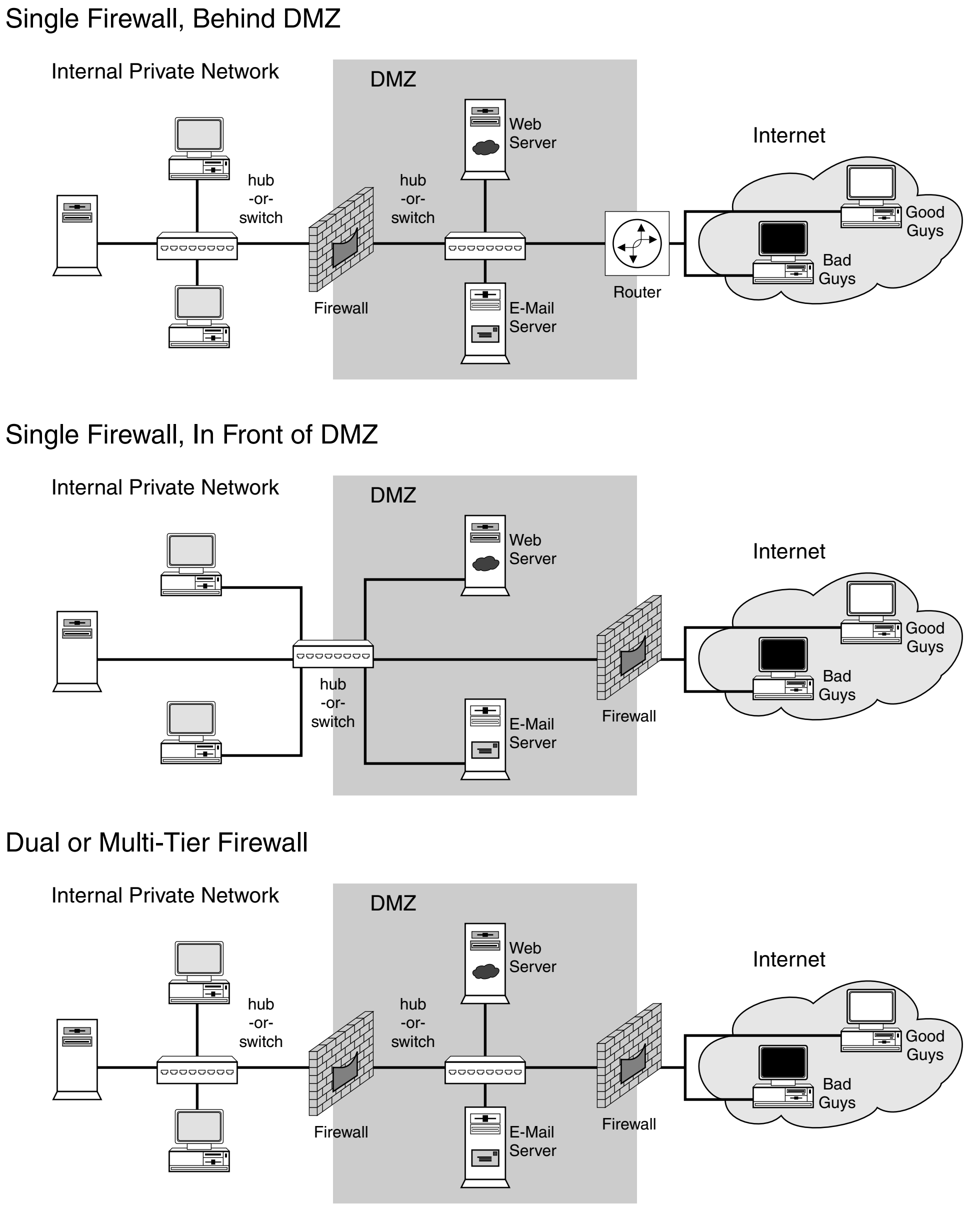

Figure 2: Enterprise firewall architectures.

Table 1 summarizes some of the key functional characteristics of firewall technology.

AIR GAP TECHNOLOGY

Some vendors try to assert the strength of their protection by using widely known terms such as "air gap" to characterize their protective mechanisms. One example of such a technology provides the same separation of the clean and dirty networks as firewalls. A hardware-based network switch is at the heart of this technology. The premise of creating a physical disconnection between the clean or secure network (Intranet) and the nonsecure or dirty network (Internet) is accomplished by connecting a server on the Internet connection that will receive all incoming requests. This server will connect to an electronic switch that strips the TCP headers and stores the packet in a memory bank, and then the switch disconnects from the external server and connects with the internal server. Once the connection is made, the internal server recreates the TCP header and transmits the packet to the intended server. Responses are made in the reverse order. The physical separation of the networks and the stripping of the TCP headers remove many of the vulnerabilities in the TCP connection-oriented protocol. Of course this provides little additional protection over other firewalls at the content level because content-level attacks are passed through the so-called air gap and responses are returned.

There is a protective device that is highly effective at limiting information flow to one direction. The so-called digital diode technology is applied in situations in which the sole requirement is that no information be permitted to leak from one area to the other while information

Table 1 Sample Functional Characteristics of Firewall Technology

FIREWALL FUNCTIONAL CHARACTERISTIC	EXPLANATION/IMPORTANCE
Encryption	Allows secure communication through firewall Encryption schemes supported: DES Encryption key length supported: 40, 56, 128 bits
Virtual Private Network (VPN) Support	Allows secure communication over the Internet in a virtual private network topology VPN Security protocols supported: IPsec
Application Proxies Supported	How many application proxies are supported? Internet application protocols (HTTP, SMTP, FTP, telnet, NNTP, WAIS, SNMP, rlogin, ping traceroute)? Real Audio? How many controls or commands are supported for each application?
Proxy Isolation	In some cases, proxies are executed in their own protected domains to prevent penetration of other proxies or the firewall operating system should a given proxy be breached
Operating Systems Supported	Unix and Varieties, Windows NT,2000,XP
Virus Scanning Included	Because many viruses enter through Internet connections, the firewall is a logical place to scan for viruses
Web Tracking	To ensure compliance with corporate policy regarding use of the World Wide Web, some firewalls provide Web tracking software. The placement of the software in the firewall makes sense because all Web access must pass through the firewall. Access to certain uniform resource locators (URLs) can be filtered
Violation Notification	How does the firewall react when access violations are detected? Options include SNMP traps, e-mail, pop-up windows, pagers, reports.
Authentication Supported	As a major network access point, the firewall must support popular authentication protocols and technology
Network Interfaces Supported	Which network interfaces and associated data link layer protocols are supported?
System Monitoring	Are graphical systems monitoring utilities available to display such statistics as disk usage or network activity by interface?
Auditing and Logging	Is auditing and logging supporting? How many different types of events can be logged? Are user-defined events supported? Can logged events be sent to SNMP managers?
Attack Protection	Following is a sample of the types of attacks that a firewall should be able to guard against: TCP denial-of-service attack, TCP sequence number prediction, source routing and RIP attacks, EGP infiltration and ICMP attacks, authentication server attacks, finger access, PCMAIL access, DNS access, FTP authentication attacks, anonymous FTP access, SNMP access remote access remote booting from outside networks; IP, MAC and ARP spoofing and broadcast storms; trivial FTP and filter to and from the firewall, reserved port attacks, TCP wrappers, gopher spoofing, and MIME spoofing
Attack Retaliation/Counterattack	Some firewalls can launch specific counterattacks or investigative actions if the firewall detects specific types of intrusions
Administration Interface	Is the administration interface graphical in nature? Is it forms based?

ARP = Address Resolution Protocol; DNS = Domain Name Server; EGP = Exterior Gateway Protocol; DES = Data Encryption Standard; FTP = File Transfer Protocol; HTTP = Hypertext Transfer Protocol; ICMP = Internet Control Message Protocol; IP = Internet Protocol; MAC = media access control; MIME = Multipurpose Internet Mail Extension; NNTP = Network News Transfer Protocol; RIP = Routing Information Protocol; SMTP = Simple Mail Transfer Protocol; SNMP = Simple Network Management Protocol; TCP = Transmission Control Protocol; WAIS = Wide Area Information Services.

is permitted to flow in the other direction. An example would be the requirement for weather information to be available to military planning computers without the military plans being leaked to the weather stations. This sort of protection typically uses a physical technology such as a fiber-optic device with only a transmitter on one end and receiver on the other end to provide high assurance of traffic directionality.

Finally, the real and widely accepted meaning of an "air gap" is a physical separation that is effective at eliminating all communications across the media.

SMALL OFFICE HOME OFFICE (SOHO) FIREWALLS

As telecommuting has boomed and independent consultants have set up shop in home offices, the need for firewalls for the SOHO market has grown as well. These devices are most often integrated with integrated services digital network–based multiprotocol routers that supply bandwidth on demand capabilities for Internet access. Some of these SOHO firewalls offer sophisticated features such as support for virtual private networks at a reasonable price. The most expensive of these costs less than $3,000 and some simpler filtering firewalls cost as little as $100. Some of these devices combine additional functionality such as network address translation, built in hub and switch ports, and load balancing in a combined hardware–software device known as a security appliance. Often DSL (digital subscriber line) or cable modems include firewall functionality because of their "always on" connection status.

Software-only solutions are also available. These products are installed on every computer and provide firewall-like functionality to each workstation. The benefits are that each workstation has an extremely inexpensive solution and that protection can be customized at the system level. The problem is that this requires all users to be firewall administrators for their computers, losing the economy of scale that was one of the original benefits associated with firewalls.

CONCLUSION

Firewalls are an essential and basic element of many organizations' security architecture. Nonetheless, technology must be chosen carefully to ensure that it offers the required functionality, and firewalls must be arranged into properly designed enterprise firewall architectures and properly configured, maintained, and monitored. Even in the best circumstances, firewalls should be seen as a relatively small solution within the overall information protection challenge and should not be considered sufficient on their own.

GLOSSARY

Address filtering A firewall's ability to block or allow packets based on internet protocol addresses.

Air gap technology Switched connections established to connect external and internal networks that are not otherwise physically connected.

Application-level gateway Application-level filters examine the entire request for data rather than only the source and destination addresses.

Bastion host Hardened server with trusted operating system that serves as the basis of the firewall.

Circuit-level proxies Proxy servers that work at the circuit level by proxying such protocols as file transfer protocol.

Demilitarized zone (DMZ) A neutral zone between firewalls or between a packet filtering router and a firewall in which mail and Web servers are often located.

Domain filtering A firewall's ability to block outbound access to restricted sites.

Dual-homed host A host firewall with two or more network interface cards with direct access to two or more networks.

Firewall A network device capable of filtering unwanted traffic from a connection between networks.

Internal firewall Firewalls that include filters that work on the data-link, network, and application layers to examine communications that occur only on an organization's internal network, inside the reach of traditional firewalls.

Multitiered DMZ A DMZ that segments access areas with multiple layers of firewalls.

Network address translation A firewall's ability to translate between private and public globally unique Internet Protocol addresses.

Packet filtering gateway A firewall that allows or blocks packet transmission based on source and destination Internet protocol addresses.

Port filtering A firewall's ability to block or allow packets based on transmission control protocol port number.

Proxy server Servers that break direct connections between clients and servers and offer application and circuit layer specific proxy services to inspect and control such communications.

Screened subnet Enterprise firewall architecture that creates a DMZ.

Stateful firewall A firewall that monitors connections and records packet information in state tables to make forwarding decisions in the context of previous transmitted packets over a given connection.

Trusted gateway In a trusted gateway, certain applications are identified as trusted, are able to bypass the application gateway entirely, and are able to establish connections directly rather than by proxy.

INTRODUCTION

To promote the use of fuzzy logic in the Internet, the 2001 BISC (Berkeley Initiative in Soft Computing, http://www-bisc.cs.berkeley.edu/) International Workshop on Fuzzy Logic and the Internet (FLINT2001) was held at the University of California, Berkeley (August 14–18, 2001; Nikravesh & Azvine, 2001), and a BISC Special Interest Group on Fuzzy Logic in the Internet was formed. Zadeh noted that "fuzzy logic may replace classical logic as what may be called the brainware of the Internet" (Zadeh, 2000). Clearly, the intelligent e-brainware based on fuzzy logic plays an important role in e-commerce applications on the Internet.

To increase the quality of intelligence of e-business on the Internet, computational web intelligence (CWI) based on computational intelligence (CI) and Web technology (WT) was proposed at the Special Session on Computational Web Intelligence at FUZZ-IEEE2002 of World Congress on Computational Intelligence (Zhang & Lin, 2002). CWI can be used to make intelligent e-business applications on the Internet and wireless networks. Fuzzy Web intelligence (FWI) is an important technology for intelligent fuzzy Internet and smart fuzzy e-commerce applications.

"In July 1964, Zadeh, a well-respected professor in the department of electrical engineering and computer science at the University of California, Berkeley, spent the evening by himself after a dinner with friends was canceled. It was then that the idea of grade of membership, which is the backbone of fuzzy set theory, occurred to him" (Yen & Langari, 1999, pp. 4–5). Zadeh published the seminal paper on fuzzy sets in 1965 (Zadeh, 1965). From 1965 to 1976, many researchers made strides in developing various fuzzy techniques such as fuzzy multistage decision making (Bellman & Zadeh, 1970), fuzzy measures (Sugeno, 1974), fuzzy automata (Mizumoto & Tanaka, 1976), fuzzy switching function (Kandel, 1973), and fuzzy optimization (Zimmermann, 1975). The first important fuzzy control system was designed by Assilian and Mamdani in 1974 (Yen & Langari, 1999). From 1977 to 1987, researchers and engineers continued to develop fuzzy techniques and use them for real applications. For example, Sendai city's subway system using fuzzy logic appeared in 1987. Since then, the fuzzy boom in Japan has been having an increasing impact on real applications of fuzzy logic theory. For example, various fuzzy products (e.g., fuzzy rice cookers, refrigerators, cameras, washing machines, etc.) on the market today. Fuzzy logic has applications in management, economics, and marketing (Zopounidis, Pardalos, & Baourakis, 2001). The fuzzy e-business boom on the Internet will likely continue into the future.

Crisp Sets and Fuzzy Sets

A crisp set is one with a binary characteristic function and thus has no uncertainty. A fuzzy set (Zadeh, 1965) is a one with a fuzzy characteristic function (or membership function), in which fuzziness, or uncertainty, exists. The key difference between a crisp set and a fuzzy set is the type of characteristic function. Assuming U to be a universe of discourse consisting of discrete objects or continuous space, a crisp set and a fuzzy set are defined as follows.

Definition 1

A crisp set A in U is defined as a set of ordered pairs:

$$A = \{(x, \phi_A(x)) \mid x \in U\},$$

where $\phi_A(x)$ is the binary characteristic function, $\phi_A(x) = 1$ if $x \in A$, and $\phi_A(x) = 0$ if $x \notin A$. $\phi_A(x) \in \{0, 1\}$.

Definition 2

A fuzzy set $\tilde{A}$ in U is defined as a set of ordered pairs:

$$\tilde{A} = \{(x, \mu_{\tilde{A}}(x)) \mid x \in U\},$$

where $\mu_{\tilde{A}}(x)$ is the fuzzy membership function that maps x to a membership degree between 0 and 1 ($\mu_{\tilde{A}}(x) \in [0, 1]$).

For example, an age space U is defined by $U = \{1, 2, 3, \ldots\ldots, 99, 100\}$. A crisp set for "young ages" is *Crisp-Young* = {(1, 1), (2, 1), (3, 1), . . . , (24, 1), (25, 1), (26, 0), (27, 0), . . . , (99, 0), (100, 0)}. We can see that there is a sharp jump from 25 years old to 26 years old, that is, 25 years old is 100% young, but 26 years old is 100% not young. In other words, if an age is less than or equal to 25, then it belongs to the crisp set *Crisp-Young*, otherwise it doesn't belong to *Crisp-Young*.

On the other hand, a fuzzy set for "young ages" is *Fuzzy-Young* = $\{(1, 1.0), (2, 1.0), \ldots, (19, 1.0), (20, 0.9), (21, 0.8), (22, 0.7), (23, 0.6), (24, 0.5), (25, 0.4), (26, 0.3), (27, 0.2), (28, 0.1), (29, 0), \ldots, (99, 0), (100, 0)\}$. We can see that there is a gradual decrease of the fuzzy membership value from 19 years old to 29 years old. In this case, 25 years old is 40% young, and 26 years old is 30% young.

Boolean Logic and Fuzzy Logic

Boolean logic (or binary logic) uses two logical values: true and false, or 1 and 0. Three basic Boolean logical operations are "AND," "OR," and "NOT," defined as follows.

Definition 3

The Boolean AND of two Boolean variables X and Y for $X, Y \in \{0, 1\}$ is denoted by $X \cap Y$. The four logical operations are $0 \cap 0 = 0$, $0 \cap 1 = 0$, $1 \cap 0 = 0$, and $1 \cap 1 = 1$.

Definition 4

The Boolean OR of two Boolean variables X and Y for $X, Y \in \{0, 1\}$ is denoted by $X \cup Y$. The four logical operations are $0 \cup 0 = 0$, $0 \cup 1 = 1$, $1 \cup 0 = 1$, and $1 \cup 1 = 1$.

Definition 5

The Boolean NOT of a Boolean variable X for $X \in \{0, 1\}$ is denoted by $\overline{X}$. The two logical operations are $\overline{0} = 1$ and $\overline{1} = 0$.

Fuzzy logic uses a logical value between 0 and 1. In other words, fuzzy logic uses not only extreme truth values (0: 100% false and 1: 100% true) but also partial truth values within 0 and 1. Three basic fuzzy logical operations are "fuzzy AND," "fuzzy OR," and "fuzzy NOT," defined as follows.

Definition 6

The fuzzy AND of two fuzzy variables x and y for $x, y \in [0, 1]$ is defined by $x \cap y = \text{t-norm}(x, y)$.

Definition 7

The fuzzy OR of two fuzzy variables x and y for $x, y \in [0, 1]$ is defined by $x \cup y = \text{t-conorm}(x, y)$.

Definition 8

The fuzzy NOT of a fuzzy variable x for $x \in [0, 1]$ is denoted by $\overline{x} = \text{negation}(x)$.

For example, three traditional fuzzy logical operations are $x \cap y = \min(x, y)$, $x \cup y = \max(x, y)$, and $\overline{x} = 1 - x$.

Various more complex crisp (fuzzy) logical expressions can be constructed by using crisp (fuzzy) NOT, crisp (fuzzy) AND, and crisp (fuzzy) OR.

Precise Rules and Fuzzy Rules

A precise rule based on Boolean logic has crisp variables with precise values. For example, "if temperature is higher than or equal to 100, then it is a fever." If a temperature is 100.001, then it's a fever (i.e., 100% true), but if a temperature is 99.999, then it's not a fever (i.e., 100% false). As this example indicates, the precise rule is not always meaningful.

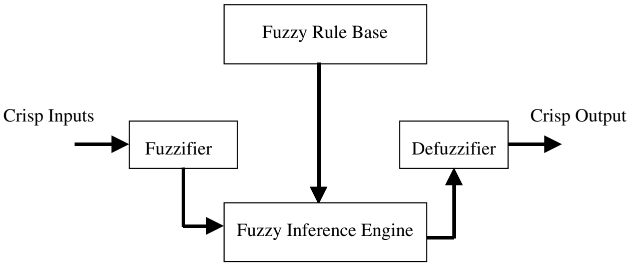

Figure 1: An example of fuzzy system architecture.

A fuzzy rule based on fuzzy logic has linguistic variables with fuzzy values. For example, "if temperature is *high*, then speed is *about 60 miles per hour*," and "if temperature is *low*, then speed is *about 30 miles per hour*." In this example, temperature and speed are two linguistic variables, temperature has two linguistic values *high* and *low*, and speed has two linguistic values *about 60 miles per hour* and *about 30 miles per hour*. These linguistic values are defined by fuzzy sets with relevant membership functions.

Based on the comparison between a precise rule and a fuzzy rule, we can see that a fuzzy rule is closer to a natural language and the natural knowledge in the human brain than a precise rule if we try to represent knowledge under uncertainty. In this sense, a fuzzy rule is more meaningful, more robust, and more useful than a precise rule.

Fuzzy Systems

A commonly used n-crisp-input-1-crisp-output fuzzy system (Figure 1) consists of four basic components: (a) a fuzzifier that can fuzzify inputs, (b) a fuzzy rule base that contains a set of fuzzy if–then rules, (c) a fuzzy inference engine that can generate fuzzy outputs for inputs by making fuzzy reasoning based on the fuzzy rule base, and (d) a defuzzifier that can defuzzify fuzzy conclusions into a crisp output.

There are different fuzzy systems such as Mamdani model (Jang, Sun, & Mizutani, 1997), TSK model (Yen & Langari, 1999), and Zhang–Kandel model (Zhang & Kandel, 1998). Because the Mamdani fuzzy system is a standard model that has been widely used in many applications, a simple 2-input–1-output Mamdani fuzzy system with a simple defuzzifier is discussed in the following section.

A fuzzy rule base contains 9 fuzzy if–then rules:

Rule 1: If x is low and y is low, then z is low,
Rule 2: If x is low and y is medium, then z is low,
Rule 3: If x is low and y is high, then z is medium,
Rule 4: If x is medium and y is low, then z is low,
Rule 5: If x is medium and y is medium, then z is medium,
Rule 6: If x is medium and y is high, then z is high,
Rule 7: If x is high and y is low, then z is medium,
Rule 8: If x is high and y is medium, then z is high,
Rule 9: If x is high and y is high, then z is high.

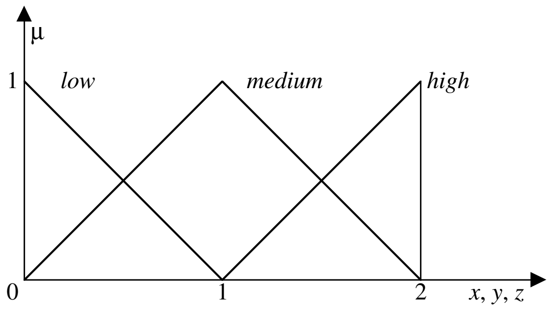

Figure 2: Three fuzzy linguistic values.

There are many types of fuzzy sets using different fuzzy membership functions, for example, trapezoidal fuzzy sets using trapezoidal fuzzy membership functions and Gaussian fuzzy sets using Gaussian fuzzy membership functions. For simplicity, three linguistic variables—x, y, and z—have the three same linguistic values *low*, *medium*, and *high*, defined by the three triangular fuzzy sets in Figure 2. The universe of discourse U is [0, 2], so x, y, $z \in [0, 2]$.

Let's assume $x = 0.25$ and $y = 1.5$ and see how a fuzzy system will generate a crisp output z. The procedure is given step by step as follows.

Step 1: Fuzzification

In Figure 3, the crisp input $x = 0.25$ is related to two linguistic values *low* with the degree 0.75 and *medium* with the degree 0.25, and the crisp input $y = 1.5$ is related to two linguistic values *medium* with the degree 0.5 and *high* with the degree 0.5.

Step 2: Fuzzy Inference

Because x is 75% low or 25% medium and y is 50% medium or 50% high, the four fuzzy Rules 2, 3, 5, and 6 are fired. The "if" part of our rule implies fuzzy AND of x and y, so $x \cap y = \min(x, y)$. In general, a t-norm operation such as $\min(x, y)$ used below can be used for the fuzzy AND.

Rule 2: If x is 0.75 low and y is 0.50 medium, then z is min(0.75, 0.50) = 0.50 low,

Rule 3: If x is 0.75 low and y is 0.50 high, then z is min(0.75, 0.50) = 0.50 medium,

Rule 5: If x is 0.25 medium and y is 0.50 medium, then z is min(0.25, 0.50) = 0.25 medium,

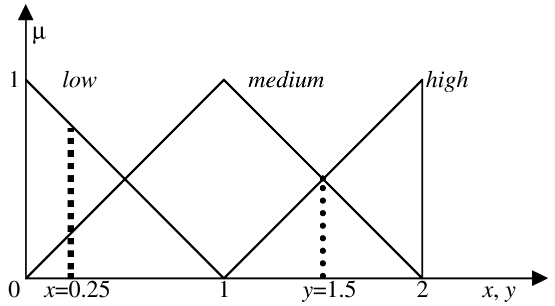

Figure 3: Fuzzifications for $x = 0.25$ and $y = 1.5$.

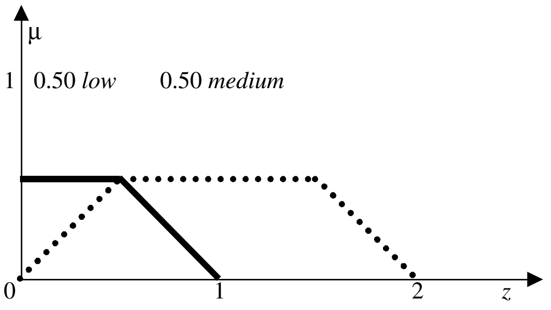

Figure 4: Fuzzy outputs of Rules 2 and 3.

Rule 6: If x is 0.25 medium and y is 0.50 high, then z is min(0.25, 0.50) = 0.25 high.

Graphical fuzzy inference results of Rules 2 and 3 are shown in Figure 4, and graphical fuzzy inference results of Rules 5 and 6 are shown in Figure 5. Therefore, four fuzzy outputs (fuzzy sets) are four partial fuzzy conclusions.

Step 3: Defuzzification

To convert the four fuzzy outputs in Figures 4 and 5 into a single crisp output, a defuzzification process is needed. Several defuzzifiers such as the center of gravity (also called center of area or centroid of area), mean of maximum, and so forth are commonly used (Yen & Langari, 1999). The center of gravity is introduced here.

The four partial fuzzy conclusions in Figures 4 and 5 are fuzzy ORed (Max operation is applied) to generate a single fuzzy conclusion (fuzzy set) $\tilde{C}$ shown in Figure 6. Then the final crisp output z_{output} (the center of gravity) is

$$\begin{aligned} z_{output} &= \frac{\int_0^2 \mu_C(z) z\, dz}{\int_0^2 \mu_C(z)\, dz} \\ &= \frac{\int_0^{1.5} 0.5z\, dz + \int_{1.5}^{1.75} (2-z) z\, dz + \int_{1.75}^{2} 0.25z\, dz}{\int_0^{1.5} 0.5\, dz + \int_{1.5}^{1.75} (2-z)\, dz + \int_{1.75}^{2} 0.25\, dz} \\ &= 0.917. \end{aligned}$$

In general, there are four types of fuzzy systems: (a) a crisp-input–crisp-output fuzzy system, (b) a crisp-input–fuzzy-output fuzzy system, (c) a fuzzy-input–crisp-output fuzzy system, and (d) a fuzzy-input–fuzzy-output fuzzy

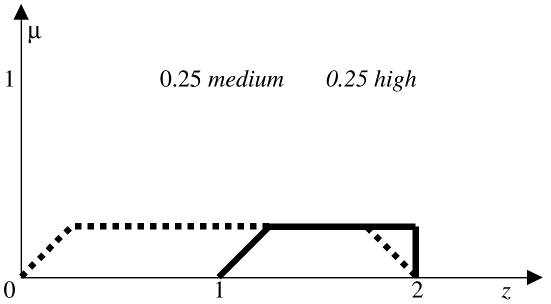

Figure 5: Fuzzy outputs of Rules 5 and 6.

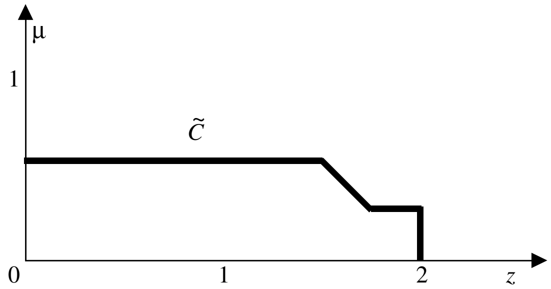

Figure 6: An integrated fuzzy output.

system. The previous example shows only how to design the crisp-input–crisp-output fuzzy system. Yen and Langari (1999) and Zhang and Kandel (1998) discuss the design of other fuzzy systems. The useful fuzzy logic Web sites are the BISC (http://www-bisc.cs.berkeley.edu/), International Fuzzy Systems Association (http://www.abo.fi/~rfuller/ifsa.html), and North American Fuzzy Information Processing Society (http://morden.csee.usf.edu/Nafipsf/).

FUZZINESS ON THE INTERNET

Data and information on the Internet are not always precise (100% accurate) but uncertain in many situations because of fuzziness, incompleteness, and other kinds of uncertainty. Fuzziness in e-commerce applications on the Internet is the major focus of this section.

E-commerce includes interactions at various levels between customers and business units, such as business to business, business to customers, and customers to customers. Communication and interactions of e-commerce are related to natural languages because customers use it as a basic tool. In general, natural languages have fuzziness in terms of words, syntax, semantics, and context. In addition, customers may have different interpretations of data and information because of fuzziness. For example, if two customers want to buy “very cheap” cars, a wealthy customer may consider a $30,000 car a “very cheap” one, whereas a less well-off customer may consider a $3,000 car “very cheap.” How to define “very cheap” is not a simple task because it is a fuzzy concept. Interestingly, fuzzy concepts are more useful and more robust than precise concepts in many e-commerce applications. For example, if a precise visitor searches accurate hotels using Google by typing in “$70” and “Hotel,” it is possible that no hotels with a rate of $70 per night will be found because the search criteria are *too* precise. If a fuzzy visitor types in “around $70” and “Hotel,” the fuzzy search engine may generate approximate robust search results such as rates of $70.05, $70.95, and so on. The visitor to the search engine may now choose the best of these fuzzy hotels.

> Fuzzy logic technology has the special ability to naturally represent human conceptualization and to make many useful contributions to the development of such a human-centered endeavors as e-commerce. Clearly, searching for information, services, and products will benefit from the facility of linguistic descriptions and partial matching available with fuzzy technologies. The business-to-business activity of automated procurement will benefit from the intelligent decision systems that can be constructed with fuzzy technology. (Yager, 2000)

FUZZY TECHNIQUES ON THE INTERNET

At the 2001 BISC International Workshop on Fuzzy Logic and the Internet (FLINT2001), Zadeh stated that fuzzy logic is the “brainware” of the Internet, and almost everything on the Internet is approximate in nature. Tim Barnes-Lee said, “Toleration of inconsistency can only be done by fuzzy systems. We need a semantic Web which will provide guarantees, and about which one can reason with logic. A fuzzy system might be good for finding a proof” (Zadeh, 2000). A Special Interest Group on Fuzzy Logic and the Internet was formed in 2001 (more detailed information can be found at http://www-bisc.cs.berkeley.edu/).

Almost any techniques can be fuzzified; for example, fuzzy expert systems, fuzzy reasoning, fuzzy optimization, fuzzy game theory, fuzzy pattern recognition. Many fuzzified techniques can be used on the Internet. Here, some sample applications are provided to show how fuzzy techniques can be used on the Internet.

Fuzzy Search Agents

Current search engines usually provide keyword-based searching tools using Boolean logic such as AND and OR. In most cases, several key words typed in by a user are ANDed for further searching. Such Boolean keyword-based search engines can return hundreds of pages, so it is very difficult to provide the user with most relevant Web links in the first several pages because precise keywords and Boolean operators have limited information for a search engine to find a small number of relevant Web links. In addition, some keywords contain uncertain information. For example, if a user types in “about $50” and “hotel”, a traditional search engine may use “about $50”, “hotel”, “about”, and “$50” to search relevant Web links, so returned Web links may not be satisfactory for the user because lots of hotels have “$49.95” per night instead of the precise “$50”. In this sense, the granular fuzzy Web search engine may return better meaningful search results using fuzzy words such as “about $50”, fuzzy operators such as fuzzy AND and fuzzy OR, and granular operators such as granular AND and granular OR (Zhang, Hang, Lin, & Yao, 2001).

Personalization is an important issue in the design of a search engine because different users may have different interests. For example, if different users input the same key word “Java”, a traditional search engine will return the same Web links, but a personalized search engine will return different Web links related to “Java” depending on ages of the users. Therefore, a personalized search engine containing a user’s profile can enhance quality of search results effectively. Furthermore, the personalized granular fuzzy Web search engine with dynamic Web mining

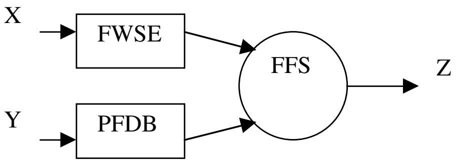

Figure 7: Logical architecture of the personalized fuzzy web search agent.

can better serve a user in terms of uncertainty and personalization.

Another problem is that many search tasks need context information to find more relevant and more meaningful search results. To deal with fuzzy context information, the conceptual fuzzy sets are introduced (Takagi & Tajima, 2001). The search engine based on conceptual fuzzy matching can search more relevant Web links (Takagi & Tajima, 2001). In general, a semantic search engine will play a more important role in Web searching than a linguistic search engine in the future.

The major challenging problem is that how to use fuzzy logic to design a fuzzy search agent using a basic search engine, users' profiles, and a fuzzy knowledge base to get more relevant and more meaningful search results. Here, a simple framework of the fuzzy search agent is introduced. Both the traditional keyword-based search method and the fuzzy personalized search algorithm are used to gain more satisfactory personalized search results for a particular user. In other words, different users may get different fuzzy search results even they type in the same key words. The basic architecture of the personalized fuzzy web search agent (PFWSA) is given in Figure 7. The PFWSA consists of the fuzzy Web search engine (FWSE) using fuzzy matching, the personalized fuzzy database (PFDB) including a user's profile, and the final fuzzy fusion system (FFS) making final selection and ranking using fuzzy reasoning. In Figure 7, X is a user's inputs (e.g., precise or fuzzy keywords and precise or fuzzy logical operators), Y is the updated user's personal information from either a user or a Web mining system, and Z is the final Web search results generated by the FFS based on results generated by the FWSE and personal information from the PFDB (Zhang, Hang, et al., 2001). In the future, how to actually implement the PFWSA will be a very interesting project. Importantly, the key thrust is how to design a better fuzzy user interface than a current precise user interface to make a user easily input fuzzy words and get more meaningful returned search results.

Here a simple fuzzy search algorithm is introduced to show how to design the key component of the PFWSA. To describe similarity between two fuzzy search key words like "around", "about", and "almost", a fuzzy relevancy matrix is created by using values between 0 and 1. To make a general purpose fuzzy relevancy matrix is very difficult, so here a small personalized fuzzy relevancy matrix is created for a single user. Initially, a personalized fuzzy relevancy matrix is created by experts and the user. Then the personalized fuzzy relevancy matrix is updated dynamically using the Web mining method.

The personalized fuzzy Web search algorithm is given as follows:

Step 1: Use fuzzy key words to find similar fuzzy key words based on the personalized fuzzy relevancy matrix, and then rank these similar fuzzy key words.

Step 2: Use these similar fuzzy key words to do regular Web search to find relevant results.

Step 3: Use the PFDB to select a small number of personalized results from the relevant results based on ranked personal preferences and context information if available.

Step 4: Return the final results in the order in terms of relevancy.

Fuzzy Information Agents

There are many types of Web information such as financial information, education information, shopping information, and science information. For particular Web information with fuzziness, a dedicated fuzzy information agent can serve an individual effectively based on the user's preferences. To show how a fuzzy Web information agent works, a personalized fuzzy stock information agent is introduced as follows.

Fuzzy logic implementation becomes complex when the number of inputs increases. Thus, to avoid system complexity and overhead while providing enough precision in output, a minimum number of inputs should be carefully selected. "Earning/share," "P/E Ratio," "dividend/share," and "yield" are chosen as inputs in the present system implementation among the values that can be fetched from Internet. The output of the fuzzy logic method is in the form of a list of predicted stock values. A general fuzzy rule has four input linguistic variables and one output linguistic variable. Each input linguistic variable has five linguistic values, so the total number of the fuzzy rule base is $5 \times 5 \times 5 \times 5 = 625$.

To get real-time stock information, a dial-up connection to the Internet is chosen to fetch stock information from Yahoo server at http://quote.yahoo.com. The trading data of each stock is fetched from Internet every 5 minutes. The services provided the personalized fuzzy stock information agent include portfolio management tools (create, display, edit, delete) and a list of "Top-10 Stocks" generated by a fuzzy inference system (Wang, Zhang, Belkasim, & Sunderraman, 2002).

Figure 8 shows the top-10 stocks determined by the fuzzy logic algorithm. The information in the list includes ticker symbol, company name, last trade time, price, and trade volume. The most attractive stock is listed first.

Fuzzy Intelligent Agents

The previous fuzzy stock information agent can provide a user with top-ranked stocks using fuzzy logic. Now a fuzzy intelligent agent can make a prediction and a decision. Following is an example of a fuzzy intelligent prediction agent.

A fuzzy neural Web-based stock prediction agent is developed using the granular neural network (GNN), which can discover fuzzy rules for future stock prediction (Zhang, Akkaladevi, Vachtsevanos, & Lin, 2001). To implement the fuzzy neural Web-based stock prediction agent, Java Servlets, Java Script, and JDBC (Java database connection) are used, and SQL (structured query language)

is used as the back-end database. The fuzzy neural Web-based stock prediction agent download real-time stock data from Yahoo, then converts the stock data into relational forms, and finally stores the relational stock data into a local database. Furthermore, the fuzzy neural Web-based stock prediction agent trains its internal GNN using the newly updated data, and then uses the trained GNN to predict future stock values. A Web user may choose different inputs to get different future predicted outputs.

The GNN can process various granules such as a class of numbers and an interval value. These granules (inputs and outputs of the GNN) are similar to multimedia data (inputs and outputs of biological neural networks in the human brain). The purpose of using the GNN is to simulate the functionality of the human brain so as to design an effective search agent.

The GNN has three inputs (open, high, and low values of past historical data of a company) and one output (the close amount for each day). A user may choose the number of input stock values (i.e., the beginning date and the last date of the historical stock data). After the GNN has been trained using the training data, the trained GNN can predict the future stock values.

For example, the GNN for stock prediction has three inputs x_1, x_2, and x_3, and one output y, where $y = f(x_1, x_2, x_3)$. x_1 is a fuzzy linguistic variable for open values, x_2 is a fuzzy linguistic variable for low values, x_3 is a fuzzy linguistic variable for high values, and y is a fuzzy linguistic variable for volume data. To make a Web user understand the predicted results easily, the graphical output user interface is designed to show the two-dimensional figures including both past data, trained data, and predicted data. An interesting future work is to embed the fuzzy neural Web-based stock prediction agent into a real-time online stock exchange system to make users use it to make decisions online. In general, an intelligent Web-based stock system can use fuzzy computing, granular computing, and neural computing to help users make reasonable decisions.

FUZZY E-COMMERCE

Fuzzy Web Shopping Agents

Various fuzzy Web shopping agents may have different functions and goals. A customer may use a fuzzy Web shopping agent to buy cheap or high-quality products, and a manager may use it to analyze customers' shopping data and then make smart decisions to make higher profits. Following is an example of a simple, manager-oriented fuzzy Web shopping agent using a fuzzy data mining method (Hearn & Zhang, 2001).

E-business has huge amounts of data for companies and costumers. To make more profit, a company needs to know costumer information by analyzing historical costumer data such as shopping habits and trends to make right business decisions. Without computers and Web mining tools, an e-business company could not find the useful costumer information quickly. So Web-based intelligent systems can greatly help employees analyze large amounts of e-business data efficiently. Unfortunately, the traditional Web-based intelligent system uses precise logic to do Web mining, so it could not process fuzzy data effectively. Because the human brain can process fuzzy data easily, an interesting problem is that how to use fuzzy logic to simulate the human brain in terms of fuzzy data mining. Therefore, analyzing the differences among fuzzy logic, traditional crisp logic, and human logic in e-business applications is an important for a design of a powerful e-business system. Here, some interesting experimental results are given for the comparison among fuzzy logic, traditional crisp logic and human logic. Based on the analysis, we will see which logic is suitable for e-business applications.

An online grocery store is used as a test bed. The data sets are generated from surveys and research. Four inputs are (1) amount of time spent online per week (in hours), (2) the number of online purchases made in the past six months, (3) the number of trips to the grocery store per week, and (4) amount spent (in dollars) at the grocery store per week. One output has five fuzzy categories (excellent, good, fair, poor, and very poor) to classify different users. So this is a 4-input–1-output classification system that can classify users into relevant fuzzy categories by using fuzzy logic, traditional crisp logic, and human logic, respectively.

The goal is to do effective marketing for relevant costumers. In this experiment, 25 "prospects" are created. Each prospect is classified by the three different types of logic. Table 1 shows the data. The three different logical systems are described below for comparison.

The first logical system is the fuzzy classification system that has four input fuzzy linguistic variables and one output fuzzy linguistic variable. An input fuzzy linguistic variable has three linguistic values (low, moderate, and high) and an output fuzzy linguistic variable has five linguistic values (excellent, good, fair, poor, and very poor). The fuzzy rule base has 81 TSK fuzzy rules (Yen and Langari, 1999).

The format of the first few TSK fuzzy rules is shown as follows:

If "time online" is low and "purchases" is low and "trips" is low and "groceries" is low, then z = (p * "time online input value") + (q * "purchases input value") + (r * "trips input value") + (s * "groceries input value") + t

If "time online" is low and "purchases" is low and "trips" is low and "groceries" is moderate, then z = (p * "time online input value") + (q * "purchases input value") + (r* "trips input value") + (s* "groceries input value") + t

If "time online" is low and "purchases" is low and "trips" is low and "groceries" is high, then z = (p * "time online input value") + (q * "purchases input value") + (r * "trips input value") + (s * "groceries input value") + t

If "time online" is low and "purchases" is low and "trips" is moderate and "groceries" is low, then z = (p * "time online input value") + (q * "purchases input value") + (r * "trips input value") + (s * "groceries input value") + t . . . ,

and so on.

In the above fuzzy rules, p, q, r, s, and t are initially set by experts. When an input data set is given, the data set

Table 1 The 25 Prospects for an Online Grocery Store

Customer	Time Online	Online Purchases	Store Trips	$ Spent at Store
1	4	8	2	$80
2	2	4	2	$125
3	9	2	0	$50
4	15	10	1	$100
5	0	0	3	$175
6	18	0	4	$150
7	5	0	2	$110
8	20	7	1	$50
9	2	0	3	$165
10	10	3	5	$180
11	1	1	7	$130
12	13	5	0	$25
13	8	9	2	$140
14	7	3	2	$100
15	3	0	3	$170
16	12	4	1	$80
17	20	10	1	$75
18	16	0	4	$145
19	9	2	2	$200
20	1	0	1	$185
21	14	1	0	$50
22	4	3	5	$200
23	6	7	3	$75
24	18	0	2	$40
25	2	5	6	$155

Table 2 Classification Rules

OVERALL Z VALUE	CLASSIFICATION
[0, 35)	Very poor
[35, 38)	Poor
[38, 42)	Fair
[42, 50)	Good
[50, 100)	Excellent

is mapped to a relevant category. The fuzzy classification system can automatically read input data from a data file, then use fuzzy reasoning to calculate the output value, and finally find out a suitable category based on the output value. For future use, the generated classification data sets are stored in an output file.

If a rule is fired, then the z value and w value for the rule must be calculated. The z value is determined based on the "then" part of the fuzzy rule. The w value is the minimum firing strength of the fuzzy sets in the rule. If the rule is not fired, the w and z values are set to 0.

If a fuzzy rule is fired for a new input data set, then the typical value z_i and the firing strength w_i for all rules are computed. The typical value z_i is determined based on the output fuzzy membership function. For example, the typical value z_i is given when the output fuzzy membership function $\mathrm{Fm}(z_i) = 1$. If fuzzy rule i is not fired, then the firing strength $w_i = 0$.

The final output Z for the prospect is calculated using the following defuzzification formula:

$$z = \frac{\sum_{i=1}^{81} w_i z_i}{\sum_{i=1}^{81} w_i}$$

The final classification is decided based on this overall Z using Table 2.

The second logical system is a crisp classification system using the same data sets for fair comparison. The crisp logic is used to make sharp classification for given input data directly based on Table 3.

The third logical system is the human classification system. The generated results by the human classification system are given in Table 4.

Table 3 Crisp Classification Rules

VARIABLE	RANGE	VALUE
Time online per week	0–5 hours	Low
	6–15 hours	Moderate
	16–20 hours	High
Online purchases in past six months	0–1 purchases	Low
	2–5 purchases	Moderate
	6–10 purchases	High
Trips to grocery store per week	0 trips	Low
	1–2 trips	Moderate
	3–7 trips	High
Amount spent in grocery store per week	$0–$75	Low
	$76–$140	Moderate
	$141–$200	High

Table 4 Comparisons Among Fuzzy Logic, Crisp Logic, and Human Logic

CUSTOMER	HUMAN	FUZZY	CRISP
1	Good	Good	Excellent
2	Good	Fair	Good
3	Poor	Very poor	Fair
4	Excellent	Excellent	Good
5	Very poor	Very poor	Poor
6	Good	Good	Excellent
7	Poor	Very poor	Very poor
8	Fair	Good	Very poor
9	Very poor	Poor	Poor
10	Good	Excellent	Excellent
11	Poor	Poor	Very poor
12	Very poor	Very poor	Fair
13	Excellent	Excellent	Excellent
14	Good	Fair	Excellent
15	Very poor	Poor	Poor
16	Fair	Poor	Good
17	Excellent	Excellent	Very poor
18	Good	Fair	Excellent
19	Excellent	Excellent	Excellent
20	Very poor	Poor	Poor
21	Poor	Very poor	Very poor
22	Excellent	Excellent	Excellent
23	Good	Fair	Fair
24	Poor	Very poor	Very poor
25	Excellent	Good	Excellent

To see the differences among the three logical classification systems, simulation results are summarized in Table 4. From Table 4, we can see that the fuzzy classification system is much closer to the human classification system than the crisp classification system. The crisp classification system may make some wrong decisions because the decision is too precise. The fuzzy classification system can make fault-tolerant decisions based on fuzzy rules as a human classification system can make robust decision based on internal uncertain rules in the human brain.

Fuzzy Mobile Wireless E-commerce

The wireless networks are growing rapidly. One may use a small handheld such as a personal digital assistant (PDA), Palm, or cell phone to do e-commerce such as mobile wireless shopping and mobile wireless stock exchanging. Such a small handheld device has limitations, however, such as low-speed processor, small memory, small communication bandwidth, and small screen. Fuzzy logic can be used to solve these problems by simplifying data classification, information processing, and decision making. There will be many application opportunities for fuzzy wireless e-commerce and fuzzy mobile e-commerce in the future. For example, the fuzzy reinforcement learning methods are used for power control in wireless transmitters (Vengerov & Berenji, 2002).

Fuzzy Game Theory in E-commerce

Classical game theory has been used in economy and business such as negotiation and auctions. Because data and information in e-commerce applications have much fuzziness, fuzzy game theory can play an important role in such fuzzy e-commerce applications. Fuzzy moves theory (Zhang et al., 1998), a novel fuzzy game theory, can be applied to e-commerce applications because there are many possible e-commerce games among customers, managers, human agents, and even software agents—for example, (a) fuzzy negotiation between customers and managers, between customers and customers, or between managers and managers; (b) fuzzy auction among customers; (c) fuzzy marketing games among different companies, and so on.

FUZZY WEB INTELLIGENCE IN E-COMMERCE

With explosive growth of the Internet, wireless networks, Web databases, and wireless mobile devices, Web users suffer from too many irrelevant Web search results (pages, links, etc.), fraud e-business transactions, nonpersonalized Web information, even wrong Web decisions. WI (Web intelligence) is studied carefully from different aspects and exploits artificial intelligence (AI) and advanced information technology on the Web and Internet (Yao, Zhong, Liu, & Ohsuga, 2001). Conventionally, AI is not the same as CI, although there is an overlap between them (Bezdek, 1998). CI has already been used in telecommunication applications (Pedrycz & Vasilakos, 2001).

CWI uses CI and Web technology (WT) to make intelligent e-Business applications on the Internet and in wireless networks. Specifically, the key focus of CWI is how to handle the uncertainty of smart e-business systems effectively to make the Internet and wireless networks intelligent.

Computational Web Intelligence

In basic terms, CWI is a hybrid technology of CI and WT that is dedicated to increasing the quality of intelligence of e-business applications on the Internet and in wireless networks. Currently, the seven major research areas of CWI are (a) fuzzy WI, (b) neural WI, (c) evolutionary WI, (d) probabilistic WI, (e) granular WI, (f) rough WI, and (g) hybrid WI. In the future, more CWI research areas will no doubt evolve.

Fuzzy Web Intelligence

FWI comprises two major techniques: (a) fuzzy logic and (b) WT. The main goal of FWI is to design intelligent fuzzy e-agents that can deal with the fuzziness of data, information, and knowledge and make satisfactory decisions for e-business applications similar to those the human brain would make. There are various applications of FWI. For example, fuzzy intelligent agents are used to help advertisers make better marketing decisions for Web site visitors. Effective FWI applications for the Internet and e-commerce are current goals. Just as rule-based models are central to the fuzzy logic used within the Web environment, so, too, is optimization of fuzzy Web systems an important goal. General optimization tools, including other techniques such as neural networks and genetic algorithms can enhance the performance of the fuzzy Web systems.

CONCLUSION

With explosive growth of e-commerce on the Internet and wireless networks, both users and managers suffer from novel wired and wireless application problems in terms of quality of intelligence and service. To improve these aspects of e-commerce and e-business, the intelligent fuzzy e-brainware using fuzzy logic techniques should be researched and developed.

Computational web intelligence—merging CI and WT—will play an important role in future intelligent e-business applications on the Internet and in wireless networks. FWI is the fundamental technology for building smart, fuzzy wired and wireless e-commerce applications. The goal of using fuzzy logic and other granular and soft computing techniques is to build intelligent Internet and smart e-commerce systems on wired and wireless networks to help diverse users conduct intelligent e-business effectively, efficiently, and safely.

GLOSSARY

Computational intelligence (CI) Broad intelligent technology including fuzzy logic, neural networks, evolutionary algorithms, probabilistic methods, granular computing, and rough set theory; soft computing is the core of CI (Yager & Zadeh, 1994).

Computational Web intelligence (CWI) A hybrid technology of computational intelligence and Web technology dedicating to increasing quality of intelligence of e-business applications on the Internet and in wireless networks.

Fuzzy logic Nontraditional logic using fuzzy variables with a truth value between 0 and 1; the three basic fuzzy logical operations are fuzzy AND (t-norm), fuzzy OR (t-conorm), and fuzzy NOT (negation).

Fuzzy reasoning The notion that a method can logically generate fuzzy conclusions from given crisp or fuzzy inputs based on a fuzzy rule base.

Fuzzy sets A generalized set characterized by a mapping from its universe of discourse into the interval [0, 1]; the degree of how an element belongs to a fuzzy set is represented by a membership function (This is the most common notion of fuzzy sets; others include type II fuzzy sets [Zadeh, 1973a, 1973b, 1973c], qualitative fuzzy sets [Lin, 2001; Thiele, 1999], and granular fuzzy sets (probability-based fuzzy sets) [Lin, 1989, 1997]).

Fuzzy Web intelligence (FWI) A fuzzy Web technology dedicated to increasing the quality of intelligence of e-business applications on the Internet and in wireless networks.
