ELAINE B. FELDMAN

Dedication

This book is dedicated to the memory of Dr. Daniel S. Feldman. Dan provided so much support to us in our efforts to produce a high quality handbook. He was responsible for converting all our color photographs into computer-compatible illustrations. He also provided much scientific and editing expertise especially in data management and analysis. Thanks Dan, we miss you.

Preface to the Second Edition

Since the first edition was prepared more than 5 years ago, a lot of the large data sets found in that edition have been placed on the web. The reader will note that far more web addresses are given in this edition than in the first edition. By deleting some of the large tables that are now on the web, we then had space to expand this reference text to include a more extensive coverage of basic nutrition concepts. Thus, the reader will note that the book has been reorganized. Part I contains five chapters relating to food. In this section there are web addresses for food composition as well as a broad treatment of food safety, food labeling, and computerized nutrient analysis systems and techniques available for such data analysis.

Part II focuses on nutrition as a science. Basic terminology, intermediary metabolism relevant to the use of nutrients, individual micronutrients, as well as nutrient–nutrient interactions can be found here. In addition, there is a chapter giving web addresses for the nutrient needs of species other than the human. This is particularly useful to the scientists wishing to make interspecies comparisons.

Nutrition need throughout the life cycle and under special circumstances is the focus of Part III. Nutrition during pregnancy and lactation, feeding the preterm and term infant, the toddler, the young child, the adolescent, the healthy adult, and the senior adult is addressed in the chapters of this section. How exercise affects nutrient need and how one can have a healthy well-nourished body consuming a vegetarian diet is also discussed in this section.

Even though we have a large national commitment to provide a wide variety of nutritious food for our population, how do we know whether our people are well nourished? Part IV addresses this question from a variety of perspectives. Education on the national scale through the provision of healthy eating guidelines helps to inform the public of ways to ensure that they are well nourished. Beyond that there are a number of ways to monitor nutritional status of a variety of age groups and cultural groups. These are described in the rest of the chapters in this section.

Lastly, Part V deals with a wide variety of clinical topics with nutritional implications. Starting with medical evaluation techniques and flowing through all the relevant issues awaiting the clinician, nutrition is addressed as these clinical states are described.

Many of the authors of the chapters in the first edition have graciously updated their original contributions and we the editors are very grateful. There are some new chapters as well as some new authors. We hope you will find this multiauthored text an excellent addition to your professional library.

Johanna Dwyer

About the Editors

Carolyn D. Berdanier is a professor emerita, nutrition and cell biology, University of Georgia in Athens. She earned her B.S. from the Pennsylvania State University and her M.S. and Ph.D. from Rutgers University. She has had a long and productive career in nutrition. She began her career as a researcher with U.S. Department of Agriculture in Beltsville, then moved to the University of Nebraska College of Medicine and shortly thereafter moved to the University of Georgia. She served as department head at UGA for 11 years before stepping down to more actively pursue her research interests in nutrient–gene interactions. Her research has been supported by grants from NIH, USDA, the Bly Fund, and several commodity research boards. Her publication record includes 134 research publications in peer-reviewed journals, 16 books (either sole authored, edited or co-edited), 30 invited reviews, 45 chapters in multiauthored scientific books, and numerous short reviews in *Nutrition Reviews*. She has served on a number of editorial boards and contributes regularly to *Nutrition Today*, a lay magazine for the nutrition practitioner. She has received numerous awards for her research accomplishments including the Borden Award, the Lamar Dodd award for creative research, The UGA Research Medal, the National 4H award for alumni, and outstanding alumna awards from both Rutgers and the Pennsylvania State University. She is a member of the American Diabetes Association, The American Society for Nutrition Science, the Society for Experimental Biology and Medicine, and the American Physiological Society. Recently she was elected a fellow of the American Society for Nutrition Science.

Elaine B. Feldman is a professor emerita, medicine, physiology and endocrinology, Medical College of Georgia in Augusta. She is also chief emerita of the section on nutrition and director emerita of the Georgia Institute of Human Nutrition. She was the founding director of the Southeastern Regional Medical Nutrition Education Network of 15 medical schools in the southeast. At the Medical College she was principal investigator of a curriculum development grant from the Department of Health and Human Services and of a clinical nutrition research unit as well as a number of diet and drug studies in hyperlipidemia. She holds an M.D., AB (Magna Cum Laude), and M.S. from New York University where she was elected to Phi Beta Kappa and Alpha Omega Alpha. She trained in internal medicine, metabolism, and nutrition at the Mount Sinai Hospital in New York. She has held research fellowships from the New York Heart Association and the NIH (Career Development Award, Department of Physiological Chemistry, Lund University, Sweden) and served on the faculty of the Department of Medicine, State University of New York Medical School in New York City. She is board certified in internal medicine, clinical lipidology, and clinical nutrition. Dr. Feldman is a noted author and lecturer on nutrition and lipidology. She has published 82 articles in peer-reviewed biomedical journals and 56 invited articles, and has edited or authored 32 books, book chapters, monographs, and a textbook. She has served on numerous review boards and currently serves on the editorial boards of *Nutrition Today* and *Nutrition Update*. She is a fellow of the American Heart Association's Council on Arteriosclerosis, the American College of Physicians, and the American Society for Nutrition Sciences. She serves as a consultant for the American Institute for Cancer Research and the American Medical Women's Association.

Dr. Johanna Dwyer is the director of the Frances Stern Nutrition Center at New England Medical Center, professor of medicine (nutrition) and community health at the Tufts University Medical School, and professor of nutrition at Tufts University School of Nutrition. She is also senior scientist at the Jean Mayer/USDA Human Nutrition Research Center on Aging at Tufts University. Since mid-2003 until the present, Dr. Dwyer is on loan from Tufts University to the Office of Dietary Supplements, National Institutes of Health, where she is responsible for several large projects, including development of an analytically substantiated dietary supplement database and other dietary supplement databases, development of research on the assessment of dietary supplement intake and motivations for their use, and other topics. Dr. Dwyer was the assistant administrator for human nutrition, Agricultural Research Service, U.S. Department of Agriculture from 2001 to 2002. Earlier in her career, Dwyer served in the executive office of the President as staff for the White House Conference on Food Nutrition and Health of 1969, and again in 1976 for the President's Reorganization Project examining the role of nutrition programs in the federal government. As the Robert Wood Johnson Health Policy Fellow (1980 to 1981), she served on the personal staffs of Senator Richard Lugar (R-Indiana) and the Hon. Barbara Mikulski (D-Maryland).

Dwyer received her D.Sc. and M.Sc. from the Harvard School of Public Health, an M.S. from the University of Wisconsin, and completed her undergraduate degree with distinction from Cornell University. She is the author or coauthor of more than 170 research articles and 300 review articles published in scientific journals on topics including preventing diet-related disease in children and adolescents; maximizing quality of life and health in the elderly; vegetarian and other alternative lifestyles; and databases for bioactive substances other than nutrients. She served on the 2000 Dietary Guidelines Committee, was a member of the Food and Nutrition Board of the National Academy of Sciences from 1992 to 2001, was elected a member of the Institute of Medicine National Academy of Sciences in 1998, and served as councilor of the Institute of Medicine from 2001 to 2003.

She is currently secretary of the American Dietetic Association Foundation, and editor of *Nutrition Today*. She is the past president and fellow of the American Institute of Nutrition, past Secretary of the American Society for Clinical Nutrition, and past president and fellow of the Society for Nutrition Education. She received the Conrad V. Elvejhem Award for public service in 2005 from the American Society for Nutrition Sciences, the Alumni Award of Merit from the Harvard School of Public Health in 2004, the Medallion Award of the American Dietetic Association in 2003, and the W.O. Atwater award in 1996.

PART IV   Nutrition Assessment

PART V   Clinical Nutrition

Part I

Food

1 Food Constituents

Carolyn D. Berdanier

Contents

INTRODUCTION

Humans and animals consume food to obtain the nutrients they need. Throughout the world there are differences in food consumption related to socioeconomic conditions, food availability, and cultural dictates. If a variety of fresh and cooked foods is consumed, in sufficient quantities, to meet the energy needs of the consumer, then the needs for protein and the micronutrients should be met. Having this in mind, it is surprising to learn that some people are poorly nourished and, indeed, may develop one or more nutrition-related diseases. The early years of nutrition research focused on diseases related to inadequate vitamin and mineral intake. An important component of this research was the determination of the vitamin and mineral content of a vast variety of foods. The composition of these foods has been compiled by the United States Department of Agriculture (USDA) and other organizations. Table 1.1 provides Web addresses to access a variety of data sets giving the nutrient content of a variety of foods. Included are some Web addresses for the composition of foods provided by some of the restaurant chains. These are particularly valuable because Americans eat more of their meals away from home than ever before. In addition, the data are from combination foods, that is, the information is for a particular menu item complete with its "fixings."

TABLE 1.1
Web Addresses for Information on the Composition of Food

Data Set	Web Address
Composition of foods, raw, processed, prepared; 6200 foods, 82 nutrients[a]	http://www.nal.usda.gov/fnic/foodcomp/Data/foods,82nutrients
Daidzein, genisten, glycitein, isoflavone content of 128 foods	Use preceding address, click on this file to open

[a] A printed format can be obtained from the Superintendent of Documents, U.S. Printing Office, Washington, DC 20402. Request USDA Handbooks 8 through 16. A CD-ROM can also be obtained. None of these are free.

A number of organizations, both governmental and nongovernmental, are interested in providing food intake recommendations to promote good health and reduce the risk of disease. Table 1.2 provides Web sites for these recommendations. Additional information on healthy eating by different age groups is provided in Chapters 8 to 13. Healthy eating focuses on food choices that promote optimal nutrition. Mainly these recommendations address the food needs of adults. However, there are several concerns about food intake that are separate from food choice. The regulation of food intake by internal signals can quantitatively affect what food is consumed and how much. These signals apparently are integrated ones that signal hunger or

TABLE 1.3
Hormones and Drugs that Influence Food Intake

Enhances	Suppresses
Insulin	Estrogen
Testosterone	Phenylethylamines[a]
Thyroxine	Mazindol
Low serotonin levels	Substance P
Glucocorticoids	Glucagon
β-endorphin	Serotonin
Low serotonin levels	Leptin
Dynorphin	Fluoxetine
Neuropeptide Y	"Satietin" (a blood-borne factor)
Galanin	Histidine (precursor of histamine)
Opioid peptides	Pain
Growth-hormone-releasing hormone	Amino acid imbalance in diet
Desacetyl-melanocyte-stimulating hormone	Tryptophan (precursor of serotonin)
Antidepressants[b]	Cholecystokinin (CCK)
Low adiponectin	Calcitonin
	Somatostatin
	Anorectin
	High-fat diet
	Thyrotropin releasing hormone
	Cachectin (tumor necrosis factor)
	Corticotropin-releasing hormone (CRH)
	Neurotensin
	Bombesin
	cyclo-His-Pro
	High-protein diets
	High blood glucose
	Enterostatin

[a] These are drugs, and all except for the drug phenylpropanolamine are controlled substances. Many have serious side effects. They are structurally related to the catecholamines. Most are active as short-term appetite suppressants and act through their effects on the central nervous system, particularly through the b-adrenergic or dopaminergic receptors. This group includes amphetamine, methamphetamine, phenmetrazine, phentermine, diethylpropion, fenfluramine, and phenylpropanolamine. Phenylpropanolamine-induced anorexia is not reversed by the dopamine antagonist haloperidol.

[b] All of these drugs are controlled substances and their use must be carefully monitored. This group includes amitriptyline, buspirone, chlordiazepoxide, chlorpromazine, cisplatin, clozapine, ergotamine, fluphenazine, imipramine, iprindole, and others that block 5-HT receptors.

the initiation of eating and satiety or the signal to stop eating. Not all of these signals are known, but Table 1.3 provides a list of the ones that have been studied.[1]

Several data sets that may not be available on the Web can be found in this chapter. Table 1.4 provides the tocopherol values for a wide variety of foods.[2] Table 1.5 provides information on the tagatose content of food.[3] Tagatose is a food additive used to reduce the amount of sugar in a food. It has a sweet taste, yet does not have the same energy value as sucrose. Other sugar substitutes are also used in the preparation of reduced-energy foods; however, data on their quantitative occurrence is not as readily available because of the proprietary interests of food producers. A list of sweeteners added to foods is provided in Table 1.6.[4] Following this table is a list of the types of food additives that change the properties of food (Table 1.7; see Reference 4, pp. 11–18). This table describes compounds that increase the shelf life of a class of foods or additives that change

the texture of a food. The specific attributes of individual food additives are described in Table 1.8 (see Reference 4, pp. 11–18). This table provides information on how these additives function in particular food products.

A number of food additives and food processing techniques are used to improve the safety of the food. Foods can be contaminated by a wide variety of organisms, some of which are listed in Table 1.9.[5] Some of these contaminants can produce toxins, which, if consumed, can be lethal. Table 1.10 is a list of mycotoxins and bacterial toxins that can occur in food (see Reference 4, pp. 24–36, 1284–1285, 1776–1785, 1790–1803, 2082–2087). The reader should also review Chapter 2 for an extensive description of food-borne illness. Table 1.11 provides a list of antinutrients sometimes found in food.[6]

Antinutritives are compounds that interfere with the use of essential nutrients. They are generally divided into three classes: A, B, and C. Type A antinutritives are substances primarily interfering with the digestion of proteins or the absorption and utilization of amino acids. They are also known as antiproteins. Strict vegetarians, for example, are in danger of nutritional inadequacy by this type of antinutritive. The most important type A antinutritives are protease inhibitors and lectins.

Protease inhibitors, occurring in many plant and animal tissues, are proteins that inhibit proteolytic enzymes by binding to the active sites of the enzymes. Proteolytic enzyme inhibitors were first found in avian eggs around the turn of the century. They were later identified as ovomucoid and ovoinhibitor, both of which inactivate trypsin. Chymotrypsin inhibitors also are found in avian egg whites. Other sources of trypsin or chymotrypsin inhibitors are soybeans and other legumes and pulses, vegetables, milk and colostrum, wheat and other cereal grains, guar gum, and white and sweet potatoes. The protease inhibitors of kidney beans, soybeans, and potatoes can additionally inhibit elastase, a pancreatic enzyme acting on elastin, an insoluble protein in meat. Animals, fed with food containing active inhibitors, show growth depression. This appears to be due to interference in trypsin and chymotrypsin activities and to excessive stimulation of the secretory exocrine pancreatic cells, which become hypertrophic. Valuable proteins may be lost to the feces in this case. *In vitro* experiments with human proteolytic enzymes have been shown that trypsin inhibitors from bovine colostrum, lima beans, soybeans, kidney beans, and quail ovomucoid were active against human trypsin, whereas trypsin inhibitors originating from bovine and porcine pancreas, potatoes, chicken

TABLE 1.5
Occurrence of D-Tagatose in Foods[1]

Food	Result (mg/kg)	Sample Preparation	Apparatus
Sterilized cow's milk	2–3000	Extracted with methanol; prepared trimethylsilyl (TMS) derivatives	Gas chromatography (GC), fused-silica capillary column (18 m × 0.22 mm) coated with AT-1000; carrier gas N2; flame ionization detector (FID)
Hot cocoa (processed with alkali) prepared with milk	140	Extracted with deionized (DI) water	High-performance liquid chromatography (HPLC); used Bio-Rad Aminex® HPX-87C column (300 mm × 7.8 mm) heated to 85°C; mobile phase DI water; flow rate 0.6 ml/min; refractive index (RI) detector
Hot cocoa prepared with milk	190	Extracted with DI water	HPLC; Bio-Rad Aminex® HPX-87C column heated to 85°C; mobile phase DI water; flow rate 0.6 ml/min; RI detector
Powdered cow's milk	800	Extracted three times with distilled water for 3 h at 60°C; column chromatography to remove organic acids and bases; fractionation by partition chromatography	Paper partition chromatography, descending method on Whatman no.1 paper; used three solvent systems
Similac® infant formula	4	Extracted with 90% ethanol; prepared TMS derivatives	GC; DB-5 fused-silica capillary column (15 m × 0.53 mm, 1.5 mm film thickness); carrier gas He; FID detector
Enfamil® infant formula	23	Extracted with 90% aqueous ethanol; prepared TMS derivatives	GC; DB-17 fused-silica capillary column (15 m × 0.53 mm, 1 mm film thickness); carrier gas He; FID detector
Parmesan cheese	10	Extracted with 80% aqueous methanol; prepared TMS derivatives	GC; DB-5 fused-silica capillary column (30 m, 0.25 mm film thickness); carrier gas He; FID detector
Gjetost cheese	15	Extracted with 80% aqueous methanol; prepared TMS derivatives	GC; DB-5 fused-silica capillary column (30 m, 0.25 mm film thickness); carrier gas He; FID detector
Cheddar cheese	2	Extracted with 80% aqueous methanol; prepared TMS derivatives	GC; DB-5 fused-silica capillary column (30 m, 0.25 mm film thickness); carrier gas He; FID detector
Roquefort cheese	20	Extracted with 80% aqueous methanol; prepared TMS derivatives	GC; DB-5 fused-silica capillary column (30 m, 0.25 mm film thickness); carrier gas He; FID detector
Feta cheese	17	Extracted with 80% aqueous methanol; prepared TMS derivatives	GC; DB-5 fused-silica capillary column (30 m, 0.25 mm film thickness); carrier gas He; FID detector
Ultrahigh-temperature milk	~5	Dried under vacuum; water was added, then volatile derivatives extracted with isooctane	GC; Rescom type OV1 capillary column (25 m × 0.25 mm, 0.1 or 0.25 mm film thickness); carrier gas H_2; FID detector
BA Nature® Yogurt	29	Extracted with DI water; passed through a strong cation exchange column followed by an amine column	HPLC; Bio-Rad Aminex® HPX-87C column heated to 85°C; mobile phase DI water; flow rate 0.6 ml/min; RI detector
Cephulac®, an orally ingested medication for treatment of portal-systemic encephalopathy	6500	Deionized with Amberlite IR-120 (H) and Duolite A-561 (free base); diluted to 20 mg/ml with a 50:50 mixture of acetonitrile and water	HPLC; Waters Carbohydrate Analysis Column (300 mm × 3.9 mm); mobile phase water: acetonitrile, 77:23 (w/w); flow rate 2 ml/min; RI detector
Chronulac®, an orally ingested laxative	6500	Deionized with Amberlite IR-120 (H) and Duolite A-561 (free base); diluted to 20 mg/ml with a 50:50 mixture of acetonitrile and water	HPLC; Waters Carbohydrate Analysis Column (300 mm × 3.9 mm); mobile phase-water: acetonitrile, 77:23 (w/w); flow rate 2 ml/min; RI detector

ovomucoid, and chicken ovoinhibitor were not. The soybean and lima bean trypsin inhibitors are also active against human chymotrypsin. Many protease inhibitors are heat labile, especially with moist heat. Relatively heat-resistant protease inhibitors include the antitryptic factor in milk, the alcohol-precipitable and nondialyzable trypsin inhibitor in alfalfa, the chymotrypsin inhibitor in potato, the kidney bean inhibitor, and the trypsin inhibitor in lima beans.

Lectin is the general term for plant proteins that have highly specific binding sites for carbohydrates. They are widely distributed among various sources such as soybeans, peanuts, jack beans, mung beans, lima beans, kidney beans, fava beans, vetch, yellow wax beans, hyacinth beans, lentils, peas, potatoes, bananas, mangoes, and wheat germ. Most plant lectins are glycoproteins, except concanavalin A from jack beans, which is carbohydrate free. The most toxic lectins in food include ricin in castor bean (oral toxic dose in man: 150 to 200 mg; intravenous toxic dose: 20 mg) and the lectins of kidney bean and hyacinth bean. The mode of action of lectins may be related to their ability to bind to specific cell receptors, in a way comparable to that

TABLE 1.6
Sweetening Agents (Sugar Substitutes)

Name	Sweetness	Classification	Uses	Comments
Acesulfame-K (sold under brand Sunette)	130	Nonnutritive; artificial	Tabletop sweetener, chewing gum, dry beverage mixes, puddings	This is actually the potassium salt of the 6-methyl derivative of a group of chemicals called oxathiazinone dioxides; approved by the Food and Drug Administration (FDA) in 1988
Aspartame	180	Nutritive; artificial	In most diet sodas; also used in cold cereals, drink mixes, gelatin, puddings, toppings, dairy products, and at the table by the consumer; not used in cooking due to lack of stability when heated	Composed of the two naturally occurring amino acids, aspartic acid and phenylalanine; sweeter than sugar, therefore less required, hence fewer calories
Cyclamate	30	Nonnutritive; artificial	Tabletop sweetener and in drugs in Canada and 40 other countries	Discovered in 1937; FDA banned all cyclamate-containing beverages in 1969 and all cyclamate-containing foods in 1970; cyclamate safety is now being reevaluated by the FDA
Dulcin (4-ethoxy-phenyl-urea)	250	Nonnutritive; artificial	None	Not approved for food use in the United States; used in some European countries; also called Sucrol and Valzin
Fructose (levulose)	1.7	Nutritive; natural	Beverages, baking, canned goods; anywhere invert sugar or honey may be used	A carbohydrate; a monosaccharide; naturally occurs in fruits; makes up about 50% of the sugar in honey; commercially found in high-fructose syrups and invert sugars; contributes sweetness and prevents crystallization
Glucose (dextrose)	0.7	Nutritive; natural	Primarily in the confection, wine, and canning industries; and in intravenous solutions	Acts synergistically with other sweeteners
Glycine	0.8	Nutritive; natural	Permissible to use to modify taste of some foods	A sweet-tasting amino acid; tryptophan is also a sweet-tasting amino acid
Mannitol	0.7	Nutritive; natural	Candies, chewing gums, confections, and baked goods; dietetic foods	A sugar alcohol or polyhydric alcohol (polyol); occurs naturally in pineapples, olives, asparagus, and carrots; commercially prepared by the hydrogenation of mannose or glucose; slowly and incompletely absorbed from the intestines; only slightly metabolized, most excreted unchanged in the urine; may cause diarrhea
Miraculin	—	Nutritive; natural	None	Actually a taste-modifying protein rather than a sweetener; after exposing tongue to miraculin, sour lemon tastes like sweetened lemon; responsible for the taste-changing properties of mircale fruit, red berries of Synsepalum dulcificum, a native plant of West Africa; first described in 1852; one attempt made to commercialize by a U.S. firm but FDA denied approval and marketing was stopped
Monellin	3000	Nutritive; natural	None; only a potential low-calorie sweetener	Extract of the pulp of the light red berries of the tropical plant *Dioscoreophyllum cumminsii*; also called Serendipity Berry; first protein found to elicit a sweet taste in humans; first extracted in 1969; potential use limited by lack of stability; taste sensation is slow and lingering; everything tastes sweet after monellin
Neohesperidin dihydrochalone (Neo DHC, NDHC)	1250	Nonnutritive; artificial	None approved; potential for chewing gum, mouthwash, and toothpaste	Formed from naringen isolated from citrus fruit; slow to elicit the taste sensation; lingering licorice-like aftertaste; animal studies indicate not toxic
P-4000 (5-nitro-2-pro-poxyaniline)	4100	Nonnutritive; artificial	None approved	Derivative of nitroaniline; used as a sweetener in some European countries but banned in the United States due to toxic effects on rats; no bitter aftertaste; major drawback of P-4000 is powerful local anesthetic effect on the tongue and mouth; used in the Netherlands during German occupation and Berlin blockade

Continued

TABLE 1.6
(Continued)

Name	Sweetness	Classification	Uses	Comments
Phyllodulcin	250	Natural	None approved	Isolated from *Hydrangea macrophylla* Seringe in 1916; displays a lagging onset of sweetness with licorice aftertaste; not well studied; possible market for hard candies, chewing gums, and oral hygiene products
Saccharin (0 benzo-sulfimide)	500	Nonnutritive; artificial	Used in beverages, as a tabletop sweetener, and in cosmetics, toothpaste, and cough syrup; used as a sweetener by diabetics	Both sodium and calcium salts of saccharin used; passes through body unchanged; excreted in urine; originally a generally recognized as safe (GRAS) additive; subsequently, saccharin was classed as a carcinogen based on experiments with rats; however, recent experiments indicate that saccharin causes cancer in rats, but not in mice and humans
Sorbitol	0.6	Nutritive; natural	Chewing gum, dairy products, meat products, icing, toppings, and beverages	A sugar alcohol or polyol; occurs naturally in many fruits commercially prepared by the hydrogenation of glucose; many unique properties besides sweetness; on the FDA list of GRAS food additives; the most widely used sugar alcohol; slow intestinal absorption; consumption of large amounts may cause diarrhea
SRI Oxime V (Perilla sugar)	450	Nonnutritive; artificial	None approved	Derived from extract of *Perilla namkinensis*; clean taste; needs research; used as sweetening agent in Japan
Stevioside	300	Nutritive; natural	None approved	Isolated from the leaves of the wild shrub *Stevia rebaudiana* Bertoni; used by the people of Paraguay to sweeten drinks; limited evidence suggests nontoxic to humans; rebaudioside A is isolated from the same plant and is said to taste superior to stevioside; its chemical structure is very similar to stevioside, and it is 190 times sweeter than sugar
Sucrose (brown sugar, liquid sugar, sugar, table sugar, white sugar)	1.0	Nutritive; natural	Many beverages and processed foods; home use in a wide variety of foods	The chemical combination of the sugars fructose and glucose; one of the oldest sweetening agents; most popular and most available sweetening agent; occurs naturally in many fruits; commercially extracted from sugar cane and sugar beets
Splenda (dextrose/ maltodextrin/ sucralose)	4.0	Non nutritive	Used in many beverages and processed foods	Stable to heat
Thaumatins	1600	Nutritive; natural	None	Source of sweetness of the tropical fruit from the plant *Thaumatococcus daniellii*; enjoyed by inhabitants of western Africa; doubtful commercial applications
Xylitol	0.8	Nutritive; natural	Chewing gums and dietetic foods	A sugar alcohol or polyhydric alcohol (polyol); occurs naturally in some fruits and vegetables; produced in the body; commercial production from plant parts (oat hulls, corncobs, and birch wood chips) containing xylans — long chains of the sugar xylose; possible diarrhea; one British study suggests xylitol causes cancer in animals

Source: Ensminger, A.H. et al., *Foods and Nutrition Encyclopedia*, 2nd ed., CRC Press, Boca Raton, FL, 1994, pp. 2082–2087.

of antibodies. Because they are able to agglutinate red blood cells, they are also known as hemaglutinins. The binding of bean lectin on rat intestinal mucosal cells has been demonstrated *in vitro*, and it has been suggested that this action is responsible for the oral toxicity of the lectins. Such bindings may disturb the intestines' absorptive capacity for nutrients and other essential compounds. The lectins, being proteins, can easily be inactivated by moist heat. Germination decreases the hemaglutinating activity in varieties of peas and species of beans.

Type B antinutritives are substances interfering with the absorption or metabolic utilization of minerals and are also known as antiminerals. Although they are toxic per se, the amounts present in foods seldom cause acute intoxication under normal food consumption. However, they may harm the organism under suboptimum nutriture. The most important type B antinutritives are phytic acid, oxalates, and glucosinolates.

TABLE 1.7
Terms Used to Describe the Functions of Food Additives

Term	Function
Anticaking and free-flow agents	Substances added to finely powdered or crystalline food products to prevent caking
Antimicrobial agents	Substances used to preserve food by preventing growth of microorganisms and subsequent spoilage, including fungicides, mold and yeast inhibitors, and bacteriocides
Antioxidants	Substances used to preserve food by retarding deterioration, rancidity, or discoloration due to oxidation
Colors and coloring adjuncts	Substances used to impart, preserve, or enhance the color or shading of a food, including color stabilizers, color fixatives, and color-retention agents
Curing and pickling agents	Substances imparting a unique flavor or color to a food, usually producing an increase in shelf-life stability
Dough strengtheners	Substances used to modify starch and gluten, thereby producing a more stable dough
Drying agents	Substances with moisture-absorbing ability, used to maintain an environment of low moisture
Emulsifiers and emulsifier salts	Substances that modify surface tension of two (or more) immiscible solutions to establish a uniform dispersion of components; called an emulsion
Enzymes	Substances used to improve food processing and the quality of the finished food
Firming agents	Substances added to precipitate residual pectin, thus strengthening the supporting tissue and preventing its collapse during processing
Flavor enhancers	Substances added to supplement, enhance, or modify the original taste or aroma of a food without imparting a characteristic taste or aroma of its own
Flavoring agents and adjuvants	Substances added to impart or help impart a taste or aroma in food
Flour-treating agents	Substances added to milled flour, at the mill, to improve its color or baking qualities, including bleaching and maturing agents
Formulation aids	Substances used to promote or produce a desired physical state or texture in food, including carriers, binders, fillers, plasticizers, film-formers, and tableting aids
Fumigants	Volatile substances used for controlling insects or pests
Humectants	Hygroscopic substances incorporated in food to promote retention of moisture, including moisture-retention agents and antidusting agents
Leavening agents	Substances used to produce or stimulate production of carbon dioxide in baked goods to impart a light texture, including yeast, yeast foods, and calcium salts
Lubricants and release agents	Substances added to food contact surfaces to prevent ingredients and finished products from sticking to them
Nonnutritive sweeteners	Substances having less than 2% of the caloric value of sucrose per equivalent unit of sweetening capacity
Nutrient supplements	Substances that are necessary for the body's nutritional and metabolic processes
Nutritive sweeteners	Substances having greater than 2% equivalent unit of sweetening capacity
Oxidizing and reducing agents	Substances that chemically oxidize or reduce another food ingredient, thereby producing a more stable product
pH-control agents	Substances added to change or maintain active acidity or alkalinity, including buffers, acids, alkalis, and neutralizing agents
Processing aids	Substances used as manufacturing aids to enhance the appeal or utility of a food or food component, including clarifying agents, clouding agents, catalysts, flocculents, filter aids, and crystallization inhibitors
Propellants, aerating agents, and gases	Gases used to supply force to expel a product or used to reduce the amount of oxygen in contact with the food in packaging
Sequestrants	Substances that combine with polyvalent metal ions to form a soluble metal complex in order to improve the quality and stability of products
Solvents and vehicles	Substances used to extract or dissolve another substance
Stabilizers and thickeners	Substances used to produce viscous solutions or dispersions, to impart body, improve consistency, or stabilize emulsions, including suspending and bodying agents, setting agents, gelling agents, and bulking agents
Surface-active agents	Substances used to modify surface properties of liquid food components for a variety of effects, including, other than emulsifiers, solubilizing agents, dispersants, detergents, wetting agents, rehydration enhancers, whipping agents, foaming agents, and defoaming agents
Surface-finishing agents	Substances used to increase palatability, preserve gloss, and inhibit discoloration of foods, including glazes, polishes, waxes, and protective coatings
Synergists	Substances used to act or react with another food ingredient to produce a total effect different or greater than the sum of the effects produced by the individual ingredients
Texturizers	Substances that affect the appearance or feel of the food

Source: Ensminger, A.H. et al., *Foods and Nutrition Encyclopedia*, 2nd ed., CRC Press, Boca Raton, FL, 1994, pp. 11–18.

Phytic acid, or myoinositol hexaphosphate, is a naturally occurring strong acid that binds to many types of bivalent and trivalent heavy metal ions, forming insoluble salts. Consequently, phytic acid reduces the availability of many minerals and essential trace elements. The degree of insolubility of these salts appears to depend on the nature of the metal, the pH of the solution, and, for certain metals, on the presence of another metal. Synergism between two metallic ions in the formation of phytate complexes has also been observed. For instance, zinc–calcium phytate precipitates maximally at pH 6, which is also the pH

TABLE 1.8
Specific Food Additives and Their Functions

Name	Function[a]	Food Use and Comments
Acetic acid	pH control, preservative	Acid of vinegar is acetic acid; miscellaneous or general purposes; many food uses; generally recognized as safe (GRAS) additive
Adipic acid	pH control	Buffer and neutralizing agent; use in confectionery; GRAS additive
Ammonium alginate	Stabilizer and thickener, texturizer	Extracted from seaweed; widespread food use; GRAS additive
Annatto	Color	Extracted from seeds of *Bixa crellana*; butter, cheese, margarine, shortening, and sausage casings; coloring foods in general
Arabinogalactan	Stabilizer and thickener, texturizer	Extracted from western larch; widespread food use; bodying agent in essential oils, nonnutritive sweeteners, flavor bases, nonstandardized dressings, and pudding mixes
Ascorbic acid (vitamin C)	Nutrient, antioxidant, preservative	Widespread use in foods to prevent rancidity or browning; used in meat curing; GRAS additive
Aspartame	Sweetener; sugar substitute	Soft drinks, chewing gum, powdered beverages, whipped toppings, puddings, gelatin; tabletop sweetener
Azodicarbonamide	Flour-treating agent	Aging and bleaching ingredient in cereal flour
Benzoic acid	Preservative	Occurs in nature in free and combined forms; widespread food use; GRAS additive
Benzoyl peroxide	Flour-treating agent	Bleaching agent in flour; may be used in some cheeses
Beta-apo-8′-carotenal	Color	Natural food color; general use not to exceed 30 mg/lb or pt of food
Butylated hydroxyanisole (BHA)	Antioxidant, preservative	Fats, oils, dry yeast, beverages, breakfast cereals, dry mixes, shortening, potato flakes, chewing gum, sausage; often used in combination with butylated hydroxytoluene (BHT); GRAS additive
BHT	Antioxidant, preservative	Rice, fats, oils, potato granules, breakfast cereals, potato flakes, shortening, chewing gum, sausage; often used in combination with BHA; GRAS additive
Biotin	Nutrient	Rich natural sources are liver, kidney, pancreas, yeast, milk; vitamin supplement; GRAS additive
Calcium alginate	Stabilizer and thickener, texturizer	Extracted from seaweed; widespread food use; GRAS additive
Calcium carbonate	Nutrient	Mineral supplement; general purpose additive; GRAS additive
Calcium lactate	Preservative	General purpose or miscellaneous use; GRAS additive
Calcium phosphate	Leavening agent, sequestrant, nutrient	General purpose or miscellaneous use; mineral supplement; GRAS additive
Calcium propionate	Preservative	Bakery products, alone or with sodium propionate; inhibits mold and other microorganisms; GRAS additive
Calcium silicate	Anticaking agent	Used in baking powder and salt; GRAS additive
Canthaxanthin	Color	Widely distributed in nature; color for foods; more red than carotene
Caramel	Color	Miscellaneous or general purpose use in foods for color; GRAS additive
Carob bean gum	Stabilizer and thickener	Extracted from bean of carob tree (locust bean); numerous foods, for example, confections, syrups, cheese spreads, frozen desserts, and salad dressings; GRAS additive
Carrageenan	Emulsifier, stabilizer, and thickener	Extracted from seaweed; a variety of foods, primarily those with a water or milk base
Cellulose	Emulsifier, stabilizer, and thickener	Component of all plants; inert bulking agent in foods; may be used to reduce energy content of food; used in foods that are liquid and foam systems
Citric acid	Preservative, antioxidant, pH-control agent, sequestrant	Widely distributed in nature in both plants and animals; miscellaneous or general purpose food use; used in lard, shortening, sausage, margarine, chili con carne, cured meats, and freeze-dried meats; GRAS additive
Citrus Red No. 2	Color	Coloring skins of oranges
Cochineal	Color	Derived from the dried female insect and coccus cacti; raised in West Indies, Canary Islands, southern Spain, and Algiers; 70,000 insects to 1 lb; provides red color for meat products and beverages
Corn endosperm oil	Color	Source of xanthophyll for yellow color; used in chicken feed to color yolks of eggs and chicken skin
Cornstarch	Anticaking agent, drying agent, formulation aid, processing aid, surface-finishing agent	Digestible polysaccharide used in many foods, often in a modified form; these include baking powder, baby foods, soups, sauces, pie fillings, imitation jellies, custards, and candies

TABLE 1.8
(Continued)

Name	Function[a]	Food Use and Comments
Corn syrup	Flavoring agent, humectant, nutritive sweetener, preservative	Derived from hydrolysis of cornstarch; employed in numerous foods, for example, baby foods, bakery products, toppings, meat products, beverages, condiments, and confections; GRAS additive
Dextrose (glucose)	Flavoring agent, humectant, nutritive sweetener, synergist	Derived from cornstarch; major users of dextrose are confection, wine, and canning industries; used to flavor meat products; used in production of caramel; variety of other uses
Diglycerides	Emulsifiers	Uses include frozen desserts, lard, shortening, and margarine; GRAS additive
Dioctyl sodium sulfosuccinate	Emulsifier, processing aid, surface-active agent	Employed in gelatin dessert, dry beverages, fruit juice drinks, and noncarbonated beverages with cocoa fat; used in production of cane sugar and in canning
Disodium guanylate	Flavor enhancer	Derived from dried fish or seaweed
Disodium inosinate	Flavor adjuvant	Derived from seaweed or dried fish; sodium guanylate is a byproduct
Ethylenediamine-tetraacetic acid (EDTA)	Antioxidant, sequestrant	Calcium disodium and disodium salt of EDTA employed in a variety of foods including soft drinks, alcoholic beverages, dressings, canned vegetables, margarine, pickles, sandwich spreads, and sausage

FD&C colors:
  Blue No. 1
  Red No. 40
  Yellow No. 5
	Color	Coloring foods in general, including dietary supplements

Gelatin	Stabilizer and thickener, texturizer	Derived from collagen by boiling skin, tendons, ligaments, bones, etc. with water; employed in many foods including confectionery, jellies, and ice cream; GRAS additive
Glycerine (glycerol)	Humectant	Miscellaneous and general purpose additive; GRAS additive
Grape skin extract	Color	Colorings for carbonated drinks, beverage bases, and alcoholic beverages
Guar gum	Stabilizer and thickener, texturizer	Extracted from seeds of the guar plant of India and Pakistan; employed in such foods as cheese, salad dressings, ice cream, and soups
Gum arabic	Stabilizer and thickener, texturizer	Gummy exudate of Acacia plants; used in variety of foods; GRAS additive
Gum ghatti	Stabilizer and thickener, texturizer	Gummy exudate of plant growing in India and Ceylon; a variety of food uses; GRAS additive
Hydrogen peroxide	Bleaching agent	Modification of starch and bleaching tripe; GRAS bleaching agent
Hydrolyzed vegetable (plant) protein	Flavor enhancer	Used to flavor various meat products
Invert sugar	Humectant, nutritive sweetener	Main use in confectionery and brewing industry
Iron	Nutrient	Dietary supplements and food; GRAS additive
Iron–Ammonium citrate	Anticaking agent	Used in salt
Karraya gum	Stabilizer and thickener	Derived from dried extract of *Sterculia urens* found primarily in India; variety of food uses; a substitute for tragacanth gum; GRAS additive
Lactic acid	Preservative, pH control	Normal product of human metabolism; numerous uses in foods and beverages; a miscellaneous general purpose additive; GRAS additive
Lecithin (phosphatidyl-choline)	Emulsifier, surface-active agent	Normal tissue component of the body; edible and digestible additive naturally occurring in eggs; commercially derived from soybeans; margarine, chocolate, and wide variety of other food uses; GRAS additive
Mannitol	Anticaking, nutritive sweetener, stabilizer and thickener, texturizer	Special dietary foods; GRAS additive; supplies half the energy of glucose; classified as a sugar alcohol or polyhydric alcohol (polyol)
Methylparaben	Preservative	Food and beverages; GRAS additive
Modified food starch	Drying agent, formulation aid, processing aid, surface-finishing agent	Digestible polysaccharide used in many foods and stages of food processing; examples include baking powder, puddings, pie fillings, baby foods, soups, sauces, candies, etc.
Monoglycerides	Emulsifiers	Widely used in foods such as frozen desserts, lard, shortening, and margarine; GRAS additive
Monosodium glutamate (MSG)	Flavor enhancer	Enhances the flavor of a variety of foods including various meat products; possible association with the Chinese restaurant syndrome
Papain	Texturizer	Miscellaneous or general purpose additive; GRAS additive; achieves results through enzymatic action; used as meat tenderizer

TABLE 1.8
(Continued)

Name	Function[a]	Food Use and Comments
Paprika	Color, flavoring agent	Provides coloring or flavor to foods; GRAS additive
Pectin	Stabilizer and thickener, texturizer	Richest source of pectin is lemon and orange rind; present in cell walls of all plant tissues; used to prepare jellies and jams; GRAS additive
Phosphoric acid	pH control	Miscellaneous or general purpose additive; used to increase effectiveness of antioxidants in lard and shortening; GRAS additive
Polyphosphates	Nutrient, flavor improver, sequestrant, pH control	Numerous food uses; most polyphosphates and their sodium, calcium, potassium, and ammonium salts; GRAS additive
Polysorbates	Emulsifiers, surface-active agent	Polysorbates designated by numbers such as 60, 65, and 80; variety of food uses including baking mixes, frozen custards, pickles, sherbets, ice creams, and shortenings
Potassium alginate	Stabilizer and thickener, texturizer	Extracted from seaweed; wide usage; GRAS additive
Potassium bromate	Flour treating agent	Employed in flour, whole wheat flour, fermented malt beverages, and to treat malt
Potassium iodide	Nutrient	Added to table salt or used in mineral preparations as a source of dietary iodine
Potassium nitrite	Curing and pickling agent	To fix color in cured products such as meats
Potassium sorbate	Preservative	Inhibits mold and yeast growth in foods such as wines, sausage casings, and margarine; GRAS additive
Propionic acid	Preservative	Mold inhibitor in breads and general fungicide; GRAS additive; used in manufacture of fruit flavors
Propyl gallate	Antioxidant, preservative	Used in products containing oil or fat; employed in chewing gum; used to retard rancidity in frozen fresh pork sausage
Propylene glycol	Emulsifier, humectant, stabilizer and thickener, texturizer	Miscellaneous or general purpose additive; uses include salad dressings, ice cream, ice milk, custards, and a variety of other foods; GRAS additive
Propylparaben	Preservative	Fungicide; controls mold in sausage casings; GRAS additive
Saccharin	Nonnutritive sweetener	Special dietary foods and a variety of beverages; baked products; tabletop sweeteners
Saffron	Color, flavoring agent	Derived from plant of western Asia and southern Europe; all foods except those where standards forbid; to color sausage casings, margarine, or product branding inks
Silicon dioxide	Anticaking agent	Used in feed or feed components, beer production, production of special dietary foods, and ink diluent for marking fruits and vegetables
Sodium acetate	pH control, preservative	Miscellaneous or general purpose use; meat preservation; GRAS additive
Sodium alginate	Stabilizer and thickener, texturizer	Extracted from seaweed; widespread food use; GRAS additive
Sodium aluminum sulfate	Leavening agent	Baking powders, confectionery; sugar refining
Sodium benzoate	Preservative	Variety of food products; margarine to retard flavor reversion; GRAS additive
Sodium bicarbonate	Leavening agent, pH control	Miscellaneous or general purpose uses; separation of fatty acids and glycerol in rendered fats; neutralize excess and clean vegetables in rendered fats, soups, and curing pickles; GRAS additive
Sodium chloride (salt)	Flavor enhancer, formulation acid, preservation	Used widely in many foods; GRAS additive
Sodium citrate	pH control, curing and pickling agent, sequestrant	Evaporated milk; miscellaneous or general purpose food use; accelerate color fixing in cured meats; GRAS additive
Sodium diacetate	Preservative, sequestrant	An inhibitor of molds and rope-forming bacteria in baked products; GRAS additive
Sodium nitrate (Chile saltpeter)	Curing and pickling agent, preservative	Used with or without sodium nitrite in smoked, cured-fish, and cured-meat products
Sodium nitrite	Curing and pickling agent, preservative	May be used with sodium nitrate in smoked- or cured-fish, cured-meat products, and pet foods
Sodium propionate	Preservative	A fungicide and mold preventative in bakery products; GRAS additive
Sorbic acid	Preservative	Fungistatic agent for foods, especially cheeses; other uses include baked goods, beverages, dried fruits, fish, jams, jellies, meats, pickled products, and wines; GRAS additive
Sorbitan monostearate	Emulsifier, stabilizer and thickener	Widespread food usage such as whipped toppings, cakes, cake mixes, confectionery, icings, and shortenings; also many nonfood uses
Sorbitol	Humectant, nutritive sweetener, stabilizer and thickener, sequestrant	A sugar alcohol or polyol; used in chewing gum, meat products, icings, dairy products, beverages, and pet foods
Sucrose	Nutritive sweetener, preservative	The most widely used additive; used in beverages, baked goods, candies, jams and jellies, and other processed foods
Tagetes (Aztec marigold)	Color	Source is flower petals of Aztec marigold; used to enhance yellow color of chicken skin and eggs, incorporated in chicken feed

TABLE 1.8
(Continued)

Name	Function[a]	Food Use and Comments
Tartaric acid	pH control	Occurs free in many fruits, free or combined with calcium, magnesium, or potassium; used in the soft drink industry, confectionery products, bakery products, and gelatin desserts
Titanium dioxide	Color	For coloring foods generally, except standardized foods; used for coloring ingested and applied drugs
Tocopherols (vitamin E)	Antioxidant, nutrient	To retard rancidity in foods containing fat; used in dietary supplements; GRAS additive
Tragacanth gum	Stabilizer and thickener, texturizer	Derived from the plant *Astragalus gummifier* or other Asiatic species of *Astragalus*; general purpose additive
Turmeric	Color	Derived from rhizome of *Curcuma longa*; used to color sausage casings, margarine or shortening, and ink for branding or marking products
Vanilla	Flavoring agent	Used in various bakery products, confectionery, and beverages; natural flavoring extracted from cured, full grown unripe fruit of *Vanilla panifolia*; GRAS additive
Vanillin	Flavoring agent and adjuvant	Widespread confectionery, beverage and food use; synthetic form of vanilla; GRAS additive
Yellow prussiate of soda	Anticaking agent	Employed in salt

[a] Function refers to those defined in Table 1.7.

TABLE 1.9
Microbial Contaminants of Fresh Food

Foods	Microorganism	Common Contaminants
Fruits and Vegetables	Bacteria	*Erwinia, Pseudomonas, Corynebacterium*
	Fungi	*Aspigillus, Botrytis, Geotrichium, Rhizopus, Penicillium, Cladosporium, Alternaria, Phytopora*, various yeasts
Fresh meat	Bacteria	*Acinetobacter, Aeromonas, Pseudomonas*
Fish Poultry	Bacteria	*Micrococcus, Achromobacter, Flavobacterium, Proteus, Salmonella, Escheria*
	Fungi	*Cladosporium, Mucor, Rhizopus, Penicillium, Geotrichium, Sporotrichium, Candida, Torula, Rhodotorula*
Milk	Bacteria	*Streptococcus, Leuconostoc, Lactococcus, Lactobacillus, Pseudomonas, Proteus*
High-sugar foods	Bacteria	*Clostridium, Bacillus, Flavobacterium*
	Fungi	*Saccharomyces, Torulla, Penicillium*

Source: Lynnes book.

of the duodenum, where mainly calcium and trace metals are absorbed. Phytates occur in a wide variety of foods, such as cereals (e.g., wheat, rye, maize, rice, and barley), legumes and vegetables (e.g., bean, soybean, lentil, pea, and vetch), nuts and seeds (e.g., walnut, hazelnut, almond, peanut, and cocoa bean), and spices and flavoring agents (e.g., caraway, coriander, cumin, mustard, and nutmeg). From several experiments in animals and humans it has been observed that phytates exert negative effects on the availability of calcium, iron, magnesium, zinc, and other trace essential elements. These effects may be minimized considerably, if not eliminated, by increased intake of essential minerals. In the case of calcium, intake of cholecalciferol must also be adequate, as the activity of phytates on calcium absorption is enhanced when this vitamin is inadequate or limiting. In many foodstuffs the phytic acid level can be reduced by phytase, an enzyme occurring in plants that catalyzes the dephosphorylation of phytic acid.

Oxalic acid is a strong acid that forms water-soluble Na^+ and K^+ salts, but is less soluble salts with alkaline earth and other bivalent metals. Calcium oxalate is particularly insoluble at neutral or alkaline pH, whereas it readily dissolves in acid medium. Oxalates mainly exert effects on the absorption of calcium. These effects must be considered in terms of the oxalate-to-calcium ratio (in milliequivalent/milliequivalent): foods having a ratio greater than 1 may have negative effects on calcium availability, whereas foods with a ratio of 1 or below do not. Examples of foodstuffs having a ratio greater than 1 are: rhubarb (8.5), spinach (4.3), beet (2.5 to 5.1), cocoa (2.6), coffee (3.9), tea (1.1), and potato (1.6). Harmful oxalates in food may be removed by soaking in water. Consumption of calcium-rich foods (e.g., dairy products and seafood), as well as augmented cholecalciferol intake, are recommended when large amounts of high-oxalate food are consumed.

TABLE 1.10
Mycotoxins or Bacterial Toxins in Foods

Toxins from bacteria	*Staphylococcus aureus*
	a exotoxin (lethal, dermonecrotic, hemolytic, leucolytic)
	b exotoxin (hemolytic)
	g exotoxin (hemolytic)
	d exotoxin (dermonecrotic, hemolytic)
	leucocidin (leucolytic)
	exfoliative toxin
	enterotoxin
	Clostridium botulinum (four strains)
	Toxins are lettered as A, B, Ca (1, 2, D), Cb, D(C1 and D), E, F, G. All of the toxics are proteolytic and produce NH_3, H_2S, CO_2, and volatile amines. The toxins are hemolytic and neurotoxic
	Escherichi coli (several serotypes)
	Induce diarrhea, vomiting; produce toxins that are heat labile
	Bacillus cereus (several types)
	Produces heat-labile enterotoxins that induce vomiting and diarrhea
Mycotoxins Produced by Fungi	*Aspergillus flavis*
	Claviceps purpura
	Fusarium graminearum
	Aspergillus ochraceus
	Aspergillus parasiticus
	Penicillium viridicatum

TABLE 1.11
Antinutrients in Food

Type of Factors	Effect of Factors	Legumes Containing the Factors
Antivitamin factors	Interfere with the actions of certain vitamins	
Antivitamin A	Lipoxidase oxidizes and destroys carotene (provitamin A)	Soybeans
Antivitamin B_{12}	Increases requirement for Vitamin B_{12}	Soybeans
Antivitamin D	Causes rickets unless extra vitamin D is provided	Soybeans
Antivitamin E	Damage to the liver and muscles	Alfalfa, common beans (*Phaseolus vulgaris*), peas (*Pisum sativum*)
Cyanide-releasing glucosides	Releases hydrocyanic acid. The poison may also be released by an enzyme in *E. coli*, a normal inhabitant of the human intestine	All legumes contain at least small amounts of these factors; however, certain varieties of lima beans (*Phaseolus lunatus*) may contain much larger amounts
Favism factor	Causes the breakdown of red blood cells in susceptible individuals	Fava beans (*Vicia faba*)
Gas-generating carbohydrates	Certain indigestible carbohydrates are acted upon by gas-producing bacteria in the lower intestine	Many species of mature dry legume seeds, but not peanuts; the immature (green) seeds contain much lower amounts
Goitrogens	Interfere with the utilization of iodine by the thyroid gland	Peanuts and soybeans
Inhibitors of trypsin	The inhibitors bind with the digestive enzyme trypsin	All legumes contain trypsin inhibitors; these inhibitors are destroyed by heat
Lathyrogenic neurotoxins	Consumption of large quantities of lathyrogenic legumes for long periods (several months) results in severe neurological disorders	Lathyrus pea (*L. sativus*), which is grown mainly in India Common vetch (*Vicia sativa*) may also be lathrogenic
Metal binders	Bind copper, iron, manganese, and zinc	Soybeans, Peas (*Pisum sativum*)
Red blood cell clumping agents (hemaglutinins)	The agents cause the red blood cells to clump together	Occurs in all legumes to some extent

Source: Ensminger et al., *Food and Nutrition Encyclopedia*, 2nd ed., CRC Press, Boca Raton, FL, 1994.

A variety of plants contain a third group of type B antinutritives, the glucosinolates, also known as thioglucosides. Many glucosinolates are goitrogenic. They have a general structure, and yield on hydrolysis the active or actual goitrogens, such as thiocyanates, isothiocyanates, cyclic sulfur compounds, and nitriles. Three types of goiter can be identified: (1) cabbage goiter, (2) brassica seed goiter, and (3) legume goiter. Cabbage goiter, also known as struma, is induced by excessive consumption

of cabbage. It seems that cabbage goitrogens inhibit iodine uptake by directly affecting the thyroid gland. Cabbage goiter can be treated by iodine supplementation. Brassica seed goiter can result from the consumption of the seeds of brassica plants (e.g., rutabaga, turnip, cabbage, and rape), which contain goitrogens that prevent thyroxine synthesis. This type of goiter can only be treated by administration of the thyroid hormone. Legume goiter is induced by goitrogens in legumes such as soybeans and peanuts. It differs from cabbage goiter in that the thyroid gland does not lose its activity for iodine. Inhibition of the intestinal absorption of iodine or the reabsorption of thyroxine has been shown in this case. Legume goiter can be treated by iodine therapy. Glucosinolates, which have been shown to induce goiter, at least in experimental animals, are found in several foods and feedstuffs: broccoli (buds), brussels sprouts (head), cabbage (head), cauliflower (buds), garden cress (leaves), horseradish (roots), kale (leaves), kohlrabi (head), black and white mustard (seed), radish (root), rape (seed), rutabaga (root), and turnips (root and seed). One of the most potent glucosinolates is progoitrin from the seeds of brassica plants and the roots of rutabaga. Hydrolysis of this compound yields 1-cyano-2-hydroxy-3-butene, 1-cyano-2-hydroxy-3, 4-butylepisulfide, 2-hydroxy-3, 4-butenylisothiocyanate, and (*S*)-5-vinyl-oxazolidone-2-thione, also known as goitrin. The latter product interferes, together with its *R*-enantiomer, in the iodination of thyroxine precursors, and so the resulting goiter cannot be treated by iodine therapy.

Type C antinutritives are naturally occurring substances that can inactivate vitamins, form unabsorbable complexes with them, or interfere with their digestive or metabolic utilization. They are also known as antivitamins. The most important type C antinutritives are ascorbic acid oxidase, antithiamine factors, and antipyridoxine factors.

Ascorbic acid oxidase is a copper-containing enzyme that catalyzes the oxidation of free ascorbic acid to diketogluconic acid, oxalic acid, and other oxidation products. It has been reported to occur in many fruits (e.g., peaches and bananas) and vegetables (e.g., cucumbers, pumpkins, lettuce, cress, cauliflowers, spinach, green beans, green peas, carrots, potatoes, tomatoes, beets, and kohlrabi). The enzyme is active between pH 4 and 7 (optimum pH 5.6 to 6.0); its optimum temperature is 38°C. The enzyme is released when plant cells are broken. Therefore, if fruits and vegetables are cut, the vitamin C content decreases gradually. Ascorbic acid oxidase can be inhibited effectively at pH 2 or by blanching at around 100°C. Ascorbic acid can also be protected against ascorbic acid oxidase by substances of plant origin. Flavonoids, such as the flavonols quercetin and kempferol, present in fruits and vegetables, strongly inhibit the enzyme.

A second group of type C antinutritives are the antithiamine factors, which interact with thiamine, also known as vitamin B_1. Antithiamine factors can be grouped as thiaminases, catechols, and tannins. Thiaminases, which are enzymes that split thiamine at the methylene linkage, are found in many freshwater and saltwater fish species and in certain species of crab and clam. They contain a nonprotein coenzyme structurally related to hemin. This coenzyme is the actual antithiamine factor. Thiaminases in fish and other sources can be destroyed by cooking. Antithiamine factors of plant origin include catechols and tannins. The most well-known ortho-catechol is found in bracken fern. In fact, there are two types of heat-stable antithiamine factors in this fern, one of which has been identified as caffeic acid, which can also be hydrolyzed from chlorogenic acid (found in green coffee beans) by intestinal bacteria. Other ortho-catechols, such as methylsinapate occurring in mustard seed and rapeseed, also have antithiamine activity. The mechanism of thiamine inactivation by these compounds requires oxygen and is dependent on temperature and pH. The reaction appears to proceed in two phases: a rapid initial phase, which is reversible by addition of reducing agents (e.g., ascorbic acid), and a slower subsequent phase, which is irreversible. Tannins, occurring in a variety of plants, including tea, similarly possess antithiamine activity. Thiamine is one of the vitamins likely to be deficient in the diet. Thus, persistent consumption of antithiamine factors and the possible presence of thiaminase-producing bacteria in the gastrointestinal tract may compromise the already marginal thiamine intake.

A variety of plants and mushrooms contain pyridoxine antagonists. These compounds interfere with the use of vitamin B_6 and are called antipyridoxine factors. They are hydrazine derivatives. Linseed contains the water-soluble and heat-labile antipyridoxine factor linatine (g-glutamyl-1-amino-D-proline). Hydrolysis of linatine yields the actual antipyridoxine factor 1-amino-proline. Antipyridoxine factors have also been found in wild mushrooms, the common commercial edible mushroom, and the Japanese mushroom shiitake. Commercial and shiitake mushrooms contain agaritine. Hydrolysis of agaritine by g-glutamyl transferase, which is endogenous to the mushroom, yields the active agent 4-hydroxymethylphenylhydrazine. Disruption of the cells of the mushroom can accelerate hydrolysis; careful handling of the mushrooms and immediate blanching after cleaning and cutting can prevent hydrolysis. The mechanism underlying the antipyridoxine activity is believed to be condensation of the hydrazines with the carbonyl compounds pyridoxal and pyridoxal phosphate (the active form of the vitamin), resulting in the formation of inactive hydrazones.

In addition to these antinutritives, foods can contain a variety of toxic substances as shown in Table 1.12 (see Reference 4, pp. 24–36, 1284–1285, 1776–1785, 1790–1803, 2082–2087). Some of these toxic substances are added inadvertently by the food processing methods, but some occur naturally. If consumed in minute quantities, some of these toxic materials are without significant effect, yet other compounds (e.g., arsenic), even in minute amounts, could accumulate and become lethal.

Table 1.13 contains information about plants commonly thought of as weeds.[6] Some of these plants may have toxic components that affect certain consumers. There can be considerable variability among humans with respect to plants that can be tolerated by them. Plants can differ from variety to variety and indeed from one growing condition to another in the content of certain of their herbal or nutritive ingredients. Lastly, Table 1.14 provides a list of toxic plants that should not be consumed under any circumstances (see Reference 4, pp. 24–36, 1284–1285, 1776–1785, 1790–1803, 2082–2087).

TABLE 1.12
Toxic Substances in Food (Toxic if Consumed in Excess)

Poison (Toxin)	Sources	Symptoms and Signs	Distribution	Magnitude	Prevention	Treatment	Remark
Aflatoxins (see Table 1.10)							
Aluminum (Al)	Food additives, mainly presented in such items as baking powder, pickles, and processed cheeses Aluminum-containing antacids	Abnormally large intakes of aluminum irritate the digestive tract. Also, unusual conditions have sometimes resulted in the absorption of sufficient aluminum from antacids, causing brain damage. Aluminum may form nonabsorbable complexes with essential trace elements, thereby creating deficiencies of these elements	Aluminum is widely used throughout the world	The United States uses aluminum more than any other minerals except iron. However, known cases of aluminum toxicity are rare	Based on the evidence presented, no preventative measures are recommended		Aluminum toxicity has been reported in patients receiving renal dialysis
Arsenic (As)	Consumption of contaminated foods and beverages Arsenical insecticides used in vineyards expose the workers (1) when spraying or (2) by inhaling contaminated dusts and plant debris Arsenic in the air is from three major sources: smelting of metals, burning of coal, and use of arsenical pesticides	Burning pain in the throat or stomach, cardiac abnormalities, and the odor of garlic on the breath. Other symptoms may be diarrhea and extreme thirst along with a choking sensation Small doses of arsenic taken into the body over a long period of time may produce hyperkeratosis (irregularities in pigmentation, especially on the trunk); arterial insufficiency; and cancer There is strong evidence that inorganic arsenic is a skin and lung carcinogen in humans	Arsenic is widely distributed, but the amount of the element consumed by humans in food and water, or breathed, is very small and not harmful	Cases of arsenic toxicity in humans are infrequent. Two noteworthy episodes occurred in Japan in 1955. One involved tainted powdered milk; the other contaminated soy sauce. The toxic milk caused 12,131 cases of infant poisoning, with 130 deaths. The soy sauce poisoned 2 20 people		Induce vomiting, followed by an antidote of egg whites in water or milk. Afterward, give strong coffee or tea, followed by Epsom salts in water or castor oil	Arsenic is known to partially protect against selenium poisoning The highest residues of arsenic are generally in the hair and nails Arsenic in soils may sharply decrease crop growth and yields, but it is not a hazard to people or livestock that eat plants grown in these fields
Chromium (Cr)	Food, water, and air contaminated by chromium compounds in industrialized areas	Inorganic chromium salt reduces the absorption of zinc; hence, zinc deficiency symptoms may become evident in chronic chromium toxicity	Chromium toxicity is not common	Chromium toxicity is not very common	It is unlikely that people will get too much chromium, because (1) only minute amounts of the element are present in most foods, (2) the body utilizes chromium poorly, and (3) the toxic dose is about 10,000 times the lowest effective medical dose		

Copper (Cu)	Diets with excess copper, but low in other minerals that counteract its effects. Acid foods or beverages (vinegar, carbonated beverages, or citrus juices) that have been in prolonged contact with copper metal may cause acute gastrointestinal disturbances	Acute copper toxicity: Characterized by headache, dizziness, metallic taste, excessive salivation, nausea, vomiting, stomachache, diarrhea, and weakness. If the disease is allowed to get worse, there may also be racing of the heart, high blood pressure, jaundice, hemolytic anemia, dark-pigmented urine, kidney disorders, and even death. Chronic copper toxicity may be contributory to iron-deficiency anemia, mental illness following childbirth (postpartum psychosis), certain types of schizophrenia, and perhaps heart attacks	Copper toxicity may occur wherever there is excess copper intake, especially when accompanied by low iron, molybdenum, sulfur, zinc, and vitamin C	The incidence of copper toxicity is extremely rare in humans. Its occurrence in significant form is almost always limited to (1) suicide attempts by ingestion of large quantities of copper salt, or (2) a genetic defect in copper metabolism inherited as an autosomal recessive, known as Wilson's disease	Avoid foods and beverages that have been in prolonged contact with copper metal	Administration of copper-chelating agents to remove excess copper	Copper is essential to human life and health, but as with all heavy metals, it may be toxic in excess
Ergot	Rye, wheat, barley, oats, and triticale carry this mycotoxin. Ergot replaces the seed in the heads of cereal grains, in which it appears as a purplish-black, hard, banana-shaped, dense mass from ¼ to ¾ in. (6 to 9 mm) long	When a large amount of ergot is consumed in a short period, convulsive ergotism is observed. The symptoms include itching, numbness, severe muscle cramps, sustained spasms and convulsions, and extreme pain. When smaller amounts of ergot are consumed over an extended period, ergotism is characterized by gangrene of the fingertips and toes, caused by blood vessel and muscle contraction stopping blood circulation in the extremities. These symptoms include cramps, swelling, inflammation, alternating burning and freezing sensations ("St. Anthony's fire") and numbness; eventually the hands and feet may turn black, shrink, and fall off. Ergotism is a cumulative poison, depending on the amount of ergot eaten and the length of time over which it is eaten	Ergot is found throughout the world wherever rye, wheat, barley, oats, or triticale are grown	There is considerable ergot, especially in rye. But, normally, screening grains before processing alleviates ergotism in people	Consists of an ergot-free diet. Ergot in food and feed grains may be removed by screening the grains before processing. In the United States, wheat and rye containing more than 0.3% ergot are classed as "ergoty." In Canada, government regulations prohibit more than 0.1% ergot in feeds	An ergot-free diet; good nursing; treatment by a doctor	Six different alkaloids are involved in ergot poisoning. Ergot is used to aid the uterus to contract after childbirth, to prevent loss of blood. Also, another ergot drug (ergotamine) is widely used in the treatment of migraine headaches

Continued

TABLE 1.12
(Continued)

Poison (Toxin)	Sources	Symptoms and Signs	Distribution	Magnitude	Prevention	Treatment	Remark
Fluorine (F) (fluorosis)	Ingestion of excessive quantities of fluorine through either the food or water, or a combination of these. Except in certain industrial exposures, the intake of fluoride inhaled from the air is only a small fraction of the total fluoride intake in humans. Pesticides containing fluorides, including those used to control insects, weeds, and rodents. Although water is the principal source of fluoride in an average human diet in the United States, fluoride is frequently contained in toothpaste, tooth powder, chewing gums, mouth-washes, vitamin supplements, and mineral supplements	Acute fluoride poisoning: Abdominal pain, diarrhea, vomiting, excessive salivation, thirst, perspiration, and painful spasms of the limbs. Chronic fluoride poisoning: Abnormal teeth (especially mottled enamel) during the first 8 years of life and brittle bones. Other effects, predicted from animal studies, may include loss of body weight and altered structure and function of the thyroid gland and kidneys. Water containing 3 to 10 ppm of fluoride may cause mottling of the teeth. An average daily intake of 20 to 80 mg of fluoride over a period of 10 to 20 years will result in crippling fluorosis	The water in parts of Arkansas, California, South Carolina, and Texas contains excess fluorine. Occasionally, throughout the United States, high-fluorine phosphates are used in mineral mixtures	Generally speaking, fluorosis is limited to high-fluorine areas. Only a few instances of health effects in humans have been attributed to airborne fluoride, and they occurred in persons living in the vicinity of fluoride-emitting industries	Avoid the use of food and water containing excessive fluorine	Any damage may be permanent, but people who have not developed severe symptoms may be helped to some extent if the source of excess fluorine is eliminated. High dietary levels of calcium and magnesium may reduce the absorption and utilization of fluoride	Fluorine is a cumulative poison. The total fluoride in the human body averages 2.57 g. Susceptibility to fluoride toxicity is increased by deficiencies of calcium, vitamin C, and protein. Virtually all foods contain trace amounts of fluoride
Lead (Pb)	Consuming food or medicinal products (including health food products) contaminated with lead. Inhaling the poison as a dust by workers in such industries as painting, lead mining, and refining. Inhaling airborne lead discharged into the air from auto exhaust fumes	Develop rapidly in young children, but slowly in mature people. Acute lead poisoning: Colic, cramps, diarrhea or constipation, leg cramps, and drowsiness. The most severe form of lead poisoning, encountered in infants and in heavy drinkers of illicitly distilled whiskey is characterized by profound disturbances of the central nervous system and permanent damage to the brain; damage to the kidneys and shortened life span of the erthrocytes	Predominantly among children who may eat chips of lead-containing paints, peeled off from painted wood	The Centers for Disease Control, Atlanta, GA, estimates that (1) lead poisoning claims the lives of 200 children each year, and (2) 400,000 to 600,000 children have elevated lead levels in the blood. Lead poisoning has been reduced significantly with the use of lead-free paint	Avoid inhaling or consuming lead	Acute lead poisoning: An emetic (induce vomiting), followed by drinking plenty of milk and ½ oz (14 g) of Epsom salts in half glass of water	Lead is a cumulative poison. When incorporated in the soil, nearly all the lead is converted into forms that are not available to plants. Any lead taken up by plant roots tends to stay in the roots, rather than move up to the top of the plant

Element	Source of exposure	Toxic effects	Treatment	Control	Remarks
	Consuming food crops contaminated by lead being deposited on the leaves and other edible portions of the plant by direct fallout. Consuming food or water contaminated by contact with lead pipes or utensils. Old houses in which the interiors were painted with leaded paints prior to 1945 — the chipped wall paint is sometimes eaten by children. Such miscellaneous sources as illicitly distilled whiskey, improperly lead-glazed earthenware, old battery casings used as fuel, and toys containing lead	Chronic lead poisoning: Colic, constipation, lead palsy especially in the forearm and fingers, the symptoms of chronic nephritis, and sometimes mental depression, convulsions, and a blue line at the edge of the gums	Chronic lead poisoning: Remove the source of lead. Sometimes treated by administration of magnesium or lead sulfate solution as a laxative and antidote on the lead in the digestive system, followed by potassium iodide, which cleanses the tracts. Currently, treatment of lead poisoning makes use of chemicals that bind the metal in the body and help in its removal		Lead poisoning can be diagnosed positively by analyzing the blood tissue for lead content; clinical signs of lead poisoning usually are manifested at blood lead concentrations above 80 mg/100 g
Mercury (Hg)	Mercury is discharged into air and water from industrial operations and is used in herbicide and fungicide treatments. Mercury poisoning has occurred where mercury from industrial plants has been discharged into water, then accumulated as methylmercury in fish and shellfish. Accidental consumption of seed grains treated with fungicides that contain mercury, used for the control of fungus diseases of oats, wheat, barley, and flax	The toxic effects of organic and inorganic compounds of mercury are dissimilar. The organic compounds of mercury, such as the various fungicides (1) affect the central nervous system and (2) are not corrosive. The inorganic compounds of mercury include mainly mercuric chloride, a disinfectant; mercurous chloride (calomel), a cathartic; and elemental mercury. Commonly the toxic symptoms are corrosive gastrointestinal effects, such as vomiting, bloody diarrhea, and necrosis of the alimentary mucosa	Limited. But about 1200 cases of mercury poisoning identified in Japan in the 1950s were traced to the consumption of fish and shellfish from Japan's Minamata Bay contaminated with methylmercury. Some of the offspring of exposed mothers were born with birth defects, and many victims suffered central nervous system damage. Another outbreak of mercury toxicity occurred in Iraq, where more than 6000 people were hospitalized after eating bread made from wheat that had been treated with methylmercury	Wherever mercury is produced in industrial operations or used in herbicide or fungicide treatments. Control mercury pollution from industrial operations	Mercury is a cumulative poison. Food and Drug Administration prohibits use of mercury-treated grain for food or feed. Grain crops produced from mercury-treated seed and crops produced on soils treated with mercury herbicides have not been found to contain harmful concentrations of this element

TABLE 1.12
(Continued)

Poison (Toxin)	Sources	Symptoms and Signs	Distribution	Magnitude	Prevention	Treatment	Remark
Poly-chlorinated biphenyls (PCBs), industrial chemicals; chlorinated hydrocarbons, which may cause cancer when taken into the food supply	Sources of contamination to humans include: 1. Contaminated foods 2. Mammals or birds that have fed on contaminated foods of fish 3. Residues on foods that have been wrapped in papers and plastics containing PCBs 4. Milk from cows that have been fed silage from silos coated with PCB-containing paint; and eggs from layers fed feeds contaminated with PCBs	Clinical effects on people are: An eruption of the skin resembling acne, visual disturbances, jaundice, numbness, and spasms. Newborn infants from mothers who have been poisoned show discoloration of the skin, which regresses after 2 to 5 months. PCBs are fat soluble	PCBs are widespread Their use by industry is declining				PCBs have been widely used in dielectric fluids in capacitors and transformers, hydraulic fluids, and heat-transfer fluids. Also, they have more than 50 minor uses including plasticizers and solvents in adhesives, printing ink, sealants, moisture retardants, paints, and pesticide carriers PCB causes cancer in laboratory animals (rats, mice, and rhesus monkeys). It is not known if it will cause cancer in humans. More study is needed to gauge its effects on the ecological food chain and on human health. When fed Coho salmon from Lake Michigan with 10 to 15 ppm PCB, mink in Wisconsin stopped reproducing or their kits died
Salt (NaCl/sodium chloride) poisoning	Consumption of high-salt food and beverages	Salt may be toxic (1) when it is fed to infants or others whose kidneys cannot excrete the excess in the urine or (2) when the body is adapted to a chronic low-salt diet	Salt is used all over the world. Hence, the potential for salt poisoning exists everywhere	Salt poisoning is relatively rare	Drink large quantities of fresh water		Even normal salt concentration may be toxic if water intake is low

Selenium (Se)	Consumption of high levels in food or drinking water. Presence of malnutrition, parasitic infestation, or other factors, which make people highly susceptible to selenium toxicity	Abnormalities in the hair, nails, and skin. Children in a high-selenium area of Venezuela showed loss of hair, discolored skin, and chronic digestive disturbances. Normally, people who have consumed large excesses of selenium excrete it as trimethyl selenide in the urine or as dimethyl selenide in the breath. The latter substance has an odor resembling garlic	In certain regions of western United States, especially in South Dakota, Montana, Wyoming, Nebraska, Kansas, and perhaps areas in other states in the Great Plains and Rocky Mountains Also, in Canada	Selenium toxicity in people is relatively rare	Selenium toxicity may be counter-acted by arsenic or copper, but such treatment should be carefully monitored	Confirmed cases of selenium poisoning in people are rare, because (1) only traces are present in most foods, (2) foods generally come from a wide area, and (3) the metabolic processes normally convert excess selenium into harmless substances that are excreted in the urine or breath
Tin (Sn)	From acid fruits and vegetables canned in tin cans. The acids in such foods as citrus fruits and tomato products can leach tin from the inside of the can. Then the tin is ingested with the canned food. In the digestive tract tin goes through a methylation process in which nontoxic tin is converted to methylated tin, which is toxic	Methylated tin is a neurotoxin — a toxin that attacks the central nervous system, the symptoms of which are numbness of the fingers and lips followed by a loss of speech and hearing. Eventually, the afflicted person becomes spastic, then coma and death follow	Worldwide	The use of tin in advanced industrial societies has increased 14-fold over the last 10 years	Tin cans are rare. Many tin cans are coated on the inside with enamel or other materials. Most cans are steel	Currently, not much is known about the amount of tin in the human diet

TABLE 1.13
Edible Weeds

Common Name	Scientific Name	Use
Maple tree	Acer (many varieties)	Sap can be collected and reduced by evaporation into syrup
Sweetflag	Acorus calamus	Rootstocks or stems are edible with a sweet taste. Young shoots can be used as salad
Quackgrass	Agropyron repens L. (has many other names)	Rootstocks can be chewed or scorched to use as coffee substitute; seeds can be used for breadstuffs and for beer
Waterplantain	Alisma spp.	Root is starchy and edible; should be dried to reduce acrid taste. Three varieties of this plant can be toxic.
Garlic mustard	Alliaria petiolata	Leaf, stem, flower, and fruit are spicy and hot. If cooked, some of this spiciness is lost. Several plants that resemble this one are not edible
Wild garlic	Allium vineale L.	Used as an herbal seasoning; there are similar plants that are not garlic in aroma; they can be toxic
Pigweed	Amaranthus spp.	Leaves from a young plant can be eaten raw as salad or boiled as is spinach
Serviceberry	Amelanchier spp.	Berries are rich and sweet; pits and leaves contain cyanide; also called shadbush or juneberry
Hog peanut	Amphicarpaea bracteata	Fleshy seedpods found underground are edible
Ground nut	Apios americana Medik	Root can be eaten raw or cooked. Seeds can also be used. Europeans use the term ground nut to refer to peanuts. This is not the same plant
Common burdock	Arctium minus	Young leaves can be eaten as salad; roots are carrot-like in shape and can be cooked (boiled) and eaten. A little baking soda added to the cooking water improves tenderness and flavor. Scorched roots can be used as a coffee substitute
Giant reed	Arundo donax L.	Young shoots and rootstalks are sometimes sweet enough to be used as a substitute for sugar cane. Infusions of the root stocks can have some herbal properties — local weak anesthetic and in some instances either a hypotensive agent or hypertensive agent (depends on dose)
Milkweed	Asclepias syriaca L.	Young shoots, flower buds boiled with at least two changes of water. The plant contains cardiac glycosides and can be toxic
Pawpaw	Asimina triloba L.	The aromatic fruits are quite tasty. Seeds and bark have pesticide properties and should be handled with caution
Wild oat	Avena fatua L.	Seeds are similar to cultivated oats. Useful when dried and ground as a cereal. Seeds can be scorched and used as a coffee substitute
Wintercress/Yellow rocket	Barbarea spp. (B. vcma; B. vulgaris)	Young leaves and stems can be used as a salad
Birches	Betula spp. (Betulacea)	Spring sap can be reduced to a syrup; bark can be boiled for tea
Mustard, black or yellow	Brassica nigra	Seeds used to prepare mustard; leaves can be boiled for consumption, as can young stalks
Bromegrass	Bromus japonicus	Seeds can be dried, ground, and used as cereal
Shepherd's purse	Capsella bursa-pastoris	Seeds are used as a spicy pot herb. Tender young shoots can be eaten raw. Has a peppery taste
Bittercress	Cardamme bulbosa	Roots can be ground for a horseradish substitute; leaves and stems can be added to salad. The roots of some species (C. bulbosa) can be toxic
Hornbeam	Carpus caroliniana	Nuts are edible
Hickory	Carya spp.	Nuts are edible
Chestnut	Castanea spp.	Nuts are edible but are covered by a prickly coat. Roasting improves flavor and texture
Sandbur	Cenchrus spp.	Seeds and burrs can be used as cereal grains
Lambsquarter	Chenopodium album L.	Leaves can be eaten raw or cooked as spinach. The Mexican version (Mexicantea, C. ambrosioides) is toxic
Oxeye daisy	Chrysanthemum leucanthemum	Leaves and flowers can be eaten raw or cooked
Chicory	Cichorium intybus L.	Leaves are good salad ingredients
Thistles	Cirsium spp.	The taproot is chewy but tasty
Wandering Jew	Commelina communis	Leaves can be used as potherbs; flowering shoots can be eaten raw
Hawthorn	Crataegus spp.	Berries are edible; thorns can be a problem when gathering the berries. Some species contain heart stimulants
Wild chervil	Cryototaenia canadensis	Roots can be boiled, with a taste like parsnips; young leaves and stems can be eaten as salad; has an herb use in stews and soups
Nutgrass	Cyperus spp.	Tubers can be eaten or ground up to make a beverage called "chufa" or "horchata"

Queen Anne's lace, also called wild carrot	*Daucus carota* L.	Root can be eaten after boiling; however, because it looks like poisonous hemlock, one should be cautious
Crabgrass	*Digitaria snaguinalis* L.	Seeds can be dried and ground for use as a cereal
Persimmon	*Diospyros virginiana* L.	Fruits when ripe are very sweet
Barnyard grass	*Echinochloa crus-galli* L.	Seeds can be dried and used as cereal
Russian olive	*Elaegnus angustifolia* L.	Fruits are edible though astringent
American burnweed	*Erechtites hieracifolia*	Leaves can be eaten raw as salad or cooked
Redstem filaree	*Erodium cicutarium*	Tender leaves are eaten as salad; can also be used as potherb
Wild strawberry	*Fragaria virginiana*	Fruits are small but delicious
Catchweed bedstraw	*Galium aparine*	Young shoots are good potherbs; leaves and stems can be steamed and eaten as vegetable
Wintergreen	*Gaultheria procumbens* L.	Berries, foliage, and bark can be used to make tea. Berries can be eaten raw
Huckleberry	*Gaylussacia baccata*	Berries can be eaten raw or cooked
Honey locust	*Gleditsia triacanthos*	The pulp around the seeds can be used as a sweetener. (Tender green pods can also be cooked and eaten as a vegetable.) The tree is similar in appearance to the Kentucky coffee tree, and the pods of this tree cannot be eaten
Jerusalem artichoke	*Helianthus tuberosus*	The tubers are crisp and can be used in place of chinese chestnuts in salads; can also be cooked and mashed
Daylily	*Hemerocallis fulva* L.	Flower buds can be used in salads. Tubers can be cooked and eaten. Can cause diarrhea in sensitive people
Foxtail barley	*Hordeum jubatum*	Seeds can be dried and used as cereal
Touch-me-not	*Impatiens* spp.	Leaves can be used for an herbal tea; leaves can be eaten as salad; pods are also edible
Burning bush	*Kochia scoparia*	Young shoots can be used as a potherb; seeds can be dried and used as cereal
Prickly lettuce	*Lactuca scariola* L.	Young leaves can be used as salad, but may have a bitter taste
Virginia peppergrass	*Lepidium virginicum*	Has a pungent mustard-like taste; used as a potherb
Bugleweed	*Lycorise* spp.	Roots can be eaten raw or cooked
Common mallow	*Malva neglecta*	Boiled leaves have a slimy consistency much like okra. Flower buds can be pickled; leaves can be used as a thickener for soup
Black medic	*Medicago lupulina*	Sprouts can be added to salads for texture; leaves can be used as a potherb
Mulberry	*Mortis* spp.	Berries can be eaten out of hand
Watercress	*Nasturtium officinale* R.	Leaves can be eaten raw or used as a potherb
American lotus	*Nelumbo lutea*	Entire plant is edible
Yellow water lily	*Nuphar luteum* L.	Tubers when cooked are a starch substitute
Fragrant water lily	*Nymphaea odorata*	Flower buds and young leaves can be boiled and eaten; seeds can be dried and used as cereal
Evening primrose	*Oenothera biennis* L.	Seeds are a source of g linolenic acid; tap roots can be eaten raw or cooked
Wood sorrel	*Oxalis* spp.	Leaves can be eaten cooked or raw; seed pods can also be eaten
Perilla mint	*Perilla frutescens* L.	Leaves can be eaten cooked or raw
Common reed	*Phragmites communis*	Young shoots are edible. Plant is similar to the poisonous *Arundo*, so the forager should be very careful to correctly identify the plant
Ground cherry (Chinese lanterns)	*Physalis heterophylla*	Berries can be eaten cooked or raw
Pokeweed	*Phytolacca americana* L.	Young shoots can be used as a potherb; berries and roots may be poisonous
Plantain	*Plantago major* L.	Leaves can be used in salads
Mayapple	*Podophyllum peltatum*	Fruits are edible raw or cooked; rest of the plant may be poisonous
Japanese knotweed	*Polygonum cuspidatum*	Young sprouts can be cooked and eaten like asparagus
Purslane	*Portulaca oleracea* L.	Young leaves can be used as a potherb or salad ingredient
Healall	*Prunella vulgaris* L.	Boiled and used as a potherb
Wild cherry	*Prunus serotina*	Fruits are edible

TABLE 1.13
(Continued)

Common Name	Scientific Name	Use
Kudzu	*Pueraria lobata*	Roots and leaves are edible
Rock chestnut oak	*Quercus prinus* L.	Nuts (acorns) are edible
Sumac	*Rhus glabra* L.	Berries are edible as are the roots; however, some people are allergic to all parts of the plant and will develop skin rash
Multiflora rose	*Rosa multiflora*	The hips are edible in small quantities
Raspberry, blackberry	*Rubus* spp.	Fruits are eaten raw or used to make juice or jam
Red sorrel	*Rumex acetosella* L.	Leaves can be eaten as salad or cooked in water. The leaves contain a lot of oxalic acid, so small quantities would be preferred
Arrowhead	*Sagittaria latifolia* Willd	Roots can be eaten raw or cooked. Plants resemble the poisonous Jack-in-the-pulpit plant, so gatherers should beware
Elderberry	*Sambucus canadensis*	Fruits can be eaten raw or cooked
Hardstem bulrush	*Scrpus acutus* Muhl	Roots can be boiled and eaten
Foxtail grass	*Setaria* spp.	Seed grains can be dried and used as cereal
Tumble mustard	*Sisymbrium altissimum* L.	All parts of the plant are edible but have a strong mustard flavor; better used as a potherb
Roundleaf cabriar	*Smilax rotundiflora* L.	Young tender shoots can be eaten raw. Young leaves can be eaten as salad; roots can be used for tea
Sowthistle	*Sonchus oleraceus* L.	Leaves are prickly and bitter but can be used as a potherb
Johnson grass	*Sorghum halepense* L.	Young shoots can be eaten raw; seeds can be dried and used as cereal; mature stalks can be ground and the liquid extracted for use as syrup
Chickweed	*Stellaria media* L.	Leaves can be eaten raw or cooked
Dandelion	*Taraxacum officinale*	All parts of the plant are edible
Stinkweed	*Thlaspi arvense* L.	All parts of the plant are edible after cooking
Western salsify	*Tragopogon dubius* Scopoli	Roots can be eaten after boiling; leaves, flowers, and stems can be eaten raw
Red clover	*Trifolium pratense* L.	Flowers can be boiled to make a broth; powdered leaves and flowers can be used as seasoning
Coltsfoot	*Tussilago farfara* L.	Can be used as a potherb in small amounts
Cattail	*Typha* spp.	Roots, stalks, and spears are edible
Stinging nettle	*Urtica dioica* L.	Can be eaten cooked or used as a potherb
Bellwort	*Uvularia perfoliata* L.	Young shoots can be cooked and eaten; leaves are bitter
Blueberry, gooseberry	*Vaccinium stamineun*	Berries can be eaten raw or used to make juice, jam, or jelly
Violet	*Viola papilionacea* Purish	Flowers are edible
Wild grapes	*Vitis* spp.	Fruits can be eaten raw or cooked
Spanish bayonnet	*Yucca filimentosa* L.	Flower buds can be eaten raw

Notes

1. Persons using this list should be aware that individuals may differ in their responses to these plants. For some consumers, allergic reactions may be elicited. For others, there may be chemicals in the plants that elicit an undesirable physiological effect. Still other plants, especially the water plants, may harbor parasites that may be injurious. The serious forager should consult a plant taxonomist to be sure that the plant gathered is an edible plant. There are many similar plants that may in fact be poisonous, while others are safe to consume.

2. Weeds are plants that grow in places where we humans do not want them to grow. As such, we may not recognize them as food. The aforementioned plants contain edible portions. Not all parts of these plants may be useful as human food. Some varieties, in fact, may contain toxic chemicals that, if consumed in large quantities, may cause problems. A number of the plants have been identified based on their use by Native Americans. These plants can have many different names as common names.

TABLE 1.14
Toxic Plants

Common and Scientific Name	Description	Toxic Parts	Geographical Distribution	Poisoning	Symptoms	Remarks
Baneberry and *Actaea* sp.	Perennial growing to 3 ft (1 m) tall from a thick root; compound leaves; small, white flowers; white or red berries with several seeds borne in short, terminal clusters	All parts, but primarily roots and berries	Native woodlands of North America from Canada south to Georgia, Alabama, Louisiana, Oklahoma, and the northern Rockies; red-fruited western baneberry from Alaska to central California, Arizona, Montana, and South Dakota	Attributed to a glycoside or essential oil, which causes severe inflammation of the digestive tract	Acute stomach cramps, headache, increased pulse, vomiting, delirium, dizziness, and circulatory failure	As few as six berries can cause symptoms persisting for hours. Treatment may be a gastric lavage or vomiting Bright red berries attract children
Buckeye (Horsechestnut) and *Aesculus* sp.	Shrub or tree; deciduous, opposite, palmately, divided leaves with five to nine leaflets on a long stalk; red, yellow, or white flowers; two- to three-valved, capsule fruit; with thick, leathery husk enclosing one to six brown shiny seeds	Leaves, twigs, flowers, and seeds	Various species throughout the United States and Canada; some cultivated as ornamentals, others grow wild	Toxic parts contain the glycoside, esculin	Nervous twitching of muscles, weakness, lack of coordination, dilated pupils, nausea, vomiting, diarrhea, depression, paralysis, and stupor	By making a "tea" from the leaves and twigs or by eating the seeds, children have been poisoned Honey collected from the buckeye flower may also cause poisoning. Roots, branches, and fruits have been used to stupefy fish in ponds. Treatment usually is a gastric lavage or vomiting
Buttercup and *Ranunculus* sp.	Annual or perennial herb growing to 16 – 32 in. (41 – 81 cm) high; leaves alternate entire to compound, and largely basal; yellow flowers borne singly or in clusters on ends of seed stalks; small fruits, single-seeded pods	Entire plant	Widely distributed in woods, meadows, pastures, and along streams throughout temperate and cold locations	The alkaloid protoanemonin, which can injure the digestive system and ulcerate the skin	Burning sensation of the mouth, nervousness, nausea, vomiting, low blood pressure, weak pulse, depression, and convulsions	Sap and leaves may cause dermatitis. Cows poisoned by buttercups produce bitter milk or milk with a reddish color
Castor bean and *Ricinus communis*	Shrub-like herb 4 – 12 ft (1.2 – 3.7 m) tall; simple, alternate, long-stalked leaves with 5 – 11 long lobes, which are toothed on margins; fruits oval, green, or red, and covered with spines; three elliptical, glossy, black, white, or mottled seeds per capsule	Entire plant, especially the seeds	Cultivated as an ornamental or oilseed crop primarily in the southern part of the United States and Hawaii	Seeds, pressed cake, and leaves poisonous when chewed; contain the phytotoxin, ricin	Burning of the mouth and throat, nausea, vomiting, severe stomach pains, bloody diarrhea, excessive thirst, prostration, dullness of vision, and convulsions; kidney failure and death 1 to 12 days later	Fatal dose for a child is one to three seeds, and for an adult two to eight seeds The oil extracted from the seeds is an important commercial product. It is not poisonous and it is used as a medicine (castor oil), for soap, and as a lubricant

TABLE 1.14
(Continued)

Common and Scientific Name	Description	Toxic Parts	Geographical Distribution	Poisoning	Symptoms	Remarks
Chinaberry and *Melia azedarach*	Deciduous tree 20 – 40 ft (6 – 12 m) tall; twice, pinnately divided leaves and toothed or lobed leaflets, purple flowers borne in clusters; yellow, wrinkled, rounded berries that persist throughout the winter	Berries, bark, flowers, and leaves	A native of Asia introduced as an ornamental in the United States; common in the southern United States and lower altitudes in Hawaii; has become naturalized in old fields, pastures, around buildings, and along fence rows	Most result from eating pulp of berries; toxic principal is a resinoid with narcotic effects	Nausea, vomiting, diarrhea, irregular breathing, and respiratory distress	Six to eight berries can cause the death of a child The berries have been used to make insecticide and flea powder
Death camas and *Zigadenus paniculatus*	Perennial herb resembling wild onions but the onion odor is lacking; long, slender leaves with parallel veins; pale yellow to pink flowers in clusters on slender seed stalks; fruit a three-celled capsule	Entire plant, especially the bulb	Various species occur throughout the United States and Canada; all are more or less poisonous	Due to the alkaloids zygadenine, veratrine, and others	Excessive salivation, muscular weakness, slow heart rate, low blood pressure, subnormal temperature, nausea, vomiting, diarrhea, prostration, coma, and sometimes death	The members of Lewis and Clark Expedition made flour from the bulbs and suffered the symptoms of poisoning. Later some pioneers died when they mistook death camas for wild onions or garlic
Dogbane (Indian hemp) and *Apocynum cannabinum*	Perennial herbs with milky juice and somewhat woody stems; simple, smooth, and oppositely paired leaves; bell-shaped, small, white to pink flowers borne in clusters at ends of axillary stems; paired, long, slender seed pods	Entire plant	Various species growing throughout North America in fields and forests, and along streams and roadsides	Only suspected, as it contains the toxic glycoside, cymarin and is poisonous to animals	In animals, increased temperature and pulse, cold extremities, dilation of the pupils, discoloration of the mouth and nose, sore mouth, sweating, loss of appetite, and death	Compounds extracted from roots of dogbane have been used to make a heart stimulant
Foxglove and *Digitalis purpurea*	Biennial herb with alternate, simple, toothed leaves; terminal, showy raceme of flowers, purple, pink, rose, yellow, or white; dry capsule fruit	Entire plant, especially leaves, flowers, and seeds	Native of Europe commonly planted in gardens of the United States; naturalized and abundant in some parts of the western United States.	Due to digitalis component	Nausea, vomiting, dizziness, irregular heartbeat, tremors, convulsions, and possibly death	Foxglove has long been known as a source of digitalis and steroid glycosides It is an important medicinal plant when used correctly
Henbane and *Hyoscyamus niger*	Erect annual or biennial herb with coarse, hairy stems 1 – 5 ft (30 – 152 cm) high; simple, oblong, alternate leaves with a few, coarse teeth, not stalked; greenish-yellow or yellowish with purple vein flowers; fruit a rounded capsule	Entire plant	Along roads, in waste places across southern Canada and northern United States, particularly common in the Rocky Mountains	Caused by the alkaloids, hyoscyamine hyoscine, and atropine	Increased salivation, headache, nausea, rapid pulse, convulsions, coma, and death	A gastric lavage of 4% tannic acid solution may be used to treat the poisoning

Plant	Description	Toxic part	Distribution	Toxic constituent	Symptoms	Remarks
Iris (rock mountain iris) and *Iris missouriensis*	Lily-like perennial plants often in dense patches; long, narrow leaves; flowers blue-purple; fruit a three-celled capsule	Leaves, but especially the rootstalk	Wet land of meadows, marshes, and along streams from North Dakota to British Columbia, Canada; south of New Mexico, Arizona, and California; scattered over entire Rocky Mountain area; cultivated species also common	An irritating resinous substance, irisin	Burning, congestion, and severe pain in the digestive tract; nausea and diarrhea	Rootstalks have such an acrid taste that they are unlikely to be eaten
Jasmine and *Geisemium sempervirens*	A woody, trailing, or climbing evergreen vine; opposite, simple, lance-shaped, glossy leaves; fragrant, yellow flowers; flattened two-celled, beaked capsule fruits	Entire plant, but especially the root and flowers.	Native to the southeastern United States; commonly grown in the Southwest as an ornamental	Alkaloids, geisemine, gelseminine, and gelsemoidine found throughout the plant	Profuse sweating, muscular weakness, convulsions, respiratory depression, paralysis, and death possible	Jasmine has been used as a medicinal herb, but overdoses are dangerous. Children have been poisoned by chewing on the leaves
Jimmyweed (Rayless goldenrod) and *Haplopappus heterophyllus*	Small, bushy, half-shrub with erect stems arising from the woody crown to a height of 2–4 ft (61–122 cm); narrow, alternate, sticky leaves; clusters of small, yellow flower heads at tips of stems	Entire plant	Common in fields or ranges around watering sites and along streams from Kansas, Oklahoma, and Texas to Colorado, New Mexico, and Arizona	Contains the higher alcohol, tremetol, which accumulates in the milk of cows and causes human poisoning known as "milk sickness"	Other species of *Haplopappus* probably are equally dangerous	White snakeroot also contains tremetol, and causes "milk sickness"
Jimsonwood (Thornapple) and *Datura stramonium*	Coarse, weedy plant with stout stems and foul-smelling foliage; large, oval leaves with wavy margins; fragrant, large, tubular, white to purple flowers; round, nodding or erect prickly capsule	Entire plant, particularly the seeds and leaves	Naturalized throughout North America; common weed of fields, gardens, roadsides, and pastures	Due to the alkaloids hyoscyamine, atropine, and hyoscine (scopolamine)	Dry mouth, thirst, red skin, disturbed vision, pupil dilation, nausea, vomiting, headache, hallucination, rapid pulse, delirium, incoherent speech, convulsion, high blood pressure, coma, and possibly death	Sleeping near the fragrant flowers can cause headache, nausea, dizziness, and weakness. Children using the flowers as trumpets while playing have been poisoned
Lantana (Red Sage) and *Lantana camara*	Perennial shrub with square twigs and a few spines; simple, opposite or whorled oval-shaped leaves with tooth margins; white, yellow, orange, red, or blue flowers occurring in flat-topped clusters; berry-like fruit with a hard, blue-black seed	All parts, especially the green berries	Native of the dry woods in the southeastern United States; cultivated as an ornamental shrub in pots in the northern United States and Canada; or a lawn shrub in the southeastern coastal plains, Texas, California, and Hawaii	Fruit contains high levels of an alkaloid, lantanin or lantadene A	Stomach and intestinal irritation, vomiting, bloody diarrhea, muscular weakness, jaundice, and circulatory collapse; death possible but not common	In Florida, these plants are considered a major cause of human poisoning. The foliage of lantana may also cause dermatitis
Larkspur and *Delphinium* sp.	Annual or perennial herb 2–4 ft (61–122 cm) high; finely; palmately divided leaves on long stalks; white, pink, rose, blue, or purple flowers each with a spur; fruit a many-seeded, three-celled capsule	Entire plant	Native of rich or dry forest and meadows throughout the United States but common in the West; frequently cultivated in flower gardens	Contains the alkaloids delphinine, delphinidine, ajacine, and others	Burning sensation in the mouth and skin, low blood pressure, nervousness, weakness, prickling of the skin, nausea, vomiting, depression, convulsions, and death within 6 h if eaten in large quantities	Poisoning potential of larkspur decreases as it ages, but alkaloids still concentrated in the seeds. Seeds are used in some commercial lice remedies

Continued

TABLE 1.14 (Continued)

Common and Scientific Name	Description	Toxic Parts	Geographical Distribution	Poisoning	Symptoms	Remarks
Laurel (mountain laurel) and *Kalmia latifolia*	Large evergreen shrubs growing to 35 ft (11 m) tall; alternate leaves dark green on top and bright green underneath; white to rose flowers in terminal clusters; fruit in a dry capsule	Leaves, twigs, flowers, and pollen grains	Found in moist woods and along streams in eastern Canada southward in the Appalachian Mountains and Piedmont, and sometimes in the eastern coastal plain	Contains the toxic resinoid, andromedotoxin	Increased salivation, watering of eyes and nose, loss of energy, slow pulse, vomiting, low blood pressure, lack of coordination, convulsions, and progressive paralysis until eventual death	The Mountain laurel is the state flower of Connecticut and Pennsylvania. Children making "tea" from the leaves or sucking on the flowers have been poisoned
Locoweed (Crazyweed) and *Oxytropis* sp.	Perennial herb with erect or spreading stems; pea-like flowers and stems — only smaller	Common throughout the south western United States	Contains alkaloid-like substances — a serious threat to livestock	In animals, loss of weight, irregular gait, loss of sense of direction, nervousness, weakness, and loss of muscular control	Locoweeds are seldom eaten by humans, and hence they are not a serious problem	There are more than 100 species of locoweeds
Lupine (Bluebonnet) and *Lupinus* sp.	Annual or perennial herbs; digitately divided, alternate leaves; pear-shaped blue, white, red, or yellow flowers borne in clusters at ends of stems; seeds in flattened pods	Entire plant, particularly the seeds	Wide distribution but most common in western North America; many cultivated as ornamentals	Contains lupinine and related toxic alkaloids	Weak pulse, slowed respiration, convulsions, and paralysis	Rarely have cultivated varieties poisoned children. Not all lupines are poisonous
Marijuana (hashish, Mary Jane, pot, grass)	A tall coarse, annual herb; palmately divided and long-stalked leaves; small, green flowers clustered in the leaf axils	Entire plant, especially the leaves, flowers, sap and resinous secretions	Widely naturalized weed in temperate North America; cultivated in warmer areas	Various narcotic resins but mainly tetrahydro-cannabinol (THC) and related compounds	Exhilaration, hallucinations, delusions, mental confusion, dilated pupils, blurred vision, poor coordination, weakness, and stupor; coma and death in large doses	Poisoning results form drinking the extract, chewing the plant parts, or smoking a so-called "reefer" (joint). The hallucinogenic and narcotic effects of marijuana have been known for more than 2000 years. Laws in the United States and Canada restrict the possession of living or dried parts of marijuana
Mescal bean (Frijolito) and *Sophora secundiflora*	Evergreen shrub or small tree growing to 40 ft (12 m) tall; stalked, alternate leaves 4 – 6 in (10 – 15 cm) long, which are pinnately divided and shiny, yellow-green above and silky below when young; violet-blue, pea-like flowers; bright red seeds	Entire plant, particularly the seed	Native to southwestern Texas and southern New Mexico; cultivated as ornamentals in the southwestern United States	Contains cytisine and other poisonous alkaloids	Nausea, vomiting, diarrhea, excitement, delirium, hallucinations, coma, and death; deep sleep lasting 2 to 3 days in nonlethal doses	One seed, if sufficiently chewed, is enough to cause the death of a young child. The Indians of Mexico and the Southwest have used the seeds in medicine as a narcotic and as a hallucinatory drug. Necklaces have been made from the seeds

Plant	Description	Part(s)	Distribution	Toxic constituent	Symptoms	Comments
Mistletoe and *Phoradendron serotinum*	Parasitic evergreen plants that grow on trees and shrubs; oblong, simple, opposite leaves, which are leathery; small, white berries	All parts, especially the berries	Common on the branches of various trees from New Jersey and southern Indiana southward to Florida and Texas; other species throughout North America	Contains the toxic amines, β-phenylethyl-amine and tyrosamine	Gastrointestinal pain, diarrhea, slow pulse, and collapse; possibly nausea, vomiting, nervousness, difficult breathing, delirium, pupil dilation, and abortion; in sufficient amounts, death within a few hours	Mistletoe is a favorite Christmas decoration. It is the state flower of Oklahoma. Poisonings have occurred when people eat the berries or make "tea" from the berries. Indians chewed the leaves to relieve toothache
Monkshood (Wolfsbane) and *Aconitum columbianum*	Perennial herb about 2 – 5 ft (61 – 152 cm) high; alternate, petioled leaves, which are palmately divided into segments with pointed tips; generally dark blue flowers with a prominent hood; seed in a short-beaked capsule	Entire plant, especially roots and seeds	Rich, moist soil in meadows and along streams from western Canada south to California and New Mexico	Due to several alkaloids, including aconine and aconitine	Burning sensation of the mouth and skin; nausea, vomiting, diarrhea, muscular weakness, and spasms; weak, irregular pulse, paralysis of respiration, dimmed vision, convulsions, and death within a few hours	Small amounts can be lethal. Death in humans reported from eating the plant or extracts made from it. It has been mistaken for horseradish
Mushrooms (toadstools) and *Amanita muscaria, Amanita verna, Chlorophyllum molybdites*	Common types with central stalk, and cap; flat plates (gills) underneath cap; some with deeply ridged, cylindrical top rather than cap	Entire fungus	Various types throughout North America	Depending on type of mushroom; complex polypeptides such as amanitin and possibly phalloidin; a toxic protein in some; the poisons ibotenic acid, muscimol, and related compounds in others	Vary with type of mushroom, but include death-like sleep, manic behavior, delirium, seeing colored visions, feeling of elation, explosive diarrhea, vomiting, severe headache, loss of muscular coordination, abdominal cramps, and coma and death from some types; permanent liver, kidney, and heart damage from other types	Wild mushrooms are extremely difficult to identify and are best avoided. There is no simple rule of thumb for distinguishing between poisonous and nonpoisonous mushrooms — only one or two bites are necessary for death from some species. During the month of December 1981, three people were killed, and two hospitalized in California after eating poisonous mushrooms
Nightshade and *Solanum nigrum, Solanum eleagnifolium*	Annual herbs or shrub-like plants with simple alternate leaves; small, white, blue, or violet flowers; black berries or yellow to yellow-orange berries depending on species	Primarily the unripe berries	Throughout the United States and southern Canada in waste places, old fields, ditches, roadsides, fence rows, or edges of woods	Contains the alkaloid solanine; possibly saponin, atropine, and perhaps high levels of nitrate	Headache, stomach pain, vomiting, diarrhea, dilated pupils, subnormal temperature, shock, circulatory and respiratory depression, and possible death	Some individuals use the completely ripe berries in pies and jellies. Young shoots and leaves of the plant have been cooked and eaten like spinach
Oleander and *Nerium oleander*	An evergreen shrub or small tree growing to 25 ft (8 m) tall; short-stalked, narrow, leathery leaves, opposite or in whorls of three; white to pink to red flowers at tips of twigs	Entire plant, especially the leaves	A native of southern Europe, but commonly cultivated in the southern United States and California	Contains the poisonous glycosides oleandrin and nerioside, which act similar to digitalis	Nausea, severe vomiting, stomach pain, bloody diarrhea, cold feet and hands, irregular heartbeat, dilation of pupils, drowsiness, unconsciousness, paralysis of respiration, convulsions, coma, and death within a day	One leaf of an oleander is said to contain enough poison to kill an adult. In Florida, severe poisoning resulted when oleander branches were used as skewers. Honey made from oleander flower nectar is poisonous

TABLE 1.14 (Continued)

Common and Scientific Name	Description	Toxic Parts	Geographical Distribution	Poisoning	Symptoms	Remarks
Peyote (Mescal buttons) and *Lophophora williamsii*	Hemispherical, spineless member of the cactus family growing from carrot-shaped roots; low, rounded sections with a tuft of yellow-white hairs on top: flower from the center of the plant, white to rose-pink; pink berry when ripe; black seeds	Entire plant, especially the buttons	Native to southern Texas and northern Mexico; cultivated in other areas	Contains mescaline, lophophorine and other alkaloids	Illusions and hallucinations with vivid color, anxiety, muscular tremors and twitching, vomiting, diarrhea, blurred vision, wakefulness, forgetfulness, muscular relaxation, and dizziness	The effects of chewing fresh or dried "buttons" of peyote are similar to those produced by LSD, only milder. In some states, peyote is recognized as a drug. Peyote has long been used by the Indians and Mexicans in religious ceremonies
Poison hemlock (poison parsley) and *Conium maculatum*	Biennial herb with a hairless purple-spotted or lined, hollow stem growing up to 8 ft (2.4 m) tall; turnip-like, long, solid taproot; large, alternate, pinnately divided leaves; small, white flowers in umbrella-shaped clusters, dry; ribbed, two-part capsule fruit	Entire plant, primarily seeds and root	A native of Eurasia, now a weed in meadows, and along roads and ditches throughout the United States and southern Canada where moisture is sufficient	The poisonous alkaloid coniine and other related alkaloids	Burning sensation in the mouth and throat, nervousness, dyscoordination, dilated pupils, muscular weakness, weakened and slowed heartbeat, convulsions, coma, and death	Poisoning occurs when the leaves are mistaken for parsley, the roots for turnips, or the seeds for anise. Toxic quantities seldom consumed because the plant has such an unpleasant odor and taste. Assumed by some to be the poison drunk by Socrates
Poison ivy (poison oak) and *Toxicondendron radicans*	A trailing or climbing vine, shrub, or small tree; alternate leaves with three leaflets; flowers and fruits hanging in clusters; white to yellowish fruit (drupes)	Roots, stems, leaves, pollen, flowers, and fruits	An extremely variable native weed throughout southern Canada and the United States with the exception of the west coast; found on flood plains, along lake shores, edges of woods, stream banks, fences, and around buildings	Skin irritation due to an oil-resin containing urushiol	Contact with skin causes itching, burning, redness, and small blisters; severe gastric disturbance and even death by eating leaves or fruit	Almost half of all persons are allergic to poison ivy. Skin irritation may also result from indirect contact such as animals (including dogs and cats), clothing, tools, or sports equipment
Pokeweed (Pokeberry) and *Phytolacca Americana*	Shrub-like herb with a large fleshy taproot; large, entire, oblong leaves which are pointed; white to purplish flowers in clusters at ends of branches; mature fruit a dark purple berry with red juice	Root stalk, leaves, and stems	Native to the eastern United States and southeastern Canada	Highest concentration of poison mainly in roots; contains the bitter glycosides, saponin and glycoprotein	Burning and bitter taste in mouth, stomach cramps, nausea, vomiting, diarrhea, drowsiness, slowed breathing, weakness, tremors, convulsions, spasms, coma, and death if eaten in large amounts	Young tender leaves and stems of pokeweed are often cooked as greens. Cooked berries are used for pies without harm. It is one of the most dangerous poisonous plants because people prepare it improperly
Poppy (common poppy) and *Papaver somniferum*	An erect annual herb with milky juice, simple, coarsely toothed, or lobed leaves; showy red, white, pink, or purple flowers; fruit an oval, crowned capsule; tiny seeds in capsule	Unripe fruits or their juice	Introduced from Eurasia and widely grown in the United States until cultivation without a license became unlawful	Crude resin from unripe seed capsule source of narcotic opium alkaloids	From unripe fruit, stupor, coma, shallow and slow breathing, depression of the central nervous system; possibly nausea and severe retching (straining to vomit)	The use of poppy extracts is a double-edged sword — addictive narcotics and valuable medicines. Poppy seeds used as toppings on breads are harmless

Name	Description	Toxic part	Distribution	Toxic constituent	Symptoms	Remarks
Rhododendron, azaleas and *Rhododendron* sp.	Usually evergreen shrubs; mostly entire, simple, leathery leaves in whorls or alternate; snowy white to pink flowers in terminal clusters; fruit a wood capsule	Entire plant	Throughout the temperate parts of the United States as a native and as an introduced ornamental	Contains the toxic resinoid, andromedotoxin	Watering eyes and mouth, nasal discharge, nausea, severe abdominal pain, vomiting, convulsions, lowered blood pressure, lack of coordination, and loss of energy; progressive paralysis of arms and legs until death, in severe cases	Cases of poisoning are rare in this country, but rhododendrons should be suspected of possible danger
Rosary pea (precatory pea) and *Abrus precatorius*	A twining, more or less woody perennial vine; alternate and divided leaves with small leaflets; red to purple or white flowers; fruit a short pod containing ovoid seeds which are glossy, bright scarlet over three-fourths of their surface, and jet black over the remaining one-fourth	Seeds	Native to the tropics, but naturalized in Florida and the Keys	Contains the phytotoxin abrin and tetanic glycoside, abric acid	Severe stomach pain in 1 to 3 days, nausea, vomiting, severe diarrhea, weakness, cold sweat, drowsiness, weak, fast pulse, coma, circulatory collapse, and death	The beans are made into rosaries, necklaces, bracelets, leis, and various toys, which receive wide distribution. Seeds must be chewed and swallowed to cause poisoning. Whole seeds pass through the digestive tract without causing symptoms. One thoroughly chewed seed is said to be potent enough to kill an adult or child
Snow-on-the-mountain and *Euphorbia marginata*	A tall annual herb, growing up to 4 ft (122 cm) high; smooth, lance-shaped leaves with conspicuously white margins; whorls of white petal-like leaves border flowers; fruit a three-celled, three-lobed capsule	Leaves, stems, milky sap	Native to the western, dry plains and valleys from Montana to Mexico; sometimes escapes in the eastern United States	Toxins causing dermatitis and severe irritation of the digestive tract	Blistering of the skin, nausea, abdominal pain, fainting, diarrhea, possibly death in severe cases	Milky juice of this plant is very caustic. Outwardly resembles a poinsettia
Skunk cabbage and *Veratrum californicum*	Tall, broadleaved herbs of the lily family, growing to 6 ft (183 cm) high; large, alternate pleated, clasping, and parallel-veined leaves; numerous whitish to greenish flowers in large terminal clusters; three-lobed, capsule fruit	Entire plant	Various species throughout North America in wet meadows, forests, and along streams	Poisoning: Contains such alkaloids as veradridene and veratrine	Nausea, vomiting, diarrhea, stomach pains, lowered blood pressure, slow pulse, reduced body temperature, shallow breathing, salivation, weakness, nervousness, convulsions, paralysis, and possibly death	These plants have been used for centuries as a source of drugs and as a source of insecticide. As the leaves resemble cabbage, they are often collected as an edible wild plant, but with unpleasant results
Tansy and *Tanacetum vulgare*	Tall, aromatic herb with simple stems to 3 ft (91 cm) high; alternate, pinnately divided, narrow leaves, flower heads in flat-topped clusters with numerous small, yellow flowers	Leaves, stems, and flowers	Introduced from Eurasia; widely naturalized in North America; sometimes found escarped along roadsides, in pastures, or other wet places; grown for medicinal purposes	Contains an oil, tanacetin, or oil of tansy	Nausea, vomiting, diarrhea, convulsions, violent spasms, dilated pupils, rapid and feeble pulse, and possibly death	Tansy and its oil are employed as an herbal remedy for nervousness, intestinal worms, to promote menstruation, and to induce abortion. Some poisonings have resulted from the use of tansy as a home remedy

Continued

TABLE 1.14
(Continued)

Common and Scientific Name	Description	Toxic Parts	Geographical Distribution	Poisoning	Symptoms	Remarks
Water hemlock and *Cicuta* sp.	A perennial with parsley-like leaves; hollow, jointed stems and hollow, pithy roots; flowers in umbrella clusters; stems streaked with purple ridges; 2 to 6 ft (61 to 183 cm) high	Entire plant, primarily the roots and young growth	Wet meadows, pastures, and flood plains of western and eastern United States, generally absent in the plains states	Contains the toxic resin-like higher alcohol, cicutoxin	Frothing at the mouth, spasms, dilated pupils, diarrhea, convulsions, vomiting, delirium, respiratory failure, paralysis, and death	One mouthful of the water hemlock root is reported to contain sufficient poison to kill manna adult Children making whistles and peashooters from the hollow stems have been poisoned The water hemlock is often mistaken for the edible wild artichoke or parsnip. However, it is considered to be one of the poisonous plants of the North Temperate Zone
White snakeroot and *Eupatorium rogosum*	Erect perennial with stems 1 to 5 ft (30 to 152 cm) tall; opposite oval leaves with pointed tips and sharply toothed edges, and dull on the upper surface but shiny on the lower surface; showy, snow white flowers in terminal clusters	Entire plant	From eastern Canada to Saskatchewan and south of Texas, Louisiana, Georgia, and Virginia	Contains the higher alcohol, tremetol and some glycosides	Weakness, nausea, loss of appetite, vomiting, tremors, labored breathing, constipation, dizziness, delirium, convulsions, coma, and death	Recovery from a nonlethal dose is a slow process, due to liver and kidney damage Poison may be in the milk of cows that have eaten white snakeroot — "milk sickness"

2 Microbiological Safety of Foods

Kumar S. Venkitanarayanan and Michael P. Doyle

CONTENTS

INTRODUCTION

The microbiological safety of foods is a major concern to consumers and to the food industry. Despite considerable progress made in technology, consumer education, and regulations, food safety continues to be a major challenge to our public health and economy. During the past two decades, food safety received considerable attention due to the emergence of several new food-borne pathogens and the involvement of foods that traditionally have been considered safe, in many food-borne disease outbreaks. Further,

industrialization of the food supply through mass production, distribution, increased globalization, and consumer demands for preservative-free, convenience foods and ready-to-eat meals highlight the significance of the microbial safety of foods. A study published by the U.S. Centers for Disease Control and Prevention (CDC), in 1999, reported an estimated 76 million cases of food-borne illnesses, which resulted in 325,000 hospitalizations and 5,000 deaths in the United States annually.[1] Besides the public health impact, outbreaks of food-borne illness impose major economic losses to both the food industry and society. The annual estimated cost of food-borne illnesses caused by the four most common pathogens alone account for approximately $6.9 billion.[2] The types of microbiological hazards associated with foods can be classified as bacterial, viral, fungal, and parasitic.

BACTERIAL FOOD-BORNE PATHOGENS

Bacteria are the major agents of microbial food-borne illnesses, and account for an estimated 4 million food-borne illnesses annually in the United States (Table 2.1).[1] Bacterial food-borne diseases can be classified into food-borne infections resulting from ingestion of foods containing viable cells of bacterial pathogens, and food-borne intoxications, which result from consumption of foods containing preformed toxins produced by toxigenic bacteria. The primary bacterial pathogens associated with food-borne diseases are discussed below.

Escherichia coli **O157:H7**

Enterohemorrhagic *Escherichia coli* O157:H7 emerged in 1982 as a food-borne pathogen, and is now recognized as a major public health concern in the United States. Many food-associated outbreaks are reported each year, with 217 confirmed cases reported in 2004.[3] Although approximately 50% of the reported outbreaks in the United States have been associated with consumption of undercooked beef burgers, a wide variety of other foods, including raw milk, roast beef, venison jerky, salami, yogurt, lettuce, unpasteurized apple juice, cantaloupe, alfalfa sprouts, and coleslaw, have been implicated as vehicles of *E. coli* O157:H7 infection.[4] In addition, outbreaks involving person-to-person and waterborne transmission have been reported.[4] Cattle have been implicated as one of the principal reservoirs of *E. coli* O157:H7,[5–8] with the terminal rectum being a principal site of colonization in adult animals.[9] *E. coli* O157:H7 can survive in bovine feces for many months,[10] hence potentially contaminating cattle, food, water, and the environment through contact with manure. Although surveys conducted in the 1980s and 1990s generally showed a low fecal prevalence of *E. coli* O157:H7 in cattle,[8,11,12] later studies using improved enrichment and isolation procedures have revealed that the overall prevalence of *E. coli* O157:H7 in cattle may be substantially higher than originally found.[13–16] A study by Elder et al.[13] revealed that, of cattle from 29 feedlots presented for slaughter in the Midwestern United States, 72% had at least one *E. coli* O157-positive fecal sample and 38% had positive hide samples. The study revealed an overall *E. coli* O157 prevalence of 28% (91 out of 327) in feces, and 11% (38 out of 355) on the hide. Studies by others revealed that the prevalence of *E. coli* O157 in feed lots in the United States can be as high as 63%, particularly during the summer, under muddy conditions, or with feeding of barley.[17,18] These results are of particular concern, because high fecal shedding and the presence of *E. coli* O157:H7 on hides can lead to contamination of foods of bovine origin with the pathogen during slaughtering and processing operations.[19] In addition, many *E. coli* O157:H7 outbreaks involving nonbovine foods, such as fruits and vegetables, are often linked to cross contamination of the implicated food with contaminated bovine manure.[20–23] Direct zoonotic and environmental transmission is a more recently recognized mode of *E. coli* O157:H7 spread to humans. Contact with the farm environment, including recreational or occupational visits, has been associated with *E. coli* O157:H7 infections in humans.[24,25] Since reduced fecal shedding of *E. coli* O157:H7 by cattle would potentially decrease food-borne outbreaks of *E. coli* O157:H7, a variety of approaches for reducing its carriage in cattle, including vaccination,[26] feeding cattle with competitive exclusion bacteria,[27] and supplementation of cattle diet with sodium chlorate,[28] have been explored.

Acidification is commonly used in food processing to control growth and survival of spoilage-causing and pathogenic microorganisms in foods. The U.S. Food and Drug Administration (FDA) does not regard foods with pH ≤ 4.6 (high-acid foods) to be microbiologically hazardous. However, *E. coli* O157:H7 has been associated with outbreaks attributed to high-acid foods, including apple juice, mayonnaise, fermented sausage, and yogurt,[29] raising concerns about the safety of these foods. Several studies have revealed that many strains of *E. coli* O157:H7 are highly tolerant to acidic conditions, being able to survive for extended periods of time in synthetic gastric juice and in highly acidic foods.[29,30] Further, exposure of *E. coli* O157:H7 to mild or moderate acidic environments can induce an acid tolerance response, which enables the pathogen to survive extreme acidic conditions. For example, acid-adapted cells of *E. coli* O157:H7 survived longer in apple cider, fermented sausage, and hydrochloric acid than nonacid-adapted cells.[31,32] However, *E. coli* O157:H7 is not unusually heat resistant[33] or salt tolerant[34] unless cells are preexposed to acid to become acid adapted. Acid-adapted *E. coli* O157:H7 cells have been determined to have increased heat tolerance.

In humans, two important manifestations of illness have been reported with *E. coli* O157:H7 infection. These include hemorrhagic colitis and hemolytic uremic syndrome (HUS).[36] Hemorrhagic colitis is characterized by a watery diarrhea that progresses into grossly bloody diarrhea, indicative of significant amounts of gastrointestinal bleeding. Severe abdominal pain is common, but fever is usually not present. The illness typically lasts from 2 to 9 days. HUS is a severe condition, particularly among the very young and the elderly, which involves damage to kidneys, leading to renal failure and death.

TABLE 2.1
Bacterial Food-Borne Pathogens

Microbe	Biochemical and Growth Characteristics	Sources/Reservoirs	Estimated No. of Food-Borne Cases Annually in the United States[1]	Vehicles	Incubation Period, Symptoms, and Duration	Detection Methods	Control/Prevention
Escherichia coli O157:H7	Gram negative, facultative anaerobe, nonsporeforming, optimum growth at 37 to 40°C, inability to grow at ≥44.5°C in presence of selective agents, inability to ferment sorbitol within 24 h, does not produce β-glucuronidase, acid tolerance	Cattle, humans	62,500	Raw or under-cooked beef, unpasteurized milk and apple juice, lettuce, alfalfa sprouts, and water	3–9 days. Severe abdominal cramps, watery diarrhea that can become bloody, absence of fever, kidney failure, seizures, and coma. Duration is days to weeks	Cultural methods followed by confirmatory biochemical tests[256,257] Latex agglutination assay[258,259] ELISA[260–262] PCR[263–265]	Adequate cooking of beef; pasteurization of milk and apple juice; use of potable water for drinking; avoid eating alfalfa and vegetable sprouts; good personal hygiene
Salmonella spp. (nontyphoid)	Gram negative, facultative anaerobe, oxidase negative, catalase positive, nonsporeforming, growth at 5–47°C, optimum growth at 37°C, metabolize nutrients by respiratory and fermentative pathways	Cattle, swine, poultry, humans	1,340,000	Raw or under-cooked meat, poultry, eggs, and milk and untreated water	6–72 h up to 4 days. Abdominal cramps, diarrhea, fever, chills, headache and vomiting. Duration is few days to 1 week, occasionally up to 3 weeks	Cultural methods followed by confirmatory biochemical tests[266–268] Latex agglutination assay[269] ELISA[270] Immunoassay[271] PCR[272–275]	Adequate cooking of food; avoid cross-contamination of raw foods of animal origin with cooked or ready to eat foods; avoid eating raw or undercooked foods of animal origin; use of potable water; good personal hygiene
Salmonella typhi	Gram negative, facultative anaerobe, ferment D-xylose	Humans	660 (>70% of cases acquired abroad)	Raw milk, shellfish, raw salads, under cooked foods	7–28 days. Remittent fever with stepwise increments over a period of days, high temperature of 103 to 104 F, abdominal pain, diarrhea, and headache. Duration is up to 3 weeks	Biochemical tests[276] Latex test[277] ELISA[278] PCR[279,280]	Good personal hygiene and food handling practices; proper sewage systems; effective surveillance of known carriers
Campylobacter jejuni and *coli*	Gram negative, microaerophilic, nonsporeforming, optimal growth at 42°C, CO_2 is required for good growth, growth optimal in 3–6% O_2, sensitive to dehydration, survives best at refrigeration temperature	Poultry Swine Cattle Sheep Wild birds	1,960,000	Raw or under-cooked, poultry, pork, and beef, and unpasteurized milk	1–11 days, usually 2 to 5 days. Abdominal pain, diarrhea, malaise, headache, fever. Duration is up to 10 days	Cultural methods followed by confirmatory biochemical Tests[69,281] Immunoassay[282,283] PCR[284–289]	Adequate cooking of meat; avoid cross-contamination of raw foods of animal origin with cooked or ready to eat foods; pasteurization of milk
Shigella spp.	Gram negative, facultative anaerobe, nonsporeforming, does not ferment lactose, growth at 10–45°C, optimal growth at 37°C	Humans	89,600	Raw foods and water contaminated with human feces; prepared salads	1–7 days. Severe abdominal and rectal pain, bloody diarrhea with mucus, fever. Dehydration. Duration is few days to few weeks	Cultural methods followed by confirmatory biochemical tests[290] ELISA[291,292] PCR[293–296]	Good personal hygiene, adequate cooking of food, drinking potable water

TABLE 2.1 (Continued)

Microbe	Biochemical and Growth Characteristics	Sources/ Reservoirs	Vehicles	Estimated No. of Food-Borne Cases Annually in the United States[1]	Incubation Period, Symptoms, and Duration	Detection Methods	Control/Prevention
Yersinia enterocolitica	Gram negative, facultative anaerobe, nonsporeforming, growth at 0–44°C, optimal growth at ~29°C, growth at pH 4.6–9.0, growth in presence of 5% NaCl but not 7% NaCl	Swine is principal reservoir of pathogenic strains Humans can also act as a source through contaminated blood transfusion	Undercooked or raw pork, especially tongue	86,700	1–11 days, usually 24–36 h Severe abdominal pain, nausea, diarrhea, fever, sometimes vomiting Duration is usually 2–3 days but may continue for up to 3 weeks	Cultural methods followed by confirmatory biochemical tests[297] PCR[298–300]	Adequate cooking of pork, disinfection of drinking water, control of *Y. enterocolitica* in pigs, prevent cross-contamination of pig viscera, feces, and hair with food and water
Vibrio cholerae	Gram negative, facultative anaerobe, nonsporeforming, growth at 18–42°C with optimal growth at 37°C, growth is stimulated in presence of 3% NaCl, pH range for growth is 6–11	Humans, marine waters, especially brackish water and estuaries	Undercooked or raw seafoods; vegetables fertilized with contaminated human feces or irrigated with contaminated water; water	49	1–3 days Profuse watery diarrhea, which can lead to severe dehydration, abdominal pain, vomiting Duration is up to 7 days	Cultural methods followed by confirmatory biochemical tests[301–303] ELISA[304,305] Immunoassay[306] PCR[307–310]	Safe disposal of human sewage, disinfection of drinking water, avoid eating raw seafood, adequate cooking of food
Vibrio parahaemolyticus	Gram negative, facultative anaerobe, nonsporeforming, growth in presence of 8% NaCl, optimal growth at 37°C with rapid generation time (≈10 min), growth at 10°C, sensitive to storage at refrigeration temperature	Coastal seawater, estuarine brackish waters above 15°C, marine fish, shellfish	Raw or under-cooked fish and seafoods	5,100	9–25 h, up to 3 days, Profuse watery diarrhea, abdominal pain, vomiting, fever Duration is up to 8 days	Cultural methods followed by confirmatory biochemical tests[301,302] ELISA[311] PCR[312–314]	Adequate cooking of seafood, rapid chilling of seafoods, prevent cross-contamination from raw seafoods to other foods and preparation surfaces
Vibrio vulnificus	Gram negative, nonsporeforming, optimal growth at 37°C	Coastal and estuarine waters	Raw seafood, especially raw oysters	47	12 h to 3 days, Profuse diarrhea with blood in feces, fulminating septicemia, hypotension Duration is days to weeks	Cultural methods followed by confirmatory biochemical tests[301,302,315] ELISA[316,317] PCR[318,319]	Avoid eating raw seafood, especially raw oysters when one has a history of liver disease or alcoholism
Enterobacter sakazakii	Gram negative, Facultative anaerobe, nonsporeforming, α-glucosidase-positive phosphoamidase-negative growth at 5.5 to 37°C, tolerant to high osmotic pressure and desiccation	Not known	Dry, powdered infant formula	Very few	Sepsis, meningitis, meningo-encephalitis, brain abscess, ventriculitis, hydrocephalus, necrotizing enterocolitis largely in preterm infants Bacteremia, osteomyelitis and pneumonia in elderly adults	Cultural and biochemical methods[320,321] PCR[322,323]	Proper refrigerated storage of reconstituted infant formula Avoid feeding formula that has been temperature abused Prepared infant formula should not be kept warm in bottle heaters for more than 2 h

Organism	Characteristics	Reservoir	Associated Foods	Cases	Symptoms/Onset	Detection Methods	Prevention
Aeromonas hydrophila	Gram negative, facultative anaerobe, nonsporeforming, oxidase positive, some strains are psychrotrophic (4°C) optimum growth at ~28°C	Aquatic environment, freshwater fish (especially Salmonids)	Untreated water Undercooked seafoods, especially fish	Very few	24 to 48 h Abdominal pain, vomiting, watery stools, mild fever Duration is days to weeks	Cultural methods followed by confirmatory biochemical tests[324–327] ELISA[328] PCR[329–331]	Avoid consumption of raw seafoods, avoid long-term storage of refrigerated foods, adequate cooking of foods, disinfection of drinking water
Plesiomonas shigelloides	Gram negative, facultative anaerobe, nonsporeforming, oxidase positive, some strains are psychrotrophic	Fresh and estaurine waters, fish, and shellfish	Fish, shellfish, oysters, shrimp, and untreated water	Very few	1 to 2 days Abdominal pain, nausea, vomiting, diarrhea, chills, headache Duration is days to weeks	Cultural methods followed by confirmatory biochemical tests[324,325] PCR[332]	Avoid consumption of raw seafoods, disinfection of drinking water
Listeria monocytogenes	Gram positive, facultative anaerobe, nonsporeforming, growth at 2 to 45°C, optimal growth at 30 to 35°C, growth in presence of 10% NaCl	Soil, sewage, vegetation, water, and feces of humans and animals	Raw milk, soft cheese, pâte, ready-to-eat cooked meat products (poultry, hot dogs) and cooked seafoods (smoked fish), and raw vegetables	2,490	Few days to several weeks Flu-like symptoms such as fever, chills, headache. abdominal pain and diarrhea are present in some cases In pregnant women, spontaneous abortion and stillbirth Duration is days to weeks	Cultural methods followed by confirmatory biochemical tests[333–336] Immunoassay[337–339] PCR[340–342]	Proper sanitation of food processing equipment and environments, adequate cooking of meat and meat products, prevent recontamination of cooked products, proper reheating of cooked food, avoid drinking raw milk, avoid certain high-risk foods (e.g., soft cheeses and pâtes) by pregnant women and immunocompromised individuals
Staphylococcus aureus (staphylococcal enterotoxin)	Gram positive, facultative anaerobe, nonsporeforming, coagulase positive, growth at 7 to 48°C, optimal growth at ~37°C, toxin production at a_w of 0.86, toxin is heat stable (can withstand boiling for 1 h)	Humans (nose, throat, and skin) and animals	Ham, chicken and egg salads, cream-filled pastries	185,000	2 to 6 h Abdominal cramps, nausea, vomiting, diarrhea, headache, chills, and dizziness Duration is up to 2 days	Cultural methods followed by confirmatory biochemical tests[343,344] PCR[345–347] Immunoassay[348–350] Detection of toxin by microslide gel double diffusion[351]	Good personal hygiene in food preparation and handling, adequate cooking of foods, proper refrigeration of cooked foods
Clostridium botulinum (botulinum neurotoxin)	Gram positive, obligate anaerobe, sporeforming, produce seven potent neurotoxins A to G (only A, B, E and rarely F associated with human illness), proteolytic strains grow at 10 to 50°C, nonproteolytic strains can grow at 3.3°C, spores are resistant to normal cooking temperatures, and survive freezing and drying	Soil, dust, vegetation, animals, birds, insects, and marine and fresh water sediments and the intestinal tracts of fish (type E)	Beef, pork, fish, vegetables, and honey (infant botulism)	58	12 to 36 h, can range from few hours to 8 days Very severe life-threatening intoxication, headache, fixed and dilated pupils, vertigo, blurred or double vision, lack of muscle coordination, dry mouth, and difficulty in breathing Gastrointestinal symptoms include abdominal pain, nausea, vomiting, and constipation Duration is days to months (8 months)	Cultural methods followed by confirmatory biochemical tests[352] PCR[353–357] Detection of toxin by mouse bioassay[358] immunoaffinity chromatograpy[359] mass spectro-photometry[360] immunodetection kit[361]	Boiling of foods will destroy toxin, adequate heat processing of home-canned foods, proper refrigeration of vacuum-packaged fresh or lightly cooked/smoked foods, acid-preserved foods should be below pH 4.6, discard swollen cans, avoid feeding honey to infants

Microbe	Biochemical and Growth Characteristics	Sources/ Reservoirs	Vehicles	Estimated No. of Food-Borne Cases Annually in the United States[1]	Incubation Period, Symptoms, and Duration	Detection Methods	Control/Prevention
Clostridium perfringens	Gram positive, anaerobe, sporeforming, optimum growth at 37 to 47°C, grows slowly below 20°C	Soil, sewage, dust, vegetation, feces of humans and animals	Cooked meat and poultry, especially roast beef, turkey, and gravies	249,000	8 to 24 h. Abdominal pain and diarrhea. Duration is 1 to 2 days	Cultural methods followed by confirmatory biochemical tests[178]. Latex agglutination test[362]. Colony hybridization assay[363]. ELISA[364,365]. PCR[362,366,367]	Adequate cooking of foods; cooked food should be rapidly cooled (<5°C) or held hot (>60°C); proper refrigeration and adequate reheating of stored cooked foods
Bacillus cereus	Gram positive, facultative anaerobe, sporeforming, some strains can grow at 4 to 6°C; optimum growth at 28 to 37°C	Widely distributed in nature, soil, dust, vegetation	Cereals, fried rice, potatoes, cooked meat products, milk and dairy products, spices, dried foods	27,000	*Diarrheal syndrome* (toxic infection): 8 to 16 h. Abdominal pain, and watery diarrhea. Duration is 24 to 36 h. *Emetic syndrome* (preformed, heat-stable toxin): 1 to 5 h. Nausea, vomiting, malaise, and sometimes diarrhea. Duration is 24 to 36 h	Cultural methods followed by confirmatory biochemical tests[368]. ELISA[369,370]. Colony blot immunoassay[371,372]. PCR[373–375]	Adequate cooking of foods; cooked foods should be rapidly cooled (<5°C) or held hot (60°C); avoid leaving cooked foods at room temperature for long period of time
Brucella spp.	Gram negative, aerobe, nonsporeforming, optimal growth at 37°C	Cattle, sheep, pig, goat	Raw milk and products made from unpasteurized milk	780	Acute form: 3 to 21 days, infrequently months. Pyrexia, profuse sweats, chills, constipation, weakness, malaise, body aches, joint pains, weight loss, and anorexia. Chronic form: several months. Long history of fever, inertia, recurrent depression, sexual impotence, and insomnia. Duration is weeks	Cultural methods[376]. ELISA[377–379]. PCR[380–382]	Vaccination of livestock against *Brucella* spp., avoid contact with infected animals, eradication of diseased animals; pasteurization of milk; avoid eating unpasteurized dairy products
Helicobacter pylori	Gram negative, microaerophile to anaerobe	Humans, cats	Untreated water, food-borne transmission of disease has not been proven	Unknown	Gastritis, dyspepsia, peptic ulcer, and gastric carcinoma	Cultural methods[191,383]. ELISA[189]. Immunoassay[384,385]. PCR[386,387]. Rapid paper urease test[388]	Avoid contact with infected animals, use of chlorinated water for cooking and drinking

Two important factors attributed to the pathogenesis of *E. coli* O157:H7 include the ability of the pathogen to adhere to the intestinal mucosa of the host, and production of Shiga toxin I or Shiga toxin II.[35] Retrospective analysis of foods implicated in outbreaks of *E. coli* O157:H7 infection suggests a low infectious dose of the pathogen, probably less than 100 cells.[36]

SALMONELLA SPECIES

Salmonella spp. are facultatively anaerobic, gram-negative, rod-shaped bacteria belonging to the family *Enterobacteriaceae*. Members of the genus *Salmonella* have an optimum growth temperature of 37°C and utilize glucose with the production of acid and gas.[37] *Salmonella* spp. are widely distributed in nature. They colonize the intestinal tract of humans, animals, birds, and reptiles, and are excreted in feces, which contaminate the environment, water, and foods.[38] Many food products, especially foods having contact with animal feces, including beef, pork, poultry, eggs, milk, fruits, and vegetables, have been associated with outbreaks of salmonellosis.[39] *Salmonella* spp. can be divided into host-adapted serovars and those without any host preferences. Most of the food-borne serovars are in the latter group.

The ability of many strains of *Salmonella* to adapt to extreme environmental conditions emphasizes the potential risk of these microorganisms as food-borne pathogens. Although salmonellae optimally grow at 37°C, the genus *Salmonella* consists of strains which are capable of growth from 5 to 47°C.[40] *Salmonella* spp. can grow at pH values ranging from 4.5 to 7.0, with optimum growth observed near neutral pH.[38] Preexposure of *Salmonella* to mild acidic environments (pH 5.5 to 6.0) can induce in some strains an acid tolerance response, which enables the bacteria to survive for extended periods of exposure to acidic and other adverse environmental conditions such as heat and low water activity.[41,42] However, most *Salmonella* spp. possess no unusual tolerance to salt and heat. A concentration of 3 to 4% NaCl can inhibit the growth of *Salmonella*.[43] Most salmonellae are sensitive to heat; hence ordinary pasteurization and cooking temperatures are capable of killing the pathogen.[44]

Salmonellosis is one of the most frequently reported food-borne diseases worldwide.[45] The overall incidence of salmonellosis in the United States has been reported to have declined by approximately 8% during the period from 1996 to 2004.[46] In the United States, food-associated *Salmonella* infections are estimated to cost $0.5 to $2.3 billion annually.[47] The most common serovars of *Salmonella* that cause food-borne salmonellosis in humans are *Salmonella enterica* subsp. *enterica* serovar Typhimurium and *Salmonella enterica* subsp. *enterica* serovar Enteritidis. A wide variety of foods, including beef, pork, milk, chicken, and turkey have been associated with outbreaks caused by *S.* Typhimurium. Although the incidence of *S.* Typhimurium in the United States has decreased by approximately 40% during 1996 to 2004,[46] the emergence of *S.* Typhimurium DT 104, a new phage type in the 1990s in the United States and Europe raised a significant public health concern. This is because *S.* Typhimurium DT 104 is resistant to multiple antibiotics, including ampicillin, chloramphenicol, penicillin, streptomycin, tetracycline, and sulfonamides.[48,49] A major risk factor identified in the acquisition of *S.* Typhimurium DT 104 infection in humans is that the infecting strain is resistant to prior treatment with antimicrobial agents, for the 4 weeks preceding infection.[50] CDC reported that 11% of the total *Salmonella* spp. isolated from humans in 2000 were resistant to at least five different antibiotics, and a few of the multidrug-resistant strains were also resistant to gentamicin and cephalosporins.[51] These aforementioned reports underscore the prudent use of antibiotics in human therapy and animal husbandry.

Salmonella Enteritidis outbreaks are most frequently associated with consumption of poultry products, especially undercooked eggs and chicken. Moreover, international travel, especially to developing countries, has been associated with human infections of *S.* Enteritidis in the United States.[52] CDC reported 677 outbreaks of egg-borne *S.* Enteritidis with 23,366 illnesses, 1,988 hospitalizations, and 33 deaths in the United States during the period of 1990 to 2001.[53] Another report estimated 700,000 cases of egg-borne salmonellosis in the United States, accounting for approximately 47% of total food-borne salmonellosis and costing more than $1 billion annually.[47] Approximately 65 billion shell eggs are sold annually in the United States,[54] with a per capita consumption of approximately 254 eggs per year. Hence, undercooked *Salmonella*-contaminated eggs are a major hazard to human health. Egg contamination with *S.* Enteritidis results by penetration through the eggshell from contaminated chicken feces during or after oviposition.[55–57] Contamination of egg contents (yolk, albumen, and eggshell membranes) may also occur by transmission of the pathogen from infected ovaries or oviducts by the transovarian route before oviposition.[58–60]

Salmonella Typhi is the causative agent of typhoid fever, a serious human disease. Typhoid fever has a long incubation period of 7 to 28 days, and is characterized by prolonged and spiking fever, abdominal pain, diarrhea, and headache.[37] The disease can be diagnosed by isolating the pathogen from urine, blood, or stool specimens of affected persons. In 2003, 356 cases of typhoid fever were reported in the United States.[61] *S.* Typhi is an uncommon cause of food-borne illness in the United States, with approximately 74% of these cases occurring in persons who traveled internationally, especially to South Asia, 6 weeks preceding the disease appearance.[61]

CAMPYLOBACTER SPECIES

The genus *Campylobacter* consists of 14 species; however, *C. jejuni* subsp. *jejuni* and *C. coli* are the dominant food-borne pathogens. *C. jejuni* is a slender, rod-shaped, microaerophilic bacterium that requires approximately 3 to 6% oxygen for growth.

It can be differentiated from *C. coli* by its ability to hydrolyze hippurate.[62] The organism does not survive well in the environment, being sensitive to drying, highly acidic conditions, and freezing. It is also readily killed in foods by adequate cooking.[63]

C. jejuni is the most commonly reported bacterial cause of food-borne infection in the United States,[63–65] with the highest incidence in Hawai.[66] Many animals including poultry, swine, cattle, sheep, horses, and domestic pets, harbor *C. jejuni* in their intestinal tracts, hence serving as sources of human infection. However, chickens serve as the most common reservoir of *C. jejuni*, where the bacterium primarily colonizes the mucus overlying the epithelial cells in the ceca and small intestine. L-Fucose, the major carbohydrate component present in the mucin of chicken cecal mucus is used by *C. jejuni* as a sole substrate for growth.[67,68] Thus, the cecal environment in chickens is favorable for the survival and proliferation of *C. jejuni*,[67] and selects colonization of *C. jejuni* in the birds. Although a number of vehicles such as beef, pork, eggs, and untreated water have been implicated in outbreaks of campylobacter enteritis, chicken and unpasteurized milk are reported as the most commonly involved foods.[69] Epidemiologic investigations have revealed a significant link between human *Campylobacter* infection, and handling or consumption of raw or undercooked poultry meat.[70–74] Since colonization of broiler chickens by *C. jejuni* results in horizontal transmission of the pathogen and carcass contamination during slaughter, a variety of approaches for reducing its cecal carriage by chickens has been undertaken. These approaches include competitive exclusion microorganisms,[75] feeding birds with bacteriophages,[76,77] and acidified feed,[78] and vaccination.[79,80] In the United States, an increasing number of fluoroquinolone-resistant (e.g., ciprofloxacin) human *Campylobacter* infections has been reported,[81] and this is attributed to the use of this antibiotic in poultry production.[82]

Usually *Campylobacter enteritis* in humans is a self-limiting illness characterized by abdominal cramps, diarrhea, headache, and fever lasting up to 4 days. However, severe cases, involving bloody diarrhea and abdominal pain mimicking appendicitis, also occur.[62] Guillain-Barre syndrome (GBS) is an infrequent sequela to *Campylobacter* infection in humans.[83] GBS is characterized by acute neuromuscular paralysis[63] and is estimated to occur in approximately 1 of every 1000 cases of *Campylobacter* enteritis.[84] A few strains of *C. jejuni* reportedly produce a heat-labile enterotoxin similar to that produced by *Vibrio cholera*e and enterotoxigenic *E. coli*.[62] Some strains of *C. jejuni* and *C. coli* can also produce a cytolethal distending toxin, which causes a rapid and specific cell cycle arrest in HeLa and Caco-2 cells.[85]

Shigella Species

Shigella is a common cause of human diarrhea in the United States. The genus *Shigella* is divided into four major groups: *S. dysenteriae* (group A), *S. flexneri* (group B), *S. boydii* (group C), and *S. sonnei* (group D) based on the organism's somatic (O) antigen. Although all four groups have been involved in human infections, *S. sonnei* accounts for more than 75% of shigellosis cases in humans,[86] and has been linked to persistent infections in community and day-care centers.[87–89] Humans are the natural reservoir of *Shigella* spp. The fecal–oral route is the primary mode of transmission of shigellae and proper personal hygiene and sanitary practices of cooks and food handlers can greatly reduce the occurrence of outbreaks of shigellosis. Most food-borne outbreaks of shigellosis are associated with ingestion of foods such as salads and water contaminated with human feces containing the pathogen. Shigellosis is characterized by diarrhea containing bloody mucus, which lasts 1 to 2 weeks. The infectious dose for *Shigella* infection is low. The ID_{50} of *S. flexneri* and *S. sonnei* in humans is approximately 5000 microorganisms and that of *S. dysenteriae* is a few hundred cells, hence secondary transmission of *Shigella* by person-to-person contact frequently occurs in outbreaks of food-borne illness. A new and emerging serotype of *S. boydii*, namely serotype 20 has been reported in the United States.[90]

Yersinia enterocolitica

Yersinia enterocolitica is a gram-negative, rod-shaped, facultative anaerobic bacterium, which was first isolated and described during the 1930s.[91] Swine have been identified as an important reservoir of *Yersinia enterocolitica*, in which the pathogen colonizes primarily the buccal cavity.[92] Although pork and pork products are considered to be the primary vehicles of *Y. enterocolitica*, a variety of other foods, including milk, beef, lamb, seafood, and vegetables, has been identified as vehicles of *Y. enterocolitica* infection.[93] One of the largest outbreaks of yersiniosis in the United States was associated with milk.[94] Water has also been a vehicle of several outbreaks of *Y. enterocolitica* infection.[94] Surveys have revealed that *Y. enterocolitica* is frequently present in foods, having been isolated from 11% of sandwiches, 15% of chilled foods, and 22% of raw milk in Europe.[95] Several serovars of pathogenic *Y. enterocolitica* have been reported, which include O:3, O:5, O:8, and O:9,[96,97] with serovar 0:3 being common in the United States.[98–100] In addition to food-borne outbreaks, reports of blood transfusion-associated *Y. enterocolitica* sepsis indicate another potential mode of transmission of this pathogen.[101,102] Among bacteria, *Y. enterocolitica* has emerged as a significant cause of transfusion-associated bacteremia and mortality (53%), with 49 cases reported since this condition was first documented in 1975.[103] A review of these cases revealed that bacteremia may occur in a subpopulation of individuals with *Y. enterocolitica* gastrointestinal infection.[96] The strains of *Y. enterocolitica* responsible for transfusion-acquired yersiniosis are the same serobiotypes as those associated with enteric infections.

An unusual characteristic of *Y. enterocolitica* that influences food safety is its ability to grow at low temperatures, even as low as –1°C.[104] *Y. enterocolitica* readily withstands freezing and can survive in frozen foods for extended periods, even after repeated freezing and thawing.[105] Refrigeration (4°C) is one of the common methods used in food processing to control growth of spoilage and pathogenic microorganisms in foods. However, several studies have revealed growth of *Y. enterocolitica* in foods stored at refrigeration temperature. *Y. enterocolitica* grew on pork, chicken, and beef at 0 to 1°C.[106,107] The psychrotrophic nature of *Y. enterocolitica* also poses problems for the blood transfusion industry, mainly because of its ability to proliferate and release endotoxin in blood products stored at 4°C without manifesting any alterations in their physical appearance. The ability of *Y. enterocolitica* to grow well at refrigeration temperature has been exploited for isolating the pathogen from foods, water, and stool specimens. Such samples are incubated at 4 to 8°C in an enrichment broth for several days to selectively culture *Y. enterocolitica* based on its psychrotrophic nature.

Y. enterocolitica is primarily an intestinal pathogen with a predilection for extra-intestinal spread under appropriate host conditions such as immunosuppression. In the gastrointestinal tract, *Y. enterocolitica* can cause acute enteritis, enterocolitis, mesenteric lymphadenitis, and terminal ileitis often mimicking appendicitis.[96] Infection with *Y. enterocolitica* often leads to secondary, immunologically induced sequelae such as arthritis (most common), erythema nodosum, Reiter's syndrome, glomerulonephritis, and myocarditis.

Vibrio Species

Seafoods form a vital part of the American diet, and their consumption in the United States has risen steadily over the past few decades from an average of 4.5 kg per person in 1960 to about 7 kg in 2002.[108,109] However, according to a recent report published by the Center for Science in the Public Interest, contaminated seafoods have been recognized as a leading known cause of most food-borne illness outbreaks in the United States.[110] Vibrios, especially *V. parahaemolyticus*, *V. vulnificus*, and *V. cholerae*, which are commonly associated with estuarine and marine waters, represent the major pathogens resulting in disease outbreaks through consumption of seafoods. *V. parahaemolyticus* and *V. vulnificus* are halophilic in nature, requiring the presence of 1 to 3% sodium chloride for optimum growth. *V. cholerae* can grow in media without added salt, although their growth is stimulated by the presence of sodium ions.

Among the three species of *Vibrio*, *V. parahaemolyticus* accounts for the highest number of food-borne diseases outbreaks in the United States. *V. parahaemolyticus* is present in coastal waters of the United States and throughout the world. *V. parahaemolyticus* being an obligate halophile, can multiply in substrates with sodium chloride concentrations ranging from 0.5 to 10%, with 3% being the optimal concentration for growth. The ability of *V. parahaemolyticus* to grow in a wide range of salt concentrations reflects on its existence in aquatic environments with various salinities. *V. parahaemolyticus* has a remarkable ability for rapid growth, and generation times as short as 12 to 18 min in seafoods have been reported at 30ºC. Growth rates at lower temperatures are slower, but counts were found to increase from 10^2 to 10^8 CFU/g after 24 h storage at 25ºC in homogenized shrimp, and from 10^3 to 10^8 CFU/g after 7 days of storage at 12ºC in homogenized oysters.[111] Because of its rapid growth, proper refrigeration of cooked seafoods to prevent regrowth of the bacterium is critical to product safety. A survey by the U.S. FDA revealed that 86% of 635 seafood samples contained *V. parahaemolyticus*, being isolated from clams, oysters, lobsters, scallops, shrimp, fish, and shellfish.[112] A new serotype of *V. parahaemolyticus*, O3:K6 that emerged in Southeast Asia in the 1990s, has been implicated in oyster-related outbreaks in the United States in 1997 and 1998.[113] An important virulence characteristic of pathogenic strains of *V. parahaemolyticus* is their ability to produce a thermostable hemolysin (Kanagawa hemolysin).[114] Studies in humans on the infectious dose of pathogenic *V. parahaemolyticus* strains revealed that ingestion of approximately 10^5 to 10^7 organisms can cause gastroenteritis.[112]

V. cholerae serovars O1 and O139, the causative agents of cholera in humans, are a part of the normal estuarine microflora, and foods such as raw fish, mussels, oysters, and clams have been associated with outbreaks of cholera.[115] Infected humans can serve as short-term carriers, shedding the pathogen in feces. Cholera is characterized by profuse diarrhea, potentially fatal in severe cases, and often described as "rice water" diarrhea due to the presence of prolific amounts of mucus in the stools. Gastroenteritis caused by non-O1 and non-O139 serovars of *V. cholerae* is usually mild in nature. During the period from 1996 to 2005, a total of 64 cases of toxigenic *V. cholerae* O1 were reported in the United States, of which 35 (55%) cases, were acquired during foreign travel and 29 (45%) cases were domestically acquired.[116] Seven (24%) of the 29 domestic cases were attributed to consumption of Gulf Coast seafood (crabs, shrimp, or oysters). Moreover, 7 of the 11 domestic cholera cases in 2005 were reported during October to December, after Hurricanes Katrina and Rita, although no evidence suggests increased risk for cholera among Gulf Coast residents or consumers of Gulf Coast seafood after the hurricanes. In 2003, a total of 111,575 cases of cholera worldwide were reported to the World Health Organization from 45 countries.[117]

V. vulnificus is the most serious of the vibrios and is responsible for most of the seafood-associated deaths in the United States, especially in Florida.[112] *V. vulnificus* results in life threatening bacteremia, septicemia, and necrotizing fasciitis in person with liver disorders and high iron level in blood.[118] Although a number of seafoods has been associated with *V. vulnificus* infection, raw oysters are the most common vehicle associated with cases of illness.[119]

ENTEROBACTER SAKAZAKII

Enterobacter sakazakii is an emerging food-borne pathogen that causes severe meningitis, meningo-encephalitis, sepsis, and necrotizing enterocolitis in neonates and infants.[120–123] The epidemiology and reservoir of this pathogen are still unknown and most strains have been isolated from clinical specimens such as cerebrospinal fluid, blood, skin, wounds, urine, and respiratory and digestive tract samples.[124] The bacterium has also been isolated from foods such as cheese, minced beef, sausage, and vegetables.[125] Recently, Kandhai et al.[126,127] isolated *E. sakazakii* from household and food production facility environmental samples, such as scrapings from dust, vacuum cleaner bags, and spilled product near equipment, and proposed that the bacterium could be more widespread in the environment than previously thought. Although the environmental source of *E. sakazakii* has not been identified, epidemiological studies implicate dried infant formula as the route of transmission to preterm infants.[123,128–130] The bacterium has been isolated from powdered infant formula by numerous investigators.[129,131–133] Muytjens and coworkers[133] isolated the pathogen from powdered infant formula from 35 different countries.

E. sakazakii possesses several characteristics that enable it to grow and survive in infant formula. For example, the bacterium can grow at temperatures as low as 5.5°C,[134] which is within the temperature range of many home refrigerators.[135] A study on the thermal resistance of *E. sakazakii* in reconstituted infant formula indicated that it is one of most thermotolerant bacteria within the family Enterobacteriaceae.[136] A recent study by Breeuwer et al.[137] revealed that *E. sakazakii* also has a high tolerance to osmotic stress and desiccation. In addition, *E. sakazakii* possesses a short lag time and generation time in reconstituted infant formula,[134] whereby improper temperature storage of reconstituted formula may permit its substantial growth. Recently, Iversen and Forsythe[138] reported the isolation of *E. sakazakii* from a variety of foods, including powdered infant formula, dried infant food, and milk powder as well as certain herbs and spices. The first case of neonatal meningitis caused by *E. sakazakii* was reported in 1958,[139] and since then a number of *E. sakazakii* infections in neonates have been reported worldwide, including the United States. In the United States, an outbreak of *E. sakazakii* infection involving four preterm infants occurred in the neonatal intensive care unit of a hospital in Memphis, resulting in sepsis, bloody diarrhea, and intestinal colonization. The source of infection was traced to contaminated infant formula that was termperature abused after reconstitution.[129] In 2002, Himelright et al. [140] reported a case of fatal neonatal meningitis caused by *E. sakazakii* in Tennessee, associated with feeding of contaminated infant formula that was temperature abused following reconstitution. The infection occurred in the neonatal intensive care unit of a hospital and surveillance studies identified two more cases of suspected infection with positive stool or urine in seven more infants. There were many recalls of *E. sakazakii*-contaminated infant formula in the United States. In November 2002, a nationwide recall of more than 1.5 million cans of dry infant formula contaminated with *E. sakazakii* was reported.[141] On April 9, 2002, the FDA issued an alert to U.S. health-care professionals regarding the risk associated with *E. sakazakii* infections among neonates-fed milk-based, powdered-infant formula. The International Commission on Microbiological Specification for Foods classified *E. sakazakii* as a "severe hazard for restricted populations, life threatening or substantial chronic sequelae of long duration," specifically for preterm infants. This places *E. sakazakii* along with other serious food- and water-borne pathogens such as *Listeria monocytogenes*, *Clostridium botulinum* types A and B, and *Cryptosporidium parvum*.[142]

The most common clinical manifestations of infections due to *E. sakazakii* are sepsis and meningitis in neonates. In more than 90% of the cases reported, patients developed meningitis with a very high prevalence for developing brain abscesses, and less frequently ventriculitis and hydrocephalus.[143,144] While the reported mortality rates of *E. sakazakii* infections in neonates has declined over time from 50% or more to less than 20% due to advances in antimicrobial chemotherapy, an increasing incidence of resistance to commonly used antibiotics necessitates a reevaluation of existing treatment strategies.[124] Biering et al.[131] indicated that besides the high rate of mortality, the central nervous system (CNS) infections due to *E. sakazakii* often lead to permanent impairment in mental and physical capabilities in surviving patients. In addition to meningitis, *E. sakazakii* is also reported to cause necrotizing enterocolitis in neonates, and rarely bacteremia, osteomyelitis, and pneumonia in elderly adults.[122,123,145,146]

AEROMONAS HYDROPHILA

Although *Aeromonas* species have been recognized as pathogens of cold-blooded animals, their potential to cause human infections, especially food-borne illness, received attention only recently. *A. hydrophila* has been isolated from drinking water, fresh and saline waters, and sewage.[147] It also has been isolated from a variety of foods such as fish, oyster, shellfish, raw milk, ground beef, chicken, and pork.[147] Although *A. hydrophila* is sensitive to highly acidic conditions and does not possess any unusual thermal resistance, some strains are psychrotrophic and grow at refrigeration temperature.[148] *A. hydrophila* can grow on a variety of refrigerated foods, including pork, asparagus, cauliflower, and broccoli.[149,150] However, considering the widespread occurrence of *A. hydrophila* in water and food and its relatively infrequent association with human illness, it is likely that most strains of this bacterium are not pathogenic for humans. *A. hydrophila* infection in humans is characterized by watery diarrhea and mild fever. Virulent strains of *A. hydrophila* produce a 52-kDa polypeptide, which possesses enterotoxic, cytotoxic, and hemolytic activities.[151]

PLESIOMONAS SHIGELLOIDES

P. shigelloides has been implicated in several cases of sporadic and epidemic gastroenteritis.[152] The pathogen is present in fresh and estuarine waters, and has been isolated from various aquatic animals.[148] Seafoods such as fish, crabs, and oysters have been associated with cases of *P. shigelloides* infection. The most common symptoms of *P. shigelloides* infection include abdominal pain, nausea, chills, fever, and diarrhea. Potential virulence factors of *P. shigelloides* include cytotoxic enterotoxin, invasins, and β-hemolysin.[148] An outbreak of *P. shigelloides* infection linked to well water and involving 30 persons was reported in New York in 1996.[153]

LISTERIA MONOCYTOGENES

Listeria monocytogenes has emerged into a significant food-borne pathogen throughout the world, especially in the United States. There are an estimated 2500 cases of listeriosis annually in the United States, with a mortality rate of ≈25%.[1] Further, *L. monocytogenes* is of economic significance, causing an estimated monetary loss of $2.3 billion annually in the United States.[154] A large outbreak of listeriosis involving more than 100 cases and associated with eating contaminated turkey frankfurters occurred during 1998 to 1999.[155] During this period of time there were more than 35 recalls of a number of different food products contaminated with listeriae.[155] In 2002, a large outbreak of listeriosis in the United States involving 46 people, 7 deaths, and 3 miscarriages, resulted in a recall of 27.4 million pounds of fresh and frozen ready-to-eat chicken and turkey products.[156] In 2003, 696 cases of listeriosis were reported in the United States, with more than 50% of the cases occurring in persons above 60 years of age.[61]

L. monocytogenes is widespread in nature, occurring in soil, vegetation, and untreated water. Humans and a wide variety of farm animals, including cattle, sheep, goat, pig, and poultry, are known sources of *L. monocytogenes*.[157,158] *L. monocytogenes* also occurs frequently in food processing facilities, especially in moist areas such as floor drains, floors, and processing equipment.[159] *L. monocytogenes* can also grow in biofilms attached to a variety of processing plant surfaces such as stainless steel, glass, and rubber.[160] A wide spectrum of foods, including milk, cheese, beef, pork, chicken, seafoods, fruits, and vegetables, has been identified as vehicles of *L. monocytogenes*.[158] However, ready-to-eat cooked foods such as low-acid soft cheese, pâtes, and cooked poultry meat, which can support the growth of listeriae to large populations ($>10^6$ cells/g) when held at refrigeration temperature for several weeks, have been regarded as high-risk foods.[161,162] *L. monocytogenes* possesses several characteristics which enable the pathogen to successfully contaminate, survive, and grow in foods, thereby resulting in outbreaks. These traits include an ability to grow at refrigeration temperature and in a medium with minimal nutrients, to survive in acidic conditions, for example, pH 4.2, to tolerate up to 10% sodium chloride, to survive incomplete cooking or subminimal pasteurization treatments, and to survive in biofilm on equipment in food processing plants and resist superficial cleaning and disinfection treatments.[155]

Approximately 3 to 10% of humans carry listeriae in their gastrointestinal tract with no symptoms of illness.[163] Human listeriosis is an uncommon illness with a high mortality rate. The infection most frequently occurs in people who are older, pregnant, or immune compromised. Clinical manifestations range from mild influenza-like symptoms to meningitis, and meningoencephalitis. Pregnant females infected with the pathogen may not present symptoms of illness or may exhibit only mild influenza-like symptoms. However, spontaneous abortion, premature birth, or stillbirth are frequent sequela to listeriosis in pregnant females.[162] Although the infective dose of *L. monocytogenes* in not known, published reports indicate that it is likely to be more than 100 CFU/g of food.[162] However, the infective dose depends on the age, condition of health, and immunological status of the host.

L. monocytogenes crosses the intestinal barrier in hosts infected by the oral route. However, before reaching the intestine, the bacterium must withstand the adverse environment of the stomach. Gastric acidity may destroy a substantial number of *L. monocytogenes* ingested with contaminated food. The site at which intestinal translocation of *L. monocytogenes* occurs is not clearly elucidated. However, both epithelial cells and M cells in the Peyer's patches are believed to be the potential sites of entry.[164] The bacteria are then internalized by macrophages where they survive and replicate. This is followed by transport of the pathogen via blood to the mesenteric lymph nodes, spleen, and the liver. The primary site of *L. monocytogenes* replication in the liver is the hepatocyte. In the initial phase of infection, the infected hepatocytes are the target for neutrophils, and subsequently for mononuclear phagocytes, which aid in the control and resolution of the infection.[162] If the immune system fails to contain *L. monocytogenes*, subsequent propagation of pathogen via blood to the brain or uterus takes place.[165] The major virulence factors in *L. monocytogenes* include hemolysin, phospholipases, metalloprotease, Clp proteases and APTases, internalins, surface protein p104, protein p60, listeriolysin O, and the surface protein *ActA*.[162]

STAPHYLOCOCCUS AUREUS

A preformed, heat-stable enterotoxin produced by *S. aureus* that can resist boiling for several minutes is the agent responsible for staphylococcal food poisoning. Humans are the principal reservoir of *S. aureus* strains involved in outbreaks of food-borne illness.

In addition, a recent study revealed that *S. aureus* can be transmitted between healthy, lactating mothers without mastitis and their infants by breast-feeding.[166] Colonized humans can be long-term carriers of *S. aureus*, and thereby contaminate foods and other humans.[167] The bacterium commonly resides in the throat and nasal cavity, and on the skin, especially in boils and carbuncles.[167] Protein-rich foods such as ham, poultry, fish, dairy products, custards, cream-filled bakery products, and salads containing cooked meat, chicken, or potatoes are the vehicles most frequently associated with *S. aureus* food poisoning.[168] *S. aureus* is usually overgrown by competing bacterial flora in raw foods, hence raw foods are not typical vehicles of staphylococcal food poisoning. Cooking eliminates most of the normal bacterial flora of raw foods thereby enabling the growth of *S. aureus*, which can be introduced by infected cooks and food handlers into foods after cooking. The incubation period of staphylococcal food poisoning is very short, with symptoms being observed within 2 to 6 h after eating toxin-contaminated food. Symptoms include nausea, vomiting, diarrhea, and abdominal pain.

S. aureus can grow in media within a wide range of pH values from 4 to 9.3, with optimum growth occurring at pH 6 to 7. *S. aureus* has an exceptional tolerance to sodium chloride being able to grow in foods in the presence of 7 to 10% NaCl, with some strains tolerating up to 20% NaCl.[168] *S. aureus* also has the unique ability to grow at a water activity as low as 0.83 to 0.86.[169] *S. aureus* produces nine different enterotoxins which are quite heat resistant, losing their serological activity at 121°C, but not at 100°C for several minutes.[169]

Besides being a food-borne pathogen, *S. aureus* has emerged as an important pathogen in nosocomial infections and community-acquired diseases, because of its toxin-mediated virulence, invasiveness, and antibiotic resistance.[170] This is especially significant due to the emergence of methicillin-resistant strains of *S. aureus* (MRSA), and 50% of health-care-acquired *S. aureus* isolates in the United States in 1997 were methicillin resistant.[171] Although MRSA is commonly linked to nosocomial infections, the first report of MRSA-associated food-borne disease in a community was reported in 2002.[171]

CLOSTRIDIUM BOTULINUM

Food-borne botulism is an intoxication caused by ingestion of foods containing preformed botulinal toxin, which is produced by *C. botulinum* under anaerobic conditions. Botulinal toxin is a neurotoxin, which causes the neuroparalytic disease called botulism. The toxin binds irreversibly to the presynaptic nerve endings of the nervous system, where it inhibits the release of acetylcholine. Unlike botulism in adults, infant botulism results from the colonization and germination of *C. botulinum* spores in the infant's gastrointestinal tract. The disease usually occurs in infants during the second month of age, and is characterized by constipation, poor feeding or sucking, and decreased muscle tone with a "floppy" head.[172] Although the source of infection is unknown in most cases, the most commonly suspected food in infant botulism is honey.[173]

There are seven types of *C. botulinum* (A, B, C, D, E, F, and G) which are classified on the basis of the antigenic specificity of the neurotoxin they produce.[174] The bacterium is present in soil, vegetation, and sedimentation under water. Type A strains are proteolytic, whereas type E strains are nonproteolytic.[175] Another classification divides *C. botulinum* into four groups: group I (type A strains and proteolytic strains of types B and F), group II (type E strains and nonproteolytic strains of B and F), group III (type C and D strains), and group IV (type G strains). Types A, B, E, and F are associated with botulism in humans. Type A *C. botulinum* occurs frequently in soils of the western United States, whereas type B strains are more often present in the eastern states and in Europe.[175] Type E strains are largely associated with aquatic environments and fish. Foods most often associated with cases of botulism include fish, meat, honey, and home-canned vegetables.[174] Type A cases of botulism in the United States are frequently associated with temperature-abused, home-prepared canned foods. Proteolytic type A, B, and F strains produce heat-resistant spores, which pose a safety concern in low-acid canned foods. In contrast, nonproteolytic type B, E, and F strains produce heat-labile spores, which are of concern in pasteurized or unheated foods.[175] The minimum pH for growth of groups I and II strains is 4.6 and 5, respectively.[174] Group I strains can grow at a minimum water activity of 0.94, whereas group II strains do not grow below a water activity of 0.97.[176] The proteolytic strains of *C. botulinum* are generally more resistant to heat than nonproteolytic strains.

CLOSTRIDIUM PERFRINGENS

C. perfringens is a major bacterial cause of food-borne disease, with 1062 cases reported in the United States in 2004.[3] *C. perfringens* strains are grouped into five types: A, B, C, D, and E, based on the type(s) of toxin(s) produced. *C. perfringens* food-borne illness is almost exclusively associated with type A isolates. *C. perfringens* is commonly present in soil, dust, water, and in the intestinal tract of humans and animals.[177] It is frequently present in foods; about 50% of raw or frozen meat and poultry contain *C. perfringens*.[178] Spores produced by *C. perfringens* are quite heat resistant, and can survive boiling for up to 1 h.[178] *C. perfringens* spores can survive in cooked foods and if not properly cooled before refrigerated storage, the spores will germinate and vegetative cells can grow to large cell numbers during holding at growth temperatures. Large populations of *C. perfringens* cells ($>10^6$/g) ingested with contaminated food will enter the small intestine, multiply and sporulate. During sporulation in the small intestine *C. perfringens* enterotoxin is produced which induces a diarrheal response. The enterotoxin is a 35-kDa heat-labile polypeptide that damages the epithelial cells of the gastrointestinal tract to cause fluid and electrolyte loss.[179,180]

Although vegetative cells of *C. perfringens* are sensitive to cold temperature and freezing, spores tolerate cold temperature well and can survive in refrigerated foods.

BACILLUS CEREUS

Bacillus cereus is a spore-forming pathogen present in soil and on vegetation. It is responsible for a growing number of food-borne illnesses in the industrial countries,[181] with 103 outbreak-associated confirmed cases reported in the United States in 2004.[3] It is frequently isolated from foods such as meat, spices, vegetables, dairy products, and cereal grains, especially fried rice.[182] There are two types of food-borne illness caused by *B. cereus*, that is, a diarrheagenic illness and an emetic syndrome.[181,183] The diarrheal syndrome, caused by heat-labile enterotoxins, is usually mild in its course and is characterized by abdominal cramps, nausea, and watery stools. Types of foods implicated in outbreaks of diarrheal syndrome include cereal food products containing corn and corn starch, mashed potatoes, vegetables, milk, and cooked meat products. The emetic syndrome, caused by a heat-stable peptide toxin,[181] is more severe and acute in its course, characterized by severe vomiting. Refried or rewarmed boiled rice, pasta, noodles, and pastry are frequently implicated vehicles in outbreaks of emetic syndrome.[184] The dose of *B. cereus* required to produce diarrheal illness is estimated at more than 10^5 cells/g.[185]

BRUCELLA SPECIES

Brucella spp. are pathogens in many animals, causing sterility and abortion. In humans, *Brucella* is the etiologic agent of undulant fever. The genus *Brucella* consists of six species, of which those of principal concern are *B. abortus*, *B. suis*, and *B. melitensis*.[186] *B. abortus* causes disease in cattle, *B. suis* in swine, and *B. melitensis* is the primary pathogen of sheep. *B. melitensis* is the most pathogenic species for humans. Human brucellosis is primarily an occupational disease of veterinarians and meat industry workers. Brucellosis can be transmitted by aerosols and dust. Food-borne brucellosis can be transmitted to humans by consumption of meat and milk products from infected farm animals. The most common food vehicle of brucellosis for humans is unpasteurized milk.[186] Meat is a less common source of food-borne brucellosis, because the bacteria are destroyed by cooking. Since the National Brucellosis Education program has almost eradicated *B. abortus* infection from U.S. cattle herds, the risk of food-borne infection of brucellosis through consumption of domestically produced milk and dairy products is minimal.[61]

HELICOBACTER PYLORI

H. pylori is a human pathogen causing chronic gastritis, gastric ulcer, and gastric carcinoma.[187,188] Although, humans are the primary host of *H. pylori*, the bacterium has been isolated from cats.[161] *H. pylori* does not survive well outside its host, but it has been detected in water and vegetables.[189,190] A study on the effect of environmental and substrate factors on the growth of *H. pylori* indicated that the pathogen likely lacks the ability to grow in most foods.[191] However, *H. pylori* may survive for long periods in low-acid environments under refrigerated conditions. *H. pylori* infections spread primarily by person-to-person transmission, especially among children, and contaminated water and food are considered potential vehicles of the pathogen. In the United States, a significant association between *H. pylori* infection and iron deficiency/anemia, regardless of the presence or absence of peptic ulcer, has been reported.[192,193]

VIRAL FOOD-BORNE PATHOGENS

Estimates by the Centers for Disease Control and Prevention of the incidence of food-borne illness in the United States indicate that viruses are responsible for approximately 67% of the total food-borne illnesses of known etiology annually (Table 2.2).[1] Viruses are obligate intracellular microbes and most food-borne viruses contain RNA rather than DNA. Since viruses are intracellular, requiring a host for multiplication, they cannot grow in foods. Therefore, the number of virus particles on foods will not increase during processing, transport, or storage, causing no deterioration in food quality.[194] Food-borne viruses are generally enteric in nature, causing illness through ingestion of foods and water contaminated with human feces. Viruses disseminated through foods also can be spread by person-to-person contact. For example, research with Hepatitis A virus has revealed that a few hundred virus particles can readily be transferred from fecally contaminated fingers to foods and surfaces.[195] Hepatitis A virus, Norovirus (previously known as Norwalk-like viruses) and possibly rotavirus are among the most significant of the viruses that are foodborne.

HEPATITIS A VIRUS

Hepatitis A virus is a member of the family *Picornaviridae* and is transmitted by the fecal-oral route. Raw shellfish harvested from waters contaminated by human sewage is among the foods most frequently associated with outbreaks of hepatitis A virus.[196] Besides shellfish, other foods including sandwiches, dairy products, baked products, salads, fruits, and vegetables have also been implicated in outbreaks of hepatitis A virus infection.[197,198] A large outbreak in Pennsylvania in 2003 involving

TABLE 2.2
Viral Food-Borne Pathogens

Microbe	Significant Characteristics	Sources/Reservoirs	Vehicles	Estimated No. of Food-Borne Cases Annually in the United States[121]	Incubation Period, Symptoms and Duration	Detection Methods	Control/Prevention
Hepatitis A virus	Single-stranded RNA virus, spherical in shape, remains viable for long periods of time in foods stored at refrigeration temperature, virus multiplies in the gut epithelium before being carried by blood to the liver. Virus is shed in feces before symptoms of liver damage become apparent	Humans, sewage-polluted waters	Raw or undercooked shellfish and seafoods harvested from sewage-polluted water, ready-to-eat foods such as salads prepared by infected food handler	4,170	15 to 45 days, usually ~25 days Loss of appetite, nausea, abdominal pain, fever, jaundice, dark urine, and pale stools Duration is a few weeks to months	Cultural methods[389,390] Enzyme immunoassay[391] PCR[392,393]	Avoid consumption of raw seafoods, disinfection of drinking water, good personal hygiene and food handling practices, vaccination of professional food handlers, safe sewage disposal
Norovirus	Single-stranded RNA virus, spherical in shape, does not multiply in any known laboratory host	Humans, sewage-polluted waters	Raw or undercooked shellfish and seafoods harvested from sewage polluted water, drinking water	9,200,000	1 to 2 days Loss of appetite, nausea, abdominal pain, diarrhea, vomiting, and headache Duration is 2 days	Enzyme immunoassay[394,395] PCR[396–398]	Avoid consumption of raw seafoods, disinfection of drinking water, good personal hygiene and food handling practices, hygienic sewage disposal, treatment of wastewater used for irrigation
Rotavirus	Double-stranded RNA virus, icosahedral in shape	Humans	To be determined	39,000	1 to 3 days Vomiting, abdominal pain followed by watery diarrhea Duration is 6 to 8 days	Cultural methods[389,390] ELISA[399,400] PCR[400–402] Flow cytometry[403,404]	Avoid consumption of raw seafoods Avoid drinking of untreated water, Good personal hygiene
Avian influenza virus	Single-stranded RNA virus, medium sized, pleomorphic, enveloped	Chicken, turkey, guinea fowl, and migratory waterfowl	Raw or undercooked contaminated egg and poultry meat	Emerging disease. Not reported in the United States 132 cases worldwide (1997–2005)	Typical flu symptoms such as fever, cough, sore throat, and muscle aches. Also eye infections (conjunctivitis), pneumonia, and acute respiratory distress can be present	Cultural method[204] Rapid antigen detection test[405] PCR[204] Serological test[204]	Properly cook poultry meat and eggs. Use pasteurized eggs for preparing foods that are not cooked Avoid handling infected birds or birds suspected of infection. Use hygienic practices during slaughter and post-slaughter operations. Keep hands away from face and wash hands following exposure to chickens and their feces

more than 500 cases was linked to ingestion of contaminated green onions.[199] Hepatitis A virus is more resistant to heat and drying than other picornaviruses.[196] The incubation period for onset of symptoms of hepatitis A infection ranges from 15 to 45 days, and symptoms include nausea, abdominal pain, jaundice, and fever. The virus is shed in feces by infected humans many days before the onset of symptoms, indicating the importance of good personal hygienic practices of cooks and food handlers who could otherwise contaminate food during the period of asymptomatic fecal shedding. The overall incidence of Hepatitis A virus infection in the United States has decreased since the implementation of routine childhood vaccination against the virus in 1996.[61]

Norovirus

Noroviruses belong to the family *Calciviridae*, and are often referred to as small, round structured viruses. Norovirus is recognized as the most common viral cause of food-borne and waterborne acute gastroenteritis in the United States.[1] The virus has a low infectious dose of less than 100 virus particles.[200] Raw or undercooked shellfish and other seafoods are common vehicles of Norovirus. The incubation period of infection ranges from 24 to 48 h, and symptoms include nausea, vomiting, and diarrhea. Infected humans shed the virus in feces for up to a week after symptoms have subsided. The virus survives freezing, heating to 60°C, and chlorine levels up to 10 ppm.[200] Qualitative studies in human volunteers indicate that the viruses are infective for up to 3 h when exposed to a medium at pH 2.2 at room temperature or for 60 min at pH 7 at 60°C.[201]

Rotavirus

Rotavirus is a nonenveloped, double-shelled virus, with a genome composed of 11 segments of double-stranded RNA. Rotavirus is the most common cause of diarrhea in children worldwide, especially in developing countries. In the United States and other countries with a temperate climate, infection with rotavirus has been reported to peak during the winter season (November to April). In the United States, there is an estimated 3.9 million cases of rotavirus diarrhea each year; however, only 39,000 cases are estimated to be acquired through contaminated foods.[1] Rotavirus infection has an incubation period of 1 to 3 days, and is characterized by fever, vomiting, and diarrhea. The virus is shed in the feces of infected humans and can survive on vegetables at 4 or 20°C for many days.[202] It also can survive the process of making soft cheese.[202] The primary mode of transmission of rotavirus is by the fecal to oral route. In 2006, the U.S. FDA approved a new live, oral vaccine (RotaTeq™) for the prevention of rotavirus gastroenteritis in infants.

Avian Influenza Virus

Avian influenza (bird flu) is a highly contagious viral infection affecting many species of birds, including chickens, turkeys, guinea fowl, and migratory waterfowl. The disease is of tremendous economic significance to the poultry industry. Recent outbreaks of avian influenza infections in poultry and humans highlight the zoonotic potential of the disease, and its impact on public health.[203] During the period from 1997 to 2005, 132 human cases of avian influenza with 64 deaths have been reported worldwide.[204] Based on virulence, avian influenza virus is classified into the highly pathogenic avian influenza (HPAI) strains that cause a systemic lethal infection, resulting in death of birds as early as 24 h to 1 week post infection, and the low pathogenic avian influenza (LPAI) viruses that rarely result in fatal disease in birds.[205] The HPAI viruses that cause "fowl plague" are restricted to the subtypes H5 and H7; however all the viruses of these subtypes do not cause HPAI. H5N1 is the influenza A virus subtype that occurs mainly in birds, causing fatal disease in chickens and turkeys.

Avian influenza viruses belonging to the family Orthomyxoviridae, are medium sized, pleomorphic, enveloped viruses with glycoprotein projections from the envelope having hemagglutinating (HA) and neuraminidase (NA) activities.[206] The genome of the virus consists of eight segments of single-stranded RNA of a negative sense, which code for ten viral proteins. Antigenically, three distinct types of influenza viruses are reported, namely type A, type B, and type C, with the former type causing natural infections in birds. Based on the antigenic properties of hemagglutinin and neuraminidase surface glycoproteins, type A influenza viruses are divided into various subtypes.[207] Currently, 15 HA and 9 NA subtypes have been reported.[205]

The hemagglutinin glycoproteins play a vital role in the pathogenicity by mediating attachment of the virus to host cell receptors followed by release of viral RNA.[203] The HA glycoprotein precursor (HA0) is post-translationally cleaved into HA1 and HA2 subunits by host proteases, with the HA2 amino terminus mediating fusion between the viral envelope and the endosomal membrane.[208] Klenk and coworkers[209] reported that proteolytic activation of HA glycoprotein is essential for viral infectivity and dissemination, thus highlighting its role in the pathogenesis of avian influenza virus. The HA precursor proteins of LPAI viruses have a single arginine at the cleavage site, hence these viruses are limited to cleavage by host proteases such as trypsin-like enzymes. Therefore replication of LPAI viruses is limited to sites (organs) where such enzymes are found (respiratory and intestinal tracts), thereby resulting in mild infections. However, the HAs of HPAI viruses contain multiple basic amino acids at the cleavage site, which are cleaved by ubiquitous proteases present in a variety of host cells. These viruses therefore are able to replicate throughout the bird, causing lethal systemic infection and death.[210,211]

The source of infection to poultry in most outbreaks is direct or indirect contact with waterbirds. Once the infection is established in birds, the disease is highly contagious. Fecal-to-oral transmission is the most common mode of spread between birds. Contact with infected material is the most important mode of transmission from bird to bird. In infected birds, the virus is excreted in the droppings and nasal and ocular discharges. Fecal shedding of the virus by infected birds has been documented up to 4 weeks postinfection. Contaminated feed, water, rodents, and insects can also play a role in the spread of virus. Movement of infected birds, contaminated equipment, egg flats, feed truck, and service crew can also spread the virus from flock to flock. Airborne transmission of the virus can potentially occur if birds are kept in close proximity and with air movement. Since lesions have been reported in the ovaries and oviducts of infected egg-laying chickens, avian influenza virus could potentially be transmitted via the egg either through viruses in internal egg contents or on the surface of virus-contaminated feces.[212] This could potentially lead to hatching of infected chicks and contamination of the hatchery. Implementation of strict biosecurity measures can greatly reduce the risk of secondary spread after an initial outbreak.

Although humans can contract avian influenza virus by handling infected birds, there is no epidemiologic evidence to suggest transmission of the virus by consumption of properly cooked eggs or other cooked poultry products derived from infected birds. Cooking poultry meat to 160 degrees Fahrenheit (71°C) inactivates the virus.[204] Consumption of raw or partially cooked eggs (runny yolk) or foods containing raw eggs should be avoided.

FUNGAL FOOD-BORNE PATHOGENS

Molds are widely distributed in nature and are an inherent part of the microflora of foods (Table 2.3). Although molds are major spoilage agents of many foods, many molds also produce mycotoxins of which some are carcinogenic and mutagenic. Mycotoxins are secondary metabolites produced by molds usually at the end of their exponential phase of growth. Some of the principal species of molds which produce mycotoxins in foods include the following.

Aspergillus Species

Aspergillus flavus and *A. parasiticus* are the most important toxigenic food-borne aspergilli. A wide variety of foods such as nuts, corn, oil seeds, and sorghum are potential vehicles of these aspergilli. *A. flavus* and *A. parasiticus* produce aflatoxins, which are difuranocoumarin derivatives.[213] The common types of aflatoxins that are produced are B_1, B_2, G_1, and G_2.[214] In addition, two other types of aflatoxins, namely M1 and M2 have also been reported as contaminants of food, especially milk. Aflatoxicosis in animals can be acute or chronic. Acute cases are characterized by severe liver damage, whereas liver cirrhosis, liver cancer, and teratogenesis occur in chronic toxicity. Chronic intake of aflatoxins in animals can lead to poor feed conversion and low weight gain.

In humans, aflatoxins have been reported to cause hepatic cancer. A significant correlation between aflatoxin exposure and stunted growth has been reported in children exposed to aflatoxin during neonatal stages.[215] Additionally, since aflatoxins can cross the placental barrier, they can potentially lead to genetic defects in the fetus.[216] Following intake, aflatoxins are metabolized into a variety of products such as aflatoxicol, aflatoxin Q1, aflatoxin P1, and aflatoxin M1 in the liver by cytochrome p450 group of enzymes. In addition, another metabolite, called aflatoxin 8,9 epoxide, can be formed, which can induce mutations by forming DNA adducts, ultimately leading to hepatic carcinoma.[217–219] Susceptibility of a given species to aflatoxins depends on its liver detoxification systems, genetic make up, age and other nutritional factors.[220]

Penicillium Species

The genus *Penicillium* consists of more than 150 species, of which nearly 100 produce known toxins. Three important food-borne toxigenic *Penicillium* species include *P. verrucosum*, *P. expansum*, and *P. citrinum*. *P. verrucosum* is present on grains grown in temperate zones, and is commonly associated with Scandanavian barley and wheat.[221] *P. verrucosum* produces Ochratoxin A which has immunosuppressive and potential carcinogenic properties.[221] Ochratoxin A also has been associated with nephritis in pigs in Scandanavia.[222] *Pencillium expansum*, a psychrotrophic mold and one of the most common fruit pathogens, causes a condition known as "blue mold rot" on a variety of fruits, including apples, cherries, nectarines, and peaches.[223–226] Besides its economic impact, *P. expansum* is also of potential public health significance because it produces patulin, a mycotoxin known to cause immunological, neurological, and gastrointestinal toxic effects in animal models.[221] Exposure to high levels of patulin also results in vomiting, salivation, anorexia, polyapnea, weight loss, leukocytosis, erythropenia, and necrotic lesions of hemorrhagic enteritis in piglets.[227] Although the toxic effects of patulin in humans have not been proven conclusively, the presence of patulin has been demonstrated in apple juice[228] and grape juice.[229] This is a concern because fruit juices, especially apple juice, are commonly consumed by infants and children. *P. expansum* is commonly present in rotten apples and pears, and to a lesser extent in cereals. Use of moldy fruits contaminated with *P. expansum* greatly increases the risk of patulin contamination in fruit juices. An unusual characteristic of *P. expansum* is its ability to grow at low temperature, that is, −2 to −3°C.[221]

TABLE 2.3
Fungal Food-Borne Pathogens

Microbe/Toxin	Significant Characteristics	Sources/ Reservoirs of Fungi	Vehicles of Toxins	Toxic Effects	Detection Methods	Control/ Prevention
Aspergillus parasiticus and *Aspergillus flavus/* Aflatoxin	Growth at 10 to 43°C, optimal growth at 32°C, produces aflatoxins at 12 to 40°C, growth at pH 3 to 11	Environment, soil, vegetation	Corn, peanuts, cottonseed	Effects of aflatoxin in animals: Acute: hemorrhage in the gastrointestinal tract, liver damage, and death Chronic: cirrhosis of liver, liver tumors, and immunosuppression	Cultural methods[406–409] ELISA[410] Immunoassay[411,412] PCR[413–416]	Proper storage of cereal products
*Penicillium expansum/*Patulin; *Penicillium citrinum/* Citrinin	*P. expansum* is psychrotrophic, capable of growth at −2 to −3°C, optimal growth at 25°C	Environment, soil, vegetation	*P. expansum*: Fruits, especially apples and pears *P. citrinum*: Cereals, especially rice, wheat, corn	Effects of patulin: Gastrointestinal, neurological, and immunological effects in animals Citrinin: Fatty degeneration and renal necrosis in pigs and dogs; significance in human health is unresolved	Cultural methods[407,408,417] PCR[418,419] Detection of mycotoxin by HPLC[420,421] mass spectrometry[422]	Avoid consumption of rotten apples and pears, proper storage of cereal products
Fusarium graminearum/ Deoxynivalenol, nivalenol, zearalenone	Growth at 5°C but not at 37°C, optimal growth at 25°C	Environment, soil, vegetation	Cereals, especially wheat, barley and corn	Effects of deoxynivolenol: Nausea, vomiting, abdominal pain, diarrhea, headache, fever, chills, throat irritation	Cultural methods followed by morphology[423,424] PCR[425–429] Immunoassay[430] ELISA[431]	Proper storage of cereal products

P. citrinin is a widely occurring mold commonly present on rice, wheat, and corn. *P. citrinin* produces the metabolite citrinin. Although the toxicological effect of citrinin in humans is not known, it has been reported to cause renal toxicity in pigs and cats.[230]

FUSARIUM GRAMINEARUM

Fusarium graminearum is a toxigenic mold commonly present in soil and on cereals such as wheat and corn. It produces a number of mycotoxins, including deoxynevalenol and zearalenone.[231] Ingestion of foods containing deoxynevalenol produces illness termed Scabby grain intoxication, which is characterized by anorexia, nausea, vomiting, diarrhea, dizziness, and convulsions. Foods most frequently implicated as vehicles of deoxynevalenol include cereal grains, wheat, barley, and noodles.

PARASITIC FOOD-BORNE PATHOGENS

Parasitic diseases account for 3% of food-borne illnesses and 21% of food-borne illness-related deaths in the United States (Table 2.4).[1] However, the actual number of parasitic diseases could be higher, because they are often underdiagnosed and underreported in the United States.[232] Parasites constitute more of a food safety concern now than in the past, because of the globalization of our food supply with increased imports of fruits, vegetables, and ethnic foods from countries, where the hygienic and quality control standards in food production may be suboptimal. Foods can be vehicles of several types of parasites, including protozoa, roundworms, and flatworms. Although food-borne transmission of parasites such as *Trichinella spiralis* and *Taenia solium* has been known for many years, the food-borne disease potential of many protozoan parasites such as *Cryptosporidium* and *Cyclospora* has only recently been recognized. Unlike bacteria, parasites do not multiply in foods. Moreover, parasites need at least one specific host to complete their life cycle. Many of the well-recognized parasites that can be transmitted to humans through foods include the following.

GIARDIA LAMBLIA

Giardiasis is the most common parasitic infection reported in the United States, with 21,300 confirmed cases in 1997.[233] *G. lamblia* is a flagellated protozoan parasite that colonizes the intestinal tract of humans and animals. It is commonly present in lakes, rivers, and stagnated waters. The life cycle of *G. lamblia* includes flagellated trophozoites, which become pear-shaped cysts.[234] The cysts contaminate water or food through feces of infected animals or humans. Following ingestion of cyst-contaminated water or food, the trophozoites reach the small intestine where they undergo excystation and multiply by binary fission. New trophozoites subsequently become cysts in the distal small intestine, and the encysted trophozoites are shed in the feces. The symptoms of giardiasis include abdominal pain, abdominal distension, nausea, vomiting, and diarrhea. Although water and foods contaminated with cysts are primary vehicles of giardiasis, little is known about the survival characteristics of the cysts in foods. In most cases of food-borne transmission, infected food handlers transfer the cysts to foods they prepare. Humans can also contract giardiasis through the use of contaminated water for irrigating or washing fruits and vegetables.[235]

ENTAMOEBA HISTOLYTICA

Entamoeba histolytica is a protozoan parasite that causes amoebiasis or amoebic dysentery in humans. Although the parasite survives in the environment and water, humans are the principal source of amoebiasis. In humans, cysts containing the trophozoites are released, which in turn multiply, and are subsequently excreted in the feces as cysts.[236] Foods and water contaminated with the cysts transmit the disease. Since the fecal-oral route is the principal route of transmission of amoebiasis, personal hygiene of infected food handlers plays a critical role in preventing food-borne amoebiasis. Human amoebiasis can occur in two forms: intestinal amoebiasis and amoebic liver abscess, which is usually a sequela to the intestinal form. Intestinal amoebiasis is characterized by abdominal pain, vomiting, and watery diarrhea containing mucus and blood. Symptoms of the hepatic form of amoebiasis include wasting, painful and enlarged liver, weight loss, and anemia. Amoebiasis is a common cause of diarrhea in tropical and subtropical countries, and most cases in the United States are reported in immigrants and persons returning from endemic areas.[235]

CRYPTOSPORIDIUM PARVUM

Cryptosporidium parvum is a protozoan parasite that infects a wide range of animals and humans. *C. parvum* is monoexenous in its life cycle, requiring only one host for its development.[234] Infected hosts shed in their feces oocysts of the parasite, sub–sequently contaminating the environment, food, and water. The life cycle of *C. parvum* can be summarized as follows.[234] Upon ingestion of contaminated water or food, or by inhalation of oocysts, sporozoites are released by excystation of oocysts into the gastrointestinal or respiratory tract. The sporozoites enter the epithelial cells and develop into trophozoites, which in turn differentiate into type I and type II meronts. The merzoites from type I meronts invade new tissues and develop into trophozoites to continue the life cycle. The merozoites from type II meronts invade infected cells, and undergo sexual multiplication to

TABLE 2.4
Parasitic Food-Borne Pathogens

Parasite	Significant Characteristics	Sources/ Reservoirs	Vehicles	Estimated No. of Food-Borne Cases Annually in the United States[1]	Incubation Period, Symptoms and Duration	Detection Methods	Control/ Prevention
Giardia lamblia	Flagellate protozoa, produces oval-shaped cysts ranging from 8 to 20 μm in length and 5 to 12 μm in width, cysts contain four nuclei and are resistant to chlorination used to disinfect water	Humans, animals, especially beavers and muskrats, water	Drinking water, raw fruits and vegetables contaminated with cysts, ready-to-eat foods such as salads contaminated by infected food handlers	200,000	4 to 25 days, usually 7 to 10 days Abdominal cramps, nausea, abdominal distension, diarrhea which can be chronic and relapsing, fatigue, weight loss, and anorexia Duration is weeks to years	Immuno-fluorescence[432] Immunochromato-graphy[433,434] PCR[435–438]	Adequate cooking of foods, filtration of drinking water, good personal hygiene and food handling practices
Entamoeba histolytica	Amoeboid protozoa, anaerobe survives in environment in crypted form, cysts remain viable in feces for several days and in soil for at least 8 days at 30°C and for more than 1 month at 10°C, relatively resistant to chlorine	Humans, dogs, rats	Foods and water contaminated with feces or irrigation water	Unknown	2 to 4 weeks Abdominal pain, fever, vomiting, diarrhea containing blood and mucus, and weight loss Duration is weeks to months	Microscopic examination Line dot hybridization assay[439] ELISA[440,441] PCR[437,442]	Good personal hygiene and food-handling practices, adequate cooking of foods, filtration of water, hygienic disposal of sewage water, treatment of irrigation water
Cryptosporidium parvum	Obligate intracellular coccidian parasite, oocysts are spherical to oval in shape with an average size of 4.5 to 5.0 μm, oocysts are resistant to chlorination used to disinfect water	Humans, wild and domestic animals, especially calves	Contaminated drinking and recreational water, raw milk from infected cattle, fresh vegetables and other foods contaminated with feces from infected humans and animals	30,000	2 to 14 days Profuse, watery diarrhea, abdominal pain, nausea, and vomiting Duration is few days to 3 weeks	Immunofluorescence assay[443] PCR[444–447] Rapid assay[448]	Thorough cooking of food, avoid contact with infected animals, filtration of drinking water, good personal hygiene and food handling practices
Cyclospora cayetanensis	Obligate intracellular coccidian parasite, oocysts are spherical in shape with an average size of 8 to 10 μm	Humans	Water, fruits and vegetables contaminated with oocysts	14,600	1 week Watery diarrhea, abdominal pain, nausea, vomiting, anorexia, myalgia, and weight loss Duration is a few days to 1 month	Staining and microscopic examination[449] Flow cytometry[450] PCR[451–453]	Good personal hygiene, filtration of drinking water

TABLE 2.4 (Continued)

Parasite	Significant Characteristics	Sources/ Reservoirs	Vehicles	Estimated No. of Food-Borne Cases Annually in the United States[1]	Incubation Period, Symptoms and Duration	Detection Methods	Control/ Prevention
Toxoplasma gondii	Obligate intracellular coccidian protozoa	Cats, farm animals, transplacental transmission from infected mother to fetus	Raw or undercooked meat, raw goat milk, raw vegetables	112,500	5 to 23 days; Fever, rash, headache, muscle pain, swelling of lymph nodes; transplacental infection may cause abortion; Duration is variable	Cell culture and mouse inoculation[454] Immunoassay[455] Serologic assay[456] Immuno fluorescence[457] PCR[458-461]	Prevent environmental contamination with cat feces, avoid consumption of raw meat and milk, safe disposal of cat feces, wash hands after contact with cats
Trichinella spiralis	Nematode with no free living stage in the life cycle, adult female worms are 3 to 4 mm in length, transmissible form is larval cyst, which can occur in pork muscle	Wild and domestic animals, especially swine and horses	Raw or undercooked meat of animals containing encysted larvae such as swine or horses	50	Initial symptoms: 24 to 72 h, Systemic Symptoms: 8 to 21 days; Initial phase: Abdominal pain, fever, nausea, vomiting, and diarrhea; Systemic phase: Periorbital edema, eosinophilia, myalgia, difficulty in breathing, thirst, profuse sweating, chills, weakness, and prostration; Duration is 2 weeks to 3 months	Microscopic examination ELISA[462-464] Immunoassay[465] PCR[466-468]	Adequate cooking of meat, freezing of meat at −15°C for 30 days or at −35°C, preventing trichinosis in pigs by not feeding swine garbage containing infected meat
Anisakis spp.	Nematode, slender thread-like parasite measuring 1.5 to 1.6 cm in length and 0.1 cm in diameter	Sea mammals	Some undercooked salt water fish, sushi, herring, sashini, ceviche	Unknown	4 to 12 h; Epigastric pain, nausea, vomiting, sometimes hematemesis; Duration is variable	ELISA[469,470] Immunoblot[471] PCR[472-474]	Adequate cooking of saltwater fish, freezing fish at −23°C for 7 days
Taenia solium Taenia saginata	Tapeworm, dependent on the digestive system of the host for nutrition	Humans, cattle, swine	Raw or undercooked beef or pork	Unknown	Few days to >10 years; Nausea, epigastric pain, nervousness, insomnia, anorexia, weight loss, digestive disturbances, weakness, and dizziness; Duration is weeks to months	Detection of eggs or proglottids in feces ELISA[475,476] PCR[477-479]	Adequate cooking of beef and pork, proper disposal of sewage and human wastes, freezing of meat at −10°C for 2 weeks
Diphyllobothrium latum	Largest human tapeworm	Saltwater fish, humans	Raw or undercooked saltwater fish	Unknown	Epigastric pain, nausea, abdominal pain, diarrhea, weakness, and pernicious anemia; Duration is months to years	Detection of eggs in feces	Adequate cooking of fish, proper disposal of sewage and human waste

give rise to male and female gametes. The zygotes resulting from fertilized gametes become infectious by sporulation, and the sporulated oocysts are excreted in feces.

Cryptosporidiosis is a self-limiting disease with an incubation period of 1 to 2 weeks, and is characterized by profuse, watery diarrhea, abdominal pain, vomiting, and low-grade fever. During the period from 1993 to 1998, seven major outbreaks of cryptosporidiosis have been reported in the United States.[235] Water is the most common source of *C. parvum* for human infections.[161] The largest outbreak of cryptosporidiosis (waterborne) in the United States occurred in Milwaukee, Wisconsin in 1993, involving more than 400,000 people with 69 deaths.[237,238] In addition to drinking water, water can also potentially contaminate produce when it is used for irrigating plants or washing fruits and vegetables. Oocysts of the pathogen have been detected in fresh vegetables, raw milk, sausage, and apple cider.[161] Infected food handlers can also transfer the oocysts to foods.[239,240] *C. parvum* oocysts are sensitive to freezing and freeze-drying. The oocysts lose infectivity in distilled water stored at 4°C.[241] However, the oocysts are quite resistant to chlorine; no loss in infectivity was observed in water containing 1 to 3% chlorine for up to 18 h.[242] However, the oocysts are sensitive to ozone, losing more than 90% infectivity in the presence of 1 ppm ozone for 5 min.[243]

CYCLOSPORA CAYETANENSIS

Cyclospora cayetanensis is an emerging foodborne, protozoan pathogen, especially in the United States. The parasite was implicated in several food-borne outbreaks in the United States during 1996 and 1997.[244] Water and foods, especially fruits and vegetables containing oocysts, are common vehicles of human infection.[235,245] During the period from 1996 to 2000, eight major outbreaks of cyclosporidiosis were reported, with imported raspberries as the vehicle of infection in 50% of the outbreaks.[235] Humans are the only identified reservoir of *C. cayetanensis.*[245] The symptoms of *C. cayetanensis* infection in humans include watery diarrhea, nausea, abdmonial pain, vomiting, and weight loss. Presently, there is very little information on the effects of heat, freezing, and disinfection agents on *Cyclospora* oocysts. Exposure of oocysts to –20°C for 24 h or 60°C for 1 h prevented oocysts from sporulating. Exposing oocysts to 4 or 37°C for 14 days delayed sporulation.[246]

TOXOPLASMA GONDII

Toxoplasma gondii is an obligate intracellular protozoan parasite for which cats are the definitive host. A survey on the prevalence of *T. gondii* in cats at spay or neuter clinics in Ohio revealed that 48% of the cats were infected with the parasite.[247] In the intestine of cats, the parasite undergoes sexual reproduction to form oocysts, which are excreted in feces.[248] The oocysts undergo maturation and survive in the environment for months, and spread by wind, insects and tapeworms. Toxoplasmosis in humans results following ingestion of food or water contaminated with oocysts. Transmission also occurs from an infected pregnant mother to child by transplacental transmission.[249] In the United States, *T. gondii* has been estimated to cause about 4000 congenital infections annually, potentially resulting in blindness, learning disabilities, and mental retardation in children.[232] *T. gondii* is also attributed as the leading cause of CNS infection in persons with AIDS.[250] Symptoms in healthy adults are usually mild, and include rash, headache, muscle pain, and swelling of lymph nodes. Although the oocysts can survive in refrigerated meat for weeks, they are inactivated by freezing at <12°C.[251] The oocysts are sensitive to irradiation and heat (>67°C). Properly cooked foods are not a vehicle of *T. gondii.*[252]

TRICHINELLA SPIRALIS

Trichinalla spiralis is a round worm that primarily infects wild and domestic animals, especially pigs. Humans contract trichinosis by consumption of raw or undercooked meat containing larvae of the parasite. Pigs are infected by consuming uncooked scraps of infected pork. The encysted larvae upon ingestion are liberated from the cyst in the intestine, where they sexually mature.[253] The mature male and female worms copulate in the lumen of the small intestine, giving rise to a new generation of larvae. The newly born larvae migrate to various tissues in the body. Those larvae that reach the striated muscles penetrate into the sarcolemma of the muscle fibers and develop to maturity as encapsulated cysts.[253] The larvae continue their life cycle when raw or undercooked meat, especially pork containing the larvae, is consumed by humans.

Trichinosis is included under the notifiable diseases in the United States, with its number of cases progressively decreasing since the 1940s.[235] The decline in trichinosis in the United States has been attributed to changes in swine feeding practices and routine inspections at slaughterhouses. The average number of trichinosis cases reported in the United States in 1997 to 2001 was 14/year, down from 400 cases/year in the 1940s.[254] On the other hand, game meat was identified as the most common source of the parasite for humans during 1997 to 2001.[235]

ANISAKIS SPECIES

Anisakiasis in humans is caused by two food-borne roundworms. These include *A. simplex*, whose definitive host is whales, and *Pseudoterranova decipiens*, which primarily inhabits seals. The eggs of these roundworms are excreted in feces by their

respective hosts. The eggs then undergo molting in suitable intermediate hosts and subsequently develop into larvae, which are ingested by fish.[255] Humans contract anisakiasis by consumption of raw or undercooked fish and seafoods containing the larvae. In noninvasive anisakiasis, the worms released from ingested foods migrate to the pharynx, resulting in "tingling throat syndrome."[255] The worms are ultimately expelled by coughing. In the invasive form of anisakiasis, the worms penetrate the intestinal mucosa, thereby causing symptoms that include epigastric pain, nausea, vomiting, and diarrhea.

Taenia Species

The genus *Taenia* includes two meat-borne pathogenic flat worms, *T. saginata* (beef tapeworm) and *T. solium* (pork tapeworm). The eggs of *T. saginata* survive in the environment, including on pastures, and are ingested by cattle in which they hatch into embryos.[253] The embryos migrate to skeletal muscles or the heart, and develop into larvae known as cysticercus bovis. Humans become infected by consuming raw or undercooked beef containing the larvae. Larvae that are released into the small intestine develop into mature, adult worms. The symptoms of *T. saginata* infection in humans include decreased appetite, headache, dizziness, diarrhea, and weight loss.

In the normal life cycle of *T. solium*, pigs serve as the intermediate host. Eggs ingested by pigs develop into embryos in the duodenum, penetrate the intestinal wall, migrate through the blood and the lymphatic system, and finally reach the skeletal muscles and myocardium, where they develop into larvae known as cysticercus cellulose. Humans consuming raw or undercooked pork are infected with the larvae, which develop into adult worms in the small intestine. The symptoms of *T. solium* infection in humans include discomfort, hunger pains, anorexia, and nervous disorders. Worms are passed in the feces. In the abnormal life cycle of *T. solium*, humans serve as intermediate hosts in which the larvae develop in striated muscles and in subcutaneous tissue.

Diphyllobothrium latum

Diphyllobothrium latum is commonly referred to as the broad tapeworm because it is the largest human tapeworm.[255] Humans contract diphyllobothriasis by consuming raw or undercooked fish containing the larval forms called plerocercoids. Upon ingestion, the larvae develop into mature worms in the intestines. Eggs produced by mature worms are excreted in feces. If feces containing the eggs contaminate water, the eggs develop into free-swimming larvae called coricidia. Coricidia are ingested by crustaceans, where they develop into a juvenile stage known as procercoid. Following ingestion of infected crustaceans by fish, procercoids develop into plerocercoids to continue the life cycle. Diphyllobothriasis in humans is characterized by nausea, abdominal pain, diarrhea, weakness, and pernicious anemia.[255] Cases of diphyllobothriasis have been associated with eating foods containing raw salmon such as sushi.

3 Food Labeling: Foods and Dietary Supplements

Constance J. Geiger

CONTENTS

OVERVIEW

DEFINITION OF FOOD LABELING

Food labeling includes all the information present on food packages: Nutrition labeling is one component of the food label. Other components include the principal display panel, the information panel, the identity of the food, the list of ingredients, the name and place of business of the manufacturer, packer, or distributor, and any claims made.[1]

This chapter reviews the regulatory history of food labeling, required sections of the nutrition label, labeling of restaurant and fresh foods, definitions of allowed nutrient content claims, and requirements for allowed health claims and structure/function claims. The chapter also provides additional resources for food labeling.

HISTORY OF FOOD LABELING

MAJOR FOOD AND NUTRITION LABELING LAWS AND REGULATIONS

Food labeling laws have progressed from merely protecting consumers from economic harm (Pure Food and Drug Act of 1906)[2] to reducing consumers' risk of chronic disease (Nutrition Labeling and Education Act [NLEA] of 1990)[3]. NLEA amended the Federal Food, Drug, and Cosmetic Act (FFDCA) of 1938[4] and required nutrition information be conveyed to consumers so they can readily understand the information and its significance in the context of a total daily diet. NLEA[3] mandated major revisions in the Food and Drug Administration's (FDA) food labeling regulations, including requiring nutrition labeling on almost all processed foods, a revised list of nutrients to be labeled, standardized serving sizes, nutrient content claims, and, for the first time, health claims. In the interest of harmony and uniformity, the U.S. Department of Agriculture's (USDA) Food Safety and Information Service (FSIS) issued similar regulations for meat and poultry products.[5] Table 3.1 summarizes the major laws and selected regulations dealing with food labeling (for further details, see References 6 and 7).

REGULATORY OVERSIGHT FOR LABELING

A number of regulatory agencies have jurisdiction over food labeling, including the FDA, Food Safety and Inspection Service (FSIS), Federal Trade Commission (FTC), and Bureau of Alcohol, Tobacco and Firearms (BATF). Table 3.2 shows their responsibilities.

TABLE 3.1
Major Food and Nutrition Labeling Laws/Selected Regulations

Law	Primary Provisions
Pure Food and Drug Act, 1906	Barred false and misleading statements on food and drug labels[2]
FFDCA, 1938	Replaced the Pure Food and Drug Act of 1906. Created distinct food labeling requirements. Required "common and usual name" of food, ingredient declarations, net quantity information, and name and address of manufacturer/distributor. Defined misbranding[4]
Fair Packaging and Labeling Act, 1966	Provided FDA with authority to regulate provision of label information and package size[8]
Regulations for the Enforcement of the FFDCA and the Fair Packaging and Labeling Act, 1972, 1973	Merged existing regulations into one entity. Required nutrition labeling on processed foods that were fortified or that carried claims. Provided for labeling of fat and cholesterol. Established standards for dietary supplements (DS). Established regulations for artificially flavored foods and imitation foods per serving. Disallowed nutrient claims unless food contained 10% or more of the U.S. Recommended Dietary Allowance (RDA). Incorporated label information: number of servings/container; calories, protein, carbohydrate, and fat content; percentage of adult U.S. RDA for protein and seven vitamins and minerals. Provided for sodium labeling without requirement of the full Nutrition Label Panel[9–11]
NLEA, 1990	Provided for mandatory nutrition labeling on almost all food products, expanded required nutrition information in a new format, created standardized serving sizes, provided consistent definitions of nutrient content claims, and delineated permissible health claims[3]
Dietary Supplement Health and Education Act (DSHEA), 1994	Defined DS, provided for nutrition labeling in a new format, required the name and quantity of every active ingredient, provided for structure/functions claims and good manufacturing practices, encouraged research on DS, created two new government entities: Commission on DS Labels and the Office of Dietary Supplements[12]
FDA Modernization Act (FDAMA), 1997	Expanded procedures by which FDA can authorize health claims and nutrient contents; for example, provided for a notification process[13]

TABLE 3.2
Agencies Having Jurisdiction over Food Labeling

Agency	Responsibility
FDA: Department of Health and Human Services	Mandatory labeling of most packaged foods, except products containing certain amounts of meat and poultry and beverages with certain amounts of alcohol. Voluntary labeling of fresh fruits and vegetables, fresh fish, game and restaurant foods, except those containing certain amounts of meat and poultry
FSIS: USDA	Mandatory labeling on most fresh and processed mean and poultry products (e.g., hot dogs and chicken noodle soup)
FTC	Claims made in food advertising
BATF	Voluntary labeling of alcoholic beverages

THE NEW LABEL FORMAT

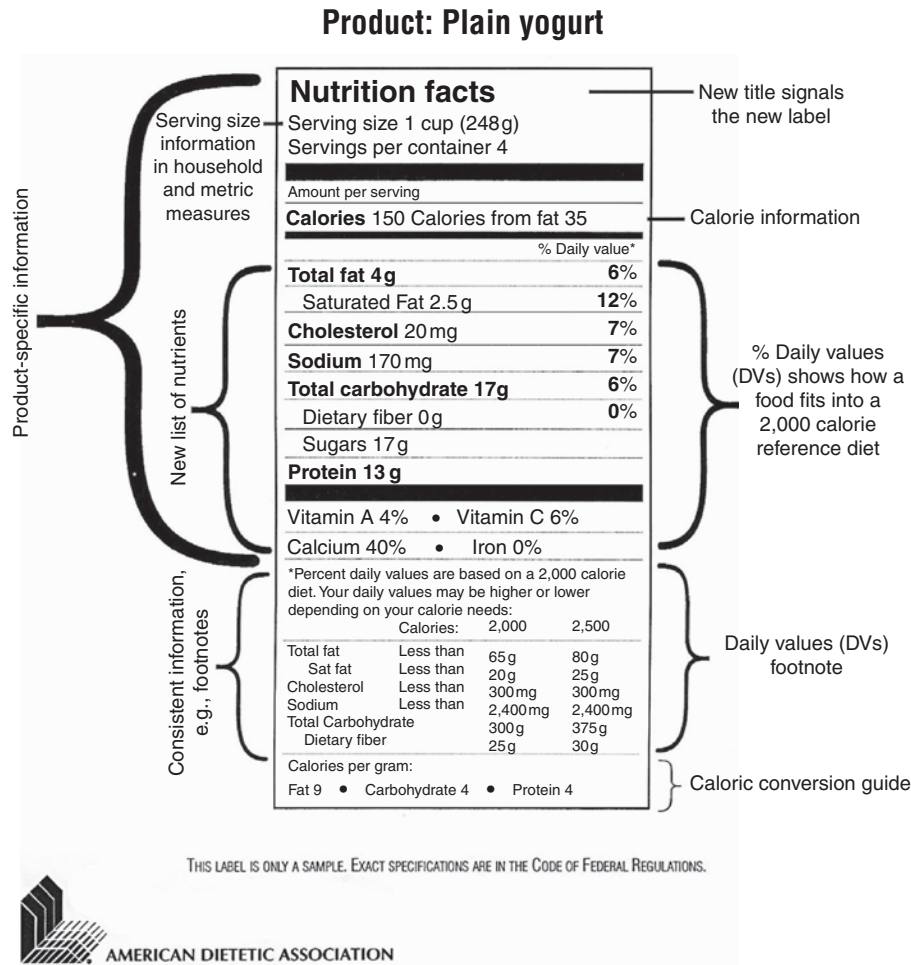
Product: Plain yogurt


FIGURE 3.1   The Nutrition Facts Panel.

REQUIRED SECTIONS OF THE FOOD LABEL

Those sections of the "Nutrition Facts Panel" that are required are illustrated here (see Figure 3.1). The "Nutrition Facts" information is normally based on a serving of the product as packaged.

REQUIRED NUTRIENTS

The nutrients required to be listed in the Nutrition Facts Panel are listed in Table 3.3. If a product is fortified or a claim is made about a voluntary nutrient, that nutrient also is to be listed. Other nutrients (voluntary nutrients) that may be included in the Nutrition Facts Panel are found in Table 3.3.

SERVING SIZE

Standardized serving sizes, known as Reference Amounts Customarily Consumed (RACCs), are established for many categories of foods. RACCs are based on average amounts people usually eat at one time as determined by the USDA survey data. The basis of using typical consumption data for the standardized serving sizes was mandated by NLEA.[3] The RACCs are based on what people typically consume, not what is recommended by government agencies or health professional associations. These uniform serving sizes help consumers compare products. See Table 3.4 for selected RACCs.

In April 2005, FDA published an Advance Notice of Proposed Rulemaking (ANPRM) entitled: "Food labeling: Serving sizes of products that can reasonably be consumed at one eating occasion; updating of references amounts customarily consumed; approaches for recommending smaller portion sizes." [14] FDA requested comments on serving size information, updating

RACCs, labeling of single-serving containers, and caloric comparisons of foods with different serving amounts. This rule will be finalized with the updating of the Daily Values (DVs) (see the section titled "Daily Values").

CALORIES AND CALORIES FROM FAT

Calories and calories from fat are required because of public health authorities' concern with fat in the diet. In 2004, FDA released the Report of the Working Group on Obesity.[15] The Working Group recommended that the calorie information on the food label be made more prominent and that realistic serving sizes be used. The Working Group also recommended that restaurants be encouraged to display nutrition information and that a consumer education program be launched focusing on a "Calorie Count" message.

In June 2005, FDA published an ANPRM requesting comments on whether calorie information should be more prominent by use of bold print, whether calories from fat should be replaced with % DV from calories, how consumers use calories, and how to reformulate foods or redesign packaging to make calorie information more prominent by other means.[16] An example of the change in calorie information format can be seen in Figure 3.2.

TABLE 3.3
Labeling of Nutrients: Required and Voluntary

Required nutrients	Voluntary Nutrients
Total calories	Calories from saturated fat
Calories from fat	Calories from polyunsaturated fat
Total fat	Calories from monounsaturated fat
Saturated fat	Potassium
trans Fat	Soluble fiber
Cholesterol	Insoluble fiber
Sodium	Sugar alcohol
Total carbohydrate	Other carbohydrates
Dietary fiber	Other essential vitamins and minerals
Sugars	
Protein	
Vitamin A	
Vitamin C	
Calcium	
Iron	

TABLE 3.4
Selected RACCs[a]

| Category	RACC
Bakery products: biscuits, bagels, tortillas, soft pretzels	55 g
Beverages: carbonated and noncarbonated beverages, wine coolers, water, coffee or tea (flavored and sweetened), juice, fruit drinks	240 ml
Breads	50 g
Cereals and other grain products	Varies from 25 g for dry pasta to 140 g for prepared rice
Cheese	30 g
Eggs	50 g
Fats and oils	1 tbsp
Fruits: fresh, canned, or frozen, except watermelon	140 g
Meat: entrees without sauce	85 g cooked; 110 g uncooked
Nuts and seeds	30 g
Soups	245 g
Vegetables: fresh, canned, or frozen	85 g fresh or frozen
	95 g for vacuum packed
	130 g for canned in liquid

[a] See Reference 1 (21 CFR 101.12) for further details.

TABLE 3.5
DRVs for Adults: Calculations and Values[a]

Nutrient	Derivation/Calculation	Label Value
Fat	30% of 2000 cal from fat = 600 cal/9 cal/g	65 g
Saturated fat	10% of calories from saturated fat = 200 cal/9 cal/g	20 g
Carbohydrate	60% of calories from carbohydrate = 1200 cal/4 cal/g	300 g
Protein	10% of calories from protein = 200 cal/4 cal/g	50 g
Fiber	11.5 g per 1000 cal	25 g (rounded up)
Cholesterol[a]	NA	Less than 300 mg
Sodium[a]	NA	Less than 2,400 mg
Potassium[a]	NA	3,500 mg

[a] Based on the 1989 National Research Council's Diet and Health Report.

DAILY VALUES

The standards for labeling of nutrients are known as Daily Values (DVs). The % DV is listed for certain nutrients on the label so that consumers can determine how a serving of a food fits into their total daily diet. The DVs include Daily Reference Values (DRVs) and Reference Daily Intakes (RDIs). DRVs are set for nutrients that previously did not have label standards, such as fat, cholesterol, and saturated fat (see Table 3.5). DRVs are based on a daily intake of 2000 cal, which is a reasonable reference number for adults and children over 4 years, and are calculated based on current nutrition recommendations. The term RDIs replaced the term U.S. Recommended Dietary Allowances (RDAs), but the values are currently the same as the U.S. RDAs, which represent the highest recommended levels of the 1968 RDAs (see Table 3.6).

The DVs for labeling are being updated. The Committee on Use of DRIs in Nutrition Labeling, Food and Nutrition Board, Institute of Medicine, National Academy of Science, developed a report to assist the U.S. FDA, the USDA, and Health Canada by "providing guiding principles for selecting reference values for labeling the nutritive value of foods based on the DRIs and for discretionary fortification of foods including meat and poultry products."[18] The committee's report was published in December 2004.[18] The committee recommended that a population-weighted Estimated Average Requirement (EAR) be used for labeling or, if one does not exist, that the Adequate Intake (AI) be used.

FDA is now finalizing an ANPRM to solicit questions about the values to be used for labeling. Once the ANPRM is published, FDA receives comments, the comments are reviewed, and a proposed rule is published. Comments are again solicited,

TABLE 3.6
RDIs for Adults and Children over 4 Years of Age[a]

Nutrient	RDI
Vitamin A	5000 IU
Vitamin C	60 mg
Calcium	1000 mg
Iron	18 mg
Vitamin D	400 IU
Vitamin E	30 IU
Vitamin K	80 μg
Thiamin	1.5 mg
Riboflavin	1.7 mg
Niacin	20 mg
Vitamin B$_6$	2.0 mg
Folate	400 μg
Vitamin B$_{12}$	6 μg
Biotin	300 μg
Pantothenic acid	10 mg
Phosphorus	1000 mg
Iodine	150 μg
Magnesium	400 μg
Zinc	15 mg
Selenium	70 μg
Copper	2 mg
Manganese	2 mg
Chromium	120 μg
Molybdenum	75 μg
Chloride	2400 mg
Choline	

[a] See References 1 (21 CFR 101.9) for further detail.

compiled, and evaluated. Then a final rule implementing the revised DVs is published. The food industry will probably have 2 years to implement these changes. The final rule is not likely to come into effect until 2012 or later.

The DVs, calorie information, and serving-size information will be finalized and implemented together. The change in DVs may affect nutrient content claim and health claim requirements.[19] For example, to carry an "excellent source of folate" claim today, a food would need to provide 20% of the DV for folate, or 80 μg per RACC. If a population-weighted EAR were used for the basis of the claim instead of the RDA, the amount required for a food to carry a health claim could drop to 62 μg. Therefore, using a population-weighted EAR vs. an RDA has important implications for dietary adequacy, educational programs and messaging, and consumer purchase selections.

A footnote is provided at the bottom of the Nutrition Facts Panel to inform consumers of the DVs for both 2000 and 2500 cal levels. The calorie information at the very bottom of the label is voluntary (see Figure 3.1).

SUBSTANCES WITHOUT DVs

Those substances without DVs, such as sugars, *trans* fats, and soluble and insoluble fibers, do not carry a % DV.

LABELING OF RESTAURANT FOODS AND FRESH FOODS

RESTAURANT FOODS

Labeling of restaurant foods is voluntary. Nutrition labeling becomes mandatory if a nutrient content claim or health claim is made. However, the full Nutrition Facts Panel is not required. Only the amount of the nutrient that is the subject of the claim is required to be labeled, for example, "low fat" contains 3 g of fat (21 CFR 101.10).[1] Because Americans spend almost 46% of their food budget on food prepared away from home, FDA commissioned the Keystone Group to hold a forum on Away-From-Home Foods.[20] The group recommended consumers be provided with nutrition information at the point of purchase.

FRESH FRUITS, VEGETABLES, AND SEAFOOD

FDA recommends food retailers provide nutrition information for raw fruits, vegetables, and fish at the point of purchase. Charts, brochures, or signs can be used to depict the nutrition information for the 20 most commonly consumed fruits, vegetables, and raw fish. FDA provides the data for retailers in the Code of Federal Regulations (CFR)[1] (21 CFR 101.45 and Appendix C to Part 101). The data are updated periodically to reflect current analyses.

MEATS AND POULTRY

FSIS recommends food retailers provide point-of-purchase information for meat and poultry.[5] As with fresh produce and fish, charts, brochures, or signs can be used to depict nutrition information. In the near future, fresh meat and poultry labeling will no longer be voluntary. FSIS will be publishing a final rule requiring nutrition labeling on single-ingredient, fresh meat, and poultry products.

NUTRIENT CONTENT CLAIMS ALLOWED FOR FOODS AND DIETARY SUPPLEMENTS

OVERVIEW

FDA and USDA have issued regulations for uniform definitions for nutrient content claims as a result of NLEA.[1,5] Current nutrient content claims have been authorized either by (1) FDA and FSIS as a result of NLEA,[3] which also allowed for petitions for new nutrient content claims or (2) notification of FDA through the FDA Modernization Act (FDAMA).[13] A nutrient content claim characterizes the level of a nutrient in a food (e.g., "high fiber"). Nutrient content claims include two types of claims: absolute (free, low, good source, high, lean, or extra lean) and comparative claims (reduced, light, less, or more). The regulations establish the allowed terms and the criteria/requirements for their use (see Table 3.7). For additional details, see 21 CFR 101.13[1] and 101.54–101.69[1] and 9 CFR 317.360–317.362[5] (Table 3.8). FDA allowed FDAMA nutrition content claims notifications to pass through for choline and omega-3 fatty acids. The labeling page of the FDA's Web site provides detail on the choline notification.[21] The omega-3 fatty acid notifications can be found on the dockets page of FDA's Web site using their docket numbers.[22]

HEALTH CLAIMS ALLOWED FOR FOODS AND DIETARY SUPPLEMENTS

OVERVIEW

NLEA allowed health claims to be carried on qualified food products. Prior to this time, these claims were considered unauthorized drug claims. A health claim describes the relationship between a food, a nutrient, or other substance in a food and the risk of a health-related condition or disease (21 CFR 101.14).[1]

Health claims can be made through third-party references, such as the American Heart Association, and with the use of symbols such as a heart, statements, and vignettes or descriptions. Regardless of the manner of presentation, the requirements for the claim must be met in order for a food or supplement to carry the claim on its product packaging or in its advertising. Health claims carry general and specific requirements. General requirements include not exceeding certain amounts of fat (13 g), saturated fat (1 g), cholesterol (60 mg), and sodium (480 mg). The food must be a "good source" of fiber, protein, vitamin A, vitamin C, calcium, or iron prior to fortification. The specific requirements for each health claim are listed in the CFR (21 CFR 101.72–101.83)[1], except for those authorized through FDAMA[13] or by the courts and enforcement discretion. The requirements for those health claims authorized through FDAMA[13] can be found on FDA's Web site.[21]

Current health claims have been authorized by (1) FDA as a result of NLEA,[3] which also allowed for petitions for new health claims (14 total) (Table 3.9); (2) notification of FDA through FDAMA[13] (Table 3.10); or (3) court action as a result of the Pearson Decision,[23] which provided for qualified health claims (QHCs) for which FDA exercises enforcement discretion (Table 3.11). QHC petitions follow a similar procedure as other health claim petitions.

FDAMA[13] allowed notification of FDA about a health claim. FDAMA health claims, unlike the other claims, allow no opportunity for public comment. A company must compile the data and use an authoritative statement. If FDA takes no action within 120 days of the notification, then the health claim can be made on the foods qualifying for the claim.

The Pearson Decision[23] was brought about by a lawsuit filed by Durk Pearson, Sandy Shaw, and the American Preventive Medical Association to allow four previously denied health claims to be made on dietary supplements (DS). The court decision mandated that FDA (1) reconsider whether to authorize the four previously denied health claims, (2) determine if the weight of the scientific evidence in support of the claims is greater than that against it, and (3) if so, determine if qualifying language would not mislead consumers. FDA was also required to define significant scientific agreement (SSA).

TABLE 3.7
Allowed Nutrient Content Claims with Definitions[a,b]

Claim	Calories	Fat	Saturated Fat	Cholesterol	Sodium	Fiber	Sugar	Protein	Vitamins/Minerals
"Free," "no," "zero," or "without"	Less than 5 cal	0.5 g or less	0.5 g or less	Less than 2 mg cholesterol and 2 g or less saturated fat and *trans* fat	Less than 5 mg	NA	Less than 0.5 g	NA	NA
"Very low"	NA	NA	NA	NA	Less than 35 mg	NA	NA	NA	NA
"Low"	40 cal or less	3 g or less	1 g or less	20 mg or less cholesterol and 2 g or less saturated fat	140 mg or less	NA	NA	NA	NA
"Reduced"	25% lower in calories than the comparable food	25% lower in calories than the comparable food	25% lower in calories than the comparable food	25% lower in calories than the comparable food	25% lower in calories than the comparable food	NA	25% lower in calories than the comparable food	NA	NA
"Light"	$1/3$ fewer calories than the reference foods, only if the reference food contains less than 50% calories from fat	50% less fat than the reference food	NA	NA	50% less sodium than the reference food; food also is "low fat" and "low calorie"	NA	NA	NA	NA
"Good source," "provides," or "contains"	NA	NA	NA	NA	NA	2.5 to 4.9 g	NA	5 g or more	10% to 19% of the DV
"High," "excellent source of," or "rich in"	NA	NA	NA	NA	NA	5 g or more	NA	10 g or more	20% or more of the DV
"More," "added," "enriched," or "fortified"	NA	NA	NA	NA	NA	NA	NA	10% more of the DV (5 g or more)	10% more of the DV

[a] Definitions vary for meal and main dishes.
[b] Complete definitions are found in Reference 1 (21 CFR 101.13 and 21 CFR 101.54–101.69) and Reference 5 (9 CFR 317.313–317.363).

TABLE 3.8
Other Nutrient Content Claims[a,b]

Claim	Definition
"% Fat free"	Must be "low fat" or "fat free." Must indicate the amount of fat present in 100 g of food.
"Healthy"	Must be "low fat" and "low saturated fat" or "extra lean." Must not exceed disclosure levels for sodium or cholesterol 21 CFR 101.13(h). Must contain 10% DV for vitamin A, vitamin C, iron, calcium, protein, or fiber. (*Exceptions*: fruits and vegetables; frozen or canned single-ingredient fruits and vegetables, except that ingredients whose addition does not change the nutrient profile of the fruit or vegetable may be added; enriched cereal-grain products that conform to a standard of identity.
Lean	Less than 10 g fat, less than 4 g saturated fat, less than 95 mg cholesterol per RACC and per 100 g.
Extra lean	Less than 5 g fat, less than 2 g saturated fat, less than 95 mg cholesterol per RACC and per 100 g.
"High potency"	Food must contain individual vitamins or minerals that are present at 100% or more of the RDI per reference amount or a multi-ingredient food product that contains 100% or more of the RDI for at least $^2/_3$ of the vitamins and minerals with DVs and that are present in the product at 2% or more of the RDI (e.g., "High potency multivitamin, multimineral DS tablets").

[a] Definitions vary for main dish and meal products and may differ for meat, poultry, seafood, and game.
[b] Complete definitions are found in Reference 1 (21 CFR 101.13 and 21 CFR 101.54–101.69) and Reference 5 (9 CFR 3177.313–317.363).

TABLE 3.9
Health Claims Authorized Through the Regulations Implementing NLEA[a]

Health Claim	Model Language	Requirements	Can be Made on Qualified
Cancer			
Fruits and vegetables and cancer	Development of cancer depends on many factors. A diet low in fat and high in fruits and vegetables, such as oranges, which are fat-free and high in vitamin C, vitamin A, and fiber, may reduce the risk of some cancers.	Food product must be or must contain a fruit or vegetable. Product is "low fat" and is a "good source" of at least one of the following: vitamin A, vitamin C, or fiber.	Foods
Fiber-containing grain products, fruits and vegetables and cancer	Low-fat diets rich in fiber-containing grain products, fruits, and vegetables may reduce the risk of some types of cancer, a disease associated with many risk factors.	Food product must be or must contain a grain product, fruit, or vegetable. Food product is "low fat" and is (prior to fortification) a "good source of dietary fiber."	Foods
Fat and cancer	Development of cancer depends on many factors. A diet low in total fat may reduce the risk for some cancers.	Food product is "low fat." Fish and game meats must be "extra lean."	Foods
Coronary heart disease (CHD)			
Fruits, vegetables and grain products that contain fiber, especially soluble fiber, and risk of coronary heart disease	Diets low in saturated fat and cholesterol and rich in fruits, vegetables, and grain products that contain some types of dietary fiber, particularly soluble fiber, may reduce the risk of heart disease, a disease associated with many factors.	Food product contains greater than 0.6 g soluble fiber. Soluble fiber is listed on Nutrition Facts Panel. Food product must be "low fat," "low saturated fat" and "low cholesterol." Food is, or must contain, a vegetable, fruit, or grain product.	Foods
Soluble fiber from certain foods (oats, psyllium, and barley) and coronary heart disease	Diets low in saturated fat and cholesterol that include [ ] g of soluble fiber per day from [name of food] may reduce the risk of heart disease. One serving of [name of food] supplies [ ] g of the [ ] g necessary to have this effect.	*Oats and Barley*: Food contains β-glucan soluble fiber from whole oats or barley. Food contains greater than 0.75 g whole oat soluble fiber or whole grain barley and dry milled barley. Soluble fiber is listed on the Nutrition Facts Panel. Food is "low saturated fat," "low cholesterol," and "low fat" *Psyllium*: Food contains greater than 1.7 g soluble fiber from psyllium husk. Food is "low saturated fat," "low cholesterol," and "low fat." Soluble fiber is listed on the Nutrition Facts Panel.	Foods
Soy protein and coronary heart disease	Diets low in fat and cholesterol that include 25 g of soy protein a day may reduce the risk of heart disease. One serving of [name of food] provides [ ] g of soy protein.	Food contains greater than 6.25 g soy protein. Food is "low saturated fat" and "low cholesterol." Food is "low fat," unless it consists of or is derived from whole soybeans and contains no fat in addition to the fat inherently present in the whole soybeans it contains or from which it is derived.	Foods

Continued

TABLE 3.9
(Continued)

Health Claim	Model Language	Requirements	Can be Made on Qualified
Saturated fat and cholesterol and coronary heart disease	While many factors affect heart disease, diets low in saturated fat and cholesterol may reduce the risk of this disease	Food must be "low saturated fat," "low fat," and "low cholesterol." Fish and game meats must be "extra lean"	Foods
Plant sterols/stanol esters and coronary heart disease	*Plant Stanol Esters*: Diets low in saturated fat and cholesterol that include two servings of foods that provide a daily total of at least 3.4 g of vegetable oil stanol esters in two meals may reduce the risk of heart disease. A serving of [name of food] supplies [ ] g of vegetable oil stanol esters *Plant Sterol Esters*: Foods containing at least 0.65 g per serving of plant sterol esters, eaten twice a day with meals for a daily total intake of at least 1.3 g, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [name of food] supplies [ ] g of vegetable oil sterol esters	Food contains 0.65 g of plant sterol esters/RACC (spreads and salad dressings) or 1.7 g of plant stanol esters/RACC (spreads, salad dressings, snack bars and dietary supplements (DS) in softgel form). Food is "low saturated fat" and "low cholesterol." Food must not exceed the fat disqualifying levels of health claims unless it is a spread or a salad dressing. Those products (spreads or salad dressings) that exceed 13 g of fat must carry a disclosure statement referring consumers to Nutrition Facts Panel for information about fat content. Food contains 10% or more of the DV for vitamin A, vitamin C, iron, calcium, protein, or fiber unless the product is a salad dressing	
Other health claims			
Calcium and osteoporosis	Regular exercise and a healthy diet with enough calcium help teen and young adult White and Asian women maintain good bone health and may reduce their high risk of osteoporosis later in life. Adequate calcium intakes are important, but daily intakes above 2000 mg are not likely to provide any additional benefit	Food or DS must be "high" calcium	Foods and DS
Sodium and hypertension	Diets low in sodium may reduce the risk of high blood pressure, a disease caused by many factors.	Food must be "low sodium"	Foods
Sugar alcohols and dental caries	Frequent eating of foods high in sugars and starches as between-meal snacks can promote tooth decay. The sugar alcohol used to sweeten this food may reduce dental caries	Food must contain less than 0.5 g sugar. Sugar alcohol in the food shall be sorbitol, isomalt, xylitol, lactitol, hydrogenated glucose syrup, hydrogenated starch hydrolysates, or a combination	Foods
Folic acid and neural tube defects	Healthful diets with adequate folate may reduce a woman's risk of having a child with a brain or spinal cord defect	Food or supplements must be a "good source" of folate. Health claim cannot be made on foods that contain more than 100% RDI for vitamin A or D	Foods and DS

[a] See Reference 1 (21 CFR101.14 and 101.72–101.83) for complete requirements.

As a result, FDA now provides enforcement discretion for health claims that are not supported by SSA. A procedure for approving these claims resulted from FDA's Consumer Health Information for Better Nutrition Initiative.[24] In July 2003, FDA published the Task Force Report and Guidance on Qualified Health Claims.[24] Key components included the following:

1. An evidence-based rating system from the Agency for Health Care Research. The strength of the evidence is assigned a rating, and the corresponding language now appears on product packages. The four levels and related qualified statements are as follows:
    "A": SSA (no qualifier).
    "B": "Although there is scientific evidence supporting the claim, the evidence is not conclusive."
    "C": "Some scientific evidence suggests … . However, FDA has determined that this evidence is limited and not conclusive."
    "D": "Very limited and preliminary scientific research suggests … . FDA concludes that there is little scientific evidence supporting this claim."
2. A proposed regulatory framework for QHCs.
3. Consumer studies research agenda.
4. Resources for the review of scientific data.

TABLE 3.10
Health Claims Allowed to Pass Through FDAMA[a]

Health Claim	Model Language	Requirements Per RACC	Can be Made on Qualified
Whole grains and risk of heart disease and certain cancers and coronary heart disease	Diets rich in whole grains and other plant foods and low in total fat, saturated fat and cholesterol, may help reduce the risk of heart disease and certain cancers.	Food contains at least 51% whole grain ingredient(s) by weight, and whole grain is the first ingredient listed. Food must be "low fat, " "low saturated fat," and "low cholesterol." Food must provide at least 16 g of whole grain. Food contains a minimum amount of dietary fiber related to RACC size: 3 g for 55 g RACC, 2.8 g for 50 g RACC, 2.5 g for 45 g RACC, and 1.7 g for 35 g RACC	Foods
Whole grains foods with moderate fat content and CHD and certain cancers	Diets rich in whole grains and other plant foods and low in total fat, saturated fat, and cholesterol may help reduce the risk of heart disease and certain cancers.	Food contains at least 51% whole grain ingredient(s) by weight, and whole grain is the first ingredient listed. Food must be "low saturated fat" and "low cholesterol" and contain less than 6.5 g total fat and 0.5 g or less *trans* fat. Food contains a minimum amount of dietary fiber related to RACC size: 3 g for 55 g RACC, 2.8 g for 50 g RACC, 2.5 g for 45 g RACC, and 1.7 g for 35 g RACC. Food contains at least 7% of fiber DV if the product does not contain at least 10% DV for protein, calcium, iron, vitamin A or C	Foods
Potassium containing foods and blood pressure and stroke	Diets containing foods that are good sources of potassium and low in sodium may reduce the risk of high blood pressure and stroke.	Food contains at least 10% DV for potassium. Potassium is listed on the Nutrition Facts Panel. Food is "low sodium," "low cholesterol," "low saturated fat," and "low fat"	Foods

[a] See http://www.cfsan.fda.gov/~dms/labfdama.html for further details.

TABLE 3.11
QHC Allowed by the Pearson Decision and FDA Enforcement Discretion[a–d]

Health Claim	Model Language	Requirements Per RACC	Can be Made on Qualified
Cancer			
Tomatoes or Tomato Sauce and Prostate, Ovarian, Gastric and Pancreatic Cancers: *Docket No. 2004Q-0201*	*Prostate cancer*: Very limited and preliminary scientific research suggests that eating one-half to one cup of tomatoes or tomato sauce a week may reduce the risk of prostate cancer. FDA concludes that there is little scientific evidence supporting this claim *Ovarian cancer*: One study suggests that consumption of tomato sauce two times per week may reduce the risk of ovarian cancer, while this same study shows that consumption of tomatoes or tomato juice had no effect on ovarian cancer risk. FDA concludes that it is highly uncertain that tomato sauce reduces the risk of ovarian cancer *Gastric cancer*: Four studies did not show that tomato intake reduces the risk of gastric cancer, but three studies suggest that tomato intake may reduce this risk. Based on these studies, FDA concludes that it is unlikely that tomatoes reduce the risk of gastric cancer *Pancreatic cancer*: One study suggests that consuming tomatoes does not reduce the risk of pancreatic cancer, but one weaker, more limited study suggests that consuming tomatoes may reduce this risk. Based on these studies, FDA concludes that it is highly unlikely that tomatoes reduce the risk of pancreatic cancer	Food is cooked, raw, dried, or canned tomatoes. Tomato sauces must contain at least 8.37% salt-free tomato solids	Foods

**TABLE 3.11
(Continued)**

Health Claim	Model Language	Requirements Per RACC	Can be Made on Qualified
Calcium and Colon/ Rectal Cancer and Calcium and Recurrent Colon/ Rectal Polyps: *Docket No. 2004Q-0097*	*Colon/Rectal cancer*: Some evidence suggests that calcium supplements may reduce the risk of colon/ rectal cancer; however, FDA has determined that this evidence is limited and not conclusive *Recurrent colon Polyps*: Very limited and preliminary evidence suggests that calcium supplements may reduce the risk of colon/rectal polyps. FDA concludes that there is little scientific evidence to support this claim	Dietary supplements are "high" calcium. DS contain bioavailable calcium that meets the U.S. Pharmacopeia (USP) standards for disintegration and dissolution applicable to their component calcium salts. For DS for which no USP standards exist, the DS must be bioavailable under conditions of use	DS
Green Tea and Cancer: *Docket No. 2004Q-0083*	*Breast cancer*: Two studies do not show that drinking green tea reduces the risk of breast cancer in women, but one weaker, more limited study suggests that drinking green tea may reduce this risk. Based on these studies, FDA concludes that it is highly unlikely that green tea reduces the risk of breast cancer *Prostrate cancer*: One weak and limited study does not show that drinking green tea reduces the risk of prostate cancer, but another weak and limited study suggests that drinking green tea may reduce this risk. Based on these studies, FDA concludes that it is highly unlikely that green tea reduces the risk of prostate cancer	Food or DS must contain green tea. Food or DS do not need to contain 10% minimum nutrient content requirement	Foods and DS
Selenium and Cancer: *Docket No. 02P-0457*	Selenium may reduce the risk of certain cancers. Some scientific evidence suggests that consumption of selenium may reduce the risk of certain forms of cancer. However, FDA has determined that this evidence is limited and not conclusive	DS must be "high selenium." DS labeling cannot recommend daily intake exceeding 400 g	DS
Antioxidant Vitamins and Cancer: *Docket No. 91N-0101*	Some scientific evidence suggests that consumption of antioxidant vitamins may reduce the risk of certain forms of cancer. However, FDA has determined that this evidence is limited and not conclusive	DS must be "high vitamin C" or "high vitamin E." DS labeling cannot recommend daily intake more than 2000 mg vitamin C or more than 1000 mg vitamin E	DS
Cardiovascular disease risk			
Omega-3 Fatty Acids and CHD: *Docket No. 2003Q-0401*	Supportive but not conclusive research shows that consumption of EPA and DHA omega-3 fatty acids may reduce the risk of CHD One serving of [Name of the food] provides [ ] gram of EPA and DHA omega-3 fatty acids. (See nutrition information for total fat, saturated fat, and cholesterol content) *Note*: DS may declare the amount of EPA and DHA per serving in "Supplement Facts," instead of making the declaration in the claim	*Fish*: Fish (i.e., "products that are essentially all fish") must have 16 g or less fat per RACC. Fish with fat content greater than 13 g per RACC must include disclosure statement. Fish may not exceed saturated fat disqualifying level and must contain less than 95 mg cholesterol per RACC and per 100 g. If fish contains more than 60 mg, claim must carry disclosure statement *Foods other than fish*: Foods other than fish may not exceed fat disqualifying levels and must be "low saturated fat" and "low cholesterol" *DS*: DS should not recommend daily intake xceeding 2 g of EPA and DHA. DS weighing 5 g or less per RACC are exempted from total fat disqualifying level, but if DS exceed fat disqualifying level must include disclosure statement DS that weigh more than 5 g per RACC must not exceed fat disqualifying level DS must meet the criterion for "low" saturated fat, but not with regard to the no more than 15% calories from saturated fat criterion	Foods and DS

TABLE 3.11
(Continued)

Health Claim	Model Language	Requirements Per RACC	Can be Made on Qualified
		DS that weigh 5 g or less per RACC are exempt from the cholesterol disqualifying level (60 mg per 50 g), but those that exceed cholesterol disqualifying level must include disqualifying statement DS that weigh more than 5 g per RACC must meet the criterion for "low cholesterol"	
Folic Acid, Vitamin B$_6$, and Vitamin B$_{12}$ and Vascular Disease: *Docket No. 99P-3029*	As part of a well-balanced diet that is low in saturated fat and cholesterol, folic acid, vitamin B$_6$, and vitamin B$_{12}$ may reduce the risk of vascular disease. FDA evaluated the above claim and found that, while it is known that diets low in saturated fat and cholesterol reduce the risk of heart disease and other vascular diseases, the evidence in support of the above claim is inconclusive	DS cannot state the daily dietary intake necessary to achieve a claimed effect because the evidence is not definitive. Products greater than 100% DV folic acid must state safe upper limit of 1000 μg. DS containing folic acid must meet USP standards for disintegration and dissolution, except that, if there are no applicable USP standards, folate must be bioavailable under conditions of use	DS
Walnuts and Heart Disease: *Docket No. 02P-0292*	Supportive but not conclusive research shows that eating 1.5 oz per day of walnuts, as part of a low-saturated-fat and low-cholesterol diet and not resulting in increased caloric intake, may reduce the risk of coronary heart disease. See nutrition information for fat (and calorie) content	Food must be whole or chopped walnuts. Food may exceed disqualifying level for fat and is not required to contain 10% minimum nutrient content requirement	Foods
Nuts and Heart Disease: *Docket No. 02P-0505*	Scientific evidence suggests but does not prove that eating 1.5 oz per day of most nuts [such as *name of specific nut*] as part of a diet low in saturated fat and cholesterol may reduce the risk of heart disease. (See nutrition information for fat content). *Notes*: The bracketed phrase naming a specific nut is optional. The bracketed fat content disclosure statement is applicable to a claim made for whole or chopped nuts, but not a claim made for nut-containing products	Food must be whole or chopped nuts or nut-containing products that contain at least 11 g of one or more of almonds, hazelnuts, peanuts, pecans, some pine nuts, pistachio nuts, and walnuts *Nuts*: Nuts must not exceed 4 g saturated fat per 50 g. Nuts may exceed fat disqualifying level. Walnuts do not need to contain 10% minimum nutrient content requirement *Nut-containing products*: Nut-containing products must be "low saturated fat" and "low cholesterol"	Foods
Monounsaturated Fatty Acids from Olive Oil and Coronary Heart Disease: *Docket No. 2003Q-0559*	Limited and not conclusive scientific evidence suggests that eating about two tablespoons (23 g) of olive oil daily may reduce the risk of coronary heart disease due to the monounsaturated fat in olive oil. To achieve this possible benefit, olive oil is to replace a similar amount of saturated fat and not increase the total number of calories you eat in a day. One serving of this product contains [ ] g of olive oil Note: The last sentence of the claim "One serving of this product contains [ ] g of olive oil" is optional when the claim is used on the label or in the labeling of olive oil	*Olive oil*: Food must be pure olive oil *Salad dressing*: Salad dressing must contain at least 6 g olive oil, be "low cholesterol," and not contain more than 4 g of saturated fat per 50 g. *Vegetable oil spreads*: Vegetable oil spreads must contain at least 6 g olive oil, be "low cholesterol," and not contain more than 4 g saturated fat *Olive oil-containing foods*: Olive-oil-containing foods must provide at least 6 g olive oil, be "low cholesterol," and contain 10% DV vitamin A, vitamin C, iron, calcium, protein, or dietary fiber. If the RACC of the olive-oil-containing food is greater than 30 g, the food cannot contain more than 4 g of saturated fat per RACC, and if the RACC of the olive-oil-containing food is 30 g or less, the food cannot contain more than 4 g of saturated fat per 50 g. *Shortenings*: Shortenings must contain at least 6 g olive oil, be "low cholesterol," and not contain more than 4 g of saturated fat per RACC	Foods

**TABLE 3.11
(Continued)**

Health Claim	Model Language	Requirements Per RACC	Can be Made on Qualified
Calcium and Hypertension, Pregnancy-Induced Hypertension and Preeclampsia: *Docket No. 2004Q-0098*	*Hypertension*: Some scientific evidence suggests that calcium supplements may reduce the risk of hypertension. However, FDA has determined that the evidence is inconsistent and not conclusive *Pregnancy-induced hypertension*: Four studies, including a large clinical trial, do not show that calcium supplements reduce the risk of pregnancy-induced hypertension during pregnancy. However, three other studies suggest that calcium supplements may reduce the risk. Based on these studies, FDA concludes that it is highly unlikely that calcium supplements reduce the risk of pregnancy-induced hypertension *Preeclampsia*: Three studies, including a large clinical trial, do not show that calcium supplements reduce the risk of preeclampsia during pregnancy. However, two other studies suggest that calcium supplements may reduce the risk. Based on these studies, FDA concludes that it is highly unlikely that calcium supplements reduce the risk of preeclampsia	Must be "high calcium." DS calcium content must be bioavailable and must meet USP standards for disintegration and dissolution applicable to their component calcium salts. For DS for which no USP standards exist, the DS must exhibit appropriate assimilability under the conditions of use	DS
Cognitive function Phosphatidylserine and Cognitive Dysfunction and Dementia: *Docket No. 02P-0413*	*Dementia*: Consumption of phosphatidylserine may reduce the risk of dementia in the elderly. Very limited and preliminary scientific research suggests that phosphatidylserine may reduce the risk of dementia in the elderly. FDA concludes that there is little scientific evidence supporting this claim *Cognitive dysfunction*: Consumption of phosphatidylserine may reduce the risk of cognitive dysfunction in the elderly. Very limited and preliminary scientific research suggests that phosphatidylserine may reduce the risk of cognitive dysfunction in the elderly. FDA concludes that there is little scientific evidence supporting this claim	The claim may not suggest level of phosphatidylserine as being useful in achieving the claimed effect. The soy-derived phosphatidylserine must be of very high purity	DS containing soy-derived phosphatidylserine
Diabetes Chromium Picolinate and Diabetes: *Docket No. 2004Q-0144*	One small study suggests that chromium picolinate may reduce the risk of insulin resistance, and therefore possibly may reduce the risk of type 2 diabetes. FDA concludes, however, that the existence of such a relationship between chromium picolinate and either insulin resistance or type 2 diabetes is highly uncertain	DS must be "high chromium"	DS
Neural tube defects 0.8 mg Folic Acid and Neural Tube Birth Defects: *Docket No. 91N-100H*	0.8 mg folic acid in a DS is more effective in reducing the risk of neural tube defects than a lower amount in foods in common form. FDA does not endorse this claim. Public health authorities recommend that women consume 0.4 mg folic acid daily from fortified foods or DS or both to reduce the risk of neural tube defects	There also is a folic acid/neural tube defect health claim authorized by regulation (see 21 CFR 101.79)	DS

[a] For all QHC requirements, the claim meets the general requirements for health claims in Reference 1 (21 CFR 101.14) (unless otherwise noted), *except* for the requirement that the evidence for the claim meet the SSA standard and be made in accordance with an authorizing regulation Reference 1 ([21 CFR 101.14(c)].

[b] All conventional foods must meet the 10% minimum nutrient requirement (vitamin A 5000 IU, vitamin C 6 mg, iron 1.8 mg, calcium 100 mg, protein 5 g, fiber 2.5 g as per RACC), prior to any nutrient addition. The 10% minimum nutrient requirement does not apply to DS [21 CFR 101.14(e)(6)].

[c] If disclosure levels of fat, saturated fat, or cholesterol are exceeded, the appropriate disclosure statements must be included immediately adjacent to the claims, for example, "See nutrition information for total fat content" with the health claim.

[d] Further detail for all claims can be found on the FDA Web site http://www.cfsan.fda.gov/~dms/lab-qhc.html

The final QHC guidance was published in spring 2006.[25] The guidance further details the process for submitting QHC petitions and the language that is used. The process of submitting QHC petitions is similar to that for health claims based on SSA petitions. However, as mentioned, the SSA requirement is not enforced. QHCs need to meet all general health claim requirements unless enforcement discretion is provided. These exceptions are noted in the QHC table (Table 3.11).

FDA authorized 7 claims as a result of NLEA.[3] Since that time, FDA has approved an additional 5 claims submitted as petitions, 3 claims submitted as notifications through FDAMA,[13] and 15 claims as a result of the Pearson Decision and the Consumer Health Information for Better Nutrition Initiative (enforcement discretion). The health claim model language and requirements are indicated in Tables 3.9 to 3.11: those resulting from NLEA[3] and petitions (Table 3.9), those not prohibited by FDA through FDAMA[13] (Table 3.10), and those allowed by court decision[23] (enforcement discretion is applied[24]) and are accompanied by extensive qualifying language (Table 3.11). The qualifying language (an appropriate disclaimer, that is, "some scientific evidence suggests ...") must be placed immediately adjacent to and directly beneath the claim, with no intervening material, and in the same size, typeface, and contrast as the claim itself.

Again, the requirements for the FDAMA[13] and court-mandated health claims[23] or those allowed through enforcement discretion[24] are not published in the CFR.[1] These requirements can be found on FDA's Web site.

Additionally, several QHCs are under review: canola oil and a reduced risk of coronary heart disease, corn oil and corn-oil-containing products and a reduced risk of coronary heart disease, and calcium and vitamin D and a reduced risk of osteoporosis.

STRUCTURE/FUNCTION CLAIMS

Overview

Structure/function claims can be made on DS.[12] A structure/function claim describes "the role of a nutrient or dietary ingredient intended to affect the structure or function in humans or that characterizes the documented mechanism by which a nutrient or dietary ingredient acts to maintain such structure of function, provided that such statements are not disease claims" (21 CFR 101.93)[1]. "Calcium helps build strong bones" is an example of a structure/function claim.

Requirements

The general requirements for structure/function claims include (1) statement be truthful and not misleading, (2) the manufacturer of the DS product carrying the claim notify the FDA within 90 days of entering the product into commerce, and (3) DS carry the following disclaimer:

This product is not meant to prevent, treat, mitigate, or cure any disease.

Specific requirements for structure/function claims are not found in the CFR. Individual claims are not approved by FDA.

RESOURCES

Food and Drug Association (http://www.fda/gov/)

The FDA Web site provides a wealth of information about FDA labeling activities, regulatory actions and positions, and industry guidance. The site provides FDA organizational structure and a telephone and e-mail directory so that staff contacts can be made. One can check out the "What's New" section for FDA's latest actions. Links are provided to other regulatory agencies such as the FTC and the FSIS.

Food Safety and Inspection Service (http://www.fsis/gov)

The USDA's FSIS is responsible for overseeing labeling of meat and poultry foods. The agency allows health claims on a case-by-case basis. (FSIS requires label approval prior to use on a product.) The FSIS Web site provides regulatory guidelines and current information.

CFR (http://www.cfsan.fda/gov/~dms/reg-2.html)

The CFR codifies all of the general and permanent rules published in the *Federal Register* by FDA and FSIS, USDA, FTC, and BATF. The CFR is divided into 50 titles, each representing an area of federal regulation, for example, 21 CFR is Food and Drugs, and 9 CFR is USDA. The titles are then divided into chapters that usually bear the name of the responsible agency. Those most pertinent to the food label include 21 CFR 100–169[1] (FDA, food labeling), 21 CFR 170–199[1] (FDA, food additives), and 9 CFR 200 to end[5] (FSIS, food labeling). The CFR can be accessed online through the FDA Web site. The CFR is updated annually.

FEDERAL REGISTER (http://www.cfsan.fda/gov/~dms/reg-2.html)

The federal government, FDA and FSIS, publishes regulations in the *Federal Register* to implement food and DS laws in various forms (notice, proposed rule, and final rule) on a daily basis. Once a final rule is published, it is incorporated into the CFR. The *Federal Register* can be accessed through FDA's Web site. It can be searched by agency, date, date range, or topic.

4 Computerized Nutrient Analysis Systems

Judith Ashley and Gwenn Snow

CONTENTS

INTRODUCTION

Since the early 1980s, the incorporation of microcomputer technology into nutrient analysis processes has resulted in the advent of computerized nutrient analysis systems. These systems offer an effective and time-efficient method by which end users can calculate the nutrient composition of foods and beverages for a variety of applications.[1–4] Health professionals can use computerized dietary analyses to provide clients with specific information about their current food/beverage choices and healthful alternatives, with the goal of fostering positive dietary changes. For nutrition educators, the hands-on application of these software programs is an integral part of student education. For researchers and government agencies, nutrient analysis software is an essential tool for analyzing and documenting the usual food intake of individuals, groups, or populations for a variety of uses (e.g., identifying diet–disease relationships). Nutrient analysis software is also important for recipe and menu development by food service managers, chefs, and caterers, and for calculating nutrient information for food labels.

Several companies and organizations offer nutrient analysis software. To be competitive in the market and to stay abreast of changes in scientific knowledge and food production, software vendors must frequently update their programs and the quality and scope of their services. In general, nutrient analysis software provides information about the nutrient composition of foods and beverages selected for analyses. To achieve this end, specific information about foods/beverages (e.g., type or quantity) is entered into the program and assigned a code. The software then uses these codes to locate and store information about the nutrient composition of the specific food items selected and, eventually, to sum across all foods for each nutrient or nutrient component. Programs vary considerably in cost, ease of use, capabilities, size, and available features. [5–7] For the prospective user, the choice of software requires careful consideration of needs and available resources, and financial support for computer hardware and peripherals.

FEATURES OF NUTRIENT ANALYSIS SOFTWARE

Primary features of nutrient analysis software include (1) food descriptions, (2) food portions and weights, (3) nutrients and food components, (4) a user interface, and (5) output options. Commonly, programs include reference standards for evaluating dietary quality (e.g., Dietary Reference Intakes [DRI] and Dietary Guidelines for Americans 2005) and allow users to enter tracking or contact information (e.g., case number, name, address, and telephone number) and data about physiological characteristics (e.g., gender, age, height, and weight; for women, pregnancy or lactation status) specific to individual subjects or clients. This latter feature makes it possible to tailor reference standards to reflect client profiles (e.g., energy needs or targeted weight goals). Refer to Table 4.1 for contact information and details about program applications and database characteristics of several of the larger programs currently available, and Table 4.2 for a comprehensive list of nutrients and food components included in such programs.

Programs vary considerably in the number and types of available output options, with some offering both electronic and printed reports, and textual and graphical data displays (e.g., two- and three-dimensional pie and bar charts). Report contents

also vary by vendor and may include simple nutrient summaries, lists of foods in descending or ascending order by nutrient contribution, or recommendations for enhancing dietary quality.

Additional software features include mechanisms for comparing food/beverage choices with food exchange lists; assessing nutrient intake by meal, food item, or food category; and classifying foods according to the glycemic index. Programs are also available that allow data to be collected and averaged for individuals or groups or for a specified time period, ranging from a single eating occasion to several days' worth of meals and snacks. Some programs allow users to export data into statistical analysis software packages or word-processing programs or to enter data by scanning questionnaires (e.g., food frequency checklists). The latter would be useful for entering large data sets or calorie-count data for patients who are hospitalized or institutionalized. Alternatively, nutrient analysis software might support multiuser platforms, interface with foodservice management software, provide information about potential food–drug interactions, contain recipe databases, and include nutrient information for nutrition support regimens. Programs are available that allow users to add or modify foods, nutrients, and recipes; scale or cost recipes; plan meals, including meals that must provide one-third of the Recommended Dietary Allowance (RDA) for nutrients; generate sample menus; or customize nutrition support regimens.

BASIC QUESTIONS TO ASK WHEN CONSIDERING DIFFERENT SOFTWARE SYSTEMS

Depending on the projected use of nutrient analysis software, many or all of the following questions may apply when evaluating individual programs:

- What are the operating system and hardware requirements? Are these requirements compatible with existing equipment and peripherals? If not, are funds available to purchase new hardware?
- How many food items are included in the database? What types of foods are included? For example, does the database contain information about baby foods, convenience foods, fast foods, regional specialties, ethnic specialties, fortified/enriched foods, fat-modified foods, sugar-free foods, or nutritional supplements? Can foods, beverages, or recipes be added?
- What specific nutrients and nutritional components are in the database? Does this list include the nutrients and food components or values (e.g., glycemic index) of interest to you? Is the number of nutrients in the database at the low-end, middle, or high-end range of available nutrients? Can information about nutrients and food components be added?
- How complete is the nutrient information? What are the origins of nutrient values? What is the extent of missing values? When data for specific nutrients are missing, are these estimated or left as zero? Are missing nutrient values identified in reports so that findings are not misleading? (Note: Methods for estimating and reporting missing values dramatically affect the accuracy of nutrient reports.)
- What dietary reference standards are available for use? Are these standards up-to-date? Are standards included for subpopulations (e.g., children, pregnant or lactating women)?
- How is the quality of the database maintained? How often is the software upgraded to reflect changes in the market or advances in scientific knowledge?
- How easy or difficult is it to enter dietary information? Do data entry options include numeric code, food name, brand name, and search features? Can users store or copy frequently used food or meal categories for ready access? Is technical support available to assist users in distinguishing among food listings?
- Can data related to portion sizes be entered using weight, volume, dimensions, or all three measures? Can data be entered in common household measures?
- Does the software allow data from standard food frequency forms to be entered? Can data from such forms be scanned? Is this option included in the usual cost of the software or available for a price?
- Are reports available for a variety of criteria such as reference standards (e.g., RDA), dietary recommendations (e.g., MyPyramid Food Guidance System), and meal planning methods (e.g., food exchange lists)? Can reports be customized to reflect specific nutrients?
- Are reports available that summarize intake data from several days or weeks for comprehensive analysis? Are reports available that summarize intake data by eating occasion? Are reports available that summarize intake data by days of the week? Are reports available that compare data from several points in time to allow for longitudinal comparisons?
- Are reports available that identify key sources of nutrients from the data entered? Can lists of food sources of nutrients be generated?
- Are on-screen reports available in a form that is suitable for use with clients? Can dietary choices be manipulated to demonstrate the effects of dietary changes on nutrient intake or dietary quality? Is this feedback provided instantaneously?

- Are printed reports available? How many options for reference criterion and nutrient content are available for printed reports? Can additional information or comments be added to printed reports?
- Are reports available that use easy-to-understand graphics (e.g., bar graphs and pie charts) to compare intake with designated standards? Are these graphical comparisons available for a variety of reference criterion (see above) and nutrients?
- Are reports accurate, descriptive, and attractive? Are key findings or recommendations readily apparent?
- What formulas are used to calculate energy requirements? If healthy or ideal body weights are suggested, how are these determined? Are such recommendations based on current and reasonable standards?
- Can exercise data be incorporated into caloric requirements? Do reports include exercise recommendations?
- Are there system utilities for backing up valuable data and reports? Are there mechanisms in place to maintain the confidentiality of client information?
- What is the quality of software documentation, online help, and tutorials? Are these easy to understand and specific to user needs? Are these comprehensive in scope?
- What is the quality of customer service, product support, and ongoing maintenance? Is there sufficient technical support provided to answer user needs? Is training available or required?
- What does the complete system, with updates and service, cost? Are there additional costs for multiple users or stations?
- How often are upgrades offered? Is there an additional cost for upgrades?
- Who is the target audience of the output? Are appropriate output options available for consumers, health professionals, medical centers or hospitals, or researchers?

IMPORTANCE OF FOOD COMPOSITION DATABASES

Nutrient analysis software relies heavily on existing food composition databases for nutrient information. Importantly, multiple factors affect the accuracy of these databases, such as the sources of nutrient composition information, the number of foods and nutrients in the database, the number of missing values, the methods by which missing values are handled, and the frequency with which databases are updated.[8] Several published reports have compared the accuracy of nutrient calculations among a limited number of database systems.[9–16] When these calculations were compared with a standard[17–19] or tested against chemical analyses from a single source,[20–22] findings indicated that most nutrients were within 15% of reference values. For example, after comparing calculations from four nutrient composition databases with chemically analyzed values for 36 menus, researchers found that the database values for the nutrients examined had relatively good accuracy: Seven nutrients deviated by values < 10%; five, by 10 to 15%; and only one, by 15 to 20%.[23] While these findings are positive, it is important to note that no standardized benchmarks have been established for comparing the different methods used to determine the nutrient content of foods/beverages. In addition to the quality of nutrient composition databases, other factors affect the accuracy of nutrient analyses (e.g., see Table 4.3).

Most nutrient analysis systems in the United States are based on the U.S. Department of Agriculture's (USDA) National Nutrient Database for Standard Reference (NNDSR) and incorporate nutrition information from other scientific sources and food companies.[24,25] The most recent version is NNDSR-Release 18. NNDSR-18 contains data for over 7146 foods and up to 136 nutrients and food components. The following changes were incorporated into SR18: (1) nutrient values for vitamins E and B_{12} for all foods used in the Food and Nutrition Database for Dietary Studies, (2) new and updated food items (e.g., new beef cuts, French fried potatoes, flaxseed, frozen novelties, sweeteners, and noncarbonated or fitness waters), and (3) expanded brand name fast food data.[25] Comprehensive information about NNDSR-18 can be found at USDA's Nutrient Data Laboratory Web site, including details about all of the foods in the database (e.g., scientific name and nutrient content), nutrient lists for selected foods and nutrients, and documentation (e.g., content of files, weights and measures, and data sources).[26] The Nutrient Data Laboratory also provides access to additional data sets that complement NNDSR-18: *Reports by Single Nutrients*, *Nutritive Value of Foods*, special interest databases for some nutrients (i.e., choline and fluoride), and specific dietary components (i.e., flavonoids, isoflavones, oxalic acid, and proanthocyanidins).[27]

TABLE 4.3
Factors That May Affect Consistency of Nutrient Analysis Outputs

- Data entry errors (e.g., misidentification of foods or incorrect food substitutions)
- Nutrient variability in the food supply
- Frequent changes in the nutrient content of processed foods
- Margin of error allowed for nutrient information from food labels
- Estimated or imputed values for missing nutrient information
- Constraints of chemically determined nutrient values used for comparison (e.g., sample collection or assayed values)

TABLE 4.4
Nutrient Analysis Software Reports: Discussion Topics for Patient Counseling

- Comments that explain and clarify results
- Synopsis of the limitations of the analysis
- Suggestions to improve dietary intake (e.g., information about good food sources of specific nutrients)
- Information about dietary supplements (if warranted)
- Information about supplementary resources, as appropriate

TABLE 4.5
Nutrient Analysis Software Systems: Current and Future Trends

- Expansion to include new or revised nutrient standards[4,24] and dietary recommendations
- Standardization of nutrient composition databases to accommodate international differences in nutrient values, food content and preparation methods, units of measure, and recognized food components[28]
- Identification of bioactive components in foods (e.g., phytochemicals, pre- and probiotics, total antioxidant capacity)[3, 29–33]
- Fortification and enrichment of foods[3]
- Adaptation for use with portable and hand-held computerized devices[7]
- Utilization of automated methods for collecting and processing dietary data such as the Automated Multiple Pass Method,[34] smart cards,[35] and bar codes[36]
- Computation of glycemic load values[37] or other, as-yet-unidentified, markers
- Inclusion of food-borne contaminants (e.g., pesticides or heavy metals)[3]
- Addition of bilingual capabilities[38]
- Determination and addition of information about the nutrient composition of dietary supplements[8,32,39]

The development of representative food composition values involves the acquisition, documentation, evaluation, and aggregation of food composition data. These data are compiled from a wide variety of sources, including published (e.g., manuscripts in the scientific and technical literature) and unpublished sources (e.g., food industry and research under restricted USDA Agricultural Research Service contracts).[25,26]

LIMITATIONS OF NUTRIENT ANALYSIS SOFTWARE

Nutrient analysis software programs have unique limitations.[6] For example, calculations of nutrient intakes may lack precision because of the multiple variables involved, including the size and quality of the databases, calculation methods, and extent of missing values. However, these software-related variables are minor when compared with the human challenges to accuracy. Food intake reports from clients and subjects (e.g., food records and food frequencies) may be inaccurate. Data entry errors may occur if operators misinterpret food descriptions or do not select the correct matches from the database.

In other cases, results may be misinterpreted. For example, computer-generated printouts might appear authoritative, giving the impression that reports are extremely precise, but this may not always be the case (e.g., database may contain multiple missing values). Additionally, individuals unfamiliar with DRI/RDA comparisons may misinterpret these values as minimal nutrient needs and assume that intake levels should be over 100% to avoid deficiencies. Even professionals may have difficulty drawing specific conclusions for individuals when using the DRI/RDA as reference standards.

With regard to these and other limitations, health professionals who use nutrient analysis software to evaluate dietary intake of clients and patients are advised to provide counseling along with software-generated reports (see Table 4.4 for suggestions).

TRENDS IN NUTRIENT ANALYSIS SOFTWARE

Continual advances in scientific knowledge and technology, changes in dietary guidance, and variations in the needs and interests of researchers, educators, and health professionals present constant challenges and multiple opportunities for the development and maintenance of and applications for nutrient analysis software (e.g., see Table 4.5).

CONCLUSION

Nutrient analysis software can be a useful tool for individuals, agencies, or organizations interested in assessing the dietary intake of individuals and populations. Output from these programs can be used to provide specific guidance or develop interventions that may ultimately improve dietary intake and health among individuals and populations.

5 Nutrient Data Analysis Techniques and Strategies

Alan R. Dyer, Kiang Liu, and Christopher T. Sempos

CONTENTS

OVERVIEW

Analyses of nutrient data pose special challenges to investigators. In such analyses, investigators need to consider:

1. Possible over- or under-reporting of intakes, leading to "impossible" or extreme values in the data set
2. How to adjust for total energy intake
3. How to model nutrients, for example, as continuous or categorical variable
4. How to avoid multicollinearity
5. How to handle dietary supplement data
6. Impact of large day-to-day variability and person-specific biases in self-reported intakes, both of which can lead to misclassification of individuals with respect to usual intake

The objectives of this chapter are to examine various approaches to addressing the aforementioned issues, to briefly describe the common types of observational and experimental studies that collect nutritional data, and to describe the most common methods of analysis used in the types of studies described.

QUALITY CONTROL

Regardless of whether investigators use a validated food frequency questionnaire or single or multiple 24 h recalls to collect dietary data, the importance of quality control in such data collection cannot be overemphasized. The phrase GIGO (garbage in, garbage out) serves as a stark reminder of the importance of ensuring that dietary data are of the highest quality when they are submitted for analysis. No amount of analytic sophistication can make up for poor-quality data.

STEPS TO ENSURE GENERAL STUDY AND INTERVIEWER QUALITY

To improve the quality of collected data, investigators should:

- Develop a "Manual of Operations" for nutrient data collection
- Train and certify dietary interviewers in collection of data and use of the manual
- Tape interviews, after obtaining the consent of the participant
- Immediately review a printout of the data collected, including nutrient totals if the system being used permits
- Develop range limits for important nutrients that result in careful review of the questionnaire or 24 h recall with the participant, if limits are exceeded
- Make inquiries to cooks for clarifying reported information when needed
- Query the participant for a 24 h recall on whether the amount consumed was typical, and if atypical, the reason the amount consumed was unusually low or high, for example, lower than usual due to illness
- Use food composition data to estimate nutrient composition for foods and recipes not found in a database when using 24 h recalls
- Randomly select tape recordings for repeat completion of questionnaires or reentry of data, with assessment of discrepancies and correction of incorrect data
- Develop criteria for recertifying interviewers based on the randomly selected recordings

PLAUSIBILITY OF INTAKES

Interviewers may also be requested to indicate whether they believe the participant has provided reliable data. Persons deemed by the interviewer as not providing reliable data should be excluded from the analyses.

Prior to conducting analyses, investigators may wish to set limits on total caloric intake above or below which persons would be excluded. For example, in the Coronary Artery Risk Development in (young) Adults Study (CARDIA),[1] men who reported intakes of >8000 kcal or <800 kcal and women who reported intakes of >6000 kcal or <600 kcal on food frequency questionnaires were excluded from analyses, because values outside these limits were not considered consistent with a normal lifestyle.[2] The INTERMAP study of macro-/micronutrients and blood pressure excluded from analysis persons who reported energy intakes <500 kcal or >5000 kcal for women or >8000 kcal for men on any of four 24 h recalls.[3,4] Food frequency questionnaires generally have larger standard deviations in total energy intake than 24 h recalls, and thus are more likely to have individuals with "impossible" or extreme values.[5] Hence, investigators using food frequency questionnaires need to be particularly attentive to establishing exclusionary cutoffs for total energy intake, such as those used in CARDIA. Investigators using 24 h recalls should consider whether to exclude persons reporting that their 24 h intakes were unusual as well as whether to establish exclusionary cutoffs similar to those used in INTERMAP.

STATISTICAL ISSUES IN ANALYSIS OF INTAKES

IDENTIFYING OUTLIERS OR EXTREME VALUES

Prior to conducting any analyses, investigators should examine the distribution of each variable of interest for outliers or extreme values. The procedure Proc Univariate in SAS is particularly useful in this regard.[6] In addition to providing the standard descriptive statistics, for example, mean, median, standard deviation, range, interquartile range, etc., this procedure also identifies the five largest and five smallest values for each variable, and the 1st, 5th, 10th, 25th, 75th, 90th, 95th, and 99th percentiles. The user can also request a box plot of the data, which can be very helpful in identifying extreme values. The box plot helps indicate how discrepant the largest and smallest values are from the rest of the data. In the Observing Protein and Energy Nutrition (OPEN) Study,[7] investigators excluded values of dietary variables that fell outside the interval given by the following: 25th percentile minus twice the interquartile range to the 75th percentile plus twice the interquartile range on the logarithmic scale.

The fact that a statistical software package identifies values as large or extreme relative to other values in the distribution should not be taken as prima facie evidence that such values are invalid or that an error was made in data collection or data entry. Values so identified should be examined for such problems. However, if the values are biologically plausible and no error appears to have been made, they should not be arbitrarily excluded from the analysis. Neter et al.[8] suggest that a safe rule is "to discard an outlier only if there is direct evidence that it represents an error in recording, a miscalculation, a malfunctioning piece of equipment, or a similar type of circumstance." When outliers are retained in a data set, the investigator needs to take special steps to assess any influence they may have on the results of the analysis. This can include analyses with and without the outlying value or values, use of nonparametric statistical methods (for example, the Spearman rank correlation instead of the usual Pearson correlation coefficient), transformations of the data that bring the outlying value closer to the other values (for example, the log or square root transformation), specific tests for influential observations,[8] or use of robust regression methods.[9]

ADJUSTMENT FOR TOTAL ENERGY INTAKE

Adjustment for total energy intake is of particular relevance for epidemiologic studies in which investigators use some form of regression models to examine the associations of specific nutrients with an outcome variable, for example, blood pressure or cholesterol in multiple linear regression, case-control status in logistic regression, or coronary heart disease incidence in the Cox proportional hazards regression. Thorough discussions on adjustment for total energy intake can be found in Reference 10 or Reference 11. Only the major issues addressed by these authors are described here. The rationale for adjusting for total energy intake is that most nutrients are correlated with total energy intake. This is because they contribute directly to total energy intake, for example, total fat or carbohydrate, or because persons who consume more kilocalories also eat more, on average, of all nutrients, for example, dietary cholesterol or sodium. For example, in participants of the Multiple Risk Factor Intervention Trial (MRFIT),[12] the baseline correlations of 10 energy energy-contributing nutrients with total energy intake ranged from 0.29 for alcohol intake to 0.87 for total fat intake. Among 24 non-energy-contributing nutrients, the correlations ranged from 0.05 for retinol to 0.78 for phosphorus, with a median of 0.52. No nutrient had a negative correlation with total energy intake. Thus, if total energy intake is positively associated with a dependent variable, almost all specific nutrients will also be positively associated with that variable. Hence, in regression analyses involving specific nutrients, there is a need to adjust associations with specific nutrients for the potential confounding effects of total energy intake.

Data from the OPEN Study[7,13] in which doubly labeled water and urinary nitrogen were used as biomarkers for total energy intake and protein intake, respectively, also strongly reinforce the importance of adjustment for energy intake. In particular, the OPEN investigators found that the attenuation of protein intake–disease associations due to within-person variability and person-specific biases can be expected to be substantially less when protein intake is energy-adjusted than when it is not, particularly if dietary data are obtained from a food frequency questionnaire. For example, based on the OPEN data, a single food frequency questionnaire would be expected to underestimate a regression coefficient relating protein intake in g/day and an outcome in men by 84.4% and in women by 86.3%, while the underestimation with protein intake expressed as percentage of kilocalories would be less at 59.4% and 68.4%, respectively.[13] A true relative risk of disease associated with protein intake in g/day of 2.0 would be estimated as 1.11 and 1.10 for men and women, respectively, while the estimated relative risks would be 1.32 and 1.24 for protein intake in percentage of kilocalories.

The most common methods of adjustment for total energy intake are typically referred to as the nutrient density method, the standard multivariate method, the residual method, and the multivariate nutrient density method.[10,11,14] The nutrient density method has been the traditional method of adjusting for total energy intake. In this approach, nutrient intake is divided by total energy intake, with energy-contributing nutrients expressed as percentage of kilocalories and non-energy-contributing nutrients expressed as intake per 1000 kcal. The strengths of this approach include ease of calculation, familiarity by nutritionists, and use in national guidelines.[10] For example, the Committee on Diet and Health of the National Research Council recommends that total fat intake be less than 30% of the total energy intake and that saturated fat intake be less than 10%.[15] The primary problem with the nutrient density method is that it does not completely eliminate potential confounding with total energy intake, because nutrients expressed as nutrient density often remain correlated with total energy intake. For example, in the MRFIT, the correlations of percentage of kilocalories from protein, fat, and carbohydrate intake with total energy intake at baseline were −0.23, 0.18, and −0.11, respectively.[12] However, with these three nutrients expressed as g/day, the corresponding correlations were 0.73, 0.87, and 0.77.

In the standard multivariate method, total energy intake is included in the multivariate regression model along with the nutrient or nutrients of interest. In this model, the regression coefficient for the nutrient of interest represents the effect of changing the nutrient by one unit while maintaining a constant total energy intake. For energy-containing nutrients, this can only be accomplished by making changes, in other energy-contributing nutrients, that are equal to the amount of energy contained in one unit of the nutrient of interest. Similarly, the regression coefficient for total energy intake does not represent the effect of changing total energy intake by 1 kcal, but the effect of changing energy intake from all other energy-contributing nutrients by 1 kcal. For example, if the nutrient in the model is total protein intake, then the total energy intake represents fat and carbohydrate intakes. In using this approach, estimates of the effect of changing the intake of the nutrient by a specific amount should use variation in the nutrient with total energy intake held constant, that is, the nutrient residual (see later) as the basis for the estimates of effect. Failure to do to so can result in estimates of effect based on unrealistic differences in the intake of the nutrient.

In the residual method, the investigator regresses each nutrient of interest on the total energy intake, and then computes a nutrient residual for each individual by subtracting from the individual's actual intake of that nutrient the amount predicted based on the individual's total energy intake. Because the mean of these residuals is equal to zero, it may be desirable to add a constant to each residual, for example, the mean intake for the nutrient. The resulting value does not, however, represent the individual's actual intake and, in fact, has no "biological" or public policy meaning. The residual method is simply one means by which investigators can adjust for total energy intake. Nutrient residuals are independent of total energy intake. Models that use nutrient residuals can also include total energy intake. The regression coefficient for a nutrient expressed as a nutrient residual is identical to the regression coefficient for the nutrient in the standard multivariate model. However, the regression coefficient for total energy intake will not be identical to that in the standard multivariate model. In the residual model, the

association of total energy intake with the dependent variable is not adjusted for intake of the specific nutrient, which could result in an inaccurate estimate of the association of total energy intake with the dependent variable.

In the multivariate nutrient density model, total energy intake is included in the model along with nutrient density. This approach addresses the problem of potential confounding by total energy intake in such analyses. In this model, the regression coefficient for the nutrient estimates the effect of a 1% difference in energy from the nutrient with total caloric intake held constant. As noted by Willett et al.,[10] a major strength of the multivariate nutrient density approach is that it separates diet into two components: composition and total amount.

Modeling Nutrient Intake

Investigators typically model nutrient intake as a continuous variable or as a series of dummy variables corresponding to quantiles of the nutrient, for example, quartiles or quintiles. The advantages of categorizing nutrient intake include reduction of the potential effects of outlying or extreme values and elimination of the need to assume a linear relation between the nutrient of interest and the dependent variable. Categorization is also more informative to readers since it allows estimation of relative risks in logistic regression and the Cox proportional hazards regression for persons in each exposure category relative to a referent category and, in multiple linear regression, the mean difference in the dependent variable for persons in each exposure category relative to the referent category. The main weakness in categorizing a continuous variable is that, when the relationship is linear, the categorization results in a loss of power. However, regardless of how nutrient intake is modeled in the definitive analysis, categorization is still an extremely useful tool and should be part of any analysis plan. This is because categorization allows the investigator to examine the shape of the relation between the nutrient and the dependent variable, and thus whether or not the relation is sufficiently linear to support inclusion of the nutrient as a continuous variable in the regression model.

When nutrient intake is categorized, one defines $k-1$ dummy variables for each individual for the k categories of the variable. For example, if nutrient intake is divided into quartiles, three dummy variables are defined. In defining the dummy variables, it is necessary to define a referent category. This is the category against which the risks or means for the other exposure categories are compared. If nutrient intake is divided into quartiles and the first quartile is to be the referent category, the three dummy variables corresponding to quartiles 2 to 4 are defined as follows:

$$X_1 = \begin{cases} 1 \text{ if intake in second quartile} \\ 0 \text{ otherwise} \end{cases}$$

$$X_2 = \begin{cases} 1 \text{ if intake in third quartile} \\ 0 \text{ otherwise} \end{cases}$$

$$X_3 = \begin{cases} 1 \text{ if intake in third quartile} \\ 0 \text{ otherwise} \end{cases}$$

These definitions produce the following values on each of the variables for individuals in the first through fourth quartiles:

Quartile of intake	X_1	X_2	X_3
1	0	0	0
2	1	0	0
3	0	1	0
4	0	0	1

In defining categories for a nutrient, investigators should adjust for total energy intake by defining the categories based on nutrient residuals or nutrient densities, rather than absolute intake.[14] While the standard multivariate method and the nutrient residual method provide identical regression coefficients for the nutrient of interest when the nutrient is entered as a continuous variable, this is not the case when nutrient intake is categorized.[14] In this case, the standard multivariate method should be avoided. It is also desirable to model total energy intake as a continuous variable in such analyses rather than as a second categorical variable, particularly if nutrient density is the variable being categorized.[11,14]

Multicollinearity

Multicollinearity in a regression model can occur when highly intercorrelated variables are entered simultaneously into the model or when a linear combination of several variables essentially equals a constant. For example, multicollinearity would occur with nutrient data if the model included percentage of kilocalories from total fat, protein, and carbohydrate because the

sum of these three variables is often 100 or quite close to 100. Hence, investigators should not attempt to enter more than two of these variables simultaneously into a regression model. Similarly, multicollinearity would also occur if these same three variables were entered into a model as g/day along with total energy intake. In this case, only three of these four variables should be entered simultaneously. In general, investigators need to ensure that they do not include in the same model variables representing total intake for a nutrient and all individual components of that intake, for example, total fat plus saturated fats, polyunsaturated fats, and monounsaturated fats. However, even if investigators are careful to ensure that the types of multi-collinearity described here do not occur, multicollinearity can still be a problem when multiple intercorrelated variables are included in a model, for example, nutrients that come from the same sources. In this situation it may be impossible to determine the separate and independent associations of the multiple variables with the dependent variable. For example, in a study on the associations of potassium, calcium, protein, and milk intakes with blood pressure, the investigators found that, while potassium had a relatively stronger association with blood pressure than the other three dietary factors, the high correlations of potassium intake with intakes of the other three made it impossible to determine the independent association of potassium intake with blood pressure.[16]

The use of nutrient residuals and nutrient densities help to reduce the likelihood of multicollinearity because energy-adjusted nutrients generally have lower intercorrelations than nutrients expressed as absolute amounts.[11] Methods for assessing and detecting multicollinearity, as well as remedial measures, can be found in Neter et al.[8]

Some investigators may believe that procedures that select variables for inclusion in regression models based on whether or not the variable is significantly related to the dependent variable is an appropriate approach for preventing multicollinearity. Such procedures include forward selection or backward elimination of variables, and stepwise regression. In forward selection of variables, variables are entered into the model one at a time, beginning with the variable that has the strongest association with the dependent variable, followed sequentially by those having the strongest residual associations with the dependent variable, that is, after taking into account the association of the entering variable with the variables previously entered and their associations with the dependent variable. Variables are entered into the model until no remaining variable would have a statistically significant association with the dependent variable, if it were to enter the model next. In backward elimination of variables, all available variables are entered into the model, and those with the weakest association are sequentially removed until only variables significantly related to the dependent variable remain. Stepwise regression combines forward selection and backward elimination of variables by removing variables that are no longer significant when a new variable is entered into the model so that the final model only contains variables significantly related to the dependent variable.

These variable selection procedures should be avoided for a number of reasons. First, the final model selected will not necessarily be optimal, for example, maximize R^2. Second, the hypothesis tests used to determine which variables remain in the model are correlated.[9] Third, if a large number of variables is involved, initial entry of all variables may not be possible if one or more is a linear combination of the other variables. Fourth, stepwise procedures may not select possible confounders that should be included whether or not the confounder has a significant association with the dependent variable, for example, age and gender, or total energy intake in the multivariate nutrient density approach. Fifth, the results of these procedures are often not unique, that is, they yield final models that do not include the same variables. For example, in a logistic analysis involving the associations of total energy intake, and intakes of protein, fat, and carbohydrate with coronary heart disease (CHD) incidence, McGee et al.[17] found that only carbohydrate intake had a significant association with CHD incidence if forward selection of variables was used. When backward elimination was used instead, the final model included fat intake and total energy intake as the only variables significantly and independently related to CHD incidence.

In model building, it is appropriate to prespecify variables to be included in models and to carefully build models by sequentially adding variables. For example, in the INTERMAP Study's report on the relationship of protein intake to blood pressure,[18] potential confounders were added sequentially to regression models. First nondiet variables were included, then diet variables were added according to known and putative associations with blood pressure. Models were run both without and with adjustment for height and weight, because of possible overadjustment and because they strongly influenced associations, possibly as a result of their high precision of measurement in comparison with dietary variables. Potential confounders added after adjustment for sample, age, and gender (Model 1) were: reported special diet, history of cardiovascular disease or diabetes, family history of hypertension, physical activity, any reported intake of dietary supplements (Model 2); urinary sodium, potassium, and 7-day alcohol intake (nutrients known to be associated with blood pressure) (Model 3); calcium, saturated fatty acids, polyunsaturated fatty acids, dietary cholesterol (nutrients with putative relationships with blood pressure) (Model 4); and dietary magnesium (Model 5a) or fiber (Model 5b) (also with putative relationship with blood pressure), considered separately to avoid possible distorting effect of multicollinearity given their high intercorrelation with vegetable protein.

It may also be appropriate to conduct additional analyses to assess the sensitivity of findings. For example, in the INTERMAP report on the relationship of protein intake to blood pressure,[18] the following additional analyses were conducted: inclusion of energy intake in all models; nutrient intakes from foods plus dietary supplements; use of g/day adjusted for energy intake (instead of nutrient densities); and exclusions (separately) of those taking antihypertensive or other cardiovascular disease medication, people with a history of cardiovascular disease or diabetes, people on special diet, people with high day-to-day variability of nutrient intakes.

DIETARY SUPPLEMENTS

Dietary supplement use poses substantial complexities for data collection as well as for analyses involving nutrient intake. The primary issue in data collection is whether investigators can obtain accurate estimates of the actual nutrients contained in the supplements. For U.S. participants in INTERMAP,[19] during each of four 24 h recalls, the interviewer asked the participant if he/she had taken vitamins, minerals, tonics, or supplements. Supplements encompassed vitamins/minerals and other products purchased over the counter. Supplements contained in the Nutrition Data System (NDS) (version 29, 1996, Nutrition Coordinating Center, University of Minnesota, Minneapolis) were directly computerized. In NDS version 29, there were 60 nutrient codes encompassing specified quantities of vitamins and minerals generally recognized as important nutritionally and meriting ingestion as supplements. For non-NDS supplements, a separate computerized database was developed with all information from product labels. Non-NDS supplements were often made up of materials of uncertain merit (herbals/botanicals, animal products, phospholipids, enzymes, as well as minerals and vitamins). Often for these supplements no information was obtainable on ingredients and/or their amounts. Twenty-three percent of U.S. INTERMAP participants reported use of non-NDS listed supplements, encompassing 920 products with 1009 specified ingredients. Among these were 294 brand-name products with unknown ingredients or amounts. Some of these products were proprietary formulas with listed ingredients but no amounts; proprietary blends stating "proprietary blend", without ingredients; supplements with no amounts for some ingredients; supplements with ingredients but no specific amounts per serving size; and supplements with unit amounts that were uninterpretable.

For analyses, the first question that must be addressed is whether supplement-based intake should be included or excluded. The approach recommended here is to analyze the data first without inclusion of the supplement-based intake and then with inclusion, because the intake from supplements is likely to be incomplete and of uncertain quality, based on INTERMAP experience.[19] In the INTERMAP report on protein intake and blood pressure,[18] any use of supplements was included as a dichotomous variable in most models, and in sensitivity analyses, intake of vegetable protein based on 24 h recalls was combined with supplemental intake.

For analyses in which food- and supplement-based intakes are combined, the investigator needs to decide whether to simply add the two intakes together as was done in INTERMAP for vegetable protein[18] or to add supplement-based intake to the energy-adjusted intake from foods.[10] It is unclear how, or if, results between these two approaches will differ. If the intake from supplements represents a large proportion of the total intake and thus the correlation between total intake of the nutrient and total energy intake is low, the easiest and probably best approach is to simply combine the supplement-based intake with the food-based intake, and then use the standard multivariate model, whether or not nutrient intake is categorized. If the supplement-based intake does not represent a large proportion of the total intake, it may be worthwhile to examine the associations using both approaches, as it is unclear how the results might differ, of if they will differ in any practical way.

WITHIN-PERSON VARIABILITY AND PERSON-SPECIFIC BIAS

The goal of examining associations of nutrients with an outcome is to estimate the association of usual intake with that outcome. However, information on nutrient intake collected from a single 24 h recall is subject to substantial within-person variability due to day-to-day variability in intake in most individuals. In addition, data from the OPEN Study[13] indicate that self-reported intake from both 24 h recalls and food frequency questionnaires is also subject to person-specific bias. Hence, nutrient intake, whether estimated from a single 24 h recall, multiple 24 h recalls, or a food frequency questionnaire, often does not reflect the individual's average or usual intake. Day-to-day variability and person-specific bias in nutrient intake constitute what is often referred to as "measurement error." Measurement error typically results in underestimation of associations of nutrients with outcomes. For example, in men from the OPEN Study[13] it was estimated that with one 24 h recall, the regression coefficient relating a dependent variable to percentage of calories from protein intake would be underestimated by 77.7% in a simple linear model.

Day-to-day variability in intake represents random error in measurement, while person-specific bias represents systematic error. If the only error present is random, the average of a large number of repeated measurements, for example, multiple 24 h recalls, approaches the true value, or for nutrient intake, the individual's usual intake. While the collection of multiple 24 h recalls can reduce the impact of random variation on observed associations, their use cannot eliminate the impact of person-specific bias or systematic error on associations. For example, in men from the OPEN Study[13] it was estimated that the association between a dependent variable and percentage of kilocalories from protein intake would be underestimated by 50.2% with four 24 h recalls compared with the 77.7% underestimation with one 24 h recall. However, even with an infinite number of recalls, the association would still be underestimated by 19.2%, because of the presence of person-specific bias in estimated intakes.[13]

While methods are available for correcting or adjusting regression coefficients for measurement error,[20–22] their use with nutrient data is problematic. Because of the presence of both random and systematic errors in nutrient data, the ability to correct for these types of error requires that the method of data collection, for example, food frequency questionnaire or multiple 24 h recalls, be validated against a "gold standard" reference method or biomarker.[7,13] Because 24 h recalls are subject to person-specific bias and their errors are generally correlated with those of the food frequency questionnaire and with true intake,

multiple 24 h recalls do not meet the criteria for a "gold standard."[23] Currently, the only valid reference measurements or biomarkers appear to be doubly labeled water for total energy intake, urinary nitrogen for protein intake, and urinary sodium for dietary sodium intake.[23] Hence, in the absence of valid "gold standard" reference measures, correction for measurement error in nutrient intakes is not recommended.

APPROACHES TO ANALYSIS OF EPIDEMIOLOGIC STUDIES

TYPES OF EPIDEMIOLOGIC STUDIES

A discussion of the types of epidemiologic studies with particular reference to nutrition can be found in Reference 24, while a more general review of the topic is given in Reference 25. There are generally two types of epidemiologic studies: observational and experimental. The main difference between an experimental and an observational study is the control that the investigator exercises over participants, procedures, and exposures. In an experiment, the investigator controls who enters the study, what drugs or procedures are given to participants, and how the study is carried out. In a nutritional intervention study, the investigator would manipulate or attempt to manipulate some or all participants' dietary intake. An observational study does not involve an intervention or manipulation. In such a study, the investigator does not control who enters the study or the factors or drugs to which participants are exposed. Observational studies of individuals include cross-sectional, case-control, and prospective studies, while studies of groups are referred to as ecologic studies. In nutritional epidemiologic studies, nutrient intake is measured but not manipulated, the frequency and pattern of outcomes are observed, and associations between nutrients and outcomes are estimated using statistical methods.

In a cross-sectional study the question asked is, "What is the correlation or association between nutrient intake and the outcome?" Individuals are included in the study without regard to their status on the outcome or nutrient intake. In these studies, nutrient intake and the outcome are both measured at the same point in time. For example, INTERMAP is a cross-sectional study of the associations of macro-/micronutrients with blood pressure.[3,4] In this study, each participant had blood pressure measured twice on each of four occasions and completed a 24 h recall on each day that blood pressure was measured.

Case-control studies, which are also referred to as retrospective and case-referent studies, are designed to answer the question, "Do persons with disease (cases) have different nutrient intake than persons who have not been diagnosed with the disease (controls)?" For example, do persons with heart disease consume more dietary cholesterol and saturated fatty acids than persons without heart disease? In case-control studies, recently diagnosed persons with the disease and a set of persons without the disease are interviewed concerning their dietary habits. The goal is to determine usual nutrient intake before the onset of disease.

Prospective studies are also referred to as cohort, incidence, follow-up, and longitudinal studies. The question asked in prospective studies when a nutrient is thought to be related to increased risk of disease is, "Do persons with higher intake develop or die from the disease more frequently or sooner than persons with lower intake?" Alternatively, if a nutrient is thought to be related to decreased risk of disease, the question asked is, "Do persons with lower intake develop or die from the disease more frequently or sooner than persons with higher intake?" For example, are persons who consume more than 50 g/day of alcohol more likely to have a stroke than persons who consume less alcohol? Persons found to be disease free at the time of the cross-sectional survey are followed up over time to determine who develops the disease and when the disease occurs.

Ecologic studies compare aggregate data representing entire populations. A common example of this type of study is one in which disease specific mortality rates for different countries are correlated with nutrient measurements based on food disappearance data.[26] The INTERSALT Study included ecologic analyses on associations of urinary electrolytes and other factors with blood pressure, as well as cross-sectional analyses on electrolyte–blood pressure associations within individuals.[27,28]

Experimental studies involving nutritional interventions include feeding or metabolic ward studies and randomized clinical trials. Feeding studies involve feeding groups of individuals precisely measured diets with one or more components varied, with an effect on a biologic variable then measured. The Keys equation for predicting change in total cholesterol from changes in intakes of saturated and polyunsaturated fatty acids and dietary cholesterol was determined from a metabolic ward study.[29] A common design for feeding studies is the crossover design, in which each participant serves as his/her own control. Randomized clinical trial is a prospective study in which individuals are randomly assigned to intervention and control groups. Following randomization, both groups are followed up over time to assess the efficacy and safety of the intervention. For example, the trial on the Primary Prevention of Hypertension was a randomized, controlled clinical trial on the effects of weight loss, reduction in sodium intake, decreased alcohol intake, and increased exercise on the 5-year incidence of hypertension in men and women with high normal blood pressure.[30]

METHODS FOR COMPARING GROUPS IN CROSS-SECTIONAL STUDIES

Table 5.1 lists methods of analysis that can be used to compare nutrient intake between two groups (for example, men and women) or among three or more groups (for example, African-Americans, Hispanics, and Whites). For nutrient intake considered as

TABLE 5.1
Methods for Comparing Nutrient Intake among Groups in Cross-Sectional Studies

Description	Number of Groups (*k*)	
	k = 2	*k* > 2
Nutrient intake continuous		
Usual method	Two-sample *t*-test	Analysis of variance
Nonparametric alternative	Wilcoxon rank-sum test	Kruskal–Wallis test
Adjustment for other variables		Analysis of covariance or multiple linear regression
Nutrient intake categorical (c categories)		
Usual method	Chi-square test for 2 × *c* contingency table	Chi-square test for *k* × *c* contingency table

a continuous variable, the goal of the analysis is to determine whether mean or median intake differs significantly between or among groups. For such analyses, the table indicates the usual method of analysis, the nonparametric alternative, and methods that can be used to adjust for potential confounders of differences between groups, for example, age or total energy intake. Nonparametric tests make fewer assumptions about the shape of the distributions of variables than parametric tests such as the two-sample *t*-test or analysis of variance. In the Wilcoxon rank-sum test and the Kruskal–Wallis test, the actual observations are replaced by their ranks in the combined sample of all observations. If nutrient intake is divided into categories, the goal of the analysis is usually to determine whether the distributions of intake are homogeneous across groups. The methods listed in Table 5.1 can also be used to compare nutrient intake at baseline in an experimental study, for example, to determine whether in a randomized clinical trial randomization has provided comparable groups with respect to intake of specific nutrients.

A useful text on these methods and those described in what follows is that of Rosner.[31]

Methods for Comparing Cases and Controls in Case-Control Studies

Table 5.2 lists methods of analysis that can be used to compare nutrient intake between cases and controls in unmatched and matched case-control studies. Matching is often done in case-control studies to make cases and controls comparable on variables that could confound associations of the variable of interest with disease. For unmatched case-control studies, the methods listed are identical to those for comparing nutrient intake between two groups in cross-sectional studies. For matched case-control studies, the methods of analysis need to take into account the matching. Hence, for a simple comparison of means between cases and controls, the investigator should use a paired *t*-test rather than a two-sample *t*-test, or the Wilcoxon signed-rank test rather than the Wilcoxon rank sum test. When multiple regression is used to adjust the mean difference between cases and controls for other variables in matched case-control studies, the investigator needs to ensure that the dependent and independent variables in the model are defined correctly. In such studies, the dependent variable is the difference in nutrient intake for each case-control pair, while the independent variables are the within-pair differences for the potential confounding variables. The test of significance for the adjusted mean difference is the test of the hypothesis that the intercept in the model is equal to zero.

Methods for Assessing Associations in Epidemiologic Studies

Table 5.3 lists methods for assessing associations of nutrient intake with outcome variables in cross-sectional or ecologic studies, matched and unmatched case-control studies, and prospective studies. For each type of study, the table indicates methods that can be used when nutrient intake is modeled as a continuous variable or as a categorical variable. The table also lists the dependent variable for each type of analysis. For example, in the Cox proportional hazards regression, the dependent variable is the time to some event, for example, death from CHD. In unmatched case-control studies, the dependent variable is typically case-control status. As cross-sectional and ecologic studies can have both continuous and dichotomous dependent variables, methods are listed for both types of dependent variables. No dependent variable is listed for conditional logistic regression, as there is no outcome variable that varies from individual to individual in this model. In conditional logistic regression, the independent variables are the case-control difference in each variable, and the model does not include a constant term. Useful texts on logistic and Cox regression methods are those of Kahn and Sempos[32] and Vittinghoff et al.[33]

TABLE 5.2

Methods for Comparing Nutrient Intake between Cases and Controls in Case-Control Studies

Description	Unmatched	Matched
Nutrient intake continuous		
Usual method	Two-sample *t*-test	Paired *t*-test
Nonparametric alternative	Wilcoxon rank-sum test	Wilcoxon signed-rank test
Adjustment for other variables	Analysis of covariance or multiple linear regression	Multiple linear regression[a]
Nutrient intake categorical (c categories)		
Usual method	Chi-square test for $2 \times c$ contingency table	McNemar's test for $c = 2$

[a] In this model, differences in each variable for the case-control pair are used, with the difference in the nutrient of interest serving as the dependent variable. The test of significance for the adjusted mean difference is the test of the hypothesis that the intercept of the model is equal to zero.

TABLE 5.3

Methods for Assessing Associations in Epidemiologic Studies

Dependent Variable	Nutrient Intake	Unadjusted	Adjusted for Other Variables
Cross-sectional or ecologic study			
Continuous	Continuous	Pearson correlation Spearman correlation Linear regression	Partial correlation Linear regression
Continuous	Categorical	Linear regression	Linear regression
Dichotomous	Continuous categorical	Logistic regression	Logistic regression
Unmatched case-control study			
Case-control status	Continuous categorical	Logistic regression	Logistic regression
Matched case-control study			
None	Continuous categorical	Conditional logistic regression	Conditional logistic regression
Prospective study			
Time to event	Categorical	Log rank test Cox regression	Cox regression
Time to event	Continuous	Cox regression	Cox regression

The Spearman correlation is listed for use in cross-sectional and ecologic studies as it is the nonparametric alternative to the Pearson product–moment correlation coefficient. The Pearson product–moment correlation coefficient should not be used if either nutrient intake or the second variable has a highly skewed distribution, because the assumption underlying its use is that each variable has a normal distribution for each value of the other variable.

In analyses involving linear regression, interest focuses on the difference in the mean of the dependent variable for a one-unit or greater change in the independent variable. Hence, the focus is on the regression coefficient. In logistic and Cox regression, interest focuses on estimates of relative risk. In logistic regression, the relative risk is given by the odds ratio, and in Cox regression the hazard ratio. In both models, relative risk estimates are obtained by exponentiation of the regression coefficient or the regression coefficient multiplied by some convenient multiplier. For example, if total energy intake is the dietary variable of interest, exponentiation of the regression coefficient gives the relative risk of the outcome for two persons who differ in total energy intake by 1 kcal. Because this is not a particularly meaningful difference for calculating relative risk, an investigator might multiply the regression coefficient by 500 to obtain the relative risk of the outcome for two persons who differ in total energy intake by 500 kcal. When nutrient intake is categorized and dummy variables are included in the regression model, exponentiation of the regression coefficient for a dummy variable gives the risk of the outcome for those in the category corresponding to the dummy variable relative to the referent category, for example, quartile 4 relative to quartile 1.

In analyses based on the Cox regression, true associations between diet and disease may not be found if there are substantial changes in nutrient intake between the baseline assessment of diet and the development of disease, or if there are substantial changes in the rank ordering of study participants with respect to intake over the course of follow-up.

ANALYSES OF INTERVENTION STUDIES WITH CHANGE IN NUTRIENT INTAKE AS OUTCOME

In nutritional intervention studies, investigators often wish to examine the effects of the intervention on intakes of specific nutrients following completion of the intervention. Investigators can use three approaches to determine whether intake of specific nutrients changed in an intervention group relative to a control group or among three or more groups:

1. Compare intake among groups at follow-up, ignoring preintervention intake using the methods for cross-sectional studies in Table 5.1.
2. Compare the change in intake from preintervention to follow-up among groups using the methods for cross-sectional studies.
3. Compare intake among groups at follow-up adjusting for preintervention intake with multiple linear regression or analysis of covariance.

Investigators typically use the second approach for intervention studies, even though it tends to be less powerful than analysis of covariance. Assumptions in regard to the analysis of covariance may or may not be met in an intervention study. The first approach may, however, be preferable to the second if there are no differences in intake among the groups being compared at the preintervention assessment and the correlation between the preintervention and follow-up assessments for the nutrient of interest is less than 0.5. Correlations smaller than 0.5 are not uncommon for many nutrients assessed on two occasions.[12] Hence, for nutrient intake, the best approach may be to ignore preintervention intake. Prior to conducting analyses in nutritional intervention studies, investigators should examine the correlations of the nutrients from preintervention to follow-up and be prepared to ignore preintervention intake in the analyses.

Finally, in conducting analyses of any specific nutrient in relation to an outcome or in relation to disease, it is important to remember that individuals consume foods, not nutrients.

Nutrition Science

6 Nutrition Terminology

Carolyn D. Berdanier

CONTENTS

As with any discipline, nutrition science has its own vocabulary and terminology. This chapter gives the reader several tables providing this terminology. The first is a table giving the conversion factors for converting the results of laboratory analysis to standard units called SI units. Many scientific journals require the use of these units in manuscripts reporting the results of laboratory investigations. The result, or common component from clinical laboratory assessment, is given in its common form with reference interval and present unit, followed by the conversion factor that is used to convert the result into SI units, its reference intervals, significant digits, and suggested minimum increment. These standard units for expressing biological data are listed in Table 6.1.[1]

Over the years, there has been some confusion over the names of the vitamins. Vitamins were named according to (a) their function; (b) their location; (c) the order in which they were discovered; or (d) combinations of a, b, or c. Some of these names became obsolete as their proposed functions or their isolated structures were found to duplicate already named and described vitamins. Obsolescence also occurred as research showed that certain of these compounds were not needed dietary factors, but were synthesized by the body in needed amounts. Table 6.2 provides a list of vitamin names (both obsolete and current), and it is hoped that the reader will find this useful. Following this is a list (Table 6.3) of all the compounds having vitamin A activity. This is a fairly lengthy list, as this vitamin is found in a variety of foods, both of animal origin and plant origin. The body can convert these forms to its useful and most active form, all *trans*-retinol. These conversions are not 100% efficient, and correction factors must be applied to determine vitamin A activity.

In the area of energy research, there are a number of terms that the workers in this area assume that the reader knows. These are listed with their definitions in Table 6.4.

BODY COMPOSITION ESTIMATION AND TERMINOLOGY

Normal bodies usually consist of 16–20% protein, 3–5% ash (mineral matter), 10–12% fat, and 60–70% water. Age, diet, genetic background, physical activity, hormonal status, and gender can affect not only the proximate composition of the whole body, that is, the magnitude of each of these components, but also their distribution. Body composition can be measured directly or estimated indirectly by using a variety of techniques. Direct measurement involves the analysis of the major body components: fat, water, protein, and ash (mineral matter). Direct measurements are usually impractical for large species, including man. The equations used for the calculation of body components from direct analysis are given in Table 6.5.

Sophisticated techniques using ultrasound, neutron activation analysis, infrared interactance, dual-energy x-ray absorptiometry, computer-assisted tomography, magnetic resonance imaging, or bioelectrical impedance are available for the indirect estimation of body composition. The equations for converting data obtained using these sophisticated techniques are available.[2]

There are locations in the body where subcutaneous fat can be assessed using calipers to measure skin-fold thickness and thereby estimate body fatness. The fold below the upper arm (triceps fold) and the fold at the iliac crest are frequently used locations. Other locations include the abdominal fold and the thigh fold. Equations have been derived (Table 6.6) to calculate body fatness using these measurements.[3] Knowing the composition of the body, particularly its fat content, suggests that there should be ways of estimating body energy need. Some of these equations are shown in Table 6.7.[4]

Perhaps more popular now is the use of body mass index (BMI). This is a useful term, in that it is an index of the body weight (kg) divided by the height (meters) squared (wt/ht^2). BMI correlates with body fatness and with the risk of obesity-related disease or diseases for which obesity is a compounding factor. Overweight is defined as BMI between 25 and 30, and obesity is a BMI over 30. The BMI varies with age. A desirable BMI for people of age 19 to 24 is between 19 and 24, while that for people of age 55 to 64 is between 23 and 28. While simple in concept, this term does not assess body composition per se. It only provides a basis for assessing the health risks associated or presumed to be associated with excess body fatness. BMI applies only to normal individuals, and not the super athlete or the body builder, who may be quite heavy yet have little body fat.

TABLE 6.1
Conversion Factors for Values in Clinical Chemistry (SI Units)

Component Present	Reference Intervals (Examples)	Present Unit	Conversion Factor	SI Reference Intervals	SI Unit	Symbol	Significant Digits	Suggested Minimum Increment
Acetaminophen (P) toxic	>5.0	mg/dl	66.16	>330	mmol/l	XXO	10	mmol/l
Acetoacetate (S)	0.3–3.0	mg/dl	97.95	30–300	mmol/l	XXO	10	mmol/l
Acetone (B,S)	0	mg/dl	172.2	0	mmol/l	XXO	10	mmol/l
Acid phosphatase (S)	0–5.5	U/l	16.67	0–90	nkat/l	XX	2	nkat/l
Adrenocorticotropin [ACTH] (P)	20–100	pg/ml	0.2202	4–22	pmol/l	XX	1	pmol/l
Alanine aminotransferase [ALT] (S)	0–35	U/l	0.01667	0–0.58	mkat/l	X.XX	0.02	mkat/l
Albumin (S)	4.0–6.0	g/dl	10.0	40–60	g/l	XX	1	g/l
Aldolase (S)	0–6	U/l	16.67	0–100	nkat/l	XXO	20	nkat/l
Aldosterone (S)								
Normal salt diet	8.1–15.5	ng/dl	27.74	220–430	pmol/l	XXO	10	pmol/l
Restricted salt diet	20.8–44.4	ng/dl	27.74	580–1240	pmol/l	XXO	10	pmol/l
Aldosterone (U): sodium excretion								
=25 mmol/d	18–85	mg/24 h	2.774	50–235	nmol/d	XXX	5	nmol/d
=75–125 mmol/d	5–26	mg/24 h	2.774	15–70	nmol/d	XXX	5	nmol/d
=200 mmol/d	1.5–12.5	mg/24 h	2.774	5–35	nmol/d	XXX	5	nmol/d
Alkaline phosphatase (S)	0–120	U/l	0.01667	0.5–2.0	mkat/l	X.X	0.1	mkat/l
α_1-Antitrypsin (S)	150–350	mg/dl	0.01	1.5–3.5	g/l	X.X	0.1	g/l
α-Fetoprotein (S)	0–20	ng/ml	1.00	0–20	mg/l	XX	1	mg/l
α-Fetoprotein (Amf)	Depends on gestation	mg/dl	10.0	Depends on gestation	mg/l	XX	1	mg/l
α_2-Macroglobulin (S)	145–410	mg/dl	0.01	1.5–4.1	g/l	X.X	1	mg/l
Aluminum (S)	0–15	mg/l	37.06	0–560	nmol/l	XXO	10	nmol/l
Amino acid fractionation (P)								
Alanine	2.2–4.5	mg/dl	112.2	245–500	mmol/l	XXX	5	mol/l
α-Aminobutyric acid	0.1–0.2	mg/dl	96.97	10–20	mmol/l	XXX	5	mmol/l
Arginine	0.5–2.5	mg/dl	57.40	30–145	mmol/l	XXX	5	mmol/l
Asparagine	0.5–0.6	mg/dl	75.69	35–45	mmol/l	XXX	5	mmol/l
Citrulline	0.2–1.0	mg/dl	75.13	0–20	mmol/l	XXX	5	mmol/l
Cystine	0.2–2.2	mg/dl	57.08	15–55	mmol/l	XXX	5	mmol/l
Glutamic acid	0.2–2.8	mg/dl	67.97	15–190	mmol/l	XXX	5	mmol/l
Glutamine	6.1–10.2	mg/dl	68.42	420–700	mmol/l	XXX	5	mmol/l
Glycine	0.9–4.2	mg/dl	133.2	120–560	mmol/l	XXX	5	mmol/l
Histidine	0.5–1.7	mg/dl	64.45	30–110	mmol/l	XXX	5	mmol/l
Hydroxyproline	0–trace	mg/dl	76.26	0–trace	mmol/l	XXX	5	mmol/l
Isoleucine	0.5–1.3	mg/dl	76.24	40–100	mmol/l	XXX	5	mmol/l
Leucine	1.2–3.5	mg/dl	76.24	75–175	mmol/l	XXX	5	mmol/l
Lysine	1.2–3.5	mg/dl	68.40	80–240	mmol/l	XXX	5	mmol/l
Methionine	0.1–0.6	mg/dl	67.02	5–40	mmol/l	XXX	5	mmol/l
Ornithine	0.4–1.4	mg/dl	75.67	30–400	mmol/l	XXX	5	mmol/l
Phenylalanine	0.6–1.5	mg/dl	60.54	35–90	mmol/l	XXX	5	mmol/l
Proline	1.2–3.9	mg/dl	86.86	105–340	nmol/l	XXX	5	mmol/l
Serine	0.8–1.8	mg/dl	95.16	75–170	mmol/l	XXX	5	mmol/l
Taurine	0.9–2.5	mg/dl	79.91	25–170	mmol/l	XXX	5	mmol/l
Threonine	0.9–2.5	mg/dl	83.95	75–210	mmol/l	XXX	5	mmol/l
Tryptophan	0.5–2.5	mg/dl	48.97	25–125	mmol/l	XXX	5	mmol/l
Tyrosine	0.4–1.6	mg/dl	55.19	20–90	mmol/l	XXX	5	mmol/l
Valine	1.7–3.7	mg/dl	85.36	145–315	mmol/l	XXX	5	mmol/l
Amino acid nitrogen (P)	4.0–6.0	mg/dl	0.7139	2.9–4.3	mmol/l	X.X	0.1	mmol/l
Amino acid nitrogen (U)	50–200	mg/24 h	0.07139	3.6–14.3	mmol/d	X.X	0.1	mmol/d
δ-Aminolevulinate [as levulinic acid] (U)	1.0–7.0	mg/24 h	7.626	8–53	mmol/d	XX	1	mmol/d

TABLE 6.1

TABLE 6.2
Vitamin[a] Terminology

Name	Comment
Vitamin A	A number of compounds have vitamin A activity but differ in biopotency
	All *trans* retinol is the standard, and the activity of other compounds can be stated as retinol equivalents. This includes the aldehyde (retinal), acid (retinoic acid), and provitamin (carotene) forms
Vitamin B	Although originally thought to be a single compound, researchers have found that eight major compounds comprised this "vitamin."
Vitamin B complex	A group of vitamins; includes thiamin, riboflavin, niacin, pyridoxine (3 forms), pantothenic acid, biotin, cyanocobalamin (B_{12}), and folacin
Vitamin B_1	Aneurin; antineuritic factor. Obsolete synonym for thiamin
Vitamin B_2	Lactoflavin, Ovoflavin. Obsolete synonyms for riboflavin
Vitamin B_3	Antipellagra factor. Obsolete synonym for niacin
Vitamin B_4	Not proven to have vitamin activity; thought to be a mixture of arginine, glycine, riboflavin, and pyridoxine
Vitamin B_5	Probably identical to niacin
Vitamin B_6	Synonym for pyridoxine, pyridoxal, pyridoxamine
Vitamin B_7	Not proven to have vitamin activity; sometimes referred to as Vitamin I, a factor that improves food digestibility in pigeons
Vitamin B_8	Not proven to have vitamin activity; found to be adenylic acid
Vitamin B_{10}, B_{11}	An unrefined mixture of folacin and cyanocobalamin; obsolete term
Vitamin B_{12}	Cyanocobalamin; B_{12a} is aquacobalamin; B_{12b} is hydroxocobalamin; B_{12c} is nitritocobalamin
Vitamin B_{13}	Orotic acid; a metabolite of pyrimidine metabolism; not considered a vitamin
Vitamin B_{15}	Synonym for "pangamic acid" a compound of no known biologic value; not a vitamin
Vitamin B_{17}	Synonym for laetrile; a cyanogenic glycoside of no known biologic value; not a vitamin
Vitamin Bc	Obsolete term for pteroylglutamic acid; a component of folacin
Vitamin Bp	A compound that prevents perosis in chicks; can be replaced by choline and manganese
Vitamin Bf	Shown to be carnitine
Vitamin Bx	Probably a mixture of pantothenic acid and p-aminobenzoic acid
Vitamin C	Synonym for ascorbic acid
Vitamin C_2	Unrecognized, unconfirmed compound purported to have antipneumonia activity; also called vitamin J
Vitamin D	Antirachitic factor; a group of sterols (the calciferols) that serve to enhance bone calcification
Vitamin D_2	Ergocalciferol; one of the D vitamins from plant sources
Vitamin D_3	Cholecalciferol; one of the D vitamins from animal sources
Vitamin E	A group of tocopherols that have an important function in the antioxidant system; suppresses free radical formation
Vitamin F	Obsolete term for the essential fatty acids (linoleic and linolenic acids)
Vitamin G	Obsolete term for riboflavin before riboflavin and niacin were recognized as separate vitamins
Vitamin H	Obsolete term for biotin
Vitamin I	Obsolete term for a mixture of B vitamins
Vitamin K	A group of fat soluble compounds that function in the post translational carboxylation of the glutamic acid residues of prothrombin and osteocalcin
Vitamin K_1	Phylloquinone; vitamin K of plant origin
Vitamin K_2	Menaquinone; vitamin K of animal origin
Vitamin K_3	Menadione; synthetic vitamin K
Vitamin L_1	Unrecognized factor that may be related to anthranitic acid and which has been proposed to be important for lactation; not proven to have vitamin activity
Vitamin L_2	See above
Vitamin M	Obsolete term for pteroylglutamic acid (folacin)
Vitamin N	Obsolete term used to designate an anticancer compound mixture; undefined and unrecognized
Vitamin P	Not a vitamin; but is a metabolite of citrin
Vitamin Q	Not a vitamin; but is probably a synonym for coenzyme Q
Vitamin R	Obsolete term for folacin
Vitamin S	Not a vitamin; but does act to enhance chick growth; related to the peptide "streptogenin" and also to biotin
Vitamin T	Not a vitamin; reported to improve protein utilization in rats; an extract from termites
Vitamin U	Not a vitamin; an extract from cabbage that has been reported to suppress gastric acid production; may be important to folacin activity
Vitamin V	Not a vitamin
Bioflavinoids	Not a vitamin
Carnitine	Not a vitamin; except in preterm infants and in severely traumatized persons
Choline	Can be synthesized by the body but some conditions interfere with adequate synthesis

**TABLE 6.2
(Continued)**

Name	Comment
Citrovorum factor	Synonym for folacin; a B vitamin
Extrinsic factor	Obsolete term for vitamin B_{12}, cyanocobalamin
Factors U, R, X	Obsolete terms for folacin
Filtrate factor	Obsolete term for riboflavin
Flavin	A general term for the riboflavin containing coenzymes, FMN, and FAD
Hepatoflavin	Obsolete term for riboflavin
Intrinsic factor	Not a vitamin; an endogenous factor needed for vitamin B_{12}, cyanocobalamin, absorption
LLD factor	Obsolete term for vitamin B_{12}, cyanocobalamin
Lipoic acid	Not a vitamin, but does serve as a cofactor in oxidative decarboxylation
Myoinositol	Sometimes a vitamin when endogenous synthesis is inadequate
Norite eluate	Not a vitamin
P–P factor	Obsolete term for niacin
Pyrroloquinoline quinone	Not a vitamin; component of metallo-oxido-reductases
Rhizopterin	Obsolete term for folacin
SLR factor	Obsolete term for folacin
Streptogenin	Not a vitamin
Wills factor	Obsolete term for folacin
Zoopherin	Obsolete term for vitamin B_{12}, cyanocobalamin

[a] A vitamin is an organic compound required in small amounts for the maintenance of normal biochemical and physiological function of the body. These compounds must be present in food and if absent, well defined symptoms of deficiency will develop. An essential nutrient such as a vitamin cannot be synthesized in amounts sufficient to meet needs.

**TABLE 6.3
Nomenclature of Compounds with Vitamin A Activity**

Recommended Name	Synonyms
Retinol	Vitamin A alcohol
Retinal	Vitamin A aldehyde, retinene, retinaldehyde
Retinoic acid	Vitamin A acid
3-Dehydroretinol	Vitamin A_2 (alcohol)
3-Dehydroretinal	Vitamin A_2 aldehyde, retinene2
3-Dehydroretinoic acid	Vitamin A_2 acid
Anhydroretinol	Anhydrovitamin A
Retro retinal	Rehydrovitamin A
5,6-Epoxyretinol	5,6-Epoxyvitamin A alcohol
Retinyl palmitate	Vitamin A palmitate
Retinyl acetate	Vitamin A acetate
Retinyl β-glucuronide	Vitamin A acid β-glucuronide
11-*cis*-retinaldehyde	11-*cis* or neo γ vitamin A aldehyde
4-Ketoretinol	4-Keto vitamin A alcohol
Retinyl phosphate	Vitamin A phosphate
β-Carotene	Provitamin A
α-Carotene	Provitamin A
γ-Carotene	Provitamin A

TABLE 6.4
Terminology Used in Energy Assessment of Humans and Animals

Anabolism	The totality of reactions that account for the synthesis of the body's macromolecules; heat is a by-product of these reactions
Android obesity	A form of obesity in which fat distribution is mainly in the shoulders and abdomen; sometimes referred to as the "apple" type of obesity
Anthropometry	Measurements of body features, that is, height, weight, skin-fold thickness, etc.
Apparent digestible energy (DE)	Energy of the consumed food (IE) less the energy of the feces (FE); DE = IE – FE
Archimedes principle	An object's volume, when submerged in water, equals the volume of the water displaced. If the mass of the body is known, then the density can be calculated. Less dense bodies have more body fat than very dense bodies
Balance	Intake = expenditure
Body mass index (BMI)	BMI = (Body weight (kg)/Height (cm)^2). Used as a general index of body fatness, however, it does not apply to persons with high muscle mass such as elite athletes.
Basal metabolic rate (BMR)	The minimal amount of energy needed to sustain the body's metabolism. Frequently expressed in terms of the amount of oxygen used to sustain this metabolism, because of the constancy between energy flux and oxygen use
Body cell mass	The metabolically active, energy — requiring mass of the body
Body Density	Mass/unit volume
Calorie	A unit of energy; a calorie is the amount of heat needed to raise the temperature of 1 kg of water 1°C; also referred to as a kilocalorie. Can be converted to kilojoules (kJ): kcal × 4.184 = kJ
Calorimetry	The measurement of heat production by the body. This measurement can be either direct (using a whole body calorimeter) or indirect using measurements of oxygen consumed and carbon dioxide produced
Catabolism	The totality of those reactions that reduce macromolecules to usable metabolites, CO_2 and water. Heat is a by product of these reactions
Digestive energy (DE)	The energy of food after the energy losses of digestion is subtracted. Similar to apparent ingestive energy (see above)
Gaseous products of digestion (GE)	The energy of the combustible gases produced in the digestive tract incident to the fermentation of food by microorganisms. In ruminants, this is a substantial component of the energy balance equation; in humans this is much smaller and perhaps negligible
Gynoid obesity	Excess body fat deposited mainly on the hips, abdomen, and thighs. Sometimes called "pear-shaped" obesity
Heat of activity (HiE)	The heat produced through muscular activity
Heat of digestion and absorption (HdE)	The heat produced in the digestive tract as a result of the activity of the digestive enzymes and the energy of the absorptive processes. Sometimes referred to as diet-induced thermogenesis (DIT)
Heat of fermentation (HfE)	Heat produced in the digestive tract due to the action of microbial action
Heat of product formation (HrE)	The heat produced associated with the production of a product, that is, milk or eggs, etc.
Heat of thermic regulation (HcE)	The heat needed to maintain the body temperature
Heat of waste formation and excretion (HwE)	The heat associated with the production of waste products such as urea in urine, etc.
Heat increment (HI)	The increase in heat production following the consumption of food
IDW	Ideal body weight
Indirect calorimetry	The calculation of energy (heat) production through the measurement of oxygen consumed and carbon dioxide released
Metabolizable energy (ME)	The energy in food minus that is lost through digestion, absorption, and excretion. ME = IE – (FE + UE + GE)
N-corrected metabolizable energy (MnE)	ME adjusted for total nitrogen retained or lost by the body tissue. MnE = ME – (k × TN) where TN = nitrogen retained in the body tissue
NPU	Net protein use
NDp Cal%	Net protein calories percent; the percent of the total energy value of the diet provided by protein
Nutrient density	The nutrient composition of food expressed in terms of nutrient quantity/100 kcal
Nutritional assessment	Measurement of indicators of dietary status and nutrition-related health status of individuals or population groups
Obesity	Excess fat stores
Postprandial	After a meal
Quantitative computed tomography	An imagine technique that allows for the calculation of body fatness and body composition
Respiratory quotient	The ratio of carbon dioxide produced to oxygen consumed
Skin-fold thickness	A double fold of skin and underlying tissue that can be used to estimate body fatness
Thermic effect of food	Same as heat increment
Total heat production (HE)	The energy lost as heat from the body as a result of its metabolism
True digestive energy (TDE)	The intake of energy in food minus that lost through the feces, HfE and digestive gases
True metabolizable energy (TME)	Food energy minus energy lost through feces and urine
Urinary energy	The gross energy of the urine

TABLE 6.5
Equations for Calculating Body Components Using Direct Analysis

$$\% \text{ body fat} = \frac{\text{body weight} - \text{fat solvent extracted body weight}}{\text{body weight}}$$

$$\% \text{ body water} = \frac{\text{body weight} - \text{dried body weight}}{\text{body weight}}$$

$$\% \text{ body ash} = \frac{\text{body weight after complete oxidation in a muffle furnace}}{\text{body weight}}$$

$$\% \text{ body protein} = \frac{\text{nitrogen content} \times 6.25}{\text{body weight}}$$

TABLE 6.6
General Formulas for Calculating Body Fatness from Skin-Fold Measurements[2]

Males $\% \text{ body fat} = 29.288 \times 10^{-2} (X) - 5 \times 10^{-4} (X)^2 + 15.845 \times 10^{-2} (\text{Age})$

Females $\% \text{ body fat} = 29.699 \times 10^{-2} (X) - 43 \times 10^{-5} (X)^2 + 29.63 \times 10^{-3} (\text{Age}) + 1.4072$

where X = sum of abdomen, suprailiac, triceps and thigh skin-folds and age is in years

Other equations for the estimation of body fat

1. $\% \text{ fat} = \dfrac{2.118 - 1.354 - 0.78}{\text{density}} \cdot \dfrac{\% \text{ TBW}}{\text{body weight}}$

where 2.118, 1.354, and 0.78 are constants and the density (g/cc), body weight (kg), and total body weight (TBW) (kg) are determined

2. $\% \text{ fat} = \dfrac{100 (5.548 - 5.044)}{\text{Specific gravity}}$

3. $\% \text{ fat} = \dfrac{100 - \text{TBW}}{0.732}$

TABLE 6.7
Methods and Equations Used for Calculating Basal Energy Need

1.	Heat production, direct measurement (calorimetry)	kcal (kJ)/m^2 (surface area)
2.	Oxygen consumption; indirect	O_2 cons/w$^{0.75}$
3.	Heat production; indirect	Insensible Water Loss (IW) = Insensible weight loss (IWL) + (CO_2 exhaled – O_2 inhaled)
		Heat production = IW × 0.58 (0.58 = kcal to evaporate 1 g water)
4.	Estimate (energy need not measured)	BMR = 66.4730 + 13.751W + 5.0033L – 6.550A (males)
		BMR = 655.0955 + 9.463W + 1.8496L – 4.6756A (females)
5.	Estimate (energy need not measured)	BMR = 71.2W$^{0.75}$ [1 – 0.004(30 –A) +0.010(L/W$^{0.33}$ – 43.4)] (men)
		BMR = 65.8W$^{0.75}$ [1 + 0.004(30 – A) +0.018(L/W$^{0.33}$ – 42.1)] (women)

Note: Abbreviations: W: weight in kg; L: height in cm; A: age in years.

7 Nutritional Biochemistry

Carolyn D. Berdanier

CONTENTS

Nutrition science is based on concepts of biochemistry, in particular the pathways that constitute intermediary metabolism. The metabolic use of the dietary macromolecules, proteins, fats, and carbohydrates, the roles for the micronutrients in these pathways, and an understanding of the physiology and endocrinology of the consumer provide the basis for studies in nutritional biochemistry. This chapter reviews these concepts and provides some basic information about the use of the macro- and micronutrients found in food.

The metabolic pathways have been worked out as have the control mechanisms for the reactions within the pathways. Metabolic maps have been drawn to illustrate the flux of nutrients through their use pathways. These pathways are illustrated in Figure 7.1 to Figure 7.30. Detailed maps can be obtained from Boehringer Mannheim (BM) at minimal cost (Boehringer Mannheim, PO Box 31 01 20, D-6800 Mannheim 31, Germany). The maps come complete with citations of the works that provided the critical information for these maps as well as notations on species differences and differences between mammals, plants, and microorganisms.

DIGESTION/ABSORPTION

Before the nutrients in food can be metabolized, they must first be ingested, chewed, swallowed, digested, and absorbed. With each of the macronutrients, the macromolecules must be broken down to their simpler components. In the stomach, the food is mixed with the gastric acid (hydrochloric acid), and moved into the small intestine. The stomach contents that move into the duodenum are called chyme. The movement of chyme into the duodenum stimulates cholesystokinin release. This gut hormone acts on the exocrine pancreas stimulating it to release pancreatic juice into the duodenum and on the gall bladder to release bile. Cholesystokinin is secreted by the epithelial endocrine cells of the small intestine, particularly the duodenum. Its release is stimulated by amino acids in the lumen and by the acid pH of the stomach contents as it passes into the duodenum. The low pH of the chyme also stimulates the release of secretin, which, in turn, stimulates the exocrine pancreas to release bicarbonate and water so as to raise the pH of the chyme. This is necessary to maximize the activity of the digestive enzymes located in and on the surface of the absorptive luminal cell. The digestive enzymes are listed in Table 7.1.

As mentioned, cholesystokinin stimulates the release of bile from the gall bladder. Bile contains the primary bile acids, cholic and chenodeoxycholic acids, that are produced from cholesterol by the liver. They are secreted into the intestine, where they serve as emulsifying agents for the digestion and absorption of fat. Bile that is not immediately used is acted on by the intestinal flora. These flora convert the bile acids to their conjugated forms by dehydroxylating carbon-7. Further metabolism occurs at the far end of the intestinal tract, where lithocholate is sulfated. While the dehydroxylated acids are reabsorbed and sent back to the liver via the portal blood, the sulfated lithocholate is not. It appears in the feces. All four of the bile acids, the primary and dehydroxylated forms, are recirculated via the enterohepatic system such that very little of the bile acids are lost. It has been estimated that the bile acid lost in the feces (~0.8 g/day) equals that newly synthesized by the liver such that the total pool remains between 3 and 5 g. The amount secreted per day is on the order of 16 to 70 g. As the pool size is only 3 to 5 g, this means that these acids are recirculated as many as 14 times a day.

Once a carbohydrate-rich food is consumed, digestion begins. As the food is chewed, it is mixed with saliva, which contains α-amylase. This amylase begins the digestion of starch by attacking the internal α-1,4-glucosidic bonds. It will not attack the branch points having α-1,4- or α-1,6-glucosidic bonds, and hence the salivary α-amylase will produce molecules of glucose, maltose, α-limit dextrin, and maltotriose. The α-amylase in saliva is an isozyme with the same function as that in the pancreatic juice. The salivary α-amylase is denatured in the stomach as the food is mixed and acidified with the gastric hydrochloric acid. The limit dextrins are further hydrolyzed by α-glucosidases on the surface of the luminal cells. The glycosidic bonds of the disaccharides are attacked by the disaccharidases, maltase, lactase, or sucrase (Table 7.1). This results in absorbable monosaccharides, glucose, fructose, and galactose. Carbohydrates having bonds that are not attacked by these glycosidic enzymes are

TABLE 7.1
Enzymes of Importance to Digestion

Enzyme	Substrate	Products
α-Amylase	Starch and amylopectin	Glucose, maltose, maltotriose, and α-limit dextrin
α-Glucosidase	α-Limit dextrin	Glucose
Lactase	Lactose	Galactose and glucose
Maltase	Maltose	Glucose
Sucrase	Sucrose	Glucose and fructose
Lipase	Triacylglycerides	Fatty acids, diglycerides (DGs), and monoglycerides (MGs)
Colipase	Triacylglycerides	Fatty acids, DGs, and MGs
Lipid esterase	Cholesterol esters	Cholesterol and fatty acids
	Vitamin A esters	Vitamin A and glycerol
Pepsin	Peptide bonds involving aromatic amino acids	Phenylalanine, tyrosine peptide fragments
Trypsin	Peptide bonds involving arginine and lysine	Arginine, lysine, and peptide fragments
Chymotrypsin	Peptide bonds involving tyrosine, phenylalanine, methionine tryptophan, and leucine	Tyrosine, leucine, tryptophan, phenylalanine, methionine, and peptide fragments
Elastase	Peptide bonds involving alanine, serine, and glycine	Alanine, serine, glycine, and peptide fragments
Carboxypeptidase A	Peptide bonds involving valine, leucine, isoleucine, and alanine	Valine, leucine, isoleucine, alanine, and peptide fragments
Carboxypeptidase B	Peptide bonds involving lysine and arginine	
Endopeptidase	Peptide fragments	Amino acids
Aminopeptidase	Peptide fragments	Amino acids
Dipeptidase	Dipeptides	Amino acids

passed to the lower part of the intestine, where they are attacked by the enzymes of the intestinal flora. Most of the products of this digestion are used by the flora themselves, but some of metabolic products (short-chain fatty acids) may be of use. The flora produces lactate, methane gas, carbon dioxide, water, and hydrogen gas. Gas production (flatus) can be uncomfortable if large amounts of undigestible carbohydrates are consumed. The carbohydrates of legumes typify the substrates these flora use. Raffinose, an α-galactose $1 \rightarrow 6$ glucose $1 \rightarrow 2$ β-fructose, and trehalose, an α-glucose $1 \rightarrow 1$ α-glucose, are the typical substrates from legumes for these flora. The flora will also attack portions of the fibers and celluloses that are the structural elements in fruits and vegetables. Again, some useful products may be produced, but the bulk of these complex polysaccharides having β-linkages and perhaps other substituent groups as part of their structure are largely untouched by both intestinal and bacterial enzymes. These undigested unavailable carbohydrates provide bulk to the diet, which, in turn, helps to regulate the rate of food passage from the mouth to the anus. They also act as adsorbants of noxious or potentially noxious materials in the food, and they assist in the excretion of cholesterol and several minerals, thereby protecting the body from overload. Populations consuming high-fiber diets have a lower incidence of colon cancer, fewer problems with constipation, and lower serum cholesterol levels.

Lipid Digestion/Absorption

Food lipids (fats and oils) are digested initially in the mouth and then in the stomach and intestine. The digestion of lipid begins in the mouth with the mastication of food and its mixing with the acid-stable lingual lipase. Digestion can proceed only when the large particles of the food are made smaller through chewing. The action of the tongue and later the churning action of the stomach mix the food particles with the various digestive juices and with hydrochloric acid in the stomach. These actions separate the lipid particles, exposing more surface area for enzyme action and providing the opportunity for emulsion formation. These changes in physical state are essential steps that precede absorption. In the stomach, the proteins of lipid–protein complexes are denatured by gastric hydrochloric acid and attacked by the proteases (pepsin, parapepsin I, and parapepsin II) of the gastric juice with the resultant release of lipid. Little degradation of fat occurs in the stomach except that catalyzed by lingual lipase. Lingual lipase originates from glands in the back of the mouth and under the tongue. This lipase is active in the acid environment of the stomach. However, because of the tendency of lipid to coalesce and form a separate phase, this lipase has limited opportunity to attack triacylglycerols. Those that are attacked release a single fatty acid, usually a short- or medium-chain one. The remaining diacylglycerol is subsequently hydrolyzed in the duodenum. In adults consuming a mixed diet, lingual lipase is relatively unimportant. However, in infants having an immature duodenal lipase, lingual lipase is quite important. In addition, this lipase has its greatest activity on the triacylglycerols commonly present in whole milk. Milk fat has more short- and medium-chain fatty acids than fats from other food sources.

Although the action of lingual lipase is slow relative to lipases found in the duodenum, its action to release diacylglycerol and short- and medium-chain fatty acids serves another function — these fatty acids serve as surfactants. Surfactants spontaneously adsorb to the water–lipid interface, conferring a hydrophilic surface to lipid droplets and thereby provide a stable interface with the aqueous environment. The dietary surfactants are the free fatty acids, lecithin, and phospholipids. The action of acid-stable lingual lipase provides more fatty acids to supplement the dietary supply. All together these surfactants plus the churning action of the stomach produce an emulsion, which is then expelled into the duodenum as chyme.

Once the chyme enters the duodenum, it is mixed with bile. This is an additional surfactant or emulsifying agent and serves to further disperse the lipid droplets at the lipid–aqueous interface, facilitating the hydrolysis of the glycerides (triglycerides [TGs], diglycerides [DGs], and monoglycerides [MGs]) by the pancreatic lipases. Pancreozymin stimulates the exocrine pancreas to release pancreatic juice, which contains three lipases (lipase, lipid esterase, and colipase) that act at the water–lipid interface of the emulsion particles. One lipase acts on the fatty acids esterified at positions 1 and 3 of the glycerol backbone, leaving a fatty acid esterified at carbon 2. This 2 monoacylglyceride can isomerize, and the remaining fatty acid can move to carbon 1 or 3. The pancreatic juice contains another less specific lipase (called a lipid esterase), which cleaves the fatty acid from cholesterol esters, MGs, or esters such as vitamin A ester. Its action requires the presence of the bile salts. The lipase that is specific for the ester linkage at carbons 1 and 3 does not have a requirement for the bile salts and, in fact, is inhibited by them. The inhibition of pancreatic lipase by the bile salts is relieved by the third pancreatic enzyme, colipase. The products of the lipase-catalyzed reaction, a reaction that favors the release of fatty acids having 10 or more carbons, are these fatty acids and MG. The products of the lipid-esterase-catalyzed reaction are cholesterol, vitamins, fatty acids, and glycerol. Phospholipids present in food are attacked by phospholipases specific to each of the phospholipids. The pancreatic juice contains these lipases as prephospholipases, which are activated by the enzyme trypsin.

The bile salts impart a negative charge to the lipids, which in turn attracts the pancreatic enzyme, colipase (see Table 7.1). Colipase binds to both the water–lipid interface and to lipase, thereby anchoring and activating the lipase. As the pH of the chyme rises, aggregates, called micelles, are formed. The micelles are much smaller in size than the emulsified lipid droplets. Micelle sizes vary depending on the ratio of lipids to bile acids but typically range from 40 to 600 Å, and it is from these structures that the products of lipid digestion are absorbed.

CHOLESTEROL ABSORPTION

Only 30 to 40% of the dietary cholesterol is absorbed; it is absorbed by diffusion with the other lipid components of the diet. Absorption requires the emulsification step with the bile acids as emulsifiers. Absorbed cholesterol passes into the lacteals and thence into the thoracic duct. The percentage of cholesterol absorbed depends on a number of factors including the fiber content of the diet, the gut passage time, and the total amount of cholesterol present for absorption. At higher intake levels, less is absorbed, and vice versa at lower intake levels. Compared with fatty acids and the acylglycerides, the rate of cholesterol absorption is very low. It is estimated that the half-life of cholesterol in the enterocyte is 12 h. With high fiber intakes, less cholesterol is absorbed because the fiber (cellulose and lignens) acts as an adsorbent, reducing cholesterol availability. These carbohydrates also shorten the residence time of the ingesta in the intestine. Thus, high-fiber diets reduce gut passage time, which, in turn, results in less time for cholesterol absorption. The mode of action of pectins and gums in lowering cholesterol absorption is different. These carbohydrates increase transit time also, but rather than acting as adsorbants, they lower serum cholesterol levels by giving chyme a gel-like consistency, rendering the cholesterol in the chyme less available for absorption.

LIPID TRANSPORT

Short-chain fatty acids are absorbed directly into the portal blood system and carried by albumin. Longer-chain fatty acids and cholesterol are taken up by the lacteals of the lymphatic system that drains the intestine. They are formed into chylomicrons (a very low-density lipid–protein complex) and then enter the blood via the thoracic duct. Once absorbed, the lipids are transported through the circulatory system by proteins in a complex called lipoprotein. Lipoproteins carry not only the absorbed food lipids but also the lipids synthesized or mobilized from organs and fat depots. Nine different lipid-carrying proteins have been identified, and each plays a specific role in the lipid-transport process. In addition, there are several minor proteins that may be involved in some aspects of lipid cycling and uptake. The proteins involved in lipid transport are listed in Table 7.2. Mutations in the genes that encode these proteins can lead to aberrant lipid transport, and the individual may have either abnormally high or low blood lipid values (see Chapter 54).

The hepatic and intestinal apolipoproteins can be distinguished using electrophoresis, a technique of separating proteins based on their electrophoretic mobility.

The intestinal cell has three apolipoproteins called A-1, A-IV, and B-48. Apolipoprotein B-48 (apo B-48) is unique to the enterocyte and is essential for chylomicron release by the intestinal cell. Apo A-1 is synthesized in the liver. Apo B-48 is actually

TABLE 7.2
Proteins Involved in Lipid Transport

Protein	Function
Apo A-II	Transport protein in high-density lipoprotein (HDL)
Apo B-48	Transport protein for chylomicrons; synthesized in the enterocyte in the human
HDl-binding protein (HDLBP)	Binds HDL and functions in the removal of excess cellular cholesterol
Apo D	Transport protein similar to retinol-binding protein
Apo (a)	Abnormal transport protein for low-density lipoprotein (LDL)
Apo A-I	Transport protein for chylomicrons and HDL; synthesized in the liver and its synthesis is induced by retinoic acid
Apo C-III	Transport protein for very-low-density lipoprotein (VLDL)
Apo A-IV	Transport protein for chylomicrons
CETP	Participates in the transport of cholesterol from peripheral tissue to liver; reduces HDL size
LCAT	Synthesized in the liver and is secreted into the plasma, where it resides on the HDL Participates in the reverse transport of cholesterol from peripheral tissues to the liver; esterifies the HDL cholesterol
Apo E	Mediates high affinity binding of LDLs to the LDL receptor and the putative chylomicron receptor; required for clearance of chylomicron remnant; synthesized primarily in the liver
Apo C-I	Transport protein for VLDL
Apo C-II	Chylomicron-transport protein required cofactor for LPL activity
Apo B-100	Synthesized in the liver and is secreted into the circulation as part of the VLDL. Also serves as the ligand for the LDL-receptor-mediated hepatic endocytosis
Lipoprotein lipase	Catalyzes the hydrolysis of plasma TG into free fatty acids
Hepatic lipase	Catalyzes the hydrolysis of TG and phospholipids of the LDL and HDL. It is bound to the surfaces of both hepatic and nonhepatic tissues

an edited version of the hepatic apo B-100. It is the result of an apo B mRNA editing process that converts codon 2153 to a translational stop codon. Apo B-48 is thus an edited form of apo B-100, and this editing is unique to the intestinal cell.

As chylomicrons circulate, they acquire an additional protein, apo C-II. This additional protein is an essential cofactor for the recognition and hydrolysis of the chylomicron by the capillary endothelial enzyme, lipoprotein lipase (LPL). LPL hydrolyzes most of the core TG in the chylomicron, leaving a remnant that is rich in cholesterol and cholesterol esters. During the LPL-catalyzed hydrolytic process, the excess surface compounds, that is, the phospholipids and apolipoproteins B, A-I, and A-IV are transferred to high-density lipoproteins (HDL) and, in exchange, apo E is transferred from the HDL to the cholesterol-ester-rich chylomicron remnant. These remnants are then cleared from the blood by the liver. On the hepatocyte is a lipoprotein receptor that recognizes apo E, and this receptor plays an important role in remnant clearance.

The chylomicron is a relatively stable way of ensuring the movement, in an aqueous medium (blood), of hydrophobic molecules such as cholesterol and triacylglycerols from their point of origin, the intestine, to their point of use or storage. As mentioned, there are several unique proteins that facilitate this movement. These lipid-transporting proteins determine which cells of the body receive which lipids. At the target cell, the particles lose their lipid through hydrolysis facilitated by an interstitial LPL, which is found in the capillary beds of muscle, fat cells, and other tissues using lipid as a fuel. This LPL is synthesized by these target cells but is anchored on the outside of the cells by a polysaccharide chain on the endothelial wall of the surrounding capillaries.

Protein Digestion/Absorption

Upon consumption, food protein is degraded into its component amino acids (Table 7.1). Protein digestion begins in the stomach, where the food is acidified with the gastric hydrochloric acid. Hydrochloric acid also serves to denature the food proteins, thus making them more vulnerable to attack by pepsin, an endopeptidase. Actually, pepsin is not a single enzyme. It consists of pepsin A, which attacks peptide bonds involving phenylalanine or tyrosine, and several other enzymes, which have specific attack points. The pepsins are released into the gastric cavity as pepsinogen. Food entering the stomach stimulates HCl release and the pH of the gastric contents fall below 2. Through the action of the acid environment, the pepsinogen loses a 44-amino-acid sequence. This happens through one of two mechanisms: the first, called autoactivation, occurs when the pH drops below 5. At low pH the bond between the 44th and 45th amino acid residue falls apart and the 44-amino-acid residue (from the amino terminus) is liberated. The liberated residue acts as an inhibitor of pepsin by binding to the catalytic site until pH 2 is achieved. The inhibition is then relieved when this fragment is acid degraded, as happens at pH 2 or below or when it is attacked by pepsin. As the fragment binds at the catalytic site of pepsin, this can happen. The other process is called autocatalysis and occurs when already active pepsin attacks the precursor pepsinogen. This is a self-repeating process and serves to ensure ongoing catalysis of the resident protein. The cleavage of the 44-amino-acid residue, in addition to providing activated pepsin, has another purpose. That is, it serves as a signal peptide for cholecystokinin release in the duodenum. This then sets the stage for the subsequent pancreatic phase of protein digestion. As described in the sections on lipid and carbohydrate digestion, cholecystokinin stimulates both the exocrine pancreas and the intestinal mucosal epithelial cells to release its digestive enzymes. The intestinal cell releases an enzyme, enteropeptidase or enterokinase, which serves to activate the protease, trypsin, released as trypsinogen by the exocrine pancreas. This trypsin not only acts on food proteins but also acts on other preproteases, released by the exocrine pancreas, activating them. Thus, trypsin acts as an endoprotease on chymotrypsinogen, releasing chymotrypsin, on proelastase, releasing elastase, and on procarboxypeptidase, releasing carboxypeptidase. Trypsin, chymotrypsin, and elastase are all endoproteases each having specificity for particular peptide bonds. Each of these three proteases have serine as part of their catalytic site, so any compound that ties up the serine will inhibit the activity of these proteases. Such inhibitors as diisopropylphosphofluoridate react with this serine, and in so doing bring a halt to protein digestion.

The daily protein intake of about 100 g in addition to that protein appearing in the gut as enzymes, sloughed epithelial gut cells, and mucins, is almost completely digested and absorbed. This is a very efficient process that ensures a continuous supply of amino acids to the whole-body amino acid pool. Less than 1% of the total protein that passes through the gastrointestinal tract appears in the feces. If the food contributes between 70 and 100 g of protein and the endogenous protein contributes another 100 g (range: 35 to 200 g), then one might expect to see about 1 to 2 g of nitrogen in the feces. This is equivalent to 6 to 12 g protein. Of the dietary protein, the fecal protein might include the hard-to-chew/digest tough fibrous connective tissue of meat or nitrogen-containing indigestible kernel coats of grains or particles of nuts that are not attacked by the digestive enzymes. Peanuts, for example, eaten whole have a structure that is difficult to broach by the digestive enzymes. Unless chewed very finely, much of the nutritive value of this food may be lost. Peanut butter, on the other hand, is very well digested because the preparation of the peanut butter ensures that its particle size is very small and is thus quite digestible.

The protein hydrolases, called peptidases, fall into two categories. Those that attack internal peptide bonds and liberate large peptide fragments for subsequent attack by other enzymes are called the endopeptidases. Those that attack the terminal peptide bonds and liberate single amino acids from the protein structure are called exopeptidases. The exopeptidases are further subdivided according to whether they attack at the carboxy end of the amino acid chain (carboxypeptidases) or the amino end of the chain (aminopeptidases). The initial attack on an intact protein is catalyzed by endopeptidases, while the final digestive

TABLE 7.3
Carriers for Amino Acids

Carrier	Amino Acids Carried
1	Serine, threonine, alanine
2	Phenylalanine, tyrosine, methionine, valine, leucine, isoleucine
3	Proline, hydroxyproline
4	Taurine, β-alanine
5	Lysine, arginine, cysteine–cysteine
6	Aspartatic and glutamic acids

action is catalyzed by the exopeptidases. The final products of digestion are free amino acids and some di- and tripeptides that are absorbed by the intestinal epithelial cells.

Amino Acid Absorption

Although single amino acids are liberated in the intestinal contents, there is insufficient power in the enzymes of the pancreatic juice to render all the amino acids singly for absorption. The brush border of the absorptive cell therefore not only absorbs the single amino acid but also di- and tripeptides. In the process of absorbing these small peptides, it hydrolyzes them to their amino acid constituents. There is little evidence that peptides enter the blood stream. There are specific transport systems for each group of functionally similar amino acids, di- and tripeptides. These carriers are listed in Table 7.3.

Most of the biologically important L-amino acids are transported by an active carrier system against a concentration gradient. This active transport involves the intracellular potassium ion and the extracellular sodium ion. As the amino acid is carried into the enterocyte, sodium also enters in exchange for potassium. This sodium must be returned (in exchange for potassium) to the extracellular medium. This return uses the sodium–potassium ATP pump. In several instances, the carrier is a shared carrier. That is, the carrier will transport more than one amino acid. Such is the case with the neutral amino acids and those with short or polar side chains (serine, threonine, and alanine). The mechanism whereby these carriers participate in amino acid absorption is similar to that described for glucose uptake. Once amino acids are absorbed and in circulation, they will either be used to synthesize body proteins, essential nitrogenous compounds (thyroxine or epinephrine), or catabolized.

CARBOHYDRATE METABOLISM

Glycolysis

Once absorbed, glucose travels to the liver and other tissues via the portal blood stream. At the target tissue it enters the glycolytic sequence. The glycolytic pathway for the anaerobic catabolism of glucose can be found in all cells in the body (Figure 7.1). The pathway begins with glucose, a six-carbon unit, and through a series of reactions produces two molecules of ATP and two molecules of pyruvate. The control of glycolysis is vested in several key steps. The first step is the activation of glucose through the formation of glucose-6-phosphate. In the liver and pancreatic β-cells, this step is catalyzed by the enzyme glucokinase. A molecule of ATP is used and magnesium is required. Glucose-6-phosphate is a key metabolite. It can proceed down the glycolytic pathway or move through the hexose monophosphate shunt (see hexose monophosphate shunt) or be used to make glycogen. How much glucose-6-phosphate is oxidized directly to pyruvate depends on the nutritional state of the animal, cell type, the genetics of the animal, and its hormonal state. Some cell types, the brain cell for example, do not make glycogen. Some people do not have shunt activity in the red cell because the code for glucose-6-phosphate dehydrogenase has mutated such that the enzyme is not functional. Insulin-deficient animals likewise have little glycolytic and shunt activity because of the lack of insulin's effect on the synthesis of key enzymes of these pathways. All these factors determine how much glucose-6-phosphate goes in which direction.

Two enzymes are used for the activation of glucose: glucokinase and hexokinase. In the liver, both enzymes are present. While hexokinase activity is product inhibited, glucokinase is not. The hexokinase in the nonhepatic tissues must be product inhibited to prevent the hexokinase from tying up all the inorganic phosphate (Pi) in the cells as glucose-6-phosphate. The Km for glucokinase is greater than that for hexokinase; so the former is the main enzyme for the conversion of glucose to glucose-6-phosphate in the liver. The other enzyme will phosphorylate not only glucose but other six-carbon sugars such as fructose. However, the amount of fructose phosphorylated to fructose-6-phosphate is small in comparison to the phosphorylation of fructose at the carbon 1 position catalyzed by fructokinase. Both kinase reactions require magnesium as a cofactor.

Glucose-6-phosphate is isomerized to fructose-6-phosphate and is then phosphorylated once again to form fructose-1,6-bisphosphate. Another molecule of ATP is used, and again magnesium is an important cofactor. Both kinase reactions are
FIGURE 7.1 The glycolytic sequence.

rate-controlling reactions in that their activity determines the rate at which subsequent reactions proceed. The phosphofructo-kinase reaction is unique to the glycolytic sequence, while the glucokinase or hexokinase step provides substrates for either the shunt or the glycogenic sequences. Thus, one could argue that the formation of fructose-1,6-bisphosphate is the first committed step in glycolysis. Glycolysis is inhibited when phosphofructokinase is inhibited. This occurs when levels of fatty acids in the cytosol rise as in the instance of high rates of lipolysis and fatty acid oxidation. Phosphofructokinase activity is increased when levels of fructose-6-phosphate rise or when cAMP levels rise. Stimulation occurs also when fructose-2,6-bisphosphate levels rise. In any event, glycolysis then proceeds with the splitting of fructose-1,6-bisphosphate to dihydroxyacetone phosphate (DHAP) and glyceraldehyde-3-phosphate. At this point another rate-controlling step occurs. This step is one which shuttles

reducing equivalents into the mitochondria for use by the respiratory chain. This is the α-glycerophosphate shuttle (Figure 7.2). This shuttle carries reducing equivalents from the cytosol to the mitochondria. DHAP picks up reducing equivalents when it is converted to α-glycerol phosphate. These reducing equivalents are produced when glyceraldehyde-3-phosphate is oxidized in the process of being phosphorylated to 1,3-diphosphate glycerate. The α-glycerophosphate enters the inner mitochondrial membrane, whereupon it is converted back to DHAP, releasing its reducing equivalents to FAD (a riboflavin-containing coenzyme), which in turn transfers the reducing equivalents to the mitochondrial respiratory chain. The reason why this shuttle is rate limiting is the need to regenerate NAD^+. Without NAD^+ the glycolytic pathway ceases. $NADH^+$ (a niacin-containing coenzyme) is produced during glycolysis when reducing equivalents are accepted by NAD^+. $NADH^+$ itself cannot pass through the mitochondrial membrane; so substrate shuttles are necessary. Another means of producing NAD^+ is by converting pyruvate to lactate. This is a nonmitochondrial reaction catalyzed by lactate dehydrogenase. It occurs when an oxygen debt is developed as happens in exercising muscle. In these muscles more oxygen is consumed than can be provided. Glycolysis occurs at a rate higher than can be accommodated by the respiratory chain that joins the reducing equivalents transferred to it by the shuttles to molecular oxygen, making water. If more reducing equivalents are generated than can be used to make water, the excess are added to pyruvate to make lactate. Thus, rising lactate levels are indicative of oxygen debt.

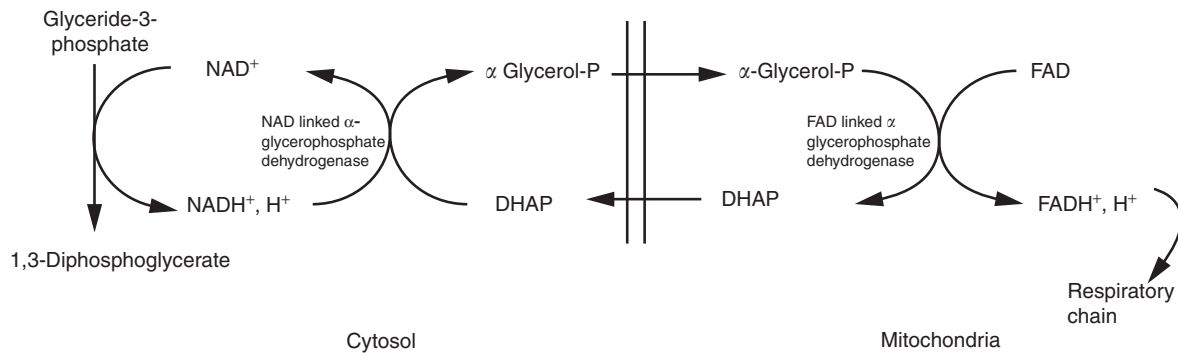
There are other shuttles that also serve to transfer reducing equivalents into the mitosol. These are the malate–aspartate shuttle (Figure 7.3) and the malate–citrate shuttle. Neither of these is rate limiting with respect to glycolysis. The malate–aspartate shuttle has rate-controlling properties with respect to gluconeogenesis, while the malate–citrate shuttle is important to lipogenesis.


FIGURE 7.2   The α-glycerol phosphate shuttle.
FIGURE 7.3   The malate–aspartate shuttle.

Once 1,3-bisphosphate glycerate is formed it is converted to 3-phosphoglycerate with the formation of one ATP. The 3-phosphoglycerate then goes to 2-phosphoglycerate and then to phosphoenolpyruvate (PEP). These are all bidirectional reactions that are also used in gluconeogenesis. The PEP is dephosphorylated to pyruvate with the formation of another ATP. Because of the great energy lost to ATP formation at this step, this reaction is not reversible. Gluconeogenesis uses another enzyme, phosphoenolpyruvate carboxykinase (PEPCK), to reverse this step. Glycolysis uses pyruvate kinase to catalyze the reaction. At any rate, pyruvate can now be converted to acetyl CoA via pyruvate dehydrogenase or carboxylated to oxalacetate via pyruvate carboxylase. Oxalacetate is the beginning substrate for the citric acid cycle.

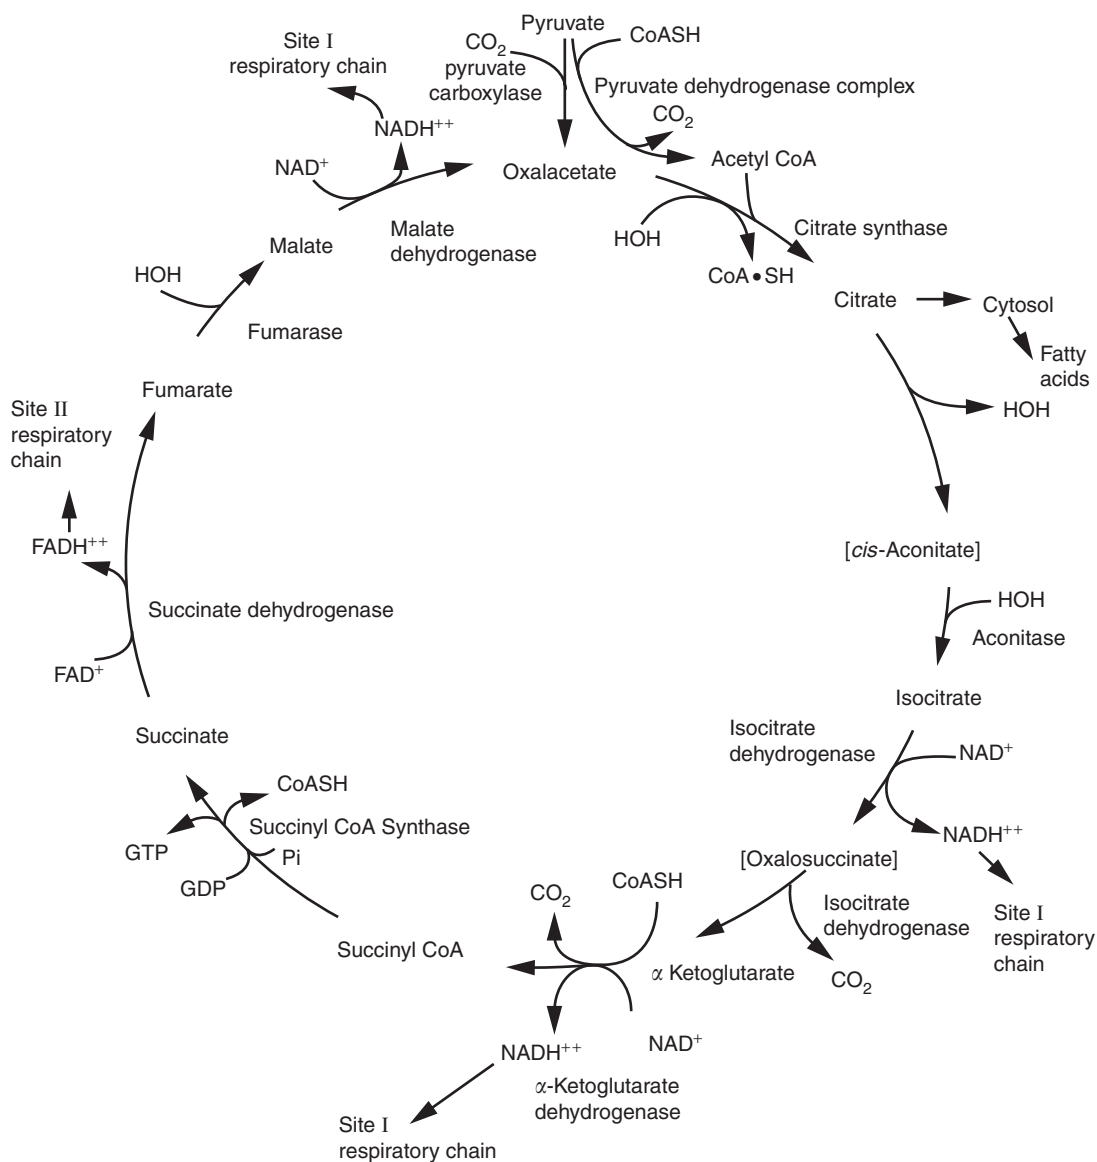
The citric acid cycle is the central cycle in intermediary metabolism. All the major macromolecules produce substrates that in one way or another enter the citric acid cycle. This cycle is shown in Figure 7.4. The purpose of this cycle is to produce reducing equivalents that can be used to make water by the respiratory chain (Figure 7.5) and CO_2. In the process of making water substantial energy is released. Some of this is captured in the high-energy bond of ATP, while the majority is released as heat. The citric acid cycle begins with joining of a two-carbon group (acetyl CoA) to oxalacetate to form citrate. The CoA is lost in the reaction and a molecule of water is added. The CoA is a pantothenic-acid-containing reactive group that plays an important role not only in the citric acid cycle but also in the many reactions of lipid metabolism. Citrate then loses a molecule of water, becoming the unstable compound, cis-aconitate. Water is added back, and isocitrate is formed. Reducing equivalents are then lost (picked up by NAD^+) and sent to the respiratory chain at site 1. Another unstable compound is formed, which in turn loses a CO_2 to become α-ketoglutarate. Another CO_2 is lost as are reducing equivalents (again picked up by NAD^+ and again sent to


FIGURE 7.4 The citric acid cycle. This cycle is sometimes called the Krebs cycle or the tricarboxylate cycle.
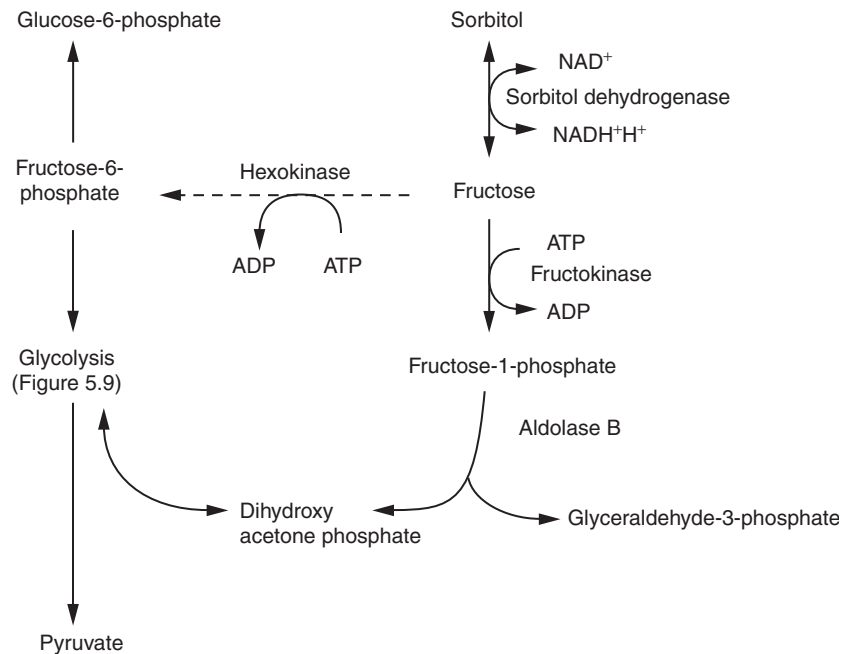
FIGURE 7.5 The respiratory chain showing the points where sufficient energy has been generated to support the synthesis of one molecule of ATP.


FIGURE 7.6 The metabolism of fructose.

site 1 of the respiratory chain), and succinyl CoA is formed. Succinyl CoA loses its CoA group to become succinate and in turn loses reducing equivalents (picked up by FAD and sent to site 2 of the respiratory chain) to become fumarate. Water is added to fumarate, and malate is produced. This malate can leave the mitochondrial compartment in the malate–citrate shuttle and become oxalacetate, the starting point of gluconeogenesis. In the citric acid cycle, malate loses reducing equivalents (picked up by NAD^+ and sent to site 1 of the respiratory chain), and once again oxalacetate is produced. The cycle has now returned to its starting point.

The glycolytic pathway is dependent on both ATP for the initial steps of the pathway, the formation of glucose-6-phosphate and fructose-1,6-bisphosphate, and on the ratio of ATP to ADP and inorganic phosphate, Pi. In working muscle the continuance of work and the continuance of glycolysis depend on the cycling of the adenine nucleotides and the export of lactate to the liver. ATP must be provided at the beginning of the pathway, and ADP as well as Pi must be provided in the latter steps. If the tissue runs out of ATP, ADP, or Pi, or accumulates lactate and H^+, glycolysis will come to a halt and work cannot continue. This is what happens to the working skeletal muscle. Exhaustion sets in when glycolytic rate is downregulated by an accumulation of lactate.

Many diets contain carbohydrates in addition to starch and glucose. These carbohydrates are metabolized to their primary monosaccharides and used. Of these monosaccharides, two are most important: fructose and galactose. Fructose is converted to glucose after phosphorylation (Figure 7.6). Although two enzymes are available for the phosphorylation of fructose one of

these, fructokinase, is present only in the liver. Hexokinase can catalyze the phosphorylation of fructose. However, fructokinase is a much more active enzyme. Its activity is so high that, in fact, most of the dietary fructose whether as the free sugar or as a component of sucrose is metabolized in the liver. This is in contrast to glucose, which is metabolized by all the cells in the body. As a result, fructose- or sucrose-rich diets fed to rats or mice will result in a fatty liver. This occurs because the dietary overload of fructose or sucrose exceeds the capacity of the liver to oxidize it, and so it uses the sugar metabolites as substrate for fatty acid and triacylglyceride synthesis. Until the hepatic lipid export system increases sufficiently to transport this lipid to the storage depots, the lipid accumulates, hence resulting in the fatty liver. Adaptation to a high fructose intake can and does occur in normal individuals, and the fatty liver disappears.

Galactose, a component of the milk sugar, lactose, is converted to glucose and eventually enters the glycolytic sequence as glucose-6-phosphate (Figure 7.7). Galactose is phosphorylated at carbon 1 in the first step of its conversion to glucose. It can be isomerized to glucose-1-phosphate or converted to uridune diphosphate (UDP)-galactose by exchanging its phosphate group for a UDP group. This UDP-galactose can be joined with glucose to form lactose in the adult mammary tissue under the influence of the hormone prolactin. However, usually the UDP-galactose is converted to UDP-glucose and thence used to form glycogen.

PENTOSE PHOSPHATE SHUNT

The pentose phosphate shunt is an alternative pathway for the metabolism of glucose (Figure 7.8). The shunt uses glucose-6-phosphate and generates phosphorylated ribose for use in DNA and RNA synthesis. It also produces reducing equivalents for use by the microsomal P450 enzymes and the lipogenic pathway. It is estimated that approximately 10% of the glucose-6-phosphate generated from glucose is metabolized by the shunt.

The shunt contains two NADP-linked dehydrogenases, glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase. These two enzymes catalyze the rate-limiting steps in the reaction sequence. In the instance where there is an active lipogenic state, these reactions provide about 50% of the reducing equivalents needed by the lipogenic process. There is an excellent correlation between this dehydrogenase activity and lipogenesis. The microsomal P450 enzymes also use the reducing equivalents carried by $NADP^+$ as does the red blood cell in the maintenance of glutathione in the reduced state. The glutathione system in the red blood cell maintains the redox state and integrity of the cell membrane. If sufficient reducing equivalents are not produced by the shunt dehydrogenase reactions to reduce glutathione, the red blood cell membrane integrity is lost and hemolytic anemia results. This is important to the red blood cell function of carrying oxygen and exchanging it for carbon dioxide. In any event, glucose-6-phosphate proceeds to 6-phosphogluconolactone, a very unstable metabolite, which is in turn reduced to 6-phosphogluconate. 6-Phosphogluconate is decarboxylated and dehydrogenated to form ribulose 5-phosphate with an unstable intermediate (keto-6-phosphogluconate) forming between the 6-phosphogluconate and ribulose 5-phosphate. Ribulose 5-phosphate can be isomerized to ribose 5-phosphate or epimerized to xylulose 5-phosphate. Xylulose and ribose 5-phosphate can reversibly form sedoheptulose 7-phosphate with release of glyceraldehyde 3-phosphate. If glucose does not proceed down the glycolytic sequence or through the pentose shunt, it can be used to make glycogen.

GLYCOGENESIS

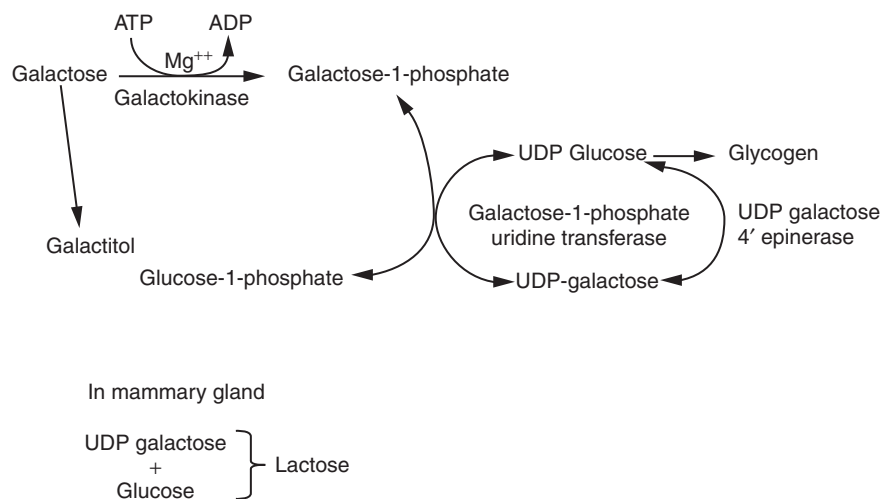
Glycogen synthesis begins with glucose-1-phosphate formation from glucose-6-phosphate through the action of phosphoglucomutase (Figure 7.9). Glucose-1-phosphate then is converted to UDP-glucose, which can then be added to the glycogen already


FIGURE 7.7   Conversion of galactose to glucose.
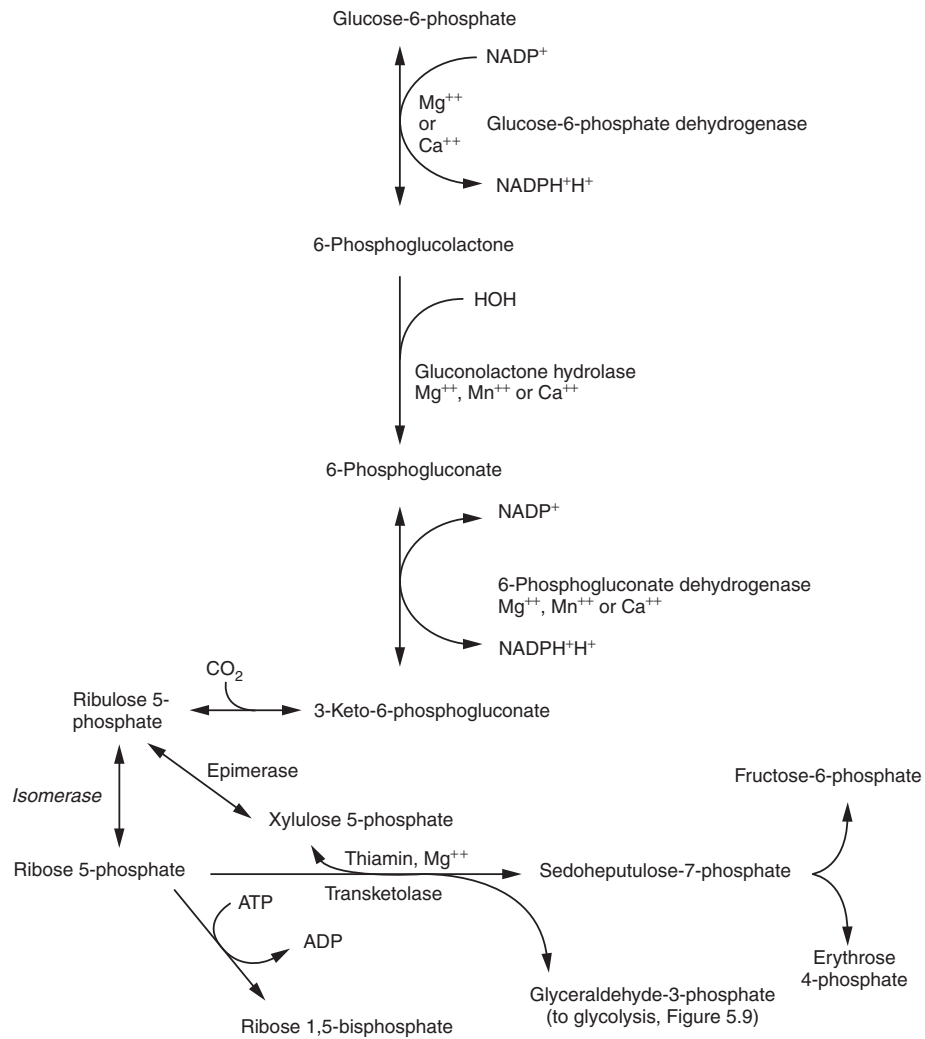

FIGURE 7.8   Reaction sequence of the hexose monophosphate shunt commonly referred to as the "shunt."
FIGURE 7.9   Glycogen synthesis (Glycogenesis).

in storage (the glycogen primer). UDP-glucose can be added through α 1,6 linkage or α 1,4 linkage. Two high-energy bonds are used to incorporate each molecule of glucose into the glycogen. The straight-chain glucose polymer is comprised of glucoses joined through the 1,4 linkage and is less compact than the branched-chain glycogen, which has both 1,4 and 1,6 linkages. The addition of glucose to the primer glycogen with a 1,4 linkage is catalyzed by the glycogen synthase enzyme, while the 1,6 addition is catalyzed by the so-called glycogen branching enzyme, amylo $(1 \rightarrow 4, 1 \rightarrow 6)$ transglucosidase. Once the liver and muscle cell achieve their full storage capacity, these enzymes are product inhibited and glycogenesis is "turned off." Glycogen synthase is inactivated by a cAMP-dependent kinase and activated by a synthase phosphatase enzyme that is stimulated by changes in the ratio of ATP to ADP. Glycogen synthesis is stimulated by the hormone insulin and suppressed by the catabolic hormones. The process does not fully cease but operates at a very low level. Glycogen does not accumulate appreciably in cells other than liver and muscle although all cells contain a small amount of glycogen. Note that a glycogen primer is required for glycogen synthesis to proceed. This primer is carefully guarded so that some is always available for glycogen synthesis. This means that glycogenolysis never fully depletes the cell of its glycogen content. When glucose is needed by the body, it can generate glucose either from glycogenolysis or through gluconeogenesis.

GLYCOGENOLYSIS

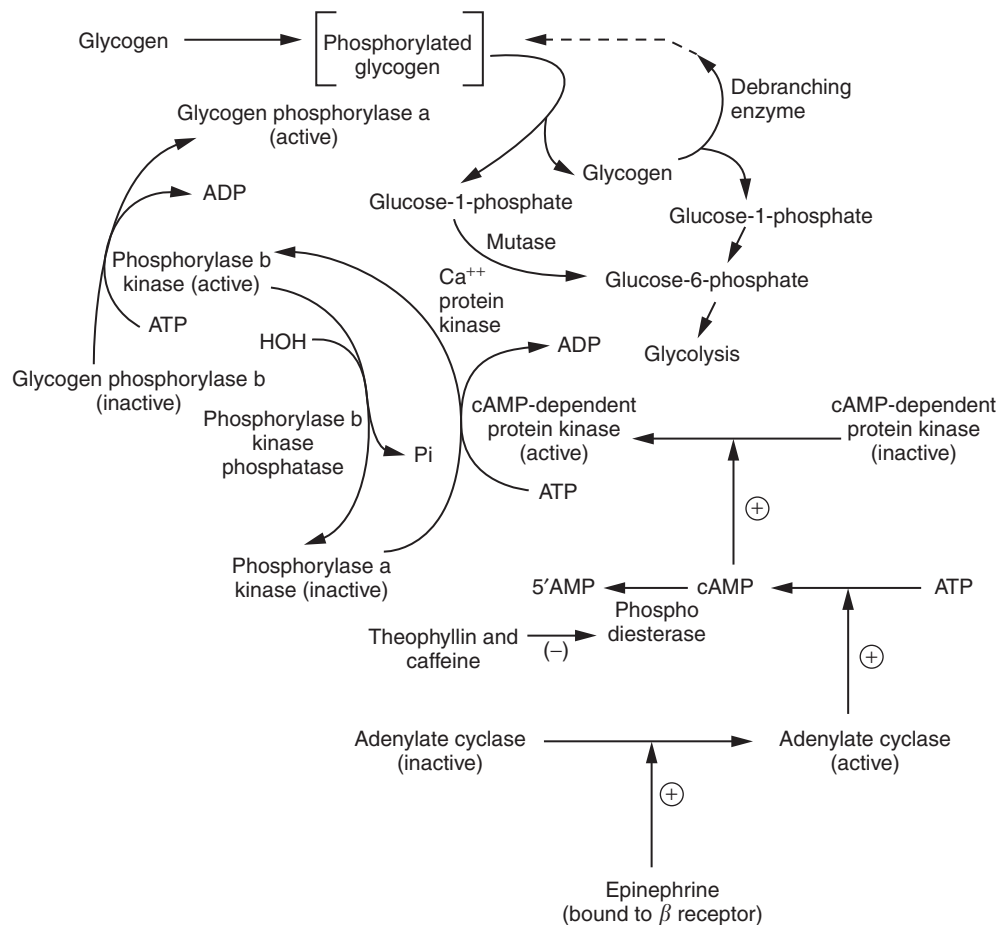
Glycogenolysis is a carefully controlled series of reactions referred to as the glycogen cascade (Figure 7.10). It is called a cascade because of the stepwise changes in activation states of the enzymes involved. To release glucose for oxidation by the glycogenolytic pathway, the glycogen must be phosphorylated. This is accomplished by the enzyme glycogen phosphorylase. Glycogen phosphorylase exists in the cell in an inactive form (glycogen phosphorylase b) and is activated to its active form (glycogen phosphorylase a) by the enzyme phosphorylase b kinase. In turn, this kinase also exists in an inactive form, which is activated by the calcium-dependent enzyme, protein kinase, and active cAMP-dependent protein kinase. These activations each require a molecule of ATP. Lastly, the cAMP-dependent protein kinase must have cAMP for its activation. This cAMP is generated from ATP by the enzyme adenylate cyclase, which, in itself, is inactive unless stimulated by a hormone such as epinephrine, thyroxine, or glucagon. As can be seen, this cascade of activation is energy dependent with three molecules of ATP needed


FIGURE 7.10 Stepwise release of glucose from glycogen, the glycogen cascade.

to get the process started. Once started, the glycolytic pathway will replenish the ATP needed initially as well as provide a further supply of ATP to provide needed energy. As mentioned, the liver and muscle differ in the use of glycogen. This also affects how ATP is generated within the glycogen-containing cell and how much is generated by cells that do not store glycogen.

Glycogenolysis is stimulated by the catabolic hormones, glucagon, epinephrine, the glucocorticoids, and thyroxine, and/or by the absence of food in the digestive tract. Because the glycogen molecule has molecules of water as part of its structure, it is a very large molecule and cumbersome to store in large amounts. The average 70 kg man has only an 18 h fuel supply stored as glycogen, while that same individual might have up to a 2-month supply of fuel stored as fat. Muscle and liver glycogen stores have very different functions. Muscle glycogen is used to synthesize ATP for muscle contraction, whereas hepatic glycogen is the glucose reserve for the entire body particularly the central nervous system. The amount of glycogen in the muscle is dependent on the physical activity of the individual. After bouts of strenuous exercise, the glycogen store will be depleted only to be rebuilt during the resting period following exercise. Hepatic glycogen stores are dependent on nutritional status. They are virtually absent in the 24 h starved animal while being replenished within hours of feeding. Clusters of glycogen molecules with an average molecular weight of 2×10^7 form quickly when an abundance of glucose is provided to the liver. The amount of glycogen in the liver is diet and time dependent. There is a 24 h rhythmic change in hepatic glycogen that corresponds to the feeding pattern of the animal. In nocturnal animals such as the rat, the peak hepatic glycogen store will be found in the early morning hours while the nadir will be found in the evening hours just before the nocturnal feeding begins. In humans accustomed to eating during the day, the reverse pattern will be observed.

GLUCONEOGENESIS

Gluconeogenesis occurs primarily in the liver and kidney (Figure 7.11). Except under conditions of prolonged starvation, the kidneys do not contribute appreciable amounts of glucose to the circulation. Most tissues lack the full complement of enzymes needed to run this pathway. In particular, the rate-limiting enzyme PEPCK is not found to be active in tissues other than liver and kidney. The other reactions use the same enzymes as glycolysis and do not have control properties with respect to gluconeogenesis. The rate-limiting enzymes are glucose-6-phosphatase, fructose-1,6-bisphosphatase, and PEPCK. Pyruvate kinase and pyruvate carboxylase are also of interest because their control is a coordinated one with respect to the regulation of PEPCK.

Oxalacetate in the cytosol is essential to gluconeogenesis because it is the substrate for PEPCK that catalyzes its conversion to PEP. This is an energy-dependent conversion that overcomes the irreversible final glycolytic reaction catalyzed by pyruvate kinase. The activity of PEPCK is closely coupled with that of pyruvate carboxylase. Whereas the pyruvate kinase reaction produces one ATP, the formation of PEP uses two ATPs — one in the mitochondria for the pyruvate carboxylase reaction and one in the cytosol for the PEPCK reaction. PEPCK requires guanosine triphosphate (GTP) provided via the nucleoside diphosphate kinase reaction that uses ATP. ATP transfers one high-energy bond to GDP to form ADP and GTP.

In starvation or uncontrolled diabetes, PEPCK activity is elevated as is gluconeogenesis. Starvation elicits a number of catabolic hormones that serve to mobilize tissue energy stores as well as precursors for glucose synthesis. Uncontrolled diabetes elicits similar hormonal responses. In both instances, the synthesis of the PEPCK enzyme protein is increased. Unlike other rate-limiting enzymes, PEPCK is not regulated allosterically or by phosphorylation–dephosphorylation mechanisms. Instead, it is regulated by changes in gene transcription of its single-copy gene from a single promoter site. This regulation is unique because all of the known factors (hormones, vitamins, and metabolites) act in the same place. They either turn on the synthesis of the messenger RNA for PEPCK, or they turn it off. What is also unique is the fact that liver and kidney cells translate this message into sufficient active enzyme protein that catalyzes PEP formation. Other cells and tissues have the code for PEPCK in their nuclear DNA but do not usually synthesize the enzyme. Instead, these cell types synthesize the enzyme that catalyzes glycerol synthesis. In effect then, only the kidney and liver have active gluconeogenic processes.

The next few steps in gluconeogenesis are identical to those of glycolysis but are in the reverse direction. When the step for the dephosphorylation of fructose-1,6-bisphosphate occurs, there is another energy barrier and, instead of a bidirectional reaction catalyzed by a single enzyme, there are separate forward and reverse reactions. In the synthesis of glucose, this reaction is catalyzed by fructose-1,6-bisphosphatase and yields fructose-6-phosphate. No ATP is involved, but a molecule of water and an inorganic phosphate are produced. Rising levels of fructose-2,6-bisphosphatase allosterically inhibits gluconeogenesis while it stimulates glycolysis. AMP likewise inhibits gluconeogenesis at this step.

Lastly, the removal of the phosphate from glucose-6-phosphate via the enzyme complex glucose-6-phosphatase completes the pathway to yield free glucose. This is an irreversible reaction that does not involve ATP. The glucose-6-phosphate moves to the endoplasmic reticulum, where the phosphatase is located and glucose is released for use.

LIPID METABOLISM

FATTY ACID ESTERIFICATION

In course of lipid absorption, the glycerides are hydrolyzed only to be reesterified for transport. This process of hydrolysis and reesterification happens every time a glyceride crosses a membrane. The resultant product of esterification is a MG, DG, or TG.

The TG is hydrolyzed by interstitial LPL, and the fatty acids are transported into the target cell and reesterified to glycerol-3-phosphate. In the fat cell, this glycerol-3-phosphate usually is a product of glycolysis rather than the glycerol liberated when stored TG is hydrolyzed. The liberated glycerol usually passes back to the liver, which has a very active glycerokinase to phosphorylate it. In the liver, the phosphorylated glycerol is either used as a substrate for glucose synthesis or recycled into hepatic phospholipids or TG or oxidized to CO_2 and water.

Triacylglycerides are formed in a stepwise fashion (Figure 7.12). First, a fatty acid (usually a saturated fatty acid) is attached at carbon 1 of the glycerophosphate. The phosphate group at carbon 3 is electronegative and because it pulls electrons toward it, it leaves carbon 1 more reactive than carbon 2. The fatty acid (as acyl CoA) is transferred to carbon 1 through the action of a transferase. The attachment uses the carboxy end of the fatty acid chain and makes an ester linkage releasing the CoA.
FIGURE 7.12 Fatty acid esterification and phospholipid formation.

Now the molecule has electronegative forces at each end — the phosphate group on carbon 3 and the oxygen plus carbon chain at carbon 1. Now carbon 2 is vulnerable and reactive and another carbon chain can be attached. In this instance the fatty acid is usually an unsaturated fatty acid. At this point, the 1,2 diacylglyceride-phosphate loses its phosphate group so that carbon 3 is now reactive. The 1,2 diacylglyceride can either be esterified with another fatty acid to make triacylglyceride or can be used to make the membrane phospholipids, phosphatidylcholine, phosphatidylethanolamine, phosphatidylinositol, cardiolipin, and phosphatidylserine. In the stored triacylglycerides and in membranes, most unsaturated fatty acids are found at carbon 2. In the membrane phospholipids, the unsaturated fatty acid at carbon 2 is usually arachidonic acid. This arachidonic acid, produced by elongation and desaturation of dietary linoleic acid, is preferentially used in the membrane phospholipid. It can either be attached to the glycerol backbone when the phospholipid is made or exchanged for another fatty acid as the lipids in and around the cells remodel themselves. There is constant hydrolysis and reesterification in the cell and there is a rapid exchange of fatty acids between those in the membranes and those inside the cell.

Endogenous Lipid Transport

Fatty acids, TG, cholesterol, cholesterol esters, and phospholipids are synthesized in the body and are transported from sites of synthesis to sites of use and storage. While the transport of these lipids is, in many instances, similar to that of the dietary lipids, there are differences in the processing and in some of the proteins involved. Endogenous fat transport involves the production and secretion of very-low-density lipoproteins (VLDL) by the liver. These lipid–protein complexes are rich in TG and contain cholesterol. The polypeptides that transport these lipids comprise approximately 10% of the weight of the VLDL. They include the polypeptides apo B, B-100, apo C-I, C-II, C-III, and apo E. As mentioned, several of these polypeptides are also involved

in exogenous lipid transport (see Chapters 42 & 43). Once the VLDLs are released by the hepatocyte, they are hydrolyzed by the interstitial LPL, and intermediate-density lipoproteins (IDL) are formed. These are cleared from the circulation as they are recognized and bound to hepatic IDL receptors. The hepatic receptors recognize the apo E that is part of the IDL. Any of the IDL that escapes hydrolysis at this stage is available for hydrolysis by the hepatic LPL. This hydrolysis leaves a cholesterol-rich particle of low-density lipoprotein (LDL). The LDL has apo B-100 as its polypeptide carrier, and both hepatic and extrahepatic cells have receptors that recognize this polypeptide. Normally, about 70% of LDL is cleared by the LDL receptors and most of this is cleared by the liver. From the foregoing, it is apparent that considerable lipid recycling occurs in the liver. The VLDLs originate in the liver and the liver is the primary site for LDL disposal. However, other organs and tissues also participate in disposal, but their participation is minor compared with that of the liver.

FATTY ACID OXIDATION

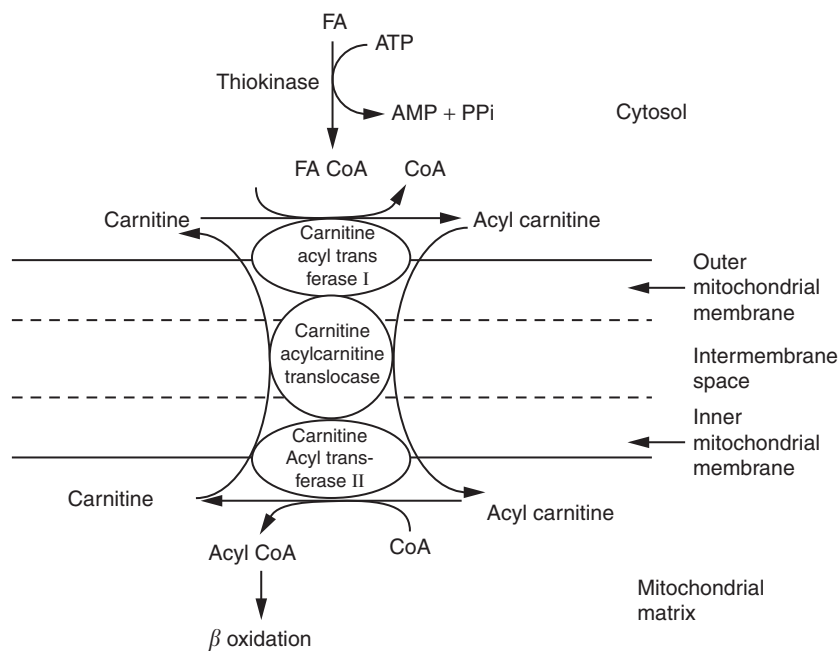
Fatty acids are a source of metabolic fuel. They are available for oxidation once they are released from the gylcerides by hydrolysis. This oxidation occurs via the β oxidation pathway and occurs in the mitochondria (Figure 7.13). Prior to oxidation, the fatty acids must be transported into the mitochondria via the acyl-carnitine-transport system (Figure 7.14). The fatty acids are activated by conversion to their CoA thioesters. This activation requires ATP and the enzyme, acyl CoA synthase or thiokinase. There are several thiokinases, which differ with respect to their specificity for the different fatty acids. The activation step is dependent on the release of energy from ATP. Once the fatty acid is activated, it is bound to carnitine with the release of CoA. The acyl carnitine is then translocated through the mitochondrial membranes into the mitochondrial matrix via the carnitine acylcarnitine translocase. As one molecule of acylcarnitine is passed into the matrix, one molecule of carnitine is translocated back to the cytosol and the acylcarnitine is converted back to acyl CoA. The acyl CoA can then enter the β oxidation pathway. Without carnitine, the oxidation of fatty acids, especially the long-chain fatty acids, cannot proceed. Acyl CoA cannot traverse the membrane into the mitochondria and thus requires a translocase for its entry. The translocase requires carnitine. While most of the fatty acids that enter the β oxidation pathway are completely oxidized via the citric acid cycle and respiratory chain to
FIGURE 7.13 Fatty acid oxidation.


FIGURE 7.14 Mechanism for the entry of fatty acids into the mitochondrial compartment.

CO_2 and HOH, some of the acetyl CoA is converted to the ketones, acetoacetate, and β-hydroxybutyrate. The condensation of two molecules of acetyl CoA to acetoacetyl CoA occurs in the mitochondria via the enzyme β-ketothiolase. Acetoacetyl CoA then condenses with another acetyl CoA to form HMG CoA. At last, the HMG CoA is cleaved into acetoacetic acid and acetyl CoA. The acetoacetic acid is reduced to β-hydroxybutyrate, and this reduction is dependent on the ratio of NAD^+ to $NADH^+H^+$. The enzyme for this reduction, β-hydroxybutyrate dehydrogenase, is tightly bound to the inner aspect of the mitochondrial membrane. Because of its high activity, the product (β-hydroxybutyrate) and substrate (acetoacetate) are in equilibrium.

HMG CoA is also synthesized in the cytosol, where it serves as a starting point for the synthesis of cholesterol. The ketones can ultimately be used as fuel but may appear in the blood, liver, and other tissues at a level of less than 0.2 mM. In starving individuals or in people consuming a high-fat diet, blood and tissue ketone levels may rise above normal (3 to 5 mM). However, unless these levels greatly exceed the body's capacity to use them as fuel (as is the case in uncontrolled diabetes mellitus with levels up to 20 mM) a rise in ketone levels is not a cause for concern. Ketones are choice metabolic fuels for muscle and brain. Although both tissues may prefer to use glucose, the ketones can be used when glucose is in short supply. Ketones are used to spare glucose wherever possible under these conditions.

The oxidation of unsaturated fatty acids follows the same pathway as the saturated fatty acids until the double-bonded carbons are reached (Figure 7.15). At this point, a few side steps must be taken that involve a few additional enzymes. Linoleate has two double bonds in the *cis* configuration. β Oxidation removes three acetyl units, leaving a CoA attached to the terminal carbon just before the first *cis* double bond. At this point an isomerase enzyme, $\Delta 3$ *cis* $\Delta 6$ *trans* enoyl CoA isomerase, acts to convert the first *cis* bond to a *trans* bond. Now, this part of the molecule can once again enter the β oxidation sequence and two more acetyl CoA units are released. The second double bond is then opened and a hydroxyl group is inserted. In turn, this hydroxyl group is rotated to the ʟ position and the remaining product can then reenter the β oxidation pathway. Other unsaturated fatty acids can be similarly oxidized. Each time the double bond is approached, the isomerization and hydroxyl group addition takes place until all of the fatty acid is oxidized.

While β oxidation is the main pathway for the oxidation of fatty acids, some fatty acids undergo α oxidation so as to provide the substrates for the synthesis of sphingolipids. These reactions occur in the endoplasmic reticulum and mitochondria and involve the mixed function oxidases because they require molecular oxygen, reduced NAD, and specific cytochromes. The fatty acid oxidation that occurs in organelles other than the mitochondria are energy-wasteful reactions because these other organelles do not have the citric acid cycle nor do they have the respiratory chain, which takes the reducing equivalents released by the oxidative steps and combines them with oxygen to make water releasing energy that is then trapped in the high-energy bonds of the ATP.

Peroxisomal oxidation in the kidney and liver is an important aspect of drug metabolism. The peroxisomes are a class of subcellular organelles that are important in the protection against oxygen toxicity. They have a high level of catalase activity, which suggests their importance in the antioxidant system. The peroxisomal fatty acid oxidation pathway differs in three important ways from the mitochondrial pathway. First, the initial dehydrogenation is accomplished by a cyanide-insensitive oxidase
FIGURE 7.15 Unsaturated fatty acid oxidation.

that produces H_2O_2. This H_2O_2 is rapidly extinguished by catalase. Second, the enzymes of the pathway prefer long-chain fatty acids and are slightly different in structure from those (with the same function) of the mitochondrial pathway. Third, β oxidation in the peroxisomes stops at eight carbons rather than proceeding all the way to acetyl CoA. The peroxisomes also serve in the conversion of cholesterol to bile acids and in the formation of ether lipids (plasmalogens).

Fatty Acid Synthesis

Fatty acid synthesis occurs in the cytosol of the living cell using two carbon units (acetyl units) that are the result of glucose oxidation or amino acid degradation (Figure 7.16).

Fatty acid synthesis begins with acetyl CoA. Acetyl CoA arises from the oxidation of glucose or the carbon skeletons of deaminated amino acids. Acetyl CoA is converted to malonyl CoA with the addition of one carbon (from bicarbonate) in the presence of the enzyme acetyl CoA carboxylase. The reaction uses the energy from one molecule of ATP and biotin as a coenzyme. This reaction is the first committed step in the reaction sequence that results in the synthesis of a fatty acid. The activated CO_2 attached to the biotin–enzyme complex is transferred to the methyl end of the substrate. Although most fatty acids synthesized in mammalian cells have an even number of carbons, this first committed step yields a three-carbon product. This results in an asymmetric molecule that becomes vulnerable to attack (addition) at the center of the molecule with the subsequent loss of
FIGURE 7.16 Fatty acid synthesis.

the terminal carbon. The vulnerability is conferred by the fact that both the carboxyl group at one end and the group at the other end are both powerful attractants of electrons from the hydrogen of the middle carbon. This leaves the carbon in a very reactive state, and a second acetyl group carried by a carrier protein with the help of phosphopantethine, which has a sulfur group connection can be joined to it through the action of the enzyme, malonyl transferase. Subsequently, the "extra" carbon is released via the enzyme β-ketoacyl enzyme synthase, leaving a four-carbon chain still connected to an SH group at the carboxyl end. This SH group is the docking end for all the enzymes that comprise the fatty acid synthase complex. These enzymes catalyze the addition of two carbon acetyl groups in sequence to the methyl end of the carbon chain until the final product palmityl CoA, and then palmitic acid is produced. Members of this fatty acid synthase complex include the aforementioned malonyl transferase and β-ketoacyl synthase, β-ketoacyl reductase, which catalyzes the addition of reducing equivalents carried by FMN, and an acyl transferase. Upon completion of these six steps, the process is repeated until the chain length is 16 carbons long. At this point, the SH-acyl carrier protein is removed through the action of the enzyme palmityl-S-enzyme deacylase and the palmitic acid is available for esterification to glycerol to form a mono-, di-, or triacylglyceride (see the section titled "Fatty Acid Esterification").

FATTY ACID ELONGATION

Elongation or the lengthening of fatty acids by the addition of two carbon units (acetyl groups), occurs in either the endoplasmic reticulum or the mitochondria (Figure 7.17). The reaction differs depending on where it occurs. In the endoplasmic reticulum, the reaction sequence is similar to that described for the cytosolic fatty acid synthase complex. The source of the two-carbon unit is malonyl CoA, and $NADPH^+H^+$ provides the reducing power. The intermediates are CoA esters, not the acyl carrier protein 4′-phosphopantetheine. The reaction sequence produces stearic acid (18:0) in all tissues that make fatty acids except the brain. In the brain, elongation can proceed further producing fatty acids containing up to 24 carbons. In the mitochondria, elongation uses acetyl CoA rather than malonyl CoA as the source of the two-carbon unit. It uses either $NADH^+H^+$ or $NADPH^+H^+$ as the source of reducing equivalents and uses, as substrate, carbon chains of less than 16 carbons. Mitochondrial elongation is the reversal of fatty acid oxidation, which also occurs in this organelle. Not all species can make all of the fatty acids found in the body tissues. Some of these fatty acids are therefore essential. In mammals the essential fatty acids are linoleic and linolenic acids. In felines the essential fatty acids include these two and arachidonic acid. Table 7.4 gives the structures and names of the important fatty acids.

FATTY ACID DESATURATION

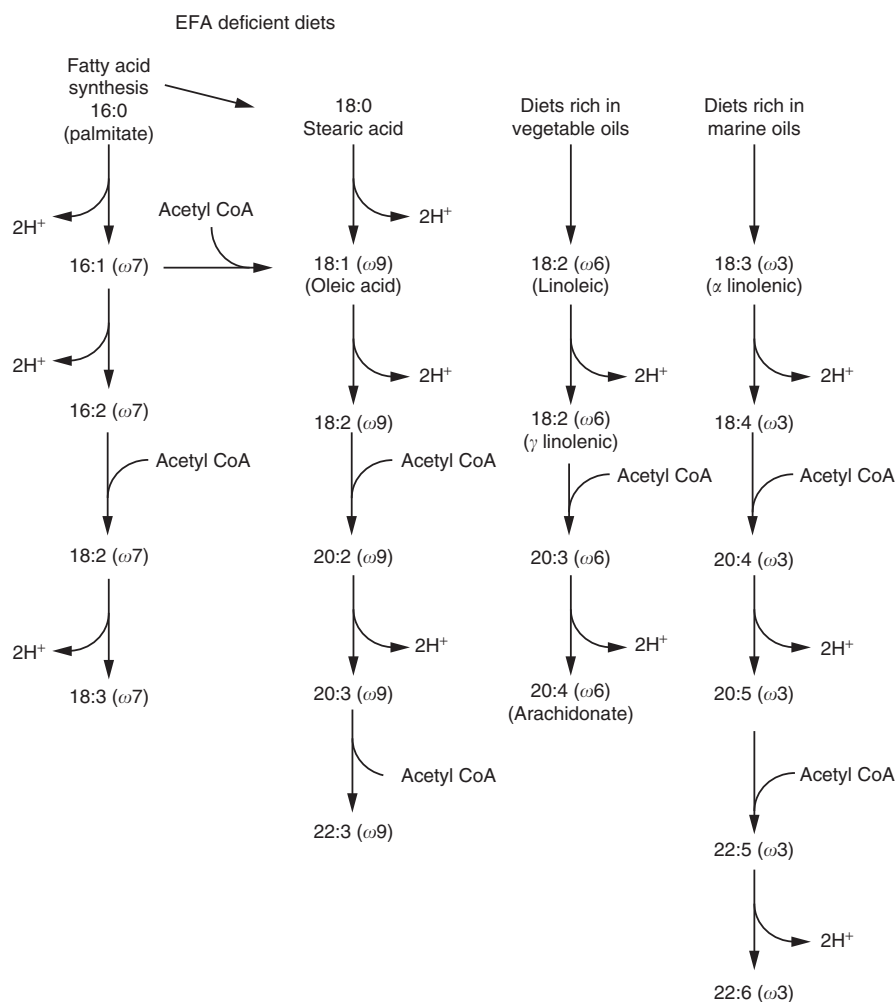
Desaturation occurs in the endoplasmic reticulum and microsomes (Figure 7.17). The enzymes that catalyze this are the $\Delta 4$, $\Delta 5$, or $\Delta 6$ desaturases. Desaturation is species specific. Mammals, for example, lack the ability to desaturate fatty acids in the n-6 or n-3 position. They cannot make linoleic or linolenic acid, and in addition, felines cannot convert linoleic to arachidonic acid.


FIGURE 7.17 Fatty acid elongation and desaturation.

TABLE 7.4
Structure and Names of Fatty Acids Found in Food

Structure	Number of Double Bonds	Systematic Name	Trivial Name	Source
Saturated fatty acids				
$CH_3(CH_2)_2COOH$	0	*n*-Butanoic	Butyric	Butter
$CH_3(CH_2)_4COOH$	0	*n*-Hexanoic	Caproic	Butter
$CH_3(CH_2)_6COOH$	0	*n*-Octanoic	Caprylic	Coconut oil
$CH_3(CH_2)_8COOH$	0	*n*-Decanoic	Capric	Palm oil
$CH_3(CH_2)_{10}COOH$	0	*n*-Dodecanoic	Lauric	Coconut oil, butter
$CH_3(CH_2)_{12}COOH$	0	*n*-Tetradecanoic	Myristic	Coconut oil
$CH_3(CH_2)_{14}COOH$	0	*n*-Hexadecanoic	Palmitic	Most fats and oils
$CH_3(CH_2)_{16}COOH$	0	*n*-Octadecanoic	Stearic	Most fats and oils
$CH_3(CH_2)_{18}COOH$	0	*n*-Eicosanoic	Arachidic	Peanut oil, lard
Unsaturated fatty acids				
$CH_3(CH_2)_5CH=CH(CH_2)_7COOH$	1	9-Hexadecenoic	Palmitoleic	Butter and seed oils
$CH_3(CH_2)_7CH=CH(CH_2)_7COOH$	1	9-Octadecenoic	Oleic	Most fats and oils
$CH_3(CH_2)_5CH=CH(CH_2)_9COOH$	1	11-Octadecenoic	Vaccenic	*trans*-Hydrogenated vegetable oils
$CH_3(CH_2)_4CH=CHCH_2CH=CH(CH_2)_7COOH$	2	9,12-Octadecadienoic	Linoleic	Linseed oil, corn oil
$CH_3CH_2(CH=CHCH_2)_3(CH_2)_7COOH$	3	9,12,15-Octadecatrienoic	Linolenic	Soybean and marine oils
$CH_3(CH_2)_4(CH=CHCH_2)_4(CH_2)_2COOH$	4	5,8,11,14-Eicosatetraenoic	Arachidonic	Cottonseed oil

Only plants can do this, and even among plants there are species differences. Cold water plants can desaturate at the n-3 position, while land plants of warmer regions cannot. The cold water plants are consumed by cold water creatures in a food chain that includes fish as well as sea mammals. These, in turn, enter the human food supply and become sources of the n-3, or omega-3, fatty acids in the marine oils. In animals desaturation of *de novo* synthesized fatty acids usually stops with the production of a monounsaturated fatty acid with the double bond in the 9 to 10 position counting from the carboxyl end of the molecule. Hence, palmitic acid (16:0) becomes palmitoleic acid (16:1) and stearic acid (18:0) becomes oleic acid (18:1). In the absence of dietary EFA most mammals will desaturate eicosenoic acid to produce eicosatrienoic acid. Increases in this fatty acid with unsaturations at the n-7 and n-9 positions characterize the tissue lipids of EFA-deficient animals. The enzymes are sometimes called mixed function oxidases because two substrates (fatty acid and NADPH) are oxidized simultaneously. These desaturases prefer substrates with a double bond in the n-6 position but will also act on n-3 fatty acids bonds and on saturated fatty acids. Desaturation of *de novo* synthesized stearic acid to form oleic acid results in the formation of a double bond at the omega-9 position. This is the first committed step of this desaturation/elongation reaction sequence. Oleic acid can also be formed by the desaturation and elongation of palmitic acid. Fatty acid desaturation can be followed by elongation and repeated such that a variety of mono- and polyunsaturated fatty acids can be formed. The body can convert the dietary saturated fatty acids to unsaturated fatty acids, thus maintaining an optimal P:S ratio in the tissues.

AUTOOXIDATION

Unsaturated fatty acids, particularly the polyunsaturated fatty acids, are more reactive than saturated fatty acids. The double bonds can be attacked by oxygen radicals in a process called autooxidation. In food, autooxidation occurs and is responsible for the deterioration of food quality. The discoloration of red meat upon exposure to air at room temperature is an indication of the autooxidation process. The off odor that accompanies this discoloration is the result of the autooxidation of the fatty acids in the meat fat. In living systems, the process of autooxidation is suppressed to a large extent. This is essential because the products of this oxidation, fatty acid peroxides, can be very damaging. Peroxides denature proteins, rendering them inactive, and attack the DNA in the nucleus and mitochondria, resulting in base pair deletions or breaks in the DNA, which, in turn, result in mutations or errors. In the nucleus, these breaks or deletions can be repaired. In the aging animal, the repair mechanism loses its efficiency and one of the characteristics of aged cells is the loss of its DNA repair ability. To prevent widespread damage to cellular proteins and DNA by these radicals, there is a potent antioxidation system. This antioxidation system includes the selenium containing enzyme, glutathione peroxidase, catalase, and superoxide dismutase (SOD). These enzymes are found in the peroxisomes. Superoxide dismutase is also found in the mitochondria. All of these components serve to suppress free radical formation.

The free radical chain reaction occurs when the oxygen atom is excited by a variety of drugs and contaminants or by ultraviolet light. The excited oxygen atom is called singlet oxygen (O_2^-). Pollutants such as the oxides of nitrogen or carbon tetrachloride can provoke this reaction. *In vivo*, the detoxification reactions catalyzed by the cytochrome P450 enzymes generate free radicals. In the respiratory chain of the mitochondria, the possibility of oxygen radical production exists, and it is for this reason the mitochondria possess a particularly potent peroxide suppressor, SOD. SOD in the mitochondria requires the manganese ion as a cofactor. The cytosol also has SOD, but this enzyme requires the copper and zinc ions. Both forms of the enzyme catalyze the reaction,

$$O_2^- + O_2^- + 2H^+ \rightarrow H_2O_2 + O_2.$$
Two superoxides and two hydrogen ions are joined to form one molecule of hydrogen peroxide and a molecule of oxygen. In turn, the peroxide can be converted to water through the action of the enzyme catalase. Peroxides can also be "neutralized" through the action of glutathione-*S*-transferase. This reaction requires 2 *M* of reduced glutathione and produces two molecules of oxidized glutathione and two molecules of water. Fatty acid radicals can also be neutralized by glutathione peroxidase producing a molecule of an alcohol with the same chain length as the fatty acid. Glutathione-*S*-transferase can duplicate the action of glutathione peroxidase. These enzymes and the reactions they catalyze are listed in Table 7.5. In addition to the reactions that counteract the *in vivo* formation of oxygen radicals or fatty acid peroxides, certain of the vitamins have this role as well. Ascorbic acid has antioxidant function as it can donate reducing equivalents to a peroxide converting it to an alcohol. β-Carotene can quench singlet oxygen and thus convert it into O_2. Vitamin E is perhaps the best known antioxidant vitamin and its action is similar to that of ascorbic acid. It donates reducing equivalents to a peroxide converting it to an alcohol.

Although the foregoing has emphasized the negative aspects of the partial reduction products of oxygen, there is some evidence that peroxide formation has some benefit. For example, leukocytes produce peroxides as a means of killing invading bacteria. Other examples, no doubt, will emerge as scientists continue in their efforts to understand the role of peroxidation (and the peroxisomes) in mammalian metabolism.

CHOLESTEROL SYNTHESIS

The body synthesizes nearly 90% of the cholesterol that is in the circulation. The starting point for cholesterol synthesis is the joining of acetyl CoA to acetoacetyl CoA to form HMGCoA (Figure 7.18). HMGCoA through the action of HMGCoA reductase

(the rate-limiting step in this pathway) is converted to mevalonate. Cholesterol-lowering drugs act on this step inhibiting *in vivo* cholesterol synthesis. Mevalonate is phosporylated to farnesyl phosphate, which in turn is converted to squalene and then, through a series of reactions, to cholesterol. Cholesterol serves as the beginning substrate for the synthesis of a variety of hormones, active vitamin D, and the bile acids (Figure 7.19). Cholesterol is also an important component of cellular membranes.

EICOSANOID SYNTHESIS

Eicosanoids are 20 carbon molecules having hormone-like activity. They are produced in their various forms and released by many different mammalian cells. When each of these compounds is produced, their site of action is local. That is, whereas insulin may be transported from the pancreas to peripheral target cells, the eicosanoids are produced, released, and have as their targets the surrounding cells. For this reason, the eicosanoids are called local hormones. They have a variety of actions. Table 7.6 lists the major eicosanoids and their functions.

The eicosanoids fall into three general groups of compounds: the prostaglandins (compounds of the PG series), the thromboxanes (compounds of the TBX series), and the leukotrienes (compounds of the LKT series). All of these compounds arise from a 20-carbon polyunsaturated fatty acid (Figure 7.20). This fatty acid is usually arachidonic acid (20 carbons, 4 double bonds at 5, 8, 11, and 14). However, in instances where the diet is rich in n-3 fatty acids, the precursor may be a twenty-carbon-5 double-bond fatty acid, eicosapentaenoic acid (double bonds at 5, 8, 11, 14, and 17). Other eicosanoids can be synthesized from a 20-carbon fatty acid, dihomo-γ-linoleic acid, which has only three double bonds at carbons 8, 11, and 14. Each of these precursors yields a particular set of eicosanoids. During their synthesis, they take up oxygen and are cyclized. Dihomo-γ-linoleic acid is the precursor of prostaglandin E_1 (PGE_1), prostaglandin $E_{1\alpha}$ ($PGE_{1\alpha}$), and subsequent prostaglandins. Arachidonic acid is the precursor of prostaglandins of the 2 series (PGE_2, $PGF_{2\alpha}$, etc.), and eicosapentaenoic acid is the precursor of prostaglandins of the 3 series (PGE_3, $PGF_{3\alpha}$, etc.).

The cyclization of these 20-carbon fatty acids is accomplished by a complex of enzymes called the prostaglandin synthesis complex. The first step is the cyclooxygenase step, which involves the cyclization of C-9 - C-12 of the precursor to the cyclic
FIGURE 7.19   Uses of cholesterol.

TABLE 7.6
Functions of Eicosanoids

Eicosanoid	Function
PGG_2	Precursor of PGH_2
PGH_2	Precursor of PGD_2, PGE_2, PGI_2, $PGF_{2\alpha}$
PGD_2	Promotes sleeping behavior
	Precursor of PGF_2
PGE_2	Enhances perception of pain when histamine or bradykinin is given
	Induces signs of inflammation
	Promotes wakefulness
	Precursor of $PGF_{2\alpha}$
	Reduces gastric acid secretion, induces partuition
	Vasoconstrictor in some tissues
	Vasodilator in other tissues
	Maintains the patency of the ductus arteriosis prior to birth
$PGF_{2\alpha}$	Bronchial constrictor
	Vasoconstrictor especially in coronary vasculature
	Increases sperm motility
	Induces partuition; stimulates steroidogenesis corpus luteum; induces luteolysis
PGI_2	Inhibits platelet aggregation
PGE_1	Inhibits motility of nonpregnant uterus increases motility of pregnant uterus
	Bronchial dilator
TXA_2	Stimulates platelet aggregation
	Potent vasoconstrictor
TXB_2	Metabolite of TXA_2
LTA_4	Precursor of LTB_4
LTB_4	Potent chemotaxic agent

form 9, 11-endoperoxide 15-hydroperoxide (PGG_2). PGG_2 is then used to form prostaglandin H_2 (PGH_2) through the removal of one oxygen from the carbonyl group at carbon 15. Glutathione peroxidase and prostaglandin H synthase catalyze the reaction shown in Figure 7.20. Prostaglandin H synthase is a very unstable short-lived enzyme with a messenger RNA that is one of the shortest-lived species so far found in mammalian cells. The expression of genes for this enzyme is under the control of polypeptide growth factors such as interleukin-1α, and colony stimulating factor-1. Interferon-α and interferon-β inhibit expression and prostanoid production by the macrophages. Glutathione peroxidase is a selenium-containing enzyme. PGH_2 is then converted through the action of a variety of isomerases to PGD_2, PGE_2, prostacylin I_2 (PGI_2), or prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$). These are the primary precursors of the prostaglandins of the D, E, and F series and PGI or thromboxane. The conversion to subsequent prostaglandins is mediated by enzymes that are specific to a certain cell type and tissue. Not all of these subsequent compounds
FIGURE 7.20 Eicosanoid synthesis from arachidonic acid.
FIGURE 7.21 Reaction sequence that produces TXA_2 and TXB_2.

are formed in all tissues. Thus, PGE_2 and $PGF_{2\alpha}$ are produced in the kidney and spleen. $PGF_{2\alpha}$ and PGE are also produced in the uterus only when signals from the pituitary induce their production and so stimulate parturition. PGI_2 is primarily produced by endothelial cells lining the blood vessels. This prostaglandin inhibits platelet aggregation and thus is important to maintaining a blood flow free of clots. It is counteracted by thromboxane A_2, which is produced by the platelets when these cells contact a foreign surface. PGE_2, $PGF_{2\alpha}$, and PGI_2 are formed by the heart in about equal amounts. All of these prostaglandins have very short half-lives. No sooner are they released than they are inactivated. The thromboxanes are highly active metabolites of the prostaglandins. As mentioned earlier, they are formed when PGH_2 has it cyclopentane ring replaced by a six-membered oxane ring shown in Figure 7.21. Imidazole is a potent inhibitor of thromboxane A synthase and is used to block TXA_2 production and platelet aggregation.

Thromboxane A_2 has a role in clot formation and the name thromboxane comes from this function (thrombus means clot). The half-life of TXA_2 is less than 1 min. TXB_2 is its metabolic end product and has little biological activity. Measuring TXB_2

levels in blood and tissue can give an indication of how much TXA_2 had been produced. PGD_2 and PGE_2 are involved in the regulation of sleep–wake cycles in a variety of species.

Although the cyclooxygenase pathway is quite important in the production of prostaglandins, equally important is the lipoxygenase pathway. This pathway is catalyzed by a family of enzymes called the lipoxygenase enzymes. These enzymes differ from the cyclooxygenase enzymes in its catalytic site for oxygen addition to the unsaturated fatty acid. One lipoxygenase is active at the double bond at carbon 5, while a second is active at carbon 11 and a third is active at carbon 15. The products of these reactions are monohydroperoxy-eicosatetraenoic acids (HPETEs) and are numbered according to the location of the double bond to which the oxygen is added. 5HPETE is the major lipoxygenase product in basophils, polymorphonuclear leukocytes, macrophages, mast cells, and any organ undergoing an inflammatory response. 12HPETE is the major product in platelets, pancreatic endocrine cells, vascular smooth muscle, and glomerular cells. 15HPETE predominates in reticulocytes, eosinophils, T-lymphocytes, and tracheal epithelial cells. The HPETEs are not in themselves active hormones; rather, they serve as precursors for the leukotrienes. The leukotrienes are the metabolic end products of the lipoxygenase reaction. These compounds contain at least three conjugated double bonds. The unstable 5HPETE is converted to either an analogous alcohol (hydroxy fatty acid) or is reduced by a peroxide or converted to leukotriene. The peroxidative reduction of 5'HPETE to the stable 5HETE (5 hydroxyeicosatetraenoic acid) is similar to that of 12HPETE to 12HETE and of 15HPETE to 15HETE. In each instance the carbon–carbon double bonds are unconjugated and the geometry of the double bonds is *trans* and *cis*, respectively. In contrast to the active thromboxanes, which have very short half-lives, the leukotrienes can persist as long as 4 h. These compounds comprise a group of substances known as the slow-acting anaphylaxis substances. They cause slowly evolving but protracted contractions of smooth muscles in the airways and gastrointestinal tract. Leukotriene C_4 is rapidly converted to LTD_4, which in turn is slowly converted to LTE_4. Enzymes in the plasma are responsible for these conversions.

The products of the lipoxygenase pathway are potent mediators of the response to allergens, tissue damage (inflammation), hormone secretion, cell movement, cell growth, and calcium flux. Within minutes of stimulation, lipoxygenase products are produced. In an allergy attack, for example, an allergen can instigate the release of leukotrienes, which are the immediate mediators of response. The leukotrienes are more potent than histamine in stimulating the contraction of the bronchial nonvascular smooth muscles. In addition, LTD_4 increases the permeability of the microvasculature. The mono-HETEs and LTB_4 stimulate the movement of eosinophils and neutrophils, making them the first line of defense in injury resulting in inflammation.

As mentioned, when dihomo-γ-linoleic acid or eicosapentaenoic acid serve as substrates for eicosanoid production, the products are either of the 1 series or 3 series. The products they form may be less active than those formed from arachidonic acid and this decrease in activity can be of therapeutic value. Hence, ingestion of n-3 fatty acids leads to the decreased production of prostaglandin E_2 and its metabolites, a decrease in the production of thromboxane A_2, a potent platelet aggregator and vasoconstrictor, and a decrease in leukotriene B_4, a potent inflammatory hormone and a powerful inducer of leukocyte hemotaxis and adherence. Counteracting these decreases are an increase in thromboxane A_3 (TXA_3), a weak platelet aggregator and vasoconstrictor, an increase in the production of PGI_3 without an increase in PGI_2, which stimulates vasodilation and inhibits platelet aggregation, and an increase in leukotriene B_5, which is a weak inducer of inflammation and a weak chemotoxic agent.

PROTEIN METABOLISM

The protein in the diet provides the essential and nonessential amino acids that are used to synthesize body proteins. Dietary amino acids fall into two categories: essential and nonessential (Table 7.7). There are species differences in the amino acids that are considered essential. An essential amino acid is one that the body cannot synthesize in sufficient quantities to meets the body's need for that amino acid. Sometimes the physiological state of the animal determines essentiality. Persons with renal disease, for example, have a greater need for arginine than healthy people. People who have been severely burned may need more essential amino acids than healthy people. Felines require taurine in their diets, while other animals do not. Good food proteins are those proteins that provide sufficient quantities of essential amino acids. Poor-quality proteins might have one or two of these essential amino acids in short supply. With careful blending of poor-quality proteins, a good array of amino acids is possible. These proteins must be consumed at or nearly at the same time in order to allow for optimal use.

Protein Denaturation

One of the most striking characteristics of proteins is the response to heat, alcohol, and other treatments that affect their quaternary, tertiary, and secondary structures. This characteristic response is called denaturation. Denaturation results in the unfolding of a protein molecule, thus breaking its hydrogen bonds and the associations between functional groups; as a result, the three-dimensional structure is lost. Denaturation affects many of the properties of the protein molecule. Its physical shape is changed, its solubility in water is decreased, and its reactivity with other proteins may be lost. When denatured, the protein loses its biological activity. Heating will denature most proteins. As low a temperature as 15°C can denature some proteins, while the

TABLE 7.7
Essential and Nonessential Amino Acids
for Adult Mammals

Essential	Nonessential
Valine	Hydroxyproline
Leucine	Cysteine
Isoleucine	Glycine
Threonine	Alanine
Phenylalanine	Serine
Methionine	Proline
Tryptophan	Glutamic Acid
Lysine	Aspartic Acid
Histidine	Glutamine
Arginine[a]	Asparagine
Taurine[b]	Hydroxylysine. Tyrosine

[a] Not essential for maintenance of most adult mammals.
[b] Felines require taurine, a metabolite of L-cysteine as a
component of their diets.
FIGURE 7.22 The formation of a peptide bond.

majority of food proteins are denatured at temperatures in excess of 60°C. Some proteins are very heat stable (those found in thermophillic bacteria for example), while others are quite labile. Heat denaturation, unless extreme, does not affect the amino acid composition of protein, and indeed, may make these amino acids more available to the body because heating provokes the unfolding or uncoiling of the protein and exposes more of the amino acid chain to the action of the proteolytic digestive enzymes. If only mild denaturation occurs, it can be reversed. This process is called renaturation. If a protein is renatured, it will resume its original shape and biological activity.

PROTEIN TURNOVER

Protein turnover consists of two processes: synthesis and degradation. In synthesis, amino acids are joined together to form peptides and proteins. Amino acids in the circulation enter a vast array of cell types, and each cell type has many uses for the amino acids brought to it by the circulation. As mentioned, small, medium, and large molecules can be made. The largest of these molecules are the proteins. Protein synthesis is dependent on the simultaneous presence of all the amino acids necessary for the protein being synthesized and on the provision of energy. If there is an insufficient supply of either, protein biosynthesis will not proceed at its normal pace. Chemically, the polymerization of amino acids into protein is a dehydration reaction between two amino acids that are joined together by a peptide bond.

The peptide bond is the most common amide bond and is formed when two amino acids and joined together as illustrated in Figure 7.22. Two amino acids joined together form a dipeptide, three form a tripeptide, and so on. Each amino acid in a chain is referred to as an amino acid residue. A chain of up to 100 amino acids joined together is called a polypeptide. If many amino acids are involved, then the compound is called a protein. Proteins have been identified that have as many as 300,000 amino acids residues and molecular weights in excess of 4×10^7.

The amino acid sequence of a given peptide or protein can vary, and its variation is controlled genetically. Proteins are complex molecules having characteristic primary, secondary, tertiary, and quaternary structures. The primary structure is determined genetically as the particular sequence of amino acids in a given protein. Protein conformation is usually divided into two categories: secondary and tertiary. The secondary and tertiary structures of a protein result from interactions between the reactive groups on the amino acids in the protein.

The process whereby proteins are synthesized provides the basis for understanding genetic differences. It is also the basis for understanding how the unique properties of each cell type are maintained as the properties that make cells unique are usually conferred by the proteins within them. Some of these proteins are the structural elements of the cell. Others are enzymes that catalyze specific reactions and processes that characterize the cell in question. Still other proteins confer a particular biochemical function on the cell. The amino acid sequence of a particular protein is genetically controlled. This control is exerted through the polynucleotide, deoxyribonucleic acid (DNA). DNA is found in both the nucleus and the mitochondria. The process of protein synthesis using DNA as the template is covered in Chapter 54.

The proteins synthesized by the body have a finite existence. They are subject to a variety of insults and modifications. Some of these modifications have already been described: a prohormone is converted to an active hormone, an enzyme is activated or inactivated with the addition or removal of a substituent, and so forth. Thus, a dynamic state within the body exists with respect to its full complement of peptides and proteins. Some proteins have very short lifetimes and very rapid turnover times; other proteins are quite stable and long lived. Their turnover time is quite long. The estimate of the life of a protein, that is, how long it will exist in the body, is its half-life. A half-life is that time interval that occurs when half of the amount of a compound synthesized at time X will have been degraded. Given the dynamic state of metabolism, some of these time estimates will be very short. Half-lives of biologically active compounds are very difficult to estimate.

Amino Acid Catabolism

Protein degradation results in amino acids that are usually recycled. There are some exceptions to this general rule; histidine in the muscle protein is methylated and excreted as 3-methyl histidine. This 3-methyl histidine cannot be reused and thus is an indication of muscle breakdown. Most of the products of protein degradation (the liberated amino acids) join the body amino acid pool from which the synthetic processes withdraw their needed supply. It is estimated that 75 to 80% of the liberated amino acids are reused.

Different proteins are degraded at different rates, and these rates are determined not only by the physiological status of the individual but also by the amino acid composition of the protein in question. High rates of degradation of the structural proteins mean that considerable structural rearrangement is occurring. Short-lived proteins such as enzymes or receptors have in common regions that are rich in proline, glutamate, serine, and threonine. These amino acids, when clustered, provide a target for rapid degradation.

The process of degradation first reduces the protein to peptides and then reduces these peptides to their constituent amino acids. Two major pathways are used for this process. Extracellular, membrane, and long-lived intracellular proteins are degraded in the lysosomes by an ATP-independent pathway. Short-lived proteins as well as abnormal proteins are degraded in the cytosol using ATP and ubiquitin. This pathway is illustrated in Figure 7.24. Proteins that are degraded via the ubiquitin-dependent pathway are derivatized by several molecules of ubiquitin. The ubiquitin is attached by nonpeptide bonds between the carboxy terminus of ubiquitin and the δ-amino groups of lysyl residues in the protein. This requires ATP.

Although the proteases of digestion are important to the degradation of dietary protein, they have no role in the intracellular protein degradation. Intracellular proteases hydrolyze internal peptides bonds. This is followed by the action of carboxy- and aminopeptidases, which remove single amino acids from the carboxy end or the amino end of the peptides.

Proteins in the extracellular environment are brought into the cell by endocytosis. This is a process similar to pinocytosis, where the cell membrane engulfs and encapsulates the extracellular material. Endocytosis occurs at indentations in the plasma membrane that are internally coated with a protein called clathrin. As in pinocytosis, the extracellular protein is surrounded by the plasma membrane to form an intracellular vesicle, which, in turn, fuses with a lysosome. Degradation then occurs via calcium-dependent proteases called calpains or cathepsin. Both the Golgi and the endoplasmic reticulum are involved in providing proteases that degrade peptide fragments that arise during the maturation of proteins in the secretory pathway.

The rate of degradation varies from protein to protein, and this rate is determined by the amino acid at the amino end of the protein amino acid chain. Proteins with short half-lives have regions rich in proline, glutamate, serine, and threonine. Proteins without these regions are degraded slowly, and therefore have slower turnover times and longer half-lives.

Those amino acids in the body's amino acid pool that are not used for peptide or protein synthesis and that are not used to synthesize metabolically important intermediates are deaminated, and the carbon skeletons are either oxidized or used for the synthesis of glucose or fatty acids. There are three general reactions for the removal of NH_3 from the amino acids: (1) transamination with the amino group transferred to another carbon chain via amino transaminases, (2) oxidative deamination to yield NH_3, or (3) deamination through the activity of an amino acid oxidase.
FIGURE 7.23 Degradation of valine, isoleucine and leucine

The amino acids can be loosely grouped in terms of their catabolism. Valine, leucine, and isoleucine, the branched-chain amino acids, are similar in that each has a methyl group on its carbon chain. They can be transaminated with α-ketoglutarate to form α-keto acids. These acids are considered homologs of pyruvate and are oxidized by a series of enzymes that are similar to those that catalyze the oxidation of α-ketoglutarate and pyruvate. The degradative steps are shown in Figure 7.23. Valine ultimately is converted to succinyl CoA, whereas isoleucine ends up as either acetyl CoA or propionyl CoA, and leucine catabolism results in HMG CoA. HMG CoA is split to acetyl CoA and acetoacetate. The HMG CoA produced in the catabolism of leucine is not used for cholesterol synthesis because it is produced in the mitochondria and does not travel to the cytosol, where cholesterol is synthesized. Instead, HMG CoA is further metabolized to acetoacetate and acetyl CoA.

Serine, threonine, and glycine are hydroxyamino acids. All three are gluconeogenic precursors. Serine can be deaminated to pyruvate, which then can be transaminated to alanine. Serine can also be demethylated to form glycine, releasing a methyl group useful in one-carbon metabolism. Threonine is degraded to acetyl CoA after deamination as shown in Figure 7.25. Glutamate may be converted to glutamine via the enzyme glutamine synthetase. This enzyme is a mitochondrial enzyme and serves to fix the ammonia released in this compartment. Rat renal tissue is particularly rich in this enzyme; however, human renal tissue is not. In birds and alligators this enzyme is a cytosolic enzyme rather than a mitochondrial enzyme. Although the brain has some urea cycle activity, it uses glutamine formation primarily to reduce its ammonia level. In order to do this, it must also synthesize glutamate from α-ketoglutarate. If it did not also convert pyruvate to oxalacetate, this synthesis of α-ketglutarate would deplete the brain of citric acid cycle intermediates. Fortunately, carboxylation of pyruvate is very active in brain tissue.

Glutamate is converted to and formed from ornithine and arginine. These two amino acids are essential components of the urea cycle (Figure 7.26). The urea cycle consists of the synthesis of carbamyl phosphate, citrulline, and then arginosuccinate,
FIGURE 7.24   Protein degradation
FIGURE 7.25   Serine, threonine, and glycine catabolism.
FIGURE 7.26 The urea cycle.

arginine, and finally urea. Ornithine and citrulline are shuttled back and forth as the cycle turns to get rid of the excess ammonia via urea release from arginine. The cycle functions to reduce the potentially toxic amounts of ammonia that arise when the ammonia group is removed from amino acids. Most of the ammonia released reflects the coupled action of the transaminases and L-glutamate dehydrogenase. The glutamate dehydrogenase is a bidirectional enzyme that plays a pivotal role in nitrogen metabolism. It is present in kidney, liver, and brain. It uses either NAD^+ or $NADP^+$ as a reducing equivalent receiver. It operates close to equilibrium using ATP, GTP, NADH, and ADP depending on the direction of the reaction. In catabolism, it channels NH_3 from glutamate to urea. In anabolism, it channels ammonia to α-ketoglutarate to form glutamate. In the brain, glutamate can be decarboxylated to form γ-aminobutyrate (GABA), an important neurotransmitter. The decarboxylation is catalyzed by the enzyme L-glutamate decarboxylase. Putrescine also can serve as a precursor of GABA either by deamination or via N-acetylated intermediates. The urea cycle is, energetically speaking, a very expensive process. The synthesis of urea requires 3 M of ATP for every mole of urea formed. The urea cycle is very elastic. That is, its enzymes are highly conserved, readily activated, and readily deactivated. Adaptation to a new level of activity is quickly achieved. While urea cycle activity can be high when protein rich diets are consumed and low when low protein diets are consumed, the cycle never shuts down completely. The cycle, shown in Figure 7.26, is fine-tuned by the first reaction, the synthesis of carbamoyl phosphate. This reaction, which occurs in the mitochondria, is catalyzed by the enzyme carbamoyl phosphate synthetase. The enzyme is inactive in the absence of its allosteric activator, N-acetylglutamate, a compound synthesized from acetyl CoA and glutamate in the liver. As arginine levels increase in the liver, N-acetylglutamate synthetase is activated, which results in an increase in N-acetylglutamate. The urea cycle is initiated in the hepatic mitochondria and finished in the cytosol. The urea is then liberated from arginine via arginase and released into the circulation, whereupon it is excreted from the kidneys in the urine. Ornithine, the other product of the arginase reaction, is recycled back to the mitochondrion only to be joined once again to carbamyl phosphate to make citrulline. Rising levels of arginine turn on mitochondrial N-acetylglutamate synthetase, which provides the N-acetylglutamate, which, in turn, activates carbamoyl phosphate synthetase, and the cycle goes on.

Arginine has many uses in metabolism. Not only is it an essential component of the urea cycle, it is precursor for nitric oxide (NO), the polyamines, proline, glutamate, and creatine. When citrulline is produced from arginine, NO is produced. This occurs not only in the liver but also in other vital organs and the vascular tree. NO production by endothelial cells is a vasodilator and thus plays a role in the regulation of smooth muscle tone. Many vasodilators such as the widely prescribed drug for angina pain, nitroglycerine, work by increasing the production of NO.

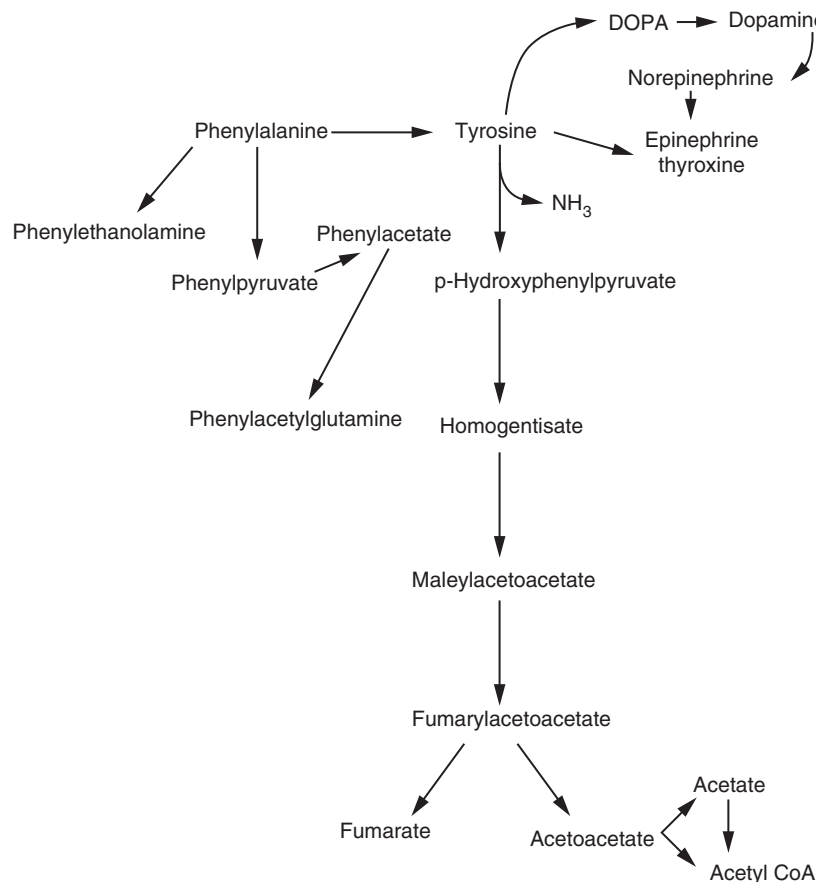
Phenylalanine is the precursor of tyrosine, and tyrosine can be used for the synthesis of thyroxine in the thyroid gland or for the synthesis of epinephrine, norepinephrine, or dopamine (see Figure 7.27). Phenylalanine is converted to tyrosine via


FIGURE 7.27   Phenylalanine and tyrosine catabolism.

the hepatic enzyme, phenylalanine hydroxylase. Tyrosine, if not used to make one of several hormones, is then deaminated and, through a series of reactions, ends up as fumarylacetate, which is split to provide acetoacetate and fumarate. Tryptophan catabolism shows no similarity to the catabolic pathways of any of the other amino acids (Figure 7.28). Tryptophan can be converted to niacin, one of the B vitamins. This conversion is not very efficient. There is considerable product feedback inhibition of this reaction sequence by niacin. The metabolism of tryptophan is dependent on adequate intakes of vitamin B_6, pyridoxine. In pyridoxine deficiency, hydroxyanthranilate formation via the enzyme kynureninase is impaired, resulting in a characteristic increase in urinary levels of xanthurenic acid. This is used as a test of vitamin B_6 sufficiency. If subjects are deficient and are given a load dose of tryptophan, these subjects will excrete abnormal amounts of xanthurenate in their urine. Tryptophan is the precursor of serotonin, an important neurotransmitter, that serves a variety of functions in the regulation of smooth muscle tone especially those smooth muscles of the vascular tree. Histidine, an amino acid especially important for muscle protein biosynthesis, is also of great importance in one-carbon metabolism. The principle pathway of histidine catabolism leads to glutamate formation and is shown in Figure 7.29 (as well as in other figures where glutamate and α-ketoglutarate act in transamination). Glutamate is an important component of the urea cycle (Figure 7.26). The decarboxylation of histidine yields histamine. This amine serves to stimulate gastric hydrochloric acid production and to stimulate vasoconstriction. A number of cold remedies and sinus remedies contain substances known as antihistamines, which interfere with the vasoconstrictor action of histamine. Histidine in muscle can be methylated and the end product 3-methyl histidine can be measured in the urine and used as a measure of muscle protein turnover.

Lysine is one of the two essential amino acids whose amino group does not contribute to the total body amino group pool; the other is threonine. Although lysine can donate its amino group to other carbon chains, the reverse does not occur. Lysine is catabolized to acetoacetyl CoA, which then enters the Krebs cycle as acetyl CoA.

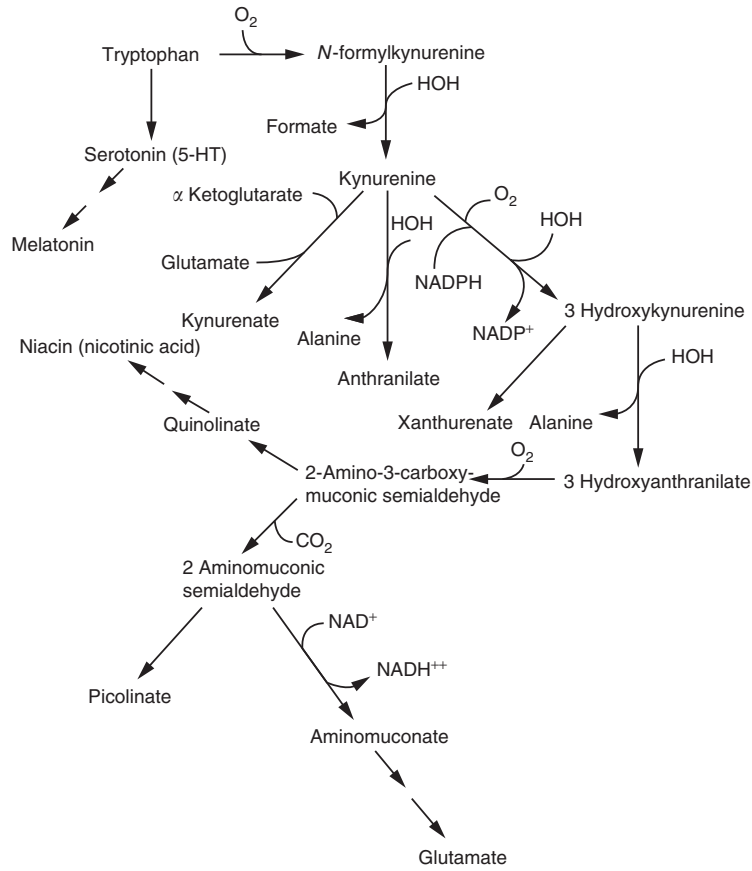
Methionine, cysteine, and cystine are important sulfur group donors. The importance of disulfide bridges in the structure of proteins has been described in the sections on protein structure and synthesis. Methionine is important for carnitine synthesis. The pathway for methionine and cysteine is shown in Figure 7.30. Propionate is also the result of methionine catabolism. Should there be a defect in propionyl CoA carboxylase, propionate will accumulate. This is not the usual situation; for, propionate is usually carboxylated to form succinyl CoA. Accumulations of methyl malonate are characteristic of vitamin B_{12} deficiency. Propionate can serve as the substrate for long-chain odd-numbered fatty acids that are incorporated into myelin, the


FIGURE 7.28 Tryptophan catabolism.
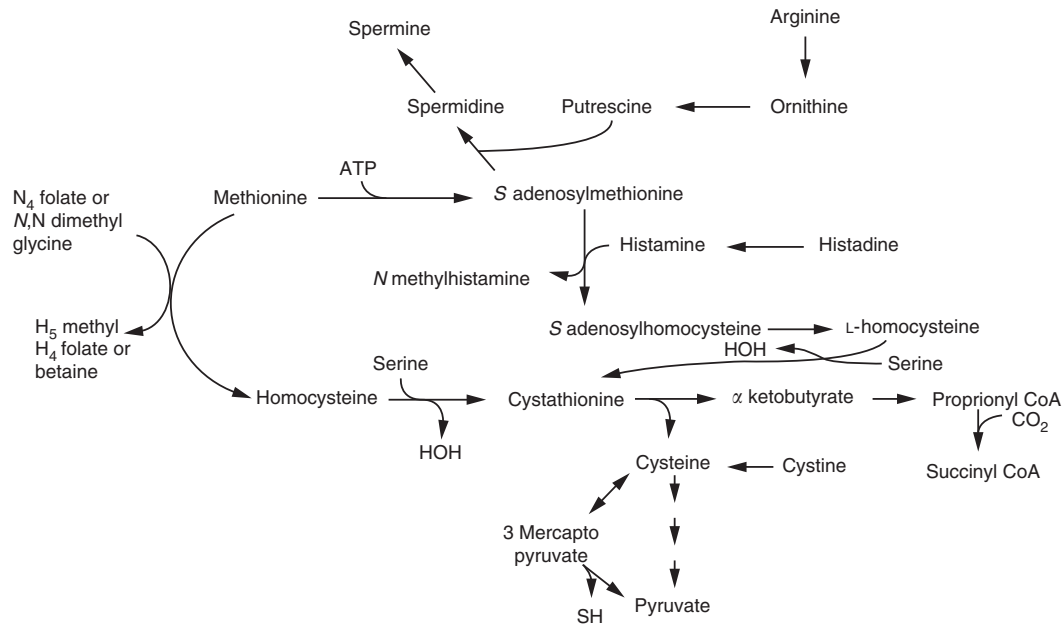
FIGURE 7.29 Histidine catabolism.


FIGURE 7.30   Methionine catabolism.

fatty covering of nerves. For some unknown reason, this myelin is abnormal in its function and fails to protect the peripheral nerve endings, which then die. This may explain the peripheral paresia that characterizes B_{12} deficiency.

AMINO ACID DERIVATIVES

Creatine phosphate is one of the amino acid derivatives that function in muscle contraction by providing energy for this process. Creatine is formed from glycine, arginine, and *S*-adenyl methionine in a reaction sequence. The creatine circulates in the blood and can be found in measurable quantities in brain and muscle. The creatine is phosphorylated to form creatine phosphate via the enzyme creatine phosphate. Creatine can be converted to creatinine by irreversible nonenzymatic dehydration. Upon hydrolysis, creatine phosphate will provide sufficient energy for muscle contraction. This hydrolysis yields creatine and inorganic phosphate. Some of the creatine can be rephosphorylated, while the remainder is converted to creatinine that then is excreted in the urine. Creatine phosphate has the same free energy of hydrolysis as ATP. Creatine phosphate is found primarily in the muscle and provides the quick burst of energy needed each time a muscle contracts. Because the muscle activity produces the end product, creatinine, measuring creatinine allows for the estimation of the muscle mass.

Choline is a highly methylated compound synthesized from serine. Choline is an essential component of the neurotransmitter acetylcholine as well as an essential ingredient of the phospholipid, phosphatidylcholine. Certain amino acids can be decarboxylated to form the polyamines. Some polyamines are very-short-lived compounds that are neurotransmitters. They are quickly broken down so as to limit their effects. The catecholamines fall into this category of polyamines. Other polyamines, putrescine and spermine, bind nucleic acids and other polyanions. They have a role in cell division.

ROLE OF VITAMINS AND MINERALS IN INTERMEDIARY METABOLISM

Vitamins (Table 7.8) and minerals (Table 7.9) are essential to life (see chapters 8–10). As described earlier, several of the vitamins as well as minerals are needed for the reaction sequences of intermediary metabolism. Niacin, thiamin, riboflavin, pyridoxine, and pantothenic acid (as part of the CoA molecule) all serve as coenzymes in these reactions. Ascorbic acid, vitamin E, and selenium function in the free radical suppression system. Magnesium, manganese, and other divalent ions serve as cofactors in a variety of reactions. Iron and copper function in the cytochromes and haemoglobin, both of which are essential to the use of oxygen. In the former, oxygen is used to make water by the respiratory chain, and in the latter, oxygen is transported to the cells for exchange for carbon dioxide. The synthesis of the purines and pyrmidines, components of DNA and RNA likewise demand that adequate micronutrients be present for this synthesis.

SYNTHESIS OF PURINES AND PYRIMIDINES

Before pyrimidines and purines can be incorporated into DNA and RNA, they must be synthesized. This synthesis requires a number of micronutrients as well as sufficient energy to support this synthesis. The purines are adenine and guanine, whereas

the pyrimidines are cytosine, uracil, and thymine. Uracil is used for RNA synthesis, whereas thymine is used mainly for DNA synthesis. The purines and pyrimidines form glycosidic bonds to ribose. The purine pathway is shown in Figure 7.31. Also shown in Figure 7.31 are the vitamins and minerals needed at each step in the pathway. Where ATP is involved in a reaction step, all of the vitamins that serve as coenzymes in intermediary metabolism are needed. This includes niacin, thiamin, riboflavin, lipoic acid, pantothenic acid, biotin, folacin, vitamin B_{12}, pyridoxine, choline, and inositol. Also needed are the minerals of importance to the redox reactions of oxidative phosphorylation (OXPHOS), that is, iron, copper, and, of course, the iodine-containing hormone thyroxine, which regulates OXPHOS and the selenium-containing enzyme (5′-deiodinase), which converts thyroxine to its active form, triiodothyronine.

MICRONUTRIENTS AS STABILIZERS

Although vitamins and minerals serve in gene expression as just described, certain of the micronutrients have a unique role in assuring that cells and tissues continue to function as intact structures and that these cells continue to produce themselves faithfully. This role is that of protection from insult by peroxides. Peroxides are a normal product of metabolism. They are useful agents in the defense against pathogens. However, peroxides are very reactive substances. They can damage the membranes that are the physical barriers to the cells and the organelles within the cell. They can react with DNA. The DNA, enclosed within the nucleus, can repair itself. Occasionally this is a missense repair, and very occasionally this results in a mutation that is random. That is, the damage and subsequent missense repair can occur anywhere in the nuclear DNA and the resultant gene product could be one of more than a million products encoded by the nuclear genome. Peroxide or free radical damage to the nuclear genome is nowhere as serious on an individual genomic basis as damage to the mitochondrial genome. This genome encodes only 13 products, but these products are important components of the mitochondrial respiratory chain and ATP synthesis. The mitochondrial DNA does not have the repair capacity of the nuclear genome. In fact, its repair capacity is quite limited. When added to the fact that the mitochondria consume about 90% of all the oxygen consumed by the cell, the potential for free radical damage is quite large. Fortunately each cell has many hundred mitochondria, and so the loss of a few has little impact on the overall health and well-being of the cell or organ or whole animal. Nonetheless, should wholesale destruction of the genome occur, the results could be quite devastating.

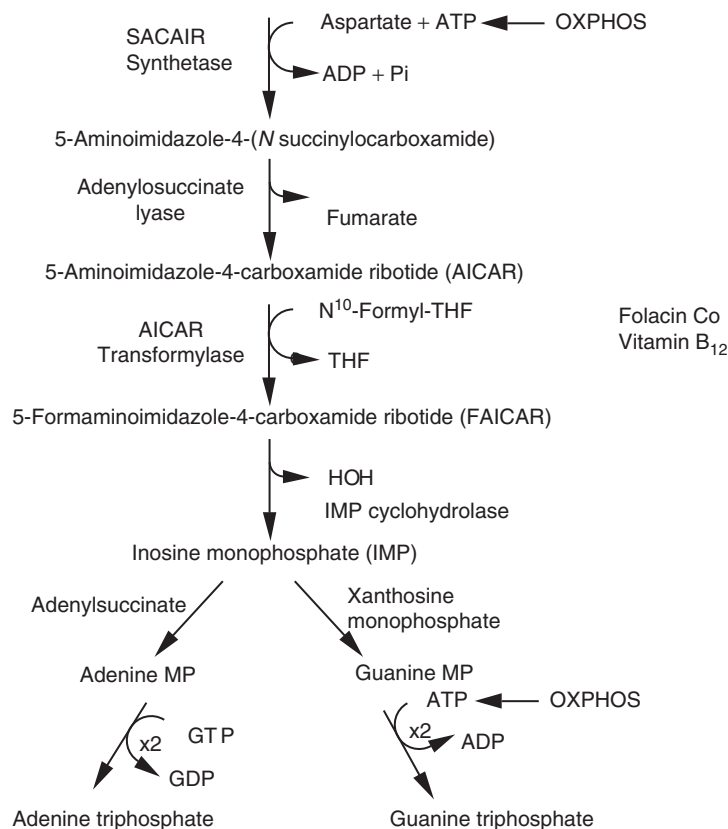
Fortunately, there is a very active antioxidant system in place that protects against such damage. Some of the vitamins and minerals play an important role in this system. Vitamin E quenches free radicals as they form via the conversion of tocopherol


FIGURE 7.31 Roles of the micronutrients in the synthesis of purines.

TABLE 7.8
Summary of Vitamin Function

Vitamin	Functions
Fat-soluble vitamins	
Vitamin A	As retinaldehyde, is essential in the visual cycle
	Essential for body growth
	As retinoic acid, plays an important role in the expression of genes that encode a wide variety of body proteins that play roles in metabolism, growth, and development
	Downregulates uncontrolled cell growth
Vitamin D	Increases calcium and phosphorus absorption from the small intestine, thus promoting the growth and mineralization of bones
	Increases resorption of phosphates from the kidney tubules
	Maintains normal level of citrate in the blood
	Protects against the loss of amino acids through the kidneys
	Serves in gene regulation
Vitamin E	Serves as an antioxidant that protects body cells from free radicals damage
	Has a role in cellular respiration
Vitamin K	Essential for the posttranslational carboxylation of glutamic acid residues in osteocalcin and in four blood-clotting proteins: Factor II, prothrombin; Factor VII, proconvertin; Factor IX, Christmas factor; and Factor X, Stuart-Power. The carboxylation of glutamic acid residues increases calcium-binding activity of these proteins
Water-soluble vitamins	
Biotin	Functions as a coenzyme mainly in decarboxylation-carboxylation and in deamination reactions
Folacin/Folate (Folic Acid)	Serves as a coenzyme in synthesis of purines, pyrmidines, hemoglobin, and in the metabolism of several amino acids and vitamins: Serine to glycine, tyrosine from phenylalanine, glutamic acid from histadine, choline from ethanolamine, *N*-metylniccotinamide from nicotinamide
Niacin (Nicotinic acid or nicotinamide)	Serves as a coenzyme (NAD and NADP) in intermediary metabolism. These coenzymes function as reducing equivalent (H^+) acceptors or donors
Pantothenic acid	Functions as part of two enzymes — coenzyme A (CoA) and acyl carrier protein (ACP). Both of these are important in intermediary metabolism
Riboflavin	Serves as coenzymes FAD and FMN. These coenzymes accept or donate reducing equivalents.
Thiamin	As a coenzyme in transketolase reactions also has a role in the maintenance of normal appetite, muscle tone, and normal mental function
Vitamin B_6	Serves as a coenzyme (pyridoxal phosphate) in transamination
Pyridoxine; al; amine	Decarboxylation, and *trans*-sulfuration reactions; also is a coenzyme in the conversion of tryptophane to niacin, the absorption of amino acids, glycogenolysis and the elongation of linoleic acid to arachidonic acid
Vitamin B_{12} (cobalamins)	Synthesis or transfer of single carbon units, in the biosynthesis of methyl groups (–CH3), and in reduction reactions such as the conversion of disulfide (S–S) to the sulfhydryl group (–SH)
Vitamin C (ascorbic acid)	Functions in redox systems and aids in the regulation of redox states. This function is due to its interconversion between a reduced an oxidized state; plays a role in collagen synthesis (hydroxylation of proline to hydroxyproline)

See Chapter 9 and Chapter 10 for more information on vitamins and vitamin deficiencies.

to the tocopheroxyl radical, which is then converted to its quinone. Vitamin K, although not truly an antioxidant, does serve as an H^+/e^- donor/acceptor in its role to facilitate the carboxylation of the peptide glutamyl residues of certain proteins to their epoxide form. Vitamin C and vitamin A are both good H^+/e^- donor/acceptors in the suppression of free radical formation. Of course, indirectly, all those vitamins that serve as coenzymes are involved as well. Shown in Table 7.5 is the free radical suppression system. Note that selenium is complimentary to the role of vitamin E in the suppression of free radicals. Some of the antioxidant role for vitamin E could be met if there is a sufficient intake of selenium. This mineral is important to the gluta-thione peroxidase enzyme is an important component of the free radical suppression system. Selenium plays a role in both the synthesis of this enzyme and as a required cofactor. As discussed in Chapter 9, several of minerals and vitamins have roles in gene expression, and these roles have overall importance in the physiological function of the body.

TABLE 7.9
Essential Minerals and Their Functions

Mineral	Function
Macrominerals	
Sodium (Na^+)	Participates in the regulation of osmotic pressure
	Functions in nerve conduction (depolarization/repolarization)
	Participates in active transport mechanisms as part of the plasma membrane Na^+K^+ ATPase
	Is part of the mineral apatite of bones and teeth
Calcium (Ca^{++})	Is an important part of the mineral apatite of bones and teeth
	Is an important cell signal with respect to metabolic regulation and the transport of metabolites (and some hormones) from one compartment to another or from one cell to the bloodstream
	Is a key mineral in cell death and in muscle contraction
Potassium (K^+)	Participates in the regulation of osmotic pressure
	Participates in active transport mechanisms as part of the Na^+K^+ATPase
	Has a role in muscle contraction
Chloride (Cl^+)	Participates in the regulation of osmotic pressure
	Is a part of gastric acid (HCl)
	Is a good oxidizing agent
	Participates in the exchange of oxygen for carbon dioxide
	Important to B_{12} absorption
Phosphorus	As a component of high-energy compounds (ATP, ADP, AMP, UTP [P as PO_4^{3-}], etc.) and phosphorylated metabolites
	Is a component of bones and teeth
	Serves as a component of nucleic acids (RNA and DNA)
Magnesium (Mg^{++})	Constituent of bones and teeth
	Essential element of cellular metabolism, often as an activator of enzymes involved in phosphorylated compounds and of high-energy phosphate transfer of ADP and ATP
	Involved in activating certain peptidases in protein digestion
	Relaxes nerve impulse, functioning antagonistically to calcium, which is stimulatory
Trace Minerals	
Cobalt (Co^{+++})	Serves as an integral part of Vitamin B_{12}
Copper (Cu^{++})	Facilitates the absorption and use of iron
	Essential for the formation of hemoglobin, although it is not a part of hemoglobin as such
	Cofactor for several enzymes
	Important for the development and maintenance of the vascular and skeletal structures (blood vessels, tendons, and bones)
	Structure and function of the central nervous system
	Required for normal pigmentation of hair
	Component of important copper-containing proteins
Fluorine (F^-)	Constitutes 0.02 to 0.05% of the bones and teeth
	Necessary for sound bones and teeth
	Assists in the prevention of dental caries
Iodine (I^-)	Serves as an important component of the thyroid hormones
Iron (Fe^{++} and Fe^{+++})	Iron (heme) combines with protein (globin) to make hemoglobin and the iron–sulfur components of the respiratory chain
Manganese (Mn^{++})	Formation of bone and the growth of other connective tissues
	Serves as a cofactor for SOD
Molybdenum (Mo)	Cofactor for iron and flavin-containing enzymes
Selenium ($Se^{2+,4+,6+}$)	Component of the enzyme glutathione peroxidase
Zinc (Zn^{++})	Component of the zinc fingers of transcription agents
	Serves as a cofactor for more than 70 enzymes

See Chapter 8 for more information on the trace minerals and Chapter 64 for more information on the mineralization of bones.

SUMMARY

From the forgoing brief review of intermediary metabolism, it can be seen that nutrients in the diet function collectively and individually to maintain the health and well-being of the consumer. Subsequent chapters in this book will provide further information on particular aspects of the roles nutrition plays in a variety of situations from conception to death.

8 Trace Mineral Deficiencies

Forrest H. Nielsen

CONTENTS

INTRODUCTION

By 1940, the concept of essential nutrients was well established; they were defined as chemical substances found in food, which could not be synthesized by the body to perform functions necessary for life. In the 1960s and 1970s, the standard for essentiality was liberalized for mineral elements that could not be fed at dietary concentrations low enough to cause death or interrupt the life cycle (interfere with growth, development, or maturation such that procreation is prevented). Thus, an essential element, during this time period, was generally defined as one whose dietary deficiency consistently and adversely changed a biological function from optimal, and this change was preventable or reversible by physiological amounts of the element. This definition of essentiality became less acceptable when numerous elements were suggested to be essential, based on small changes in physiological or biochemical variables. Many of these changes were questioned as to whether they were necessarily the result of suboptimal function, and sometimes were suggested to be the consequence of a pharmacologic or toxic action in the body, including an effect on intestinal microorganisms. As a result, if the lack of an element can not be shown to cause death or to interrupt the life cycle, the element is now not generally considered essential, unless it has a defined biochemical function. However, some elements (e.g., chromium) whose essentiality is based on older criteria are still often designated as essential in current literature. Other elements that have defined biochemical functions in lower species (e.g., nickel), or have been found to interrupt the life cycle in only a limited number of vertebrates (e.g., boron) and, only occasionally, are designated as essential. Thus, there is no universally accepted list of essential trace elements. Some elements (e.g., silicon, vanadium, etc.) have

beneficial actions when supplemented in supranutritional amounts; these actions may be an indication of an essential function. Thus, because some mineral elements, other than those firmly established as essential, may be of nutritional importance; these possibly essential or beneficial elements are also discussed in this section.

BIOLOGICAL ROLES OF MINERAL ELEMENTS

Trace elements have at least five roles in living organisms. In close association with enzymes, some trace elements are integral parts of catalytic centers at which the reactions necessary for life occur. Working in concert with a protein, and frequently with other organic coenzymes, trace elements are involved in attracting substrate molecules and converting them into specific end products. Some trace elements donate or accept electrons in reactions of reduction or oxidation. In addition to the generation and utilization of metabolic energy, redox reactions frequently involve the chemical transformation of molecules. One trace element, iron, is involved in binding, transporting and releasing oxygen in the body. Some trace elements have structural roles; that is, imparting stability and three-dimensional structure to important biological molecules. Some trace elements have regulatory roles. They control important biological processes through actions such as making hormones active, facilitating the binding of molecules to receptor sites on cell membranes, altering the structure or ionic nature of membranes to prevent or allow specific molecules to enter a cell, and inducing gene expression.

HOMEOSTATIC REGULATION OF MINERAL ELEMENTS

Homeostasis is the term used to describe the ability of the body to maintain the content of a specific substance within a certain range despite varying intakes. Homeostasis involves the processes of absorption, storage, and excretion. The relative importance of these three processes varies among the trace elements. The amount absorbed from the gastrointestinal tract often is a primary controlling factor for trace elements needed in the cationic state such as copper, iron, and zinc. Trace elements absorbed as negatively charged anions such as boron and selenium are usually absorbed quite freely and completely from the gastrointestinal tract. Excretion through the urine, bile, sweat, and breath is, therefore, the primary mechanism for controlling the amount of these trace elements in an organism. By being stored in inactive sites, some trace elements are prevented from causing adverse reactions when present in high quantities. An example of this homeostatic process is the storage of iron as ferritin. Release of a trace element from a storage site also can be important in preventing deficiency.

FACTORS AFFECTING THE MANIFESTATION OF DEFICIENCY SIGNS

Although trace elements play key roles in a variety of processes necessary for life, except for iodine and iron, the occurrence of overt, simple, or uncomplicated deficiency of any trace element in humans is not a common occurrence. The reasons for this are the powerful homeostatic mechanisms for trace elements described above, and the consumption of diets with different types of foods from different sources. However, reductions in health and well-being due to suboptimal status in some trace elements probably are not uncommon, because of other factors affecting their metabolism or utilization. For example, inborn errors of metabolism and diseases that affect absorption, retention, or excretion of a trace element can result in deficiency, even though dietary intake may meet dietary guidelines. Thus, many trace elements become nutritional concerns when their metabolism or utilization is impaired or their need is increased by nutritional, metabolic, hormonal, or physiological stressors. For example, it is difficult to produce signs of simple selenium deficiency in animals or humans. A stressor such as vitamin E deficiency or viral infection is needed to obtain marked pathology such as that seen with Keshan disease, a cardiomyopathy that primarily affects children and women of child-bearing age in some areas of China.

TREATMENT OF MINERAL DEFICIENCIES

Regardless of whether they are essential or not, all mineral elements are toxic when ingested in high amounts. Thus, for most essential and possibly essential trace minerals, the Food and Nutrition Board of the Institute of Medicine[1–3] has set tolerable upper intake levels, which are defined as the maximum level of daily intake likely to pose no risk of adverse effects. The preferred way to treat or prevent trace mineral deficiencies is by consuming a variety of nutrient-dense foods. A diet based on the USDA Food Pyramid[4] is an example of one that is likely to provide trace minerals in adequate amounts. If it is decided that a mineral supplement is needed to overcome a deficiency or for "insurance" to prevent deficiency, consuming those that supply the Recommended Dietary Intake (RDA) or Adequate Intake (AI) of the mineral[1] should be adequate and result in intakes that do not exceed the upper intake level (UL). Higher amounts, however, may be indicated if a deficiency is caused by a factor causing malabsorption or excessive excretion of a mineral. These amounts should be adjusted to intakes that will maintain normal status after indicators of deficiency have abated.

MINERAL ELEMENTS ESSENTIAL FOR HUMANS

ESSENTIAL TRACE ELEMENTS

Trace elements essential for life are ones that generally occur in the body in micrograms per gram of tissue and are usually required by humans in milligrams per day amounts; these elements are copper, iron, manganese, and zinc. The evidence for essentiality for humans is substantial and not controversial for these elements. Specific biochemical functions have been found for each of these minerals. Because magnesium has many characteristics of a trace element, it also will be included in this group of elements. Another element that will be included is boron, because it is required to complete the life cycle of zebrafish[5] and frogs,[6] which suggests that it is essential for higher animals and humans.

Boron

Although it has not been definitively established that boron deficiency interrupts the life cycle of mammals, or has an essential biochemical function in humans, substantial evidence exists for boron being a bioactive food component that is beneficial, if not required, for optimal bone, neurological and immune function in higher animals and humans. Boron deprivation apparently has numerous physiological effects, because it influences the concentration and activity of numerous biochemical substances in tissues and fluids (see Table 8.1). These numerous responses to boron deprivation occur, because boron apparently acts at

TABLE 8.1
Biochemical, Clinical and Nutritional Aspects of Boron

Biological Function

Established	None
Hypothesized	• A metabolic regulator affecting cell membrane function that influences the responses to hormone action, transmembrane signaling, or transmembrane movement of regulatory cations or anions
	• A metabolic regulator, through complexing with a variety of substrate or reactant compounds which contain hydroxyl and amine groups in favorable positions. Regulation is mainly through an inhibitory effect on enzymes

Signs of Deficiency

Biochemical	Because boron apparently has a regulatory role, low dietary boron induces a variety, most likely indirect, of biochemical changes in humans. These include:
	• *Calcium metabolism*: decreased serum 25-hydroxycholecalciferol; increased serum calcitonin
	• *Energy metabolism*: increased serum glucose; decreased serum triglycerides
	• *Nitrogen metabolism*: increased blood urea; increased serum creatinine; decreased urinary hydroxyproline excretion
	• *Reactive oxygen metabolism*: decreased erythrocyte superoxide dismutase; decreased ceruloplasmin
	• *Response to estrogen*: decreased serum 17B-estradiol; decreased plasma copper
Physiological	Because boron can cause a variety of biochemical responses, it is not surprising that boron deprivation also has a variety of physiological effects. These include:
	• Altered electroencephalograms that suggest impaired behavior activation (e.g., more drowsiness) and decreased mental alertness
	• Impaired psychomotor skills
	• Impaired cognitive processes (e.g., attention and memory)
	• Increased platelet and erythrocyte numbers; decreased white blood cells
	A number of physiological signs of deficiency have been found in animals that may have some counterparts in humans. Reported signs include:
	• Impaired bone development and decreased bone strength
	• Impaired inflammatory and immune responses

Pathological Consequences of Deficiency

Established	None
Suggested	• Increased susceptibility to osteoporosis and arthritis
	• Impaired cognitive and psychomotor function
Predisposing Factors for Deficiency	• Stressors that affect hormone action or signal transduction at the cell membrane level including vitamin D deficiency and magnesium deficiency
	• Dietary changes that can increase oxidative stress at the cell membrane level such as high intakes of polyunsaturated fatty acids (e.g., omega-6 fatty acid-rich safflower oil)

Recommended Intakes

Prevention of deficiency	1.0 mg/day has been suggested[14]
Therapeutic or beneficial	Luxuriant intakes (e.g., ≥3 mg/day) *may* be beneficial when stressors are present that lead to osteoporotic or arthritic changes
Food Sources	Food and drink of plant origin, especially noncitrus fruits, leafy vegetables, nuts, pulses, wine, cider

the membrane level to affect the response to hormones, transmembrane signaling, and the movement of regulatory cations and anions. Thus, the numerous reported signs of boron deprivation, shown in Table 8.1, may be mostly secondary responses to an unidentified primary deficient or changed biochemical function at the cell membrane level. Indicators of boron status are still being established. However, plasma boron concentrations lower than 25 ng/ml may be indicative of a low boron status. Most of the information in Table 8.1 can be found in reviews by Nielsen,[7–10] Hunt,[11,12] and Penland.[13]

Copper

Although copper is well established as an essential trace element, its practical nutritional importance for healthy humans, and thus its dietary requirement, still is debated. Well-established consequences of copper deprivation in humans have come mainly from findings from special populations receiving nutrition from limited sources (e.g., parenteral nutrition solutions, milk, or formulas with no supplemental copper), consuming drugs (e.g., penicillamine) or undergoing dialysis resulting in excessive loss of copper, or having a genetic disorder (e.g., Menkes' disease) that results in defective copper metabolism. Other consequences of inadequate copper intakes for humans have been projected or hypothesized from epidemiological, animal, and short-term human copper deprivation studies. Most of the information found in Table 8.2 has been obtained from reviews by Harris,[15] Klevay and Medeiros,[16] Milne,[17] Cordano,[18] Uauy et al.,[19] and Failla et al.[20]

TABLE 8.2
Biochemical, Clinical and Nutritional Aspects of Copper

Biological Function	Copper is a cofactor for several oxidoreductase enzymes that are involved in the generation of oxidative energy, oxidation of ferrous iron, synthesis of neurotransmitters, bestowment of pigment to hair and skin, provision of strength to bones and arteries, assurance of competence of the immune system, and stabilization of the matrices of connective tissues. These enzymes include: amine oxidase, lysyl oxidase, ferroxidase (ceruloplasmin), dopamine B-monooxygenase, tyrosinase, alpha-amidating monooxygenase, cytochrome c oxidase, and superoxide dismutase. Thus, copper is essential for several fundamental processes, including angiogenesis, neuropeptide and neurohormone signaling, iron metabolism, oxygen transport, energy production and the regulation of genetic expression
Signs of Deficiency	
Biochemical	• Decreased plasma copper
	• Short-term human copper depletion studies have inconsistently resulted in several biochemical changes, including decreased erythrocyte superoxide dismutase
	• Decreased enzymatic and immunoreactive ceruloplasmin and ratio
	• Decreased platelet and mononuclear white cell cytochrome c oxidase
	• Increased plasma cholesterol; and decreased interleukin-2
Physiological	Copper deficiency in premature and malnourished infants and infants with Menkes' disease has established numerous physiological deficiency signs including:
	• hematologic changes characterized by hypochromic, normocytic, or macrocytic anemia accompanied by reduced reticulocyte count, neutropenia and thrombocytopenia
	• bone abnormalities that mimic scurvy, for example, osteoporosis, fractures of the long bones and ribs, epiphyseal separation, fraying and cupping of the metaphyses with spur formation, and subperiosteal new bone formation
	• hypopigmentation of hair
	• impaired growth
	• impaired immunity
	• impaired neurological function
Pathological Consequences of Deficiency	
Established	• *Premature and malnourished infants*: anemia, osteoporosis, bone fractures, poor growth, and increased incidence of infections
	• *Menkes' disease*: "Kinky-type" steely hair, progressive neurological disorder, death
Suggested	• *Fetus and children*: impaired brain development[21]
	• *Adults*: Osteoporosis,[22] ischemic heart disease,[23–25] increased susceptibility to infections,[26] and accelerated aging[27]
Predisposing Factors for Deficiency	
Impaired absorption	High intakes of zinc, celiac disease, short bowel syndrome, cystic fibrosis, diarrhea, and jejunoileal bypass surgery
Excessive loss	Peritoneal dialysis, burn trauma, penicilliamine therapy, dexamethasone treatment, and excessive use of antacids
Increased oxidative stress	High iron intake or iron overload and marginal zinc deprivation

TABLE 8.2
(Continued)

Recommended Intakes	
Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[3] (mg/day) are: infants age 0–0.5 year, (0.20) and age 0.5–1 year, (0.22); children age 1–3 years, 0.34 and age 4–8 years, 0.44; adolescents age 9–13 years, 0.70 and age 14–18 years, 0.89; adults, 0.90; pregnancy, 1.0; lactation, 1.3
Therapeutic or beneficial	Increased intakes of copper (e.g., 3 mg/day for adults) *may* be beneficial for preventing osteoporosis, overcoming the adverse effects of high zinc intake, and more quickly overcoming the consequences of copper deficiency
Food Sources	Legumes, whole grains, nuts, organ meats (e.g., liver), seafood (e.g., oysters, crab), peanut butter, chocolate, mushrooms, and ready-to-eat cereals

TABLE 8.3
Biochemical, Clinical and Nutritional Aspects of Iron

Biological Function	Iron is involved in oxygen transport and storage, electron transport, and in numerous enzymatic reactions involving substrate oxidation and reduction. The classes of enzymes dependent on iron for activity include the oxidoreductases (e.g., xanthine oxidase/dehydrogenase), monooxygenases (e.g., cytochrome P450), dioxygenases (e.g., amino acid or amine dioxygenases), lipoxygenases, peroxidases, fatty acid desaturases, nitric oxide synthases, and miscellaneous enzymes such as aconitase
Signs and Symptoms of Deficiency	
Biochemical	Decreased tissue and blood iron enzymes, myoglobin, hemoglobin, ferritin, transferrin saturation, and iron, and increased erythrocyte protoporphyrin
Physiological	Anemia, glossitis, angular stomatitis, spoon nails (koiloncychia), blue sclera, lethargy, apathy, listlessness, and fatigue
Pathological Consequences of Deficiency	
Established	Impaired thermoregulation, immune function, mental function and physical performance; complications in pregnancy including increased risk of premature delivery, low birth weight, and infant morbidity
Suggested	Osteoporosis,[30–32] and impaired brain development[33]
Predisposing Factors for Deficiency	Blood loss (e.g., menstruation) and vegetarian diets
Recommended Intakes	
Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[3] for iron (mg/day) are: infants age 0–0.5 year, (0.27) and age 0.5–1 year, 11; children age 1–3 years, 7, and age 4–8 years, 10; adolescents age 9–13 years, 8, males age 14–18 years, 11, and females age 14–18 years, 15; males age ≥19 years, 8; females age 19–50 years, 18, age >50 years, 8, pregnant, 27, lactating age ≤18 years, 10, and age >19 years, 9
Therapeutic or beneficial	Higher doses than the above can be given to more quickly overcome iron deficiency, usually caused by blood loss; doses used include 50 to 60 mg/day or 120 mg/week.[34,35] However, caution is in order because high intakes of iron have been associated with cardiovascular disease and cancer[3,36]
Food Sources	Red meat, organ meats (e.g., liver), seafood (e.g., oysters, shrimp), fortified cereals, potatoes with skin, tofu; some whole grains and vegetables (e.g., spinach) are high in iron but the bioavailability of this iron may be low

Iron

Among the mineral nutrients, iron has the longest and best-documented history. Despite long and effective intervention activities, iron deficiency is the most prevalent mineral deficiency in the United States and the world. Recently, it has been suggested that high intakes of iron also may be a health concern. Table 8.3 only briefly outlines some of the important aspects of iron nutrition which has been obtained from reviews by Beard and Dawson[28] and Baynes and Stipanuk.[29]

Magnesium

Magnesium is the fourth most abundant cation in the human body, and is second only to potassium in intracellular concentration. This concentration reflects that magnesium is critical for a great number of cellular functions including oxidative phosphorylation, glycolysis, DNA transcription, fatty acid degradation, and protein synthesis. Although it is such a critically important element, surprisingly, reported signs and symptoms of magnesium deficiency in humans through dietary restriction alone are very limited. Described cases of clinical magnesium deficiency have generally been conditioned deficiencies where

factors interfering with absorption or promoting excretion were present (see Table 8.4). However, short-term human magnesium depletion experiments suggest that low magnesium intakes similar to those consumed by a significant number of people may induce heart arrhythmias and soft tissue calcium retention that may exacerbate disorders induced by oxidative stress.[37–39] Table 8.4 briefly outlines some of the important aspects of magnesium deficiency, most of which were obtained from reviews by Rude[40] and Shils.[41]

Manganese

The essentiality of manganese for animals has been known for over 50 years. Deficiency causes testicular degeneration (rats), slipped tendons (chicks), osteodystrophy, severe glucose intolerance (guinea pigs), ataxia (mice, mink), depigmentation of hair, and seizures. However, descriptions of signs of manganese deficiency in humans are very limited. The most convincing case of manganese deficiency is that of a child with a postoperative short bowel on long-term parenteral nutrition with low manganese content. The child developed short stature and diffuse bone demineralization resulting in brittle bones.[56] Because manganese deficiency has been so difficult to identify in humans, it is generally not considered to be of great nutritional concern. Most of the information in Table 8.5 has been obtained from reviews by Leach and Harris,[57] Nielsen,[58] and Freeland-Graves and Llanes.[59]

Zinc

Signs of zinc deficiency in humans were first described in the 1960s. However, the prevalence of zinc deficiency is still unknown because of the lack of satisfactory indicators of zinc status. Zinc supplementation studies indicate that a mild zinc deficiency

---

TABLE 8.4
Biochemical, Clinical and Nutritional Aspects of Magnesium

Biological Function	Magnesium is a cofactor for more than 300 enzymes in the body. This cofactor role is either as a direct allosteric activator of enzymes or as a part of enzyme substrates for some enzyme reactions (e.g., MgATP and MgGTP). Magnesium also has functions that affect membrane properties and thus influences potassium and calcium channels and nerve conduction
Signs and Symptoms of Deficiency	
Biochemical	• Low blood potassium, calcium and magnesium
	• Decreased intracellular potassium
	• Excessive renal potassium excretion
	• Impaired parathyroid hormone secretion and vitamin D metabolism
	• Renal and skeletal resistance to parathyroid hormone
Physiological	• Neuromuscular signs (e.g., positive Trousseau's signs, tremors, fasiculations, gross muscle spasms, muscle cramps and weakness, seizures, dizziness, disequilibrium)
	• Electrocardiographic abnormalities
	• Cardiac arrhythmias (e.g., rapid heart rate, ventricular premature discharges, atrial and ventricular fibrillation)
Pathological Consequences of Deficiency	
Established	Conditioned deficiencies result in cardiac arrhythmias, seizures, cramps, depression, and psychosis
Suggested	Based on numerous epidemiological studies and magnesium supplementation trials, low magnesium status is associated with numerous disorders including coronary heart disease,[42,43] hypertension,[44–46] diabetes,[46,47] various types of headaches,[48–50] pain sensitivity,[51] some cancers,[52] nephrolithiasis,[53] and osteoporosis[54]
Predisposing Factors for Deficiency	Factors interfering with absorption and utilization or promoting excretion including alcoholism, kidney failure, malabsorption syndromes, extensive bowel resection, gastroileal bypass, severe or prolonged diarrhea, protein-calorie malnutrition, acute pancreatitis, hyperaldosteronism, diabetes mellitus, thyroid gland disease, parathyroid gland disease, vitamin D resistance or deficiency, burns, and diuretic therapy
Recommended Intakes	
Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[1] for magnesium (mg/day) are: infants age 0–0.5 year, (30) and age 0.5–1 year, 75; children age 1–3 years, 80, age 4–8 years, 130 and age 9–13 years, 240; males age 14–18 years, 410, age 19–30 years, 400, and age 31+ years, 420; females age 14–18 years, 360, age 19–30 years, 310, age 31+ years, 320, pregnant, +40
Therapeutic or beneficial	Infusion of magnesium has been indicated as a means to quickly overcome a magnesium deficiency. An effective treatment[55] has been found to be intravenous administration of 24 mmol of magnesium as a 50% solution over 24 h for 3 to 7 days. Patients who are hypomagnesemic and have seizures or an acute dysrhythmia may be given 4 to 8 mmol of magnesium over 5 to 10 min followed by the same regimen
Food Sources	Whole grains, nuts, legumes, green leafy vegetables

TABLE 8.5
Biochemical, Clinical and Nutritional Aspects of Manganese

Biological Function	Manganese is a cofactor for enzymes involved in protein and energy metabolism, antioxidant action, and mucopolysaccharide synthesis. These enzymes include the metalloenzymes manganese-dependent superoxide dismutase, pyruvate carboxylase and arginase, and the manganese-activated enzymes phosphoenolpyruvate carboxykinase, glycosyl transferases, glutamine synthetase and farnesyl pyrophosphate synthetase. Manganese also can activate numerous other enzymes including oxidorectases, lyases, ligases, hydrolases, kinases, decarboxylases, and transferases; these enzymes are activated by other metals, especially magnesium
Signs of Deficiency	
Biochemical	None firmly established
Physiological	Impaired growth and brittle bones (found in one child); another possible sign is a fleeting dermatitis
Pathological Consequences of Deficiency	
Established	Osteoporosis (one case report in a child)[56]
Suggested	Low dietary manganese or low blood and tissue manganese has been associated with osteoporosis, diabetes, epilepsy, atherosclerosis, cataracts, and impaired wound healing[60]
Predisposing Factors for Deficiency	High dietary intakes of calcium, phosphorus, iron, fiber, phytate, and polyphenolic compounds. (Based on human absorption experiments and animal studies)
Recommended Intakes	
Prevention of deficiency	AIs set by the Food and Nutrition Board[3] for manganese (mg/day) are: infants age 0–0.5 year, 0.003, and age 0.5–1 year, 0.6; children age 1–3 years, 1.2, and age 4–8 years, 1.5; males age 9–13 years, 1.9, age 14–18 years, 2.2, and age ≥19 years, 2.3; females age 9–18 years, 1.6, age ≥ 19 years, 1.8, pregnant, 2.0, and lactating, 2.6
Therapeutic or beneficial	Caution is indicated against high intakes of manganese because of potential neurotoxicological effects,[61,62] especially in people with compromised homeostatic mechanisms, or infants whose homeostatic control of manganese is not fully developed
Food Sources	Unrefined grains, nuts, green leafy vegetables, and tea

that results in growth retardation or impaired immune function may be quite prevalent. Unquestionable zinc deficiency has been induced by providing zinc deficient total parenteral nutrition, and by feeding cow's milk to infants who have a genetic inability to absorb zinc from such a source. The information in Table 8.6 primarily comes from reviews by Chesters,[63] Prasad,[64] and Dibley.[65]

ESSENTIAL ULTRA TRACE ELEMENTS

In 1980, the term *ultra trace elements* began to appear in the nutritional literature; the term was defined as an element required by animals in amounts of 50 ng or less per gram of diet. For humans, the term has been used recently to indicate elements with established or estimated requirements quantified by micrograms per day.[58] There are four essential ultra trace elements. The evidence of essentiality for humans is substantial and not controversial for cobalt, iodine, molybdenum, and selenium; specific biochemical functions have been identified for each. Another element, chromium, in the past has been considered an essential ultra trace element, and thus is included in this section. However, it should be noted that a critical review of the findings suggesting essentiality reveal that chromium is unable to meet any definition of essentiality[75–77] and probably belongs in the possibly essential ultra trace element category.

Chromium

Flaws in the early studies of chromium nutrition inhibited the acceptance of chromium as an essential nutrient until 1977. In that year, it was reported that signs of chromium deficiency were found in a patient receiving long-term total parenteral nutrition thought to be low in chromium. This patient developed impaired glucose tolerance and a resistance to insulin, which were reversed by an infusion of chromium.[78] However, skepticism about the nutritional essentiality of chromium began in 1980 when it was found that chromium analyses before then were not valid, and repeated efforts to definitively characterize a chromium-containing glucose tolerance factor were unsuccessful. At present, a clearly defined biochemical function has not been established for chromium. Neither has a chromium deficiency been induced in any animal species that causes death or interrupts the life cycle. Chromium is also unable to meet the older criteria of essentiality, because a consistent reduction in a biological function from optimal that is prevented by physiological amounts of chromium has not been conclusively demonstrated. This inability to fulfill the requirements to be classified as essential does not preclude the possibility that chromium may be found essential in the future. There is no question, however, about chromium being a bioactive beneficial element; supranutritional

TABLE 8.6
Biochemical, Clinical and Nutritional Aspects of Zinc

Biological Function	Zinc has catalytic, structural, and regulatory functions. Zinc is unique in that it is the only trace element with essential actions in all six enzyme classes. Zinc is required for catalytic activity of >300 enzymes. Zinc stabilizes the tertiary structure of some enzymes and also imparts stability to cell membranes. Zinc has a function as a component of transcription factors also known as zinc finger proteins that bind to DNA and activate transcription of a message
Signs of Deficiency	
Biochemical	Decreased plasma, leukocyte, erythrocyte, hair and saliva zinc; plasma metallothionein, thymulin and alkaline phosphatase; extracellular superoxide dismutase; and T-helper cell production of interlukin-2 and interferon-γ.[63–67] Increased plasma 5'-nucleotidase, platelet amyloid precursor protein, and lymphocyte mRNA ZIP1 (a zinc transporter) expression[63–67]
Physiological	Depressed growth; anorexia; parakeratotic skin lesions; diarrhea; and impaired testicular development, immune function, and cognitive function
Pathological Consequences of Deficiency	
Established	Dwarfism, delayed puberty, failure to thrive (acrodermatitis enteropathica infants), mental lethargy, hypogueusia (poor taste), impaired dark adaptation, impaired wound healing, and increased susceptibility to infectious disease
Suggested	Osteoporosis, infertility, impaired neuropsychological function, and increased susceptibility to diabetes, cancer, Alzheimer disease, and rheumatic disease, especially rheumatoid arthritis[64,68–73]
Predisposing Factors for Deficiency	• Factors causing impaired absorption including phytate, vegetarianism, intestinal infestation by bacteria, protozoa and helminthes, gastric and intestinal resection, inflammatory bowel disease, exocrine pancreatic insufficiency, bilary obstruction, and high intakes of zinc, copper and iron • Factors causing excessive loss, including protein-losing enteropathies, renal failure, renal dialysis, chronic blood loss (e.g., sickle cell disease), and exfoliative dermatoses • Factors inducing increased need including rapid tissue synthesis and postcatabolic convalescence
Recommended Intakes	
Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[3] for zinc (mg/day) are: infants age 0–0.5 year, 2 (AI) and age 0.5–1 year, 3; children age 1–3 years, 3, and age 4–8 years, 5; males age 9–13 years, 8, and age ≥14 years, 11; females age 9–13 years, 8, age 14–18 years, 9, age ≥19 years, 8, pregnant age ≤18 years, 12, and age ≥19 years, 11, lactating age ≤18 years, 13, and age ≥19 years, 12
Therapeutic or beneficial	High zinc intakes have been used for the alleviation and prevention of colds, treatment of macular degeneration, acute diarrhea and Wilson's disease; doses have ranged from 20 mg/day for children with diarrhea to 150 mg/day for treatment of Wilson's disease[64,74]
Food Sources	Red meats, organ meats (e.g., liver), shellfish, nuts, legumes

amounts of chromium enhance insulin sensitivity or action. The information in Table 8.7 comes primarily from reviews by Offenbacher et al.[79] Nielsen,[80] Vincent,[81] and Cefalu and Hu.[82]

Cobalt

Ionic cobalt is not an essential nutrient for humans; however, vitamin B_{12}, in which cobalt is an integral component, is an essential nutrient for humans. In the nineteenth century, a megaloblastic anemia was described that was called pernicious anemia, because it was invariably fatal. The first effective treatment for this disease was 1 lb of raw liver daily. In 1948, the antipernicious anemia factor in liver was isolated and named vitamin B_{12}, and was found to contain 4% cobalt. Vitamin B_{12} deficiency is rarely caused by a dietary insufficiency and most commonly arises from a defect in vitamin B_{12} absorption. People with low vitamin B_{12} status (e.g., vegetarians) can also display signs of deficiency if stressed with a substance such as nitrous oxide (used in dentistry), which destroys vitamin B_{12}. Most of the information in Table 8.8 was obtained from reviews by Smith,[83] Shane,[84] and Stabler.[85]

Iodine

Recognition that iodine is nutritionally important began in the 1920s when it was found that iodine prevented goiter and increased iodine intake was associated with decreased endemic cretinism. The consequences of iodine deficiency, which is common, are so profound that it is one of the largest public health problems in the world today. Iodine deficiency is most prevalent in areas of high new mountains (e.g., Himalayas, Andes, and Alps), areas of frequent flooding, rainfall, and sublimation (e.g., Ganges river plain of northeastern India, Taklamakan desert of western China, and central sub-Saharan Africa), and inland areas of central and Eastern Europe. Most of the information in Table 8.9 has been obtained from reviews by Hetzel and Wellby,[87] Freake,[88] and Stanbury and Dunn.[89]

TABLE 8.7
Biochemical, Clinical and Nutritional Aspects of Chromium

Biological Function

Established	None
Hypothesized	As part of a low-molecular-weight chromium-binding organic complex (LMWCr), chromium enhances insulin sensitivity or action. A naturally occurring biologically active LMWCr called chromodulin has been described as an oligopeptide of about 1500 Da that binds four chromic ions. *In vitro* findings have resulted in the hypothesis that chromodulin acts in a unique autoamplification system for insulin signaling

Signs of Deficiency

Biochemical	Based on the response to relatively high amounts of parenteral chromium by some patients, biochemical signs of chromium deficiency *may* be elevated serum glucose, cholesterol, triglycerides and insulin; glycosuria; decreased insulin binding and insulin receptor number
Physiological	Based on the response to relatively high amounts of parenteral chromium by a few patients, physiological signs of chromium deficiency *may* be impaired glucose tolerance, weight loss, neuropathy, and encephalopathy

Pathological Consequences of Deficiency

Established	None
Suggested	Impaired glucose tolerance, diabetes, and atherosclerosis
Predisposing Factors for Deficiency	Factors that promote urinary excretion including acute strenuous exercise, physical trauma, and high dietary sugar. Factors that inhibit absorption including phytate and drugs that reduce stomach acidity (e.g., antacids)

Recommended Intakes

Prevention of deficiency	AIs set by the Food and Nutrition Board[3] for chromium (μg/day) are: infants age 0–0.5 year, 0.2, and age 0.5–1 year, 5.5; children age 1–3 years, 11, and age 4–8 years, 15; males age 9–13 years, 25, age 14–50 years, 35, and age ≥51 years, 30; females age 9–13 years, 21, age 14–50 years, 25, age ≥51 years, 20, pregnant age ≤18 years, 29, and age ≥19 years, 30, lactating age ≤18 years, 44, and age ≥19 years, 45
Therapeutic or beneficial	Doses of 200 to 1000 μg/day of chromium, especially as an organic complex (e.g., chromium picolinate), have been shown to enhance the action of low amounts of insulin or improve the efficacy of insulin such that the need for exogenous sources was reduced or eliminated, plasma glucose was decreased, and HbA$_{1c}$ (glycosylated hemoglobin) was decreased in some persons with type I, type II, gestational and steroid-induced diabetes
Food Sources	Whole grains, pulses (e.g., dried beans), some vegetables (including broccoli and mushrooms), liver, processed meats, ready-to-eat cereals, and spices

TABLE 8.8
Biochemical, Clinical and Nutritional Aspects of Cobalt

Biological Function	Vitamin B$_{12}$ is a cofactor for two enzymes, methionine synthase which methylates homocysteine to form methionine, and methyl-malonyl CoA mutase, which converts L-methylmalonyl CoA, formed by the oxidation of odd-chain fatty acids, to succinyl CoA

Signs of Deficiency

Biochemical	Decreased erythrocyte and plasma folate and plasma vitamin B$_{12}$, and increased plasma homocysteine and urinary formiminoglutamate and methylmalonate
Physiological	Megaloblastic anemia; spinal cord demyelination and peripheral neuropathy

Pathological Consequences of Deficiency

Established	Pernicious anemia, memory loss, dementia, irreversible neurological disease called subacute degeneration of the spinal cord, and death.
Suggested	Cardiovascular disease associated with elevated plasma homocysteine
Predisposing Factors for Deficiency	• Factors causing malabsorption including Type A atrophic gastritis, *Helicobacter pylori* infection, GI bacteria overgrowth caused by achlorhydria and intestinal blind loops, total gastrectomy leading to loss of intrinsic factor excretion, pancreatic insufficiency, and celiac disease • Factors inhibiting utilization including drugs such as histamine H$_2$ receptor antagonists, proton pump inhibitors, oral biguanides (used in the treatment of type II diabetes), and nitrous oxide anesthesia • Vegetarian diets

Recommended Intakes

Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[86] for vitamin B$_{12}$ (μg/day) are: infants age 0–0.5 year, (0.4) and age 0.5–1 year, (0.5); children age 1–3 years, 0.9, age 4–8 years, 1.2, and age 9–13 years, 1.8; males age ≥14 years, 2.4; females age ≥14 years, 2.4, pregnant, 2.6, and lactating, 2.8
Therapeutic or beneficial	Milligram doses are used to treat vitamin B$_{12}$ malabsorption and deficiency; a common dose is 1 mg/day of cobalamin
Food Sources	Meat, dairy products, some sea foods, and fortified cereals

TABLE 8.9
Biochemical, Clinical and Nutritional Aspects of Iodine

Biological Function	Iodine has only one function; it is a component of thyroid hormones. However, thyroid hormones have an impact on a wide range of metabolic and developmental functions
Signs of Deficiency	
Biochemical	Decreased plasma or serum thyroxine (T_4) and triiodothyronine (T_3), and urinary iodine, and increased plasma or serum thyroid stimulating hormone (TSH) and cholesterol
Physiological	Decreased basal metabolic rate; increased heart rate, size, stroke volume and output; reduced muscle mass and delayed skeletal maturation; abnormal production of glial cells and myelinogenesis; and goiter
Pathological Consequences of Deficiency	
Established	• The spectrum of iodine deficiency disorders is large and includes fetal congenital anomalies and perinatal mortality
	• Neurological cretinism characterized by mental deficiency, deaf mutism, spastic diplegia and squint
	• Psychomotor defects
	• Fatigue and slowing of bodily and mental functions
	• Weight increase and cold intolerance caused by slowing of the metabolic rate
Predisposing Factors for Deficiency	Residence in an area with low soil iodine and treatment with lithium
Recommended Intakes	
Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[3] for iodine (μg/day) are: infants age 0–0.5 year, (110), and age 0.5–1 year, (130); children age 1–8 years, 90, and age 9–13 years, 120; males age ≥ 14 years, 150; females ≥14 years, 150, pregnant, 220, and lactating, 290
Therapeutic or beneficial	Iodized oil, in which the fatty acids are chemically modified by iodination, slowly releases iodine over a period of months or years in the body. In populations with a high prevalence of severe iodine deficiency disorders (goiter incidence 30% or more), 1 ml of iodized oil containing 480 mg of iodine administered orally or by injection is a therapeutic measure for long term protection against iodine deficiency. An oral iodine dose as potassium iodide or iodate of 30 mg monthly or 8 mg biweekly has been found to be an effective prophylaxis for iodine deficiency
Food Sources	Iodized salt has been the major method for assuring adequate iodine intake since the 1920s. Other sources are sea foods and foods from plants grown on high-iodine soils

Molybdenum

Because molybdenum is a cofactor for some enzymes, its essentiality is well established. However, molybdenum deficiency has not been unequivocally identified in humans other than in an individual nourished by total parenteral nutrition and in individuals with inborn errors of metabolism that affect the synthesis of molybdenum cofactor used in molybdoenzymes. Thus, molybdenum is not of much practical concern in human nutrition. The information in Table 8.10 has been obtained primarily from reviews by Nielsen.[58,80]

Selenium

Although selenium was first suggested to be essential in 1957, it was not firmly established as so until a biochemical role was identified in 1972. The first report of human selenium deficiency appeared in 1979; the subject resided in an area with low-selenium soil and was receiving total parenteral nutrition low in selenium after surgery. Subsequent findings of selenium-responsive disorders in certain populations (e.g., Keshan disease in China) and selenium supplementation reducing the incidence of certain cancers, suggest that a significant number of people may benefit by increasing their intake of selenium. The information in Table 8.11 primarily comes from reviews by Sunde.[91–93]

POSSIBLY ESSENTIAL ULTRA TRACE ELEMENTS

Circumstantial evidence often is used to contend that an element is essential. This evidence generally fits into four categories. These are:

1. Dietary deprivation in some animal model consistently results in a changed biological function, body structure, or tissue composition that is preventable or reversible by an intake of an apparent physiological amount of the element in question.
2. The element fills the need at physiological concentrations for a known *in vivo* biochemical action to proceed *in vitro*.
3. The element is a component of known biologically important molecules in some life form.
4. The element has an essential function in lower forms of life.

TABLE 8.10

Biochemical, Clinical and Nutritional Aspects of Molybdenum

Biological Function	In humans, three molybdoenzymes have been identified; these are aldehyde oxidase, xanthine oxidase/dehydrogenase and sulfite oxidase in which molybdenum exists as a small nonprotein factor containing a pterin nucleus. Molybdoenzymes oxidize and detoxify various pyrimidines, purines and pteridines; catalyze the transformation of hypoxanthine to xanthine and xanthine to uric acid; and catalyze the conversion of sulfite to sulfate
Signs of Deficiency	
Biochemical	● A patient on total parenteral nutrition exhibited hypermethioninemia, hypouricemia, hyperoxypurinemia, hypouricosuria, and low urinary sulfate excretion
	Patients with inborn errors of molybdenum cofactor synthesis exhibited increased plasma and urine sulfite, sulfate, thiosulfate, S-sulfocysteine, taurine, and xanthine; increased serum S-sulfonated transthyretin; and decreased urine and serum uric acid
Physiological	Total parenteral nutrition patient: mental disturbances progressing to coma. Genetic errors patients: seizures, failure to thrive, and brain atrophy/lesions
Pathological Consequences of Deficiency	
Established	Patients with inborn errors of molybdenum cofactor synthesis: mental retardation, dislocated lenses, and death at early age
Suggested	Increased susceptibility to cancer[90]
Predisposing Factors for Deficiency	A high sulfur amino acid intake may increase the need for molybdenum
Recommended Intakes	
Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[3] for molybdenum (μg/day) are: infants age 0–0.5 year, (2), and age 0.5–1 year, (3); children and adolescents age 1–3 years, 17, age 4–8 years, 22, age 9–13 years, and age 14–18 years, 43; adults, 45; pregnant and lactating females, 50
Therapeutic or beneficial	None have been proposed
Food Sources	Milk and milk products, pulses, organ meats (e.g., liver and kidney), cereals, baked goods

TABLE 8.11

Biochemical, Clinical and Nutritional Aspects of Selenium

Biological Function	Selenium is a component of enzymes that catalyze redox reactions; these enzymes include various types of glutathione peroxidases, iodothyronine 5'-deiodinases, and thioredoxin reductases
Signs and Symptoms of Deficiency	
Biochemical	Decreased plasma and erythrocyte selenium, plasma selenoprotein P and erythrocyte glutathione peroxidase
Physiological	Bilateral muscular discomforts, muscle pain, dry flaky skin, and wasting
Pathological Consequences of Deficiency	
Established	In the presence of other contributing factors, Keshan disease, a multiple focal myocardial necrosis resulting in acute or chronic heart function insufficiency, heart enlargement, arrhythmia, pulmonary edema, and death; other consequences include impaired immune function and increased susceptibility to viral infections
Suggested	Increased susceptibility to certain types of cancer; Kashin-Beck disease, an endemic osteoarthritis; and mood disturbances[93,94]
Recommended Intakes	
Prevention of deficiency	RDAs (and AIs) set by the Food and Nutrition Board[2] for selenium (μg/day) are: infants age 0–0.5 year, (15), and age 0.5–1 year, (20) children age 1–3 years, 20, age 4–8 years, 30; and age 9–13 years, 40; males age ≥14 years, 55; females age ≥14 years, 55, and lactating, 70
Therapeutic or beneficial	A supplement of 200 μg/day of selenium was found to have cancer protective effects
Food Sources	Fish, eggs, and meat from animals fed luxuriant selenium, grains grown on high-selenium soil

An element is considered to have strong circumstantial support for essentiality if all four types of evidences exist for it. There is strong circumstantial evidence for the essentiality of arsenic, nickel, silicon, and vanadium; thus, they are considered possibly essential ultra trace elements.

Arsenic

In addition to the information in Table 8.12, other findings, supporting arsenic essentiality, are that arsenic can activate some enzymes and enhance DNA synthesis by unsensitized and phytohemagglutinin-stimulated human lymphocytes *in vitro*.

TABLE 8.12

Arsenic: Biological Function in Lower Forms of Life, Deficiency Signs in Animals, and Speculated Importance and Postulated Adequate Intake for Humans

Biological Function in Lower Forms of Life	A biochemical function for arsenic has not been identified in lower forms of life. But, the bacterium *Chrysiogenes arsenatis* reduces As^{5+} to As^{3+} to gain energy for growth. There are enzymes in higher animals and humans that methylate arsenic with S-adenosylmethionine as the methyl donor. Arsenite methytransferase methylates arsenite to monomethylarsenic acid, which is methylated by monomethylarsenic acid methyltransferase to yield dimethylarsinic acid, the major form of arsenic in urine
Possible Biological Function in Humans	Arsenic possibly has a function involving the utilization of labile methyl groups arising from methionine, and thus influencing the function of systems dependent upon or regulated by methyl incorporation
Deficiency Signs in Selected Experimental Animals	
Goat	Depressed growth and serum triglycerides; abnormal reproduction characterized by impaired fertility and elevated perinatal mortality; and death during lactation with myocardial damage
Pig	Depressed growth and abnormal reproduction characterized by impaired fertility and elevated perinatal mortality
Rat	• Depressed growth and hepatic putrescine, spermidine, spermine and S-adenosylmethionine • Elevated hepatic S-adenosylhomocysteine • Abnormal reproduction
Speculated Importance for Humans	Deficient intakes may increase the risk for some types of cancers
Predisposing Factors for Deficiency	• Stressors that affect the utilization of the labile methyl group including high dietary arginine and taurine, and low dietary methionine and choline • Stressors that affect arsenic metabolism including low dietary zinc and high dietary selenium
Postulated Adequate Intake for Humans	Based on the hypothesized requirements for experimental animals, 12–25 μg/day may be beneficial or adequate for humans
Food Sources	Shellfish, fish, grains, and cereal products

Interestingly, although arsenic is considered to be carcinogenic, it has recently been found to be effective in the treatment of acute promyelocytic leukemia[95] and cancer risk is decreased in populations that drink water containing small amounts of arsenic.[96] Hypothesized explanations for the decreased risk range from arsenic having an essential function that protects against oxidative damage and DNA repair inhibition to it having a hormetic effect. Hormesis is a process in which a low dose of a substance stimulates a response that is beneficial, because it protects against adverse actions that are induced by mechanisms similar to toxic doses of the substance. The information in Table 8.12 primarily comes from reviews by Nielsen.[58,97]

Nickel

By 1984, extensive signs of nickel deprivation had been reported for six animal species. Unfortunately, many of the reported signs may have been misinterpreted manifestations of pharmacologic actions, because nickel was provided in relatively high amounts to supplemented controls in some experiments. Thus, many of the early reported nickel deprivation findings are not shown in Table 8.13. Recent animal experiments have shown that nickel is beneficial, if not essential, for optimal reproductive function, bone composition and strength, energy metabolism, and sensory function. Additional evidence supporting the possible essentiality of nickel is that it is essential for some lower forms of life, where it participates in hydrolysis and redox enzyme reactions, regulates gene expression, and stabilizes certain structures. Interestingly, the substrates or products for all the nickel-requiring enzymes are dissolved gases: hydrogen, carbon monoxide, carbon dioxide, methane, oxygen, and ammonia. The gene expression function of nickel also involves the diffusion of oxygen and hydrogen into the cell. The information in Table 8.13 primarily comes from reviews by Nielsen,[58,80,97,98] and Eder and Kirchgessner.[99]

Silicon

In addition to the information in Table 8.14, other findings supporting silicon essentiality include its localization in the active growth areas, or osteoid layer, and within the osteoblasts of bone in young experimental animals; its consistent presence in collagen and glycosaminoglycan fractions from several types of connective tissues; and its increased intake associated with increased cortical bone mineral density in men and premenopausal women. Also, orthosilicic acid at physiological concentrations was found to stimulate collagen type I synthesis in human osteoblast-like cells and enhance osteoblast differentiation in culture. The information in Table 8.14 primarily comes from reviews by Nielsen,[58,80,97,98] and Carlisle.[100]

TABLE 8.13

Nickel: Biological Function in Lower Forms of Life, Deficiency Signs in Animals, and Speculated Importance and Postulated Adequate Intake for Humans

Biological Function in Lower Forms of Life	In lower forms of life, nickel has been identified as an essential component of seven different enzymes: urease, hydrogenase, carbon monoxide dehydrogenase, methyl-S-coenzyme-M reductase, Ni-superoxide dismutase, glyoxalase I, and acireductone dioxygenase. Nickel has been reported to be required for the hydrogenase gene to be expressed in *Bradyrhizobium japonicum*
Possible Functions in Humans	• Nickel may have a function affecting signaling by a gaseous molecule (e.g., carbon monoxide) or regulated by cyclic guanosine monophosphate channels
	• Intracellular calcium ion signaling by affecting a calcium channel or receptor
	• Enzyme reactivity or gene expression requiring a gaseous molecule
Deficiency Signs in Selected Experimental Animals	
Goat	Depressed growth, hematocrits, and reproductive performance
Pig	Depressed growth, and altered distribution and proper functioning of zinc and calcium
Rat	• Depressed growth
	• Altered iron metabolism, brain and erythrocyte fatty acid composition, long bone shape, taste preference to saccharin, and eye mitochondrial morphology
	• Diminished sperm quantity and movement
	• Impaired brightness discrimination
	• Decreased long bone strength and circulating thyroid hormone concentration
	• Increased urinary excretion of nitrate/nitrite and phosphorus
Sheep	• Depressed growth, total serum protein, erythrocyte counts, ruminal urease activity, total hepatic lipids, and cholesterol
	• Altered tissue distribution of copper and iron
Speculated Importance for Humans	Deficient intakes may impair sensory functions and bone strength
Predisposing Factors for Deficiency	• Stressors that affect labile methyl metabolism (e.g., folic acid, vitamin B_6 and vitamin B_{12} deficiencies, low dietary protein, and homocysteine supplementation)
	• Affect iron metabolism (e.g., iron deficiency)
	• Affect signaling (e.g., high dietary sodium chloride)
Postulated Adequate Intake for Humans	Based on hypothesized requirements for animals, 25–35 μg/day may be beneficial or adequate for humans
Food Sources	Nuts, pulses, grains, and chocolate

Vanadium

There is no question that vanadium is a bioactive element. Its ability to selectively inhibit protein tyrosine phosphatases at sub-micromolar concentrations probably explains the broad range of effects that relatively high (supranutritional or pharmacologic) intakes have on cellular regulatory cascades. Protein tyrosine phosphatase inhibition is thought to be the basis for vanadium having insulin-like actions at the cellular level and stimulating cellular proliferation and differentiation. Nutritional intakes may also affect phosphorylation/dephosphorylation such that a regulatory cascade is altered. This may be the basis for the observations that vanadium deprivation altered the response to low and high dietary iodine, impaired reproduction, and induced abnormal bone morphology in experimental animals. The information suggesting vanadium is essential for humans shown in Table 8.15, as well as being essential for some lower forms of life, primarily comes from reviews by Nielsen,[58,80,97,98,101,102] Marzan and McNeill,[103] and Hulley and Davison.[104]

OTHER ELEMENTS WITH BENEFICIAL OR BIOLOGICAL ACTIONS

There are several elements that have limited circumstantial evidence suggesting that they may be essential. This evidence is generally limited to a few gross beneficial effects or apparent signs of deficiency in one or two animal species observed by one or two research groups. Therefore, these elements do not have widespread support for being possibly essential. However, some of these elements have beneficial pharmacological actions (fluoride and lithium), and others may eventually be found to be of some importance from the nutritional point of view. Elements that fit in this category include aluminum, bromine, cadmium, fluorine, germanium, lead, lithium, rubidium, and tin. The information in Table 8.16 comes from reviews by Nielsen[80,97,105] and Anke et al.[106–110]

TABLE 8.14

Silicon: Biological Function in Lower Forms of Life, Deficiency Signs in Animals, and Speculated Importance and Postulated Adequate Intake for Humans

Biological Function in Lower Forms of Life	Silicon has a structural role in some primitive classes of organisms including diatoms (unicellular microscopic plants), radiolarians, and some sponges. Diatoms have an absolute requirement for silicon as monomeric silicic acid for normal cell growth. The diatom, *Cylindrotheca fusiformis*, has five transporter genes that tightly control silicon uptake and use in cell wall formation
Possible Biological Function in Humans	Silicon may be involved in the interaction between a macromolecule and a cell resulting in changes in cell synthetic activity or cytokine secretion such that it affects wound healing, immune function, and cartilage composition and ultimately calcification
Deficiency Signs in Experimental Animals	
Chick	Skulls with a more primitive type of bone and structural abnormalities associated with depressed collagen content; long bone abnormalities characterized by defective endochondral bone growth associated with depressed contents of articular cartilage, water, hexosamine, and collagen
Rat	• Increased humerus hexose; decreased humerus hydroxyproline, femur alkaline and acid phosphatase and plasma ornithine aminotransferase activity (a key enzyme in collagen synthesis) • Increased urinary helical peptide (collagen breakdown product) excretion
Speculated Importance for Humans	Deficient intakes may impair bone growth and remodeling, wound healing, and immune function
Predisposing Factors for Deficiency	• Stressors that affect the metabolism of silicon including high dietary fiber and aluminum • Stressors that affect the utilization of silicon including wounds (tooth extraction), conditions causing an immune or inflammatory response (e.g., arthritis), and low dietary calcium
Postulated Adequate Intake for Humans	Based on animal findings and human urinary excretion data, suggested beneficial or adequate intakes for humans range from 5 to 25 mg/day. On the basis of weak balance data, a silicon intake of 30 to 35 mg/day was suggested for athletes, which was 5 to 10 mg higher than that suggested for nonathletes
Food Sources	Unrefined grains of high fiber content and cereal products

TABLE 8.15

Vanadium: Biological Function in Lower Forms of Life, Deficiency Signs in Animals, and Speculated Importance and Postulated Adequate Intake for Humans

Biological Function in Lower Forms of Life	Vanadium is an essential cofactor for some nitrogenases that reduce nitrogen gas to ammonia in bacteria, and for bromoperoxidase, iodoperoxidase and chloroperoxidase in algae, lichens and fungi, respectively. The haloperoxidases catalyze the oxidation of halide ions by hydrogen peroxide, thus facilitating the formation of a carbon–halogen bond
Possible Biological Function in Humans	Vanadium may have a role that promotes phosphorylation and/or inhibits dephosphorylation such that a regulatory cascade is altered
Deficiency Signs in Selected Experimental Animals	
Goat	Depressed milk production and life span; increased rate of spontaneous abortion; death, sometimes preceded by convulsions, between ages 7 and 91 days; skeletal deformations in the forelegs; and thickened forefoot tarsal joints
Rat	Increased thyroid weight and thyroid weight/body weight ratio, decreased erythrocyte glucose-6-phosphate dehydrogenase, and altered response to high and low dietary iodide
Speculated Importance for Humans	Low intakes may impair thyroid hormone metabolism and proper bone development
Predisposing Factors for Deficiency	Stressors of thyroid or iodine metabolism and factors that reduce vanadium absorption including high dietary iron, aluminum hydroxide, and chromium
Postulated Adequate Intake for Humans	Based on animal data, a daily dietary intake of 10 μg probably would be adequate for humans. Pharmacologic doses used to experimentally treat diabetes have been in the range of 40 to 50 mg vanadium/day in the form of vanadyl sulfate, sodium orthovanadate, and organic complexes such as bis(maltoalto)oxovanadium (IV). It should be noted that the Food and Nutrition Board[3] has set a tolerable upper intake level (UL) of 1.8 mg vanadium/day for male adults
Food Sources	Shellfish, mushrooms, prepared foods, whole grains

TABLE 8.16

Reported Deficiency Signs in Experimental Animals and Usual Human Dietary Intakes of Apparently Bioactive Beneficial Mineral Elements

Element	Deficiency Signs (Experimental Animals)	Usual Daily Dietary Intake (Humans)	Food Sources
Aluminum	*Chick*: Depressed Growth *Goat*: Depressed growth and insemination success, increased abortions and kid mortality, and uncoordinated and weak hind legs	2–10 mg	Baked goods prepared with chemical leavening agents, grains, vegetables, and tea
Bromine	*Goat*: Depressed feed intake, growth, conception rate, hematocrit and hemoglobin, and increased abortions and kid mortality	2–8 mg	Grains, nuts, and fish
Cadmium	*Goat*: Muscular weakness, degenerative changes in liver and kidney mitochondria, decreased insemination success and milk production, and increased mortality *Rat*: Depressed growth	5–20 μg	Shellfish, grains, and leafy vegetables
Fluorine	*Goat*: Decreased feed efficiency and growth, kid mortality, and skeletal deformities *Rat*: Depressed growth and altered incisor pigmentation	0.4–1.8 mg without fluoridated water	Fish, tea, and fluoridated water
Germanium	*Rat*: Decreased tibial DNA and altered bone and liver mineral composition	0.4–3.4 mg	Vegetables, wheat bran, and leguminous seeds
Lead	*Pig*: Depressed growth and elevated serum cholesterol, phospholipids and bile acids *Rat*: Depressed growth and liver glucose and lipids, increased liver cholesterol and serum ceruloplasmin, and anemia	15–100 μg	Seafood and food from plants grown under high-lead conditions
Lithium	*Goat*: Depressed conception rate, birth weight, milk production, serum citric acid cycle enzyme and liver monoamine oxidase activities, and increased mortality and serum creatine kinase activity *Rat*: Depressed fertility, birth weight, litter size, and weaning weight	100–600 μg	Meat, eggs, fish, milk, milk products, processed meats, potatoes, and vegetables (content varies with geological origin)
Rubidium	*Goat*: Depressed growth, food intake, conception rate, milk production, and plasma progesterone and estradiol, and increased abortions and kid mortality *Rat*: Altered tissue mineral concentrations	1–3 mg	Fruits, vegetables (especially asparagus), poultry, fish, coffee, and tea
Tin	*Rat*: Depressed growth, feed efficiency, and response to sound, altered mineral composition of heart, tibia, muscle, spleen, kidney, and lung	1–5 mg	Canned foods

SUMMARY

Except for iodine and iron, the full extent of the pathological consequences of marginal or deficient intakes of the trace and ultra trace elements has not been established. In addition, it is quite likely that not all the essential mineral elements for humans have been identified, and the mechanisms for the beneficial effects of many bioactive mineral elements have not been clearly defined. Thus, it is difficult to tabulate trace mineral deficiency signs and symptoms for humans. The tables in this section are works in progress, and the presented data can rapidly change because of ongoing research. However, findings to date indicate that many trace and ultra trace minerals are of more practical nutritional concern than currently acknowledged.

9 Vitamin Deficiencies

Richard S. Rivlin

CONTENTS

In this era of increasing obesity and growing portion sizes, with food fortification well established and nutritional supplements widely consumed by the public, it is important to keep in mind those special circumstances in which vitamin deficiencies still continue to occur. A diet high in calories is not necessarily high in nutrients. In fact, a high-fat diet based to a large degree on "fast foods" may be low in some of the essential vitamins and minerals.

GENERAL COMMENTS ON VITAMIN DEFICIENCIES

In general, vitamin deficiencies arise when the diet is inadequate in its content of one or more nutrients or when the body is unable to utilize dietary nutrients adequately. Impaired intestinal absorption or defects in metabolic processes, storage, or excretion can each result in vitamin deficiency. Single-nutrient deficiencies are rare these days, because a diet that is suboptimal in one vitamin is nearly always suboptimal in others. Thus, a poor diet tends to have multiple inadequacies. Furthermore, some vitamins are involved in the metabolism of other vitamins, and therefore deficiencies may be interconnected.

A number of exogenous factors may serve to intensify the biological effects of a poor diet. For example, excess alcohol consumption has specific and selective effects on vitamin metabolism, interfering with the absorption of some vitamins (e.g., thiamin and riboflavin) and accelerating the metabolic degradation of another (B_6). In addition, a number of medications may affect vitamin metabolism and at multiple sites. From a practical point of view, laxatives and diuretics, often used for minimal indications and prolonged periods by vulnerable elderly patients, are probably among the most common causes of drug-induced vitamin deficiencies.

The concept of risk factors, utilized effectively in the evaluation and prevention of heart disease, needs to be applied to the assessment of vitamin deficiency. Thus, a patient who abuses alcohol, requires several medications chronically, and suffers from malabsorption due to alcohol will have a greatly enhanced risk of becoming grossly vitamin deficient.

A much greater understanding is needed of the effects of herbal products and the so-called alternative/complementary remedies on vitamin metabolism. Many prescription drugs are known to affect vitamin metabolism. With large numbers of people consuming a wide variety of unregulated products about which there is little information, a potential exists for developing significant forms of malnutrition. We urgently need more information on drug–herbal and food–herbal interactions and their implications for vitamin metabolism. Several comments about the patterns of vitamin deficiencies currently emerging in the United States are summarized in Table 9.1.

TABLE 9.1
Some Features of Vitamin Deficiencies at the Present Time

1. Dietary vitamin deficiencies tend to be multiple, not single
2. Clinical evidence of vitamin deficiencies develops gradually, and early symptoms, such as fatigue and weakness, may be vague, ill-defined, and nonspecific
3. The physical examination cannot be relied upon to make a diagnosis of early vitamin deficiency; classic features of vitamin deficiencies, such as the corkscrew hairs of scurvy, are only detectable after a profound deficiency state has been attained
4. The rate of development of vitamin deficiencies is highly variable. In general, most water-soluble vitamins may be depleted within several weeks; longer periods are needed for significant depletion of fat-soluble vitamins. Several years are required for clinical manifestations of vitamin B_{12} deficiency unless there are complicating factors, such as ileal resection or inflammatory bowel disease involving the ileum
5. The impact of dietary deficiencies of vitamins is greatly augmented by the long-term chronic use of certain medications that may affect absorption, utilization, or excretion of vitamins. Chief among these are laxatives and diuretics. These considerations are particularly relevant to older individuals, who use the largest number of drugs and remedies, for the longest duration, and may have marginal diets to begin with
6. The concept of "risk factors" may be helpful in assessing factors, such as drugs and alcohol, that contribute to accelerating the clinical presentation of a given dietary inadequacy

TABLE 9.2
Some Considerations in Correction of Vitamin Deficiencies

1. Approach the clinical setting in its entirety; ask yourself, how could a vitamin deficiency develop in the first place? Ask whether there are complicating conditions, that is, other risk factors, in addition to the poor diet

2 Unless there are specific indications of a single-nutrient deficiency, such as vitamin B_{12} in pernicious anemia, most malnourished patients will have multiple deficiencies and require rehabilitation with multiple nutrients. Repletion is best accomplished primarily with diet, and additionally with specific supplementation, if necessary

3. Simple steps can often improve a diet significantly, such as discarding old produce, avoiding "fast food" meals on a regular basis, and increasing the intake of fresh fruits and vegetables. In modern nutrition, one speaks of "junk diets" rather than single "junk foods," and of the necessity of moderation and variety in one's daily diet

4. Learn how to read a label from a nutritional supplement bottle so that you can properly instruct your patients. The array of choices of nutritional supplements is bewildering, and patients must learn that more is not necessarily better

5. Remember that vitamins may behave like drugs and have a defined toxic: therapeutic ratio. Some vitamins, such as vitamins A and D, have a real potential for causing toxicity. B vitamins may also cause problems, as exemplified by the sensory neuropathy resulting from large doses of vitamin B_6

6. A multivitamin supplement containing all nutrients at the levels of the RDI is safe to take by nearly everyone and may help to alleviate deficiencies and prevent them in the future

While the effects of full-blown vitamin deficiencies are well known and have been thoroughly described, the effects of lesser or marginal deficiencies are not as well appreciated by health professionals. In recent years, both scientists and the general public have been paying more attention to marginal vitamin and mineral deficiencies in attempting to gain maximal benefits from diet for health. Recent findings suggest that the concept of so-called "normal" needs to be carefully reconsidered, inasmuch as there may be different risks for disease within the range considered "normal."

For example, individuals with serum folic acid levels in the lower part of the normal range have been shown to have significantly elevated serum concentrations of homocysteine compared with those whose folic acid concentrations are in the upper range of normal. With elevated serum homocysteine concentrations emerging as a risk factor for heart disease, these observations suggest that perhaps we should set higher standards and more defined expectations for the "normal" range.

In the prevention and treatment of vitamin deficiencies, one must approach the patient in a logical fashion and proceed in an orderly direction. Medical history is of greatest importance and one needs to know details of food intake, portion size supplement use, remedies, and drugs. The physical examination only rarely reveals pathognomonic signs of specific vitamin deficits. Laboratory tests, appropriately utilized, may be helpful in documenting vitamin deficiencies. Long-term compliance with an appropriate diet and the use of supplements, if indicated, is the goal, but may be difficult to achieve. Some of the points regarding correction of vitamin deficiencies are summarized in Table 9.2.

VITAMIN A

FUNCTIONS

Vitamin A has a wide variety of functions, including specific roles in vision, embryogenesis, cellular differentiation, growth, reproduction, immune status, taste sensations, and, increasingly, in disease prevention and treatment.

DEFICIENCY

Deficiency of vitamin A is of crucial importance as a worldwide nutritional problem. The resultant xerophthalmia is a cause of blindness in at least half a million preschool children each year in the developing countries. In these areas, the diet is composed primarily of such items as rice, wheat, maize, and tubers, which contain far from adequate amounts of vitamin A precursors. The World Health Organization (WHO) and other groups have made great efforts to plan programs that identify people at risk and to institute appropriate preventive measures on a broad scale. It is now recognized that dietary deficiency of vitamin A is a clear risk factor for severe cases of measles. Many of the deaths that result from measles in young children could be greatly reduced by large doses of vitamin A given parenterally. The diet prevailing in these areas simply does not contain enough vitamin A precursors or vitamin A itself to prevent a deficient state from developing.

Clinical deficiency of vitamin A may be overt or subclinical. One of the earliest signs of vitamin A deficiency is night blindness, observed in both children and adults. The development of xerophthalmia follows a defined sequence, leading eventually to keratomalacia, in which perforation of the cornea occurs. A characteristic sign that is observed later in advanced vitamin A deficiency is Bitot's spots, collections of degenerated cells in the outer aspects of the conjunctivae that appear white in color.

Vitamin-A-deficiency eye disease in its end stages is irreversible, but if abnormalities are detected earlier and treated vigorously, they may be potentially preventable.

Vitamin A deficiency also causes skin disorders in the form of follicular hyperkeratosis. Although characteristic skin changes occur in response to a deficiency of vitamin A, in practical terms one should remember that skin lesions of some kind may be caused by other nutrient deficiencies such as zinc, biotin, niacin, and riboflavin.

Children significantly deficient in vitamin A manifest increased incidence of serious and life-threatening infections and elevated mortality rates. It has been recognized that deficient vitamin A status is a risk factor for the maternal-to-fetal transmission of human immunodeficiency virus; the relative risk of transmission of the virus is fourfold greater in vitamin-A-deficient than in vitamin-A-sufficient mothers.

Vitamin A deficiency in the United States is identified largely with certain risk groups: the urban poor, elderly persons (particularly those living alone), abusers of alcohol, patients with malabsorption disorders, and persons with poor diets. Vitamin A deficiency is generally found in a setting in which there are multiple vitamin and mineral deficits. Special attention must be paid to deficiency of zinc, a frequent finding in alcoholism, as depletion of zinc interferes with the mobilization of vitamin A from its storage sites in liver. This effect is achieved by blocking the release of holo-retinol-binding protein from the liver. Even in Western countries, severe cases of measles have been found in children with borderline vitamin A stores, suggesting that perhaps parenteral vitamin A should be administered in this setting as well.

Health professionals must keep in mind that deficiency of vitamin A in the United States may develop after the long-term use of several medications. Drug-induced nutritional deficiencies, in general, particularly those involving vitamin A, occur most frequently among elderly persons, because they use medications in the largest number for the most prolonged duration, and they may have borderline nutritional status to begin with. Among the drugs most relevant to compromising vitamin A status are mineral oil, which dissolves this nutrient; other laxatives, which accelerate intestinal transit and may diminish the magnitude of vitamin A absorption; cholestyramine and colestipol, which bind vitamin A; and, under certain conditions, neomycin and colchicines. Olestra may possibly interfere with absorption of a number of vitamins, including A: patients using this agent have been advised to take a multivitamin supplement regularly.

LABORATORY DIAGNOSIS OF DEFICIENCY

The laboratory diagnosis of vitamin A deficiency is based on the finding of a low plasma retinal; levels below 10 μg/dl signify severe or advanced deficiency. Interpretation of plasma retinal concentrations may be confounded, however, by a number of other factors, such as generalized malnutrition and weight loss. Some authorities have preferred to utilize a form of retinal tolerance test, measuring the increment in serum vitamin A levels over 5 h following an oral load of vitamin A.

PREVENTION

Deficiency of vitamin A can be prevented by a diet high in carotenes, which serve as precursors to vitamin A. The carotenes, particularly β-carotene, are derived exclusively from plant sources, the richest of which are palm oil, carrots, sweet potatoes, dark green, leafy vegetables, cantaloupe, oranges, and papaya. Preformed vitamin A is derived only from animal sources, such as dairy products, meat, and fish. The commercial preparations of fish oils are rich, sometimes too rich, as sources of preformed vitamin A.

The nutritional value of dietary sources of vitamin A may be compromised when food items are subject to oxidation, particularly in the presence of light and heat. Antioxidants, such as vitamin E, may prevent the loss of vitamin A activity under these conditions.

TREATMENT

Vitamin A deficiency has been treated worldwide with single intramuscular injections of massive amounts (100,000 to 200,000 IU) of vitamin A, repeated at intervals of approximately 6 months to 1 year. WHO has recommended that doses of 200,000 IU of vitamin A be given initially and at 2 days to children admitted to hospitals in areas of the world where the case fatality rate is very high. Such doses have been effective and are associated with remarkably little toxicity, perhaps because body stores are markedly depleted at the time of therapy. These doses, however, may produce some acute toxic symptoms in well-nourished persons.

Clinical vitamin A deficiency in the United States can be treated with either β-carotene if there is normal body conversion to vitamin A or vitamin A itself. Daily doses in the range of 25,000 IU of β-carotene are being consumed by many healthy individuals. The yellowish discoloration of the skin associated with prolonged use of β-carotene is not believed to be harmful. Vitamin A, in contrast, is quite toxic when ingested in amounts considerably higher than the RDI, especially for prolonged periods. It is probably advisable not to exceed two to three times the RDI for vitamin A when planning a domestic treatment program involving vitamin A administration.

Congenital malformations, a particularly disturbing consequence of vitamin A overdosage, have been reported in women consuming 25,000 to 50,000 IU daily during pregnancy. The lowest dose of vitamin A that would be completely safe as a supplement for pregnant women is not known definitely. Therefore, it is not a good idea for pregnant women to take supplementary vitamin A unless there are specific indications, such as malabsorption, or proven dietary deficiency. Many advisory groups caution that the maximal intake of preformed vitamin A consumed during pregnancy should not exceed 10,000 IU/day.

At present, there is widespread interest in newer therapeutic applications of vitamin A and its derivatives. Certain forms of leukemia have been found to respond to derivatives of vitamin A. The therapeutic potential of this vitamin is being expanded greatly in studies of chemoprevention and treatment of cancer. The toxicity of large doses of vitamin A places important limits on its feasibility in cancer prevention. Attention has turned to β-carotene and related agents, which, in addition to their role as precursors of vitamin A, have strong antioxidant activity and other effects as well. β-Carotene, however, may possibly pose a risk in heavy smokers — two studies in this population have shown an actual increase in prevalence of lung cancer when β-carotene was administered for several years.

Diminished prevalence of certain cancers has been found among people whose intake of fruits and vegetables is high; this finding has been attributable at least in part to the high content of carotenoids in the diet. However, many phytochemicals in addition to carotenoids have been found in fruits and vegetables with potential health benefits. Some data show that a combination of antioxidants (i.e., vitamin E, vitamin C, and β-carotene) may be more effective than any of these single agents, providing more evidence in favor of moderation and variety in the diet.

VITAMIN E

FUNCTIONS

A generally accepted role for vitamin E is as a scavenger of free radicals, and in this capacity it protects cell membranes from damage. The role of vitamin E as an antioxidant in health and disease has attracted wide interest. It has many other properties as well. Vitamin E is essential for the immune system, particularly T-lymphocytes, and has a role in DNA repair. Interest is growing in the effect of vitamin E on inhibiting oxidation of low-density lipoprotein (LDL); oxidized LDL becomes more atherogenic. The neuromuscular system and the retina also require vitamin E for optimal function.

Vitamin E may have additional cellular protective effects. There is evidence that this vitamin may protect sulfhydryl groups in enzymes and other proteins. Similarly, stores of vitamin E may be conserved by the glutathione-S-transferase system, which utilizes reduce glutathione and serves similar antioxidant functions.

DEFICIENCY

Dietary vitamin E deficiency is relatively unusual in the United States under ordinary circumstances, as sources of vitamin E are widely available from the food supply. The recognizable cases of vitamin E deficiency tend to arise in debilitated patients who have had severe and prolonged periods of fat malabsorption. Vitamin E is incorporated into chylomicrons with other products of fat digestion during the process of intestinal absorption. Any illness that interferes with fat digestion, absorption, or metabolism may also impair absorption of vitamin E. Disorders in which symptomatic vitamin E deficiency develops include cystic fibrosis, celiac disease, cholestatic liver disease, and short-bowel syndrome from any cause.

Major abnormalities of neurologic function are observed in a severe and prolonged vitamin E deficiency state. Patients display areflexia, ophthalmoplegia, and disturbances of gait, proprioception, and vibration. In premature infants, vitamin E deficiency results in hemolytic anemia, thrombocytosis, edema, and intraventricular hemorrhage. There is increased risk of retrolental fibroplasia and bronchopulmonary dysplasia under these circumstances.

In hemolytic anemia, such as that caused by glucose-6-phosphate dehydrogenase deficiency and sickle cell anemia, vitamin E levels in blood tend to be decreased. Inborn errors of vitamin metabolism have been identified, but are rare. There are severe neurologic abnormalities in this category. In abetalipoproteinemia, there is a defect in the serum transport of vitamin E. A hallmark of this disease is the finding of extremely low serum cholesterol levels together with very low serum levels of vitamin E.

LABORATORY DIAGNOSIS OF DEFICIENCY

Ideally, the diagnosis of vitamin E deficiency should be made by detailed chromatographic analysis of the various E isomers. In practice, such a procedure is not realistic, and the clinical evaluation usually depends on measurement of total plasma E alone. Plasma concentrations of vitamin E below 0.50 μg/ml are generally regarded as indicative of deficiency. It has been observed that despite a wide range of dietary intake, the serum variations in vitamin E levels often tend to be in a much more limited range.

It is important to keep in mind that vitamin E is transported in blood bound to lipoproteins, particularly LDL. In any condition in which the serum cholesterol is abnormally high or low, the vitamin E level will vary accordingly. Therefore, before concluding that anyone is vitamin-E-deficient or has an excess of vitamin E, the plasma level of this vitamin should be evaluated in relation

to the prevailing cholesterol concentrations. Furthermore, an α-tocopherol transport protein has been identified recently; its physiological role is at present under study.

PREVENTION

Deficiency of vitamin E can be avoided by regular consumption of the many sources of this vitamin in the food supply. The richest sources of vitamin E in the U.S. diet are vegetable oils, including corn, cottonseed, safflower and soybean oils, and the margarines and other products made from these oils. Green, leafy vegetables are also good sources of vitamin E. In evaluating the adequacy of any given dietary regimen, one should keep in mind the losses of the vitamin often occur during storage, cooking, and food processing, particularly with exposure to high temperatures and oxygen.

Because vitamin E deficiency frequently occurs as a result of severe intestinal malabsorption, it is essential to identify this condition early and avoid measures that may intensify the degree of malabsorption of vitamin E and other fat-soluble vitamins. Specific supplementation with vitamin E and other vitamins may be needed. The usual multivitamin supplement containing 400 IU should be adequate for this purpose.

There is evidence that dietary zinc is necessary in order for vitamin E to achieve adequate concentrations in peripheral blood. The relationship has been shown in both experimental animals and in patients.

There is a wide margin of safety in the therapeutic administration of the vitamin. Daily doses of vitamin E in the range of 100 to 800 IU can be given safely to nearly all-deficient patients. This dosage is higher than that usually found in multivitamin supplements. This dose range can be used appropriately in those patients with vitamin E deficiency diagnosed in association with celiac disease, inflammatory bowel disease, or other chronic and prolonged forms of intestinal malabsorption. In such instances, many other nutrient deficiencies are likely to be found in association with that of vitamin E, and they, too, necessitate treatment.

In the genetic disorders of vitamin E metabolism, such as isolated vitamin E deficiency, doses in the range of 800 to 1000 IU or higher must be taken. Large doses of vitamin E given therapeutically under these conditions appear to be generally safe. Some investigators have suggested that pharmacologic doses of vitamin E may interfere with the intestinal absorption of vitamins A and K, but there is little data with which to evaluate this potential risk. In addition, there are suggestive reports that doses of vitamin E in excess of 1200 IU/day may possibly interfere with the action of vitamin K and intensify the effects of anticoagulant drugs. Further information is needed on this subject.

The role of vitamin E in prevention of heart disease remains controversial. Some clinical studies have supported this concept while others have not. More research is needed before public health recommendations can be made for the general population.

VITAMIN K

FUNCTIONS

Vitamin K is a cofactor for posttranslational modification in a diverse group of calcium-binding proteins, whereby selective glutamic acid (Glu) residues are transformed into gamma-carboxyglutamic acid (Gla). The vitamin-K-dependent proteins that are best known include the four classic vitamin procoagulants (factors II, VII, IX, and X) and two feedback anticoagulants (proteins C and S), all synthesized by the liver. Therefore, severe liver disease leads to extensive abnormalities in vitamin K metabolism and frequent disturbances in blood coagulation.

Gla proteins also occur in several other tissues besides liver. Actions of vitamin K in bone have assumed greater importance in recent years. Osteocalcin, which contains three Gla residues, is synthesized by the osteoblasts of bone. It is one of the ten most abundant proteins in the body and may play a role in regulating bone turnover. A second protein isolated from bone that is related structurally to osteocalcin is matrix Gla protein. This protein is more widely distributed, and there is now evidence that this protein is an important inhibitor of calcification of arteries and cartilage. Gla residues provide efficient chelating sites for calcium ions that enable vitamin-K-dependent proteins to bind to other surfaces (e.g., procoagulants to platelet and vessel wall phospholipids, and osteocalcin to the hydroxyapatite matrix of bone). The carboxylation reaction is catalyzed by a microtome vitamin-K-dependent gammaglutamyl carboxylase, which requires the dietary quinone form of vitamin K to be first reduced to the active cofactor vitamin K hydroquinone, vitamin KH_2.

In bone, vitamin K achieves gamma-carboxylation of osteocalcin. In addition, vitamin K regulates interleukin-6 production, synthesis of prostaglandin E_2, and urinary excretion of calcium. It is not surprising, therefore, that in patients with long-term low dietary intake of vitamin K, the risk for hip fractures is increased.

DEFICIENCY

Isolated deficiency of vitamin K due entirely to inadequate dietary intake tends to be unusual in adults in the United States, because this vitamin is widely distributed in the food supply. Overt deficiency of vitamin K is more likely to be observed in

conditions in which there are significant complicating factors, such as long-term use of broad-spectrum antibiotics, or illnesses and drugs associated with fat malabsorption. It is essential to recognize that vitamin K is synthesized by intestinal bacteria. Antibiotic treatment will largely eliminate these bacterial sources of vitamin K and may have some clinical impact, particularly when treatment is prolonged. One class of antibiotics, the cephalosporins, cause vitamin K deficiency by an entirely different mechanism, namely, by inhibiting the vitamin-K-dependent hydroxylase. The extent to which the bacterial source of vitamin K provides a significant contribution to the bodily supply of the vitamin is a subject of debate among experts.

Fat malabsorption is regularly observed as a feature of severe regional enteritis, nontropical sprue, cystic fibrosis, ulcerative colitis, and a number of other disorders. Following extensive intestinal resection, patients are left with a short-bowel syndrome, in which fat malabsorption is prominent because of the reduction in intestinal surfaces available for absorption and transport. In a recent study of more than 100 patients with cystic fibrosis, evidence of insufficient vitamin K nutrition was found in 70% of the sample. The clinical severity of deficiency was highly individualized.

Vitamin K deficiency with the most serious consequences is that associated with the hemorrhagic disease of the newborn. The pathogenesis of this syndrome derives from (a) the poor placental transport of vitamin K combined with (b) lack of fetal production of vitamin K by intestinal bacteria as the intestinal tract is sterile, and (c) diminished synthesis by an immature liver of prothrombin and its precursors. In adults with vitamin K deficiency, multiple purpuric lesions may be noted (Figure 9.1*).

As noted earlier, dietary sources of vitamin K are widespread in the food supply in the United States. The highest amounts are found in green leafy vegetables, such as broccoli, Brussel sprouts, spinach, turnip greens, and lettuce. Interestingly, the risk of hip fracture is reported to be the highest in women who have the lowest consumption of lettuce, which contributes significantly to vitamin K nutrition. Some vitamin K at lower amounts can be found in meat, dairy products, coffee, and certain teas. Green leafy vegetables contain vitamin K largely as phylloquinone. Meat, cheese and certain fermented foods contain vitamin K in the form of menaquinone.

LABORATORY DIAGNOSIS OF DEFICIENCY

Vitamin K in body fluids and in foods can be measured by biological and chemical methods. The vitamin is light sensitive and must be shielded from light during storage and analysis. In practice, functional vitamin K status is assessed indirectly by measurements of serum prothrombin. Clinical vitamin K deficiency should be suspected wherever there is an unusual hemorrhagic tendency. In assessing vitamin K deficiency clinically, it is important to remember that adequate carboxylation of proteins in bone requires higher doses of vitamin K than the carboxylation of proteins in liver. Thus, in repleting deficient patients, the blood coagulation profile could be normalized early but bone metabolism still compromised.

PREVENTION

For healthy individuals, dietary vitamin K deficiency should be preventable by maintaining a diet high in green, leafy vegetables. When antibiotics are prescribed long-term, they should be kept to the minimal time period and doses necessary. Efforts should be

FIGURE 9.1 **(See color insert following page 654.)** Adult female patient with severe vitamin K deficiency illustrating multiple purpuric areas accuring spoentaneously. (Photo courtesy of Elaine B. Feldman.)

initiated early to recolonize the gastrointestinal tract by providing live-culture yogurt or other sources of normal flora. Similar guidelines should be followed in cases in which drugs causing malabsorption of vitamin K are required. Vitamin supplements containing vitamin K may be advisable. Effective treatment of an underlying disorder of the gastrointestinal tract should be undertaken in a specific fashion where possible, such as a gluten-free diet for nontropical sprue. All of these measures should help to prevent vitamin K deficiency.

TREATMENT

Treatment of vitamin K deficiency can be accomplished by oral administration of the purified vitamin, consumption of vitamin-K-rich foods, or parenteral injection of vitamin K. Water-soluble preparations of vitamin K are available. An oral dose of approximately 500 μg/day should correct vitamin K deficiency in terms of the coagulation profile and serum concentration of prothrombin. A poor or inadequate improvement of prothrombin time after vitamin K administration is generally indicative of severe underlying liver disease.

THIAMIN (VITAMIN B$_1$)

FUNCTIONS

Dietary thiamin functions as precursor of the coenzyme thiamin pyrophosphate, which by the process of oxidative decarboxylation converts α-ketoacids to aldehydes. These reactions are an important source of generating energy, and are widely distributed throughout intermediary metabolism. Thiamin pyrophosphate is also the coenzyme for transketolase, which converts xylulose-5-P0$_4$ and ribose-5-P0$_4$ to sedoheptulose-7-P0$_4$ and glyceraldehyde. The efficient generation of energy from oxidation of glucose requires adequate concentrations of thiamin pyrophosphate in the tissues.

More recent evidence suggests that thiamin has a role beyond that of coenzyme in regulating transmission of impulses in peripheral nerves. Some patients with peripheral neuropathy have been improved by thiamin administration. The metabolic role of thiamin in this proposed function is not well understood.

DEFICIENCY

Initial clinical presentations of thiamin deficiency are often subtle and nonspecific, comprising anorexia, general malaise, and weight loss. The typical Western diet is high in carbohydrate and may not be adequately matched in its thiamin content. An increase in carbohydrate content of the diet lowers the plasma and urinary levels of thiamin. Nonspecific symptoms of thiamin deficiency as it progresses are often followed by more intense weakness, peripheral neuropathy, headache, and tachycardia. When thiamin deficiency is far advanced, the patient usually exhibits prominent cardiovascular and neurological features.

Cardiac findings include an enlarged heart, tachycardia, edema, and ST-segment and T-wave changes. There is high-output failure due, at least in part, to peripheral vasodilatation. This clinical syndrome has a number of similarities to that of apathetic hyperthyroidism, with which it is often confused.

The central nervous system findings in advanced thiamin deficiency are those of the Wernicke–Korsakoff syndrome with vomiting, horizontal nystagmus, ataxia, weakness of the extraocular muscles, mental impairment, memory loss, and confabulation. There may be significant peripheral neuropathy as well. It is important to remember that the Wernicke–Korsakoff syndrome is not restricted to alcohol abuse and occurs with severe malnutrition, gastrointestinal disorders, and congestive heart failure. Some investigators have suggested that the reduction of thiamin pyrophosphate concentrations in brains of patients with Alzheimer's disease may have functional significance. Treatment of these patients with thiamin has been reported to be beneficial in some instances.

LABORATORY DIAGNOSIS OF DEFICIENCY

The diagnosis of thiamin deficiency is usually based on the analysis of this vitamin in blood by bioassay or by microbiological, chemical, or functional assays. In practice, urinary thiamin excretion and the erythrocyte transketolase are the most widely utilized assays of thiamin status. One must remember that urinary thiamin excretion reflects recent intake and may be increased after intake of diuretics.

The transketolase assay relies on an indirect measurement of the extent to which the apoenzyme is saturated with its coenzyme, thiamin pyrophosphate. When thiamin stores are depleted, addition of thiamin pyrophosphate *in vitro* to an erythrocyte lysate produces a large increase in measured enzyme activity. When the percentage increase in activity (activity coefficient) exceeds 15% to 20%, significant thiamin deficiency is diagnosed. Well-nourished individuals have much smaller activity coefficients when tested in a similar fashion. Lead intoxication lowers brain thiamin levels, and prompt thiamin treatment helps to restore brain thiamin levels while reducing brain lead levels.

PREVENTION

Thiamin deficiency can best be prevented by a diet consistently high in meat, grains, peas, beans, and nuts. Heating and treating vegetables with baking soda, which is alkaline, a practice often used to preserve the bright green colors, inactivates thiamin.

Intestinal absorption of dietary thiamin is very sensitive to alcohol. Persons who drink alcoholic beverages all day long, but never appear to be intoxicated, are nevertheless at risk for the development of thiamin deficiency. Thiaminases and antithiamin factors in raw fish, seafood, and other food items significantly break down dietary thiamin and may intensify the effects of a dietary deficiency. Polyphenols present in tea and coffee, when consumed excessively, may also inactivate dietary thiamin.

TREATMENT

Large doses of thiamin (50 to 100 mg) may be administered safely by the parenteral route in the acute syndrome, and the results are often dramatic, with rapid resolution of nystagmus. Following several days of treatment with doses at this level, treatment with 5 to 10 mg/day of thiamin is then appropriate. There is little, if any, toxicity when thiamin is given at levels of several times the RDI.

RIBOFLAVIN (VITAMIN B$_2$)

FUNCTIONS

To fulfil its metabolic functions, dietary riboflavin must be converted to its flavin coenzymes, flavin mononucleotide (riboflavin-5′-phosphate; FMN) and flavin adenine dinucleotide (FAD). In addition, several percent of flavins, such as monoamine oxidase, sarcosine dehydrogenase and succinate dehydrogenase, are bound covalently to tissue proteins. The flavin coenzymes as a group catalyze many different types of reactions, particularly oxidation-reduction reactions, dehydrogenations, and oxidative decarboxylation. Most importantly, flavin coenzymes are involved in the respiratory chain, lipid metabolism, the cytochrome P-450 system, and drug metabolism.

Riboflavin has antioxidant activity in its role as precursor to FAD, the coenzyme required by glutathione reductase. The glutathione redox cycle provides major protection against lipid peroxides. Glutathione reductase generates reduced glutathione (GSH) from glutathione (GSSG), which is the substrate required by glutathione peroxidase to inactivate hydrogen peroxide and other lipid peroxides. Thus, increased lipid peroxidation is a feature of riboflavin deficiency, and one that is not widely appreciated.

Some flavoproteins contain both FMN and FAD as coenzymes. Included in this category of biflavin enzymes are microsomal NADPH-cytochrome P450-reductase, nitric oxide synthase, and methionine synthase.

DEFICIENCY

Clinically, patients with advanced riboflavin deficiency exhibit seborrheic dermatitis, severe burning and itching of the eyes, abnormal vascularization of the cornea leading to cataract, cheilosis, angular stomatitits, anemia, and neuropathy. A smooth red tongue is classically observed in riboflavin deficiency (Figure 9.2), but is not pathognomonic of this deficiency.
FIGURE 9.2 **(See color insert following page 654.)** Adult female patient with advanced deficiency of riboflavin (vitamin B$_2$) illustrating large, red, smooth tongue, Paller and Cheelosis. (Photo courtesy of Elaine B. Feldman, MD.)

The clinical features of human riboflavin deficiency are not unique compared with the specificity of some aspects of vitamin C deficiency such as scurvy. The earliest symptoms of riboflavin deficiency include weakness and fatigue, mouth pain, itching eyes, and occasionally personality disorders.

The evolution of dietary riboflavin deficiency may be intensified by diseases, drugs, and endocrine disorders that block riboflavin utilization. The conditions in which such effects are observed include thyroid and adrenal insufficiency, treatment with the psychotropic drugs, chlorpromazine, imipramine, and amitriptyline; the antimalarial, quinacrine; and the cancer chemotherapeutic drug, adriamycin. Alcohol ingestion may be a significant cause of riboflavin deficiency by its interference with both its digestion from food sources and its intestinal absorption.

Riboflavin deficiency seldom occurs as an isolated entity, and is nearly always detected in association with deficiencies of other B vitamins.

LABORATORY DIAGNOSIS OF DEFICIENCY

Riboflavin and its derivatives can be analyzed precisely by high-performance liquid chromatography (HPLC). Other available techniques are not generally utilized in clinical practice. Urinary riboflavin excretion is reduced with long-term dietary deficiency, but may rise abruptly after recent intake of the vitamin. Therefore, the test must be run in the truly basal state. Collections have to be made carefully in subdued light and stored in dark bottles because of the light sensitivity of the vitamin.

A functional test, the erythrocyte glutathione reductase activity coefficiency (EGRAC), measures saturation of the enzyme with its coenzyme (FAD) by the same principle as that developed earlier to assess thiamin status with transketolase. The larger the increase in EGRAC noted after the addition of FAD *in vitro,* the greater the degree of unsaturation of the apoenzyme with its cofactor and the more severe the deficiency of riboflavin.

PREVENTION

Riboflavin deficiency can be prevented by maintaining a diet high in meat and dairy products, the major sources of the vitamin in the United States. Certain green vegetables, including broccoli, asparagus, and spinach, also contain significant quantities of riboflavin, as do fortified cereals. In developing countries, vegetables constitute the major sources of riboflavin.

It should be recalled that because of its heat and light sensitivity, considerable amounts of the vitamin can be lost when liquids are stored in clear bottles, when fruits and vegetables are sun-dried, and when baking soda is added to fresh vegetables to maintain color and texture. Under the latter conditions, riboflavin loss is accelerated by photodegradation.

Riboflavin has been reported to decrease the frequency of migraine attacks, the severity of lactic acidosis in AIDS patients undergoing therapy, and in rare genetic defects of the respiratory chain. The utilization of dietary folate requires adequate FAD, and for this reason, riboflavin (B_2) as well as B_6, B_{12}, and folic acids are needed to regulate homocysteine metabolism optimally.

TREATMENT

Treatment of clinical deficiency can be accomplished by oral intake of the vitamin. Levels greater than 25 mg cannot be completely absorbed as a single dose. This dose level is certainly safe to administer. The parenteral administration of riboflavin is limited by its low solubility. Riboflavin-5'-phosphate is more soluble than riboflavin, but is not usually available for clinical use.

A theoretical risk involved in treatment with riboflavin lies in its photosensitizing properties. *In vitro,* phototherapy results in DNA degradation and increased formation of lipid peroxides. Riboflavin forms an adduct with tryptophan and accelerates its photodegradation. The extent to which these observations have implications for conditions prevailing *in vivo* in humans needs to be elucidated.

NIACIN (SOMETIMES REFERRED TO AS VITAMIN B$_3$)

FUNCTIONS

Niacin is the dietary precursor of two important coenzymes, nicotinamide adenine dinucleotide (NAD) and nicotinamide adenine dinucleotide phosphate (NADP). Both coenzymes catalyze oxidation-reduction reactions, and are involved in a wide variety of reactions in intermediary metabolism. These reactions include glycolysis and lipid, amino acid, and protein metabolism.

DEFICIENCY

As with the other B vitamins, dietary deficiency of niacin generally occurs together with other vitamin deficiencies. An unusual aspect of niacin compared with other vitamins is that it is not obtained entirely from the diet. Niacin is formed from dietary tryptophan, an essential aromatic amino acid. Thus, high-quality protein sources tend to protect against niacin deficiency, and poor protein sources that are inadequate in tryptophan, such as corn, tend to accelerate niacin deficiency. For this reason, in parts

of the world where the diet is based primarily on corn or maize as the dietary staple without other varied sources of protein, pellagra can develop readily.

Alcoholism may result in niacin deficiency, as will drugs, such as isonicotinic acid hydrazide (isoniazid; INH), which interfere with niacin metabolism. The anticancer agent 6-mercoptopurine may produce severe niacin deficiency. One may also find niacin deficiency in the rare inborn error of Hartnup's disease and in the malignant carcinoid syndrome. In this syndrome, dietary tryptophan is diverted to the synthesis of serotonin at the expense of niacin.

Early manifestations of niacin deficiency are generally nonspecific, with anorexia, weight loss, weakness, and irritability. In later stages of deficiency, as pellagra, the patient may develop glossitis, stomatitis, characteristic scaling, and skin lesions, as shown in Figure 9.3 and Figure 9.4. Scaling skin lesions tend to be particularly prominent in sun-exposed areas, such as the arms, legs, and the V of the neck. In advanced disease, one may encounter "the four Ds": dermatitis, diarrhea, dementia, and death.

FIGURE 9.4 **(See color insert following page 654.)** Same patient as in Figure 9.3 showing hands with dark, scaly thickened skin lesions. (Photo courtesy of Elaine B. Feldman MD.)

LABORATORY DIAGNOSIS AND DEFICIENCY

In practice, the diagnosis of niacin deficiency can be established by assay of the urinary excretion of niacin metabolites, specifically *N*-methylnicotinamide, and, less commonly, 2-pyridone. Accurate determinations can be made by high-performance liquid chromatography (HPLC).

PREVENTION

As noted earlier, the diet needs to be adequate in protein of high biological value that contains tryptophan. Intake of meat and dairy products tends to assure adequate intake of tryptophan. A vegetarian diet may contain adequate amounts of niacin if it is sufficiently balanced and varied.

TREATMENT

The syndrome of niacin deficiency can be treated rapidly and effectively with oral administration of the vitamin. Doses in the range of 50 to 150 mg/day of nicotinamide are recommended to treat severe deficiency, and need to be maintained during the initial treatment period. Improvement is usually noted clinically after only a few days of treatment. The patient usually reports relief of pain and pruritis.

Niacin as a drug in the form of nicotinic acid is a first-line agent for the management of an abnormal serum lipid profile. Doses in the range of 1.5 to 6.0 g are administered daily. Niacin may be effective alone and in combination with other agents in lowering LDL-cholesterol, raising HDL-cholesterol, and reducing serum triacylglycerols (triglycerides). There may, however, be significant side effects noted at this dose range, including worsening of diabetes, abnormalities in liver function tests, elevation of the serum uric acid, and ocular abnormalities. Flushing may be troublesome to the patient, but is often transient. In most instances, the flushing can be minimized by taking a tablet of aspirin shortly before the niacin, taking a long-acting preparation of niacin, or taking the niacin at bedtime so that the flushing occurs as the patient sleeps.

The form of niacin selected for the improvement of the serum lipid profile is crucial. Nicotinic acid is the only form that is effective. Often patients choose niacinamide on their own from a health food store because it does not cause a flush. Unfortunately, it also does not benefit the abnormal serum lipid concentrations.

PYRIDOXINE (VITAMIN B$_6$)

FUNCTIONS

The role of vitamin B$_6$ is primarily that of precursor to pyridoxal phosphate. This coenzyme participates in a large number of reactions in intermediary metabolism, particularly transamination and decarboxylation. In addition, pyridoxal phosphate is involved in side-chain cleavage, dehydratase activity, and racemization of amino aids. These reactions relate to gluconeogenesis, lipid metabolism, immune function, cerebral metabolism, nucleic acid synthesis, and steroid hormone action. Deficiency of vitamin B$_6$ can lead to secondary deficiencies of other vitamins because it plays a role in the metabolic pathway leading to synthesis of niacin from tryptophan. Vitamin B$_6$, together with B$_{12}$, folic acid, and probably B$_2$, is involved in synthetic and degradative pathways of homocysteine metabolism.

Although some B$_6$ is present in the diet in the form of pyridoxal, the majority is in other forms. In plants, B$_6$ is present largely as pyridoxine, whereas animal sources comprise pyridoxamine as well as pyridoxal phosphate, and other forms.

DEFICIENCY

As with other B vitamins, isolated pyridoxine deficiency entirely on a dietary basis is seldom found. In some instances a marginal diet may result in overt deficiency if there are other complicating factors, such as the long-term use of specific pyridoxine antagonists. Two common examples of this effect are isoniazid and cycloserine, used to treat tuberculosis and generally prescribed for an extended period to eradicate the organism. In some individuals a genetic trait leads to delays in inactivating isoniazid; as a result, these patients become unusually susceptible to developing B$_6$ deficiency.

Pyridoxine deficiency is a common feature of chronic alcoholism, found in association with overall malnutrition and inadequate intake of many other vitamins and minerals. An unusual feature of the pathogenesis of B$_6$ deficiency in alcoholism is that the major effect of alcohol appears to be that of accelerating the rate of degradation of pyridoxal into its inactive metabolites, particularly pyridoxic acid.

B$_6$ deficiency is not recognizable as a distinct, pathogenomic clinical syndrome. Patients develop degrees of dermatitis, glossitis, cheilosis, and weakness. In more severe deficiency, patients may progress to have dizziness, depression, peripheral neuropathy, and seizures. The risk of kidney stones is increased because of hyperoxaluria. In children, B$_6$ deficiency is an important cause of anemia and seizures. Deficiency of B$_6$ causes a hypochromic, microcytic anemia that resembles the anemia due to iron deficiency.

The diagnosis of B_6-deficiency anemia is suggested when a bone marrow aspiration reveals that stainable iron, instead of being reduced as in iron deficiency, is normal or even increased in amounts.

In a group of rare genetic disorders, called pyridoxine dependency syndromes, large doses of B_6 are required for control of symptoms. Among these disorders are pyridoxine-dependent convulsions, cystathioninuria, and xanthurenicaciduria.

LABORATORY DIAGNOSIS OF DEFICIENCY

Vitamin B_6 can be measured directly in blood, with levels less than 50 ng/ml generally considered to represent deficiency. The measurement needs to be interpreted in the light of the patient's diet, as exceptionally high dietary protein intake depresses plasma pyridoxal phosphate levels, probably because of increased utilization of the coenzyme in protein and amino acid metabolism.

Urinary tests measure the excretion of metabolites of pyridoxine, most commonly 4-pyridoxic acid. Indirect assessments of vitamin B_6 deficiency can be made using functional assays of the enzymes aspartate or alanine aminotransferase with and without the addition of their cofactors *in vitro*. The principle of these assays is similar to that discussed earlier for thiamin and riboflavin deficiency. Activity coefficients greater than 1.2 for alanine aminotransferase and 1.5 for aspartate aminotransferase are generally considered as diagnostic of a deficient state.

At one time, a specific diagnosis of B_6 deficiency was made by measuring xanthurenic acid after a tryptophan load, inasmuch as B_6 is the coenzyme involved in the metabolic transformation. This procedure, although theoretically sound, is very laborious and has largely been abandoned in routine clinical diagnosis.

PREVENTION

Vitamin B_6 is widely available in the food supply and is found in vegetables, beans, (especially soy beans), meat, nuts, seeds, and cereals. A diet that is adequate and diversified in these dietary items will generally prevent vitamin B_6 deficiency. It is evident that this kind of diet will prevent deficiencies of the other B vitamins as well. Certain kinds of food processing, particularly heat sterilization, can result in significant losses of activity of vitamin B_6.

TREATMENT

Once vitamin B_6 deficiency is diagnosed, it can be satisfactorily managed at a level of 2 to 10 mg/day, which represents doses several times those of the RDI. Vitamin B_6 deficiency during pregnancy should be treated with higher doses in the 10 to 20 mg range because of the increased requirement at this time.

Vitamin B_6 is routinely advised during prolonged treatment with isoniazid, which is a pyridoxine antagonist. In doses of 50 to 100 mg/day, vitamin B_6 has been noted to reduce peripheral neuropathy without apparently lessening efficacy of INH against tuberculosis. In patients with Parkinson's disease receiving treatment with L-DOPA, too much pyridoxine will interfere with drug action; therefore, as a general rule, these large doses should not be taken unless there is a specific indication.

It is important not to exceed certain limits in therapeutic administration of vitamin B_6. Cases of sensory neuropathy have been occasionally noted in patients taking 1 to 2 g/day and noted rarely when taking only 500 mg/day. The genetic B_6 dependency syndromes can be managed on doses of 100 to 200 mg/day. There have been some encouraging reports that B_6 supplementation may be beneficial in managing premenopausal young women with depression. These findings require confirmation and extension in larger groups of depressed young women.

VITAMIN C (ASCORBIC ACID)

FUNCTIONS

Ascorbic acid serves in both oxidation and reduction reactions, based on the prevailing environmental conditions. Therefore, depending on circumstances, ascorbic acid may act as either an antioxidant or a prooxidant. An important function of ascorbic acid is that of preventing oxidation of tetrahydrofolate. Ascorbic acid is involved in collagen biosynthesis, wound healing, immune function, and drug metabolism. It enhances the intestinal absorption of nonheme iron. This vitamin is involved in the biosynthesis of neurotransmitters and carnitine.

Ascorbic acid concentrations in plasma are inversely related to markers of inflammation, such as C-reactive protein (CRP). Recent findings suggest that ascorbic acid may have anti-inflammatory effects in addition to its other actions.

DEFICIENCY

Dietary deficiency develops when the diet does not contain adequate amounts of citrus fruits, vegetables, and tomatoes, most commonly among the elderly and the urban poor. Vitamin C deficiency may also arise when there is food faddism or very limited food choices, behaviors that are commonly observed these days. The classical "tea and toast" diet, followed by some

elderly people, is particularly deficient in vitamin C. The macrobiotic diet may lead to scurvy both because of poor dietary sources as well as the practice of pressure-cooking food, which destroys ascorbic acid.

In infancy and childhood, a diet composed exclusively of unsupplemented cow's milk is deficient in vitamin C and may lead to scurvy. Chronic alcoholism at any age is associated with poor ascorbic acid intake, and if prolonged, will greatly increase the risk for development of scurvy.

The clinical symptoms of vitamin C deficiency develop slowly, and as with other vitamins, are often vague and nonspecific. Patients complain of weakness and fatigue, progressing to dyspnea and lethargy. The characteristic features of scurvy are not observed until the deficiency syndrome is well advanced. Bone and joint pain may occur because of hemorrhages in the subperiosteum. Perifollicular hemorrhages, especially in relation to hair follicles, are observed, as shown in Figure 9.5. Hairs may show a recognizable corkscrew pattern. Swollen, bleeding gums are observed in advanced deficiency, as shown in Figure 9.6, followed by loss of teeth. Pallor may be due to bleeding or reduced hematopoiesis. Scurvy results in poor wound healing and secondary breakdown of wounds that had healed previously. It is generally believed that clinical features of scurvy become evident after about 3 months without adequate intake of vitamin C, usually because of failure to consume fruits or vegetables.

FIGURE 9.5   **(See color insert following page 654.)** Adult female patient with advanced scurvy resulting from severe deficiency of vitamin C illustrating multiple perifollicular hemorrhages and sore corkscrew hairs. (Photo courtesy of Elaine B Feldman MD.)

SCORBUTIC GUMS
FIGURE 9.6   **(See color insert following page 654.)** Same patient as in Figure 9.5 showing bleeding, swollen gingeval tissues (Photo courtesy of Elaine B Feldman MD.)

Estimates of the prevalence of vitamin C deficiency in the United States were released in 2004, based upon the results of the Third National Health and Nutrition Examination Survey (HANES), conducted from 1988 to 1994. Evidence of early vitamin C depletion was found in 13% to 23% of the individuals surveyed and evidence of frank ascorbic acid deficiency in 5% to 17% of them. The highest risks for deficiency were found among smokers, non-Hispanic Black males, and persons who did not use nutritional supplements of any kind.

LABORATORY DIAGNOSIS OF DEFICIENCY

Ascorbic acid can be measured directly in the blood serum or plasma by a variety of chemical methods, most commonly spectrophotometric or fluorometric. Levels of 0.1 mg/dl or lower are generally indicative of vitamin C deficiency. Serum levels may be reduced in many chronic digestive disorders in smokers and in some women taking oral contraceptive drugs. Vitamin C concentrations may be measured accurately in leukocytes, but this assay is not commonly available.

Blood levels tend to segregate in a relatively narrow range in the face of very large differences in dietary intake. Megadoses of ascorbic acid remain almost entirely unabsorbed in the gastrointestinal tract, and what little is absorbed is rapidly metabolized by an efficient hepatic drug-metabolizing enzyme system. With its low renal threshold, ascorbic acid is excreted rapidly in the urine.

PREVENTION

Vitamin C deficiency can be prevented simply by consuming a diet adequate in citrus fruits and vegetables. Consuming orange juice with meals may be a healthy habit that increases the intestinal absorption of nonheme iron several-fold. Avoiding heating or prolonged storage of foods containing vitamin C can also help maintain adequate concentrations. Educating people about the potential hazards of a macrobiotic diet, food faddism, and sharply limited food choices should also help to prevent scurvy in the general population.

The prevention of scurvy may be accomplished by ingestion of very small amounts of ascorbic acid. Some authorities believe that doses as low as 10 mg/day may be effective. The maintenance of an adequate vitamin C status has generally been considered to be in the 40 to 60 mg range, as reflected in the RDI.

Recently it has been proposed that the optimal intake of ascorbic acid should be one that not only prevents deficiency but also achieves full concentrations in tissue stores. Based on these assumptions, daily doses of 100 to 200 mg/day may be needed. To achieve this level of intake, major public health efforts will need to be made, particularly to reach the urban poor.

TREATMENT

Doses of ascorbic acid as low as 10 mg/day, as noted earlier, may prevent scurvy and can achieve benefits in treatment. In advanced cases, a dose range of 100 to 200 mg/day orally may be administered safely and effectively, with therapeutic benefit evident within a few days. As noted earlier, it has been proposed that these larger doses need to be maintained to achieve tissue saturation. Meat sources containing heme iron are more bioavailable than the nonheme iron present in vegetables. As noted, the efficiency of absorption of nonheme iron can be greatly improved by simultaneous consumption of orange juice.

Megadoses of vitamin C have been given to patients with advanced cancer, but their anticancer efficacy is unproven. Vitamin C has also been advocated to prevent cancer, because its content in fruits and vegetables may be part of the reason that cancer prevalence is reduced in patients who consume several servings a day. One must keep in mind, however, that fruits and vegetables contain many other beneficial phytochemicals whose full potential is only beginning to be explored. There is also a suggestion from some *in vitro* studies that large amounts of vitamin C may not be advisable in terms of possibly accelerating tumor metabolism.

There is some risk for toxicity in doses greater than 1 to 2 g/day in a highly individual fashion. Gastrointestinal upset may occur. Inasmuch as oxalic acid is a direct metabolite of ascorbic acid, the risk of kidney stones theoretically should be increased with large doses of ascorbic acid. The exact prevalence of symptomatic stone formation after ingestion of variable doses of vitamin C is not known with certainty.

Caution in administering vitamin C should be followed when giving it to individuals with hemochromatosis or those at risk for this disorder, as the intestinal absorption and tissue storage of iron may be increased excessively. As the gene for hemochromatosis is one of the most common genetic abnormalities known, there may be risk associated with indiscriminate use of megadoses of ascorbic acid supplements by the general population.

VITAMIN D

See Chapter 64 on calcium in bone health and Chapter 10 on calcium and vitamin D in dietary supplements.

10 Potential Benefits for the Use of Vitamin and Mineral Supplements

Richard Cotter, Judith Moreines, and Leon Ellenbogen

CONTENTS

INTRODUCTION

Emerging scientific evidence suggests that vitamins and minerals provide health benefits that may go beyond the repletion of potential nutritional deficiency states. This science indicates that these benefits may be conveyed by intakes at or above recommended daily allowances. For some of these health benefits, the scientific evidence base is convincing, while support for the potential benefits are just emerging for others. In many cases, the association between a particular vitamin and mineral and its beneficial effects is derived from nutritional epidemiological studies. Intervention studies are either underway, or are warranted, in order to demonstrate a casual nutrient benefit link. Additionally, in the case of multivitamin supplementation, further investigation is needed in order to determine and characterize the nutrient or nutrient interactions that may produce a particular beneficial effect. What follows is an up-to-date description of the emerging benefits of vitamins and minerals and the scientific support for each.

As the increasing importance of nutrients and their health benefits become known, the need to update the science surrounding these nutrients became apparent. The U.S. Food and Nutrition Board, Institute of Medicine, National Academy of Sciences undertook such a review between 1997 and 2004, publishing the updated science series, "Dietary Recommended Intakes," in which all of the essential vitamin and minerals were reviewed. In addition, various health agencies and related organizations continue to recognize the importance of good nutrition and issue recommendations for vitamin and mineral supplementation and food fortification. These include the U.S. Public Health Service, Centers for Disease Control, the National Osteoporosis Foundation, and the Department of Health and Human Services, who, in 2005, issued the "Dietary Guidelines for Americans" for 2005. Internationally, many agencies and organizations have, and are, issuing similar guidelines.

VITAMIN A

Dietary antioxidants, including carotenoids and vitamin A, are hypothesized to decrease the risk of age-related cataracts and age-related macular degeneration (AMD) by preventing oxidation of proteins or lipids within the lens.[1,2] Information on the role of vitamins in eye disease is discussed in Chapter 58.

Vitamin A deficiency appears to be common in individuals with HIV infection. Low levels of vitamin A are associated with greater disease severity.[3,4] Transmission of the virus from mothers deficient in vitamin A to their infants has been reported.[5] However, there have been no intervention studies to determine whether vitamin A supplementation is helpful. However, recent studies in HIV infected women have demonstrated a reduction in the progression of this disease as a result of daily multivitamin supplementation.[6]

The potential benefit of vitamin A therapy for measles was first reported in 1932,[7] and a recent study in South African children under 13 years of age showed that large doses (400,000 IU) of vitamin A resulted in lower complication rates and mortality. Low vitamin A levels are associated with the highest mortality in young children with measles.[8] WHO, UNICEF, and the American Academy of Pediatrics recommend that children with measles be examined for vitamin A deficiency.

Large quantities of analogs of vitamin A, on the order of 300,000 IU/day for females and 400,000 to 500,000 IU/day for males, have been used successfully to treat a severe type of acne known as cystic acne.[9] However, such high doses of vitamin A are potentially toxic, and topical retinol therapy is more appropriate.

Vitamin A is needed for the growth and repair of cells that line both the small and large intestines. Over the years, reports have appeared of individuals with Crohn's disease responding to vitamin A therapy at a dose of 50,000 IU/day.[10–12] See Table 10.1 and Table 10.2 for the established and potential benefits of vitamin A.

Although Vitamin A has been shown to have many of the positive benefits indicated above, one should be cautious of the long-term use of vitamin A supplements greater that approximately 6000 IU, since a series of studies indicate such supplementation may result in accelerated bone resorption.[13–15]

β-CAROTENE

Based on the unanimous recommendation by health professionals that diets rich in fruits and vegetables may help reduce the risk of cancer, heart disease, and diabetes, scientists have started to identify the components in these foods that are responsible for the health benefits. Because β-carotene is one of the more abundant carotenoids in fruits and vegetables, it dominated the research on carotenoids in the 1980s, following the report published in *Nature* by Dr. Richard Peto et al., titled "Can dietary β-carotene materially reduce cancer rates?"[16] See Table 10.3 for the established benefits of β-carotene.

In addition to extensive epidemiological data, β-carotene showed strong promise in laboratory studies with cancer cells and animals (see Albanes and Hartman, *Antioxidants and Cancer*,[17] for the long list of epidemiological studies). The results of three

TABLE 10.4
Important *β*-Carotene Cancer Trials

α-Tocopherol, *β*-Carotene Cancer Prevention Study[18] (ATBC Study) — also called the Finnish study	29,133 male smokers, 50 to 69 years of age	50 mg vitamin E, 20 mg *β*-carotene or both for 5 to 8 years	No evidence of prevention of lung and other cancers. *β*-carotene group had a 16% greater incidence of lung cancer in smokers
β-Carotene and Retinol Efficacy Trial[19] (CARET)	18,314 men and women smokers and former smokers	25,000 Iu vitamin A, 30 mg *β*-carotene	Increase of 28% in lung cancer and 17% in cancer mortality
Physicians' Health Study[20] (PHS)	22,071 males, mainly nonsmokers	50 mg *β*-carotene every other day for 12 years	No effect on cancer rates for prostate, bowel, or lung or for overall incidence of cancer or mortality

major double-blind, randomized, placebo-controlled clinical studies, however, were surprising and perplexing in that not only was there no cancer benefit shown, but in both the ATBC and the CARET study, the data actually indicated potential risk for smokers and asbestos workers.[18,19] The Physicians Health Study (PHS), on the other hand, using higher levels of *β*-carotene, showed no such risk[20] (see Table 10.4).

The conclusions demonstrating a potentially adverse effect of *β*-carotene in smokers were questioned because of the evidence from epidemiological and basic biochemical studies whose results were contrary. It has been suggested that the very high doses of *β*-carotene used in the above studies might have interfered with the absorption of carotenoids other than *β*-carotene.

Several ongoing intervention studies may help clarify the inconsistency of these findings. The Chinese Cancer Prevention Study[21] evaluated *β*-carotene (15 mg), vitamin E (30 mg), and selenium (50 *μ*g) and found an insignificant 10% decrease in cerebrovascular mortality in a group receiving treatment compared to that of an untreated group. There was a 13% reduction of borderline significance in total cancer mortality in the treated group and a 21% reduction in gastric cancer, which was significant. Because *β*-carotene was evaluated in combination with other nutrients, it is not possible to isolate the effect attributable to *β*-carotene alone. Other nutrients may have had an effect in the poorly nourished group included as study subjects, and results may not be applicable to well-nourished individuals.

Several smaller studies of *β*-carotene and premalignant lesions have shown interesting preliminary results. A 66% reduction in the frequency of premalignant buccal micronuclei was observed after supplementation of 26 mg of *β*-carotene for 9 weeks.[22] A 71% reduction was observed in patients with oral leukoplakia after a 6-month intake of 30 mg/day of *β*-carotene.[23]

Apart from cancer prevention, *β*-carotene has been studied for its effect in coronary heart disease and cataract. A subgroup of the PHS, which included 333 physicians with unstable angina or a prior coronary revascularization procedure, had a 20 to 30% reduction in vascular disease associated with treatment. High dietary intakes of *β*-carotene were found to be associated with a decreased risk of myocardial infarction in the Rotterdam study, which investigated the dietary intakes of 4802 elderly men and women over the course of 4 years.[24]

A similar effect was not seen for either vitamins C or E. See Table 10.5 for emerging benefits of *β*-carotene. The results of several additional important prospective studies are included in Table 10.6.

People with low blood levels of antioxidants and those who eat few antioxidant-rich fruits and vegetables are at high risk for cataract.[28,29] See information in Chapter 58 on eye disease.

Lycopene is an antioxidant carotenoid found commonly in tomatoes. Although not a vitamin per se, or a provitamin (for vitamin A), specific benefits of lycopene are beginning to be elucidated, particularly with respect to certain cancers. Of particular note is an observational finding that high intakes of tomato products containing lycopene are associated with lower rates of prostate cancer. An excellent overview by Giovannucci[30] covers lycopene and the epidemiological evidence supporting its currently known health benefits in the prevention of cancer.

Lycopene has also more recently been associated with cardiac benefits. As the most powerful antioxidant of the carotenoid family, it has naturally aroused interest in the cardiac community. A complete overview of this emerging area can be found in a review by Rao.[31]

Lutein, another carotenoid that is found in large amounts in fruits and vegetables, is as important in eye health for the prevention of both age-related macular degeneration and age-related cataracts. See chapter 58 for further discussion of these benefits.

Massachusetts Elderly Cohort Study[27]				
β-Carotene Intake and Risk of Cardiovascular Disease				
Endpoint				
CVD death			0.57	.02
Fatal MI			0.32	.02

Further, lutein is found in high concentrations in the skin, where it appears to offer a mild sun protection benefit based on its antioxidant nature.[32]

In conclusion, basic metabolic research, as well as animal and epidemiological studies, all suggests major benefits from carotenoids. These benefits, however, have yet to be confirmed in double-blind intervention studies.

RIBOFLAVIN

Deficiency of riboflavin, a precursor of flavin adenine dinucleotide, has been believed by some to be associated with cataract formation.[33,34] Lenticular reduced glutathione, diminished in all forms of human cataract, requires flavin adenine dinucleotide as a coenzyme for glutathione reductase. Despite this putative connection with riboflavin, clinical results of studies in this area are equivocal, and the degree of riboflavin deficiency encountered in the general population would not be considered to be cataractogenic. Clinically, lower intakes of riboflavin are not found to be a risk factor for cataract.[35,36]

Review of riboflavin requirements associated with exercise in several different study groups yields equivocal results. Aerobic exercise may deplete riboflavin as well as other B-vitamins.[37] However, riboflavin status, assessed using erythrocyte glutathione reductase activity coefficient, shows that while riboflavin requirements of women increase with exercise training, additional riboflavin intake does not enhance or result in improvements in endurance.[38,39] Additionally, riboflavin depletion is not related to the rate or composition of weight loss in overweight women.[40] Interestingly, in a cohort of pregnant women who exercised and took vitamin-mineral supplements, participation in a walking program slightly improved aerobic capacity without affecting riboflavin or thiamin status.[41]

Minimal data are available from one study of high doses (400 mg/day) of riboflavin that successfully treated migraine patients.[42]

Riboflavin has recently emerged as playing a role in the folate one carbon methylation pathways, which, in association with vitamin B_{12} and B_6, may decrease the risk of heart disease. This due to their combined role in reducing the levels of homocysteine,

TABLE 10.7
Riboflavin — Established Benefits

Essential for building and maintaining body tissues
Necessary for healthy skin
Prevents sensitivity of the eyes to light
Necessary for protein, fat, and carbohydrate metabolism
Important for the proper function of the nervous system

Niacin — Potential Benefits

Use	Findings	Reference
Hypercholesterolemia	Lowers elevated cholesterol levels	44–47
Hypertriglyceridemia	Lowers elevated triacylglycerol levels	44

an amino acid when present at high levels is associated with increased risk of cardiovascular disease.[43] Riboflavin deficiency has also been reported as playing an important role in overcoming genetic polymorphisms of the folate pathway important in the prevention of birth defects. Further work in this area is needed. See Table 10.7 and Table 10.8 for established and potential benefits of riboflavin.

NIACIN

The body uses niacin in the process of releasing energy from carbohydrates, to form fat from carbohydrates, and to metabolize alcohol. Niacin comes in two basic forms: niacin (also called nicotinic acid) and niacinamide (also called nicotinamide).

High levels of niacin — usually several grams per day — lower cholesterol, triglyceride, and triacylglycerol levels and raise HDL cholesterol levels.[44] The niacinamide form, commonly found in multivitamin preparations, does not decrease elevated cholesterol. See Table 10.9 and Table 10.10 for established and emerging benefits of niacin.

A variation of niacin, called inositol hexaniacinate, has also been used and has not been linked with the flushing seen with high doses of niacin. Physicians in Europe sometimes prescribe it to help lower cholesterol. Dosages used are 500 to 1000 mg, taken three times a day.[45,46] This form of niacin lowers serum cholesterol but appears to have fewer side effects.[47] A form of sustained release niacin (Niaspan®) is available on the U.S. market, by prescription only. It is again aimed at providing the cholesterol benefits of niacin, while reducing the potential of the flushing side effect.

VITAMIN B$_6$

Vitamin B$_6$ has a significant role to play, along with folate and vitamin B$_{12}$, in the reduction of elevated homocysteine levels associated with increased risk of cardiovascular disease — specifically, coronary artery disease and stroke. This topic is covered in the section on folate.

Vitamin B$_6$ also plays a significant role in the immune function of the elderly. *In vitro* indices of cell-mediated immunity in healthy elderly adults indicate that deficiency of vitamin B$_6$ is associated with impairment of immune function. This impairment appears to be reversible with vitamin B$_6$ repletion.[48] The levels of vitamin B$_6$ absorption, phosphorylation, and excretion appear not to be affected by age.[49]

Vitamin B$_6$ has been shown to reduce the preovulatory side effects of estrogen in animals. Since excess estrogen may be responsible in part for premenstrual symptoms (PMS), a number of studies in humans have demonstrated that 200 to 400 mg of vitamin B$_6$ per day for several months can relieve symptoms of PMS.[49–53] In other studies, however, the amount of vitamin B$_6$ used may be too low,[54] or the length of the trial too short,[55] and other studies have not found vitamin B$_6$ so helpful.[56,57]

Many diabetics have low blood levels of vitamin B$_6$.[58,59] Levels of vitamin B$_6$ are even lower in diabetics with nerve damage.[60] Vitamin B$_6$ supplements have been demonstrated to improve glucose tolerance in women with diabetes associated with pregnancy.[61,62] Vitamin B$_6$ is also partially effective for glucose intolerance induced by birth control pills.[63] For some individuals with diabetes, a form of vitamin B$_6$ — pyridoxine α-ketoglutarate — improves glucose tolerance dramatically.[64]

It appears that many people with carpal tunnel syndrome (CTS) have vitamin B$_6$ deficiencies.[67] Some studies show that people with CTS are helped when given 100 mg of vitamin B$_6$ three times per day.[68,69] Although a few researchers have found benefits with lesser amounts,[70–72] the results have not been consistent.[73–75]

Lastly, it is worth noting that vitamin B$_6$ deficiency was found in more than one-third of HIV-positive men, and a deficiency of this vitamin is associated with decreased immune function.[76] See Table 10.11 and Table 10.12 for established and emerging benefits of vitamin B$_6$.

VITAMIN B$_{12}$

Higher blood levels of vitamins B$_6$, B$_{12}$, and folic acid are associated with low levels of homocysteine,[77] and supplementing with these vitamins helps to lower homocysteine levels.[78,79] Preliminary evidence indicates that vitamin B$_{12}$ may be beneficial when included in supplements or in a food-fortification regimen together with folic acid. This topic is discussed further in the section on folate.

The addition of vitamin B$_{12}$ enhances the homocysteine-lowering potential of a folic acid supplement. In one study, female volunteers were given folic acid alone or folic acid combined with one of two supplements containing different doses of vitamin B$_{12}$. Significant reductions in plasma homocysteine were observed in all groups receiving vitamin treatment. The combination of folic acid 400 μg plus 400 μg of vitamin B$_{12}$ resulted in an 18% decrease in homocysteine levels. This was significantly larger than that obtained with a supplement containing folic acid alone (homocysteine decrease of 11%). Folic acid in combination

TABLE 10.11
Vitamin B$_6$ — Established Benefits

Important in protein absorption and metabolism
Necessary for red blood cell formation
Necessary for the proper function of the nervous and
  immune systems
Helps maintain healthy teeth and gums
Needed for serotonin and melatonin production

TABLE 10.12
Vitamin B$_6$ — Potential Benefits

Use	Findings	Reference
Immune function	Improves immune function in the elderly	48, 49
Premenstrual symptoms	High doses administered long-term may be helpful	50–57
Diabetes	Low levels are associated with diabetes	58–66
Carpal tunnel syndrome	Inconsistent results	67–75
HIV	Deficiency frequently found and associated with decreased immune function	76

with a low vitamin B_{12} dose (6 μg) affected homocysteine as well (decrease of 15%). These results suggest that the addition of vitamin B_{12} to folic acid supplements or enriched foods helps maximize the reduction of homocysteine and may thus increase the benefits achieved with the use of folic acid in the prevention of vascular disease.[80] The cardiovascular and cerebrovascular intervention trials were B_{12}, $B_{6,}$ and folate. These nutrients have been shown to reduce homocysteine levels, but not reduce the risk of secondary events.

However, one recent trial reanalyzed the VISP results with respect to association of homocysteine and stroke. A subset of the study population who were initially deficient in B_{12}, then as study participants received 0.4 mg of B_{12} daily for 7 years, showed both a lowering of homocysteine as well as of stroke risk by 23%.[81] Thus, many of the negative trials may need to be reevaluated based on the participants' B_{12} sufficiency and the level of B_{12} that was administered.

Recently, a very important study was published that did not get the attention it deserved. This was a national, population-based, cohort study, conducted by the Centers for Disease Control and Prevention. In this study they compared the stroke occurrence prior to folate fortification of grain (1990 to 1997) in both the United States and Canada to the period after fortification (1998 to 2002).

This was a quasi-experimental intervention, because the entire populations of both of these countries were exposed to folate fortification. These populations were then compared with the populations of England and Wales, who were not exposed to folate fortification. As expected, the folate levels increased and homocysteine levels declined in the fortified populations. The ongoing decline in stroke mortality observed in fortified populations prior to fortification accelerated post fortification with an overall change in the United States from –0.3 to –2.9% (p = .0005) and in Canada from –1 to –5.4% (p = .0001). This is equal to a combined effect of preventing of 15,700 fewer stroke deaths per year. In contrast, the decline in stroke mortality in England and Wales did not change significantly during this period.[82] Thus, many of the negative trials may need to be reevaluated based on their power to detect cardiovascular events and focus on the potential stroke effect that may be easier to demonstrate based on the sufficiency of B_{12} in participants and the level of B_{12} that was administered.

Lastly, vitamin B_{12} has a role in preventing vitamin B_{12} deficiency in the presence of folate use, especially in light of the increased fortification of foods with folic acid. (See rationale by Oakley.[83]) Table 10.13 and Table 10.14 lists the established and potential benefits of vitamin B_{12}.

FOLIC ACID

For the last 40 years, folic acid has almost exclusively been used to treat megaloblastic macrocytic anemia. There is now significant evidence that folate deficiency is associated with increased risk of several diseases. The most convincing is the association of folic acid deficiency with neural tube defects (NTDs) such as spina bifida and anencephaly, a predisposition to occlusive vascular disease associated with hyperhomocysteinemia, and several neoplastic or preneoplastic diseases. In addition, preliminary evidence suggests some association of folate deficiency with neuropsychiatric diseases.

The British Medical Research Council conducted studies on folate and NTDs in 1991.[84] These demonstrated that high-dose folic acid supplements (4.0 mg/day) used by women who had a prior NTD-affected pregnancy reduced the risk of having a subsequent NTD-affected pregnancy by 70%. A conclusive trial conducted in Hungary showed that a multivitamin containing 0.8 mg folic acid protected against a first occurrence of NTD.[85]

TABLE 10.13
Vitamin B_{12} — Established Benefits

Necessary for DNA synthesis
Helps prevent pernicious anemia
Helps to form red blood cells
Enhances utilization of nickel

TABLE 10.14
Vitamin B_{12} — Potential Benefits

Use	Findings	Reference
Hyperhomocysteinemia	Alone and together with folate reduces homocysteine levels	77–80
Folate-induced vitamin B_{12} deficiency	Administration helps unmask vitamin B_{12} deficiency associated with folate use	83

In 1992, the Centers for Disease Control (CDC) in the United States issued a recommendation that all women of childbearing age, capable of becoming pregnant, should consume 0.4 mg of folic acid per day to help prevent NTDs.[86] The U.K. Expert Advisory Group and other countries in Europe made similar recommendations.[87] The U.S. Food and Drug Administration has recently authorized a health claim on food labels and dietary supplements that folic acid contained in these products may help reduce the risk of NTD.[88] More recently, two major studies one in Europe[89] and one in the United States by the CDC[90] have implicated folate in other classes of birth defects. These classes cover a far greater number of birth defects than just neural tube defects. The most interesting findings in these two studies were the similarities in the data; both showed the relationship and magnitude of folate to the same classes of birth defects in both populations studied (Table 10.16).

A large body of evidence reveals that elevated blood homocysteine is a risk factor for cardiovascular disease, including atherosclerotic coronary heart disease and thromboembolic stroke. There is abundant evidence that folate deficiency or a genetic defect in the enzymes involved in homocysteine metabolism give rise to hyperhomocysteinemia. In addition to folate deficiency, vitamin B_6 and B_{12} deficiency has also been associated with elevated homocysteine levels. Patients with higher blood levels of these vitamins are at lower risk for occlusive vascular disease.[91]

Many studies show that folic acid alone or in combination with vitamins B_6 and B_{12} can reduce blood homocysteine levels.[92–101] Observational studies have shown that people who consume multivitamins or cereal fortified with folic acid also have reduced homocysteine levels.[102–106]

Levels of supplemental folic acid as low as 0.4 mg appears to be effective. A meta-analysis of 12 randomized trials confirms that folic acid has the dominant blood-homocysteine-lowering effect.[101] The fortification of enriched grain with folic acid has been shown to increase folate plasma levels and decrease homocysteine levels in middle-aged and older adults.[105] While folic acid fortification was undertaken primarily to reduce the risk of NTDs, it may also have a beneficial effect on vascular disease. This possibility is strongly indicated in the results of recent data on stroke collected by the CDC in both fortified and nonfortified populations .[82]

Based on a meta-analysis of 27 studies relating homocysteine to vascular disease and 11 studies of folic acid effects on homocysteine levels, Boushey and Beresford[92] concluded that an increase of 350 μg/day of folate intake by men and 280 μg/day increase by women could potentially prevent 30,500 and 19,000 vascular deaths annually in men and women, respectively. Recent reports show that a small percentage of children, with or without a positive family history of cardiovascular disease,[107–109] have elevated homocysteine levels. Hyperhomocysteinemia may also be a risk factor for ischemic stroke in children. The data on children suggest that tracking of homocysteine levels from childhood on may be helpful in the planning and evaluation of future initiatives aimed at the prevention of cardiovascular disease.

While it has been shown that higher intake of folate may reduce homocysteine levels and that lower homocysteine levels are associated with reduced cardiovascular mortality, clinical intervention trials are needed to prove unequivocally that higher intakes of folate will help reduce the risk of cardiovascular disease. In a preliminary report, a vitamin mixture of 2.5 mg of folic acid, 25 mg vitamin B_6, and 250 μg vitamin B_{12} stopped the progression of carotid plaques; some regression was also observed.[111] Excellent detailed reviews on homocysteine and vascular disease have been published.[112–116] Hankey and Eikelboomb [110] have published an excellent review of prospective cohort and case-control studies, as well as cross-sectional and retrospective case-control studies concerning the association between homocysteine and cardiovascular risk.

The intervention trials that have been conducted to date Vitamin Intervention for Stroke Prevention (VISP)[117] trial and the recently presented NORVIT and HOPE TWO trials[118,119] have been disappointing. However, as VISP was conducted in a fortified population and NORVIT was are based on treatment of secondary events rather than primary prevention, the question of whether lowering homocysteine prevents cardiovascular disease remains unanswered. The most promising double blind randomized controlled studies in this area are those that have been conducted on patients who have undergone angioplasty and are then studied for their rate of restenosis. A number of studies[120,121] conducted using this human model show a positive effect of folate. In one trial, folate reduced homocysteine and reduced the rate of restenosis by up to 48% in balloon angioplasty only; while in another trial, a trend of 14% reduction was seen in stented lesions with folate supplementation. Further, homocysteine-lowering therapy provided an additional benefit of a 40% relative reduction in major adverse events at six months in these studies. The mechanism of restenosis in balloon angioplasty compared with that in stent restenosis differ; consequently, the failure of folate in one condition may not preclude success in the other. There are currently some large international intervention trials in place to further evaluate the causal relationship of folate, homocysteine, and cardiovascular disease. Hopefully, these trials will help answer the question in the next few years.

Several reports suggest an increased risk of colon, tracheobronchial tree, and cervical cancer, and preneoplastic dysplasia associated with folate deficiency.[122,123] Supplemental folic acid has been shown to partially reverse some cervical dysplasia.[122,124] In some instances, poor folate status may not by itself be carcinogenic, but it may predispose to the carcinogenicity of other agents.[125,126]

Lashner and Heidenreich[126] reported that the rate of colon cancer was 62% lower in patients with ulcerative colitis who were supplemented with folic acid. Giovannucci and Stampfer[127] examined the relationship between the intake of folate, both from supplements and food, and the risk for colon cancer in women in the Nurses Health Study. The results indicate that the use of multivitamin supplements for 15 or more years may decrease the risk for colon cancer by about 75%. The data are consistent

with the hypothesis that folate intake is the principal nutritional factor associated with risk reduction. These findings support several recent studies, including the Health Professional Follow-Up Study, which have found a higher risk for colon cancer among persons with low folate. In the Giovannucci report, the association between colon cancer and folate was stronger with supplemental than with dietary folate. This is probably due to the fact that food folate is less bioavailable than supplemental folate. More recently, Zhang and Hunter[128] reported that the excess risk of breast cancer associated with moderate alcohol consumption might be reduced by folate. Alcohol is a known folate antagonist, and this could increase the requirement for folate.

Blount et al.[129] presented data on the possible mechanism by which folate deficiency enhances cancer risk. Folate deficiency results in abnormal DNA synthesis due to misincorporation of uracil into DNA, leading to chromosome breakage. This breakage contributes to the risk of colon cancer.

FOLATE AND DEMENTIA

Prevention and treatment of age-related cognitive impairment and dementia are challenging to the health care system. Products that may help reduce the risk of slow the progression of these disabling events would provide great public health benefits. Several epidemiological studies report that elevated homocysteine levels appear to be correlated with an increased risk of cognitive decline and cerebral atrophy in normal and demented elderly adults.[130–145] Hence, scientists have postulated that lowering homocysteine by supplementation with folic acid, B_6, and B_{12}, may reduce the risk of cognitive decline and dementia, or at least slow the process.[132,146]

Few intervention trials, to determine if lowering homocysteine via B-vitamin supplementation reduces the risk of cognitive decline via B-vitamin supplementation, exist. No studies to date have been conducted in healthy populations. However, two open intervention trials examined supplementation with B-vitamins on cognitive function in the demented elderly. One intervention failed to show an improvement in cognitive function after treatment with folate, B_{12}, and B_6 for approximately nine months in individuals with high homocysteine levels (defined as >13.5 nmol/l).[147] However, another clinical trial found that supplementation with folate and B_{12} for 2 months in individuals with homocysteine levels >19.9 nmol/l could greatly improve cognitive function .[148] This suggests that B-vitamin supplementation may be more effective in treatment of dementia in individuals with higher homocysteine levels (~20 nmol/l). See Table 10.15 and Table 10.16 for the established and potential benefits of folate.

Data to help elucidate the role of folate in Alzheimer's disease and depression are sparse and just emerging. Low blood levels of folate and vitamin B_{12} are often found in individuals with Alzheimer's disease.[149] The role of elevated homocysteine levels has been reported and needs to be expanded further.[150] Low folate blood levels may be associated with the weaker responses of depressed patients to antidepessants.[151] Factor contributing to low serum levels among depressed patients, as well as the circumstances under which folate may have a role in antidepressant therapy, must be further clarified.

VITAMIN C

Vitamin C has many functions in the body, including serving as an antioxidant and as a cofactor for several enzymes involved with biosynthesis.[152] The relationship between vitamin C and total serum cholesterol has been investigated in several studies.[153–158]

TABLE 10.15
Folic Acid — Established Benefits

Necessary for DNA synthesis
Important for cell formation
Prevents certain types of anemias
Neural tube defects
Helps maintain the function of the intestinal tract

TABLE 10.16
Folic Acid — Potential Benefits

Use	Findings	Reference
Neural tube defects	0.4 mg/day prevents neural tube and other common birth defects	84–89
Hyperhomocysteinemia	Lowers homocysteine levels	91–115
Cancer	Deficiency is associated with an increased risk of colon, lung, and cervical cancer	116–128
Cognitive function	Low levels are associated with risk of cognitive decline and dementia	130–145

In one intervention study, consumption of 1000 mg of vitamin C per day for 4 weeks resulted in a reduction in total serum cholesterol.[155] In another study, supplementation with 60 mg/day for 2 weeks had no effect.[153] Two observational studies found an inverse relationship between vitamin C status and total serum cholesterol concentrations.[157,158]

Low concentrations of plasma vitamin C have been associated with hypertension.[157,159–162] Several studies have reported beneficial effects of the administration of high doses of vitamin C on vasodilation.[163–166] One study found a 128% increase in brachial artery dilation in coronary artery disease patients, while a second found an insignificant increase of 27% in chronic heart failure patients.[166] Infusion of 10 mg of vitamin C per minute was observed to effect a 100% reversal of epicardial artery vasoconstriction in coronary spastic angina patients.[167]

Some prospective cohort studies have shown that vitamin C intake is associated with reduced cardiovascular disease risk. A recent analysis from the Nurses Health Study indicates that women in the highest quintile had a 27% lower risk of coronary heart disease, and women taking vitamin C supplements had a 28% lower risk of nonfatal MI and fatal CHD compared with women who took no vitamin C. Table 10.17 (adapted from Carr[185]) lists prospective cohort studies of vitamin C intake associated with reduced cardiovascular disease risk. There is, however, no long-term, controlled-intervention studies using supplemental vitamin C alone which show that supplemental vitamin C prevents heart disease. The recent review from the American College of Cardiology Task Force concludes that vitamin C is not effective in preventing CHD.[168]

As an antioxidant, vitamin C may protect against cancer through several mechanisms, including inhibition of DNA oxidation. One potential mechanism is chemoprotection against mutagenic compounds such as nitrosamines.[169,170] In addition, vitamin C may reduce carcinogenesis through stimulation of the immune system, via a beneficial effect on phagocyte functions, such as chemotaxis,[171–174] or on the activity of natural killer cells and the proliferation of lymphocytes.[175–177]

Two recent prospective studies reported increased total cancer in men but not women with low serum vitamin C levels.[178,179] Recent studies also reported an inverse association between dietary vitamin C and oral cancer,[180] gastric cancer,[181] and premenopausal breast cancer.[182] However, a recent cohort study showed no relationship with vitamin C intakes, and a prospective study showed no association between prediagnostic vitamin C levels and breast cancer risk.[183,184] These are no controlled intervention studies using vitamin C alone that show supplemental vitamin C can prevent cancer (Table 10.18).

TABLE 10.17
Vitamin C Intake Associated with Reduced Cardiovascular Disease Risk (Prospective Cohort Studies)

Reference	Population (Duration in Years)	Endpoint (Events)	Risk and Associated Dietary Intake of Vitamin C
Enstrom[186]	3119 Men and women (10 years)	CVD (127 deaths)	>250 compared with <250 mg/day: no ↓ risk
Enstrom[187,188]	4479 Men (10 y)	CVD (558 deaths)	>50 mg/d + vitamin supplement: ↓ risk by 42%
	6809 Women (10 years)	CVD (371 deaths)	>50 mg/day + vitamin supplement: ↓ risk by 25%
Manson[189,190]	87,245 Female nurses (8 years)	CAD (52 cases)	>359 compared with <93 mg/day: ↓ risk by 20% (NS)
		Stroke (183 cases)	>359 compared with <93 mg/day: ↓ risk by 24%
Rimm[26]	39,910 Male health professionals (4 years)	CAD (667 cases)	392 compared with 92 mg/day median: no ↓ risk
Fehily[191]	2512 Men (5 years)	CVD (148 cases)	>67 compared with <35 mg/d: ↓ risk by 37% (NS)
Knekt[192]	2748 Finnish men (14 years)	CAD (186 deaths)	>85 compared with <60 mg/day: no ↓ risk
	2385 Finnish women (14 years)	CAD (58 deaths)	>91 compared with <61 mg/day: ↓ risk by 51%
Gale[193]	730 U.K. elderly men and women (20 years)	Stroke (125 deaths)	>45 compared with <28 mg/d: ↓ risk by 50% (NS)
		CAD (182 deaths)	>45 compared with <28 mg/day: ↓ risk by 50% (NS)
Kritchevsky[194]	4989 Men (3 years)	Carotid atherosclerosis	>982 compared with <56 mg/day: ↓ intima thickness
	6318 Women (3 years)	Carotid atherosclerosis	>728 compared with <64 mg/day: ↓ intima thickness
Pandey[195]	1556 Men (24 years)	CAD (231 deaths)	>113 compared with <82 mg/day: ↓ risk by 25%
Kushi[196]	34,486 Women (7 years)	CAD (242 deaths)	>391 compared with <112 mg/day (total)2: no ↓ risk, >196 compared with <87 mg/day (dietary): no ↓ risk, regular supplement compared with no supplement: no ↓ risk
Losconczy[197]	11,178 Elderly men and women (6 years)	CAD (1101 deaths)	Regular supplement compared with no supplement: no ↓ risk
Sahyoun[198]	725 Elderly men and women (10 years)	CVD (101 deaths)	>388 compared with <90 mg/day: ↓ risk by 62% (NS)
Mark[199]	29,584 Chinese men (5 years)	Stroke	180 mg/d supplement: no ↓ risk (+30 μg Mo/day cosupplement)

Note: CVD = Cardiovascular disease; CAD = Coronary artery disease.

TABLE 10.19
Vitamin C — Established Benefits

Prevents scurvy
Maintains health of teeth, gums, and blood
 vessels necessary for wound repair
Important for collagen formation
Enhances iron absorption

    See under vitamin E Table for the effects of vitamin C in combination with other vitamins on CHD. It remains unclear whether the positive effects in atherosclerosis prevention study (ASAP) and the Cardiac Transplant Study are due to the vitamin C alone or the antioxidant mixture.

    Several epidemiologic studies that have investigated the association of vitamin C intake with the incidence of cataract are discussed in Chapter 58. See Table 10.19 for the established benefits of vitamin C.

VITAMIN D

Vitamin D investigations present an exciting area in both research and debate. In 1997, the vitamin D DRI Committee set the adult and elderly vitamin D requirements to approximately 200 and 400 IU/day based on the available science. Now, less than 10 years later, the thought leaders in the field are recommending that every one should receive at least between 600 and 1000 IU of vitamin D per day.[209] Recent data from the National Health and Nutrition Examination Survey (NHANES) database indicate

large segments of the population are vitamin D deficient. Recent studies[210] clearly indicate that those living in northern latitude in the United States (North of Boston) are seasonally deficient throughout the winter months. Supplementation in deficient populations especially, during these seasonal periods is necessary to attain and maintain nutritional adequacy. During periods when adequate vitamin D may be obtained from sun exposure, only short periods of sun skin exposure are required (i.e., 5 to 10 min, 2 to 3 times a week).[211] The role of overexposure to sun in stimulating skin cancer is the balancing concern. As to the overall safety intake levels, much debate remains. The DRI safety committee has set the Tolerable Upper Intake Level (UL) at 2000 IU/day. However, several experts suggest that a more reasonable limit should be set at 10,000 IU/day.

Vitamin D is an essential element in the maintenance of healthy bones, because it helps optimize calcium absorption and prevents increased parathyroid hormone (PTH) secretion.[212] High PTH levels stimulate resorption of bone, which may result in a gradual weakening of bones (osteomalacia) leading to an increase in the incidence of fractures.

Increasing evidence suggests that a large portion of the elderly population is vitamin D deficient.[213] Vitamin D deficiency in the elderly may be caused by little exposure to sunlight, a reduced ability of the skin to synthesize cholecalciferol, and decreased dietary intakes.[214] This deficiency leads to hyperparathyroidism, bone loss, and increased incidence of fractures.[215] Vitamin D is synthesized in the skin by the action of ultraviolet light.[1] Vitamin D deficiency was found to be common in the elderly due to lack of mobility, which prevents adequate sun exposure.[216] Various studies have also demonstrated that hypovitaminosis D appears prevalent in the winter months due to a reduction in the number of hours spent outside coupled with the use of more protective clothing.[212,215–220]

The effect of age on vitamin D synthesis in the skin may be due to an age-related decline in the dermal production of 7-dehydrocholesterol, the precursor of previtamin D_3.[221] MacLaughlin and Holick compared the amount of previtamin D_3 produced by the skin of young subjects (8 and 18 years old) with the amount produced by the skin of elderly subjects (77 to 82 years).[222] This study revealed that aging appears to produce a greater than twofold reduction in previtamin D_3 production in subjects over 77 years of age.

Vitamin D deficiency, which can cause osteomalacia, is also important in the pathogenesis of age-related osteoporosis.[214] In a study of 3270 elderly women (mean age 84), 800 IU of vitamin D was given in combination with 1.2 g of elemental calcium to 1634 women, and 1636 women received a placebo. The number of hip fractures was reduced by 43% in the group treated with the combination of vitamin D and calcium after 18 months.[217,223] A recent report based on pooled results of double-blind randomized controlled trials found that oral vitamin D supplementation in doses of 700 to 800 IU/day appears to reduce the risk of hip and nonvertebral factures in ambulatory or institutional elderly persons. An oral vitamin D dose of 400 IU/day is not sufficient for fracture prevention .[209]

Treatment of the elderly with vitamin D may be a cost-effective method of maintaining bone density and reducing the incidence of osteoporotic fractures.[224] Further, it has now been established that vitamin D plays a role in both nerves and muscles and as such appears to be important in reducing fractures by preventing falls.[225]

Vitamin D as 1,25 dihydroxycholecalciferol appears to be potentially useful for people with psoriasis.[224] Topical application has worked well in some,[227–230] but not all, studies.[231,232] Use of vitamin D in psoriatic patients may work by helping skin cells replicate normally. High doses of calcium combined with vitamin D have also been useful in treating cases of migraine[233,234] at a dose of 400 IU of vitamin D combined with 800 mg of calcium per day.

From epidemiological data, Giovannucci[235] reported that high circulating levels of 1,25(OH)$_2$ vitamin D, the biologically active form, may decrease the risk of developing prostate cancer, and that diets high in calcium, phosphorus, and sulfur-containing amino acids from animal protein tend to decrease 1,25(OH)$_2$ vitamin D. This effect of vitamin D on prostate cancer may be mediated via vitamin D receptors found on prostate cancer cells, and may be genotype specific.[236]

Animal models suggest that low vitamin D and calcium intake, as commonly found in Western-style diets, may be associated with an increased risk of both colon[237] and breast cancer,[238] although a long-term study of serum vitamin D levels and the incidence of breast cancer in humans did not reveal a direct association.[239] The role of vitamin D in cancer prevention has recently received renewed interest, and a series of positive reports reviews[240,241] have appeared. Presently, there is a 5-year, NIH (National Institute of Health)-funded interventional polyp prevention trial underway to look at the effect of vitamin D alone (1000 IU/day) and in combination with calcium. See Table 10.20 and Table 10.21 for the established and potential benefits of vitamin D.

TABLE 10.20
Vitamin D — Established Benefits

Necessary for the proper formation of bones
  and teeth
Important for calcium absorption
Aids in the deposition of calcium and
  phosphorus into bones

TABLE 10.21
Vitamin D — Potential Benefits

Use	Findings	Reference
Osteoporosis	Reduces the incidence of osteoporosis-related fracture	212–224
Psoriasis	Useful in topical application	226–232
Migraine	May be useful	233,239
Cancer	May reduce the risk of prostate cancer	235–239
	Low intake is associated with an increased risk of colon and breast cancer	

TABLE 10.22
Vitamin E — Established Benefits

Essential for the formation of red blood cells, muscle, and other tissues
Necessary for the proper function of the nervous system
Protects the fat in tissues from oxidation

TABLE 10.23
Vitamin E and Coronary Heart Disease — Epidemiological Trials

Stampfer et al.[25]	87,000 Female nurses aged between 34 and 59 years	8-year follow-up	Vitamin E supplements for short periods had little apparent benefit, but those who took them for more than 2 years had a 41% reduction in the risk of major coronary artery disease
Rimm et al.[26]	40,000 U.S. male health professionals aged between 40 and 75 years	4-year follow-up	Men consuming >60 IU/day of Vitamin E had a 36% decreased risk of CHD

VITAMIN E

The potential health benefits of vitamin E are extensive and include reduction in cardiovascular risk, protection against certain forms of cancer, enhanced immunity, and a potential role in the treatment of certain neurological diseases. See Table 10.22 for the established benefits of vitamin E. Early research identified that antioxidant scavengers such as vitamin E may reduce oxidative stress that can affect lipid metabolism, thereby producing oxidized low density lipoprotein (LDL), which is more atherogenic than the unoxidized form.[242,243] Because of this action, vitamin E was investigated to determine its efficacy in reducing the risk of cardiovascular disease.

Vitamin E (tocopherol) is a major lipid antioxidant that inhibits oxidation of low density lipoprotein cholesterol (LDL). Studies *in vitro* have shown that vitamin E inhibits smooth muscle cell proliferation, platelet adhesion, and aggregation, and can improve endothelial function.[244]

Epidemiological studies found a significant inverse correlation between LDL levels, vitamin E concentration, and degree of coronary artery stenosis,[245] or mortality from ischemic heart disease.[246] The Cholesterol Lowering Atherosclerosis Study demonstrated that supplementary vitamin E intake greater than 100 IU/day was associated with a significant reduction in the progression of atherosclerosis in subjects not treated with lipid lowering drugs.[247]

Two major epidemiological studies offer evidence that vitamin E can reduce the incidence and mortality from coronary heart disease. Data from Stampfer et al. [247] and Rimm et al.[26] support the evidence that suggests that antioxidants, especially fat-soluble antioxidants such as vitamin E, may protect against atherosclerosis by reducing the generation of oxidized LDL. Details of the two studies are listed in Table 10.23.

In the past few years, several controlled randomized clinical trials have been completed that investigated the effects of vitamin E and vitamin E in combination with other antioxidants. Some studies showed benefits (see Table 10.24). However, most results failed to show benefits of vitamin E in patients with cardiovascular disease (CVD) or at high risk of cardiovascular disease. See Table 10.25 for a tabulation of the various clinical trials showing no overall benefit in CVD. The Women's Health Study (WHS) was very meaningful due to the very large number (39,876) of apparently healthy persons evaluated for 10 years.[261] Although vitamin E supplementation failed on the primary outcome, that is, overall-reduction in cardiovascular events, there was a 24% reduction in cardiovascular deaths and 26% reduction in major cardiovascular events among the subgroup of women age at least 55 years. The report of the WHS study is indeed surprising as data from some 87,000 women in the Nurses Health Observational Study and 40,000 male health professionals had a 30 to 40% reduction in heart disease (Table 10.23).

TABLE 10.24
Summary of Randomized Clinical Trials of Vitamin E Benefits

Study	Patent Type	Dose Vitamin E – IU	Duration Years	Study Outcome
CHAOS[248]	CHD	400–800	1½	Decreased nonfatal MI
SPACE[249]	Hemodialysis patients	800	1½	Decreased MI stroke and angina
Transplant-associated athrosclerosis[250]	Transplant patients	800 and 1 g vitamin C	1	No increase in intimal thickness compared to placebo
ASAP[251]	CHD	272 and 50 mg vitamin C	6	Progression of intimal thickness reduced — men only, not women
SUVI-MAX[252]	Healthy	30 and 6 mg β-carotene 120 mg vitamin C 100 mg Se 20 mg Zn	7½	Lower cancer incidence and all cause mortality in men, not women.

TABLE 10.25
Summary of Randomized Clinical Trials of Vitamin E — No Benefits 10.25

Study	Patent Type	Dose (IU)	Duration (Years)
ATBC[253]	Male smokers no history of MI	50 plus 20 mg β-Carotene	5–8
GISSI[254,267]	Post MI	330	3–5
Hope & Hope Too[255,266]	CHD & Diabetes	400	4–7
PPP[256]	CHD	300	3.6
Veap, Kleveled[257]	LOL cholesterol	400	3
Hats[258]	CHD	800 1000 mg vitamin C 25 mg β-carotene	3
Wave[259]	CHD in postmenopausal women	800 plus 1 gm vitamin C	
HPS[260]	CHD	600 250 mg vitamin C 20 mg β-carotene	5
WHS[261a]	Healthy	600 every other day	10

a No overall benefit on cardiovascular disease or total cancer. There was, however, a 24% reduction in hemorrhagic stroke and a 26% reduction in major cardiovascular events among the subgroup of women aged at least 65 years.

The discrepancy between observational studies and randomized clinical trials is extremely striking. It may be as Kris-Etherton et al.[262] has stated that the lifelong exposure to an antioxidant may be different than exposure to an antioxidant for 5 to 10 years. Other factors such as type and form of antioxidant or combination of antioxidants may also be important in explaining the discrepancy.

Blumberg[263] recently commented on the failure of some of the clinical trials with vitamin E alone. He stated, "Thus, they ignored the established dynamic relationship within the antioxidant network with its complex arrangement of recycling and sparing and of differential quenching capacities to specific free radicals without various cell compartments." Jialal Devaraj[264] also commented on this subject in a recent review. The results of the SUVIMAX study[252] would indicate that a combination of antioxidants, well balanced, and at low doses together with a well balanced healthy diet, can give positive results.

Many carcinogens create free radicals that damage DNA and cellular structure, and therefore, can promote tumor development. Vitamin E can neutralize these free radicals, thereby preventing cell damage and subsequent malignant tumors. Vitamin E can also prevent cancer by inhibiting cell proliferation and angiogenesis.

Data from a number of epidemiologic studies have shown that individuals with higher intakes of vitamin E have lower risk of cancer. These data are summarized in Table 10.26. There are, however, no controlled intervention studies to confirm that supplemental vitamin E can lower the risk of cancer.

Large intakes of vitamin E are associated with slowing the progression of Alzheimer's disease, according to research from the Alzheimer's Disease Cooperative Study. A 2-year study of 341 individuals with Alzheimer's disease of moderate severity found that 2000 IU/day of vitamin E extended the time patients were able to care for themselves compared with that of those taking a placebo.[265,294]

It has been hypothesized that Parkinson's patients may lack sufficient antioxidant protection and are susceptible to increased attack by free radicals.[288] A small, open trial of patients with early symptoms of Parkinson's disease, conducted in 1989, provided individuals with 400 to 3200 IU of vitamin E per day for up to 7 years. Treated individuals were found to have an increased ability to carry out activities of daily living as compared with age-matched, unsupplemented controls.[289] A larger trial involved 160 patients with early symptoms of Parkinson's disease given 3200 IU of vitamin E and 3000 mg of vitamin C per day for an extended time. Using these two antioxidants prolonged the time to required treatment with levodopa.[290]

The Deprenyl and Tocopherol Antioxidant Therapy of Parkinsonism (DATATOP) study[291,292] was a double-blind, placebo-controlled, multicenter trial involving 800 patients with early Parkinson's disease. Subjects were given deprenyl (a monoamine oxidase inhibitor), or 2000 IU of vitamin E per day. The study showed that deprenyl alone after 9 months of treatment increased the ability to perform activities of daily living; however, there was no effect seen from vitamin E alone or in combination with the deprenyl. An analysis of the results of this trial revealed that a synthetic form of vitamin E was used as opposed to a natural form of vitamin E, which is much more lipid-soluble. This difference in the form of vitamin E may have explained why more positive results were not seen in the antioxidant supplementation group.

The Rotterdam study was a nutritional epidemiological study of 5342 free-living individuals between the ages of 55 and 95, including 31 individuals with pre-existing Parkinson's disease. In examining dietary intakes, there was a significant correlation between the level of daily dietary intake of vitamin E, β-carotene, and vitamin C and protection against development of Parkinson's disease.[293]

TABLE 10.26
Vitamine E Levels and Cancer Incidence

Reference	Cancer Site	Sample Size	Location of Study	Correlation
Stahelin (1984)[270]	Lung, stomach, and colon	4224	Switzerland	Vitamin E levels low in colon and stomach cancer cases
Wald (1984)[271]	Breast	5004	U.K.	Five time greater cancer risk for women with lowest vitamin E level

Rationale for Use of Vitamin and Mineral Supplements

VITAMIN K

Vitamin K is the collective name for a group of compounds, all of which contain the 2-methyl-l,4-naphthoquinone moiety. Human tissue contains phylloquinone (vitamin K_1) and several menaquinones (types of vitamin K_2).[295] Phytonadione is the name given to common pharmaceutical preparations,[296] and menadione (vitamin K_3) is the name of a synthetic vitamin K derivative used in animal feed.

Compounds with vitamin K activity are essential for the formation of prothrombin and at least five other proteins involved in the regulation of blood clotting, including Factors VII, IX, and X, as well as protein C and protein S. Although vitamin K is also required for the biosynthesis of several other proteins found in the plasma, bone, and kidney, defective coagulation of the blood is the predominant major known sign initially observed in vitamin K deficiency states.[295,297] Vitamin K deficiency in adults is frequently associated with fat malabsorption syndromes.

Although a wide variation exists, decreased vitamin K levels are generally associated with a decrease in the proportion and absolute amount of carboxylated osteocalcin. Osteocalcin is a vitamin K-dependent protein found in bone matrix, and its levels are a reflection of osteoblastic activity. It has therefore been hypothesized that decreased vitamin K levels might be related to an increased risk for osteoporosis.[298–300]

Vitamin K deficiency has been shown to be associated with decreased bone mass in postmenopausal women with aortic atherosclerosis, but not in a similar group without atherosclerosis.

This may be due to the fact that γ-carboxyglutamate, an amino acid formed by vitamin K action, is known to be involved with regulation of calcification in both bone tissue and atherosclerotic vessel walls, and that abdominal calcification is known to be associated with decreased vitamin K status.[301] Patients treated with warfarin appear to have structural alterations in circulating osteocalcin, which suggest the pathophysiological implication of an association of the use of warfarin with osteoporosis.[302] The use of coumarin (warfarin) therapy in many elderly subjects is often noted as a negative to the intake of vitamin K containing food or supplements. However a recent review[303] of this area concludes that a stable background of vitamin K at the level of 100 mcg would give those undergoing such therapy a nutritionally stable vitamin K background, allowing them the benefits of vitamin K without interfering with there antithrombotic therapy.

Low vitamin K intake is known to be associated with an increased risk of hip fracture in women.[302] Vitamin K supplementation in a group of 20 postmenopausal women with osteoporotic fractures resulted in improved carboxylation of osteocalcin.[304] In summary, these studies suggest a possible link between vitamin K deficiency and osteoporosis. Administration of vitamin K appears to improve a key biochemical parameter that has been associated with decreased bone mass; namely, carboxylated osteocalcin. Additional studies of vitamin K functions and forms active in bone metabolism are warranted. See Table 10.27 and Table 10.28 for established and potential benefits of vitamin K.

CALCIUM

Abundant evidence exists indicating that adequate dietary calcium intake minimizes bone loss in postmenopausal women[305–309] and reduces the increased risk of fracture associated with osteoporosis.[310–313] Additionally, calcium supplementation has been demonstrated to augment the bone-preserving effect of estrogen replacement therapy in postmenopausal women.[306,314] The U.S. Food and Drug Administration permits a health claim for calcium in the prevention and treatment of osteoporosis.

Use of vitamin D in combination with calcium supplementation is particularly important in preventing loss of bone in women who are borderline deficient[315] and reducing the incidence of fractures in the advanced elderly.[316–318] Vitamin D is an essential

Calcium — Potential Benefits

Use	Findings	Reference
Osteoporosis and osteoporotic fracture	Increased bone mass, decreased risk of fracture	302, 304–317
Colon cancer, breast cancer	Reduces the incidence of colorectal adenomas	318–321
Premenstrual syndrome	Reduces severity of PMS symptoms	322
Improved hormone replacement therapy	Permits lower dose of HRT to be used	323
Hypertension	May lower high blood pressure in individuals with calcium-poor diet	324, 325

element in the maintenance of healthy bones, because it helps optimize calcium absorption and prevents increased parathyroid (PTH) secretion.[212] High PTH levels stimulate resorption of bone that may result in a gradual weakening of bones leading to an increase in the incidence of fractures.

Calcium supplementation has recently been shown to help prevent colorectal adenomas,[256,257] which are precursors of colon cancer (see also Mobarhan[321] and Lipkin et al.[322] for an excellent review of this subject, and a separate review by Lipkin and Newmark[323] on vitamin D, calcium, and breast cancer) and to effectively reduce premenstrual symptoms associated with the luteal phase.[324]

The administration of 1000 mg of calcium in the presence of normal blood levels of vitamin D has also been demonstrated to permit a lower dose of hormone replacement therapy (HRT) to increase bone density and provide a bone-sparing effect in elderly women similar to or better than that provided by higher dose HRT without calcium and vitamin D supplementation.[325]

A recent study[326] has now indicated that calcium plus vitamin D will prevent the bone loss that accompanies the long-term use of oral contraceptives. This is an important finding as 80% of women of childbearing age in the United States use oral contraceptives.

The value of calcium in control of blood pressure is debatable. Despite conflicting data, meta-analysis of a large number of observational and randomized controlled clinical trials indicates that calcium intake has an impact in reducing blood pressure, particularly in persons regularly consuming low levels of dietary calcium.[327,328] Additional work in this area remains to be done. See Table 10.29 and Table 10.30 for established and potential benefits of calcium. See chapter 64 for additional information on macromineral nutrition.

MAGNESIUM

Magnesium appears to be directly involved in bone metabolism, helping in the formation of bone and indirectly interfacing with hormones regulating bone metabolism. Tranquilli et al.[329] demonstrated that both daily intake and bone mineral content of calcium, phosphorus, and magnesium were significantly reduced in a group of postmenopausal women with osteoporosis compared with nonosteoporotic controls. Additionally, supplementation with magnesium has been shown to help increase bone density in postmenopausal osteoporosis.[330]

Magnesium is a known vasodilator exerting its effect by inhibition of calcium in the vascular smooth cell and through the release of nitric oxide. Magnesium deficiency is found often in diabetics and in people with hypertension.[168] Magnesium deficiency can result in electrocardiographic changes, arrhythmia, and increased sensitivity to cardiac glycosides.[331]

Epidemiological studies suggest that diets high in magnesium as well as magnesium supplements decrease the incidence of cardiovascular disease.[332] A report from the Honolulu Heart Program found a higher risk of CHD among those subjects in the lowest vs. the highest quintile of magnesium intake.[333]

Although not all studies have found that magnesium intake can lower blood pressure, a recent meta-analysis of 20 randomized studies showed blood pressure reduction with magnesium supplementation.[334] The DASH diet (high in magnesium) can cause a reduction in blood pressure in normotensive and hypertensive patients.[335] This reduction, however, could be due to the nutrients in the high fruit and vegetables content of the diet as well as the high calcium content of the diet (dairy products).

TABLE 10.31
Magnesium — Established Benefits

Regulates heart beat, muscle contractions, and nerve
  transmissions
Aids in calcium absorption and the deposition of calcium
  and phosphorus into bones

TABLE 10.32
Magnesium — Potential Benefits

Use	Findings	Reference
Osteoporosis	Helps increase bone mass	327,328
Hypertension	May help lower blood pressure, especially where magnesium has been depleted	329,330,338–340
PMS symptoms	Deficiency is associated with PMS symptoms	341–344
Intermittent claudication	May respond to magnesium	345

Magnesium supplementation decreases the frequency of ventricular arrhythmias in patients with high risk of congestive heart failure, due to magnesium deficiency.[336]

Since the recent NHANES survey data have shown that magnesium intake is suboptimal in U.S. diets, magnesium supplementation can be useful in hypertension and possibly in CVD.[337] Tables 10.31 and 10.32 provide the established and potential benefits of magnesium.

ZINC

Zinc supplementation may be helpful in promoting wound healing in individuals who are zinc deficient. A dose of 220 mg of zinc sulfate (equivalent to 50 mg of elemental zinc) given three times a day for 7 to 8 weeks has been shown to improve wound healing in zinc-deficient patients.[348,349] There is no evidence that zinc supplementation benefits wound healing in individuals whose zinc nutriture is adequate.

Although popular in some countries, the role of zinc supplementation in improving male sexual function is unproven. Studies have shown that zinc is involved in the reproductive process for humans as well as animals. In humans, zinc is thought to be necessary for the formation and maturation of sperm, for ovulation, and for fertilization. High levels of zinc are found in most male reproductive organs, with the highest concentrations located in the prostate. In animal studies, the normal male testis and prostate contain a high concentration of zinc, and zinc deficiency has been shown to lead to defects in sperm along with a depletion of testosterone.[350–353] For men with low testosterone levels, zinc supplementation raises testosterone and increases fertility.[354] For men with low semen zinc levels, zinc supplements may increase both sperm counts and fertility.[355] Most published studies involve infertile men who have taken zinc supplements for at least several months.

Zinc deficiency in humans has been shown to cause retarded growth and slowed skeletal development.[356] Yamaguchi demonstrated that reduced bone growth is sometimes found in conditions associated with zinc deficiency. Additionally, he demonstrated that zinc has a stimulatory effect on bone growth.[357] Other studies have demonstrated a significant correlation between zinc content and bone strength.[358,359] Zinc has an important role in osteogenesis and bone metabolism, although the exact mechanism remains unknown.[356]

Studies have examined the role of zinc in the treatment of anorexia nervosa and in lozenge form to help decrease the duration of symptoms of the common cold. More research is needed to fully characterize the possible benefits of zinc in these conditions. Recent data from cohort epidemiological studies show zinc to be weakly protective against the development of some forms of early age-related macular degeneration (AMD).[360] Zinc was one of the main components in the multivitamin formulation used in the large and successful NIH, Age Related Eye Disease Study (AREDS l).[361] In this study, the formulation containing zinc at approximately 80 mg/day was shown to prevent the progression of AMD. (See Chapter 58.)

Zinc also helps support immune function. An older comprehensive review of the literature by Good et al.,[363] as well as information from Chandra and McBean[364] and Prasad et al.,[365] suggest that inadequate diet, defective absorption of zinc, disturbances in zinc metabolism, or abnormally increased losses of zinc may be associated with deficits in immune function. Low-dose supplementation of zinc (20 mg) and selenium (100 μg) has been shown to provide significant improvement in elderly patients by increasing humoral response after vaccination.[366] Improved cell-mediated immune response was seen following the

TABLE 10.33
Zinc — Established Benefits

Osteoporosis	May help increase bone strength	354–357
Age-related macular degeneration	Possibly protective	358–362
Immunity	Increases immune response	360, 362–365

administration of zinc 25 mg in an institutionalized elderly population.[367] In this study, a similar effect was not seen for vitamin A 800 μg. See Table 10.33 and Table 10.34 for established and potential benefits of zinc.

SELENIUM

Epidemiological associations between increased selenium intakes and reduced cancer risk, as well as the antioxidant role of selenium in glutathione peroxidase, have provided a basis for research on the potential anticarcinogenic effects of selenium. While the exact mechanism by which selenium exerts its preventative effect against certain types of cancer in humans is unknown, selenium supplementation in animal experiments has been shown to result in enhanced primary immune response in mice, as measured by the plaque-forming cell test and hemagglutination.[368] The addition of supplemental amounts of selenium to the diet has been demonstrated to increase humoral antibody production in swine in response to an antigenic challenge with sheep red blood cells.[369] Selenium deficiency is also known to cause impaired mitogen response in cultures of murine spleen cells.[370]

Two clinical intervention trials published to date have demonstrated that selenium, in combination with other nutrients, may reduce cancer risk. In one study,[21] daily administration of 50 μg of selenium in combination with vitamin E and β-carotene resulted in a moderate reduction in the risk of total mortality, total cancer mortality and stomach cancer mortality. More recently, Clark et al.[371] showed that treatment with 200 μg of selenium per day significantly decreased total mortality and mortality from lung cancer, as well as the incidence of colorectal and prostate cancer.

To test whether supplemental dietary selenium is associated with changes in the incidence of prostate cancer, in another study by Clark, a total of 1312 men with a history of either basal cell or squamous cell carcinoma were randomized to a daily supplement of 200 μg of selenium or a placebo.[372] Patients were treated for a mean of 4.5 years and followed for a mean of 6.4 years. There was no significant change in incidence for the primary endpoints of basal and squamous cell carcinoma of the skin; however, selenium treatment was associated with a significant reduction (63%) in the secondary endpoint of prostate cancer incidence. There were also significant health benefits for other secondary endpoints of total cancer mortality and the incidence of total, lung, and colorectal cancer.

In another study,[373] patients with histories of basal/squamous cell carcinomas of the skin were assigned randomly to either daily oral supplements of selenium-enriched yeast (200 μg Se/day) or a placebo. The results of this study indicate that supplemental selenium intake did not significantly affect the incidence of recurrent basal/squamous cell carcinomas of the skin; however, selenium treatment was associated with reductions in total mortality, mortality from all cancers combined, and the incidence of all cancers combined, lung cancer, colorectal cancer, and prostate cancer.

The consistency of these findings over time strongly suggests that there is an anticancer benefit to selenium supplementation, particularly in reducing the incidence of prostate cancer. An excellent review of selenium and prostate cancer prevention[374] and a review of the mechanisms of the chemopreventive effects of selenium[375,376] have been published.

As emphasized in a recent review by Combs,[377] further randomized clinical trials are needed to confirm and extend previous studies. The Selenium and Vitamin E Cancer Prevention Trial (Select) is currently in progress with an enrollment of 32,400 men. Selenomethionine is the compound that is being tested for the prevention of prostate cancer.

See Table 10.35 for the established and potential benefits of selenium.

TABLE 10.35

Prevents certain types of anemia
Helps maintain the function of the intestinal tract

Emerging
Hyperglycemic control
Increased bone mass
Control of hypertension
Improved lipid profiles

CHROMIUM

Chromium is an essential trace element that is a constituent of glucose tolerance factor and is required for effective insulin action in humans. Data in the literature suggesting a positive benefit of chromium supplementation on glycemic control in diabetes are equivocal, because a consistent beneficial effect of chromium supplementation remains unproven.

The American Diabetes Association (ADA) does not currently recommend supplementation with chromium for individuals with diabetes. The ADA position statement, "Nutrition Recommendations and Principles for People with Diabetes Mellitus,"[378] states:

> The only known circumstance in which chromium replacement has any beneficial effect on glycemic control is for people who are chromium deficient as a result of long-term chromium-deficient parenteral nutrition. However, it appears that most people with diabetes are not chromium deficient and, therefore, chromium supplementation has no known benefit.

A great deal of discussion on this topic centers on the chelated form of chromium and chromium picolinate. Several studies[379–391,393,394] indicate that supplementation with chromium may help reduce insulin resistance.

Further studies to assess the effects of dietary chromium supplementation on insulin sensitivity, as well as on other processes such as increased bone mass, improved blood pressure, and lipid profiles in humans are needed.

For further information on this topic, the reader is referred to an excellent review by Schmidt Finney[392] as well as an extensive bibliography of material on this subject.[393–410] See Table 10.36 for the established and potential benefits of chromium.

11 Nutrient–Nutrient Interactions

Carolyn D. Berdanier

CONTENTS

No nutrient acts alone. All the nutrients together, when consumed in the appropriate amounts, help to maintain the body in its optimal healthy state. There are however, some nutrient interactions that should be noted. This chapter addresses these interactions and describes their effects within the body.

MINERAL INTERACTIONS

Minerals are found in every cell, tissue, and organ. They are important constituents of essential molecules such as thyroxine (T_4), hemoglobin, and vitamin B_{12}. They serve as critical cofactors in numerous enzymatic reactions (see Chapter 7) and form the hard mineral complexes that comprise bone (see Chapter 64). Minerals serve in the maintenance of pH, osmotic pressure, nerve conductance, muscle contraction, and in almost every aspect of life. Minerals interact such that bioavailability or use is affected.[1,2] The ratios of calcium to phosphorus, iron to copper to zinc, and calcium to magnesium, and other factors are examples of such interactions. Some of these interactions are mutually beneficial while others are antagonistic. Most of these interactions occur at the level of the gut, in that many are concerned with mineral absorption. For example, zinc absorption is impaired by high iron intakes; high zinc intake impairs copper absorption. Molybdenum and sulfur antagonize copper, and tungsten (not an essential nutrient) interferes with molybdenum absorption. These antagonisms contribute to the relative inefficiency of absorption of minerals that are poorly absorbed and just as poorly lost once absorbed.

Many of the trace minerals have more than one charged state; and living cells have preferences for these states. For example, the uptake of iron is much greater when the iron is in the ferrous (+2) state than when in the ferric (+3) state. Minerals that keep iron in the ferric state will interfere with iron absorption and use. Minerals that do the reverse will enhance iron uptake. Such is the beneficial action of copper on iron. The cuprous ion keeps the ferrous ion from losing electrons and becoming the ferric ion. The interactions of essential minerals are best illustrated in Figure 11.1.

The availability of iron from food depends on its source. Soybean protein, for example, contains an inhibitor of iron uptake. Diets such as those in Asia contain numerous soybean products, and iron absorption is adversely affected by this soybean inhibitor. Tannins, phytates, certain fibers (not cellulose), carbonates, phosphates, and low-protein diets also adversely affect the apparent absorption of iron. In contrast, ascorbic acid, fructose, citric acid, high-protein foods, lysine, histidine, cysteine, methionine,
FIGURE 11.1   Trace mineral interaction.

and natural chelates (i.e., heme) all enhance the apparent absorption of iron.[3,4] Zinc and manganese reduce iron uptake by about 30% to 50% and 10% to 40%, respectively. Excess iron reduces zinc uptakes by 13% to 22%. Stearic acid, one of the main fatty acids in meat, enhances iron uptake.

Two types of iron are present in the food, namely, heme iron, which is found principally in animal products, and nonheme iron, which is inorganic iron bound to various proteins in the plant. Most of the iron in the diet, usually greater than 85%, is present in the nonheme form. The absorption of nonheme iron is strongly influenced by its solubility in the upper part of the intestine. Absorption of nonheme iron depends on the composition of the meal and is subject to enhancers of absorption such as animal protein and by reducing agents such as vitamin C. On the other hand, heme iron is absorbed more efficiently. It is not subject to these enhancers. Although heme iron accounts for a smaller proportion of iron in the diet, it provides quantitatively more iron to the body than dietary nonheme iron.

Carcinogenesis can be instigated by some minerals. Nickel subsulfide, for example, is a potent carcinogen, having the renal tissue as its target. In the presence of high to moderate iron levels, the activity of the nickel compound (with respect to carcinogenesis) is increased. In copper excess due to a genetic disorder involving the protein that transports copper, hepatic cancer develops, and this cancer is potentiated by high iron levels. It would appear in these last examples that the role of iron is that of a cancer promoter rather than that of an initiator as described for colon cancer.

Although high iron intakes can be harmful, it should be noted that optimal iron intakes can protect against lead toxicity. Lead competes with iron for uptake by the enterocyte. If the transporter is fully saturated by its preferred mineral, iron, then the lead will be poorly absorbed and get excreted in the feces. Well-nourished individuals with respect to iron nutriture are at lesser risk for lead toxicity than are those whose iron intake is marginal or deficient.

As with iron, zinc absorption is relatively poor. Of the approximately 4 to 14 mg/day consumed, only 10% to 40% is absorbed.[5,6] Absorption is decreased by the presence of binding agents or chelating agents, which bind the mineral making it unavailable. Zinc binds to ligands that contain sulfur, nitrogen, or oxygen. Zinc will form complexes with phosphate groups (PO_4^-), chloride (Cl^-), and carbonate groups (HCO_3^-) as well with cysteine and histidine. Low zinc status impairs the absorption of calcium.[6]

Zinc can sometimes be displaced on the zinc fingers of DNA-binding proteins (receptors) by other divalent metals.[7] Iron, for example, has been used to displace zinc on the DNA-binding protein that also binds estrogen. This protein binds to the estrogen response element of the DNA promoter region encoding the estrogen responsive gene products. When this occurs in the presence of H_2O_2 and ascorbic acid, damage to the proximate DNA, the estrogen response element, occurs. It has been suggested that, in this circumstance of an iron-substituted zinc finger, free radicals are more readily generated with the consequence of genomic damage. This suggestion has been offered as an explanation of how excess iron (iron toxicity) could instigate the cellular changes that occur in carcinogenesis.

In excess, cadmium can also substitute for zinc in the zinc fingers. In this substitution, the resultant zinc fingers are nonfunctional. Because of the importance of these fingers in cell survival and renewal, a cadmium substitution is lethal. Cadmium toxicity is an acute illness with little lag time needed for the symptom of cell death to manifest itself.

Excess zinc intake can adversely affect copper and iron absorption. Further, excess zinc can interfere with the function of iron as an antioxidant and can interfere with the action of cadmium and calcium as well. Ferritin, the iron storage protein, can also bind zinc. In zinc excess, zinc can replace iron on this protein.[8] Other interactions include a copper–zinc interaction. Copper in excess can interfere with the uptake and binding of zinc by metallothionine in the enterocyte. In humans consuming copper-rich diets, the apparent absorption of zinc is markedly reduced. In part, this is due to a copper–zinc competition for enterocyte transport and in part due to a copper effect on metallothionine gene expression. Metallothionine has a greater affinity for copper than for zinc, and thus zinc is left behind while copper is transported to the serosal side of the enterocyte for export to the plasma, whereupon the copper rather than the zinc is picked up by albumin and transported to the rest of the body. Fortunately, excess copper in the normal diet is not common. Zinc is usually present in far greater amounts, and this interaction is of little import in the overall scheme of zinc metabolism. The metallothionine proteins, in addition to binding zinc and copper, also bind other heavy metals such as mercury and cadmium. This occurs when the individual is acutely exposed to toxic levels of these metals.

Selenium is an integral part of the enzyme, type 1 iodothyronine deiodinase, which catalyzes the deiodination of the iodothyronines notably the deiodination of T_4 to triiodothyronine (T_3), the most active of the thyroid hormones.[9] This deiodination is also catalyzed by type II and type III deiodinases, which are not selenoproteins. While all the deiodinases catalyze the conversion of T_4 to T_3, there are differences in the tissue distribution of these enzymes. The pituitary, brain, central nervous system, and brown adipose tissue contain types II and III, whereas type I is found in liver, kidney, and muscle. These two isozymes (II and III) contribute very little T_3 to the circulation except under conditions (i.e., starvation) that enhance reverse triiodothyronine (rT_3) production. In selenium-deficient animals, type I synthesis is markedly impaired, and this impairment is reversed when selenium is restored to the diet. Under these same conditions, the ratio of T_3 to T_4 is altered. There is more T_4 and less T_3 in selenium-deficient animals, and the ratio of the two is reversed when selenium is restored. Because type II and III deiodinase also exist, these enzymes should increase in activity so as to compensate for the selenium-dependent loss of function. However, they do not do this because their activity is linked to that of the type I. When T_4 levels rise (as in selenium deficiency), this rise feeds

back to the pituitary, which in turn alters (reduces) thyroid-stimulating hormone (TSH) release. The conversion of T_4 to T_3 in the pituitary is catalyzed by the type II deiodinase, yet TSH release falls. T_4 levels are high because the type I deiodinase is less active. Whereas the deficient animal might have a T_3/T_4 ratio of 0.01, the selenium-sufficient animal has a ratio of 0.02, a doubling of the conversion of T_4 to T_3. The effect of selenium supplementation on the synthesis and activity of the type I deiodinase probably explains the poor growth of deficient animals. Bermano et al.[10] have reported significant linear growth in deficient rats given a single selenium supplement, and this growth was directly related to the supplement-induced increase in type I deiodinase activity. In turn, the observations of changes in selenium status coincident with changes in thyroid hormone status provided the necessary background for establishing the selenium–iodine interaction that today is taken for granted. The role of selenium in the synthesis of type I deiodinase clearly explains the lack of goiter (enlarged thyroid gland) in cretins who lack both iodine and selenium in their diet. Thus, low selenium intakes impair thyroid hormone activity, and there is a selenium–iodine interaction.

Other trace mineral interactions also exist. Copper-deficient rats and mice have been shown to have reduced glutathione peroxidase activity.[11] Glutathione peroxidase is a selenium-containing enzyme. Copper deficiency increases oxidative stress, yet oxidative stress affects all of the enzymes involved in free radical suppression. Even though glutathione peroxidase does not contain copper, the expression of the genes for this enzyme and for catalase is reduced in the copper-deficient animal. There are numerous nutrient interactions required for the maintenance of the optimal redox state in the cell. This is important not only because it stabilizes the lipid portion of the membranes within and around the cells but also because it optimizes the functional performance of the many cellular proteins. Copper, zinc, magnesium, and manganese are part of the antioxidant system as is $NADPH^+$ and NAD^+ (niacin-containing coenzymes). The NAD^+, although not usually shown as part of the system, is involved because it transfers reducing equivalents via the transhydrogenase cycle to $NADP^+$. Excess selenium intake interferes with zinc absorption and use, reduces tissue iron stores, and increases copper level in heart, liver, and kidney.[12] Manganese and calcium share a uniport mechanism for mitochondrial transport.[13] Manganese can accumulate in this organelle because it is cleared very slowly. Mitochondrial manganese efflux is not sodium dependent, and in fact appears to inhibit both the sodium-dependent and sodium-independent calcium efflux. This manganese effect on calcium is not reciprocal; calcium has no effect on manganese efflux.

As already mentioned, cobalt in excess can block iron absorption. Cobalt together with manganese and iodine are involved in the synthesis of T_4. Whether they interact or are merely essential cofactors in T_4 synthesis has not been satisfactorily resolved.[14]

As ions, minerals react with charged amino acid residues of intact proteins and peptides. Table 11.1 provides a list of minerals and the amino acids with which they react. Depending on their valence state, these electrovalent bonds can be very strong or very weak associations, or anything in between. The marginally charged ion (either an electron acceptor or an electron donor) will be less strongly attracted to its opposite number than will an ion with a strong charge.

The formation of mineral–organic compound bonds is also seen when one examines the roles of minerals in gene expression. Almost every mineral is involved in one or more ways. Zinc–cysteine or zinc–histidine linkages form the zinc fingers that bond with certain base sequences of DNA, thereby affecting transcription. Mineral–protein complexes serve as *cis*- or *trans*-acting elements that enhance or inhibit promoter activity and/or RNA polymerase II activity. Minerals can bond either by themselves or in complexes with proteins to inhibit or enhance translation. Lastly, minerals by themselves or in a complex can influence posttranslation protein modification. Additional information regarding the trace minerals can be found in Chapter 8.

INTERACTIONS OF VITAMINS WITH MINERALS

The uptake of both calcium and phosphorus by bone as well as the regulation of flux of these two minerals by vitamin D is well known. In this instance, vitamin D acts as a hormone in the regulation of calcium homeostasis. Already mentioned is the interaction of ascorbic acid and iron with respect to iron uptake by the intestinal mucosa. There is the interaction of vitamin E and selenium, as well; each of these nutrients plays a role in the maintenance of the free radical suppression system. One can replace the other to a certain extent, and so both are considered partners in this important system. If there is a deficiency of intake of selenium, for example, the effects of this deficiency can be ameliorated to some extent by an adequate intake of vitamin E.

TABLE 11.1
Minerals–Amino Acid Interactions

Minerals	Amino Acid
Calcium	Serine, carboxylated glutamic acid (GLA)
Magnesium	Tyrosine, sulfur containing amino acids
Copper	Histidine
Selenium	Methionine, cysteine
Zinc	Cysteine, histidine

TABLE 11.2
Vitamin–Vitamin Interactions[15]

Vitamins[a]	Effect
B_6–B_{12}	Optimizes absorption of both; together both optimize absorption of thiamin
E–K	One interferes with the absorption of the other
B_6–Niacin	One interferes with the absorption of the other
B_6–Thiamin	B_6 protects against excess thiamin intake
B_{12}–Thiamin	B_{12} deficiency results in increased urinary loss of thiamin
B_{12}–Pantothenic acid	B_{12} spares pantothenic acid
Biotin and Folacin–Pantothenic acid	Biotin and folacin optimize the use of pantothenic acid
Thiamin–Riboflavin	One interferes with the absorption of the other
Riboflavin–B_6–Niacin	One needed for the metabolism of the other
B_6–Niacin	B_6 needed for the synthesis of niacin from tryptophan
C–B_6	C protects B_6 from excess catabolism and urinary excretion
	A deficiency of B_6 reduces blood C levels
E–A	E protects A from oxidative destruction
C–E	C protects E from oxidative destruction
C–A	When A is consumed in excess, tissue C levels fall
A–D	A protects against some of the signs of D excess
A–E	When A is consumed in excess, E requirement is increased
A–K	When A is consumed in excess, K requirement increases
A–C	C can increase the conversion of β-carotene to retinol
E–C	Both are synergistic in maintaining redox state in the cell
Folacin–Thiamin	Folacin optimizes thiamin absorption
Folacin–B_{12}	If B_{12} is deficient, folacin can mask deficiency signs
Riboflavin–Folacin	Riboflavin needed for conversion of folic acid to its coenzyme

[a] Abbreviations used: A, vitamin A (retinal, retinol, retinoic acid); D, vitamin D; E, vitamin E (tocopherols); K, vitamin K; B_6, pyridoxine, pyridoxal, pyridoxamine; C, ascorbic acid.

Although each of these nutrients has a different role in the maintenance of the redox state, their roles are both complementary and substitutive. Additional information on the vitamins can be found in Chapter 9 and Chapter 10.

VITAMIN INTERACTIONS

A number of vitamin interactions have been reported. Table 11.2 summarizes these reports. In the chapter on nutritional biochemistry (Chapter 7), the interacting and complementary roles of the B vitamins were described. These vitamins serve as coenzymes in many reactions of intermediary metabolism. Other interacting and complementary vitamin interactions include that of vitamin C and vitamin E. Both have roles in the regulation of the redox state in the cell. In species that synthesize their own vitamin C (i.e., in rats, mice, etc.), vitamin E deficiency leads to vitamin C deficiency, because the former plays a role in ascorbic acid synthesis from glucose. Vitamin E also interacts with vitamin B_{12} and zinc. Vitamin-E-deficient animals, although furnished with adequate vitamin B_{12}, have been found to have B_{12} deficiency symptoms. Probably this is due to a role of vitamin E on the use of B_{12} as a coenzyme for the enzyme, methylmalonyl-coenzyme A mutase. With respect to zinc, the interaction has to do with the complementary roles of both nutrients as membranes stabilizers.

The fat-soluble vitamins A and D can be toxic if consumed in excess over a period of time. The toxicity of vitamin A can be ameliorated by vitamin E. Vitamin E can downregulate the conversion of the carotenes to retinol and thereby reduce the toxicity of vitamin A. Vitamin E can also ameliorate the cellular responses to excess vitamin A through its actions on membrane stability and its function in the free radical suppression system.

MACRONUTRIENT INTERACTIONS

The need for an adequate energy intake to support growth and development is a long-established principle of nutrition science. The energy intake is primary; for, without sufficient energy, protein synthesis cannot take place at a normal rate. This meets the definition of a nutrient interaction. However, having this as a principle, there are other interactions that are important in intermediary metabolism.

Students of intermediary metabolism have long recognized that these macronutrients share some of the pathways of metabolism. Excess carbohydrate intake results in carbohydrate being converted to lipid. Inadequate energy intake means a depletion of the fat stores, with a subsequent rise in fatty acid oxidation and an increase in glucose production from gluconeogenesis and glycogenolysis (see Chapter 7). The composition of the diet can affect these pathways. Rats fed a 65% sucrose (as compared with those fed starch) have a heightened rate of hepatic lipogenesis. If the fat source is fish oil rather than corn oil or beef tallow, lipogenesis is reduced. If the fat source is coconut oil, lipogenesis is increased.[16–18] In humans, a similar interacting effect of carbohydrate and fat sources has been reported.[19] In this human study, serum cholesterol levels were lower and triglyceride levels were higher in humans fed a sucrose-saturated fat diet vs. a starch-saturated fat diet compared with humans fed a sucrose-unsaturated or starch-saturated fat diet. Thus, there is an interaction between the two energy sources with respect to lipogenesis and overall lipid dynamics.

Amino Acid Interactions

It has long been recognized that interactions and competitions exist between amino acids in the small intestine. The amino acid carriers (carriers that transport amino acids from the lumen into the absorptive cell) will transport more than one amino acid.[20] Neutral amino acids share a common carrier, as do those with short or polar side chains (serine, threonine, and alanine). There is also a carrier for phenylalanine and methionine and a specific one for proline and hydroxyproline. Similarly, there are carriers that transport amino acids across the blood–brain barrier, and there is some competition among amino acids for these carriers. For example, tryptophan competes with tyrosine for entry through the blood–brain barrier. Both tryptophan and the aromatic amino acids (phenylalanine and tyrosine) serve as precursors of neurotransmitters, and a competition between them for transport may have a role in the regulation of the balance of these transmitters in the body. Sulfur-containing amino acids are spared by each other, that is, methionine is spared by cysteine.[21]

In intermediary metabolism, there appears to be an interaction between leucine, isoleucine, and valine.[22] All are branched-chain amino acids and share the same enzymes for their metabolism. All are needed for appropriate rates of protein synthesis. Should one be in short supply, the rate of protein synthesis will fall. Thus, amino acid interactions occur as part of the overall body amino acid economy to ensure appropriate body protein homeostasis.

SUMMARY

Components of the diet can interact sometimes with beneficial and sometimes with deleterious effects. So much depends on the dietary mixture consumed and the physiological status of the consumer. Where the consumer is marginally nourished, the interacting nutrients can have unexpected results. However, in the well-nourished individual consuming a wide variety of foods and not consuming an excess of any one nutrient or class of nutrients, such interactions are probably insignificant. It is only when individuals restrict their food selections and consume unbalanced supplements, should there be concern over deleterious nutrient interactions.

12 Comparative Nutrition

William P. Flatt and Carolyn D. Berdanier

CONTENTS

INTRODUCTION

The nutritional requirements for different species of animals, including mammals, birds, and fish, vary markedly. Many factors influence the requirements for specific nutrients. Within species, some of the factors affecting nutritional requirements are age, gender, stage of maturity, level of activity (work), body size, type and level of production (i.e., lean or adipose body tissue, milk, eggs, wool, bone growth, etc.), environment, physiological function (i.e., maintenance, pregnancy, lactation, etc.), health, and endocrinological factors. Between and among species, the type of gastrointestinal tract greatly influences the nutritional requirements of the animal, and the type of food it may eat to provide the nutrients it needs. For example, ruminants (cattle, sheep, goats, and deer), as a result of microbial fermentation in the upper gastrointestinal tract, have quite different nutritional requirements than nonruminants (humans, swine, dogs, cats, nonhuman primates, etc.). Ruminants and other herbivores have extensive microbial fermentation, which allows these species to utilize the cellulose, hemicellulose, and other high-fiber diets that animals without this fermentation cannot use. This fermentation alters the needs for many of the micronutrients, as well as dictates the sources of macronutrients to optimize health, growth, and meat, egg, or milk production.

Other species differences relate to the difference in the basic anatomy and physiology of the animals themselves. For example, humans, swine, cattle, sheep, and chickens store bile from the liver in the gallbladder, whereas rats, horses, deer, elk, moose, and camels have no reservoir to store bile, and this in turn may affect lipid digestion. Another species difference is in nitrogen utilization. For example, mammals excrete excess nitrogen resulting from protein catabolism as urea, whereas birds excrete it as uric acid. Many different species of animals have been used extensively as research models to obtain data on nutrient metabolism and function in humans, and to learn the mode of action of various dietary ingredients. The researcher must be aware of differences in the nutritional requirements of different species, or erroneous conclusions could be drawn. For example, dietary vitamin C is required by humans and other primates, fruit bats, and guinea pigs, but not by swine, mice, and rats. These species are frequently used as animal analogs for human nutrient needs and human health problems (Table 12.1). Animal analogs are useful, because they have a shorter lifespan and are far more uniform with respect to genetic background than are humans. Questions about the efficacy of dietary manipulation, drugs, and environmental conditions have all been answered through the use of such animals. Animals such as rats, guinea pigs, hampsters, gerbils, and mice have been developed (through selective breeding or through biotechnology) to develop human-like diseases such as diabetes mellitus, hyperlipidemia, cardiovascular disease, obesity, and so forth. Many of these special breeds are listed in Table 12.1. The investigator must remember, however, that there can be differences in response between the species and, if dietary variables are being used, the species difference in nutrient need as well as the lifespan difference must be accommodated in the interpretation of the results and the application of these results to humans. The American Society for Nutrition, formerly the American Institute of Nutrition, periodically reviews the diet composition of diets for rodents. It provides guidance for the composition of the standard rodent diet designed to meet rodent needs and to provide baseline data for the investigator using these animals in research. The composition of this basal diet is given in Table 12.2.

The nutrient needs for livestock, poultry, and fish have also been studied, and information is available for food producers, veterinarians, animal caretakers, biomedical research scientists, and others. People involved in caring for and feeding animals need to know what nutrients are required and the amounts of each, the effects of different factors on the efficiency of nutrient utilization, and how best to provide optimal feeds for each of these animals. Because of the economic importance of this knowledge, scientists throughout the world have conducted research with different species of animals, birds, and fish, and feeding standards based on this research have been developed. Diets and rations have been formulated for domestic livestock, poultry, companion animals, laboratory animals, and other species.

During the past century, scientists from many nations have conducted research on the specific nutritional requirements of numerous species of animals, but there are so many interactions among nutrients — and so many factors that influence nutrient utilization by different species — that tables or formulae for calculating nutritional requirements must be modified periodically.

TABLE 12.1
Small Animal Analogs for Human Diseases[1,2]

Type 1 Diabetes Mellitus
Streptozotocin-treated animals of most Species
Alloxan can be substituted for streptozotocin
Pancreatectomy will also produce IDDM
BB rat (autoimmune disease)
db/db mouse
NOD mouse
FAT mouse
NZO mouse
TUBBY mouse
Adipose mouse
Chinese hamster (*Cricetulus griseus*)
South African hamster (*Mystromys albicaudatus*)
Tuco-Tuco (*Clenomys tabarum*)

Type 2 Diabetes Mellitus
ob/ob mouse
KK, yellow KK mouse
Avy, Ay yellow mouse
P, PB13/Ld mouse
db PAS mouse
BHE/Cdb rat
Zucker diabetic rat
SHR/N-cp rat
Spiny mouse
HUS rat
LA/N-cp rat
Wistar Kyoto rat

Obesity
Zucker rat
SHR/N-cp rat
LA/N-cp rat
ob/ob mouse
Ventral hypothalamus lesioned animals
Osborne-Mendel rats fed high-fat diets

Hypertension
SHR rats
JCR:LA rats
WKY rats
Transgenic rats

Gallstones
The rat does not have a gall bladder, nor does it have stones
Gerbil fed a cholesterol-rich, cholic-acid-rich diet
Hamster, prairie dog, squirrel monkey, or tree shrew fed a
  cholesterol-rich diet

Lipemia
Zucker fatty rat
BHE/cdb rat
NZW mouse
Transgenic mice given gene for atherosclerosis

Atherosclerosis
Transgenic mice given gene for atherosclerosis
NZW mouse
JCR:LA cp/cp rat

TABLE 12.2
Composition of the AIN-93 Maintenance (M) and
Growth (G) Diets for Rats[3]

Ingredient	AIN-93M (g/kg)	AIN-93G (g/kg)
Casein	140	200
Cornstarch	465.692	397.486
Dextrose	155	132
Sucrose	100	100
Cellulose	50	50
Soybean oil	40	70
Mineral mix	35	35
Vitamin Mix	10	10
L-cystine	1.8	3
Choline bitartrate	2.5	2.5
t-Butylhydroquinone	0.008	0.014
Energy	~3.8 kcal or ~16 kJ/g	~3.9 kcal or ~16.4 kJ/g

In the United States, the National Academy of Sciences, National Research Council (NRC), Board on Agriculture, Committee on Animal Nutrition has been responsible for developing nutrient intake requirements and feeding recommendations for a variety of animals. These publications are listed in Table 12.3. These recommendations are periodically reviewed and updated as new information becomes available. The information is also available on the web, and the web addresses are listed in Table 12.4. The general address for books published by the National Academy of Sciences is http://books.nap.edu. One can order these books online. In addition to the nutrient requirements, the tables of nutrient composition of the most commonly used feed ingredients that are needed are also given. The 1999 Feedstuffs Reference Issue (Volume 71, Number 31, July 30, 1999, pages 40–84) has

tables based on the NRC publications for swine, beef cattle, dairy cattle, chickens and turkeys, horses, and pets (dogs and cats) (Table 12.5).

It should be remembered that the tables giving the nutrient requirements for each species are different from the recommended intakes for humans. In the latter species, intake recommendations include a very broad (approx. twofold) safety factor and should not be considered as a requirement figure but rather a recommended daily intake figure that should satisfy the need

TABLE 12.5
Publications Providing Information on the Nutrient Needs of Specific Animals

Species	NRC Publication	Year Last Revised	Pages of Tables	Computer Disk	NAP Web Site of Tables
A. Nutrient requirements of companion animals (cats and dogs), rabbits, mink and foxes, and laboratory animals (rats, mice, guinea pigs, hamsters, gerbils, and voles) and rabbits, mink, and foxes. Other Species					
Fish	*Nutrient Requirements of Fish*	1993	62–63	No	Yes
Nonhuman primates	*Nutrient Requirements of Nonhuman Primates*	1978 (2000 in press)	18–19	No	No
Horses	*Nutrient Requirements of Horses*	1989	39–48	Yes (5.25 in.)	Yes
Swine	*Nutrient Requirements of Swine*	1998	110–123	Yes (Laser optical disk) (4.75 in.)	Yes
C. Nutrient requirements of ruminants (beef cattle, dairy cattle, sheep, and goats). Tables of nutrient requirements from Nutrient Requirements of Domestic Animals: A Series. National Research Council, National Academy Press (http://books.nap.edu)					
Ruminant Species					
Beef cattle	*Nutrient Requirements of Beef Cattle*	2000	102–112	Yes (3.5 in.)	Yes
Dairy cattle	*Nutrient Requirements of Dairy Cattle*	1989	78–88	Yes (5.25 in.)	Yes
Sheep	*Nutrient Requirements of Sheep*	1985	45–53	No	Yes
Goats	*Nutrient Requirements of Goats: Angora, Dairy and Meat Goats in Temperate and Tropical Countries*	1981	10–12	No	Yes

for that nutrient by most people. The figures for animals, on the other hand, have a safety factor but it is fairly narrow and should thus be considered closer to the requirement rather than a recommended intake. The reason for this species difference in recommendations is due to the large database for species other than humans and the degree to which nutrient adequacy can be determined in these species. Investigators using rats, for example, can examine in detail particular organs and tissues in the rat, but investigators using humans cannot do these same examinations in humans. Ethical considerations aside, the long life span

of humans also makes such investigations difficult. Mice and rats have short life spans by comparison, and so the effects of nutritional manipulation on the long-term responses of these species are possible.

Comparative nutrition studies, therefore, need to remember these differences, and care must be exercised when the results of work with one species is compared to or assumed to be similar to that in another species.

Part III

Nutrition Throughout Life

13 Nutrition during Pregnancy and Lactation

Kathryn M. Kolasa and David G. Weismiller

CONTENTS

RECOMMENDATIONS FOR WOMEN BEFORE PREGNANCY

It seems logical that the nutritional status of a woman prior to pregnancy as well as maternal nutrition should affect fetal development and subsequent pregnancy outcome. However, many confounding variables are common to the investigation of maternal nutrition and fetal development.[1] This section briefly summarizes recommendations for maternal nutrition.[2–13] It also includes

comments about lactation, because maternal diet plays a central role in the transfer of nutriments to the infant. Table 13.1 includes special recommendations for women during childbearing years. Suggestions for counseling and treatment during preconception care office visits are given in Table 13.2.

TABLE 13.1
Special Recommendations for Women before Pregnancy

Maintain a healthy weight

Engage in physical activity regularly

If you need to gain or lose weight, do so gradually (no more than 1 to 2 lb/week)

If trying to become pregnant and ordinarily drink alcoholic beverages, stop drinking or cut back on the amount you drink

If you smoke, quit. Cutting back does not suggest overall improvement in outcomes

To minimize risk of having an infant with a neural tube defect, eat a highly fortified breakfast cereal that provides 100% of the Daily Value (DV) for folate or take a vitamin supplement that provides 600 μg/day of folic acid (4 weeks preconception through 12 weeks postconception). Folic acid, the synthetic form of folate, is obtained only from fortified foods or vitamin supplements. It is not yet known whether naturally occurring folate is as effective folic acid in the prevention of neural tube defects. For secondary prevention, the dosage is 4 mg/day

---

TABLE 13.2
Nutritional Care at Preconception, Prenatal, and Postnatal Visits

Visit	Assessment	Counseling/Treatment
Preconception care	Determine body mass index (BMI)	If <18 or >25, counsel on appropriate weight
	Evaluate diet/supplement intake	Develop a concrete plan for eating enough food to achieve/maintain a healthy weight
		Begin prenatal vitamin/mineral supplement
		Prescribe calcium supplement if intake <1000 mg
		Prescribe synthetic folic acid supplement of 400 μg/day
	Botanical use	Discontinue those with known or potential toxicities
	Evaluate for anemia	If Hgb <12g/dl, start therapeutic regimen of approximately 60 to 120 mg/day of ferrous iron; give multivitamin/ mineral supplement that contains ~15 mg of zinc and ~2 mg of copper
		When anemia has resolved, discontinue high-dose iron
Prenatal	Use of harmful substances	Reinforcement for any constructive steps already taken; provide assistance with quitting, and refer for further evaluation
	Evaluate diet	Utilize dietary intake questionnaire, for example, Diet Score, and food frequency questionnaires
	Optimal weight gain during pregnancy is controversial	BMI <19.8 28–40 lb
		• 19.8–26.0 25–35 lb
		• 26.1–29.0 15–25 lb
		• >29 ~15 lb
	Optimal weight gain for women carrying twins	Weekly weight gain of 0.75 kg during second and third trimesters to a total of 35 to 44 lbs
	Rate of weight gain, singleton pregnancy	First trimester: 1½ to 5 lb
		Second and third trimester: ½ to 2 lb/week
		Intensive assessment and counseling
		The additional calories needed are 200 to 300 cal/day in patients second and third trimester
	Poor weight gain <2 lb/month <10 lb by midpregnancy	If patient is economically unable to meet nutritional needs — referral to federal food and nutrition programs (Women, Infants, and Children, or WIC)
	Nutritional needs/barriers	Increase knowledge with dietary counseling
	Vitamin/mineral supplementation	No requirement for routine supplementation except folate (400 μg/day) and iron (30 to 60 mg elemental iron/day)
		Dietary supplements should be given if the adequacy of a patient's diet is questionable or if she is at high nutritional risk
		Excessive vitamin and mineral intake (more than twice the Recommended Dietary Allowances [RDA]) should be avoided
	Prophylaxis for iron deficiency	Supplement of ferrous iron is 30 mg elemental iron daily
		Zinc supplements are recommended if taking high doses of iron

TABLE 13.2
(Continued)

Visit	Assessment	Counseling/Treatment
	Iron-deficiency anemia	60 to 120 mg elemental iron daily
	Calcium supplementation	Recommended for women who have diet deficient in calcium, have prepregnancy hypertension, history of eclampsia or chronic use of heparin or steroids, and adolescents
	Evaluate use of alcohol, tobacco, and drugs	Effects of substance use/abuse on perinatal outcomes Abstinence from alcoholic beverages
	Caffeine intake	Consumption of 2 to 3 servings of caffeinated beverages is unlikely to have adverse effects; in general, caffeinated beverages provide few essential nutrients and often crowd out better sources of nutrients *Moderate intake* is <300 mg/day — recently not linked to adverse effects on pregnancy 5 oz • Cup of coffee = 115 mg • Iced tea = 40 mg • Cola = 15mg • Hot Chocolate = 4 mg *High Intake* (>500 mg/day) Increased risk (2.2 ×) of first trimester spontaneous abortions
	Lactose intolerance	May result in insufficient calcium intake Supplemental calcium necessary if insufficient calcium consumed from food sources
	Gestational diabetes mellitus	Referral for nutrition assessment and counseling. Generally diet is 40% carbohydrate, 30% fat, 30% protein
	Nausea and vomiting during pregnancy	Eat crackers before getting out of bed in the morning; eat frequent small meals; eat low-fat, bland foods; eat ginger (soda, tea, or ginger snaps); suck on hard candy; eat salty/tart foods combined (e.g., potato chips with lemonade); supplement with vitamin B_6 (25 mg three times daily); wear Sea Band® (an elastic band worn on wrists to counter nausea caused by seasickness) Strong evidence for taking a multivitamin at the time of conception decreasing the severity Vitamin B_6 with or without doxalamine is safe and effective and should be considered a first-line treatment Doxylamine dosage is 12.5 to 25 mg three times daily; lesser evidence for ginger in any form (tea, soda, and tablets [250-mg capsule, four times daily for 4 to 5 days]); antihistamines, phenothiazines, benzamines — safe and effective in refractory cases Early treatment may prevent progression to hyperemesis Methylprednisolone may be effective in severe cases — treatment of last resort because of potential risk to the fetus
	Constipation	Foods high in dietary fiber, including cereals, bread fruits and vegetables; adequate fluids; moderate exercise; soluble fiber (e.g., Metamucil, Citrucel, or Benefiber); docusate; change brand of iron supplement DRI for water is 3.0 l/day DRI for dietary fiber is 28 g/day
Postpartum	Diet	Utilize dietary intake questionnaire Dietary guidelines are similar to those established during pregnancy Continue multiple vitamin–mineral supplements
	Caloric requirement	Balanced, nutritious diet will ensure both the quality and quantity of milk produced without depletion of maternal stores. Increased need of 300 to 500 calories. At least three servings of milk daily. The Adequate Intakes (AI) for water for lactating women is 3.8 l/day
	Vitamin/mineral supplement	Not needed routinely although recommended for the 400 μg/day folic acid; mothers at nutritional risk should be given a multivitamin supplement with particular emphasis on calcium and vitamins B_{12} and D
	Weight retention	The relationship between BMI or total weight gain and weight retention is unclear. It appears that women who gain more than the Institute of Medicine (IOM) guidelines retain twice as much weight as those who gain within the guidelines
	Residual postpartum weight retention	Aging, rather than parity, is the major determinant of increases in a woman's weight over time Special attention to lifestyle, including exercise and eating habits

RISK FACTORS FOR PRENATAL NUTRITION RISK AND INDICATIONS FOR REFERRAL

Table 13.2 includes nutrition assessment, counseling, and treatment strategies for women seeking care in both the prenatal and postnatal stages. Fetal growth is affected by the quality and quantity of the maternal diet, the ability of the mother to digest and absorb nutrients, maternal cardiorespiratory function, uterine blood flow, placental transfer, placental blood flow, and appropriate

distribution and handling of nutrients and oxygen by the fetus. Factors that put women at nutritional risk for pregnancy are listed in Table 13.3.[5,14–16] Patients at high nutritional risk should be provided professional nutritional counseling and/or referral to a nutrition intervention program (Table 13.4). The Women, Infants, and Children (WIC) Program is a food prescription program designed and proven to reduce poor pregnancy outcomes (Table 13.5).

TABLE 13.3
Risk Factors for Prenatal Nutritional Risk

Risk Factor	Low Risk	High Risk
Is the patient pre- or adolescent or <3 years postmenarche?	No	Yes
Is the patient economically disadvantaged or have limited income for food?	No	Yes
Does the patient have history of anemia or is anemic (hematocrit <32mg/% during pregnancy)?	No	Yes
Is the patient's BMI <19.8 or >26.1?	No	Yes
Does the patient have history of fad dieting or restrictive eating?	No	Yes
Does the patient have illness or medication that will interfere with absorption; is she HIV+?	No	Yes
Does the patient use tobacco, alcohol, or drugs?	No	Yes
Does the patient practice pica (consume ice, starch, clay, or other substances in large amounts)?	No	Yes
Does the patient experience nausea and/or vomiting?	No	Yes
Is the patient lactose intolerant?	No	Yes
Is the weight gain 0.8 to 1.0 lb/week?	No	Yes
Does the patient stay within the weight gain range recommended for her prepregnancy BMI?	Yes	No
Weight gain <15 lbs or >45 lbs?	No	Yes
Prior bariatric surgery	No	Yes

TABLE 13.4
Indications for Referral of Pregnant Patients for Nutrition Assessment and Counseling

Patient has interest in and desire to see a nutritionist
Patient has inappropriate weight gain
Patient has gestational diabetes
Patient has chronic condition managed with diet (e.g., diabetes or hyperlipidemia)
Patient has history of anemia
Patient has inadequate or inappropriate food supply
Patient has history of prepregnancy anorexia or bulimia
Patient has significant discomforts of pregnancy (e.g., heartburn, nausea, or vomiting)
Patient has multiple gestation
Patient is adolescent
Patient is vegetarian
Patient is interested in or undecided about breastfeeding

TABLE 13.5
Characteristics of Women, Infants, and Children (WIC) Program

Target audience	Pregnant women
	Breast-feeding women
	Non-breast-feeding mothers of infants <6 months old
	Infants <1 year old
	Children <5 year old
Purpose	Provide nutritious foods, health checks, referrals, nutrition education, and counseling
Eligibility criteria	Low income: <185%, the U.S. federal poverty level for women and children
Food	Nutrient rich, high in protein, calcium, iron, and vitamins A & C
	Limited brand names
	Patient-purchased food and infant formula from local supermarkets
Nutrition education	Individual and group
	Specific to risk
Health checks	Height, weight, and anemia testing for women, infants children
	1-year-old test for lead

WEIGHT GAIN AND PREGNANCY

PREGNANCY WEIGHT GOALS

There is a lack of consistent findings concerning relationships of birth interval, parity, prepregnancy weight or body mass index (BMI), height, and physical activity to maternal weight or weight gain.[9,17–30] The Cochrane Pregnancy and Childbirth Group[31] summarized the findings on the effects of advising pregnant women to increase their energy and protein intakes, on gestational weight gain, and on the outcome of pregnancy. They found that nutritional advice appears to be effective in increasing pregnant women's energy and protein intakes, but the implications for fetal, infant, or maternal health cannot be judged from the available trials.

Less than 50% of pregnant women gain in the outlined weight ranges. Some researchers question the notion that African-American women gain more weight than Caucasian women, suggesting that the data only showed questionable benefit in reducing risks for low-birth-weight babies.[7] Some experts believe that the weight-gain guidelines are too high for all and that it should be individualized.

Obese women have a greater risk of pregnancy complications, especially excessive weight gain, gestational diabetes, hypertensive disorders, prolonged and difficult labor, postdate pregnancy, meconium, postpartum hemorrhage, operative delivery, and weight retention after pregnancy. Infants of obese women may be at greater risk for perinatal mortality, prematurity, and low birth weight with is associated with diabetes mellitus, hypertension, and heart disease in adulthood.[26,31–32]

The recommendations in Table 13.6 were established by the National Academy of Sciences of the National Institute of Medicine in 1990.[3] They were reviewed and left unchanged by the Maternal Weight Gain Expert Group in 1996.[29] These recommendations remain controversial.[33] Weight-gain goals have been determined to provide optimal risk reduction for delivering a low-birth-weight baby while avoiding adverse effects on the mother's health. The recommendations vary based on pregnancy weight, age, and ethnicity. The weight gain expected is essentially linear, as demonstrated in Figure 13.1.[34] There is no evidence that weight gain in the Institute of Medicine ranges is harmful to the mother or infants of women starting pregnancy at a normal BMI. There is little guidance on appropriate weight gain for women who are not at a normal BMI at the beginning of pregnancy. Women with prepregnant BMIs >35 are at increased risk for gestational diabetes, preeclampsia, placenta abrupta, operative delivery, and endometriosis.[32]

TABLE 13.6
Pregnancy Weight Goals

Optimal Weight Gain (Pounds)	Characteristic
25–35	Most women and normal pregnancy
	Prepregnancy BMI 19.8 to 26.0 or 100% prepregnancy ideal body weight
28–40	Women at higher risk for low-birth-weight babies, including adolescents and African-American women
	Prepregnancy BMI <19.8 (underweight) or 90% ideal body weight
	Twin pregnancy
15–25	Prepregnant BMI >26.1 (overweight or obese) or >120% ideal body weight
15	Prepregnant BMI >29 or >135% ideal body weight
35–44	Women pregnant with twins or 50 to 75% increase based on prepregnant BMI
FIGURE 13.1 Graph for tracking weight and fundal height. (With permission from Kolasa, K.M. and Weismiller, D.G. Nutrition during pregnancy, Am Fam Phys. 56(1): 206, July 1995.)

RATE OF WEIGHT GAIN

In 1996, the Maternal and Weight Gain Expert Group[29] suggested a weight gain of 1 lb/week for normal-weight women during the second and third trimester of a singleton pregnancy. Weight gain is the single most reliable indicator of pregnancy outcome.[17,28] Weight status should be routinely assessed for amount and rate. Figure 13.1 depicts an example of a graph for tracking weight.[34] Weight charts should be shown to women and their support partners. Table 13.7 gives recommended weight gains. The optimal weight for a newborn infant of 39 to 41 weeks gestation is 6.6 to 8.8 lb.[15]

Women with inadequate weight gain should eat more frequently, be referred to a dietitian for nutrient assessment and counseling, choose more nutrient-dense foods, avoid alcohol and tobacco use, limit activity, and avoid caffeine or other appetite depressants. Women with excessive gain should reduce portion sizes, limit intake of sweets and foods high in fat, increase activity, and be evaluated by a registered dietitian.

WEIGHT-GAIN DISTRIBUTION DURING PREGNANCY

Weight gain by pregnant women consists of water, protein, and fat. Measurements of maternal water gain may predict birth weight better than measurements of composite weight gain. The total amount of weight gained, the composition of gain, and the rate of energy metabolism all differ among healthy pregnant women. Table 13.8 is a typical teaching tool about weight-gain distribution.

NUTRITION SNACKS

Pregnant women may need suggestions for healthy snacks. Table 13.9 includes snacks of about 100 calories.

DIETARY REQUIREMENTS FOR PREGNANCY AND LACTATION

DIETARY REFERENCE INTAKE (DRI)

Dietary reference Intakes are the levels of intake of essential nutrients considered adequate to meet or exceed known nutritional needs of practically all healthy people. Table 13.10 includes the Recommended Dietary Allowances (RDA) and Adequate Intakes (AI) as available in 2005 for pregnancy and lactation.[35,36] These levels are set by the Food and Nutrition Board of the National Academy of Sciences. Nutrient needs that are increased during pregnancy are for calcium in women at high risk for gestational hypertension — teenagers, previous preeclampsia, women with increased sensitivity to angiotensin II, preexisting hypertension, and in communities with low dietary intake of calcium (<900 mg/day), choline, chromium, copper, folate, magnesium, manganese, molybdenum, niacin, pantothenic acid, riboflavin, selenium, thiamin, vitamin B_6, vitamin B_{12}, vitamin C,

TABLE 13.7
Rate of Weight Gain (Pounds)

Timing (Trimester)	Appropriate	Inadequate	Excessive
First	3–5 Total	Less	More
Second, Third	1/week	Less than 2 lb in a single month for normal-weight women or <1 lb in obese	More than 6.5 lb in a single month

TABLE 13.8
Weight-Gain Distribution during Pregnancy (Pounds)

Source	Pounds
Amniotic Fluid	2–2.6
Baby	7–8.5
Fat/breast tissue stores for breastfeeding	1–4
Increased blood volume	4–5
Increased weight of uterus	2
Maternal fat stores	4–7
Placenta	0.7–1.0
Tissue fluid	3–5
Total	25–35

TABLE 13.9
Nutritious Snacks of 100 kcal or Less

Food Item	Serving Size
Applesauce	$^2/_3$ cup
Bagel	$^1/_2$
Carrot, raw	1 cup or 1 large
Cheese, low-fat	1 oz
Cottage cheese, low-fat	$^1/_3$ cup
Entenmann's fat-free cakes/pastries	1 small slice
Figs, low-fat, or other Newton cookies	1–$^1/_2$ tsp
fruit, dried (like apricots, raisins, prunes)	4 tsp.
Fruit, fresh	1 medium
Graham crackers	2
Grits	1 package
Milk, skim	1 cup
Pretzels	15
Pudding made with skim milk	$^1/_3$ cup
Rice cakes, flavored	2
Tortilla chips, baked, low-fat, and with salsa	12
Tuna	$^1/_2$ cup
Yogurt, frozen	$^1/_2$ cup
Yogurt, low-fat	$^1/_2$ cup

TABLE 13.10

Food and Nutrition Board, National Academy of Sciences — National Research Council Recommended Dietary Allowances, and Dietary Reference Intakes (DRI)
Designed for the Maintenance of Good Nutrition of Practically All Healthy People in the United States

Category	Condition	Protein (g)	Vitamin A (μg RE)[b]	Vitamin E (mg α-TE)[c]	Vitamin K (μg/day)	Vitamin C (mg)	Iron (mg)	Zinc (mg)	Iodine (μg)	Selenium (μg)
Pregnant		71	770	15	90	85	27	11	220	60
Lactating	First 6 months	71	1300	19	90	120	9	12	290	70
	Second 6 months	71	1300	19	90	120	9	12	290	70

[a] The allowances, expressed as average daily intakes over time, are intended to provide for individual variations among most normal persons as they live in the United States under unusual environmental stresses. Diets should be based on a variety of common foods in order to provide other nutrients for which human requirements have been less well defined.

[b] Retinol equivalents. 1 retinol equivalent = 1 μg retinol or 6 μg β-carotene.

[c] α-Tocopherol equivalents. 1 mg d-α tocopherol = α-TE.

Note: Dietary Reference Intakes for calcium, phosphorus, magnesium, vitamin D, and fluoride (1997) and Dietary Reference Intakes for thiamin, riboflavin, niacin, vitamin B, folate, vitamin $B_{12,}$ pantothenic acid, biotin, and choline (1998).

and zinc, protein (10% to 35% of calories), carbohydrate (45% to 65% of calories), total fiber, and omega-3 and omega-6 fatty acids. In lactation, requirements for carbohydrates, dietary fiber, water, biotin, choline, chromium, copper, manganese, pantothenic acid, riboflavin, selenium, zinc, vitamin A, vitamin B_6, vitamin B_{12}, vitamin E, vitamin C, iodine, and potassium are increased over the increased pregnancy needs. In lactation, the iron requirements are reduced. Energy needs are also increased by 340 kcal/day (recommend 200 to 300 kcal/day) in the second trimester of pregnancy and by 452 kcal/day (recommend 200 to 500 kcal/day) during lactation so that adequate breast milk supply is produced.

The 2005 Dietary Guidelines for Americans and MyPryamid[37] include some recommendations for pregnant women but no specific plan. Women are encouraged to obtain adequate nutrients within calorie needs. During the first trimester they should consume adequate synthetic folic acid daily (from fortified foods or supplements) in addition to food forms of folate from a varied diet. They should ensure appropriate weight gain as specified by a health care provider. In the absence of medical or obstetric complications 30 min or more of moderate-intensity physical activity on most, if not all, days of the week should be incorporated. Activities with a high risk of falling or abdominal trauma should be avoided. Alcoholic beverages should not be consumed. Raw (unpasteurized) milk or any products made from unpasteurized milk, raw or partially cooked eggs, foods

TABLE 13.11

Food and Nutrition Board, Institute of Medicine — National Academy of Sciences Designed Reference Intake: Recommended Intakes for Individuals

Life-Stage Group	Calcium (mg/Day)	Phosphorus (mg/Day)	Magnesium (mg/Day)	Vitamin D (μg/Day)[a,b]	Fluoride (mg/Day)	Thiamin (mg/Day)	Riboflavin (mg/Day)	Niacin (mg/Day)[c]	Vitamin B$_6$ (mg/Day)	Folate[d] (μg/Day)	Vitamin B$_{12}$ (μg/Day)	Pantothenic Acid (mg/Day)	Biotin (μg/Day)	Choline[e] (mg/Day)
Pregnancy (in years)														
≤18	1300*	1250	400	5*	3*	1.4	1.4	18	1.9	600[f]	2.6	6*	30*	450*
19–30	1000*	700	350	5*	3*	1.4	1.4	18	1.9	600[f]	2.6	6*	30*	450*
31–50	1000*	700	360	5*	3*	1.4	1.4	18	1.9	600[f]	2.6	6*	30*	450*
Lactation (in years)														
≤18	1300*	1250	360	5*	3*	1.5	1.6	17	2.0	500	2.8	7*	35*	550*
19–30	1000*	700	310	5*	3*	1.5	1.6	17	2.0	500	2.8	7*	35*	550*
31–50	1000*	700	320	5*	3*	1.5	1.6	17	2.0	500	2.8	7*	35*	550*

[a] As cholecalciferol. 1 μg cholecalciferol = 40 IU vitamin D.

[b] In the absence of adequate exposure to sunlight.

[c] As niacin equivalents (NE). 1 mg of niacin = 60 mg of tryptophan; 0–6 months = performed niacin (not NE).

[d] As dietary folate equivalents (DFE). 1 DFE = 1 μg food folate = 0.6 μg of folic acid (from fortified food or supplement) consumed with food = 0.5 μg of synthesis (supplemental) folic acid taken on an empty stomach

[e] In view of evidence linking folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant consume 400 μg of synthetic folic acid from fortified food or supplements in addition to intake of food folate from a varied diet.

[f] It is assumed that women will continue consuming 400 μg of folic acid until their pregnancy is confirmed, and they enter prenatal care, which ordinarily occurs after the end of the periconceptual period — the critical time for formation of the neural tube.

Note: This table presents Recommended Dietary Allowances (RDAs) in bold type and Adequate Intakes (AIs) in ordinary type followed by an assessment asterisk (*).

containing raw eggs, raw, or undercooked meat and poultry, raw or undercooked fish or shellfish, unpasteurized juices, and raw sprouts should be avoided. Only deli meats and frankfurters that have been reheated to steaming hot can be eaten. Women are advised to avoid some types of fish and shellfish and to eat fish and shellfish that are lower in mercury. Food and Drug Administration (FDA) maintains toll-free information at 1-888-SAFEFOOD.

There are no specific diet plans for pregnant women. Personalized pyramids showing food groups and amounts of foods from each food group, based on calorie needs, can be downloaded from http://mypyramid.gov. Pregnant women should drink at least 3.0 l of water each day.

DIETARY ASSESSMENT OF THE PREGNANT WOMAN

Individualized nutrition assessment and planning is important because of the strong associations between extremes in prepregnancy BMI, extremes in weight gain, and adverse pregnancy outcomes.[3,7,34,38–40]

There are special nutrition implications for pregnant women who have had bariatric surgery, especially the Roux-en-Y procedure.[41] Adequate weight gain to promote fetal growth is advised. There are no published weight-gain criteria for post-gastric-bypass. Serum iron and TIBC, CBC, folate, and vitamin B_{12} levels should be monitored.

BEHAVIOR-CHANGE TOOL

Assessment relies on the woman's medical record, history, and physical examination. Nutritional factors of importance include previous nutritional challenges, eating disorders, pica, fad dieting, botanicals and teas, strict vegetarian diet, medications, and quantity and quality of current diet. The Institute of Medicine provides a sample dietary history tool (Table 13.12).[3]

What one eats and some of the lifestyle choices one makes can affect nutrition and health now and in the future. One's nutrition can also have an important effect on one's baby's health. Please answer these questions by circling the answers that apply to you in Table 13.12.

Systematic assessment of the diet is preferable to questions such as "How are you eating?" The 24 h dietary recall method is commonly used to recall the types and amounts of foods and beverages consumed during the previous day. The food frequency questionnaire has been demonstrated to detect pregnancy-related changes in diet.

TABLE 13.12
Behavior-Change Dietary Assessment Tool

Eating Behavior

1. Are you frequently bothered by any of the following? (circle all that apply)

    Nausea   Vomiting   Heartburn   Constipation

2. Do you skip meals at least three times a week?	No	Yes
3. Do you try to limit the amount or kind of food you eat to control your weight?	No	Yes
4. Are you on a special diet now?	No	Yes
5. Do you avoid any foods for health or religious reasons?	No	Yes

Food Sources

6. Do you have a working stove?	No	Yes
Do you have a working refrigerator?	No	Yes
7. Do you sometimes run out of food before you are able to buy more?	No	Yes
8. Can you afford to eat the way you should?	No	Yes

9. Are you receiving any food assistance now? (circle all that apply)

    Food stamps   School breakfast   School lunch
    Donated food   Commodity Supplemental   Food Program
    Food from a food pantry, soup kitchen, or food banks

10. Do you feel you need help in obtaining food?	No	Yes

Food and Drink

11. Which of these did you drink yesterday? (circle all that apply)

    Soft drinks   Coffee   Tea   Fruit drink
    Orange juice   Grapefruit juice Other juices   Milk
    Kool-Aid   Beer   Wine   Alcoholic drinks
    Water   Other beverages (list)

12. Which of these foods did you eat yesterday? (circle all that apply):

    Cheese   Pizza   Macaroni and cheese
    Yogurt   Cereal with milk

Continued

TABLE 13.12
(Continued)

Food and Drink (Continued)

13. Other foods made with cheese (such as tacos, enchiladas, lasagna, and cheeseburgers)

Corn	Potatoes	Sweet potatoes	Green salad
Carrots	Collard greens	Spinach	Turnip greens
Broccoli	Green beans	Green peas	Other vegetables
Apples	Bananas	Berries	Grapefruit
Melon	Oranges	Peaches	Other fruit
Meat	Fish	Chicken	Eggs
Peanut butter	Nuts	Seeds	Dried beans
Cold cuts	Hot dog	Bacon	Sausage
Cake	Cookies	Doughnut	Pastry
Chips	French fries	Deep fried foods, such as fried chicken or egg rolls	
Bread	Rolls	Rice	Cereal
Noodles	Spaghetti	Tortillas	

Were any of these whole grains?	No	Yes
Is the way you ate yesterday the way you usually eat?	No	Yes

Lifestyle

14. Do you exercise for at least 30 min on a regular basis — three times a week or more?	No	Yes
15. Do you ever smoke cigarettes or use smokeless tobacco?	No	Yes
16. Do you ever drink beer, wine, liquor, or any other alcoholic beverages?	No	Yes

17. Which of these do you take? (circle all that apply)

Prescribed drugs or medications

Any over-the-counter products (such as aspirin, acetaminophen, antacids, or vitamins)

Source: Institute of Medicine, 1992.

NUTRITIONAL RISK TOOL

Table 13.13 is an example of a more quantitative method for assessing the diet.[38] The mother's usual intake is determined for each of the food groups (meats and alternatives, dairy, bread and cereal, fruits, and vegetables) and the score is tallied. A patient with fewer than 80 points is at nutritional risk. The evaluator should determine whether the patient has problems such as nausea/vomiting, lactose intolerance, constipation, or cravings for nonfood items. Women with a score of fewer than 50 points should be referred to a registered dietician for counseling.

COMPLICATIONS OF PREGNANCY THAT MAY IMPACT NUTRITIONAL STATUS

A number of complications of pregnancy may impact nutritional status. Some of these include nausea and vomiting, constipation, caffeine intake, and alcohol intake.

NAUSEA AND VOMITING

About 70% of pregnant women report nausea during the first 14 to 16 weeks of pregnancy, and 37% to 58% experience vomiting. The etiology is unknown. The remedies include diet, fluids, and reassurance.[42,43] Table 13.14 is a collection of remedies.

HYPEREMESIS GRAVIDARUM

Vomiting that produces weight loss, dehydration, acidosis from starvation, alkalosis from loss of hydrochloric acid in vomitus, and/or hypokalemia may be treated pharmacologically. Management is to correct dehydration, fluid and electrolyte deficits, acidosis, and alkalosis. Table 13.15 includes some pharmacological approaches.

CONSTIPATION

Constipation is extremely common in pregnancy because of decreased motility of the gastrointestinal (GI) tract. Constipation can be exacerbated by iron supplementation. Constipation is often related to low dietary fiber intake and low fluid intake. Table 13.16 includes foods rich in dietary fiber. The recommended intake is 28 g of dietary fiber daily.

TABLE 13.13
Nutritional Risk Score (Massachusetts Department of Health)

Foods Usually Eaten	Amount
Meat or alternates	
Meats, fish, poultry, (fresh or processed), liver eggs, nuts, peanut butter, legumes	_____servings
1 oz = 5 points	_____oz meat, fish, cheese[a]
Maximum score = 40 points	_____oz alternate
Milk (type) 1 unit = 5 people	_____fluid
1 unit = 8 fl oz	_____cups
Cheese[b] (type) _____	_____oz
Maximum score = 15 points	
Bread and cereal[c] — whole grain, enriched, other maximum	_____servings
Score = 15 points	
Fruits and vegetables	
Citrus and/or vitamin-C-rich vegetables	_____servings
Green and yellow vegetables	_____servings
All other, including potato	_____servings
	Total fruits

Vitamin A Vitamin C
1 unit = 5 points   1 unit = 5 points
2 units = 15 points   2 units = 15 points   _____servings
Supplements[d] (type)   _____amount
Other foods and beverages
Total score: >80 = no risk, less, <80 = risk, <50 = high risk

[a] Cheese in excess of the 3 units scored in milk; 1 oz cheese equals 1 unit.
[b] Maximum of 3 oz scored.
[c] Unit = 1 slice of bread or 1 oz cereal. Less than 3 units = 0, 3 units = 5 points, 4 units = 10 points, 5 units = 15 points.
[d] Not given a score.

TABLE 13.14
Nonpharmacological Remedies for Nausea and Vomiting

Eat small, frequent meals
Eat dry foods/cold foods
Take dietary supplements after meals
Suck on candy
Switch brands of iron supplements
Eat combinations of foods that are salty and tart
Eat vitamin-B_6-rich foods
Try seabands or acupressure bands
Avoid beverages with meat
Avoid caffeine
Avoid spicy, acidic foods, and strong odors
Sniff lemon
Drink ginger root tea, ginger ale; eat ginger snaps; take ginger tablets
  (250 mg tablets four times daily for 4 to 5 days)
Drink plenty of fluids to avoid dehydration

CAFFEINE DURING PREGNANCY AND LACTATION

The literature is mixed on the effects of caffeine during pregnancy. The official FDA position advises pregnant women to avoid caffeine or consume it sparingly. Most experts agree that caffeine should be limited to less than two servings per day. Caffeine is known to decrease availability of calcium, iron, and zinc. It is known to exert effects on the fetus. The relationship of caffeine

TABLE 13.15
Hyperemesis Gravidurum

Medication	Dosage
Vitamin B_6	25 mg t.i.d. along with doxylamine
Doxylamine	12.5–25 mg t.i.d. along with vitamin B_6
Emetrol	5–10 cc in the morning and every 3–4 h as needed
Antiemetic/antinausea medications, for example, trimethobenyamine (Tigan)	200 mg suppository q 8 prn
Promethazine	12.5–25 mg po. Pr or iv q 4–6

TABLE 13.16
Dietary Sources of Fiber

Serving Size	Food	Grams of Fiber
Breads, Cereals, Pastas		
3 cups	Air-popped popcorn	4
1 medium	Bran muffin	3
⅔ cup	Brown rice	3
1 slice	Whole wheat bread	3
½ cup	Cooked legumes	5
½ cup	Baked beans	10
½ cup	Great northern beans	7
½ cup	Lima beans	7
½ cup	Selected fiber cereals (Read label)	14
Fruit		
1 cup	Raisins	6
3	Dried prunes	5
1 medium	Pear with skin	4
1 medium	Apple with skin	3
1 cup	Strawberries	3
1 medium	Banana	3
1 medium	Orange	3
Vegetables		
½ cup	Cooked frozen peas	4
1 medium	Baked potato with skin	4
½ cup	Brussels sprouts	3
½ cup	Cooked broccoli tops	3
½ cup	Cooked carrots	3
½ cup	Cooked corn	3

to spontaneous abortion remains controversial. A recent report suggests that risk increases with the consumption in the range of 6 to 18 cups of coffee per day (>450 mg/day of caffeine).[44]

Caffeine does pass into breast milk, and therefore consumption during lactation should be limited. Table 13.17 lists caffeine values for popular beverages.

Some suggestions for reducing caffeine consumption include: (1) switching to decaffeinated coffee or soft drinks, (2) cutting down on caffeinated beverages, (3) mixing caffeinated and decaffeinated coffee grounds together before making coffee, and (4) limiting consumption of caffeinated beverages to a preselected number and then switching to decaffeinated beverages over time.

ALCOHOL

Consumption of alcohol during pregnancy and lactation is controversial.

Pregnancy

A safe lower limit of alcohol during pregnancy is not known. Therefore, the only sure way to avoid the possible harmful effects of alcohol on the fetus is to abstain. Binge drinking or excessive drinking during pregnancy can result in fetal alcohol syndrome. However, even small amounts of alcohol can temporarily alter fetal function. Adverse outcomes have not been found with daily

TABLE 13.17

TABLE 13.18

Effects of Alcohol, Tobacco, and Drug Use on Nutritional Status and Pregnancy Outcomes and Lactation

Effect	Cause
Increased nutrient requirements/impaired nutrient absorption	Smokers have reduced vitamin C levels
	Drinkers have reduced serum folate and vitamin C levels
Impaired growth of the fetus/stunted growth of child	Drinkers of one to two alcoholic beverages/day associated with LBW, slow weight gain, and failure to thrive
	Smokers
Infant sleep disruption/increased arousal	Consumption of one drink/day in the first trimester
Delayed development/mental retardation	Drinkers have children who are more at risk for hyperactivity, poor attention span, language dysfunction
Reduced fertility	Chronic drinking and smoking associated with lower fertility in men and women
Transfer to baby during lactation disrupted sleep pattern of infant	Alcohol is concentrated in breast milk. An occasional small drink is acceptable but breast-feeding should be avoided for 2 h.

consumption of fewer than two standard drinks. The danger from light drinking should not be overstated. This may cause undue stress in some patients who had few drinks before realizing they were pregnant (see Table 13.18).

Lactation

Alcohol does not increase milk volume. Chronic consumption can inhibit milk production. The American Academy of Pediatrics does suggest that an occasional celebratory single, small alcoholic drink is acceptable, but breast-feeding should be avoided for 2 h after the drink as alcohol is concentrated in breast milk.[53,45]

HYPERTENSION

The Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 7) outlines five classifications of hypertension in pregnancy. Treatment includes lifestyle modification for women with stage 1 hypertension. Data are sparse but many experts recommend restricting sodium intake to 2.4 g/day. Pharmacological management is described.[45,46]

VITAMIN AND MINERAL REQUIREMENTS, FOOD SOURCES, AND SUPPLEMENTATION

In the United States, vitamin and mineral supplementation is common among pregnant women. During pregnancy, maternal requirements for almost all nutrients increase. Higher RDAs have been defined for calcium in adolescents, choline, chromium, copper, folate, magnesium, manganese, molybdenum, niacin, pantothenic acid, riboflavin, selenium, thiamin, vitamin B_6, vitamin B_{12}, vitamin C, and zinc. For some nutrients, the evidence indicates a direct link between chronic maternal deficiency and poor outcome for the mother and infant. Excessive intake (usually defined as more than twice the RDA) of some nutrients may be harmful to the fetus, especially very early in the pregnancy.[21,36]

Supplementation, with the exception of folic acid, is recommended only after assessment of dietary practices of pregnant women. The Institute of Medicine does not recommend routine use of prenatal vitamins; however, many physicians prescribe them because of the marginal nutritional status of their patients or because it difficult to be completely sure of their patients' nutritional status.[3] Prenatal vitamins and minerals are indicated for high-risk populations and those with an obstetric history of high parity, previous delivery of a low-birth-weight infant, a short interval between births, and smokers, drug or alcohol abusers, and those with multiple pregnancies.

PRENATAL VITAMINS

Indications for vitamin and mineral supplementation are shown in Table 13.19, which lists nutrient dose and indication for use. The contents of typical prenatal vitamin–mineral supplements are shown in Table 13.20, which includes usual formula of an over-the-counter (OTC) and a prescription supplement recommended to pregnant women.

VITAMIN A

Most pregnant women do not need supplemental vitamin A, the teratogenic threshold of which may be lower than previously thought. Vitamin A is essential for embryogenesis, growth and epithelial differentiation. The RDA in pregnancy is only slightly increased to 770 mg/day. Case reports have suggested an association between high doses of vitamin A (>25,000 IU) during pregnancy and birth defects. The American College of Obstetricians and Gynecologists established 10,000 IU (or 3,000 mcg RAE) as the cutoff for supplemental vitamin A (retinol) prior to or during pregnancy. There is no concern about β-carotene intake.

CALCIUM AND MAGNESIUM

About 99% of calcium in pregnant women and their fetus is located in their bones and teeth. Pregnancy and lactation are associated with increased bone turnover to meet needs. If dietary deficiencies occur, maternal bone will supply the calcium to the fetus. Calcium supplementation during pregnancy has been shown to lead to an important reduction in systolic and diastolic blood pressure.[10] Controlled clinical trials to test the hypothesis that calcium supplements during pregnancy reduce the incidence of pregnancy-induced hypertension have had mixed results. Therefore, there is no support for routine supplementation with 2000 mg/day for all pregnant women. In pregnant women who have diets deficient in calcium (<900 mg/day) , are adolescent, have prepregnancy hypertension, history of preeclampsia, or chronic use of heparin and steroids supplemental calcium is recommended.[47]

The fetus absorbs 6 mg of magnesium each day. Maternal magnesium levels remain constant during pregnancy despite reported inadequate intakes. The RDA for most pregnant women is increased to 350 mg/day. Magnesium supplementation has been associated with fewer hospitalizations, fewer preterm births, and more perinatal hemorrhages compared with placebo-supplemented women. Thus, further study is needed before routine supplementation is recommended.

FOLATE AND IRON

The available data from controlled trials provide clear evidence of an improvement in hematological indices in women receiving routine iron and folate supplementation during pregnancy. Iron supplementation with and without folic acid results in substantial reduction of women with hemoglobin levels <100 g/l late in pregnancy, at delivery, and 6 weeks postpartum.[48] The Cochrane Pregnancy and Childbirth Group recommends iron supplementation.[49] Both foliate intake from food and synthetic folic acid should be included in assessing and planning diet. The literature contains a variety of recommendations. The DRI is

TABLE 13.19
Indications for Vitamin and Mineral Supplementation

Indication	Nutrient	Dose
Inadequate diet; during first two trimesters for women at risk for preterm labor or low-birth-weight baby	Prenatal supplements	Read label
Up to 1200 mg/day if dairy or fortified foods not consumed	Calcium	250–300 mg
For women receiving supplemental iron	Copper	2 mg
For all women of child bearing age	Folate	400 μg
Inadequate diet; anemia	Iron[a]	30–60 mg elemental
Inadequate diet	Vitamin B$_6$	2 mg
Inadequate diet	Vitamin C	50 mg
Inadequate diet; no exposure to sunlight	Vitamin D	10 μg
For women receiving supplemental iron	Zinc	15 mg

[a] Supplements containing high levels of folate or iron negatively affect zinc metabolism. Supplementary forms of folic acid are better absorbed than folate occurring in food.

TABLE 13.20
Prenatal Vitamin Mineral Supplements

	Flintstones Complete Chewables	Prenatal Vitamin (PreCare®)
Vitamin A	5000 IU	—
Vitamin C	60 mg	50 mg
Vitamin D	400 IU	6 μg
Thiamin	1.5 mg	—
Riboflavin	1.7 mg	—
Niacin	20 mg	—
Vitamin B$_6$	2 mg	2 mg
Folic acid	400 μg	1 mg
Vitamin B$_{12}$	6 μg	—
Biotin	40 μg	—
Pantothenic acid	10 mg	—
Calcium (as carbonate)	100 mg	250 mg
Iron	18 mg	40 mg
Phosphorus	100 mg	—
Iodine	150 μg	—
Magnesium	20 mg	50 mg
Zinc	15 mg	15 mg
Copper	2 mg	2 mg
Vitamin E	—	3.5 mg

higher than that usually obtained from food. The current recommendation during pregnancy is 600 μg/day of folic acid. It is well established that periconceptional use of folic acid supplementation reduces the risk of first occurrence and recurrence of neural tube defect (NTD) affected pregnancies by 70%. The Center for Disease Control (CDC) recommends supplementation of 400 μg/day for all women of childbearing age. Research is needed to determine effective strategies for disseminating information about the protective effects of folate.[49]

For women with previously affected pregnancy, the recommendation is 4 mg/day starting 1 to 3 months prior to conception and to continue through the first 3 months of pregnancy.

Additional iron is needed by most pregnant women in the United States. A substantial amount of iron is required, given the amount of erythropoiesis. For example, a term infant contains an average of 225 mg of iron and the placenta and cord contain 50 mg of iron through the pregnancy, and the maternal red blood count volume increases by 500 ml. The RDA for iron is increased to 27 mg/day (assuming 75% is heme iron). It is suggested that vegetarians require twice the amount of nonheme iron. Although maternal absorption of iron from the gastrointestinal tract is increased by about 15%, it remains difficult to meet the increased iron need through diet alone. Iron absorption is increased in the presence of ascorbic acid. Adverse pregnancy outcomes are associated with hemoglobin levels below 10.4 g/dl or above 13.2 g/dl. Clinical diagnosis of anemia is made based

on hemoglobin below 10.5 g/dl, a low MCV, and a serum ferritin level below 12 μg/dl. Supplementation of 30 to 60 mg/day of elemental iron is usually prescribed, although the benefit of routine iron supplementation for healthy, well-nourished women during pregnancy is unproven, and the USPSTF concludes that there is insufficient evidence to make a recommendation for or against routine iron supplementation.[50] Common side effects include stomach upset, nausea, and constipation. These effects may be relieved by reducing the dosage or switching the brand of iron supplement. Some, but not all, sustained release preparations have been clinically shown to be associated with fewer discomforts. The safety of iron supplementation at dosages <100 mg/day has been questioned. Researchers suggest that excess iron may lead to zinc depletion, which is associated with intrauterine growth retardation.

ZINC

The prevalence and effects of mild zinc deficiency in pregnancy are poorly defined. However, there have been a few case reports of severe human zinc deficiency in pregnancy that led to major obstetric complications and congenital malformation in the fetus. Supplementation studies have yielded mixed results. Iron appears to depress plasma zinc in pregnant women; therefore, zinc supplementation is recommended when >30 mg supplemental iron is taken.[57] Higher birth weights in infants of women with low prepregnancy weight (BMI <26) and low plasma zinc levels have been reported in women who received 25 mg zinc daily. The RDA is increased to 11 mg/day. Vegetarians may need more zinc.

VITAMIN B$_6$

The value of supplementation with Vitamin B$_6$ in pregnancy is controversial. However, it is included in most prenatal vitamins. The RDA is increased to 1.9 mg/day.

VITAMIN C

Taking iron tablets along with a source of vitamin C facilitates iron absorption. The RDA is increased to 75 mg/day.

VITAMIN D

Vitamin D is critical in the absorption, distribution, and storage of calcium. Relatively few foods, except those fortified, are good sources of vitamin D. The RDA is unchanged in pregnancy.

FOOD SOURCES OF SELECTED NUTRIENTS

There are a variety of published recommendations for calcium in pregnancy and lactation. The optimal calcium intake recommended by the National Institutes of Health is 1200 mg/day. This is difficult to meet with a diet containing little dairy or calcium-fortified foods. The DRI for pregnancy and lactation varies, based on age, from 1000 to 1300 mg/day. Meeting usual calcium needs has been demonstrated in reducing pregnancy-induced hypertension in women at high risk for gestational hypertension (teenagers, women with previous preeclampsia, women with increased sensitivity to angiotensin II, and women with preexisting hypertension) and in communities with low dietary calcium intakes (mean intake <900 mg/day). However, no benefit in reducing preeclampsia is seen with supplementing calcium daily. Table 13.21 lists common dietary sources of calcium; Table 13.22, common food sources of folate; Table 13.23, common dietary sources of iron; and Table 13.24, common dietary sources of zinc.

TABLE 13.21
Dietary Sources of Calcium (DRI = 1000–1300 mg/day)

Food item	Serving size
Good > 200 mg	
Broccoli/greens	2 cups
Calcium fortified foods (juice, cereal)	Varies, read label
Canned salmon with bones	3 oz
Canned sardines with bones	3 oz
Cheese (cheddar, edam, Monterey jack, mozzarella, Parmesan, provolone, ricotta)	1 oz
Ice cream	1 cup
Ice milk	1 cup
Milk (skim, 2%, whole, buttermilk)	1 cup
Yogurt	6–8 oz

TABLE 13.22
Dietary Sources of Folate (DRI = 500–600 μg/day of Dietary Folate Equivalents [DFE])

Food item	Serving size
Excellent >100 μg	
Asparagus	½ cup
Baked beans	1 cup
Bean burritos	2
Black-eyed peas	1 cup
Fortified grain and cereal products	Varies, read label
Kidney beans	1 cup
Lentils	1 cup
Liver and other organ meats	
Beef	3.5 oz
Chicken	3.5 oz
Orange juice	1 cup
Peanuts	4 oz
Spinach	½ cup
Good: 15–99 μg	
Almonds	4 oz
Bread, fortified	1 slice
Beets	½ cup
Broccoli, cooked	½ cup
Cantaloupe/Honeydew melon	1 cup
Cauliflower	½ cup
Egg	1 large order
French fries	½ cup
Lettuce (romaine)	
Orange	1 medium
Turnip greens	½ cup

TABLE 13.23
Dietary Sources of Iron (DRI = 15–30 mg/day)

Food item	Serving size
Excellent >4 mg	
Beef liver	3 oz
Clams	½ cup
Figs (dried)	10
Iron-fortified infant cereal	½ cup
Iron-fortified infant cereal	3 tsp
Kidney beans	1 cup
Molasses (blackstrap)	3 tbsp
Peaches (dried)	10 halves
Pinto beans	1 cup
Ready-to-eat, fortified cereals (such as Product 19®, Total®)	¾ cup
Sunflower seeds (dried, hulled)	⅔ cup
Good: 2–4 mg	
Beef	3 oz
Egg yolks	3
Iron-fortified infant formula	4 oz
Lamb	3 oz
Lima beans	½ cup
Oysters	3 oz
Peas	1 cup
Pork	3 oz
Prune juice	1 cup
Raisins	⅔ cup
Soybeans	½ cup

PHYSICAL ACTIVITY DURING PREGNANCY

Several factors influence physical activity during pregnancy, including prepregnancy exercise levels, current levels, personal preferences, risk, limitations, and contraindications.[19] Table 13.25 to Table 13.29 include guidelines for physical activity.

TABLE 13.24
Dietary Sources of Zinc (DRI = 15–19 mg/day)

Food item	Serving Size	mg/Serving
Excellent: >4 mg		
Beef (lean, cooked)	3 oz	5.1
Calves' liver (cooked)	3 oz	5.3
Lamb (lean, cooked)	3 oz	4.0
Oysters, Atlantic	3 oz	63.0
Oysters, Pacific	3 oz	7.6
Good: 0.9–3.4 mg		
Black-eyed peas (cooked)	½ cup	3.4
Chicken	3 oz	2.4
Crabmeat	½ cup	3.4
Green peas (cooked)	½ cup	0.9
Lima beans (cooked)	3 oz	0.9
Milk (whole)	1 cup	0.9
Pork loin (cooked)	3 oz	2.6
Potato (baked with skin)	1 medium	1.0
Shrimp	½ cup	1.4
Tuna (oil-packed, drained)	3 oz	0.9
Whitefish	3 oz	0.9
Yogurt (plain)	1 cup	1.1

TABLE 13.25
Benefits of Physical Activity during Pregnancy and Postpartum

Improvement in circulation
Improved posture
Improved or maintained cardiovascular fitness
Reduced risk of cesarean section, decreased labor time, and decreased use of
  epidural and forceps
Positive effects on mood, energy level
Release of tension and reduction of stress
Prevention of injury
Primary prevention of gestational diabetes, especially in women with BMI > 33
After pregnancy, associated with decreased incidence of postpartum depression

TABLE 13.26
Contraindications to Physical Activity

Active myocardial disease, congestive heart failure,
  and rheumatic heart disease
Thrombophlebitis
Risk of premature labor, incompetent cervix,
  uterine bleeding, and ruptured membranes
Intrauterine growth restriction
Severe hypertensive disease
Suspected fetal intolerance

TABLE 13.27
Warning Signs to Stop Physical Activity

Vaginal bleeding
Uterine contractions
Nausea, vomiting
Dizziness or faintness
Difficulty walking
Decreased fetal activity
Palpitations or rapid heart rate
Numbness in any part of the body
Problems with vision

TABLE 13.28
Guidelines for Physical Activity

Activity	Guideline
Intensity	Reduce the intensity of exercise by 25%
Heart rate	Not to exceed 140 beats/min
Temperature	Not to go above 101°F
Time	Moderate activity of 30 min or more
Position	Avoid supine positions and motionless standing
Frequency	Exercise should be performed on most, if not all days of the week
Duration	Physiological and morphologic changes of pregnancy persist 4 to 6 weeks postpartum

TABLE 13.29
Guidelines for Recreational Activity

Activity	Guideline
General conditioning exercises	Kegal, breathing, calf pumping, abdominal, bridging, lower trunk rotation, tail wagging
Jogging	May be continued moderately, but should not be started as a new activity after pregnancy; watch out for joint pain and decrease overall distance — recommendation is 2 mi or less per day
Aerobics	Avoid high-impact or step aerobics; as for jogging, look out for joint pain or signs of over exertion; avoid exercises that involve lying on the back for more than 5 min
Bicycling	In the third trimester it may be necessary to switch to a stationary bike due to problems with balance
Weight lifting	Can be continued during pregnancy — use light weights and moderate repetitions; avoid heavy resistance
Avoid during pregnancy	Downhill skiing, gymnastics, horseback riding, scuba diving, and any contact sports

POSTPARTUM WEIGHT LOSS

While a great deal of attention is given to counseling women about appropriate weight gain for pregnancy, clinicians have typically given less assistance in achieving postpartum weight loss. Researchers are beginning to link failure to return to prepregnancy weight with increased risks for chronic disease later in life. Table 13.30 includes currently recommended strategies for postpartum weight loss.

Generally, participation in a wide rage of recreational activities appears to be safe; however, each sport should be reviewed for its potential risk and activities.

NUTRITION AND LACTATION

The RDA and AI for lactation are listed in Table 13.10. Suggestions for maternal nutrition to meet the increased energy and nutrient needs are listed in Table 13.31. Until relatively recently, breast-feeding has been considered too imprecise to study.

TABLE 13.30
Strategies for Postpartum Weight Loss

Encourage a healthy diet based on current dietary guidelines
Make energy intake less than energy expenditure
Reduce portion size but do not restrict kilocalories to <1800/day
Determine foods high in fats and calories and substitute with fruits,
   vegetables, lean meats and fish, skinless poultry
Avoid cooking in oil, butter, margarine
Drink 8 to 10 glasses of no/low calorie fluids per day
Discuss feasible physical activity
Monitor women who
    Restrict intake to <1800 kcal/day
    Are vegans (avoid all animal products including dairy, eggs, and meats)
    Avoid foods enriched with vitamin D and have limited exposure to sunlight

TABLE 13.31
Maternal Nutrition during Breast-Feeding

Encourage a healthy diet based on current dietary guidelines
Reinforce that milk quality is generally not affected by the mother's diet
Suggest eating meals and snacks that are easy to prepare
Provide patient with information on normal postpartum weight loss in a breastfeeding woman
Drink enough fluids to keep from getting thirsty
Eat at least 1800 kcal/day
Use appetite as a guide to amount of food eaten in first six weeks
Keep intake of coffee, cola, or other sources of caffeine to two servings or less per day. Caffeine
  accumulates in the infant and use should be discontinued if infant becomes wakeful, hyperactive,
  or has disturbed sleep patterns. This reaction is intensified with a smoking mother

TABLE 13.32
Benefits of Frequent, Early, Unrestricted Nursing

Provides colostrum that the baby needs
Helps decrease newborn jaundice because of the laxative effect of colostrums
Provides a period of practice time before milk volume increases
Stimulates uterine contractions, lessening chances of maternal postpartum hemorrhage
Prevents infant hypoglycemia

TABLE 13.33
Signs of Insufficient Milk Intake in the Newborn

Failure to regain birth weight by 2 to 3 weeks of age; weight loss >7% at
  discharge and >10% at day 3 to 5
Weight gain of <7 oz/week after regaining birth weight and <4 lb in 4 months

A wealth of information is being developed about lactation and breast milk.[51] Table 13.32 lists some of the benefits of unrestricted nursing for the infant. Many women and their clinicians still are concerned about ways to identify whether an infant is obtaining enough nutriture. Table 13.33 lists signs of insufficient milk intake. The social history of infant feeding from the late 1800s to the 1950s in the United States shows a transition from breast-feeding to scientific feeding of infants. As a result of that, much cultural knowledge and support for breast-feeding was lost. Guidebooks are important for women and clinicians.[45,52–54] Table 13.34 and Table 13.35 include common concerns and recommended actions to support breast-feeding.

TABLE 13.34
Breast-Feeding Tips: Common Concerns about the Infant

Concern	Recommended action
Jaundice	Continue to breast-feed at least every 2 h around the clock. Pump breasts to maintain milk supply. Avoid water or formula feeding
Latch-on	Latch-on is necessary for baby to begin sucking at the breasts. Poor latch-on is a major cause of sore nipples. Baby's mouth should be at nipple level. Support the breast by placing the thumb on the top and four fingers underneath. Tickle baby's bottom lip with nipple until baby opens mouth very wide. Center nipple quickly and bring baby very close. Baby's nose and chin should be touching breast. Ear, shoulder, and hip should be in alignment
Leaking	Leaking is a sign of normal letdown in the early weeks of breast-feeding. Use pads in bra between feedings. Avoid pads with plastic lining. During sexual activity, leaking may occur; breast-feed baby first
Duration of breast-feeding: how long and how often?	Frequent (every 2–3 h) and unrestricted breast-feeding for the first weeks. Baby should empty one breast, be burped, and offered the second breast. Watch baby for signs that he or she is full, such as falling asleep, losing interest in feeding, or stopping breast-feeding
Early first feeding	Put baby to breast soon after delivery, within 1 h. Cuddling, licking, and brief sucking are good signs that baby is learning to breast-feed. Offer breast often to let baby practice. Ask a supportive nurse or lactation consultant for help. Offer breast whenever infant shows signs of early hunger. In general there should be 8 to 12 feedings per 24 h
Extra feedings	Healthy breast-fed newborns do not need formula, water, or juice. Breast-feed at least every 2 to 3 h during the first month. Complementary foods should be added at 6 months of age

TABLE 13.35
Breast-Feeding Tips: Common Discomforts that Lead to Breast-Feeding Termination

Concerns	Recommended action
Hospital survival skills	"Rooming in" with the baby is a consumer right. Keep baby with mother as much as possible to facilitate breast-feeding often. Do not give bottles of formula or water. Do not limit feeding time at a breast. Ask a supportive nurse or lactation consultant for help. Do not offer/accept formula gift packs
Mastitis	Mastitis is a swollen, inflamed, or infected area in the breast. Watch for flu-like symptoms such as fever above 101°F, chills and muscle aches, and a reddened, hot, tender, or swollen area in the breasts. Rest, breast-feed often, and drink more fluids. Avoid tight bra or clothing. Apply warm water soaks or cold packs (whichever gives relief). Massage affected area. Antibiotics may be needed. Not a reason to stop breast-feeding
Myths and misconceptions	Breast sagging is not a result of breast-feeding. Breast size does not affect ability to breast-feed. Drinking beer, manzanilla tea, or large amounts of fluids does not make more milk
Nipples, flat or inverted (before birth)	Flat or inverted nipples retract or move in toward the breast. Air-dry nipples if leaking occurs. Breast shells should not be used by women at risk for preterm labor. There is no evidence of harm or benefit for breast shells
Nipples, flat or inverted (after birth)	Begin breast-feeding as soon as possible after birth. Breast-feed frequently to avoid engorgement. Use nipple rolling or stretching before each breast-feeding. Pump breasts for a short period before breast-feeding, or apply ice wrapped in a cloth and place on the nipple before feeding. Breast shells (milk cups) may be used between feedings. Remove the breast shell just before placing baby at breast. Referral to a lactation consultant may be indicated
Engorgement	Engorgement may occur when milk first comes in or when feeding are missed or delayed. Use cold compresses or shower before feedings. Hand-express to soften areola, making it easier for baby to latch on. Breast-feed every 1 to 2 h for 10 to 30 min/breast. Gently massage breast toward nipple. Take nonaspirin pain reliever
Breast care	Nipple pulling, tugging, or rolling during pregnancy is not necessary to prepare for breast-feeding. Avoid soaps or lotions to the nipples. Air dry nipples after breast-feeding
Breast creams	Vitamin E, breast creams, or ointments are not recommended. No evidence exists that they heal the nipple. May make soreness worse by keeping the nipple moist. Use pure lanolin. Can massage drops of breast milk on nipples. Use hydrogel dressings
Breast surgery	Any type of breast surgery can interfere with milk supply. Referral to lactation consultant is appropriate
Operative delivery	Breast-feed baby as soon as possible after delivery, preferably in the recovery room. Hold baby in a comfortable position. Use pillows across abdomen to protect the incision and support baby. Use side lying position

14 Feeding the Premature Infant

Beth Baisden, Chantrapa Bunyapen, and Jatinder Bhatia

CONTENTS

With the ever-increasing survival of low-birth-weight and very-low-birth-weight infants, understanding the principles of nutritional therapy becomes all the more important. It is estimated that there are over 4 million births in the United States every year; with an increased estimated prematurity rate of 12%,[1] the number of infants requiring such management is enormous. This review will focus on the nutritional goals, nutrient requirements, and enteral and parenteral routes of nutritional therapy.

NUTRITIONAL GOALS FOR THE PREMATURE INFANT

A premature infant is an infant born before completion of 37 weeks of gestation. A postterm infant is one whose birth occurs from the beginning of the first day of week 43 (>42 weeks). Classifying infants as preterm, term, or postterm assists in establishing the level of risk for neonatal morbidity, nutritional needs, and long-term sequelae. Assessment of gestational age is based on maternal dates, obstetrical dating by ultrasonography, and by physical examination.[2] The Ballard exam, which uses physical and neurological criteria, may overestimate the age of premature infants and, on the other hand, may underestimate that of postterm infants.[3] Because of the error in gestational age assessment, particularly in very-low-birth-weight infants, a new Ballard Score is currently used.[4] This modified examination is particularly suited for the very small premature infant, and the estimated gestational age is accurate to within 1 week. Items of neuromuscular maturity and physical maturity are scored from −1 to 5: a total score obtained and gestational age estimated based on maturity rating score. However, in the case of the very-low-birth weight infant, early estimation of gestational age is more accurately obtained by obstetrical dating vs. the Ballard exam.[5]

Infants are considered low-birth-weight if birth weight is less than 2500 g regardless of gestational age. Very-low-birth weight defines infants with weight less than 1500 g with an additional classification of extremely-low-birth weight describing infants less than 1000 g.

Crown heel length, performed by two examiners, is measured by achieving full extension of the infant on a measuring board with a fixed head piece and movable foot piece. The infant needs to be supine, head held in the Frankfurt plane vertical, legs extended, ankles flexed, and the movable foot piece is brought to rest firmly against the infant's heels. An average of two

measurements documents the length. If crown–heel length cannot be measured due to limb anomalies or if there is a discrepancy between weight and length, a crown–rump length is sometimes measured. In preterm infants, this measurement is fraught with error even when performed by a trained team. In addition, measurement in an open bed or on a ventilator or with multiple intravenous lines makes accurate measurements difficult to achieve.

Head circumference measured with a nonstretchable tape is the largest of three measurements around the head with the tape held snugly above the ears.

Weight, length, and head circumference are then plotted on standard curves to classify an infant as appropriate, small, or large for gestational age for each measurement. Most measurements define appropriate for age as measurements that fall within the 10th to 90th percentiles, ideally based on charts constructed for similar race and height above sea level. Infants who are

FIGURE 14.1 Classification of newborns (both sexes) by intrauterine growth and gestational age[2,3].

appropriate for age on the three measures are at the lowest risk, within that gestational age grouping, for problems associated with neonatal morbidity and mortality.

An example of growth curves commonly used in neonatal nurseries is depicted in Figure 14.1.

GROWTH AND NUTRIENT REQUIREMENTS

Estimation of nutrient requirements, in premature infants, is based on the goals for growth of this cohort of infants. The common goal has been to achieve growth similar to that of the "reference fetus" as described.[6] These growth standards serve as a reference to judge the adequacy of growth; however, postnatal changes in energy requirements as well as environmental stresses are likely to be different, and the ideal growth of these infants remains to be defined. An alternative approach may be to achieve the best possible growth without adverse metabolic consequences. In a recent NICHD evaluation of more than 1600 preterm infants, most had not achieved the growth rates of the reference fetus of the same postmenstrual age by the time they were discharged.[7]

Nutrient requirements for preterm infants have been estimated by various methods, including the factorial method based on the reference fetus, nitrogen balance studies, and turnover studies or based on nutrient values in the serum. For example, Figure 14.2 depicts the composition of weight gain in normal human fetuses.[8] In a more recent publication, Ziegler[9] provides estimated nutrient intakes needed to achieve fetal weight gain, representing the current best estimates. This approach serves not only as a basis for calculation of nutrient needs, but also as a measure of sufficiency of particular nutrients as discussed above (Table 14.1). The factorial approach is based on the assumption that the requirement for a nutrient is the sum of losses (fecal,
FIGURE 14.2   Composition of weight gain in the human fetus.

TABLE 14.1
Estimated Nutrient Intakes and Fetal Weight Gain

Body Weight (g)	500–700	700–900	900–1200	1200–1500
Fetal weight gain (g/kg/d)	21	20	19	18
Protein intake required, parenteral	3.5	3.5	3.5	3.4
Protein intake required, enteral	4.0	4.0	4.0	3.9
Energy intake required, parenteral	89	92	101	108
Energy intake required, enteral	105	108	119	127

urinary, dermal, etc.) and the amount required for growth, that is, incorporation into new tissues. Advisable intakes of protein are obtained by adding 8 to 10% of the estimated requirement.

PROVISION OF NUTRIENTS

Energy Needs

Energy needs are based on basal metabolic rate, cost of growth, and losses in stool and urine. The factorial method cannot be used to estimate energy requirements. It is generally recognized that preterm infants have higher energy requirements compared to their term counterparts.[10] To gain the predicted growth in weight for premature infants (10 to 15 g/kg/d), it is estimated that premature infants would need between 110 and 130 kcal/kg/d, an estimate higher than the usually held notion that infants need 120 kcal/kg/d regardless of size or age. Energy requirements must take into account the route of administration, enteral vs. parenteral, since 90 to 95 kcal/kg/d may satisfy energy requirements by the parenteral route. Disease states such as sepsis, chronic lung disease,[11,12] and concomitant use of corticosteroids will increase energy needs. The mainstay of energy support should be balanced between carbohydrates, fats, and amino acids.

Amino Acid Needs

The factorial approach is commonly used to estimate protein requirements. The protein need will be greater if catch up growth is also to be produced. It is generally accepted that the newborn infant will lose up to 10% of his/her body weight. In sick premature infants, where nutrition cannot be provided or is not tolerated, the amount of catch up growth may be greater. Several studies suggest that endogenous protein losses in the absence of exogenous protein intake are at least 1 g/kg/d.[13] When fed in the conventional manner, premature infants run the risk of undernutrition. Therefore, strategies to optimize amino acid intakes to include provision for catch up growth need to be developed, since early initiation of parenteral nutrition results in positive nitrogen balance and has been shown to be safe.[14–17] The more employed traditional method is to start with 0.5 mg/kg/day of amino acids and slowly increase by 0.5 mg/kg to reach a goal of 3 to 3.5 mg/kg/day. With improvements in amino acid solutions and preterm formulas, recent studies have demonstrated that preterm infants can safely tolerate up to 3.5 mg/kg/day of protein in just a few days after birth.[18,19] In fact, in one randomized controlled trial, infants <1500 g on day of life 1 were given glucose only and protein added in a stepwise fashion, or glucose and 2.4 g/kg/day of amino acid solution from the first day of life, and this trial showed that high amino acid concentrations could be safely tolerated from birth.[20]

Cysteine and tyrosine are provided as cysteine hydrochloride (40 mg/g/amino acid; not to exceed 100 mg/kg/d) and *N*-acetyl-L-tyrosine (0.24 g%),[21] it has been demonstrated that infants receiving cysteine retain significantly more nitrogen than do infants receiving an isonitrogenous amino acid intake without cysteine.[15]

It is generally accepted that infants receiving between 80 and 90 kcal/kg/d from parenteral nutrition with an adequate amino acid intake should gain weight similar to the intrauterine rate.[22] Most of this energy intake is provided by glucose and lipid. The glucose utilization rate of a preterm infant is 5 to 8 mg/kg/min. Carbohydrates, most readily available as glucose, should provide approximately 35% of the daily kilocalories. However, premature and sick infants may not tolerate increasing glucose concentrations/delivery, without concomitant hyperglycemia making the goal of achieving adequate energy intake difficult in the first week of life.

Lipid Needs

Lipid emulsions are used in conjunction with glucose and amino acid solutions. Generally, lipids are started at 0.5g/kg/d intravenously; increasing by 0.5g/kg to a maximum of 3.0 g/kg/d. The goal is to provide 50% of the daily caloric intake as fat. Infusion rates are maintained between 0.15 and 0.25 g/kg/h in order to avoid hypertriglyceridemia (triglycerides > 175 mg/dl). Essential fatty acid deficiency may be prevented by lipid intakes as low as 0.5 to 1.0 g/kg/d.

Clearance of lipids by premature infants may be limited, thereby requiring frequent assessment of tolerance. Emulsions of 20% are preferred due to lower total phospholipid and liposome content per gram of triglyceride.[23]

Parenteral Nutrition

It is common practice to provide the initial nutrient requirements, especially in a sick neonate, by the parenteral route. A typical parenteral regimen is depicted in Table 14.2. It is generally recommended that parenteral nutrition be started within the first day of life in preterm infants and advanced in a systematic fashion to achieve 3 to 3.5 g/kg/d of amino acids and 90 to 100 kcal/kg/d of energy. Most preterm infants do not achieve these intakes until well into the second week of life because of issues such as glucose and lipid intolerance.

TABLE 14.2
Parenteral Nutrition Regimen

Component	Amount/kg/d	
Amino acids (g)	3–3.5	
Glucose (g)	15–25	
Lipid (g)	0.5–3.0	
Sodium (mEq)[a]	2–5	
Potassium (mEq)[b]	2–4	
Calcium (mg)	80–100	
Magnesium (mg)	3–6	
Chloride (mEq)	2–3	
Phosphorus (mg)[b]	40–60	
Zinc (μg)	200–400	
Copper (μg)	20	
Iron (μg)	100–200	
Other trace minerals[c]	<14 days	>14 days
Manganese (μg)	0.0–0.75	1.0
Chromium (μg)	0.0–0.05	0.2
Selenium (μg)	0.0–1.3	2.0
Iodide (μg)	0.0–1.0	1.0
Molybdenum (μg)	0	0.25
Vitamins[d]		
C (mg)	80	
A (mg)	0.7	
D (μg)	10 (= 400u)	
B_1 (mg)	1.2	
B_2 (mg)	1.4	
B_6 (mg)	1	
Niacin (mg)	17	
Total volume	120–150 ml	

[a] Sodium requirements may vary between infants and within the same infant and should be tailored to serum values.

[b] Phosphorus intakes are maintained in a ratio of 1:2 to 1:2.6 with calcium (mEq:mM) and may be limiting in parenteral nutrition because of insolubility; in general, the more acidic the TPN, the more calcium and phosphorus can be dissolved in the solution without precipitation. Care must be taken to avoid hyperphoshatemia with its resultant hypocalcemia.

[c] amount/kg/d.

[d] Provided as MVI-Pediatric[R]; each 5 ml provides (MVI is to be provided in amounts not exceeding 2.0 ml/kg/d).

Mineral Requirements

Mineral requirements have also been estimated based on body composition of the reference fetus.[6,8] From a practical standpoint, daily needs for sodium, potassium, and chloride are based on serum measurements, while calcium and phosphorus are based on the factorial method.[6,8] Requirements are listed in Table 14.2. In general, it is accepted that sodium is not added to parenteral nutrition regimens until the sodium is below 130 mEq/l. It should be noted that premature infants in general, and very-low-birth-weight infants in particular, receive large amounts of sodium inadvertently.[24] In general, the preterm infant has higher requirements of most minerals compared to term infants. During total parenteral nutrition, requirements for calcium and phosphorus may not be met because of the insolubility of calcium salts. Human milk may not provide adequate amounts of sodium, and hyponatremia has been reported.[25] Calcium and phosphorus needs of preterm infants cannot be met by human milk, whether from mothers delivering preterm or term infants, and will need to be supplemented.[26] Since calcium transfer across the placenta occurs in the third trimester, the very premature infant is relatively "osteopenic," and prolonged parenteral nutrition and or unfortified human milk feedings puts the infant at great risk for further osteopenia and metabolic bone disease.

Iron is accumulated in the fetus in the third trimester with an iron content of 75 mg/kg at term. Gestational age infants, preterm infants, and infants of diabetic mothers have low iron stores at birth. Coupled with the need for frequent blood sampling, the premature infant is at great risk for the development of iron deficiency anemia, and the exact time for supplementation remains controversial. However, given that the criteria for blood transfusion have become more stringent,[26] iron should be supplemented as early as 2 weeks. If recombinant erythropoietin is used to stimulate endogenous iron production,[27] iron requirements may be 6.0 mg/kg/d or higher.

Nutrient Delivery

Delivery of enteral nutrients is based on gestational age. In general, infants of 33 weeks gestation and beyond can be fed orally soon after birth. However, if medical or surgical illness precludes enteral feedings, parenteral nutrition is indicated. Parenteral nutrition can be considered as total (where all nutrients are delivered for example in an infant with a surgical condition precluding enteral nutrition: gastroschisis) or supplemental (to complement enteral nutrition). It can be further described as peripheral parenteral nutrition (provided by a peripheral intravenous line) or central (where the tip of the catheter is in a central location or deep vein). The latter should be the route if long-term parenteral nutrition (e.g., >2 weeks) or the need for >12.5% dextrose in water is anticipated.

A typical nutrition plan for a very-low-birth-weight infant is depicted in Table 14.3.

TABLE 14.3
Initiation and Advancement of Parenteral and Minimal Enteral Feedings in an Infant with a Birthweight of <1000 g

	Parenteral				
Age, Days	Amino Acid (g/kg)	Glucose	Lipids (g/kg)	Electrolytes	Enteral ml/h[a]
1	2.5	D_5W	0.0	0.0	0.0
2	3.0	D_5W	0.5	Add if Na < 130 mEq/l	0.25
3	3.0–3.5	Increments of 2.5%	1.0[b]	Standard	0.25
4	Same	Increase as tolerated	1.5[b]	Standard	0.5
5	Same	Increase as tolerated	2.0[b]	Standard	0.5
6	Same	Increase as tolerated	2.5[b]	Standard	0.75
7	3.0 or higher[c]	Same or higher	3.0[b]	Standard	0.75

[a] In larger infants, studies have demonstrated that feeding of 20 ml/kg/d and advancing at that rate is safe,[28] while other studies have demonstrated an increased incidence of NEC, when feeds are advanced at that rate.[29]

[b] Monitor triglycerides to assess lipid tolerance.

[c] Optional; infants requiring catch up growth, on corticosteroids or demonstrating low BUN despite adequate protein intakes may need higher amino acid intakes at later stages.

Parenteral Nutrition is indicated in the following conditions:

Medical	Inadequate enteral nutrition
	Necrotizing enterocolitis
	Feeding intolerance/difficulty
	Ileus
	Prematurity
Surgical	Omphaolcele
	Gastroschisis
	Tracheo-esophageal fistula
	Atresias
	of the intestine (duodenal/jejunal/ileal)
	Diaphragmatic hernia
	Hirschsprung's disease

Complications of Parenteral Nutrition:

Metabolic	Hypo- or hyperglycemia
	Electrolyte imbalance
	Metabolic bone disease
	Hepatic dysfunction
Infectious	Bacterial sepsis
	Fungal sepsis
Mechanical	Extravasation
	Thrombosis
	Pericardial effusion
	Diaphragmatic palsy
	Pleural effusion

TABLE 14.4
Suggested Monitoring During Parenteral Nutrition

Component	Initial	Later[a]
Weight	Daily	Daily
Length	Weekly	Weekly
Head Circumference	Weekly	Weekly
Na, K, Cl, CO2	Daily until stable	Weekly
Glucose	Daily	PRN
Triglycerides	With every lipid change	Weekly or biweekly
Ca, PO4	Daily until stable	Weekly or biweekly
Alkaline phosphatase	Initial	weekly or biweekly
Bilirubin	Initial	weekly or biweekly
Mg	Initial	weekly or biweekly
Ammonia	PRN	PRN
Gamma GT	Initial	weekly or biweekly
ALT/AST	initial	weekly or biweekly
Complete blood count	Initial	weekly or PRN

[a] A practical way to monitor parenteral nutrition may simply include measurement of direct bilirubin and alkaline phosphatase at 2–4 weeks of age. If they are increased, a comprehensive metabolic panel may be ordered to evaluate the traditional "liver function tests" and calcium and phosphorus. This may achieve the same end point as monitoring the parameters routinely.

The metabolic complications can be avoided by careful assessment of tolerance to the macronutrients as nutrition delivery is advanced. Premature infants do not tolerate high concentrations of glucose or rapid advances in glucose delivery; similarly, rates of fat infusion of greater than 2.0 g/kg/d may result in hypertriglyceridemia, particularly in the small or ill preterm infant (triglycerides >175 mg/dl). A suggested regimen of monitoring parenteral nutrition is depicted in Table 14.4. A multidisciplinary approach with physicians, pharmacists, nutritionists, and nursing staff who are knowledgeable in parenteral nutrition and monitoring should be involved in the care of such infants. Early recognition of metabolic effects (pharmacist/nutritionist) or catheter-related effects (nursing) could assist in minimizing the potential complications of parenteral nutrition. The most common metabolic complications observed are hepatic dysfunction and metabolic bone disease.

Hepatic dysfunction is defined as an increase in serum bile acids, followed by an increase in direct bilirubin, alkaline phosphatase, and gamma-glutamyl transferase. The hepatocellular enzymes, ALT and AST, are late to increase and often seen in the more severe cases. γ-Glutamyl transferase is probably the most sensitive but least specific indicator, whereas elevation in direct bilrubin is the most specific and least sensitive indicator of hepatic dysfunction. The etiology is multi-factorial,[30–32] but the incidence appears to be declining both as a result of specialized amino acid solutions and early provision of enteral nutrients.

Premature infants are at high risk for the development of metabolic bone disease, most commonly due to inadequate intakes of calcium and phosphorus during parenteral nutrition. Infants born before 32 weeks of gestation have some degree of

hypomineralization, which is worsened during the subsequent period of hospitalization, especially, coupled with inadequate intakes of calcium and phosphorus. In general, both calcium and phosphorus levels are maintained in serum, while the bones appear more osteopenic on radiographs, and ultimately hypophosphatemia with increasing alkaline phosphatase is observed. Rising alkaline phosphatase in the absence of elevated "liver" enzymes is a strong indicator of metabolic bone disease. Incidence of rickets (metabolic bone disease) is inversely proportional to birth weight and has been reported to be as high as 50 to 60% in very-low-birth-weight infants.[33] Diagnosis is made by routine radiographs that, in the initial stages, would demonstrate bone undermineralization, especially in the ribs and scapula, subsequently showing the classic forms of rickets in the wrists and long bones. Strategies to increase calcium and phosphorus delivery should be considered.

Unfortunately, the very small preterm infant is more often at risk for these complications, given the duration of parenteral nutrition and the coexistence of hepatic dysfunction.

Enteral Nutrition

Even if enteral nutrition is started in the first days after birth, it is suggested that supplemental parenteral nutrition be started because immaturity, feeding intolerance, and GI motility may affect the rate of advancement of enteral nutrition. Further, intakes are also dictated by the feedings used: human milk or formula. Composition of human milk (Table 14.5) from a mother delivering a preterm infant is different from that of mothers delivering at term; further, differences between and within the same woman makes the average content difficult to estimate. Breast milk does appear to provide the best protection from infection and the development of necrotizing enterocolitis. However, it may not provide adequate amounts of calcium, phosphorus, protein, and sodium for the growing premature infant. Various fortifiers are available and appear to enhance short-term weight gain and to be safe. Whether the content is mostly in the form of carbohydrates or fat, the result is increased fat deposition.[34,35]

The route of enteral nutrition is dictated not only by the gestational age of the infant, but also the coexistence or medical or surgical morbidity. Routes and types of delivery are depicted in Table 14.6.

Motor responses to feedings are similar whether feedings are provided by the gastric or transpyloric route.[36] However, when feeds are provided slowly over 120 min as compared to 15 min, gastric emptying is better, suggesting that in the smaller premature infant, slow infusions may be better tolerated.[37,38]

Oral Feeding

Term and preterm infants greater than 33 to 34 weeks gestation may be fed soon after birth by the oral route. This should be attempted in the delivery room in healthy infants or initiated soon after birth. Human milk feedings (i.e., breast feeding) should be encouraged and all steps taken by the medical team and hospital staff to encourage breast feeding once the decision is made. If breast feeding is precluded, due to craniofacial anomalies such as cleft clip or palate, feeding devices are available and speech therapy or feeding teams may need to be involved. Lactation consultation should be sought for mothers who have difficulty in either initiation or maintenance of breast feeding. Hospitals should avoid practices of supplementing breast-fed infants or the use of pacifiers.

Most mothers delivering preterm infants have not made a decision about breast feeding and should be counseled appropriately. All delivery sites should have facilities to pump breast milk if actual breastfeeding is not possible and the mother wishes to breastfeed. Teaching should include appropriate techniques for pumping and storing milk.

Nutrient Delivery

For infants born after 33 to 34 weeks of gestation, enteral feedings may be started *per os*. Although it is recognized that infants at this gestational age can coordinate their suck, swallow, and respiratory activities, thus enabling feedings, not all infants respond in such a fashion, and careful assessment is warranted. In the event of nipple feedings not being achieved, the infant may be fed by the gastric route.

In general, the alternatives to feedings by mouth are delineated as follows: (1) gastric and (2) transpyloric. Gastric feedings can be further described as (1) bolus, provided intermittently every 2 to 3 h or (2) continuous, where the feeds are provided by a pump at a constant hourly rate. Transpyloric feeds are provided continuously with the tip of the feeding tube in the second part of the duodenum. General indications for the latter include failure to tolerate gastric feeding due to delayed gastric emptying, gastric distention due to positive pressure ventilation, or gastroesophageal reflux. In a 2002 review of transpyloric vs. gastric feeds, no difference in the incidence of NEC, aspiration, or perforation was found. There was no difference in weight or head circumference at 3 and 6 months chronological ages. An increased incidence of feeding difficulties was noted with the transpyloric route.[39]

Feedings can also be planned based on birth weight. In general, infants below 1250 g are fed by the continuous, gastric method, whereas bigger infants by the intermittent method.

A further concern with preterm infants is the amount needed to start feedings and how fast to increase feeds. This concern arises from observations that "too much, too soon" can increase the incidence of NEC and feeding intolerance. In neonatal

TABLE 14.6
Routes of Feeding Preterm Infants

Route	<34 weeks	>34 weeks
Per os	No	Yes
Continuous gastric	<1250 g	Failure to tolerate bolus gastric, significant GER
Bolus gastric (every 3 h)	>1250 g; infants <1250 g not tolerating continuous	Failure to tolerate per os
Transpyloric, continuous	Failure to tolerate gastric feeds, gastric distention due to positive pressure, poor gastric emptying	Same as <34 weeks

dogs, as little as 10% of the total daily intake, induced mature gastric motor patterns.[40] Advancement of the feeds by 20 ml/kg/ day appears to be well tolerated by most preterm infants. Full-strength formula given slowly (over longer than 15 min) appears to induce the best duodenal motor response.[41]

Special Considerations

Essential Fatty Acids

Vegetable oils contain the parent essential fatty acids linoleic acid (18:2w-6) and, in most cases, alpha-linolenic acid (18:3w-3). Linoleic and linolenic acids serve as precursors for the synthesis of long-chain polyunsaturated fatty acids (LC-PUFA), including arachdonic (20:4w-6) and docosahexaenoic (22:6w-3) acids. Human milk lipids contain preformed LC-PUFA ; LC-PUFA are essential components of membrane systems and are incorporated in membrane-rich tissues such as the brain during early growth.[42,43] The fetus and the fully breast-fed infant do not depend on active synthesis of LC-PUFA since the placenta and human milk provide LC-PUFA in amounts considered appropriate.[44–47] Preterm birth halts the transfer of DHA and AA — 80% of which is transferred during the third trimester. Preterm infants have high cord blood levels of DHA, AA, and other LC-PUFA, but these levels decline rapidly.[48] Premature infants, fed with formulas without LC-PUFA, develop depletion of LC-PUFA in plasma and red cell membranes, indicating limited endogenous LC-PUFA synthesis.[49]

DHA and AA are important for growth and development and visual acuity. Addition of DHA and AA to preterm formulas leads to levels similar to human milk in North America. This can be achieved with DHA between 0.24 and 0.76% and AA between 0.32 and 1.1%[50] from single oils. Both are required for effective growth and development. Supplementation with DHA alone led to decreased growth in preterm infants in most studies.[51] Supplementation with the precursor ALA did not sustain DHA levels found in breast milk or confer the benefits on growth and visual acuity. Furthermore, ALA supplementation appeared to lower AA levels possibly secondary to competition between AA and DHA for precursor enzymes or the previously mentioned inability of preterm infants to synthesize DHA and AA from precursors.[52–54]

Early trials of DHA and AA supplementation did not show sustained, significant differences in weight, length, or head circumference in larger, healthy preterm infants,[55] but more recent studies including younger, sicker infants have shown improvement in growth.[50,56] DHA is found in large amounts in the retina in the photoreceptor outer segment. In studies of visual acuity, using Teller acuity cards or ERG or VEP, transient improvements in visual acuity were seen in infants fed the supplemented formula, but they were not sustained.[55,57] While some trials showed improvement in Bayley scores of infant development, others did not. A large, randomized, controlled trial by O'Connor et al.[57] in 2001 showed better vocabulary comprehension at 14 months. A recent review by Fleith and Clandinin[58] concurred that there was improvement in development, while a 2004 Cochrane review of the literature did not find benefit in supplementation.[55] DHA and AA supplementation appears to be safe, and blood levels equal to those in breast milk can be achieved. Large differences in numbers of patients studied, birth weights and gestational ages and doses of DHA and AA make comparisons between studies difficult.

Carnitine

Current parenteral nutrition regimens do not contain carnitine. Low plasma concentrations of carnitine and its decline with postnatal age has been demonstrated in infants receiving carnitine-free nutrition.[59,60] Although fatty acid metabolism has not been shown to be impaired in short-term parenteral nutrition, carnitine is an accepted additive for infants requiring parenteral nutrition for longer periods.[61–63] Carnitine is provided at doses of 8.0 to 20 mg/kg/d.

Glutamine

Glutamine is the most abundant amino acid in the human body and is the most important "nitrogen shuttle," accounting for 30 to 35% of all amino acid nitrogen transported in the blood.[64] Glutamine concentrations in blood and tissue fall following

starvation, surgery, infection, and trauma.[65,66] In addition, glutamine plays an important role in protein and energy metabolism, nucleotide synthesis, and lymphocyte function.[67] Glutamine is known to be an important fuel for small intestinal enterocytes[68]; however, an absolute need of glutamine for gut growth has not been demonstrated with either detrimental or negligible effects reported in the literature.[69,70] A recent review of six randomized, controlled trials of glutamine supplementation in preterm infants did not show significant decreases in mortality and no significant effect on the incidence of NEC, sepsis, days to full feeds or length of hospitalization.[71]

Taurine

Taurine is considered to be an essential amino acid in preterm infants. Those premature infants fed with formulas enriched with the nutrient had better Bayley scores at 18 months than those fed with term formula without taurine.[72]

Donor Breast Milk

Most women are not able to supply enough breast milk to meet the needs of their growing premature infant, but they still recognize the benefits of human milk, including the prevention of NEC and late-onset sepsis. Donor milk banks grew out of this desire. There are drawbacks to donor human milk. Most of the supply is from women who delivered term infants and, therefore, is not adequate to meet the nutritional needs of a premature infant. In some studies, donor milk use led to slower growth.[39,73] The pasteurization process, while necessary to reduce unwanted bacteria, destroys important bioactive components of breast milk.[74] However, adequate amounts of LC-PUFA and cytokines are still present in pasteurized donor milk. A recent randomized trial using preterm donor milk did not find the expected decrease in NEC and late onset sepsis compared to preterm formula.[22]

POSTNATAL GROWTH

The plotting of growth, as alluded to earlier, facilitates the assessment of trends in growth. The intrauterine charts represent fetal growth; however, as has been described, most small preterm infants fall below the birth percentile and the 10th percentile. Thus, the need to address catch up growth and strategies to minimize postnatal weight loss. The postnatal charts reflect the initial weight loss, which occurs in the first week of life, and growth similar to the in utero counterpart once the infant returns to birth weight has been demonstrated.[7]

Despite the many questions that remain regarding optimal nutritional management of the neonate, it is nonetheless important to develop rational protocols for the management of nutritional issues that arise. This chapter has provided some guidelines and the framework from which these guidelines arose. There are numerous different approaches to feeding a neonate. The ultimate goal should be to optimize nutrition and hence growth and ultimately development in this ever-increasing population of premature infants.

15 Feeding the Term Infant

Yvette Gamble, Chantrapa Bunyapen, and Jatinder Bhatia

CONTENTS

Growth, particularly in weight, length, and additional anthropometric measurements, remains a measure of adequacy of nutritional regimens for the growing infant and child. Infant feeding decisions have an impact on lifelong medical illnesses, growth, and developmental abilities well beyond infancy. This chapter will review normal growth and nutrient requirements in healthy term infants.

GROWTH

The average weight of a healthy term infant is 3.5 kg. With an anticipated loss of 10% in body weight in the first week of life, birth weight is regained by two weeks of age in both breast-fed and formula-fed infants, with the formula-fed infants demonstrating a tendency to regain birth weight sooner than their breast-fed counterparts.

Mean weight and selected centiles for weight are summarized in Table 15.1. In clinical practice, however, weight and other anthropometric measurements including length, head circumference, and weight for length are plotted on growth charts (Figure 15.1 and Figure 15.2) adapted from Hamill et al.[1] The plotting of growth on these charts will suffice for monitoring of normal infants; however, a different and more sensitive approach will be needed for infants with faltering growth. The "reference data" provided by Fomon[2] combine data from the University of Iowa and the Fels Longitudinal Study, the latter data used in the growth charts. Current growth charts may be replaced in the future by the World Health Organization (WHO) growth curves generated from an "international" rather than national cross-sectional standard.

A variety of other measures to define growth include skin fold thickness, limb length and circumference, and body mass index (BMI). The latter, BMI, is calculated by dividing the weight in kilograms by the square of the length in meters, replacing weight for length in older children. BMI is becoming an increasingly important parameter to track given the explosion of obesity and/or overweight in the pediatric population, especially among non-Hispanic Black and Mexican-American adolescents.[3]

Normal growth is a strong indicator of nutritional sufficiency and overall health of an infant. Since infancy is a period of rapid growth, particularly early infancy, identifying growth failure is important and requires prompt medical attention. As we

understand more about the complex interactions between genetic, immunologic, metabolic, physiologic, and psychologic factors and their effects on long-term outcomes of infant feeding decisions, defining appropriate growth becomes a very important issue for health care providers of children.

ENERGY

Energy requirements during infancy may be partitioned into basal metabolism, thermic effect of feeding, thermoregulation, physical activity, and growth. The energy requirements for growth relative to maintenance, except in early infancy, are small, and satisfactory growth can be considered a sensitive indicator that energy requirements are being met. Energy balance may be defined as

$$\text{gross energy intake} = \text{energy excreted} + \text{energy expended} + \text{energy stored}.$$

Gross energy intake, measured by the heat of combustion, is greater than energy available when fed because most foods are not completely digested and protein oxidation is incomplete. Fat absorption varies widely among infants fed various formulas, particularly in infancy. Urea and other nitrogenous compounds are excreted in the urine. Gross energy intake is calculated as 5.7, 9.4, and 4.1 kcal/g obtained from protein, fat, and carbohydrate, respectively, and therefore it varies given the type of diet. The term "digestible energy" refers to gross energy intake minus energy excreted in the feces. Metabolizable energy is defined as digestible energy minus energy lost in urine. The metabolizable energy values for protein, fat, and carbohydrate are close to 4, 9, and 4 kcal/g, respectively. Losses of energy, other than via feces and urine, are negligible and are ignored for practical purposes.

The energy intake of normal infants per unit body weight is much greater than in adult counterparts. Energy requirements for term infants have been estimated by various groups and vary from 100 to 116 kcal/kg/day from 0 to 3 months and decline to about 100 kcal/kg/day by the end of the first year.[4–8] These recommendations are based on the median intake of thriving infants; the intakes of breast-fed infants are lower than that of formula-fed infants, with an average of 3 to 4% lower in the first 3 months and 6 to 7% from 3 to 6 months. As new, more precise estimates of energy expenditure become available, these recommendations are apt to change, given that current recommendations are higher than the "gold" standard — the breast-fed infant. Energy intakes of infants from 6 to 12 months of age have been reported to be between 91 and 100 kcal/kg/day.[9–11]

PROTEIN

Intakes of protein and essential amino acids are generally sufficient in developed countries, in contrast to developing countries, where protein and protein-energy malnutrition are still a frequent occurrence. In appropriately fed infants, protein is not a

Birth to 36 Months: Girls
Length-for-Age and Weight-for-Age Percentiles
FIGURE 15.1 Physical growth of girls, birth to 36 months, according to National Center for Health Statistics percentiles. (Published May 30, 2000 (modified 4/20/01). Developed by the National Center for Health Statics in Collaboration with the National Center for Chronic Disease Prevention and Health Promotion (2000). http://www.cdc.gov/growthcharts

limiting dietary component in infancy and is clearly essential for normal growth and development. For the human infant, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, and valine are considered essential amino acids. The data for cysteine are conflicting[12,13] for the term infant, although the data are clear for the preterm infant. Conditionally essential amino acids are those that become essential under certain circumstances as they may be produced in inadequate amounts endogenously. An example of this is taurine, which is now added to formulas based on reports of greater concentrations of taurine in the plasma and urine of preterm[14,15] and term[16] infants. The concern about taurine depletion stems from the observations of growth retardation, abnormal retinal findings, and impaired bile acid metabolism in taurine-deficient animals and humans.

Recommended dietary intakes of protein are summarized in Table 15.2. In contrast, intakes recommended by WHO[17] are 2.25, 1.86, 1.65, and 1.48 g/100 kcal from 1 to 2, 3 to 6, 6 to 9, and 9 to 12 months, respectively. Both of these recommendations are generally higher than the intakes observed in human milk-fed infants.

FAT

The importance of dietary fat is underscored by the fact that 35% of the weight gain of an infant in early infancy is accounted for by fat.[18] Most of the dietary fat is in the form of triglyceride formed by three fatty acids esterified to a glycerol backbone. In the body, triglycerides are the main form of storage and transport of fatty acids. Phospholipids and cholesterol are indispensable components of the lipid bilayer of all cell membranes, and the amount of different phospholipids and cholesterol, as well as the
FIGURE 15.2 Physical growth of boys, birth to 36 months, according to National Center for Health Statistics percentiles. (Published May 30, 2000 (modified 4/20/01). fatty acid pattern of incorporated phospholipids, modulate membrane fluidity, permeability, enzyme and receptor activity, and signal transduction. Cholesterol is required for the synthesis of steroids and bile acids, although the majority of the cholesterol pool in tissue and plasma is derived from endogenous synthesis; dietary cholesterol contributes to the pool, and diet modifies liver synthesis.[19] Fatty acids (4 to 26 carbon atoms) are either saturated (no double bonds in the carbon chain), monounsaturated (one double bond), or polyunsaturated (two or more double bonds). Double bonds occur in two isomeric forms: *cis* and *trans*; unsaturated fatty acids are folded at the site of each double bond, *cis-* and *trans-*fatty acids have straight carbon chains.

Human milk contains approximately 4% lipids, but the reported variation is between 3.1% and 5.2% [20,21] with 99% of the fat present in the form of triglycerides and the rest in the form of diglycerides, monoglycerides, free fatty acids, phospholipids, and cholesterol. The fat content of human milk increases with duration of lactation.[20,22] During this period, the average size of the fat globules increases and the ratio of phospholipids and cholesterol to triglycerides decreases.[23] The concentration of fat in human milk remains similar regardless of maternal diet or nutritional status, although poor nutrition has been shown to decrease fat content.[24] Fatty acid content of human milk has been reported by numerous investigators and demonstrates a wide range, as summarized by Fomon.[2] Fatty acid content of human milk is also altered by dietary manipulation.[25–28] Human milk fat provides the essential fatty acids linoleic and α-linolenic acids, along with the long-chain polyunsaturated fatty acids such as arachidonic (ARA) and docosahexaenoic (DHA) acids. The latter are now routinely added to all infant formulas but vary in concentration depending on the manufacturer. The decrease of milk phospholipid content during the first few weeks after birth is accompanied by a decrease in ARA and DHA.[29] Fat content of human milk and commonly used formulas is summarized in Table 15.3.

ESSENTIAL FATTY ACID METABOLISM

Human milk lipids contain preformed long-chain polyunsaturated fatty acids (LC-PUFA) in considerable amounts, whereas vegetable oils (with the exception of coconut oil) are also rich in PUFA. The latter has a higher percentage of medium- and short-chain fatty acids.

For the healthy full-term infant, the concerns of the premature infant may not apply given the larger body stores of LC-PUFA at birth and the lower requirements compared with the preterm infant because of slower growth. However, nutritional requirements for PUFAs are not clearly defined for infants, and the issue is complicated by the fact that linoleic acid ($18:2n-6$) and α-linolenic acid ($18:3n-3$) can be converted to both 20- and 22-carbon-length long-chain PUFAs with significant biological activities. The absence of linoleic acid from the diet results in growth retardation and dermatologic manifestations. Intakes of linoleic acid, as low as 0.6% of daily energy intake, can obviate essential fatty acid deficiency as defined by the triene-to-tetraene ratio, and current recommendations[30] specify a minimum level of 0.3 g/100 kcal in infant formulas. During the first postnatal year, there is a rapid accretion of ARA and DHA in the brain, DHA in retina, and ARA in the whole body in infants fed human milk.[31] In order to achieve similar results in formula-fed term infants, both DHA and ARA have to be provided in formulas. SanGiovanni et al.[32] demonstrated a significant overall advantage in visual acuity during the first 2 to 4 months of life for LC-PUFA-supplemented groups of term infants compared with those not supplemented by LC-PUFA. Similar results were observed by Birch et al.,[33] who observed a benefit in visual acuity development for the first year of life in infants fed LC-PUFA formulas compared with infants fed standard formulas. The developmental outcome of these infants also showed significantly better scores on the Bayley Mental Development Index II.[34] However, results of studies assessing development are variable.[35] Improved developmental scores at 18 months of age have been reported, but less than half of the studies reviewed showed beneficial effects on visual, mental, or psychomotor functions.[35] The addition of LC-PUFA to infant formulas is safe with no negative effects reported, and blood LC-PUFA status is similar to that of breast-fed infants.[35]

Fully breast-fed infants have a dietary lipid intake of approximately 50% of their energy intake (3.1 to 5.2 g/dl; see earlier discussion), whereas formulas contain between 3.4 and 3.8 g/dl. Although the importance of limiting the dietary intake of saturated and total fats to prevent cardiovascular disease, obesity, and diabetes is well recognized, adverse effects of limiting fat on weight gain and growth[36,37] should be balanced against providing increased amounts of fat.

CARBOHYDRATE

Carbohydrates generally account for 35% to 42% of the energy intake of breast- or formula-fed infants, and the usual carbohydrates in infants' diets are listed in Table 15.4. Carbohydrates may be classified as monosaccharides, oligosaccharides, and polysaccharides. Monosaccharides can be further defined as aldoses (glucose, galactose, and xylose for example) or ketoses (fructose). Oligosaccharides are consumed in the diet mainly in milk with lactose, maltose, and sucrose being the main sugars present. Polysaccharides are starches, starch hydrolysates, glycogen, or components of fiber. The major carbohydrate in human milk is lactose, although small amounts of glucose and other oligosaccharides are also present. Carbohydrate content of human milk and various formulas is listed in Table 15.3. Carbohydrate malabsorption, apart from genetic causes, is unusual. When the colonic capacity to ferment carbohydrate is exceeded by the unabsorbed load, symptoms of carbohydrate intolerance, usually in the form of diarrhea, occur. The diarrhea improves when dietary carbohydrates are reduced or eliminated from the diet, making the diagnosis of carbohydrate intolerance. Normally, electrolytes in the distal gastrointestinal tract and unabsorbed carbohydrates (fermented to volatile fatty acids) are rapidly absorbed. Inadequate colonic salvage results in diarrhea. In young infants and children with disorders of carbohydrate metabolism, the ultimate goal of carbohydrate digestion and absorption is to render all available carbohydrates into smaller compounds that the body can use — chiefly, glucose and fructose. Lactase deficiency is exceedingly rare in newborn infants. Infants usually develop diet-induced diarrhea following introduction of lactose-containing milk. The disease, thought to be autosomal recessive, is treated with the elimination or limitation of lactose in the diet. More commonly, transient lactose intolerance can occur after acute or repeated bouts of diarrhea. Sucrase-isomaltase deficiency is a rare disease that does not appear until diets containing sucrose, dextrin, or starch are begun. Bouts of diarrhea may be observed

TABLE 15.5
Commonly Used Formulas and their Indications

Formula	Carbohydrate	Protein	Fat	Indication
Bovine milk based	Lactose	Bovine whey and casein	Vegetable, animal	Normal function
Soy-protein-based	Sucrose, glucose	Soy	Soy	Lactose intolerance, vegetarian, galactosemia (RARE)
Hydrolyzed protein	Sucrose, glucose	Hydrolyzed whey or casein	Medium chain triglycerides	Cow milk and soy protein hypersensitivity, pancreatic insufficiency, history of allergy in sibling and/or parents
Casein-based (modular)	Modified tapioca starch, added carbohydrate	Casein hydrolysate with added amino acids	MCT oil, corn oil	Lactase, sucrose, and maltase deficiency, impaired glucose transport
Elemental	Lactose- and sucrose-free, corn syrup solids, modified corn starch	Hydrolyzed casein	Vegetable	Cow milk allergy
"Metabolic"	Depends on condition	Corn syrup solids/sucrose	Corn oil/coconut oil	Specific metabolic disorders

in infants with this deficiency, and management includes eliminating sucrose and limiting starch in the diet. Older affected children and adults usually tolerate normal quantities of carbohydrates. Glucose-galactose deficiency manifests itself with diet-induced diarrhea soon after birth and responds to withdrawal of these carbohydrates from the diet. The defect appears to be a specific absence of glucose and galactose transport mechanisms, whereas amino acid transport is normal. Fructose transport is normal, and these infants respond to a diet containing fructose with relief from diarrhea. With age, variable amounts of starch and milk may be tolerated. Commonly used formulas for various forms of intolerance are listed in Table 15.5.[38]

IRON

Iron deficiency is the most common nutritional deficiency in the United States and worldwide, with young children being the most susceptible. The increased susceptibility comes from an increased iron requirement for the rapid growth during this period and inadequate amounts of iron in the diet unless adequately supplemented.[39] One of the U.S. Department of Health and Human Services' national health objective is to reduce iron deficiency in infants, children, and adolescents by 3 to 4 percentage points.[40] The estimated prevalence of iron deficiency is greatest among toddlers aged 1 to 2 years (7%).[41] According to the Centers for Disease Control and Prevention, iron deficiency remains 2 to 5 percentage points above the 2010 national health objectives.[41] To prevent iron deficiency, infants and toddlers should eat iron-rich foods and breast-feed or use iron-fortified formulas.[42] The stages of iron nutritional status are listed in Table 15.6.

One should distinguish between anemia and iron deficiency anemia, as the latter occurs when hemoglobin concentration falls below the 90% to 95% range for the same age and sex.[43] A diagnosis of iron deficiency is made when the anemia is accompanied by evidence of iron deficiency or when there is a rise in hemoglobin following treatment with iron. In this regard, serum transferrin receptor may offer an advantage for screening for iron deficiency because it rises with iron deficiency and is not affected by infection or acute liver disease.[44]

Iron deficiency peaks between 6 and 9 months of age and is a consequence of multiple factors: rapid growth, depleted stores, low iron content of the diet, and early feeding of cow's milk.[45,46] Because a milk-based diet is the predominant

TABLE 15.6
Stages of Iron Deficiency

Iron Nutritional Status	Indices
Adequate stores	Normal
Decreased stores	Ferritin (10 to 20 ng/ml) decreased, transferrin normal, erythrocyte protoporphyrin normal, MCV normal, hemoglobin normal, transferrin receptor normal
Iron deficiency	Ferritin decreased, transferrin saturation decreased, erythrocyte protoporphyrin increased, MCV normal, hemoglobin normal, transferrin receptor increased
Iron deficiency anemia	Ferritin decreased, transferrin saturation decreased, erythrocyte protoporphyrin increased, MCV decreased, hemoglobin decreased, transferrin receptor increased

source of energy, at least in the first 6 months of life, the iron content and its bioavailability are strong predictors of iron nutritional status.[47] The estimated requirement of absorbed iron from birth to 1 year is 0.55 to 0.75 mg/day, thereby underscoring the need for adequate iron in the diet to meet these needs. Iron concentration in human milk is low (0.3 to 0.5 mg/l), and although well absorbed, iron content declines between 14 and 183 days of age.[48] Therefore, even given the better absorption as milk intake increases and iron content decreases, it is easy to see that the amount of absorbed iron will be inadequate to meet the estimated requirements. Therefore, breast-fed infants who do not receive iron supplements or iron from other sources are at risk of becoming iron deficient between 6 and 12 months of age.[49] Iron-fortified cow's milk or soy-based formulas are effective in preventing iron deficiency, and the decline in iron deficiency anemia over the past few decades has been attributed to their use.[43] Systemic manifestations of iron deficiency anemia include behavioral and cognitive abnormalities expressed as lower scores on tests of psychomotor development. These effects have to be interpreted keeping the confounding variables of poor nutrition, environment, and poor socioeconomic background that often coexist. Studies suggest that infants with iron deficiency anemia, but not iron deficiency without anemia, have impaired performance of mental and psychomotor development.[50–54] These deficiencies do not improve with iron therapy, and follow-up studies at 5 to 6 years of age still demonstrate poorer scores in the children who were previously anemic.[52,53] Strategies to prevent iron deficiency could include the feeding of iron-fortified formulas, avoidance of non-iron-fortified milks and cow's milk (the latter, at least, till beyond 12 months of age), the feeding of meats and iron-fortified foods, and, if needed, medicinal iron supplementation in the form of ferrous sulfate.

BREAST-FEEDING

The benefits of breast-feeding to the infant, mother, family, and society are numerous and impressive, but they must be put into context when making individual decisions about breast-feeding. These include ready availability, possible enhancement of intestinal development, resistance to infection, and bonding between mother and infant. It is the preferred feeding method for the normal infant. Breast milk, in addition to providing the required nutrients for the healthy infant, has unique constituents, as listed in Table 15.7.

PROTEIN

Approximately 20% of the total nitrogen in human milk is in the form of nonprotein nitrogen compounds, such as free amino acids, and urea, which is considerably greater than the 5% found in bovine milk,[55] although there remains a debate about their contribution to nitrogen utilization.[56] The quality of the protein differs from that of bovine milk as well, with the whey-to-casein-protein ratios being 70:30 and 18:82 in human and bovine milk, respectively. These differences in whey-to-casein ratio are reflected in the plasma amino acid profile of infants and are readily observed within the first 3 days of age.[57] Further, plasma amino acid patterns in human-milk-fed infants has been used as a reference in infant nutrition.[58,59] In addition, specific human whey proteins — lactoferrin, lysozyme, and sIgA — are involved in host defense.[60,61]

LIPIDS

Lipids in human milk provide 40 to 50% of the energy content and are vehicles for fat soluble vitamins. The total fat content varies from 2% in colostrum to 2.5 to 3.0% in transitional milk, and 3.5 to 4.5% in mature human milk.[20] Cholesterol, phospholipids, and essential fatty acids are highest in colostrum, and more than 98% of human milk fat comes from 11 major fatty acids of 10- to 20-carbon length. Human milk lipids can inactivate enveloped viruses including herpes simplex I, measles, and cytomegalovirus, to name a few. Monoglycerides also exert antiviral activity.

TABLE 15.7
Unique Constituents of Breast Milk

Constituent	Function
Docosahexanoic acid	Necessary for growth and development of the brain and retina and for myelinization of nervous tissue
Cholesterol	Enhances myelinization of nervous tissue
Taurine	Second most abundant amino acid in human milk, important for bile acid conjugation
Choline	May enhance memory
Enzymes	Numerous enzymes such as lipases that are important in digestion and absorption of fat
Lactoferrin	Prevents iron from being available to bacteria
Inositol	Enhances synthesis and secretion of surfactant in immature lung tissue
Poly- and oligosaccharides	Inhibit bacterial binding to mucosal surfaces
Protein (α-lactalbumin)	Supply amino acids to the infant, help synthesize lactose in the mammary gland, and bind calcium and zinc
Bifidobacterium species	Predominant bacterial flora in the gastrointestinal tract of breast-fed infants, creates unfavorable pH conditions for the growth of enteric pathogens
Macrophages	Macrophages in human colostrum have high concentrations of sIgA, which is released during phagocytosis
Epidermal growth factor	Promotes cell proliferation in the gastrointestinal mucosa

Fat content of human milk is variable, with the fat content rising throughout lactation but with changes apparent within the course of one day, within feeds, and between women.[62] The effects of these differences in thriving infants is not clear, even given that hind milk has a higher fat content than fore milk. Human milk lipids provide preformed LC-PUFAs in amounts sufficient to meet nutrient needs. In term infants, plasma concentrations of DHA and ARA at 2 and 4 weeks of age were significantly lower in infants fed formula without LC-PUFA compared with breast-fed infants. DHA concentrations were similarly lower at 4 and 8 weeks of age. Neuringer and colleagues showed that visual acuity and learning abilities correlate well with the amount of DHA in the retina and brain phospholipids.[63]

NUCLEOTIDES

Nucleotides represent 2% to 5% of the nonprotein nitrogen in human milk.[64] Nucleotides participate in many biological functions such as forming the basis of genetic information (DNA, RNA) and storing energy (AMP, GMP), and they play roles in immunity as well as cellular activities. Although they can be produced by the liver, the body's requirements vary considerably, especially during infancy.[65] The effect of nucleotides on immune function is not well understood, but infants fed breast milk or nucleotide-supplemented formula have been shown to exhibit increased natural killer cell activity compared with infants fed formulas that are not supplemented.[66] Infants fed nucleotide formulas had enhanced haemophilus influenza type B and diphtheria humoral responses compared with infants fed formulas that are not supplemented.[67] Feeding of human milk resulted in significantly higher neutralizing antibody titers to polio virus at 6 months of age than were found in control or formula-fed cohorts. These data suggest that dietary factors play a role in the antibody response to immunization, and more studies are needed to better understand the mechanisms involved.

INFECTION

There are several enzymes present in human milk that appear to be important in the prevention of infection. These include glutathione peroxidase, alkaline phosphatase, and xanthine oxidase. In addition, other anti-inflammatory agents such as catalase, lactoferrin, immunoglobulins, and lysozyme are also present in human milk. The antimicrobial activities of these are generally found at mucosal surfaces, such as the gastrointestinal, urinary, and respiratory tracts. Specific factors, such as lactoferrin, lysozyme, and sIgA, resist proteolytic degradation and can line the mucosal surfaces, preventing microbial attachment and inhibiting microbial activity. Each of the mammary immune systems is active against a variety of antigens. Prospective studies in developing countries indicate that breast-milk-feeding reduces the incidence or severity of diarrhea,[68] lower-respiratory-tract infection,[69] otitis media,[70] bacteremia,[71] bacterial meningitis,[72] botulism,[73] urinary tract infection,[74] and necrotizing enterocolitis.[75]

Hyperbilirubinemia is more common in breast-fed than formula-fed infants. This is usually transient, and discontinuation of breast-feeding is not recommended unless bilirubin values reach excessively high levels or jaundice persists. Usually, switching

to a formula for 1 to 2 days is therapeutic and diagnostic, and breast-feeding can be safely resumed. Other causes of jaundice should be sought before making a firm diagnosis of breast-milk jaundice.

Certain chemicals, drugs, foreign proteins, and viruses may be present in human milk.[76] However, the risk–benefit ratio of artificial milk needs to be weighed, especially if the water sources for mixing the milk are contaminated. Breast-feeding is currently contraindicated in disease states such as active herpes, tuberculosis, and AIDS.

FORMULA FEEDING

A variety of formulas are available for feeding infants (Table 15.3). The most commonly used formulas are from bovine milk, and nutrient specifications for infant formulas are available.[77] Commercially available formulas are recommended when breast-feeding is not chosen. Cow's milk is not recommended in the first year of life because of its nutritional limitations and inappropriate nutrient concentrations. Cow's milk has higher concentrations of protein and phosphorus, a lower calcium-to-phosphorus ratio, limited iron, less essential fatty acids, vitamin C, and zinc than human milk. Increased renal solute load due to cow's milk and increased occult blood loss via the gastrointestinal tract leading to iron deficiency and anemia in infants fed cow's milk not supplemented by other nutrients are additional reasons to discourage the feeding of cow's milk in early infancy.

HYDROLYZED INFANT FORMULAS

Hydrolyzed formulas have been used for the treatment of food allergies and intolerances and for the prevention of atopic disease in high-risk infants. The use of a hydrolyzed infant formula when compared with a cow's milk formula in infants who are not exclusively breast-fed reduces allergies.[78] There is no evidence, however, to support the use of a hydrolyzed formula to prevent allergy in preference to exclusive breast-feeding. Although many infants with atopy do not have a family history,[79–81] a positive family history in one or both parents still remains the most useful method of identifying allergy-prone infants.[82] Hydrolyzed formulas are cow's milk proteins that are subjected to chemical and enzymatic hydrolysis to reduce the molecular weight, the peptide size, and consequently, the allergenicity of the proteins. They are either extensively hydrolyzed casein (molecular weights <3,000 Da) or partially hydrolyzed whey (3,000 to 10,000 Da).

The American Academy of Pediatrics (AAP),[82] the European Society for Paediatric Allergology and Clinical Immunology,[83] and the European Society for Paediatric Gastroenterology, Hepatology and Nutrition[83] recommend extensively hydrolyzed formulas for allergy treatment in high-risk infants — they acknowledge a potential role for partially hydrolyzed formulas in the primary prevention of atopic disease. The German Infant Nutritional Intervention Study[84] found a significantly lower incidence of atopic dermatitis in infants fed partially and extensively hydrolyzed formulas when compared with cow milk formulas at 12 months of age. A recent literature review[85] showed no significant difference in allergy incidence in infancy of partially and extensively hydrolyzed formulas.

SOY-PROTEIN-BASED FORMULAS

The Committee on Nutrition of the AAP reviewed the indications of soy-protein-based formulas.[86] Some of the conclusions include:

1. Isolated soy-protein-based formulas are safe and effective alternatives to provide appropriate nutrition if breast milk or cow-milk-based formulas do not meet the nutritional needs in term infants. However, no advantage is provided over cow-milk-protein-based formulas as a supplement for breast-feeding.
2. Soy-protein-based formulas are appropriate for use in infants with galactosemia and hereditary lactase deficiency.
3. There is no proven value of the routine use of soy-protein-based formula in the prevention or management of infantile colic.
4. There is no proven value of the routine use of soy-protein-based formula in the prevention of atopic disease in healthy or at-risk infants.
5. Infants with documented cow-milk-protein-induced enteropathy or enterocolitis should not be given soy-protein-based formula routinely.

The nutritional needs of infants aged 0 to 6 months can be met by breast milk or infant formulas. Although both groups of infants need to have health surveillance including growth and development, breast-fed infants need to be followed up closely over the first few weeks to assure appropriate feeding practices and resultant growth. Appropriate counseling for common breast-feeding problems needs to be provided, and community support groups can be involved if needed. Beyond 6 months, recommendations for infant feeding are variable, and the recommendations are largely based on extrapolation from data on younger infants. Nutritional composition of "follow-up" formulas is specified with minimum lower limits for energy (60 kcal/dl), higher minimum limits for protein (2.25 to 3.0 g/100 kcal), and lower minimum limits for fat (3.0 to 4.0 g/100 kcal) compared with formulas for younger infants. Nonetheless, iron-fortified formulas designed for younger infants may be safely fed from

6 to 12 months. Infants by this age are physiologically and developmentally ready to accept a variety of dietary items, and feeding practices vary based on ethnic, cultural, and economic reasons. As stated earlier, feeding of bovine milk is discouraged during this period, although a substantial number of infants are indeed fed bovine milk.[87] In addition, there are concerns about the substitution of low-fat or skimmed milks during this period because of higher intakes of protein and sodium and lower intakes of iron and essential fatty acids. However, if infants are being fed nonmilk foods, the actual intake of energy may not be lower than of infants fed bovine milk or formula.[88]

BONE DENSITY

Infants exclusively breast-fed have lower bone accretion and total body bone mineral content than do formula-fed infants.[89] The low vitamin D content in human milk[90] and the decreasing phosphorus concentration with increasing lactation are thought to be the cause.[91,92] Early mineral intake during the first 6 months of age is associated with early bone mass accretion.[89] The Committee on Nutrition and Section of Breast Feeding Medicine of the AAP recommends supplement of 200 IU/day of vitamin D to all breast-fed infants unless weaned to at least 500 ml/day of vitamin-D-fortified formula or milk.[93]

Older-infant studies on soy-based formulas showed a lower radius bone mineral density in infants fed soy-based formulas than did infants fed cow-milk-based formulas.[94,95] Newer formulations of soy formulas have improved both calcium and phosphorus content and availability. Bainbridge et al. [96] showed no difference in bone accretion between these newer formulas and cow-milk-based formulas.

WEANING

The transition from suckling to eating of nonmilk foods occurs during the first year of life based on cultural beliefs and practices, physicians beliefs, mothers' perceptions of their infants' needs, and economic realities. Complementary foods are introduced from before 3 months to nearly 6 months of age, and a variety of foods are offered.[97–99] In the United States, the total transition to beikost usually occurs by the end of the first year of life and continues during the second year.

The weaning process can be considered in three ways. First, it could be the weaning from breast-feeding to other milks that may replace breast-feeding partially or completely. In the second form, weaning could be considered the transition from liquid to nonliquid diet. Health concerns may arise during this period if the added foods are too nutrient dense (protein or energy) or nutrient-deficient (iron or protein), thus altering the protein-to-energy ratio or causing deficiency of specific nutrients. The third aspect of weaning may be the transition from human milk or formula to bovine milk in addition to the provision of beikost. Because weaning typically occurs during a period of rapid growth, attention to both nutritional and developmental issues during this period is warranted. Complementary foods, in addition to providing the required nutrients, are also important in establishing lifelong patterns of eating. The current consensus is to introduce one solid food at a time and wait for several days to a week to assess tolerance before adding a new food. For most babies, it does not matter what the first foods are, but cereals, followed by fruits, strained vegetables and meats are suggested. Teaching good food habits, including offering a variety, will lead to lifelong eating habits. A suggested algorithm for the feeding of term infants and the transition to complementary foods is depicted in Figure 15.3.

FAILURE TO THRIVE

Growth, as assessed by weight, length (and subsequently height), and head circumference, is an important part of anticipatory guidance provided in well-child care. These anthropometric measurements, especially weight, can be used to detect inadequate attained growth or reduced growth velocity. The average birth weight of a full-term infant is 3300 to 3500 g; after a weight loss of ~10%, infants should regain their birth weight by 2 weeks, with formula-fed infants tending to regain their birth weight a little sooner than their breast-fed counterparts. On an average, infants gain about 1 kg/month for the first 3 months, $\frac{1}{2}$ kg/month for the next 3 months, $\frac{1}{3}$ kg/month from 6 to 9 months and $\frac{1}{4}$ kg/month from 9 to 12 months. Full-term infants double their weights by 4 months and triple their weights by 12 months, while doubling their lengths during the same period. Both weight and length gains are slower in the second year of life, underscoring the anticipatory nutritional guidance needed during that period. Growth faltering, or failure to thrive, a descriptive term, is then identified by the following criteria: (1) weight less than 80% to 85% of the 50th percentile on the National Center for Health Statistics (NCHS) growth charts, (2) weight for age less than the 3 to 5 percentile on the NCHS growth charts, (3) drop in weight that crosses two or more percentile categories on standard growth charts from previously established pattern of adequate growth, and (4) a Z-score of −2 SD below the normal 50th percentile. If growth velocity is used, a decrement of 2 SD over a 90-day period and loss of >1 SD Z-score over 90 days is used as a measure of growth faltering.

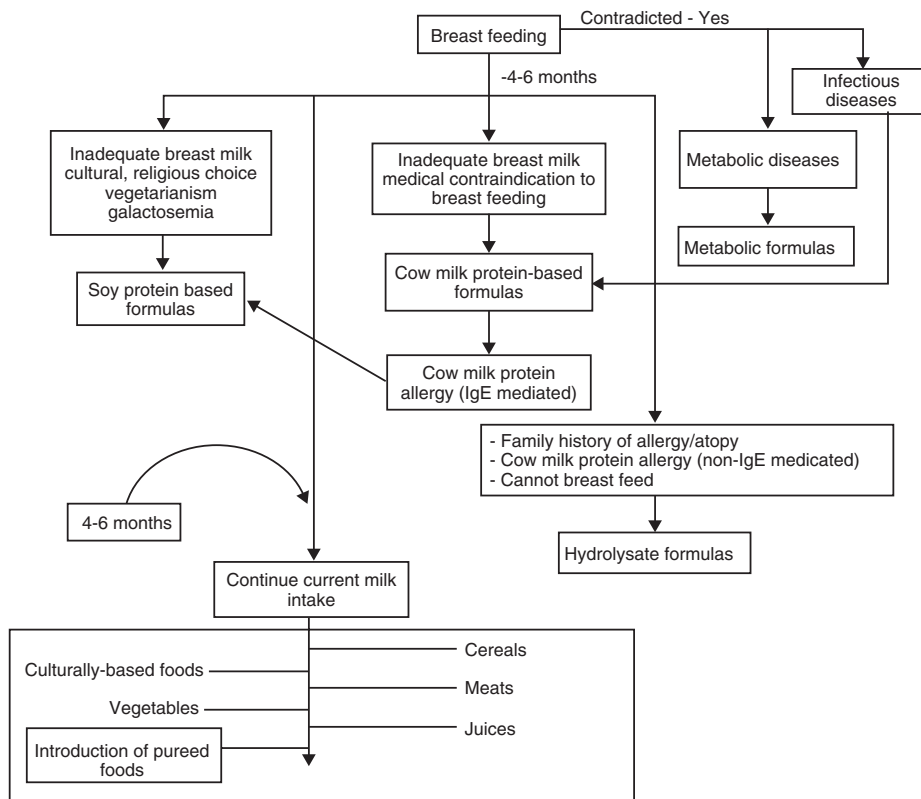
As decline in rate of weight gain or growth velocity is more sensitive than decline in length or head circumference, serial measurements of weight are an important part of the anticipatory guidance given during well-child checks, and provide an early


FIGURE 15.3   Birth to 36 months: Boys Head circumference-for-age and weight-for-length percentiles.

TABLE 15.8

Recommendations for Feeding Healthy Full-Term Infants

Breast-feeding is strongly recommended.

Infant formulas that meet AAP guidelines are recommended when breast-feeding is not chosen or breast milk is not available.

Breast milk or infant formula is the preferred feeding in the first year of life.

Adequate intakes of human milk or formula meet all nutrient requirements for the first 6 months of life (exception may be vitamin D in dark-skinned, sun-deprived breast-fed infants). Infant formula or "follow-up" formula may be fed in the second 6 months of life.

Introduction of complementary foods should be based on growth, developmental, cultural, social, psychological, and economic considerations. As a general rule, when an infant is consuming 32 oz of milk per day and appears to want more, supplemental feedings may be indicated. This usually occurs between 4 and 6 months of age.

warning of growth faltering.[100,101] BMI, calculated by dividing weight in kilograms by the square of length/height in meters, has largely replaced weight for stature. It should be recognized that there are growth differences between breast- and formula-fed infants. As reported by Nelson et al.[102] mean gains in both weight (g/day) and length (cm/day) were greater in formula-fed males and females than their breast-fed counterparts from 8 to 122 days of age. As the NCHS growth charts were made from data that was cross-sectional and the infants were fed formulas, attention to growth faltering in the breast-fed infant requires both understanding of the growth of breast-fed infants and the early recognition of decrease in weight or growth velocity.[103] New growth charts from a cross section of breast-fed infants need to be assessed for their use in the United States. There are numerous organic and nonorganic causes of growth failure or faltering that need to be addressed during such an evaluation. It is important to realize that failure to thrive or malnutrition may occur in hospitalized infants and children, as well, and efforts to recognize and nourish these infants and children should be made.

SUMMARY

In summary, the period of infancy is one of rapid changes in growth and attainment of developmental milestones. This period imposes unique nutritional needs and challenges for the health care provider. Understanding nutritional needs, ways of meeting these needs (Table 15.8), deviations in growth and their causes, and providing nutrition in age-appropriate and culturally and ethnically sensitive ways while addressing economic issues is the task of the health care team. Ideally, the infant's nutritional

need (expressed as hunger), developmental progress (as observed in attainment of feeding skills), and mother's and care provider's beliefs within the context of the family will guide the infant's feeding experience and transition to the next phase in life.

16 Nutrition for Healthy Children and Adolescents Aged 2 to 18 Years

Suzanne Domel Baxter

CONTENTS

PHYSICAL GROWTH AND DEVELOPMENT

A child's first year of life is marked by rapid growth, with birth weight tripling and birth length increasing by 50%. After the rapid growth of the first year, physical growth slows down considerably during the preschool and school years, until the pubertal growth spurt of adolescence. Birth weight does not quadruple until 2 years of age, and birth length does not double until 4 years of age. A 1-year-old child has several teeth, and his or her digestive and metabolic systems are functioning at or near adult capacity. By 1 year of age, most children are walking or beginning to walk; with improved coordination over the next few years, activity increases dramatically. Although increased activity in turn increases energy needs, a child's rate of growth decreases. Growth patterns vary in individual children, but each year children from 2 years to puberty gain an average of 4.5 to 6.5 pounds (2 to 3 kg) in weight and 2.5 to 3.5 in. (6 to 8 cm) in height. As the growth rate declines during the preschool years, a child's appetite decreases and food intake may become unpredictable and erratic. Parents and other caregivers need to know that these changes are normal so that they can avoid struggles with children over food and eating.

After the first year of life, more development that is significant occurs in fine and gross motor, cognitive, and social-emotional areas than during the first year of life. During the second year of life, children learn to feed themselves independently. By 15 months of age, children can manage a cup, but with some spilling. At 18 to 24 months of age, children learn to tilt cups by manipulating their fingers. Children are able to transfer food from bowls to their mouths with less spilling by 16 to 17 months of age when well-defined wrist rotation develops. However, 2-year-old children often prefer foods that can be picked up with their fingers without having to chase it across their plates.

The normal events of puberty and the simultaneous growth spurt are the primary influences on nutritional requirements during the second decade of life. During puberty, height and weight increase, many organ systems enlarge, and body composition is altered due to increased lean body mass and changes in the quantity and distribution of fat. The timing of the growth spurt is influenced by genetic as well as environmental factors. Children who weigh more than average for their height tend to mature early, and vice versa. Although stature tends to increase most rapidly during the spring and summer, weight either tends to increase at a fairly steady rate over the entire year or undergoes a more rapid increase during the autumn. The most rapid linear growth spurt for an average American boy occurs between 12 and 15 years of age. For the average American girl, the growth spurt occurs about 2 years earlier, between 10 and 13 years of age. The growth spurt during adolescence contributes about 15% to final adult height, and approximately 50% to adult weight. During adolescence, boys tend to gain more weight than girls do, and to gain it at a faster rate. Furthermore, the skeletal growth of boys continues for a longer time than that of adolescent girls. Adolescent boys deposit more muscle mass, and adolescent girls deposit relatively more total body fat. Menarche, which is closely linked to the growth process, has a lasting impact on nutritional requirements of adolescent girls.

Adolescence is a period of various cognitive challenges. For example, when an adolescent realizes that his or her body is in the process of maturing, he or she may begin to assess changes in his or her own body size and shape, compare them with those of others, and form opinions about any differences. Adolescent girls and boys may be very self-conscious, especially during early and mid-adolescence. According to Piaget's developmental levels, it is usually during adolescence that abstract thinking

supersedes concrete thinking. Thus, an adolescent may consider his or her body not just as it is, but also as it *might* be. In addition, an adolescent can contemplate new or different ways of combining or eating food. Furthermore, an adolescent can more easily conceptualize nutrients such as calories and fat, and skillfully manipulate their dietary intake.

ENERGY AND NUTRIENT NEEDS

DIETARY REFERENCE INTAKES

The Dietary Reference Intakes (DRIs)[1] expand and replace reports called *Recommended Dietary Allowances*,[2] published from 1941 to 1989 by the National Academy of Sciences, and *Recommended Nutrient Intakes*, published by the Canadian government. The DRIs include Recommended Dietary Allowance (RDA), Estimated Average Requirement (EAR), Adequate Intake (AI), and Tolerable Upper Intake Level (UL). Within the DRI framework, the RDA serves as a goal for daily intake by individuals; it is the average daily dietary intake level that is sufficient to meet the nutrient needs of almost all (97 to 98%) healthy individuals in a life stage and sex group. The EAR is a nutrient intake value that is estimated to meet the nutrient needs of 50% of the healthy individuals in a life stage and sex group; it is the basis for the RDA and used to assess adequacy of intakes of population groups and to plan intakes of groups. The AI is used instead of an RDA when sufficient scientific evidence is not available to calculate an EAR; the AI is based on observed or experimentally determined approximations of nutrient intake by a life stage and sex group (or groups) of healthy people. The UL is the highest level of nutrient intake per day that is likely to pose no risks of adverse health effects to almost all individuals in the general population. The risk of adverse effects increases as intake increases above the UL.[1] Although the DRIs are based on data, scientific judgment was required in setting all reference values, because data were often scanty or drawn from studies with limitations; this is especially true in deriving DRIs for infants, children, adolescents, the elderly, and pregnant women.[1] The DRIs have been published in a series of 12 reports to date.[1,3–13] Table 16.1 provides new reference heights, weights, and body mass indexes (BMIs) for children and adolescents in the United States. Table 16.2 provides RDAs and AIs for children and adolescents. Table 16.3 provides Acceptable Macronutrient Distribution Ranges (AMDRs) for children and adolescents. Table 16.4 provides additional macronutrient recommendations for children and adolescents. Table 16.5 provides ULs for children and adolescents. Table 16.6 provides EARs for groups of children and adolescents.

ENERGY

Energy is needed to maintain the various functions of the body including respiration, circulation, physical work, and protein synthesis. Energy is supplied in the diet by carbohydrates, proteins, fats, and alcohol. An individual's energy balance depends on his or her intake of dietary energy and expenditure of energy. Within the DRIs, Estimated Energy Requirements (EERs) were established at four levels of energy expenditure, and recommendations were provided for levels of physical activity associated with a normal BMI range.[1] The EER is the average dietary energy intake predicted to maintain energy balance in a healthy individual of a defined age, sex, weight, height, and level of physical activity, consistent with good health.[1] Table 16.7 provides

TABLE 16.1

Dietary Reference Intakes (DRIs): New Reference Heights, Weights, and Body Mass Index (BMIs) for Children and Adolescents in the United States

	Children		Boys		Girls	
	1 to 3 Years	4 to 8 Years	9 to 13 Years	14 to 18 Years	9 to 13 Years	14 to 18 Years
Median Reference Height,[a] cm (in.)	86 (34)	115 (45)	144 (57)	174 (68)	144 (57)	163 (64)
Reference Weight,[b] kg (lb)	12 (27)	20 (44)	36 (79)	61 (134)	37 (81)	54 (119)
Median BMI[a] (kg/m^2)	—	15.3	17.2	20.5	17.4	20.4

[a] Taken from height-for-age data and median BMI data for boys and girls from the Centers for Disease Control and Prevention (CDC)/National Center for Health Statistics (NCHS) Growth Charts from Kuczmarski et al., *Adv Data*, 314, 1–28, 2000.

[b] Calculated CDC/NCHS Growth Charts from Kuczmarski et al., *Adv Data*, 314, 1–28, 2000; median BMI and median height for ages 4 through 19 years.

Source: Adapted from: Institute of Medicine, *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids,* National Academies Press, Washington, DC, 2002/2005. This report may be accessed via www.nap.edu.

criteria and DRI values for energy by active children and adolescents by life stage group. In children, the EER includes needs associated with the deposition of tissues. Although equations are provided for estimating four levels of activity, the *active* physical activity level is recommended to maintain health. There is no RDA for energy, because energy intakes above the EER would be expected to result in weight gain. Likewise, the UL concept does not apply to energy, because any energy intake above an individual's requirement would lead to undesirable and potentially hazardous weight gain.[1]

Components of energy expenditure include basal and resting metabolism, thermic effect of food, thermoregulation, physical activity, physical activity level, and total energy requirement.[1] Factors that affect energy expenditure and requirements include body composition and body size (i.e., effects on basal and resting metabolic rate, effects on total energy expenditure, and obesity), physical activity (i.e., effect of exercise on postexercise energy expenditure, spontaneous nonexercise activity), sex, growth, older age, genetics, ethnicity, environment (i.e., climate altitude), and adaptation and accommodation.[1]

TABLE 16.2
(Continued)

	Children		Boys		Girls	
	1 to 3 Years	4 to 8 Years	9 to 13 Years	14 to 18 Years	9 to 13 Years	14 to 18 Years
Linoleic Acid (g/day)	7*	10*	12*	16*	10*	11*
α-Linolenic Acid (g/day)	0.7*	0.9*	1.2*	1.6*	1.0*	1.1*
Protein (g/day)	**13[l]**	**19[m]**	**34[n]**	**52[o]**	**34[n]**	**46[p]**
Protein (g/kg/day)	**1.05**	**0.95**	**0.95**	**0.85**	**0.95**	**0.85**

[a] Recommended Dietary Allowances (RDAs) are presented in **bold type** and Adequate Intakes (AIs) in ordinary type followed by an asterisk (*). RDAs and AIs may both be used as goals for individual intake. RDAs are set to meet the needs of almost all (97 to 98%) healthy individuals in a group. The AI for life stage and sex groups is believed to cover needs of all individuals in the group, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of persons covered by this intake.

[b] As retinol activity equivalents (RAEs). 1 RAE = 1 μg retinol, 12 μg β-carotene, 24 μg α-carotene, or 24 μg β-cryptoxanthin. The RAE for dietary provitamin A carotenoids is twofold greater than retinol equivalents (RE), whereas the RAE for preformed vitamin A is the same as RE.

[c] As cholecalciferol. 1 μg cholecalciferol = 40 IU vitamin D.

[d] In the absence of adequate exposure to sunlight.

[e] As α-tocopherol. α-Tocopherol includes *RRR*-α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the *2R*-stereoisomeric forms of α-tocopherol (*RRR*-, *RSR*-, *RRS*-, and *RSS*-α-tocopherol) that occur in fortified foods and supplements. It does not include the *2S*-stereoisomeric forms of α-tocopherol (*SRR*-, *SSR*-, *SRS*-, and *SSS*-α-tocopherol), also found in fortified foods and supplements.

[f] As niacin equivalents (NE). 1 mg niacin = 60 mg tryptophan.

[g] As dietary folate equivalents (DFE). 1 DFE = 1 μg food folate = 0.6 μg folic acid from fortified food or as a supplement consumed with food = 0.5 μg of a supplement taken on an empty stomach.

[h] In view of evidence linking folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant consume 400 μg from supplements or fortified foods in addition to intake of food folate from a varied diet. It is assumed that females will continue consuming 400 μg from supplements or fortified food until their pregnancy is confirmed and they enter prenatal care.

[i] Although AIs have been set for choline, there are few data to assess whether a dietary supply of choline is needed at all stages of the life cycle, and it may be that the choline requirement can by met by endogenous synthesis at some of these stages.

[j] Total water includes all water contained in drinking water, food, and beverages.

[k] ND = Not determined.

[l] 13 g/day of protein or 1.05 g protein per kg of body weight.

[m] 19 g/day of protein or 0.95 g protein per kg of body weight.

[n] 34 g/day of protein or 0.95 g protein per kg of body weight.

[o] 52 g/day of protein or 0.85 g protein per kg of body weight.

[p] 46 g/day of protein or 0.85 g protein per kg of body weight.

These reports may be accessed via www.nap.edu.

Physical Activity Level (PAL) is the ratio of total energy expenditure to basal daily energy expenditure (TEE/BEE); it is a convenient comparison used in the DRIs to describe and account for physical activity habits.[1] The PAL categories were defined as sedentary (PAL ≥ 1.0 < 1.4), low active (PAL ≥ 1.4 < 1.6), active (PAL ≥ 1.6 < 1.9), and very active (PAL ≥ 1.9 < 2.5).[1]

The EER for boys and girls varies considerably because of variations in growth rate and physical activity. To derive total energy requirements, data from doubly-labeled water studies were utilized to develop equations to predict TEE based on sex, age, height, weight, and PAL category. To obtain the EER, the calculated TEE is increased for estimated energy deposition by an average of 20 kcal/day for ages 3 through 8 years and by 25 kcal/day for ages 9 through 18 years. EER predictions for children and adolescents with reference weights, at yearly intervals by sex, are available and are summarized below for age categories by sex.[1]

For boys age 3 through 8 years,

EER = TEE + energy deposition = $88.5 - (61.9 \times$ age [years]$) + PA \times (26.7 \times$ weight [kg] $+ 903 \times$ height [m]$) + 20$ kcal

For boys age 9 through 18 years,

EER = TEE + energy deposition = $88.5 - (61.9 \times$ age [years]$) + PA \times (26.7 \times$ weight [kg] $+ 903 \times$ height [m]$) + 25$ kcal

Where PA is the physical activity coefficient and, for boys, is 1.00 if PAL is sedentary, 1.13 if PAL is low active, 1.26 if PAL is active and 1.42 if PAL is very active.

For girls age 3 through 8 years,

EER = TEE + energy deposition = $135.3 - (30.8 \times$ age [years]$) + PA \times (10.0 \times$ weight [kg] $+ 934 \times$ height [m]$) + 20$ kcal

For girls age 9 through 18 years,

EER = TEE + energy deposition = $135.3 - (30.8 \times$ age [years]$) + PA \times (10.0 \times$ weight [kg] $+ 934 \times$ height [m]$) + 25$ kcal

Where PA is the physical activity coefficient and, for girls, is 1.00 if PAL is sedentary, 1.16 if PAL is low active, 1.31 if PAL is active and 1.56 if PAL is very active.

TABLE 16.3
Dietary Reference Intakes (DRIs): Acceptable Macronutrient Distribution Ranges (AMDRs) for Children and Adolescents[a]

	Range (Percent of Energy)	
	1 to 3 Years	**4 to 18 Years**
Macronutrient		
Fat	30–40	25–35
$n-6$ Polyunsaturated fatty acids[a] (linoleic acid)	5–10	5–10
$n-3$ Polyunsaturated fatty acids[a] (α-linolenic acid)	0.6–1.2	0.6–1.2
Carbohydrate	45–65	45–65
Protein	5–20	10–30

[a] Approximately 10% of the total can come from longer-chain $n-3$ or $n-6$ fatty acids.

Source: Adapted from: Institute of Medicine, *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids,* National Academies Press, Washington, DC, 2002/2005. This report may be accessed via www. nap.edu.

TABLE 16.4
Dietary Reference Intakes (DRIs): Additional Macronutrient Recommendations for Children and Adolescents[a]

Macronutrient	Recommendation
Added sugars	Limit to no more than 25% of total energy
Dietary cholesterol	As low as possible while consuming a nutritionally adequate diet
Saturated fatty acids	As low as possible while consuming a nutritionally adequate diet
Trans fatty acids	As low as possible while consuming a nutritionally adequate diet

Source: Adapted from: Institute of Medicine, *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids,* National Academies Press, Washington, DC, 2002/2005. This report may be accessed via www.nap.edu.

Separate EERs were developed for pregnant and lactating girls aged 14 through 18 years.[1] In addition, separate weight maintenance TEE predictive equations were developed for overweight (i.e., above the 95th percentile for BMI) boys and girls age 3 through 18 years.[1] An accepted and practical method for assessing the adequacy of a child or adolescent's energy intake is to monitor growth by tracking height and weight on growth charts developed by the National Center for Health Statistics; these CDC growth charts may be accessed via http://www.cdc.gov/growthcharts.

PROTEIN

Protein is essential for growth, development, and maintenance of the body; it also provides energy. Protein yields 4 kcal/gram (g). Food sources of protein include meat, fish, poultry, milk, cheese, yogurt, dried beans, peanut butter, nuts, and grain products. Protein from animal sources is called "complete protein," because it contains all nine indispensable amino acids. Protein from plant sources is called "incomplete protein," because it tends to be deficient in one or more of the indispensable amino acids. A vegetable protein may be paired with another vegetable protein or with a small amount of animal protein to provide adequate amounts of all the indispensable amino acids. For example, black-eyed peas can be paired with rice, peanut butter with wheat bread, pasta with cheese, or cereal with milk.

TABLE 16.5
Dietary Reference Intakes (DRIs): Tolerable Upper Intake Levels (ULs) for Children and Adolescents[a]

	1 to 3 Years	4 to 8 Years	9 to 13 Years	14 to 18 Years

Continued

TABLE 16.5
(Continued)

	1 to 3 Years	4 to 8 Years	9 to 13 Years	14 to 18 Years
Elements (*Continued*)				
Zinc (mg/day)	7	12	23	34
Sodium (g/day)	1.5	1.9	2.2	2.3
Chloride (g/day)	2.3	2.9	3.4	3.6

[a] UL = The maximum level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. Unless otherwise specified, the UL represents total intake from food, water, and supplements.

[b] As preformed vitamin A only.

[c] As α-tocopherol; applies to any form of supplemental α-tocopherol.

[d] The ULs for vitamin E, niacin, and folate apply to synthetic forms obtained from supplements, fortified foods, or a combination of the two.

[e] ND = Not determinable due to lack of data of adverse effects in these age groups and concern with regard to lack of ability to handle excess amounts. In the absence of ULs, extra caution may be warranted in consuming levels above recommended intakes. Sources of intake should be from food only to prevent high levels of intake.

[f] β-Carotene supplements are advised only to serve as a provitamin A source for individuals at risk of vitamin A deficiency.

[g] Although the UL was not determined for arsenic, there is no justification for adding it to food or supplements.

[h] The ULs for magnesium represent intake from a pharmacological agent only and do not include intake from food and water.

[i] Although silicon has not been shown to cause adverse effects in humans, there is no justification for adding it to supplements.

[j] Although vanadium in food has not been shown to cause adverse effects in humans, there is no justification for adding it to food and vanadium supplements should be used with caution. The UL for adults is 1.8 mg/day of elemental vanadium; the UL for adults is based on adverse effects in laboratory animals, but this data could not be used to set a UL for children and adolescents.

Source: Adapted from: Institute of Medicine, *Dietary Reference Intakes for Calcium, Phosphorus, Magnesium, Vitamin D, and Fluoride*, National Academy Press, Washington, DC, 1997; Institute of Medicine, *Dietary Reference Intakes for Thiamin, Riboflavin, Niacin, Vitamin B₆, Folate, Vitamin B₁₂, Pantothenic Acid, Biotin, and Choline*, National Academy Press, Washington, DC, 1998; Institute of Medicine, *Dietary Reference Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids,* National Academy Press, Washington, DC, 2000; Institute of Medicine, *Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybedenum, Nickel, Silicon, Vanadium, and Zinc,* National Academy Press, Washington, DC, 2001; and Institute of Medicine, *Dietary Reference Intakes for Water, Potassium, Sodium, Chloride, and Sulfate,* National Academies Press, Washington, DC, 2005. These reports may be accessed via www.nap.edu.

Proteins in the body are continuously being degraded and resynthesized. Because the process is not entirely efficient and some amino acids are lost, a continuous supply of amino acids is needed to replace these losses, even after growth has stopped. The primary factor that influences protein needs is energy intake, because when energy intake is insufficient, protein is used for energy. Thus, all protein recommendations are based on the assumption that energy needs are adequately met. In addition, protein recommendations are based on intakes of complete protein; appropriate corrections must be made for diets that customarily provide incomplete proteins.

Three ounces of poultry or lean meat provide about 25 g of protein. Three ounces of fish or 1 cup of soybeans provides about 20 g of protein. One cup of yogurt provides about 8 g of protein. One cup of milk provides about 8 g of protein. One egg provides about 6 g of protein. One ounce of cheese provides about 6 g of protein. One cup of legumes provides about 15 g of protein. Cereals, grains, nuts, and vegetables provide about 2 g of protein per serving.[1]

The RDAs for protein for children and adolescents are provided in Table 16.2 in g/day and g/kg/day. The EARs for protein for children and adolescents are provided in Table 16.6 in g/kg/day. The EARs and RDAs for indispensable amino acids for children and adolescents are provided in Table 16.8. As Table 16.2 indicates, protein requirements slowly decline relative to weight during the preschool to mid-elementary school years, and during the upper elementary to high-school years. A 14-year-old adolescent boy who weighs 61 kilograms (kg) [134 pounds] needs 52 g of protein each day; assuming that energy needs are met, this protein need can be met by eating a hamburger (3-ounce meat patty on a bun for a total of 29 g of protein) and two slices of pizza topped with meat and cheese (for a total of 23 g of protein).

Children aged 1 to 3 years should get 5 to 20% of their daily energy from protein.[1] Children and adolescents aged 4 to 18 years should get 10 to 30% of their daily energy from protein.[1] (See Table 16.3.)

CARBOHYDRATES

Carbohydrates (starches and sugars) provide energy to cells in the body, especially the brain, because it is a carbohydrate-dependent organ. The new RDA for carbohydrate for children, adolescents, and adults is set at 130 g/day based on the average

TABLE 16.6

Dietary Reference Intakes (DRIs): Estimated Average Requirements (EARs) for Groups of Children and Adolescents[a]

	Children		Boys		Girls	
	1 to 3 Years	4 to 8 Years	9 to 13 Years	14 to 18 Years	9 to 13 Years	14 to 18 Years
Carbohydrate (g/day)	100	100	100	100	100	100
Protein (g/kg/day)	0.87	0.76	0.76	0.73	0.76	0.71
Vitamin A (μg/day)[b]	210	275	445	630	420	485
Vitamin C (mg/day)	13	22	39	63	39	56
Vitamin E (mg/day)[c]	5	6	9	12	9	12
Thiamin (mg/day)	0.4	0.5	0.7	1.0	0.7	0.9
Riboflavin (mg/day)	0.4	0.5	0.8	1.1	0.8	0.9
Niacin (mg/day)[d]	5	6	9	12	9	11

Iodine (μg/day)	65	65	73	95	73	95
Iron (mg/day)	3.0	4.1	5.9	7.7	5.7	7.9
Magnesium (mg/day)	65	110	200	340	200	300
Molybdenum (μg/day)	13	17	26	33	26	33
Phosphorus (mg/day)	380	405	1055	1055	1055	1055
Selenium (μg/day)	17	23	35	45	35	45
Zinc (mg/day)	2.5	4.0	7.0	8.5	7.0	7.3

[a] EARs serve 2 purposes: for assessing adequacy of population intakes and as the basis for calculating Recommended Dietary Allowances (RDAs) for individuals. EARs have not been established for vitamin D, vitamin K, pantothenic acid, biotin, choline, calcium, chromium, fluoride, manganese, or other nutrients not yet evaluated via the DRI process.

[b] As retinol activity equivalents (RAEs). 1 RAE = 1 μg retinol, 12 μg β-carotene, 24 μg α-carotene, or 24 μg β-cryptoxanthin. The RAE for dietary provitamin A carotenoids is twofold greater than retinol equivalents (RE), whereas the RAE for preformed vitamin A is the same as RE.

[c] As α-tocopherol. α-Tocopherol includes RRR-α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the $2R$-stereoisomeric forms of α-tocopherol (RRR-, RSR-, RRS-, and RSS-α-tocopherol) that occur in fortified foods and supplements. It does not include the $2S$-stereoisomeric forms of α-tocopherol (SRR-, SSR-, SRS-, and SSS-α-tocopherol), also found in fortified foods and supplements.

[d] As niacin equivalents (NE). 1 mg niacin = 60 mg tryptophan.

[e] As dietary folate equivalents (DFE). 1 DFE = 1 μg food folate = 0.6 μg folic acid from fortified food or as a supplement consumed with food = 0.5 μg of a supplement taken on an empty stomach.

These reports may be accessed via www.nap.edu.

amount of glucose utilized by the brain.[1] (See Table 16.2.) However, this level of intake is typically exceeded to meet energy needs while consuming acceptable intake levels of protein and fat.[1] No recommendations based on glycemic index are made due to a lack of sufficient evidence on the prevention of chronic diseases in generally healthy individuals.[1]

Children and adolescents should get 45 to 65% of their daily energy from carbohydrates.[1] (See Table 16.3.) Complex carbohydrates (starchy foods such as pasta, breads, cereals, rice, and legumes) should provide the majority of energy from carbohydrates, and simple carbohydrates (naturally occurring sugars in fruits and vegetables) should provide the rest. The Institute of Medicine recommends that added sugars be limited to no more than 25% of total energy (Table 16.4).[1] Carbohydrate yields 4 kcal/g. An active 6-year-old boy who needs about 1750 kcal/day would need about 788 to 1138 kcal (or 197 to 284 g) from

TABLE 16.7

Criteria and Dietary Reference Intake (DRI) Values for Energy by Active Children and Adolescents by Life Stage Group[a]

Life Stage Group (Years)	Criterion	Active PAL EER[b] (kcal/Day)	
		Boys	Girls
1 through 2	Energy expenditure plus energy deposition	1046	992 (24 months)
3 through 8	Energy expenditure plus energy deposition	1742	1642 (6 years)
9 through 13	Energy expenditure plus energy deposition	2279	2071 (11 years)
14 through 18	Energy expenditure plus energy deposition	3152	2368 (16 years)

[a] For healthy active American and Canadian children and adolescents. Based on the cited age, an active physical activity level, and the reference heights and weights in Table 16.1. Individualized EERs can be determined from the predictive equations in the text for this chapter.

[b] PAL = Physical Activity Level, EER = Estimated Energy Requirement. The intake that meets the average energy expenditure of individuals at the reference age, height, and weight (see Table 16.1).

Source: Adapted from: Institute of Medicine, *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids,* National Academies Press, Washington, DC, 2002/2005. This report may be accessed via www.nap.edu.

TABLE 16.8

Estimated Average Requirements (EARs) and Recommended Dietary Allowances (RDAs) for Amino Acids for Children and Adolescents

	Children		Boys		Girls	
	1 to 3 Years	4 to 8 Years	9 to 13 Years	14 to 18 Years	9 to 13 Years	14 to 18 Years
EAR[a] (mg/kg/day)						
Histidine	16	13	13	12	12	12
Isoleucine	22	18	18	17	17	16
Leucine	48	40	40	38	38	35

Tryptophan	8	6	6	6	6	5
Valine	37	28	28	27	27	24

[a] EAR for age 1 through 13 years = maintenance + amino acid deposition × 1.72. EAR for age 14 through 18 years = maintenance + amino acid deposition × 2.13.

[b] RDA for age 1 through 13 years = EAR + 2 × $\sqrt{[(0.12 \times \text{maintenance})^2 + (0.43 \times 2.13 \times \text{mean protein deposition})^2]}$.

Source: Adapted from Institute of Medicine, *Dietary Reference Intakes for Energy, Carbohydrate, Fiber, Fat, Fatty Acids, Cholesterol, Protein, and Amino Acids,* National Academies Press, Washington, DC, 2002/2005. This report may be accessed via www.nap.edu.

carbohydrates daily. An active 11-year-old girl who needs about 2075 kcal/day would need about 934 to 1349 kcal (or 233 to 337 g) from carbohydrates daily.

Fat and Cholesterol

Fat is a major source of energy for the body and helps in the absorption of fat-soluble vitamins and carotenoids. Neither an AI nor RDA was set for total fat, because there is insufficient data to determine a defined level of fat intake at which risk of inadequacy or prevention of chronic disease occurs.[1] Likewise, a UL was not set for total fat, because there is no defined intake level of fat at which an adverse effect occurs.[1] However, the AMDR for total fat was set at 30 to 40% of energy for children aged 1 to 3 years and 25 to 35% of energy for children and adolescents age 4 to 18 years (Table 16.3).[1] In the 2005 Dietary Guidelines for Americans, the level for total fat intake is between 30 to 35% of energy for children age 2 to 3 years of, and between 25 to 35% of energy for children and adolescents age 4 to 18 years of, with most fats coming from sources of polyunsaturated and monounsaturated fatty acids, such as fish, nuts, and vegetable oils.[14] The levels of total fat intake for children and adolescents found in the 2005 Dietary Guidelines for Americans are recommended by the American Heart Association and the American Academy of Pediatrics.[15,16]

For saturated fatty acids, neither an AI nor RDA was set because they have no known role in preventing chronic diseases and because they are synthesized by the body to provide adequate levels needed for their physiological and structural functions.[1] A UL was not set, because any incremental increase in saturated fatty acid intake increases risk of coronary heart disease.[1] The Institute of Medicine recommends that intake of saturated fatty acids be as low as possible while consuming a nutritionally adequate diet.[1] A key recommendation from the 2005 Dietary Guidelines for Americans is that less than 10% of energy come from saturated fatty acids.[14] The American Heart Association and the American Academy of Pediatrics recommend diets low in saturated fats for children and adolescents.[15,16]

Linoleic acid serves as a precursor to eicosanoids; it is the only $n-6$ polyunsaturated fatty acid that is an essential fatty acid.[1] $n-3$ Polyunsaturated fatty acids (α-linolenic acid) play an important role as structural membrane lipids, especially in nerve tissue and the retina, and are precursors to eicosanoids.[1] AIs and AMDRs are found in Table 16.2 and Table 16.3, respectively, for linoleic acid and α-linolenic acid for children and adolescents. There was insufficient evidence to set a UL for $n-6$ polyunsaturated fatty acids or $n-3$ polyunsaturated fatty acids.[1]

No AI or RDA was set for *trans* fatty acids because they are not essential and provide no known benefit to human health.[1] A UL was not set, because any incremental increase in intake of *trans* fatty acids increases risk of coronary heart disease. The Institute of Medicine and the 2005 Dietary Guidelines for Americans recommend that intake of *trans* fatty acids be as low as possible while consuming a nutritionally adequate diet.[1,14] The American Heart Association and the American Academy of Pediatrics recommend diets low in *trans* fatty acids for children and adolescents.[15,16] Based on data collected in 1994 through 1996, approximately 80% of *trans* fat in the diet is provided by processed foods and oils, and 20% occurs naturally in food from animal sources; however, *trans* fat content of certain processed foods has changed and is likely to continue to change as the industry reformulates products.[14]

Although cholesterol plays an important role in steroid hormone and bile acid biosynthesis and is an integral component of cell membranes, there is no evidence for a biological requirement for dietary cholesterol because all tissues are capable of synthesizing sufficient amounts of cholesterol. Thus, neither an AI nor a RDA was set for dietary cholesterol.[1] An UL was not set, because any incremental increase in intake of dietary cholesterol increases risk of coronary heart disease.[1] The Institute of Medicine recommends that intake of dietary cholesterol be as low as possible while consuming a nutritionally adequate diet.[1] A key recommendation from the 2005 Dietary Guidelines for Americans is to consume less than 300 mg/day of cholesterol.[14]

Dietary recommendations for children and adolescents by the American Heart Association and the American Academy of Pediatrics include a focus on ensuring adequate intakes of omega-3 fatty acids by consuming two servings of fish per week.[15–17] Along with the Food and Drug Administration, they advocate consumption of a wide variety of fish and shellfish and stress that seafood is an important part of a healthy diet. However, young children, women who may become pregnant or are already pregnant, and nursing mothers should avoid shark, swordfish, king mackerel, and tilefish due to high levels of mercury. Commonly eaten varieties of fish that are low in mercury include shrimp, canned light tuna, salmon, pollack, and catfish.[15,16]

Fat yields 9 kcal/g. Dietary sources of fat include oils, margarine, butter, fried foods, egg yolks, mayonnaise, salad dressings, ice cream, hard cheese, cream cheese, nuts, fatty meats, chips, and doughnuts. To keep saturated fat intake low, limit intake of animal fats (e.g., full-fat dairy products such as cheese, milk, butter, and ice cream; fatty meat, bacon, sausage, and poultry skin and fat). To keep *trans* fat intake low, limit intake of foods made with partially hydrogenated vegetable oils. To keep cholesterol intake low, limit egg yolks and organ meats especially, as well as meat, shellfish, and poultry, and dairy products that contain fat. Table 16.9 provides the total fat, saturated fat, and cholesterol content of various foods. Information regarding the safety of low-fat diets for children is provided later in this chapter.

FIBER

Because a variety of definitions of dietary fiber existed worldwide, the Institute of Medicine convened a special panel to develop a proposed definition of fiber.[10] Based on the panel's deliberations, along with consideration of public comments and subsequent modifications, the following definitions were developed[1]:

- *Dietary fiber* consists of nondigestible carbohydrates and lignin that are intrinsic and intact in plants.
- *Functional fiber* consists of isolated, nondigestible carbohydrates that have beneficial physiological effects in humans.
- *Total fiber* is the sum of dietary fiber and functional fiber.[1]

The different properties of fibers result in different physiological effects.[1] For example, viscous fibers may delay gastric emptying; this results in a sensation of fullness, which may contribute to weight control. In addition, delayed gastric emptying may reduce postprandial blood glucose concentrations and potentially have a beneficial effect on insulin sensitivity. Viscous fibers may reduce blood cholesterol concentrations by interfering with the absorption of dietary fat and cholesterol, as well

TABLE 16.9
Total Fat, Saturated Fat, and Cholesterol Content of Various Foods

Food	Amount	Total Fat (g)	Saturated Fat (g)	Cholesterol (mg)	Kcal
Almonds, dry roasted	1 oz (~22 nuts)	15.0	1.1	0	169
Bacon, cured, broiled/pan fried	3 med. slices	9.4	3.3	16	109
Bread, white	0.88 oz slice	0.9	0.1	<1	67
Butter	1 T	11.5	7.2	31	102
Cheese, American processed	1 oz	8.9	5.6	27	106
Cheese, cheddar	1 oz	9.4	6.0	30	114
Chicken breast with skin, roasted	½ breast (3.5 oz)	7.6	2.1	82	193
Chicken breast without skin, roasted	½ breast (3 oz)	3.1	0.9	73	142
Coconut, dried, sweetened, flaked, packaged	1 oz	9.1	8.1	0	134
Corn oil	1 T	13.6	1.7	0	120
Cottonseed oil	1 T	13.6	3.5	0	120
Egg (chicken), boiled, hard/soft	1 large	5.3	1.6	212	78
Egg (chicken), white, raw	1 large	0.0	0.0	0	17
Egg (chicken), yolk, raw	1 large	5.2	1.6	218	61
Finfish, flounder/sole, cooked by dry heat	3 oz	1.3	0.3	58	99
Ground beef, 25% fat, patty, broiled	3 oz patty	15.9	6.1	76	236
Ground beef, 5% fat, patty, broiled	3 oz patty	5.6	2.4	65	145
Ice cream, vanilla, regular (10% fat)	½ c	7.9	4.9	32	145
Lard (pork fat), raw	1 T	12.8	5.0	12	115
Margarine, corn, stick	1 t	3.8	0.7	0	34
Margarine, liquid	1 T	11.4	1.9	0	102
Milk (cow), whole, 3.3 % fat	8 fl oz	8.1	5.1	34	149
Milk (cow), reduced fat, 2% fat	8 fl oz	4.7	2.9	20	122
Milk (cow), low fat, 1% fat	8 fl oz	2.6	1.6	10	102
Milk (cow), nonfat	8 fl oz	0.4	0.3	5	86
Olive oil	1 T	13.5	1.8	0	119
Peanut butter, chunk style/crunchy	2 T	16.0	3.1	0	188
Peanuts, dry roasted	1 oz (~28 nuts)	14.1	2.0	0	166
Pecans, dried	1 oz (20 halves)	20.4	1.8	0	196
Pork, tenderloin, lean, roasted	3 oz	4.1	1.4	67	139
Safflower oil, >70% linoleic acid	1 T	13.6	0.8	0	120
Shrimp, cooked by moist heat	3 oz (15 ½ large)	0.9	0.2	166	84
Soy oil	1 T	13.6	2.0	0	120
Tuna, light, canned in oil, drained	3 oz	7.0	1.3	15	168
Tuna, light, canned in water, drained	3 oz	0.7	0.2	26	99
Turkey, breast with skin, roasted	3 oz	2.7	0.7	77	130
Yogurt, frozen, soft serve, vanilla	½ c	4.0	2.5	1	114

as with the enterohepatic recirculation of cholesterol and bile acids. Fecal bulk, laxation, and constipation are improved by consumption of dietary fiber and certain functional fibers, especially those that are poorly fermented. Normal laxation can be a problem for many children. The AIs for total fiber in foods for children and adolescents are found in Table 16.2; ULs were not set for dietary fiber or functional fiber due to insufficient evidence.[1]

The American Health Foundation recommends that children age 2 years and older consume a minimal amount of fiber equal to their age plus 5 g/day, and a maximum amount of age plus 10 g/day, to achieve intakes of a maximum of 35 g/day after the age of 20 years.[18,19] These recommendations were endorsed at a conference held in May 1994 about dietary fiber in childhood.[20] This range is thought to be safe, reasonable, and practical.[21,22] The "age plus 5" recommendation results in a gradual increase in fiber intake over time with a 3-year-old eating 8 g/day and an 18-year-old eating 23 g/day.

Fiber intake should be increased gradually through consumption of a variety of fruits, vegetables, legumes, cereals, and other whole-grain products such as breads and crackers. Fiber supplements for children are not recommended as a means of meeting dietary fiber goals.[18] Increased intakes of dietary fiber should be accompanied by increased intakes of water, because dietary fiber increases water retention in the colon, which leads to bulkier and softer stools.[18] For most children and adolescents, dietary fiber goals can be met if the daily diet includes two servings of vegetables, three servings of fruits, two slices of whole wheat bread, and a serving of breakfast cereal containing three or more grams of fiber.[19] Table 16.10 provides a list of foods containing fiber that most U.S. children and adolescents will eat.

High-fiber diets do have the potential for reduced energy density, reduced kcal intake, and poor growth, especially in very young children. Furthermore, high-fiber diets may reduce the bioavailability of minerals such as iron, calcium, and zinc. However, the potential health benefits of a moderate increase in dietary fiber intake in childhood are thought to outweigh the potential risks significantly, especially in highly industrialized countries such as the United States.[18]

WATER

Water is the largest single constituent of the human body; it is essential for cellular homeostatis and life.[13] A low intake of total water (from drinking water, water in beverages, and food) has been associated with some chronic diseases, but this evidence is

---

TABLE 16.10
Fiber Content of Foods that Most U.S. Children and Adolescents Will Eat[a]

Food	Serving Size	Approximate Grams of Dietary Fiber
Baked Beans	1 c	13
Chili with beans	1 c	7
Refried beans	4 oz	6
Brown rice	1 c	4
Peanuts (dry roasted)	2 oz	4
Strawberries	1 c	4
Whole-wheat bread	2 slices	4
Potato, baked, with skin	1 medium	3.5
Apple	1 medium	3
Banana	1 large	3
Carrot (raw)	1 medium	3
Corn	½ c	3
Kiwi	1 large	3
Raisins	1/3 c	3
Whole-grain crackers	½ oz	2–3
Cereal	1 c	2–3[a]
Applesauce	½ c	2
Broccoli	½ c	2
Orange	1 medium	2
Peanut butter	2 tbsp	2

[a] Dietary fiber content of cereal varies widely. Best fiber choice for children has 3 + g/cup.

insufficient to establish water intake recommendations in order to reduce the risk of chronic diseases; thus, an AI for total water (see Table 16.2) was set to prevent deleterious (mainly acute) effects of dehydration, which include metabolic and functional abnormalities.[13]

About 80% of total water intake comes from drinking water and other beverages.[13] Although diuretic effects have been shown in some studies from consumption of caffeinated beverages, available information indicates that this may be transient in nature and thus, such beverages do contribute to total water intake similar to that contributed by noncaffeinated beverages.[13] Deficits in body water can occur over the course of a few hours due to decreased intake or increased water losses from physical activity and environmental factors (e.g., heat, exposure). However, on a daily basis, fluid intake, which is driven by a combination of thirst and consumption of beverages at meals, allows for hydration status and normal levels of total body water to be maintained.[13]

An UL was not set for water, because healthy individuals have considerable ability to excrete excess water and thus maintain water balance.[13] However, there have been reports of acute water toxicity due to rapid consumption of large quantities of fluids that greatly exceeded the kidney's maximal excretion rate of about 0.7 to 1.0 L/h.[13]

SELECTED VITAMINS AND MINERALS

VITAMIN D

Throughout the world, the major source of vitamin D for humans is the exposure of the skin to sunlight; vitamin D that is synthesized in the skin during the summer and fall months can be stored in the body's fat for use in the winter, which minimizes requirements for vitamin D. In nature, very few foods contain vitamin D; thus, children and adolescents who live in far northern latitudes (e.g., northern Canada and Alaska) may need vitamin D supplements. Food sources of vitamin D include some fish liver oils, eggs from hens that have been fed vitamin D, the liver and fat from aquatic mammals such as seals and polar bears, and the flesh of fatty fish. Foods fortified with vitamin D include milk products and other foods such as margarine and breakfast cereals; the majority of human intake of vitamin D is from fortified foods. Fortified milk is supposed to contain 10 μg (400 IU) per quart regardless of the fat content of milk; however, several recent surveys have indicated that many milk samples contained less than 8 μg per quart. Although it is well recognized that vitamin D deficiency causes abnormalities in calcium and bone metabolism, it is premature to suggest that cancer risk is increased by vitamin D deficiency. The AIs for vitamin D for children and adolescents (see Table 16.2) were set to cover the needs of almost all children and adolescents regardless of exposure to sunlight. Currently, there is no scientific evidence that demonstrates an increased requirement for vitamin D during puberty even though metabolism of vitamin D increases during puberty to enhance intestinal calcium absorption to provide adequate calcium for the rapidly growing skeleton. [3]

Calcium

Over 99% of total body calcium is found in teeth and bones. Approximately 45% of adult skeletal mass is accounted for by skeletal growth during adolescence; thus, achieving and maintaining adequate calcium intake during adolescence is necessary for the development of a maximal peak bone mass, which may help reduce the risk of osteoporosis later in adulthood.

The calcium AIs for adolescents are higher than for children because from age 9 through 18 years (see Table 16.2), calcium retention increases to a peak and then declines. However, the calcium AIs remain the same for adolescents from age 9 to 18 years, because calcium absorption efficiency decreases. Thus, during this developmental period, measures of sexual maturity are better predictors of calcium retention than chronological age.[3]

Major food sources of calcium include milk, yogurt, cheese, and green leafy vegetables. Calcium-fortified orange juice is also an excellent source of calcium, as is tofu. Table 16.11 contains the approximate calcium content for one serving of various common foods. Vitamin D (discussed previously in this chapter) is needed for the body to absorb calcium.

The calcium content of food is generally of greater importance than bioavailability when evaluating food sources of calcium. The efficiency of calcium absorption is fairly similar from most foods, including milk and milk products and grains, which are major food sources of calcium in North American diets. Calcium may be poorly absorbed from foods such as spinach, beans, sweet potatoes, and rhubarb which are rich in oxalic acid, and from unleavened bread, raw beans, seeds, nuts, and grains, and soy isolates, which are rich in phytic acid. Calcium absorption is relatively high from soybeans, although they contain large amounts of phytic acid. Compared to calcium absorption from milk, calcium absorption from spinach is about 1/10, and from dried beans is about half.[3]

Children and adolescents (and adults) with lactose intolerance may develop symptoms of diarrhea and bloating after ingesting lactose; however, the likelihood of developing the symptoms depends on the amount of residual lactase activity, the amount of lactose consumed, and the composition of the meal.[23] People who generally are lactose digesters include Northern Europeans, Finns, Hungarians, probably Mongols, the Fulani and Tussi tribes of Africa, and the Punjabis of India; the remainder of the world's population are lactose nondigesters.[24] However, as digesters intermix reproductively with nondigesters, the rate of lactose malabsorption falls. In general, evidence for lactose malabsorption as a clinical problem is not manifest until after

TABLE 16.11
Approximate Calcium Content for One Serving of Various Common Foods[a]

Food	Serving Size	Approximate Calcium Content (mg)
Milk (whole, 1%, 2%, or buttermilk)	8 oz	300
Yogurt	8 oz	300
Cheese (swiss)	1 oz	272
Cheese (cheddar)	1 oz	204
Cheese (mozzarella, part nonfat)	1 oz	183
Cheese (American processed)	1 oz	175
Calcium-fortified orange juice	8 oz	350
Canned salmon (with bones)	3 oz	181
Cooked greens (collards)	1 c	226
Pudding	½ c	150
Spinach (cooked)	1 c	245
Frozen yogurt (vanilla, soft serve)	½ c	103
Ice cream (vanilla, 10% fat)	½ c	92
Cooked greens (mustard, kale)	1 c	100
Cottage cheese	1 c	140
Spinach (raw)	1 c	30
Orange	1 medium	52
Beans, canned (baked)	½ c	60
Sweet potatoes (mashed)	1 c	77
Broccoli (cooked)	1 med. stalk	83

5 to 7 years of age, although this age can vary. Individuals with lactose intolerance can increase their tolerance by adding small amounts of lactose-containing foods to their diet.[24] Fermented dairy products, such as yogurt and hard cheese, may be tolerated better than milk; in addition, lactose-free and low-lactose milks are available, and calcium may be obtained by consuming calcium-supplemented foods (such as calcium-fortified soy milk and calcium-fortified juice) and nondairy foods (such as broccoli, collards, and baked beans).[25] Many children with lactose intolerance can drink small amounts of milk without discomfort, especially when they consume other foods with it.[25] Although lactose intolerance may influence intake, lactose-intolerant individuals absorb calcium normally from milk; thus, there is no evidence to suggest that it influences the calcium requirement.[3]

Folate

Folate is important during periods of increased cell replication and growth due to its role in DNA synthesis and the formation of healthy red blood cells; thus, the RDAs for folate are 1.5 times greater for children age 9 to 13 years than for children age 4 to 8 years (see Table 16.2).[4] There is strong evidence that the risk of having a fetus with a neural tube defect decreases with increased intake of folate during the periconceptional period. Therefore, it is recommended that all females capable of becoming pregnant take 400 μg of synthetic folic acid daily, from fortified foods or supplements, in addition to consuming food folate from a varied diet. Folate fortification became mandatory for enriched grain products in the United States as of January 1998. Besides fortified grains and cereals, other food sources of folate include leafy green vegetables, orange juice, liver, cantaloupe, yeast, and seeds.[4]

Iron

According to the American Academy of Pediatrics,[26] iron deficiency is the most common nutritional deficiency in the United States. Children aged 1 to 2 years are the most susceptible to iron deficiency due to increased iron needs related to rapid growth during the first 2 years of life and a relatively low iron content in most infant diets when iron is not added by supplementation or fortification. Children aged 3 to 11 years are at less risk for iron deficiency until the rapid growth of puberty. Preadolescent school-age children who consume a strict vegetarian diet are at greater risk for iron deficiency anemia. Adolescent boys are at risk for iron deficiency anemia during their peak growth period when iron stores may not meet the demand of rapid growth;

however, the iron deficiency anemia generally corrects itself after the growth spurt. Adolescent girls are at greater risk for iron deficiency anemia due to blood losses during menstruation. A major consequence of iron deficiency is that significant iron deficiency adversely affects child development and behavior. Furthermore, iron deficiency leads to enhanced lead absorption, and childhood lead poisoning is a well-documented cause of neurological and developmental deficits. These consequences, along with evidence that dietary intake during infancy is a strong determinant of iron status for older infants and younger children, emphasize the importance of prevention. Significant improvements have been made in the iron nutritional status of infants and young children in the United States during the past 2 decades, perhaps because during this same time frame, several changes were made in infant feeding patterns.[26] These changes included increased dietary iron content or iron bioavailability, increased incidence of breastfeeding, increased use of iron-fortified formula, and reduced use of whole milk and low-iron formula during the first year of life.[26]

Dietary iron is classified as "heme" or "non-heme" iron. Heme iron is found in foods from animals such as meat, fish, and poultry. Non-heme iron is provided by plants; good sources include dark-green leafy vegetables, tofu, lentils, white beans, dried fruits, and iron-fortified breads and cereals. On average, healthy people absorb about 5 to 10% of the iron consumed, and people who are iron deficient absorb about 10 to 20%. Heme iron is more easily absorbed than non-heme iron. About 20% of heme iron consumed is absorbed regardless of how it is prepared and served; however, the absorption rate of non-heme iron can be increased by eating foods with non-heme iron with either meat, foods rich in vitamin C, or foods that contain some heme iron at the same meal. Non-heme iron absorption can be hindered by as much as 50% when tannins, phytates, and calcium (which are found in foods such as tea, bran, and milk, respectively) are eaten at the same meal.

The RDAs for iron for children and adolescents are included in Table 16.2.[9] Because the amount of iron available in the American diet is estimated to be about 5 to 7 mg/1000 kcal, it may be difficult for adolescent girls to obtain 15 mg of iron from dietary sources alone if their caloric intake is between 2000 and 2400 kcal/day. Groups of adolescents who are at special risk of iron deficiency include (1) older adolescent girls due to their increased iron need and their low dietary intake, (2) pregnant adolescents, and (3) female athletes such as runners who may lose iron through occult gastrointestinal bleeding.

The Committee on the Prevention, Detection, and Management of Iron Deficiency Anemia Among U.S. Children and Women of Childbearing Age was established under the Food and Nutrition Board of the Institute of Medicine; its recommended guidelines were published in 1993.[27] They concluded that iron enrichment and fortification of the U.S. food supply should remain at current levels rather than increasing or decreasing the levels. Furthermore, they recommended that dietary sources of iron be consumed instead of supplemental sources when possible. Iron supplements should be kept out of reach of children, because iron is a very common cause of poisoning in children.[27]

Zinc

Zinc is needed for protein synthesis, wound healing, and sexual maturation; thus, zinc is especially important during adolescence due to the rapid rate of growth and sexual maturation. (See Table 16.2 for the RDAs for zinc for children and adolescents.[9]) Adolescents undergoing rapid growth are at risk for inadequate zinc levels, and should be encouraged to include zinc-rich foods in their daily diet. Foods high in zinc include red meats, certain seafood, and whole grains; many breakfast cereals are fortified with zinc. The bioavailability of zinc in foods varies widely. Zinc from whole grain products is less available than zinc from meat, liver, eggs, and seafood (especially oysters). Furthermore, consumption of phytate-rich foods limits absorption and maintenance of zinc balance.[9]

Potassium

Potassium is required for normal cellular function. The level of potassium from dietary intake according to the AI (see Table 16.2) should maintain lower blood pressure levels, reduce adverse effects of sodium chloride intake on blood pressure, decrease the risk of recurrent kidney stones, and possibly decrease bone loss.[13] Currently, dietary intake of potassium by all groups in the United States and Canada is much lower than the AI.[13] African Americans would especially benefit from an increased intake of potassium due to their relatively low intake of potassium and a high prevalence of elevated blood pressure and salt sensitivity.[13]

Good sources of potassium are fruits and vegetables. Relatively high amounts of potassium are found in spinach, cantaloupe, dry roasted almonds, Brussels sprouts, mushrooms, bananas, oranges, grapefruit, and potatoes. An UL was not set, because potassium intake from foods above the AI poses no potential for increased risk as excess potassium is readily excreted in the urine in the generally healthy population with normal kidney function.[13]

FOOD GUIDE PYRAMID

In April 2005, USDA released *MyPyramid*[28] as the new food guidance system to replace the original Food Guide Pyramid released in 1992.[29] *MyPyramid* translates the principles of the 2005 Dietary Guidelines for Americans[14] and other nutritional

standards to help consumers make healthier food and physical activity choices. The *MyPyramid* symbol was designed to be simple and has no foods pictured on it. Each person has a pyramid that is right for them based on their age, sex, and physical activity level; consumers are encouraged to find out what they need to eat each day and their physical activity level at MyPyramid.gov.[28] The *MyPyramid* Food Guidance System includes a new motivational symbol and slogan, "Steps to a Healthier You," clear and concise nutrition messages for educational materials like posters and brochures that communicate the new food guidance recommendations in ways consumers can more easily understand and put into practice, and interactive activities on the internet at www.mypyramid.gov to help consumers personalize their diet and get more information on topics of interest to them.[28] *MyPyramid* is appropriate for children aged 2 years and older.[28]

MyPyramid includes food intake patterns that identify what and how much food an individual should eat for health based on the individual's age, sex, and activity level. As explained in Table 16.12, there are 12 different calorie levels in increments of 200 from 1000 to 3200 calories. There are food intake pattern calorie levels that identify the calorie level assigned to an individual in the *MyPyramid* plan, based on the individual's sex, age, and activity level. Table 14.13 can be used to help assign children and adolescents to the food intake pattern at a particular energy expenditure. Table 14.4 gives sussgested amounts of

TABLE 16.12
Daily *MyPyramid* Food Intake Patterns

Calorie Level [a]	Fruit Group[b] (Cups)	Vegetable Group[c] (Cups)	Grains Group[d] (oz-eq)	Meats and Beans Group[e] (oz-eq)	Milk Group[f] (Cups)	Oil [g] (tsp)	Discretionary Calorie Allowance[h]
1000	1	1	3	2	2	3	165
1200	1	1.5	4	3	2	4	171
1400	1.5	1.5	5	4	2	4	171
1600	1.5	2	5	5	3	5	132
1800	1.5	2.5	6	5	3	5	195
2000	2	2.5	6	5.5	3	6	267
2200	2	3	7	6	3	6	290
2400	2	3	8	6.5	3	7	362
2600	2	3.5	9	6.5	3	8	410
2800	2.5	3.5	10	7	3	8	426
3000	2.5	4	10	7	3	10	512
3200	2.5	4	10	7	3	11	648

The table provides suggested amounts of food to consume each day from each of the basic food groups, subgroups, and oils to meet recommended nutrient intakes at 12 different calorie levels. Nutrient and energy contributions from each group are calculated according to the nutrient-dense forms of foods in each group (e.g., lean meats and fat-free milk). In addition, the table shows the discretionary calorie allowance that can be accommodated within each calorie level.

[a] **Calorie Levels** are set across a wide range to accommodate the needs of different individuals. Table 16.13 "Estimated Daily Calorie Needs" can be used to help assign children and adolescents to the food-intake pattern at a particular calorie level.

[b] The **Fruit Group** includes all fresh, frozen, canned, and dried fruits and fruit juices. In general, 1 cup of fruit, 1 cup of 100% fruit juice, or ½ cup of dried fruit can be considered as 1 cup from the fruit group.

[c] The **Vegetable Group** includes all fresh, frozen, canned, and dried vegetables and vegetable juices. In general, 1 cup of raw or cooked vegetables or vegetable juice, or 2 cups of raw leafy greens can be considered as 1 cup from the vegetable group. Table 16.14 provides recommended amounts from each of the vegetable subgroups per week.

[d] The **Grains Group** includes all foods made from wheat, rice, oats, cornmeal, or barley, such as bread, pasta, oatmeal, breakfast cereals, tortillas, and grits. In general, 1 slice of bread, 1 cup of ready-to-eat cereal, or ½ cup of cooked rice, pasta, or cooked cereal can be considered as 1 ounce equivalent from the grains groups. *At least half of all grains consumed should be whole grains.*

[e] For the **Meats and Beans Group**, in general, 1 ounce of lean meat, poultry, or fish, 1 egg, 1 tablespoon peanut butter, ¼ cup cooked dry beans, or ½ ounce of nuts or seeds can be considered a 1 ounce equivalent from the meat and beans group.

[f] The **Milk Group** includes all fluid milk products and foods made from milk that retain their calcium content, such as yogurt and cheese. Foods made from milk that have little to no calcium (e.g., cream cheese, cream, butter) are not part of the milk group. Most milk group choices should be fat-free or low-fat. In general, 1 cup of milk or yogurt, 1.5 ounces of natural cheese, or 2 ounces of processed cheese can be considered as 1 cup from the milk group.

[g] **Oils** include fats from different plants and from fish that are liquid at room temperature, such as canola, corn, olive, soybean, and sunflower oil. Some foods are naturally high in oils, like nuts, olives, some fish, and avocados. Foods that are mainly oil include mayonnaise, some salad dressings, and soft margarine.

[h] The **Discretionary Calorie Allowance** is the remaining amount of calories in a food intake pattern after accounting for the calories needed for all food groups — using forms of foods that are fat-free or low-fat and with no added sugars.

[a] Calorie levels are based on the Estimated Energy Requirements (EER) and activity levels from the Institute of Medicine Dietary Reference Intakes Macronutrients Report, 2002.

Sedentary = less than 30 min a day of moderate physical activity in addition to daily activities.

Moderately Active = at least 30 min up to 60 min a day of moderate physical activity in addition to daily activities.

Active = 60 or more min a day of moderate physical activity in addition to daily activities.

Note: MyPyramid assigns individuals to a calorie level based on their sex, age, and activity level. The chart above identifies the calorie levels for children and adolescents by sex, age, and activity level (sedentary, moderately active, active).

Source: Adapted from: USDA, Center for Nutrition Policy and Promotion, *MyPyramid Food Intake Pattern Calorie Levels*, Washington, DC, April, 2005, CNPP-XX. Available at http://www.mypyramid.gov/downloads/MyPyramid_Calorie_Levels.pdf

group on the graphic encourage schoolchildren to make healthy eating choices and be more physically active.[31] The key messages of *MyPyramid for Kids* are[32]:

- Be physically active every day — the child climbing the steps reminds children that physical activity should be done every day.
- Choose healthier foods from each group — every food group has foods that children should eat more often than others.
- Eat more of some food groups than others — the different-sized stripes suggest how much food children should choose from each group.
- Eat foods from every food group every day — the different colors of the pyramid represent the five different food groups plus oils.
- Make the right choices for you — myPyramid.gov gives everyone in the family personal ideas on how to eat better and exercise more.
- Take it one step at a time — start with one new, good thing a day, and continue to add another new one every day.[32]

The messages of *MyPyramid for Kids* are the same as the messages of *MyPyramid*, but are written in simpler language for children.[31] The graphic, slogan, and messages were developed for and tested with children.[31]

Numerous materials are available from USDA about *MyPyramid for Kids* for children, parents, and families.[30] An interactive computer game called "MyPyramid Blast Off" is available by CD-ROM (or via the internet at http://mypyramid.gov/kids/kids_game.html_game.html). In the game, children can reach Planet Power by fueling their rocket with food and physical activity; "fuel" tanks for each food group help children keep track of how their choices fit into *MyPyramid*. A two-sided poster
FIGURE 16.1 *MyPyramid* for Kids (simplified graphic). Available at: http://teamnutrition.usda.gov/resources/mpk_poster.pdf

has one side for younger children that features a simplified *MyPyramid for Kids* graphic (see Figure 16.1), and the other side for advanced elementary children that features both the graphic and healthy eating and physical activity messages (see Figure 16.2). A mini-poster for families has the *MyPyramid for Kids* graphic on one side and tips to "eat right" and "exercise" on the other side; Figure 16.3 illustrates the side of this mini-poster with tips for families (available at http://teamnutrition.usda.gov/resources/mpk_tips.pdf). Classroom materials for elementary school educators are available from USDA.[33] Lesson plans integrate nutrition with science, math, health, and language arts; physical activity is emphasized as well. Lessons communicate nutrition concepts through age-appropriate and fun activities, contain handouts to be duplicated, may be taught with minimal preparation, include a link with the school lunch program, and provide an activity to send home to parents.[33]

The USDA food guide (i.e., *MyPyramid*) is one example of an eating pattern that exemplifies the 2005 Dietary Guidelines for Americans which are for Americans over 2 years of age.[14] Another example of an eating pattern that exemplifies the 2005 Dietary Guidelines for Americans is the DASH (Dietary Approaches to Stop Hypertension) eating plan,[14] which was originally developed to study the effects of an eating pattern on the prevention and treatment of hypertension in adults.[34,35] According to the American Heart Association and the American Academy of Pediatrics, although there are no comparable clinical trial data in children, there is no reason to suspect that the DASH diet would not be safe for older children and adolescents.[15,16]

WHAT ARE CHILDREN AND ADOLESCENTS EATING?

1989 TO 1991 CONTINUING SURVEY OF FOOD INTAKES OF INDIVIDUALS (CSFII), UNITED STATES

The 1989 to 1991 CSFII sample consisted of individuals residing in households in the 48 contiguous States (US); a separate survey was conducted in each of the three years and combined to create one large nationally representative data set. Each year, the survey included two independent samples, basic (all income) and low income. Intake information was requested for all household members; for each individual, this included three consecutive days of dietary data, which consisted of one 24-hour recall and a 2-day food record. A knowledgeable adult (usually the primary meal planner/preparer) reported the food intakes of household members younger than 12 years.[36]

Data from the 1989 to 1991 CSFII have been analyzed in numerous ways to provide insight into what children and adolescents are eating. For example, data were analyzed to determine dietary sources of nutrients among 4008 children aged 2 to 18 years.[37] Fortified foods (e.g., ready-to-eat cereals) were influential contributors of many vitamins and minerals; furthermore,

MyPyramid For Kids

Eat Right. Exercise. Have Fun.

MyPyramid.gov

Grains	Vegetables	Fruits	Milk	Meat & Beans
Make half your grains whole	Vary your veggies	Focus on fruits	Get your calcium-rich foods	Go lean with protein
Start smart with breakfast. Look for whole-grain cereals. Just because bread is brown doesn't mean it's whole-grain. Search the ingredients list to make sure the first word is "whole" (like "whole wheat").	Color your plate with all kinds of great-tasting veggies. What's green and orange and tastes good? Veggies! Go dark green with broccoli and spinach, or try orange ones like carrots and sweet potatoes.	Fruits are nature's treats — sweet and delicious. Go easy on juice and make sure it's 100%.	Move to the milk group to get your calcium. Calcium builds strong bones. Look at the carton or container to make sure your milk, yogurt, or cheese is lowfat or fat-free.	Eat lean or lowfat meat, chicken, turkey, and fish. Ask for it baked, broiled, or grilled – not fried. It's nutty, but true. Nuts, seeds, peas, and beans are all great sources of protein, too.

For an 1,800-calorie diet, you need the amounts below from each food group. To find the amounts that are right for you, go to MyPyramid.gov.

Eat 6 oz. every day; at least half should be whole	Eat 2½ cups every day	Eat 1½ cups every day	Get 3 cups every day; for kids ages 2 to 8, it's 2 cups	Eat 5 oz. every day

Oils Oils are not a food group, but you need some for good health. Get your oils from fish, nuts, and liquid oils such as corn oil, soybean oil, and canola oil.

Find your balance between food and fun
- Move more. Aim for at least 60 minutes everyday, or most days.
- Walk, dance, bike, rollerblade – it all counts. How great is that!

Fats and sugars — know your limits
- Get your fat facts and sugar smarts from the Nutrition Facts label.
- Limit solid fats as well as foods that contain them.
- Choose food and beverages low in added sugars and other caloric sweeteners.

FIGURE 16.2 *MyPyramid* for Kids (graphic with healthy eating and physical activity messages). Available at: http://teamnutrition.usda.gov/resources/mpk_poster2.pdf

low nutrient-dense foods were major contributors of energy, (fats, and carbohydrates,) and these compromise the intakes of more nutrient-dense foods, and may impede compliance with current dietary guidance.[37]

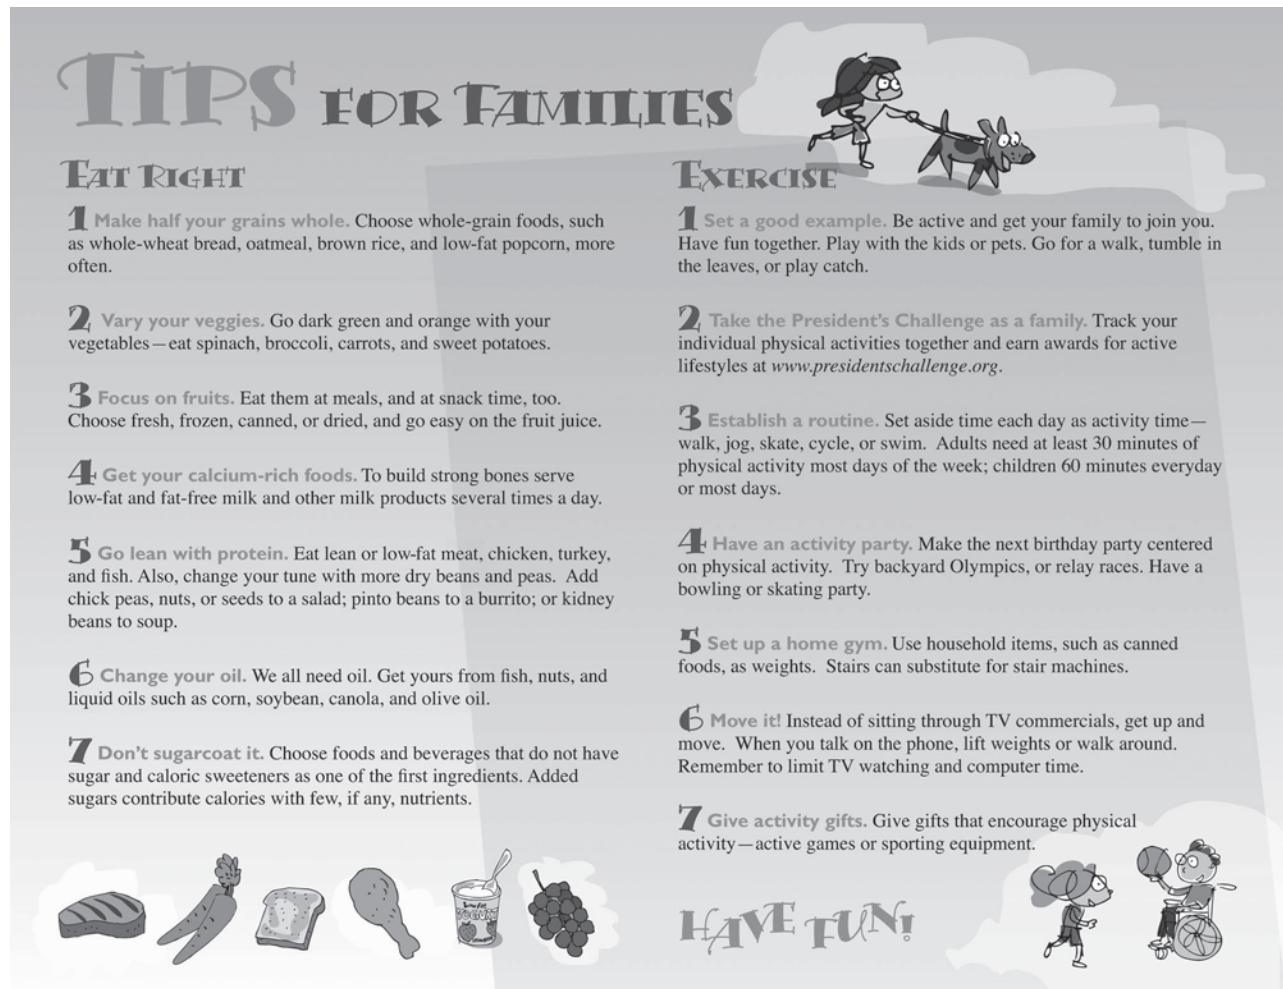
Data from the 1989 to 1991 CSFII were analyzed to determine fruit and vegetable consumption among 3148 children aged 2 to 18 years.[38] Only 1 in 5 children consumed five or more servings of fruits and vegetables per day. Intakes of all fruits and of


FIGURE 16.3 Tips for Families from *MyPyramid* for Kids. Available at: http://teamnutrition.usda.gov/resources/mpk_tips.pdf

dark green and deep yellow vegetables were very low. Furthermore, almost one-fourth of all vegetables consumed by children and adolescents were french fries.[38]

Data from the 1989 to 1991 CSFII were analyzed to determine what percentage of children aged 4 to 6 years (*n* = 603) and 7 to 10 years (*n* = 782) met the American Health Foundation's age plus 5 recommendation for fiber,[18,19] and what the leading contributors to total dietary fiber intake were.[39] Only 45% of 4- to 6-year-olds and 32% of 7- to 10-year-olds met the age plus 5 rule. Children who met the rule did so by consuming significantly more high- and low-fiber breads and cereals, fruits, vegetables, legumes, nuts, and seeds. Furthermore, children who met the rule had significantly higher energy-adjusted intakes of vitamins A and E, folate, magnesium, and iron compared to children with low fiber intakes who had significantly higher energy-adjusted intakes of fat and cholesterol. Surprisingly, low-fiber breads and cereals provided 21% and 19% of total dietary fiber for 4- to 6-year-olds and 7- to 10-year-olds, respectively, whereas high-fiber breads and cereals provided only 6% of total dietary fiber for both age groups. Conclusions from these results include that substituting high-fiber breads and cereals for low-fiber ones would increase children's fiber intakes and should be relatively easy to accomplish.[39]

1994 TO 1996 CSFII, UNITED STATES

The 1994 to 1996 CSFII sample consisted of individuals residing in households in the 50 states, and included an oversampling of the low-income population. Only selected household members were asked to provide intake information. For each individual, two nonconsecutive days of dietary data were requested using the 24-h recall method through in-person interviews.[36] Proxy interviews were conducted routinely for children under 6 years, and children 6 to 11 years were asked to describe their own food intake assisted by an adult household member (referred to as the assistant). The preferred proxy or assistant was the person responsible for preparing the child's meals.[40]

Data from the 1994 to 1996 CSFII were analyzed to determine whether carbonated soft drink consumption was associated with consumption of milk, fruit juice, and the nutrients concentrated in these beverages among 1810 children and adolescents aged 2 to 18 years.[41] Adolescents (13 to 18 years) were more likely to consume soft drinks than preschool-aged children (2 to

5 years) and school-aged children (6 to 12 years). Among preschool-aged children, school-aged children, and adolescents, 50, 36, and 18%, respectively, did *not* consume any soft drinks during the 2 days of dietary recall; furthermore, the majority of children in each age category were nonconsumers of diet soft drinks (95, 89, and 86%, respectively). White preschool-aged children and adolescents were more likely to consume soft drinks than black preschool-aged children and adolescents. Among adolescents, boys were more likely than girls to consume soft drinks. Among preschool-aged children and adolescents, those who resided in central city metropolitan statistical areas (within a metropolitan area containing the largest population) were more likely to consume soft drinks than those residing in noncentral city metropolitan statistical areas (within a metropolitan area not containing the largest population). No significant differences in soft drink consumption were found by poverty status or region of the country. In general, soft drink consumption was inversely associated with consumption of milk, fruit juice, and the nutrients concentrated in these beverages. For all age groups, energy intake was higher among those in the highest soft drink consumption category compared with nonconsumers. These results indicate that nutrition education messages for children and parents should encourage limited consumption of soft drinks.[41]

Data from the 1994 to 1996 CSFII were analyzed to characterize whole grain consumption among 4802 youth aged 2 to 18 years.[42] Average daily intake of whole grains ranged from 0.8 serving for preschool-aged children to 1.0 serving for adolescents. The major sources of whole grains were ready-to-eat cereals, corn and other chips, and yeast breads, accounting for 31, 22, and 18% of whole grain intake, respectively, among this group of youth. These low levels of intake indicate that interventions are needed to increase the intake of whole-grain foods among youth.[42]

Suitor and Gleason analyzed data from the 1994 to 1996 CSFII by using DRI-based methods to estimate the prevalence of inadequate usual intakes of nutrients by 2692 youth aged 6 to 18 years.[43] Nutrients identified as potential problems for sex/age groups of youth based on comparisons to EARs included vitamin A for teenage girls, vitamin E for all sex/age groups of youth, vitamin C for teenage girls, folate for preteen and teenage boys and girls, phosphorus for preteen and teenage girls, magnesium for teenage boys and for preteen and teenage girls, and zinc for teenage girls. In contrast, most youth had adequate intakes of iron, thiamin, riboflavin, niacin, vitamin B_6, and vitamin B_{12}.[43]

1994 TO 1996 AND 1998 CSFII

The Supplemental Children's Survey to the 1994 to 1996 CSFII (1998 CSFII) was conducted to add intake data from 5559 children age birth through 9 years to the intake data collected from 4253 children of the same age who participated in the 1994 to 1996 CSFII. The 1998 CSFII was designed to be combined with the 1994 to 1996 CSFII, thus, approaches to sample selection, data collection, data file preparation, and weighting were consistent.[44]

Data from the 1994 to 1996 and 1998 CSFII were analyzed to determine the nutritional consequences of flavored-milk consumption by 3888 youth aged 5 to 17 years.[45] Youth who consumed flavored milk had significantly higher total milk intake and lower soft drink and fruit drink intake but similar fruit juice intake compared with youth who were nonconsumers of flavored milk. In addition, youth who consumed flavored milk had higher calcium intakes but similar percentage of energy from total fat and added sugars compared with youth who were nonconsumers of flavored milk.[45]

Data from the 1994 to 1996 and 1998 CSFII were analyzed to determine associations between intakes of the primary food and beverage sources of added sugars and intakes of key nutrients and food pyramid groups among 3038 children and adolescents aged 6 to 17 years.[46] Consumption of sweetened dairy products was positively associated with calcium intakes; furthermore, the consumption of presweetened cereals had a positive impact on meeting recommendations for calcium, folate, and iron. In contrast, consumption of sugar-sweetened beverages, sugars and sweets, and sweetened grains had a negative impact on diet quality.[46]

Data from the 1994 to 1996 and 1998 CSFII were analyzed to quantify the impact of dairy foods on nutrient intakes among 17,959 people over age 2 years, including 8,605 children and adolescents less than 19 years.[47] Although analyses were conducted on the total sample as well as numerous age/sex subgroups, only data for the total sample were reported, because results were consistent for all age/sex groups. Higher intakes of total dairy and milk were associated with significant and often large increase in intakes of essential nutrients including calcium, folate, iron, magnesium, potassium, riboflavin, vitamin A, and zinc. Fat intake generally was not associated with total dairy intake, although fat did increase as cheese intake increased. Dietary cholesterol was lower as intakes of any dairy categories increased, although the opposite was true for saturated fat. Dairy foods contributed an average of 51% of dietary calcium, 19% of total fat, 32% of saturated fat, and 22% of cholesterol. These results reinforce the importance of dairy foods and milk as key calcium sources as well as "packages" of nutrients, and suggest that people who consume more dairy foods and milk also consume other more nutrient-rich foods. Results with saturated fat and cheese suggest the usefulness of continued modification of product composition and education to select lower fat versions.[47]

Data from the 1994 to 1996 and 1998 CSFII were analyzed to examine the dietary profile associated with fast food use among 17,370 people over age 2 years, including 8,550 youth less than 19 years.[48] Results indicated that fast food was consumed by 42% of youth on either of the 2 survey days. Youth with fast food consumption had a significantly lower intake of breads and cereals, dark green vegetables and other vegetables, noncitrus fruits and juices, milk, and legumes, but a higher intake of fried potato, chicken, meat mixture, and carbonated soft drinks. In terms of energy and nutrients, youth with fast food consumption had a significantly lower intake of protein, vitamin A, and β-carotene, and higher intake of total energy and fat compared with youth who did not consume fast food. Fast food consumption may contribute to higher energy and fat intake, and lower intake of healthful nutrients.[48]

TRENDS IN CONSUMPTION AMONG CHILDREN AND ADOLESCENTS

Data for children aged 6 to 11 years from the 1977 to 1978 Nationwide Food Consumption Survey ($n = 4107$), 1989 to 1991 CSFII ($n = 1,476$), and 1994 to 96 and 1998 CSFII ($n = 2,000$) were examined to monitor trends in dietary intake.[49] Intakes increased for total grain products, grain mixtures, crackers/popcorn/pretzels/corn chips, fried potatoes, noncitrus juices/nectars, low-fat milk, skim milk, cheese, candy, fruit drinks/fruitades, and soft drinks. Intakes decreased for yeast breads/rolls, corn/green peas/lima beans, green beans, whole milk and total milk, beef, pork, and eggs. Percentages of calories from fat decreased, partly due to increased carbohydrate intakes. Intakes of thiamin and iron increased, but vitamin B_{12} decreased. Despite these shifts in intake, guidance is needed to continue to encourage increased intakes of whole grains, dark-green and deep-yellow vegetables, fruits (both citrus and noncitrus, but emphasizing whole fruits instead of juices), legumes, lean meats and meat alternates, nonfat or low-fat dairy products, and decreased intakes of fat used in cooking and added sugars.[49]

Data for children and adolescents aged 6 to 17 years from the 1977 to 1978 Nationwide Food Consumption Survey ($n = 8908$) and combined 1994 to 1996 and 1998 CSFII ($n = 3177$) were examined to monitor trends in the prevalence, amounts, and sources of soft drink consumption.[50] Among this group, the prevalence of soft drink consumption increased 48%, from 37% in 1977/1978 to 56% in 1994/1998. Mean daily intake of soft drinks more than doubled, from 5 fluid ounces to 12 fluid ounces per day. The home environment remained the largest source of soft drink access for this group; however, an increasing share was obtained from restaurants and fast food establishments, vending machines, and other sources.[50]

Longitudinal data on selected nutrient intake of youth with emphases on differences by sex and race/ethnicity was examined in a sample from the Child and Adolescent Trial for Cardiovascular Health (CATCH) for which nutrient data was provided by 24-h diet recalls from a cohort of third- ($n = 1874$), fifth- ($n = 1360$), and eighth-grade ($n = 1493$) youth.[51] Between the third grade (Fall, 1991) and the eighth grade (Spring, 1994), nutrient consumption differed by sex and race/ethnicity for numerous nutrients. Specifically, relative to boys' intake, girls' intake of energy from total fat, calcium, folic acid, iron, vitamin A, and vitamin D decreased over time, controlling for overall energy intake. African-American youth increased their intake of energy from total fat and saturated fat over time compared with the other ethnic/racial groups.[51]

WHAT WE EAT IN AMERICA

The integration of the Continuing Survey of Food Intakes by Individuals (CSFII) and the National Health and Nutrition Examination Survey (NHANES) has progressed.[52] The dietary portion of the new integrated survey, which is called "What We Eat in America," is collected as part of NHANES. The year 2002 was the first year of full integration of the CSFII (conducted by the USDA) and NHANES (conducted by the U.S. Department of Health and Human Services [HHS]).[53] Data collection for What We Eat in America, will be on a continuous yearly basis; 2 days of data will be collected for all respondents with the Day 2 interview conducted by telephone. Food intake data, from What We Eat in America, can be linked to health status data from other NHANES components to allow researchers to explore relationships between dietary intake and health status. Under the integrated framework, USDA is responsible for the survey's dietary data collection methodology, maintenance of the databases used to code and process the data, and data review and processing HHS is responsible for the sample design and data collection.[52,53] In addition, USDA is funding the collection and processing of the Day 2 data. Each year, the total sample is 5,000.[52] Each annual sample is nationally representative, but the 2-year sample should be used to provide adequate sample sizes for subgroup analyses.[53]

The 2001 to 2002 dataset, which includes NHANES data collected in 2001 along with What We Eat in America data collected in 2002, has recently become available for public use. Table 16.16 through Table 16.18 provide information about the usual nutrient intake from food by children and adolescents who participated in What We Eat in America and NHANES 2001 to 2002, compared to the DRIs.[54]

Table 16.16 provides national estimates of usual nutrient intake from food for 17 nutrients and dietary components by children and adolescents compared to EARs. As discussed previously in this chapter, the EAR is the average daily nutrient intake level estimated to meet the requirement of half of the healthy individuals in a particular life stage and sex group; the EAR is used to estimate the prevalence of inadequate intakes in a population group. As indicated in Table 16.16, based on comparisons to EARs, nutrients identified as potential problems for sex/age groups of youth include vitamin A for teenage boys and for preteen and teenage girls, vitamin E for all sex/age groups of youth, vitamin C for teenage boys and teenage girls, phosphorus for preteen and teenage girls, magnesium for teenage boys and for preteen and teenage girls, and zinc for teenage girls. Most youth had adequate intakes of thiamin, riboflavin, niacin, vitamin B_6, folate, vitamin B_{12}, iron, copper, selenium, carbohydrate, and protein.[54] Many of the results for youth from What We Eat in America and NHANES 2001 to 2002 are similar to results by Suitor and Gleason for youth from 1994 to 1996 CSFII mentioned previously.[43]

Table 16.17 provides national estimates of usual nutrient intake from food for seven nutrients and dietary components by children and adolescents compared to AIs. An AI cannot be used to estimate the prevalence of inadequacy in a population. Table 16.17 provides the percentages of youth with intakes at or greater than the AI (not less than the AI), but this percentage should not be interpreted as a prevalence of "adequacy." If at least 50% of the sex/age group has intakes greater than the AI, then the prevalence of inadequacy should be low; however, if less than 50% have intakes greater than the AI, then no assumption can be made about the prevalence of inadequacy. As indicated in Table 16.17, nutrients for which no EARs have been

* Standard error not displayed when percentage < EAR is < 3 or >97.

[a] Retinol Activity Equivalents. 1 RAE = 1 μg retinol, 12 μg β-carotene, 24 μg α-carotene.

[b] The intake of niacin is for preformed niacin only. However, the EAR for niacin is given as niacin equivalents that include preformed niacin and contributions from tryptophan. Therefore, the estimated percentage less than the EAR may be overestimated.

[c] Dietary Folate Equivalents. 1 DFE = 1 μg food folate = 0.6 μg of folic acid from fortified food. It is recommended that all females capable of becoming pregnant consume 400 μg from supplements or fortified foods in addition to intake of food folate from a varied diet.

[d] Comparison to EAR for iron was determined using a probability approach; standard errors for the estimated percentage less than the EAR were not produced.

[e] For children 1 to 3 years, reference weights were used. For children 4 years and older, actual body weight was used if BMI was in a healthy range; otherwise, the weight that would place the child at the nearest endpoint of the healthy range was used. The sample size excludes children without BMI available from NHANES 2001–2002; thus, the sample sizes for protein were 798 for children 1 to 3 years, 885 for children 4 to 8 years, 566 for boys 9 to 13 years, 717 for boys 14 to 18 years, 587 for girls 9 to 13 years, and 666 for girls 14 to 18 years.

established that may be of concern among youth include vitamin K, calcium for youth over age 8 years, potassium, and dietary fiber.[54]

Table 16.18 provides the proportion of children and adolescents with usual nutrient intakes (from food only) greater than the ULs. The UL is the maximum level of daily nutrient intake that is likely to pose no risk of adverse health effects for almost all individuals in the general population; as intake increases above the UL, the potential risk of adverse effects may increase. As indicated in Table 16.18, nutrients of concern due to intakes above the UL include zinc for children less than 3 years, and sodium for youth of all ages. The proportions of youth with intakes greater than the ULs, as indicated in Table 16.18, may be

underestimated because they do not include intakes from dietary supplements or water (which were not available when the analyses were done).[54]

Researchers nationwide will have numerous opportunities to analyze this dataset for What We Eat in America, and subsequent ones, using the DRIs and updated recommendations in the 2005 Dietary Guidelines for Americans and *MyPyramid*.

HEALTHY EATING INDEX

To assess and monitor the dietary status of Americans, the USDA Center for Nutrition Policy and Promotion developed the Healthy Eating Index (HEI) and first computed the Index by using 1989 CSFII data.[55] The HEI is computed on a regular basis by USDA as a summary measure of people's diet quality. It consists of ten components, each representing different aspects of a healthy diet. Components 1 to 5 measure the degree to which a person's diet conforms to USDA's Food Guide Pyramid serving recommendations for the five major food groups: grains, vegetables, fruits, milk, and meat/meat alternatives. Components six and seven measure total fat and saturated fat consumption, respectively, as percentages of total kcal intake. Components eight and nine measure total cholesterol and sodium intake, respectively. Component ten measures the degree of variety in a person's diet. Each component has a maximum score of 10 and a minimum score of 0. High component scores indicate intakes close to recommended ranges or amounts; low component scores indicate less compliance with recommended ranges or amounts. The maximum combined score for the 10 components is 100. A HEI score above 80 implies a good diet, a score between 51 and 80 implies a diet that needs improvement, and a score less than 51 implies a poor diet.[55]

The HEI was used to examine the diets of 5354 children age 2 to 18 years from the 1994 to 96 CSFII.[56] Most children had a diet that was poor or needed improvement. Furthermore, older children had lower HEI scores than younger children, which were associated with lower fruit and milk component scores of the HEI. Thus, the percentage of children with a diet that needed improvement or was poor was higher for older children than for younger children. For children age 2 to 3 years, 35% had a good diet, and 5% had a poor diet. For children age 4 to 6 years, 16% had a good diet, and 9% had a poor diet. For children age 7 to 10 years, 14% had a good diet, and 10% had a poor diet. For girls age 11 to 18 years, ~7% had a good diet, and ~18% had a poor diet. For boys age 11 to 18 years, ~6% had a good diet, and ~21% had a poor diet. Except for cholesterol and variety to a smaller extent, most children did not meet most recommendations.[56]

The HEI was used to examine the diets of 4,011 children age 2 to 9 years from the 1998 CSFII.[57] Most children age 2 to 9 years had a diet that needed improvement or was poor. Furthermore, older children (age 7 to 9 years) in this age group had lower HEI scores than younger children (age 2 to 3 years), which were associated with lower fruit and sodium component scores of the HEI. The overall HEI score for children age 2 to 9 years did not change significantly from 1989 to 1998, and indicated a diet that needed improvement.[57]

The HEI was used to examine the diets of 7,177 children age 2 to 9 years from 1994 to 1996 and 1998 CSFII.[55] Most children had a diet that needed improvement or was poor; furthermore, the quality of children's diets varied significantly based on age, sex, household income, receipt of food stamps, food sufficiency, and area of residence. Compared with their respective counterparts, diet quality was better for younger children, boys, and children living in suburban areas. Diet quality was worse if children were in households with a low income, that received food stamps, and who categorized themselves as food insufficient.[55]

The HEI was used to examine the diets of 8070 people age 2 to 51+ years from NHANES 1999 to 2000.[58] The diets of most people, including children age 2 to 18 years, need improvement, although children less than 11 years of age had better scores than did most other age groups.[58]

The quality of a child's diet according to the HEI continues to be related to the income of his or her family, with children in families below poverty being less likely than higher-income children to have a diet rated as good.[59] As indicated in Table 16.19, for example, in 1989 to 1990, for children age 2 to 6 years, 9% of those in poverty had a good diet compared with 23% of those living above poverty; the respective percentages were 16 and 22% in 1994 to 1996, and 17 and 22% in 1999 to 2000.[59]

CAVEATS

Assessment of dietary intake is challenging, especially among children who eat several meals and snacks at school or daycare when their parents are not present. Nevertheless, parents are often asked to provide information about their children's intake; unfortunately, several studies underscore concerns that these parents' reports cannot be taken as truth.[60–62] In addition, parents are often asked to provide joint reports with their children about their children's intake. A 1989 study by Eck et al.[63] found that consensus recalls provided by mother, father, and child yielded better estimates of observed intake of a single cafeteria meal by 34 children aged 4 to 9.5 years than did recalls from either the mother or father alone. Unfortunately, the Eck et al.[63] study is often incorrectly cited as the rationale for obtaining joint recalls from parents and children. However, for that study, children by themselves did not provide recalls, so no comparison could be made of the accuracy of child-only recalls, parent-only recalls, and joint parent–child recalls of the child's intake. Furthermore, consensus recalls were always obtained after the mother and father had each provided separate recalls, but having the mother and father provide two back-to-back recalls about the child's intake could have altered reporting accuracy during the second recall, which was always the consensus parent–child recall.

TABLE 16.19
Percentages of Children Aged 2 to 18 by Age, Poverty Status, and Diet Quality as Measured by the Healthy Eating Index, 1989–1990, 1994–1996, and 1999–2000[a]

	Characteristic		
	Good Diet	Needs Improvement	Poor Diet
1989 to 1990			
Ages 2 to 6 years			
At or below poverty	9	74	17
Above poverty	23	74	3
Ages 7 to 12 years			
At or below poverty	11	75	15
Above poverty	11	83	5
Ages 13 to 18 years			
At or below poverty	3	72	25
Above poverty	5	72	23
1994 to 1996			
Ages 2 to 6 years			
At or below poverty	16	72	12
Above poverty	22	69	9
Ages 7 to 12 years			
At or below poverty	7	74	19
Above poverty	10	75	15
Ages 13 to 18 years			
At or below poverty	3	66	31
Above poverty	5	69	26
1999 to 2000			
Ages 2 to 6 years			
At or below poverty	17	78	5
Above poverty	22	72	6
Ages 7 to 12 years

Above poverty	8	81	11
Ages 13 to 18 years			
At or below poverty	3	78	19
Above poverty	4	76	20

[a] A Healthy Eating Index (HEI) score above 80 implies a good diet, a score between 51 and 80 implies a diet that needs improvement, and a score less than 51 implies a poor diet. Data for the 3 time periods are not necessarily comparable due to methodological differences in data collection.

The report is also available on the World Wide Web at http://childstats.gov. (accessed March 24, 2006).

Sobo et al.[64,65] provided recommendations to improve the accuracy of data about children's intake obtained during parent-assisted dietary recalls based on a study with 34 children aged 7 to 11 years. Sobo et al. found that parents "*contributed primarily by adding food details and, secondarily, by prompting children*;" in addition, "*children rejected a notable proportion of items added*" by parents, and "*children's knowledge of food details was considerable.*"[64,65] Unfortunately, their study did not validate the children's actual intake, and unassisted children's dietary recalls were not obtained.

Dietary reporting studies with adults have found interesting relationships between reported intake and various characteristics of adults such as BMI, sex, social desirability, body image, and self-esteem. There is some concern that these adult characteristics could affect dietary intake reported during joint parent–child reports about children's intake. Validation studies are needed to determine the impact on accuracy of dietary information obtained from joint parent–child dietary recalls about children's intake.

Children in upper elementary school are able to provide self-reports of dietary intake. Methodological research that has used observations of school meals to validate elementary school children's recalls (obtained without parental assistance) is providing insight into their accuracy; this type of research is needed with adolescents in middle and high school. Among first graders, specific prompting (preference, food category, or visual) after free recall hurt more than helped recall accuracy; in contrast, among fourth graders, prompting for food category after free recall yielded small gains in recall accuracy with minimal losses.[66] When interviewed in the morning about the previous day's intake, individual fourth-grade children were inconsistent in recall accuracy from one interview to the next, but overall accuracy improved slightly between the first and third recalls.[67] Fourth-grade boys were more accurate when prompted to report meals and snacks in reverse order (evening-to-morning), while girls were more accurate in forward order (morning-to-evening).[68] When interviewed in the evening about that day's intake, fourth-grade children's recall accuracy did not depend significantly on whether interviews were conducted in person or by telephone.[69] Accuracy by meal component for school lunch recalls was less when the lunch recalls were obtained in the context of a 24-h dietary recall than as a single meal.[70] Providing meal cues elevated false reports compared to allowing fourth-grade children to report using an open interview format.[71] Fourth-grade children's recall accuracy was significantly better when interviewed about prior 24-h intake (e.g., between 3.00 p.m. on Monday and 3.00 p.m. on Tuesday for an interview on Tuesday at 3.00 p.m.) compared to the previous day's intake (e.g., from midnight to midnight on Monday for an interview anytime on Tuesday).[72] A study that investigated BMI, sex, interview protocol, and fourth-grade children's accuracy for reporting kcal found results consistent with those concerning BMI and sex from studies with adults.[73] Additional validation studies are needed to determine how to obtain more accurate dietary information from youth of various ages.

More information regarding dietary assessment methods with children and adolescents is found in Chapters 29, 33 and 35.

VITAMIN–MINERAL SUPPLEMENTS

A basic premise of the *2005 Dietary Guidelines for Americans* is that nutrient needs should be met primarily through consuming foods, because foods provide an array of nutrients as well as other compounds that may have beneficial effects on health.[14] In certain cases, supplements and fortified foods may be useful sources of one or more nutrients that otherwise might be consumed in less than recommended amounts. Dietary supplements may be recommended in some cases, but they cannot replace a healthful diet.[14]

According to the American Dietetic Association,[74] children can best achieve healthful eating habits by consuming a varied diet in moderation[14] that includes foods from each of the major food groups, as illustrated by *MyPyramid*[75] or *MyPyramid for Kids*.[76] Routine supplementation is not necessary for healthy growing children who consume a varied diet, according to the American Academy of Pediatrics.[77] If parents wish to give supplements to their children, a standard pediatric vitamin–mineral product with nutrients in amounts no larger than the DRI (EAR or RDA) poses no risk; however, megadose levels should be discouraged due to potential toxic effects. Parents should be cautioned to keep vitamin–mineral supplements out of the reach of children, because the taste, shape, and color of most pediatric preparations make them quite appealing to children.[77]

Although the American Academy of Pediatrics advocates that routine vitamin–mineral supplementation is *not* necessary for healthy growing children who eat a varied diet, it does identify groups of children at nutritional risk who may benefit from supplementation;[77] these groups are identified in Table 16.20. Dietary intake over several days should be assessed by a Registered Dietitian to determine if an individual child from one of these groups needs to take a supplement.

LEARNING TO EAT

Widespread evidence indicates that the nutrition guidelines are not being followed by most children. For example, intake for most children is low for fruits, vegetables, fiber, and whole grains,[38,39,42,49,78–80] but high for total fat, saturated fat, and cholesterol.[44,81] Furthermore, the incidence of childhood obesity has increased dramatically during the last three decades.[82–86] To help understand why children eat less of what is recommended by nutrition guidelines and more of what is not recommended, and why the incidence of childhood obesity is increasing, Birch and Fisher[87] recommend that consideration be given to factors that impact children's food preferences and consumption patterns (i.e., what and how much is consumed). Extensive evidence suggests that children's food preferences are shaped by early experience with food and eating, and that family environment and practices used by parents and other adults (e.g., school staff; caregivers, etc.) may permanently affect dietary practices of children.[88] Birch and colleagues[89] have repeatedly found that exposure to novel foods, as well as the social environment in which food is eaten, are crucial in the development of preschool children's food preferences and consumption patterns. Children's food preferences are

TABLE 16.20

Groups of Children at Nutritional Risk Who may Benefit from Vitamin–Mineral Supplementation

- Children from deprived families or who suffer parental neglect or abuse
- Children with anorexia or an inadequate appetite or who consume fad diets
- Children with chronic disease (e.g., cystic fibrosis, inflammatory bowel disease, hepatic disease, etc.)
- Children who participate in a dietary program to manage obesity
- Children who consume a vegetarian diet without adequate dairy products
- Children with failure to thrive
- Children who do not get regular sunlight exposure, who do not ingest at least 500 ml/day of vitamin D-fortified milk, or who do not take a daily multivitamin supplement with at least 200 IU of vitamin D

important, because research indicates they are major determinants of consumption;[90–95] therefore, not eating certain items (such as vegetables) is related to low preferences. According to Hill and Trowbridge,[88] insights gained from research concerning children's food preferences and consumption patterns "*can assist in developing interventions to improve child-feeding practices, which may lead to development of healthier eating patterns.*" Parents, caregivers, and school staff need to expose children to healthful foods, provide opportunities for children to learn to like rather than dislike healthful foods, encourage children to respect their own feelings of hunger and satiety, and reduce the extent to which learning and experience potentiate children's liking for high-sugar and/or high-fat foods.[96] This section provides an overview of past and continuing research regarding the influence of learning on children's food preferences and consumption patterns.

Neophobia (Rejection of Novel Foods)

During pregnancy, flavors from a pregnant woman's diet are transmitted to amniotic fluid and swallowed by the fetus; thus, the types of food eaten by women during pregnancy and, hence, the flavor principles of their culture may be experienced by infants before birth and well before their first exposure to solid foods.[97] For example, Mennella et al.[97] demonstrated that prenatal and early postnatal exposure to carrot juice enhanced infants' enjoyment of that flavor in cereal during weaning. After birth and during the first years of life, an enormous amount of learning about food and eating occurs as infants transition from consuming only milk (i.e., breast milk or formula) to consuming a variety of foods,[87] and from eating when hungry to eating due to a variety of social, cultural, environmental, or physiological cues.[98] According to Birch and Fisher,[87] this transition from univore to omnivore is shaped by the infant's innate preference for sweet and salty tastes and the rejection of sour and bitter tastes,[99] and by the predisposition of infants and children to be neophobic or to reject novel foods.[100] In addition, a child's experience with food and flavors is shaped by the parents' decision to breastfeed or formula-feed.[87] Research by Sullivan and Birch[101] indicated that infants ate more of novel foods after repeated dietary exposure to the novel foods; furthermore, although they did not differ initially, breastfed infants had greater increases in intake of the novel foods after exposure and an overall greater level of intake than formula-fed infants.

Table 16.21 provides an overview of three studies by Birch and colleagues,[102–104] indicating that preschool children's neophobia or rejection of new foods can be overcome by exposure. Results from these studies indicate that preschool children's food preferences, which are major determinants of consumption, are learned through repeated exposure to foods. Thus, although children may reject novel foods initially, parents and caregivers should continue to make them available to children.

Children's age is a factor when considering exposure to novel foods. For example, results from a study with infants ages 4 to 7 months indicated that exposure dramatically increased infants' intake of a new food and other, similar new foods; however, much of the pre-post increase in intake of the new food actually occurred very early in the sequence of feedings.[105] These rapid increases in intake by infants contrast with the slower changes over repeated exposures seen in young children.[105] Loewen and Pliner[106] found that for older (10- to 12-year-old) children, exposure to novel-good foods increased their willingness to taste novel foods compared to the familiar-good control, but exposure to novel-bad foods had no effect; in contrast, for younger (7- to 9-year-old) children, exposure to both novel-good and novel-bad foods decreased willingness to taste novel foods. Results from a study by Hearn et al.[107] indicated that availability and accessibility to fruits and vegetables (as assessed by telephone interviews with parents) was positively related to upper elementary school children's preferences and consumption.

Reluctance to try novel foods can be decreased by adding the familiar flavor principle (the distinctive combinations of seasonings that characterize many cuisines) to the unfamiliar food. For example, Pliner and Stallberg-White[108] found that 10- to 12-year-old children were more willing to try a novel food when it was accompanied by a familiar flavor principle than when it was served alone.

TABLE 16.21

Research Concerning Exposure to Novel Foods and Preschool Children's Food Preferences and Consumption

Reference #, Authors, & Year	Subjects	Study Design	Results
102, Birch and Marlin, 1982	14 children age 2 years	Each child received 2 to 20 exposures to 5 novel fruits or cheeses over 25 to 26 days	Children ate more of items with higher exposures when given pairs of items, tasted both and picked 1 to consume
103, Birch et al, 1987	43 children in 3 age groups: 26, 38, or 64 months	Each child received 5, 10, or 15 exposures to 7 new fruits, and was asked to taste some and look at others	For all age groups, preferences increased significantly only when foods were tasted
104, Sullivan and Birch, 1990	39 children, age 4 to 5 years	Each child tasted 1 of 3 versions of tofu (sweetened, salty, or plain) 15 times over several weeks	Preferences increased with exposure regardless of added sugar, salt, or plain; 10 exposures were needed

SOCIAL ENVIRONMENT

The social environment of eating is crucial, because children learn about what to eat and why to eat, and receive reinforcements and incentives for eating from their families and the larger environment.[109] Most of this learning occurs during routine mealtime experiences, in the absence of formal teaching.[89] This section provides an overview of several studies that investigated various aspects of the social environment (e.g., rewards, choice offerings, modeling by adults, modeling by peers, class challenges, etc.); Table 16.22 provides details for several of these studies in chronological order by year of publication.

Parents (and researchers) who want young children to eat may offer rewards. Caution is warranted because of the relationship between rewards, children's food preferences, and children's food consumption. For example, a 1980 study by Birch et al.[110] (see Table 16.22) indicated that when specific foods were used as rewards with preschool children, preferences for those "reward" foods were enhanced. In contrast, providing rewards to preschool children for consuming specific foods may result in later decreases in preferences for the foods that had to be consumed to obtain rewards, as illustrated in a 1982 study by Birch et al.,[111] a 1984 study by Birch et al.,[112] and a 1992 study by Newman and Taylor[113] (all described in Table 16.22). In a 1999 study by Hendy[114] (see Table 16.22), modeling by the teacher, insisting that children try one bite, and simple exposure were less effective than choice-offering and reward of a special dessert to encourage acceptance of new fruits and vegetables during preschool lunches. A 2003 study by Wardle et al.[115] indicated that preschool children's preferences for and consumption of vegetables can be enhanced if parents offer children daily tastes for 14 days and keep a daily vegetable "sticker" diary with children.

For elementary school children, research indicates that rewards, if used appropriately, may enhance consumption without negatively affecting preferences. Another 2003 study by Wardle et al.[116] (see Table 16.22) found that exposure increased elementary school children's preferences and consumption more than rewards, but that rewards did not decrease preferences. A 2004 study by Perry et al.[117] (see Table 16.22) found that a 2-year, elementary school, cafeteria-based lunch intervention with daily activities (such as increased availability during lunch and encouragement by food service staff to select foods) and special events (including class competitions) increased fruit but not vegetable intake. A 2005 study by Hendy et al.[118] (see Table 16.22) indicated that token reinforcements provided to elementary school children for eating fruits or vegetables during school lunch did not result in decreased preferences during the program or 2 weeks after it ended. According to Hendy et al.,[118] the token reinforcement used in their program avoided the "overjustification effects" of later decreases in food preferences because it included three recommended components: (1) small and delayed reinforcement, (2) food choice along with the requirement to eat only a small amount, and (3) conditions that encourage peer participation and modeling.

Research studies are providing insight into the effect of modeling by adults and peers on young children's consumption. A series of small studies in 2000 by Hendy and Raudenbush[119] (see Table 16.22) suggest that to encourage preschool children's acceptance of novel foods, teachers should provide enthusiastic modeling (*Mmm! I like mangos!*) rather than silent modeling, and avoid placing competing peer models at the same table with fussy eaters, especially girls. A small 2002 study by Hendy[120] (see Table 16.22) indicated that teachers may train preschool girls as peer models to encourage acceptance of novel foods by other preschool age children during preschool meals; however, the modeling effects on novel food acceptance of observing children may not be present one month later. A small but well-controlled 2005 study by Addessi et al.[121] (see Table 16.22) demonstrated that adult modeling can positively impact preschool children's acceptance of "unusual" and novel foods (e.g., cooked semolina, colored red and flavored with anchovy). Although caregivers may believe they positively influence children's eating behaviors, observed behaviors of caregivers at mealtimes were inconsistent with expert recommendations in a study of influential factors of caregiver behavior at lunch in early child-care programs.[122]

Research indicates that infants are born with the ability to self-regulate their caloric intake by adjusting their formula intake when the caloric level of the formula changes[123] and when solid foods are added.[124] Preschool children are able to adjust the

TABLE 16.22

Research (in Chronological Order by Year of Publication) Concerning the Social Environment and Children's Food Preferences and Consumption

Reference #, authors & Year	Subjects	Description of Study	Results
110, Birch et al., 1980	64 children aged 3 to 4 years; 16 per context	Children given sweet or nonsweet foods (with initially neutral preferences) over several weeks in 1 of 4 contexts: (1) as reward for behavior, (2) paired with adult greeting, (3) as nonsocial behavior (put in child's locker), or (4) at snack time	Preferences increased when foods presented as rewards, or paired with adult greeting; effects lasted longer than 6 weeks after contexts ended. Suggest positive social contexts can be used to increase preferences for foods not liked but more nutritious
111, Birch et al., 1982	12 children aged 3 to 5 years	Children told *if* they drank juice, *then* they could play	Instrumental ("if") use of juice reduced preferences for it
112, Birch et al., 1984	31 children aged 3 to 5 years	Children told *if* they drank milk drink, *then* they received verbal praise or a movie	Instrumental ("if") use of milk beverage reduced preferences for it
113, Newman and Taylor, 1992	86 children aged 4 to 7 years	Children told that *if* they ate 1 snack, *then* they could eat another snack (with both of neutral preference initially)	"If" snacks became *less* preferred and "then" snacks became *more* preferred
114, Hendy, 1999	64 preschool children	To encourage acceptance of 4 new fruits and vegetables during 3 preschool lunches, teachers used 1 of 5 actions: (1) choice-offering ("*Do you want any of this?*"), (2) reward (special dessert), (3) insisting children try 1 bite, (4) modeling by teacher, or (5) simple exposure	Choice-offering and reward were more effective than other actions. Hendy concluded that dessert rewards are *not* needed because the less expensive and more nutritious action of choice-offering works as well
119, Hendy and Raudenbush, 2000	*Study 1:* 58 teachers of preschool children *Study 2:* 18 boys, 16 girls (preschool) *Study 3:* 13 boys, 10 girls (preschool) *Study 4:* 12 boys, 14 girls (preschool) *Study 5:* 6 boys, 8 girls (preschool)	*Study 1:* Teacher questionnaire to rate effectiveness of 5 teacher actions to encourage children's food acceptance *Study 2:* Familiar foods presented under silent teacher modeling or exposure *Study 3:* Novel foods presented under silent teacher modeling or exposure *Study 4:* Novel foods presented under enthusiastic teacher modeling ("*Mmm! I love mangos!*") or exposure *Study 5:* Novel foods presented under enthusiastic teacher modeling versus peer modeling versus exposure Preschool lunch was setting for Studies 2 to 5. Preferences assessed only for Study 5, and after one-month delay	*Study 1:* Teachers rated modeling as most effective over choice-offering, insist, tangible reward, and exposure *Study 2:* Silent teacher modeling ineffective to encourage acceptance of familiar foods *Study 3:* Silent teacher modeling ineffective to encourage acceptance of novel foods *Study 4:* Enthusiastic teacher modeling maintained novel food acceptance across 5 meals *Study 5:* Boys ate and liked novel foods equally under all 3 conditions. Girls ate and liked novel foods most when modeled by peers. Enthusiastic teacher modeling ineffective if peer models were present; peer modeling more effective for girls than boys
120, Hendy, 2002	38 preschool children	Three novel foods presented to 8 tables of 38 children during 5 preschool lunches. After 3 baseline lunches, 16 of 38 children were trained to serve as peer models of food acceptance for 1 novel food in exchange for small toy rewards; each novel food was assigned to either girl model, boy model, or no model conditions for next 2 lunches. Remaining 22 of 38 children were observed and their food bites were recorded during baseline and modeled lunches	For children of either gender, girl models were more effective than boy models at increasing food acceptance by observed children from baseline to modeled lunches. One month later, neither food preferences nor consumption decreased for trained peer models, but both decreased for observed children

Reference	Sample	Design/Intervention	Results/Conclusion
116, Wardle et al., 2003	49 children age 5 to 7 years	Randomized controlled design with children from 3 primary schools in London assigned to 1 of 2 intervention groups (exposure, reward) or a no-treatment control group for a 2-week period with liking for, and consumption of, red pepper assessed before and after 2-week period. Children in each intervention group had 8 daily, individual sessions with those in exposure group offered a taste of red pepper and told they could eat as much as they liked, and those in reward group shown cartoon stickers and told they could pick 1 if they ate at least 1 piece of pepper	Liking and consumption were increased for the exposure group compared to the control group. For the reward group, the outcomes were intermediate, lying between, and not significantly different from, the exposure and control groups. Contrary to results from previous studies by others, rewards did not decrease liking
115, Wardle et al., 2003	156 children (mean age = 53 months; range from 34 to 82 months) and parents (95% mothers) who had participated in larger study (n=564) of predictors of children's fruit and vegetable intake	Randomized controlled trial with parents of children assigned to 1 of 3 groups: Exposure (offer child taste of target vegetable daily for 14 consecutive days; encourage tasting without offering rewards; keep "vegetable" diary with space for children to record liking using small "face" stickers after each tasting; modeling "taste" was suggested), Information (nutritional advice and leaflet), or Control (no treatment)	Only the Exposure group had significant increases in liking, ranking, and consumption of the target vegetable from pre- to post-intervention. The authors concluded that a parent-led, exposure-based intervention involving daily tasting of a vegetable, along with a daily vegetable "sticker" diary, holds promise for improving children's acceptance of vegetables
117, Perry et al., 2004	Baseline — 1,668 children (in first or third grade); End (2 years later) — 1,168 of same children (in third or fifth grade); 26 schools (13 intervention, 13 delayed-program control); Data collected on ~23 children per grade per school	Randomized controlled trial of school cafeteria-based intervention which lasted two school years and included daily activities (increased availability, appeal, and encouragement of fruits and vegetables in lunch program; changes in lunch line and school snack cart) and special events (2-week kickoff campaign with posters; monthly samplings served at lunch by peers with help from parents; theater production; 2 challenge weeks when students competed to eat 3 fruit and vegetable daily lunch servings and classes rewarded at week's end with frozen fruit yogurt; final meal demonstration)	Students in intervention schools significantly increased total fruit intake by 0.14 to 0.17 servings at lunch with no differences for vegetables. Process measures indicated that verbal encouragement by food service staff was associated with outcomes. Authors concluded that environmental interventions alone may have limited impact without classroom and home (parental) activities, and interventions are needed that focus solely on vegetable intake among children
118, Hendy et al., 2005	188 children in first, second, or fourth grade at baseline	School-cafeteria-based intervention. For 18 lunches (3 per week), children (in classes) randomly assigned to receive token reinforcement for eating either fruits or vegetables. Lunch observers recorded intake and punched holes into nametags each day for children who ate assigned foods. Weekly during lunch, children traded token "punches" for small prizes. Preferences assessed with individual interviews at baseline and follow-up at 2 weeks and 7 months after program	Fruit and vegetable consumption increased for all grades and lasted throughout the program. Preferences increased 2 weeks after the program for both fruits and vegetables, but returned to baseline levels 7 months after the program
121, Addessi et al., 2005	27 children age 2 to 5 years	Children's behaviors towards novel foods (cooked semolina, colored and flavored as yellow cumin, green caper, or red anchovy) were assessed when an adult model (1) was not eating (*Presence* condition), (2) was eating food of different color (*Different color* condition), and (3) was eating food of same color (*Same color* condition). Adult models given same colored semolina but flavored with sugar so they would eat it enthusiastically	Children accepted and ate novel food more in *Same color* condition than in *Different color* and in *Presence* conditions. Children ate less food in *Different color* and in second and third trials. Authors concluded that "*social influences — together with repeated experiences with novelty — are a powerful instrument to promote the acceptance of novel foods in young children*"

calories eaten in a snack or meal, based on the calories eaten in a preload snack.[125,126] Furthermore, preschool children are able to adjust the calories eaten at various meals and snacks during the day, so that the number of calories consumed in a 24-h period is relatively constant.[127]

Although children have the ability to self-regulate their caloric intake, well-conducted laboratory studies[128,129] indicate that this ability may be negatively impacted by child-feeding practices that encourage or restrict children's eating. Using observations of family meal times, Klesges and colleagues[130] found that parental prompts, especially encouragements to eat, were highly correlated to preschool children's relative weight, and increased the probability that a child would eat. Furthermore, a child's refusal to eat usually led to a parental prompt to eat more food, whereas a child's food request was not likely to elicit either a parental prompt to eat or subsequent eating by the child. Results from a small but well-controlled study by Fisher and Birch[94] indicated that preschool children's preferences for dietary fat were related to their own triceps' skin-fold measurements, as well as to the composite BMI of their parents. Laboratory experiments with preschool children indicate that restricting access to palatable foods can sensitize children to external rather than internal eating cues, and increase children's desire to obtain and consume the restricted foods.[131] For preschool girls (but not boys), child and maternal reports of restricting access were predictive of girls' snack food intake, with higher levels of snack food intake predicted by higher levels of restriction.[132] Child-feeding practices have been found to be key behavioral variables that explain more of the variance in children's total fat mass than energy intake.[133] Among girls, longitudinal data provide evidence that maternal restriction can promote overeating in the absence of hunger.[134]

Over the past 2 decades, portion sizes have increased significantly (http://hin.nhlbi.nih.gov/portion/index.htm). Young children require fewer calories and smaller amounts of food from each of the food groups compared to adolescents. (See Table 16.12 and Table 16.15 for information from *MyPyramid* about food intake patterns and calorie levels, respectively.) For example, a 4-year-old girl and a 16-year-old girl (each with a moderate activity level), require 1400 and 2000 calories per day, respectively; in terms of amounts of food by food group, this is a difference of one half cup of fruit, 1 cup of vegetables, 1 ounce of grains, 1.5 ounces of meat, 1 cup of milk, 2 teaspoons of oil, and almost 100 discretionary calories.

Research indicates interesting insight into the relationship between portion sizes and young children's intake. In a study by Rolls et al.,[135] 16 younger (3 years) and 16 older (5 years) preschool children participated in three lunches during their usual lunchtime at the day care. Each lunch consisted of macaroni and cheese served in small, medium, or large portion sizes, along with set portion sizes of carrot sticks, applesauce, and milk. Results indicated that older preschoolers consumed more macaroni and cheese, when served the large portion compared to the small portion ($p < .002$). However, portion sizes did not significantly affect food intake among younger preschoolers. These results indicate the important role of portion size in shaping children's dietary intake, and imply that portion size can either promote or prevent the development of overweight among older preschool children. Furthermore, these results indicate the importance of encouraging preschool children to focus on their own internal cues of hunger and satiety instead of "*eating everything to clean the plate.*"[135]

Fisher et al.[136] extended the previous investigation in a study with 30 children aged 3 to 5 years who participated in a series of lunches once a week for 12 weeks during their usual lunchtime at the day care. Each lunch consisted of an entrée of macaroni and cheese served either as an age-appropriate portion, a large portion that was double the size of the age-appropriate one, or a portion self-served by the child, along with standard portion sizes of carrots, applesauce, milk, and sugar cookies. Results indicated that doubling an age-appropriate portion of the entrée increased entrée and total lunch energy intakes by 25 and 15%, respectively. Changes were attributable to increases in children's average bite size of the entrée without compensatory decreases in the intake of other foods served at the lunch. Children's average self-served portion size did not differ significantly from the size of the age-appropriate portion served to them. Furthermore, when the children served their own entrée, they ate 25% less of it than when they were served a large entrée portion. According to the authors, their results "*provide initial evidence that allowing children to self-select portion sizes can affect the amount consumed and may play an important role in reducing the effects of exposure to large portion sizes on children's intake.*"[136]

McConahy et al.[137] analyzed data from 1994 to 1996 and 1998 CFSII for children aged 2 to 5 years to evaluate the relationship of portion size for 10 commonly eaten foods, number of eating occasions per day, and number of foods consumed per day with children's total energy intake. Results indicated that body weight accounted for only 4% of the variability in energy intake in contrast to food portion size, number of eating occasions, and number of foods that accounted for 17–19%, 9%, and 6–8%, respectively. The authors concluded that feeding recommendations for children should focus on moderation in portion sizes as well as frequent feeding.[137]

DIVISION OF FEEDING RESPONSIBILITY

According to Birch,[98] child feeding practices that encourage children to eat in response to external cues instead of internal cues regarding hunger and satiety "*may form the basis for the development of individual differences in styles of intake control that exist among adults. Some of the problems of energy balance seen in adulthood may result from styles of intake control in which hunger and satiety cues are not particularly central.*" According to the American Dietetic Association,[74] "*perhaps some of the best advice regarding child feeding practices continues to be the division of parental and child responsibility advocated by Satter.*" Satter advocates that parents (or adults) are responsible for presenting a variety of nutritious and safe foods to children

at regular snack- and mealtimes, as well as the physical and emotional setting of eating; children are responsible for deciding how much, if any, they will eat.[138–140]

Dietary recommendations from the American Heart Association and the American Academy of Pediatrics advocate a similar division of feeding responsibility: Parents choose the time for meals and snacks, provide a wide variety of nutrient-dense foods and beverages, and provide an appropriate social context for eating that include family meals. Children can then choose how much to consume.[15,16] Furthermore, the eating behavior of adults (whether parents, guardians, or caregivers) must provide appropriate role modeling to influence children with "*do as I do*" instead of "*do as I say.*" [15, 16]

CHILDHOOD OBESITY

Overwhelming evidence indicates that the incidence of obesity among children and adolescents has increased dramatically during the last three decades.[82–86] According to Dietz, "*obesity is now the most prevalent nutritional disease of children and adolescents in the United States.*"[141] Critical periods during the childhood years for the development of obesity include the period of adiposity rebound that occurs between 5 and 7 years of age, and adolescence.[141] The causes of childhood obesity are multifactorial, including both genetics and environment. Inactivity appears to play a major role in the increasing rate of childhood obesity, as does television viewing. Results from NHANES III indicated that children aged 8 to 16 years who watched 4 h or more of television each day had greater body fat and greater BMI than children who watched television less than 2 h each day;[142] furthermore, television watching was positively associated with obesity among girls, even after controlling for age, race/ethnicity, family income, weekly physical activity, and energy intake.[143] According to the Youth Behavior Risk Surveillance System, in 2003, 38% of students in grades 9 through 12 watched television for 3 h or more per day on an average school day.[144] With the advances in technology, especially regarding computers, more children are spending more hours in sedentary states.

Preventing childhood obesity is more desirable than trying to treat obesity during adolescence and adulthood. One critical component of obesity prevention is increased physical activity; another is educating parents and caregivers regarding the development of children's food preferences and food consumption patterns. The American Academy of Pediatrics Committee on Nutrition issued a policy statement in 2003 which recommends that parents and caregivers promote healthful eating patterns by offering nutritious snacks, encouraging children's autonomy in self-regulation of food intake, setting appropriate limits on food choices, and modeling healthful food choices, and that television and video time be limited to a maximum of 2 h/day.[145]

In the 2005 Dietary Guidelines for Americans, a key recommendation regarding overweight children is to reduce the rate of weight gain while allowing growth and development.[14] A healthcare provider should be consulted before placing a child on a weight-reduction diet. The topic of childhood obesity is covered thoroughly in Chapter 51 (not so).

LOW-FAT DIETS

Emphasis regarding low-fat, low-cholesterol diets has increased during the past decade, as has the debate over whether low-fat diets are appropriate for children.[146–151] Parental concern about later atherosclerosis or obesity has led to failure to thrive in some infants aged 7 to 22 months who were fed very-low-fat and calorie-restricted diets.[152] However, the safety and efficacy of lower-fat diets in children have been confirmed by results from several studies. The Special Turku Coronary Risk Factor Intervention Project for Babies (STRIP) was a prospective trial for which a total of 1062 healthy infants were randomized at age 7 months into an intervention group ($n = 540$) or usual care control group ($n = 522$). The intervention group received repeated, individualized counseling aimed at promoting a fat intake of 30% of energy, a 1:1:1 ratio of saturated to monounsaturated to polyunsaturated fat intake, and low cholesterol. Growth and development data from the STRIP trial support the safety of a low saturated-fat, low-cholesterol diet administered to infants beginning at age 7 months and continuing through the first several years of life.[153–155] The Dietary Intervention Study in Children (DISC) was a multicenter, randomized controlled trial with preadolescent children;[156] an intervention group ($n = 334$) followed a diet with 28% of kcal from total fat, ~10% of kcal from saturated fat, and 95 mg/day of cholesterol, and a comparable usual care group ($n = 329$) consumed ~33% of kcal from total fat, ~12% of kcal from saturated fat, and 113 mg/day of cholesterol. Results from DISC indicated that dietary fat modifications can be achieved and sustained safely with no adverse effects in pubertal children up to 7 years later, and that children who received the intervention made healthier food choices.[156–159] Further evidence regarding the safety and efficacy of lower fat diets in upper elementary school children (third through fifth grades) was provided by the Child and Adolescent Trial for Cardiovascular Health (CATCH), which is described more fully later in this chapter. Results failed to indicate any evidence of deleterious effects of the 3-year intervention on growth or development of children.[160]

EXCESSIVE FRUIT JUICE CONSUMPTION

Fruit juice is an increasingly common beverage for young children.[77] Although fruit juice is a healthful, low-fat, nutritious beverage, there are health concerns regarding excessive fruit juice consumption by young children. For example, drinking fruit juice helps

fulfill nutrition recommendations to eat more fruits and vegetables. However, as children increase their intake of fruit juices, they may decrease their intake of milk,[161] that can decrease their intake of calcium unless the juice is calcium-fortified. Carbohydrate malabsorption is common following the ingestion of several fruit juices in young children with chronic nonspecific diarrhea as well as in healthy young children.[162] Excessive fruit juice consumption may be a contributing factor in nonorganic failure to thrive.[163] Drinking 12 or more fluid ounces of fruit juice per day is associated with short stature and with obesity in young children.[164] In 2001, the Committee on Nutrition of the American Academy of Pediatrics issued a policy statement about the use and misuse of fruit juice, which recommended limiting daily fruit juice intake to 4 to 6 ounces for children aged 1 to 6 years, and to 8 to 12 ounces for children aged 7 to 18 years.[165] In addition, the policy statement recommended that children be encouraged to eat whole fruits (instead of drinking fruit juice) to meet their recommended daily fruit intake, and that unpasteurized juice not be consumed.

CAFFEINE

Caffeine is a stimulant for the central nervous system; it tends to decrease drowsiness and reduce the sense of fatigue, but too much can cause palpitations, stomach upset, insomnia, and anxiety. Its effects vary among individuals, depending on the amount ingested, body size of the individual, and personal tolerance. Some people are able to build up a tolerance to caffeine through regular use; others are more sensitive to it. If someone who has regularly consumed caffeine suddenly stops using it, mild withdrawal symptoms (e.g., headaches, craving for caffeine, etc.) may occur. Substantial amounts of caffeine are found in several soft drinks, coffee, tea, and some pain relievers; smaller amounts are found in chocolate and foods with cocoa.

Consumption of caffeine increases during adolescence with greater intakes of soft drinks, tea, and coffee. This can be a concern, because caffeine has a modest negative impact on calcium retention, yet consumption of foods high in calcium decreases as children get older,[54] especially among girls.[43] Furthermore, the stimulating effect of caffeine may set the stage for needing stimulation; although caffeine is classified as a drug, society is very accepting of this stimulant and has not considered it a nuisance.[166]

NUTRITIVE AND NONNUTRITIVE SWEETENERS

Although there are widespread beliefs that both sugar (i.e., sucrose) and nonnutritive sweeteners (e.g., aspartame) produce hyperactivity and other behavioral problems in children, both dietary challenge and dietary replacement studies have demonstrated that sugar has little if any adverse effects on behavior.[167] For example, Wolraich et al.[168] conducted a double-blind controlled trial with 25 normal preschool children and 23 school-age children who were described by their parents as sensitive to sugar. The different diets that children and their families followed for each of three consecutive 3-week periods were either high in sucrose, aspartame, or saccharin (placebo). Children's behavior and cognitive performance were evaluated weekly. Results strongly indicated that even when intake exceeded typical dietary levels, neither sucrose nor aspartame had discernible cognitive or behavioral effects in normal preschool children or in school-age children who were believed to be sensitive to sugar. Furthermore, the few differences associated with the ingestion of sucrose were more consistent with a slight calming effect than with hyperactivity.[168] Results from a 1995 meta-analytic synthesis of 16 reports containing 23 controlled double-blind challenge studies found that sugar did not affect the behavior or cognitive performance of children; however, a small effect of sugar or effects on subsets of children could not be ruled out.[169]

According to Kanarek,[167] the strong belief of parents, educators, and medical professionals that sugar has adverse effects on children's behavior may be attributed to several factors. First, adults may misconceive the relationship between sugar and behavior. Children in general have difficulty altering their behavior in response to changing environmental conditions, such as shifting from the unstructured nature of a party or snack time at school to the more rigorous demands of class work. If the party or snack included foods with high sugar content, adults may relate the child's sugar intake with behavioral problems as the child tries to adapt from an unstructured activity to one with structure. Second, sugar-containing foods such as candy are often forbidden or given to children in very limited amounts; the prohibited nature of these foods may contribute to the belief that associates them with increased activity. Finally, expectations of both adults and children could promote the idea that sugar leads to hyperactivity. Children hear adults comment that "*too much sugar makes children hyper*" and children believe them and act accordingly to fulfill the prophecy.[167]

Although experimental evidence fails to indicate that sugar affects children's behavior and cognition, children should not have unlimited access to sugar, because undernutrition may occur if foods with essential nutrients are replaced by calories from sugar; furthermore, sugar (and starch) can promote tooth decay. According to *MyPyramid*,[170] the "discretionary calorie allowance" may be used to eat more foods from any food group than the food guide recommends, to select forms of foods that contain solid fats or added sugars (such as sweetened cereal and sweetened yogurt), to add fats or sweeteners (such as sugar) to foods, or to eat or drink items that contain only fats, caloric sweeteners (such as candy and soft drinks), or alcohol. Furthermore, in *MyPyramid*, added sugars are addressed in the overarching theme of "proportionality," which is to eat more of some foods (fruits, vegetables, whole grains, fat-free or low-fat milk products), and less of others (foods high in saturated or *trans* fats,

added sugars, cholesterol, salt, and alcohol), and the overarching theme of "moderation," which is to choose forms of foods that limit intake of saturated or *trans* fats, added sugars, cholesterol, salt, and alcohol.[170] According to the 2005 Dietary Guidelines for Americans,[14] key recommendations for carbohydrates include that foods and beverages should be chosen and prepared with little added sugars or caloric sweeteners, and that the incidence of dental caries be reduced by practicing good oral hygiene and consuming sugar- and starch-containing foods and beverages less frequently. According to the DRIs, added sugars should be limited to no more than 25% of total energy, after which dietary quality might be reduced.[1] The position of the American Dietetic Association[171] is that "consumers can safely enjoy a range of nutritive and nonnutritive sweeteners when consumed in a diet that is guided by current federal nutrition recommendations, such as the Dietary Guidelines for Americans and the Dietary Reference Intakes, as well as individual health goals."

MEDIA INFLUENCES

Children's food preferences and consumption patterns can be altered either positively or negatively by media and advertising. Youth are the target of intense and specialized food marketing and advertising efforts via television advertising, in-school marketing, the Internet, toys and products with brand logos, product placements, kids clubs, and youth-targeted promotions.[172] However, foods marketed to youth are predominantly high in fat and sugar, which is inconsistent with dietary recommendations. For example, a 2005 study by Harrison and Marske[173] found that snacks, convenience, fast foods, and sweets dominated food advertisements aired during television programs heavily viewed by children. Furthermore, advertised foods exceeded recommended daily values for total fat, saturated fat, and sodium, but failed to provide recommended daily values for fiber, vitamin A, vitamin C, calcium, and iron.[173] A review by Story and French[172] examines the food advertising and marketing channels used to target youth in the United States, the impact on eating behavior of food advertising, and current regulations and policies. A 2004 Kaiser Family Foundation Issue Brief reviews more than 40 studies and explores what is and is not known about the role of media in the dramatically increasing rates of childhood obesity in the United States.[174] It outlines media-related policy options that have been proposed to help address this important public health problem, such as decreasing the time children spend with media to reducing their exposure to food advertising. In addition, it identifies ways in which media could play a positive role in helping address childhood obesity, such as increasing the number of media messages that promote fitness and sound nutrition.[174]

VEGETARIAN DIETS

There is considerable variation in the eating patterns of vegetarians. For the lacto–ovo–vegetarian, the eating pattern is based on grains, vegetables, fruits, legumes, seeds, nuts, dairy products, and eggs; meat, fish, and fowl are excluded. For the vegan, or total vegetarian, the eating pattern is similar to the lacto–ovo–vegetarian pattern except for the additional exclusion of eggs, dairy, and other animal products. However, considerable variation may exist in the extent to which animal products are avoided within both of this patterns.[175]

The position of the American Dietetic Association and Dietitians of Canada is that "appropriately planned vegetarian diets are healthful, nutritionally adequate, and provide health benefits in the prevention and treatment of certain diseases."[175] Well-planned vegan and other types of vegetarian diets are appropriate for all stages of the life cycle, including childhood and adolescence.[175] Appropriately planned vegan and lacto–ovo–vegetarian diets satisfy nutrient needs of infants, children, and adolescents and promote normal growth.[176] Dietary deficiencies are more common in populations with very restrictive vegetarian diets. Vegan children need a reliable source of vitamin B_{12}; in addition, vitamin D supplements or fortified foods should be used if sun exposure is limited.[175] For vegetarian children, emphasis should be placed on foods rich in calcium, iron, and zinc, along with dietary practices that enhance absorption of iron and zinc from plant foods. Vegetarian children can be helped to meet energy needs through frequent meals and snacks, as well as the use of some refined foods and foods higher in unsaturated fat.[175] Messina and Mangels[177] reviewed research on the growth and nutrient intake of vegan children and provided recommendations for feeding balanced diets to vegan children. Modifications to the vegetarian food guide for children (aged 4 to 8 years) and adolescents (aged 9 to 18 years) are available.[178] During the adolescent years, when there is increased independence and decision making and greater influence by peers and role models, vegetarian diets may be relatively common. Chapter 20 contains additional information regarding vegetarian diets.

FEEDING TODDLERS AND PRESCHOOL CHILDREN

Young children cannot innately choose a well-balanced diet. They depend on adults to offer them a variety of nutritious and developmentally appropriate foods. A child's intake at individual meals may vary considerably, but the total daily caloric intake remains fairly constant.[127] Many parents become anxious about the adequacy of their young child's diet or frustrated with their child's unpredictable eating behavior, which may include refusals to eat certain foods and food jags. Table 16.23 contains suggestions for concerns that parents may commonly encounter when feeding young children.

TABLE 16.23
Suggestions for Concerns Parents Commonly Encounter when Feeding Young Children

If a child refuses to try new foods or refuses to eat what is served …
- Remember, this is normal! Continue to offer each new food 10 to 12 times, twice per week
- Serve a new food with familiar ones
- Ask the child if she or he would like to try some of the new food. Be an effective role model and enthusiastically eat some of the new food yourself; comment to the child about how much you like it
- Involve the child in shopping for and preparing food, and in setting and clearing the table
- Remember, children may have strong likes and dislikes, but this does *not* mean they need to be served different foods than the rest of the family
- Allow the child to choose from the foods available at a meal what she or he will eat, but avoid forcing or bribing him or her to eat
- Include at least one food at each meal that you know your child will eat, but do not cater to a child's likes or dislikes. Avoid becoming a short-order cook. The less attention paid to this behavior, the better
- Avoid pressuring, coaxing, bribing, or nagging the child to eat
- Attempt to have family meals be as pleasant as possible by avoiding arguments and criticism. Use the child's developmental stage to determine expectations for manners and neatness while at the same time setting limits on inappropriate behaviors (such as throwing food)
- Let children determine when they are full and have had enough instead of insisting that they clean their plates
- Schedule meals at regular times. Avoid having a child get too hungry or too tired before mealtime. Snacks should be 1.5 to 2 h before meals

If a child is stuck on a food jag or wants to eat the same food over and over …
- Children may want to eat only one or two foods day after day, meal after meal; common food jags occur with peanut butter and jelly sandwiches, pizza, macaroni, and cheese, and dry cereal with milk
- Relax, and realize this is normal and temporary. Refuse to call attention to the behavior
- Continue to offer regular meals, but do not force or bribe the child to eat them
- Serve the food jag item as you normally would (maybe once or twice a week)

If a child refuses to eat meat …
- Tough meat is often difficult for children to chew. Offer bite-size pieces of tender, moist meat, poultry, or boneless fish
- Use meat in casseroles, meatloaf, soup, spaghetti sauce, pizza, or burritos
- Try other high-protein foods such as eggs, legumes, and peanut butter

If a child refuses to drink milk or drinks too little milk...
- Offer cheese, cottage cheese, yogurt, or pudding either alone or in combination dishes (such as macaroni and cheese, pizza, cheese sauce, banana pudding)
- Use milk when cooking hot cereals, scrambled eggs, macaroni and cheese, soup, and other recipes
- Offer flavored milks
- Use calcium-fortified juices

If a child drinks too much milk or juice …
- Offer water between meals to quench thirst
- Limit milk to one serving with meals or at the end of meals, and offer water for seconds

If a child refuses to eat vegetables and fruits …
- Offer more fruits if a child refuses vegetables, and vice versa
- Avoid overcooking vegetables; serve vegetables steamed or raw (if appropriate). Include dips or sauces (e.g., applesauce with broccoli or carrots)
- Include vegetables in soups, casseroles, and pizza
- Add fresh or dried fruit to cold and hot cereals
- Continue to offer a variety of fruits and vegetables

If a child eats too many sweets …
- Avoid using sweets as a bribe or reward
- Limit the purchase and preparation of sweet foods in the home
- Incorporate sweets into meals instead of snacks for better dental health. Also, by serving desserts (if any) with the meal, they become less important and cannot be used as a reward
- Decrease sugar by half in recipes for muffins, quick breads, cookies, etc.
- Try using fruit as dessert

Source: Adapted from Lucas, B and Ogata, B Normal Nutrition from Infancy through Adolescence, *Handbook of Pediatric Nutrition*, 3rd edition., (Samour, P Q. and, King, K, Eds.), Jones and Bartlett, Boston, 2005, p. 107–130.

SNACKS

Most young children fare best when fed four to six times a day due to their smaller stomach capacities and fluctuating appetites. Snacks should be considered as mini-meals that contribute to the total day's nutrient intake. Snacks generally accepted by many children include fresh fruit, cheese, whole-grain crackers, breads (e.g., bagels, tortilla, etc.), low-fat milk, raw vegetables, 100% fruit juices, sandwiches on whole-grain breads, peanut butter on crackers, or whole-grain bread, and yogurt.

CHOKING

Chewing and swallowing functions are not fully developed until 8 years of age; thus, precautions should be followed to avoid choking.[77] Foods to avoid because they are most likely to cause problems by becoming easily lodged in the esophagus include round candy, nuts, raw carrots, and popcorn. Other potentially problematic foods (e.g., hot dogs, grapes, and string cheese) may be modified by cutting them into small strips. Any food can cause choking if the child is not supervised while eating, if the child runs while eating, or if too much food is stuffed in the mouth. Thus, an adult should always be present when children are eating, children should sit down while eating, and the mealtime environment ideally should be free of distractions such as television, loud music, and activities. Allowing children to eat in the car is discouraged, because it can be difficult to help a choking child if the only adult present is driving.[77]

FEEDING SCHOOL-AGE CHILDREN AND ADOLESCENTS

During the school-age years (ages 6 to 12), steady growth is paralleled by increased food intake. Although children tend to eat fewer times a day, after-school snacks are common.

Studies indicate that eating breakfast is related positively to children's cognitive function and school performance, especially for undernourished children (for a review, see Pollitt[179]). Specifically, schoolchildren who had fasted both overnight and in the morning, particularly children who were nutritionally at risk, demonstrated slower stimulus discrimination, increased errors, and slower memory recall.[180] According to Grantham-McGregor, "*studies to date have provided insufficient evidence to determine whether children's long-term scholastic achievement is improved by eating breakfast daily.*"[181]

Although eating breakfast is important, research indicates that between 6 and 16% of elementary school children skip breakfast.[182–184] Furthermore, between 1965 and 1991, breakfast consumption declined significantly for each age group of children (1 to 4 years, 5 to 7 years, 8 to 10 years) and adolescents (11 to 14 years and 15 to 18 years), especially for older adolescents aged 15 to 18 years; breakfast was consumed by 90% of boys and 84% of girls in 1965, and by 75 and 65%, respectively, in 1991.[185] Children who skip breakfast tend to have a lower kcal intake and consume fewer nutrients than children who eat breakfast.[182,183] When breakfast nutrient consumption patterns of third graders were examined using 1991 baseline data from CATCH, a surprisingly large percentage of the sample (94% of the 1872 children from 96 public schools in four states) reported eating breakfast on the day of the survey;[182] of the 94% who ate breakfast, 80% ate at home, 13% ate at school, 3% ate at both home and school, and 4% ate breakfast elsewhere. During the second decade of life, breakfast skipping tends to increase, perhaps due to time constraints or lack of appetite in the morning.

Adolescents often experience newly found independence, busy schedules, searches for self-identification, dissatisfaction with body image, difficulty accepting existing values, and a desire for peer acceptance.[186] Each of these events may help explain changes in food habits of adolescents. Common characteristics of food habits of adolescents include an increased tendency to skip meals (especially breakfast and lunch), eating more meals outside the home, increased snacking (especially on candy), consumption of fast foods, and dieting.[186]

Insight regarding adolescents' perceptions about factors influencing their food choices and eating behaviors was provided from a 1999 study for which focus groups were conducted with 141 seventh or tenth graders (40% white, 25% Asian American, 21% African American, 7% multiracial, 6% Hispanic, 1% Native American) from two urban schools in St. Paul, Minnesota.[187] Factors identified by the adolescents as being most influential on their food choices included hunger and food cravings, appeal of food (primarily taste), time considerations of themselves and their parents, and convenience of food. Factors identified by the adolescents to be of secondary importance included food availability, parental influences on eating behavior (including the family's culture or religion), perceived benefits of food (e.g., for health, energy, body shape), and situational factors (e.g., place, time). Additional factors discussed included mood, body image concerns, habit, cost, media influences, and vegetarian lifestyle choices. A sense of urgency about personal health in relation to other concerns, and taste preferences for other foods were major barriers to eating more fruits, vegetables, and dairy products and eating fewer high-fat foods. Suggestions provided by the adolescents to help adolescents eat a more healthful diet included making healthful food taste and look better, making healthful food more available and convenient, limiting the availability of unhealthful options, teaching them good eating habits at an early age, and changing social norms to make it "cool" to eat healthfully. These results suggest that if interventions to improve adolescent nutrition are to be effective, they need to have adolescent input and address a broad range of factors, especially environmental factors (e.g., increased availability and promotion of appealing, convenient foods in homes, schools, and restaurants).[187]

Evidence of a strong positive association between frequency of family meals and quality of dietary intake among adolescents was provided by a 2003 study that included 4746 middle and high-school students of diverse racial and socioeconomic backgrounds who attended public schools in Minneapolis/St. Paul.[188] Variability in the frequency of family meals during the previous week was wide and ranged from never (14%), 1 or 2 times (19%), 3 or 4 times (21%), 5 or 6 times (19%), 7 times (9%), and more than 7 times (18%). Sociodemographic characteristics associated with more frequent family meals included socioeconomic status (high), mother's employment status (not employed), race (Asian American), school level (middle), and sex (boy). Frequency of family meals was negatively associated with soft drink consumption and positively associated with intake of calcium-rich foods, grains, fruits, and vegetables. Because of the important role family meals appear to play in promoting healthful dietary intake among adolescents, feasible ways of increasing the frequency of family meals need to be explored with adolescents and their families.[188]

The Minnesota Adolescent Health Survey (MAHS) was completed by more than 30,000 adolescents from 1986 through 1987. The MAHS was a comprehensive assessment of adolescent health status, health behaviors, and psychosocial factors; although it included relatively few nutrition-related items, a wealth of knowledge about adolescent nutrition was gained. Neumark-Sztainer et al. summarized the knowledge gained from a decade of subsequent analyses of data collected in the MAHS, as well as implications for working with youth.[189] Major concerns identified included overweight status, unhealthful weight-control practices, and high prevalence rates of inadequate intakes of fruits, vegetables, and dairy products. Risk factors for inadequate food intake patterns or unhealthful weight-control practices included low socioeconomic status, minority status, chronic illness, poor school achievement, low family connectedness, weight dissatisfaction, overweight, homosexual orientation among boys, and use of health-compromising behaviors. The results suggest a need for innovative outreach strategies that include educational and environmental approaches to improve adolescent eating behaviors. A critical issue that needs to be addressed is the validity of adolescents' self-reported behaviors.[189]

Story et al.[190] proposed an ecological model to help understand and explain the numerous and interacting influences on adolescent eating behavior. Four levels of influence described include individual or intrapersonal (such as biological and psychosocial), social environmental or interpersonal (such as peers and family), physical environmental or community settings (such as school, fast food restaurants, and convenience stores), and macrosystem or societal (such as social and cultural norms, mass media, marketing, and advertising). Interventions that address factors at these different levels of influence, as well as complement and build on each other, are needed to improve eating behaviors of youth.[190]

YOUTH RISK BEHAVIOR SURVEILLANCE — UNITED STATES, 2003 (YRBS 2003)

The Youth Risk Behavior Surveillance System (YRBSS) monitors six categories of priority health-risk behaviors among high-school youth in grades 9 through 12.[144] The YRBSS includes a national school-based survey conducted by the Centers for Disease Control and Prevention as well as state and local school-based surveys conducted by education and health agencies. A report was published in 2004 with results from the national survey, 32 state surveys, and 18 local surveys conducted in 2003; a total of 15,214 questionnaires completed by youth in 158 schools in 43 states and 22 large cities were usable.[144] Table 16.24 provides an overview of YRBS 2003 results overall and those with significant differences for the risk behaviors regarding fruit and vegetable consumption, milk consumption, at risk of overweight, overweight, perceived overweight, and attempts to lose weight or keep from gaining it; significant differences were evident by sex, race/ethnicity, grade level, and/or their interactions for each risk behavior included in the table.[144]

Data from YRBSS are being used to measure progress toward achievement of numerous national health objectives for 2010 as well as several of the leading health indicators.[144] Furthermore, YRBSS data are used by education and health officials at the national, state, and local levels to improve policies and programs to decrease priority health-risk behaviors among youth.[144]

HEALTH BEHAVIOUR IN SCHOOL-AGED CHILDREN STUDY: INTERNATIONAL REPORT FROM THE 2001/2002 SURVEY

The Health Behaviour in School-Aged Children Study is a unique cross-national research study conducted by an international network of research teams in collaboration with the World Health Organization (WHO) Regional Office for Europe.[191] The first survey was carried out in 1983 to 1984; since 1985, surveys have been conducted at 4-year intervals in an increasing number of countries. The target population for the study is young people attending school ages 11, 13, and 15. The aim was to increase understanding of young people's health, well-being, health behavior, and social context. The 2001/2002 survey was the sixth in the series and the most recent; it was conducted in 35 countries and regions including the United States, with approximately 1500 youth in each of the three age groups targeted in every country.[191] Youth were selected using a clustered sampling design, where the initial sampling unit was either the school class or the school. Results regarding eating habits indicated that the percentage of youth on average who eat breakfast every morning on school days was higher for boys at 69% than for girls at 60%, and decreased as age increased respectively from 11 to 13 to 15 years for both sexes (boys at 73, 68, and 64%; girls at 69, 57, and

TABLE 16.24

Results (Overall and those with Statistically Significant Differences) Regarding Dietary Behaviors, Overweight and Weight Control from the Youth Risk Behavior Survey, United States, 2003

Ate fruits and vegetables (defined as 100% fruit juice, fruit, green salad, potatoes [excluding French fries, fried potatoes, or potato chips], carrots, or other vegetables) ≥ 5 times/day during the 7 days preceding the survey:
  Overall (22%)
  Boys (24%) vs. Girls (20%)
  Black boys (26%) vs. Black girls (20%)
  Ninth-grade boys (25%) vs. ninth-grade girls (21%)
  Eleventh-grade boys (25%) vs. eleventh-grade girls (18%)
  Hispanics (24%) vs. Whites (21%)
  Black boys (26%) and Hispanic boys (27%) vs. White boys (21%)
  Ninth graders (23%) and tenth graders (23%) vs. twelfth graders (20%)
Drank ≥ 3 glasses/day of milk during the 7 days preceding the survey:
  Overall (17%)
  Boys (23%) vs. Girls (11%)
  White boys (27%) vs. White girls (13%)
  Black boys (16%) vs. Black girls (8%)
  Hispanic boys (17%) vs. Hispanic girls (9%)
  Ninth-grade boys (25%) vs. ninth-grade girls (14%)
  Tenth-grade boys (24%) vs. tenth-grade girls (12%)
  Eleventh-grade boys (23%) vs. eleventh-grade girls (10%)
  Twelfth-grade boys (18%) vs. twelfth-grade girls (9%)
  Whites (20%) vs. Blacks (12%) and Hispanic (13%)
  White girls (13%) vs. Black girls (8%)
  White boys (27%) and Black boys (16%) vs. Hispanic boys (17%)
  Ninth graders (20%) vs. twelfth graders (14%)
  Ninth-grade girls (14%) vs. twelfth-grade girls (9%)
  Ninth-grade boys (25%) vs. twelfth-grade boys (18%)
At risk for becoming overweight (defined as ≥ 85th percentile but < 95th percentile for BMI, by age and sex, based on reference data) using self-reported height and weight:
  Overall (15%)
  Blacks (18%) and Hispanics (17%) vs. Whites (13%)
  Black girls (21%) vs. White girls (12%) and Hispanic girls (16%)
  Hispanic boys (19%) vs. White boys (14%)
  Eleventh graders (17%) vs. twelfth graders (14%)
  Eleventh-grade girls (16%) vs. twelfth-grade girls (12%)
Overweight (defined as ≥ 95th percentile for BMI, by age and sex, based on reference data) using self-reported height and weight:
  Overall (12%)
  Boys (16%) vs. Girls (8%)
  White boys (14%) vs. White girls (7%)
  Hispanic boys (21%) vs. Hispanic girls (12%)
  Ninth-grade boys (18%) vs. ninth-grade girls (11%)
  Tenth-grade boys (16%) vs. tenth-grade girls (8%)
  Eleventh-grade boys (15%) vs. eleventh-grade girls (7%)
  Twelfth-grade boys (13%) vs. twelfth-grade girls (7%)
  Blacks (16%) and Hispanics (16%) vs. Whites (10%)
  Black girls (14%) and Hispanic girls (12%) vs. White girls (7%)
  Black boys (18%) and Hispanic boys (21%) vs. White boys (14%)
  Ninth graders (14%) and tenth graders (12%) vs. twelfth graders (10%)
  Ninth graders (14%) vs. eleventh graders (12%)
  Ninth-grade girls (11%) vs. eleventh-grade girls (7%) and twelfth-grade girls (7%)
  Ninth-grade boys (18%) vs. twelfth-grade boys (13%)

Considered themselves as slightly or very overweight:
  Overall (30%)
  Girls (36%) vs. boys (24%)
  White girls (39%) vs. White boys (24%)
  Black girls (26%) vs. Black boys (18%)
  Hispanic girls (36%) vs. Hispanic boys (27%)
  Ninth-grade girls (33%) vs. ninth-grade boys (23%)
  Tenth-grade girls (36%) vs. tenth-grade boys (23%)
  Eleventh-grade girls (37%) vs. eleventh-grade boys (24%)
  Twelfth-grade girls (39%) vs. twelfth-grade boys (24%)
  Whites (31%) and Hispanics (32%) vs. Blacks (22%)
  White girls (39%) and Hispanic girls (36%) vs. Black girls (26%)
  White boys (24%) and Hispanic boys (27%) vs. Black boys (18%)
  Twelfth graders (31%) vs. ninth graders (28%)
  Twelfth-grade girls (39%) vs. ninth-grade girls (33%)
Trying to lose weight:
  Overall (44%)
  Girls (59%) vs. Boys (29%)
  White girls (63%) vs. White boys (28%)
  Black girls (47%) vs. Black boys (23%)
  Hispanic girls (62%) vs. Hispanic boys (37%)
  Ninth-grade girls (54%) vs. ninth-grade boys (31%)
  Tenth-grade girls (62%) vs. tenth-grade boys (28%)
  Eleventh-grade girls (60%) vs. eleventh-grade boys (28%)
  Twelfth-grade girls (62%) vs. twelfth-grade boys (28%)
  Whites (45%) and Hispanics (49%) vs. Blacks (35%)
  White girls (63%) and Hispanic girls (62%) vs. Black girls (47%)
  White boys (28%) and Hispanic boys (37%) vs. Black boys (23%)
  Tenth-grade girls (62%) and twelfth-grade girls (62%) vs. ninth-grade girls (54%)
Ate less food, fewer calories, or foods low in fat during the 30 days preceding the survey to lose weight or to keep from gaining weight:
  Overall (42%)
  Girls (56%) vs. boys (29%)
  White girls (61%) vs. White boys (29%)
  Black girls (39%) vs. Black boys (22%)
  Hispanic girls (55%) vs. Hispanic boys (34%)
  Ninth-grade girls (53%) vs. ninth-grade boys (29%)
  Tenth-grade girls (58%) vs. nenth-grade boys (28%)
  Eleventh-grade girls (56%) vs. eleventh-grade boys (29%)
  Twelfth-grade girls (58%) vs. twelfth-grade boys (30%)

  Twelfth graders (44%) vs. ninth-graders (40%)
  Twelfth-grade girls (58%) vs. ninth-grade girls (53%)

Continued

TABLE 16.24
(Continued)

Exercised during the 30 days preceding the survey to lose weight or to keep from gaining weight:

Overall (57%)

Girls (66%) vs. boys (49%)

White girls (70%) vs. White boys (48%)

Hispanic girls (64%) vs. Hispanic boys (54%)

Ninth-grade girls (66%) vs. ninth-grade boys (50%)

Tenth-grade girls (69%) vs. tenth-grade boys (50%)

Eleventh-grade girls (65%) vs. eleventh-grade boys (49%)

Twelfth-grade girls (63%) vs. twelfth-grade boys (46%)

Whites (59%) and Hispanics (59%) vs. Blacks (48%)

White girls (70%) and Hispanic girls (64%) vs. Black girls (49%)

Hispanic boys (54%) vs. Black boys (46%)

Went without eating for ≥ 24 h during the 30 days preceding the survey to lose weight or to keep from gaining weight:

Overall (13%)

Girls (18%) vs. Boys (9%)

White girls (18%) vs. White boys (7%)

Black girls (15%) vs. Black boys (11%)

Hispanic girls (18%) vs. Hispanic boys (9%)

Ninth-grade girls (19%) vs. ninth-grade boys (11%)

Tenth-grade girls (19%) vs. tenth-grade boys (7%)

Eleventh-grade girls (20%) vs. eleventh-grade boys (8%)

Twelfth-grade girls (16%) vs. twelfth-grade boys (7%)

White girls (18%) and Hispanic girls (18%) vs. Black girls (15%)

Black boys (11%) vs. White boys (7%)

Ninth graders (15%) vs. twelfth graders (11%)

Eleventh-grade girls (20%) vs. twelfth-grade girls (16%)

Ninth-grade boys (11%) vs. tenth-grade boys (7%) and twelfth-grade boys (7%)

Took diet pills, powders, or liquids during the 30 days preceding the survey to lose weight or to keep from gaining it:

Overall (9%)

Girls (11%) vs. boys (7%)

White girls (13%) vs. White boys (7%)

Tenth-grade girls (11%) vs. tenth-grade boys (6%)

Eleventh-grade girls (13%) vs. eleventh-grade boys (8%)

Twelfth-grade girls (13%) vs. twelfth-grade boys (9%)

Whites (10%) and Hispanics (11%) vs. Blacks (5%)

White girls (13%) and Hispanic girls (12%) than Black girls (5%)

Vomited or took laxatives during the 30 days preceding the survey to lose weight or to keep from gaining weight:

Overall (6%)

Girls (8%) vs. boys (4%)

White girls (9%) vs. White boys (3%)

Tenth-grade girls (9%) vs. tenth-grade boys (4%)

Eleventh-grade girls (9%) vs. eleventh-grade boys (3%)

Twelfth-grade girls (7%) vs. twelfth-grade boys (4%)

White girls (9%) and Hispanic girls (10%) vs. Black girls (6%)

Source: Adapted from Grunbaum, J, Kann, L, Kinchen, S. et al, *Youth Risk Behavior Surveillance — United States*, 2003, In CDC Surveillance Summaries, MMWR 53 (No. SS-2), 2004; available at http://www.cdc.gov/mmwr/PDF/SS/SS5302.pdf (accessed March 7, 2006).

52%); the respective percentages of U.S. youth by age followed a similar pattern but were among the lowest across all countries at 65, 55, and 41% for boys, and 54, 40, and 29% for girls. On average, the percentages of youth who eat fruit every day was lower for boys at 30% than for girls at 37%, and decreased as age increased respectively for both sexes (boys at 36, 30, and 25%; girls at 41, 36, and 33%); the respective percentages of U.S. youth by age followed a similar pattern at 34, 29, and 21% for boys, and 33, 28, and 22% for girls. On average, the percentages of youth who eat vegetables every day was lower for boys at 28% than for girls at 34%, and decreased slightly as age increased for both sexes (boys at 31, 28, and 26%; girls at 36, 33, and 32%); the respective percentages of U.S. youth were similar at 29, 26, and 25% for boys, and 34, 33, and 31% for girls. On average, the percentages of youth who drink soft drinks every day was higher for boys at 32% than for girls at 25%, and increased slightly as age increased for both sexes (boys at 29, 33, and 35%; girls at 23, 27, and 26%); unfortunately, U.S. youth were among the leaders for daily soft drink consumption with percentages by age of 41, 48, and 47% for boys, and 38, 41, and 40% for girls. On average, approximately one-third of the youth eat sweets every day; however, the age and sex differences were negligible compared to those for the other food and drink items presented. Although results varied substantially across countries and regions, they indicate the need to improve the eating habits of youth, because on a daily basis, large percentages of youth worldwide skip breakfast, drink soft drinks, consume sweets, and do not eat fruits or vegetables.[191]

Eating Disorders

Increases in the incidence and prevalence of eating disorders in youth have made it increasingly important for health professionals to be familiar with the early detection and appropriate management of eating disorders.[192] Eating disorders are a common chronic illness in adolescent girls; the average onset of bulimia nervosa occurs between mid-adolescence and the late 20s, with a great diversity of socioeconomic status.[193] Optimal assessment and ongoing management of eating disorders requires an interdisciplinary team with professionals from medicine, nursing, nutrition, and mental health.[193] According to the YRBS 2003,

44% of adolescents in grades 9 to 12 reported trying to lose weight; furthermore, to lose weight or to keep from gaining weight, during the 30 days preceding the survey, risky behaviors were reported by 13% of adolescents in grades 9 to 12 who had gone without eating for ≥ 24 h, 9% who had taken diet pills, powders, or liquids; and 6% who had vomited or taken laxatives.[144] As indicated in Table 16.24, these risky behaviors were more commonly reported by adolescent girls than by adolescent boys in the YRBS 2003.[144] More information regarding eating disorders may be found in Chapter 56.

TEEN PREGNANCY

Per year, about 500,000 live births are reported for teenage girls, with more than one-tenth of the girls aged 15 years or younger.[186] The adolescent growth spurt is not complete until a few years after menarche; thus, fetal demand for nutrients could jeopardize maternal growth, especially in girls who mature early and in girls whose nutritional status is unsatisfactory prior to pregnancy.[186] Eating habits of adolescents (e.g., skipped meals, increased snacking, consumption of fast foods, and dieting) create a health risk for pregnant adolescents, because during pregnancy, nutritional needs for the fetus are met before needs of the mother are met.[166] However, pregnancy may provide a unique opportunity to help the adolescent girl understand and improve her eating habits. Adolescents who are pregnant should be cautioned against skipping meals, especially breakfast, because skipping meals may increase the risk of ketosis.[186] More information regarding teen pregnancy may be found in Chapter 13.

GROUP FEEDING

Many young children spend some or most days away from home in childcare centers, preschools, Head Start programs, or home childcare centers where they may eat up to two meals and two snacks daily. Federal and state regulations or guidelines exist for food service in childcare centers, Head Start programs, and preschool programs in public schools. Some centers participate in USDA-sponsored child nutrition programs. When choosing a childcare center or preschool, parents should be encouraged to consider the feeding program, including food variety, quality, safety, cultural aspects, and developmental appropriateness. A report by the American Dietetic Association provides guidance for nutrition professionals, health care practitioners, childcare providers, and parents regarding meal plans, food preparation and service, physical and social environment, and nutrition training and consultation for childcare settings.[194]

Children have acquired knowledge about eating and have developed food preferences by the time they enter school; however, their food preferences and consumption patterns are continually modified, because they eat daily.[195] More than 95% of children in the United States are enrolled in school, where they may eat one or two meals per school day.[196] One in ten children gets two of their three major meals in school, and more than half get one of their three major meals in school.[197] Thus, schools play a critical role in shaping children's food acceptance patterns and can, therefore, help improve their diet.[198] No other public institution has as much continuous and intensive contact with children during their first two decades of life than public schools.[199] School staff have a greater potential influence on a child's health than any other group outside of the home.[200] School-based programs offer a systematic and efficient means to improve the health of youth in America by promoting positive lifestyles.[201] Health promotion programs in schools have the potential to help prevent chronic diseases in U.S. adults.[200] Although school-based health programs may promote healthful lifestyles, classroom lessons are not sufficient to produce lasting changes in students' eating behaviors.[109] In fact, curriculum-based nutrition education in schools has had minimal effects on student's eating behavior.[202] Children's food preferences and consumption are influenced by the school environment through familiarity and reinforcement.[203] Students of public schools generally attend for 7 h a day, 180 days a year. Although students have options for obtaining food in schools, the most prominent federally supported programs are the National School Lunch Program and the School Breakfast Program.

NATIONAL SCHOOL LUNCH PROGRAM AND SCHOOL BREAKFAST PROGRAM

The National School Lunch Program (NSLP) is a federally assisted meal program that operates in approximately 100,000 public and nonprofit private schools and residential childcare institutions; it provides nutritionally balanced, free, low-cost, or full-price lunches to more than 28 million children each school day.[204] In 1998, Congress expanded the NSLP to include reimbursement for snacks served to children in afterschool educational and enrichment programs.[204]

The School Breakfast Program (SBP) is a federally assisted meal program that operates in nearly 80,000 public and nonprofit private schools and residential childcare institutions.[205] It provides nutritionally balanced, free, low-cost, or full-price breakfasts to more than 8 million children each school day.[205]

Regulations stipulate that NSLP lunches and SBP breakfasts meet the applicable recommendations of the Dietary Guidelines for Americans, which recommend no more than 30% of energy from fat, and less than 10% of energy from saturated fat.[204,205] In addition, regulations stipulate that a NSLP lunch provide one-third, and that a SBP breakfast provide a quarter, of the RDAs for energy, protein, iron, calcium, and vitamins A and C.[204,205] Although NSLP lunches and SBP breakfasts must meet federal nutrition requirements, decisions about what specific foods to serve and how they are prepared are made by local school food authorities.[204,205]

Any child at a participating school may purchase a NSLP lunch or a SBP breakfast.[204,205] Children from families with incomes at or below 130% of the poverty level are eligible for free breakfasts and lunches. Children from families with incomes between 130% and 185% of the poverty level are eligible for reduced-price breakfasts and lunches, for which students can be charged no more than 40 cents. Children from families with incomes over 185% of the poverty level pay a full price, but their meals are still subsidized to some extent. Although local school food authorities set their own prices for full-price meals, they must operate their meal services as nonprofit programs. The majority of the support provided by the USDA to schools in the NSLP and SPB comes in the form of a cash reimbursement for each lunch or breakfast served that meets NSLP and SBP requirements, respectively; in addition, schools participating in the NSLP receive donated commodities from the USDA for each meal served.[204,205]

USDA School Meals Initiative (SMI) for Healthy Children and Team Nutrition

The USDA issued the final *School Meals Initiative* (SMI) *for Healthy Children* regulations in 1995 after the *Healthy Meals for Healthy Americans Act of 1994* (P. L. No. 103-448, sec. 106, 1994) was passed; the SMI requires that meals in the NSLP and SBP meet the Dietary Guidelines for Americans, and thus SMI regulations define how the Dietary Guidelines are applied to school meals.[206]

Team Nutrition is USDA's integrated, behavior-based, comprehensive plan for improving school meals and promoting the nutritional health and education of school children in the United States; the goal of Team Nutrition is "*to improve children's lifelong eating and physical activity habits by using the principles of the Dietary Guidelines for Americans and MyPyramid.*"[207] The focal point for Team Nutrition is schools, and three strategies are used to change behavior — training and technical assistance, nutrition education, and school and community support. Training and technical assistance are provided to Child Nutrition food service professionals (e.g., NSLP, SBP) to help them serve meals that look good, taste good, and meet nutrition standards. Nutrition education for children and their parents encourages children to eat a variety of foods; eat more fruits, vegetables, and grains; eat lower-fat foods more often; get calcium-rich foods; and be physically active. Support for schools and communities focuses on behavioral outcomes for school and community leaders to adopt and implement school policies that promote healthy eating and physical activity, provide school resources adequate to achieve success, and foster school and community environments that support healthy eating and physical activity. Six communication channels utilized include food service initiatives, classroom activities, school-wide events, home activities, community programs and events, and media events and coverage. A network of public and private organizations is used to promote Team Nutrition, develop and disseminate materials, leverage resources, expand the reach of messages, and build a broad base of support; the network includes private sector companies and nonprofit and advocacy organizations including nutrition, health, education, industry, and entertainment groups.[207]

Team Nutrition has developed resources to help foster healthy school nutrition environments. For example, *Changing the Scene — Improving the School Nutrition Environment* is a tool kit that addresses the entire school nutrition environment from a commitment to nutrition and physical activity, pleasant eating experiences, quality school meals, other healthy food options, nutrition education, and marketing the issue to the public.[208]

School Nutrition Dietary Assessment Study (SNDAS) and SNDAS-II

During the 1991 to 1992 school year, the School Nutrition Dietary Assessment Study (SNDAS) collected information on school meals from a nationally representative sample of schools ($n = 545$) and 24-h recalls from approximately 3350 students from these schools.[209] Results from the SNDAS regarding dietary intakes of NSLP participants and nonparticipants[210] indicated that (1) NSLP participants had higher lunch intakes of vitamin A, calcium, and zinc, and lower intakes of vitamin C than nonparticipants who ate lunch; (2) NSLP participants' lunches provided a higher percentage of kcal from fat and saturated fat, and a lower percentage of carbohydrate than nonparticipants' lunches; (3) NSLP participants were more than twice as likely as nonparticipants to consume milk and milk products at lunch; and (4) NSLP participants also consumed more meat, poultry, fish, and meat mixtures than nonparticipants.

Results from the SNDAS regarding dietary intakes of SBP participants and nonparticipants[210] indicated that (1) SBP participants had higher average breakfast intakes of kcal, protein, and calcium, and derived a greater proportion of kcal from fat and saturated fat than nonparticipants; (2) SBP participants were three times more likely than nonparticipants to consume meat, poultry, fish, or meat mixtures at breakfast; and (3) SBP participants were also more likely than nonparticipants to consume milk or milk products at breakfast. The most surprising finding from the SNDAS was that the presence of the SBP in schools did not affect the likelihood that a student ate breakfast before starting school. Research is needed to determine the best ways to encourage elementary school students to consume healthful breakfasts. Universal school breakfast, which allows all students to eat school breakfast for free, has been advocated by some as a means to increase the percentage of children who eat breakfast. However, results from the SNDAS indicated that approximately 42% of children who were eligible for free or reduced price school breakfast did not eat it.[184] Perhaps scheduling the SBP for classes to eat as a part of regular school hours (similar to the NSLP) is what is needed to increase the percentage of children who eat breakfast.

During the 1998 to 1999 school year, SNDAS-II was conducted to provide information about how schools are progressing toward meeting nutrition standards of the *School Meals Initiative* (SMI) *for Healthy Children* (discussed previously in this chapter), and to provide information about menu planning practices used in school food service programs.[211] Data collection was primarily a mail survey completed by 1075 cafeteria managers who each provided data for meals served during a single week; in addition, a telephone interview was completed by 430 school food service directors, who provided supplementary information about district and school characteristics.[211] Results from SNDAS-II indicated that more than 1 in 5 elementary schools served lunches which met the SMI standard for ≤30% of calories from fat, and about 1 in 7 met the SMI standard for <10% of calories from saturated fat; for secondary schools, about 1 in 7 schools met each of the SMI standards. Even when the average lunch served to (i.e., selected by) students did not meet the SMI standards for fat and saturated fat, 82% of elementary schools and 91% of secondary schools offered options that were consistent with these SMI standards. Lunches served in elementary and secondary schools provided more than a third of the recommended levels for all targeted nutrients, except in secondary schools where they fell short of providing one third of the recommended level for calories. Breakfasts served were consistent with the SMI standard for calories from fat, and came very close to meeting the SMI standard for calories from saturated fat. Breakfasts served in both elementary and secondary schools provided one-fourth or more of the recommended levels for all targeted nutrients, but fell short of providing one-fourth of the recommended level of calories.[212] Results from SNDAS-II confirm the important role that school meals have towards helping youth achieve nutritional recommendations, and that more research is needed to determine how to encourage more youth to actually select the healthful options available in schools.

Feeding Children and Adolescents in Elementary, Middle, and High Schools

Research with upper elementary school children indicates that they prefer vegetables less than fruits.[92,213,214] Results from studies in the mid-1990s that conducted focus groups with ~600 fourth and fifth graders from Georgia, Alabama, and Minnesota indicate that children predominantly believe that vegetables taste "*nasty*"[214] and "*if it's good for you, then it must taste bad,*"[213,214] *which are related to statements made by adults such as "I don't care if they don't taste good; eat your vegetables because they're good for you."*[214] Research concerning the influence of a variety of psychological and social factors on children's fruit and vegetable consumption indicates that preferences are the strongest predictors.[93,215] This suggests that interventions that alter children's preferences for fruits and vegetables may be more effective in increasing their consumption than other strategies pursued to date. However, intensive, school-based interventions designed to specifically increase children's *preferences* for fruits and vegetables have had limited success.[79,216,217] Furthermore, although some elementary school programs have helped children to improve their dietary intake,[218] intensive interventions specifically designed to increase children's *consumption* of fruits and vegetables have had only limited success.[79,117,216,217,219–221] Changes in fruit consumption were better than changes in vegetable consumption in several of these studies,[79,117,220] which suggests that future interventions should focus solely on vegetables. Finally, schools may represent a potentially useful setting for preventing childhood obesity, but comprehensive elementary school programs in the United States such as CATCH and Know Your Body have not had major effects on children's body weight.[199,218,222]

School breakfast and lunch menus typically follow a cycle that repeats several times during the school year; thus, youth are provided with repeated exposures to healthful foods (e.g., fruits and vegetables).[223] However, schools also provide youth with repeated exposures to other foods (e.g., candy and pizza) which are used by school staff as rewards.[224] Unfortunately, some of the social contexts in which vegetables are available at school (e.g., "*If you eat your peas, then you can eat your cookie*") probably negatively affects preferences for them, thereby potentially decreasing their consumption.[223] In contrast, the social context in which candy and pizza are offered probably positively affects preferences for them, thereby potentially increasing their consumption.[223] These repeated exposures to vegetables and foods such as candy and pizza in negative and positive social contexts, respectively, may enhance the associative learning that help youth develop food consumption patterns that are inconsistent with nutrition guidelines[89] which recommend increased intake of vegetables but decreased sugar and fat intake. In addition, school staff may encourage youth to finish all of their food, regardless of whether or not they are still hungry,[225] which encourages them to disregard their own feelings of hunger and satiety.

Nevertheless, research also indicates the positive role schools can have in promoting healthful dietary intake by youth. For example, a 1997 study by Baranowski et al.[226] indicated the important contribution that school lunch makes in increasing children's consumption of fruits and vegetables. Differences in children's consumption of fruits and vegetables by meal and day of the week were assessed using 7-day food records completed by third graders (*n* = 2984) from 48 elementary schools in the Atlanta, Georgia area. Fruits and vegetables were most frequently consumed at weekday lunch, and participation in school lunch accounted for a substantial proportion of fruits and vegetables consumed at lunch. Few fruits and vegetables were consumed at breakfast or snack.[226]

Verbal encouragement by school food service staff during school lunch was associated with increased total fruit intake by children during school lunch according to process measures obtained during the elementary school cafeteria-based intervention in a 2004 study by Perry et al.[117] mentioned previously (see Table 16.22). Perry et al. concluded that school food service staff should be encouraged to play an active role in promoting fruit and vegetable consumption among children during lunch.[117]

The perceptions that adolescents have about school food service and nutrition programs were assessed in a 2000 study that surveyed 2566 adolescents in grades 6 through 8 (which covers ages 10 to 15 years).[227] Results indicated that the top predictors of satisfaction were school menus which include food that students like, quality of the food choices, and prices that are acceptable for what students get. Girls were more satisfied with school-prepared foods than boys, perhaps, because girls mature faster than boys during these years, which may be reflected as willingness to try new foods at an earlier age. Sixth-grade students were more satisfied than either seventh- or eighth-grade students. This may be because as adolescents move into the early teenage years, they become more independent from their parents and begin making their own decisions instead of eating school meals because their parents want or expect them to do so.[227]

In a 2002 study, a survey completed by 235 food service staff members from 16 high schools in Minneapolis/St. Paul and observations of 210 staff–student interactions, indicated that food service staff members could play an important role in encouraging healthful food choices by high-school students during school meals.[228] Although the majority of food service staff members indicated they were comfortable giving recommendations to students about which foods to purchase, only about one-fourth believed their suggestions were influential with students. Observations of staff–student interactions indicated that none of the staff spontaneously made food product recommendations to students to purchase. Only 16 students (8%) asked for a recommendation about their purchase; in each case, the staff person recommended a product, and the student purchased the product recommended by the staff person in 15 of these 16 interactions. The authors concluded that food service staff could be trained to encourage students to make healthful food choices at the point of purchase and thus enhance the dietary intake of adolescents.[228]

The effects of pricing strategies on sales of fruits and vegetables with adolescents in two high schools (1431 students at an urban school and 1935 students at a suburban school) were examined in a 1997 study by French et al.[229] Fruit, carrot, and salad purchases were monitored in each school cafeteria during an initial baseline period. Next, prices for these items were reduced by 50%, and sales were monitored. Finally, prices were returned to baseline, and sales were monitored for an additional 3 weeks. Results indicated that even though promotion was minimal, lower pricing significantly increased sales for fruit and carrots but not salads among high-school students. However, the magnitude of the intervention effects differed by school, which suggests that contextual factors (e.g., packaging, display) may modify pricing effects. These results imply that adolescents can be encouraged to select fruits and vegetables when the prices of these items are lowered, and that this may occur without measurable changes in the overall a la carte sales revenue or the number of meal pattern customers, which are both important considerations for school food service operations.[229]

The effects of pricing and promotion strategies on purchases of low-fat snacks from 55 vending machines in 12 secondary schools and 12 diverse worksites were examined in a 2001 study by French et al.[230] Low-fat snacks were added to vending machines, and four pricing levels (equal price, 10% price decrease, 25% price decrease, 50% price decrease) were crossed with three promotional conditions (none, low-fat label, low-fat label plus promotional sign). Throughout the 12-month intervention, sales of low-fat vending snacks were measured continuously. Results indicated that significant increases in low-fat snack sales by 9, 39, and 93% were associated with price reductions on low-fat snacks of 10, 25, and 50%, respectively, at both worksites and secondary schools. Promotional condition was independently but weakly associated with increases in low-fat snack sales. Average profits per vending machine were not affected by the intervention. These results indicate that lowering prices is a very effective method for promoting lower-fat snack purchases from vending machines in both adolescent and adult populations.[230]

LOCAL WELLNESS POLICIES IN SCHOOL DISTRICTS

Concern about food rewards as well as issues regarding competitive foods, vending machines, "pouring rights" issues, scheduling of meals and recess, time allowed for meals, and physical education programs, along with growing concern about childhood obesity have increased momentum for addressing school-based nutrition issues legislatively.[231] Congress now requires each local education agency participating in USDA Child Nutrition Programs to develop local wellness policies beginning in the 2006 to 2007 school year.[231] The USDA has reviewed and compiled web-based resources to help schools and communities develop and implement local wellness policies that promote healthy eating and physical activity; the USDA's local wellness policy website was placed on the Team Nutrition website (http://teamnutrition.usda.gov/Healthy/wellnesspolicy.html).[231,232] The dietary recommendations for children and adolescents from the American Heart Association and the American Academy of Pediatrics summarizes some strategies being implemented in many schools, as well as types of legislation under consideration to improve children's nutrition.[15,16]

The position of the American Dietetic Association is that "Educational goals, including the nutrition goals of the National School Lunch Program and School Breakfast Program, should be supported and extended through school district wellness policies that create overall school environments that promote access to healthful school meals and physical activity and provide learning experiences that enable students to develop lifelong healthful eating habits."[231] That position statement includes a

summary of selected resources for changing school nutrition environments as well as a sample of web-based resources to help with developing local wellness policies.[231]

The joint position of the American Dietetic Association, Society for Nutrition Education, and the American School Food Service Association is that "*comprehensive nutrition services must be provided to all of the nation's preschool through twelfth-grade students. These nutrition services shall be integrated with a coordinated, comprehensive school health program and implemented through a school nutrition policy. The policy should link comprehensive sequential nutrition education; access to and promotion of child nutrition programs providing nutritious meals and snacks in the school environment; and family, community, and health services' partnerships supporting positive health outcomes for all children.*"[233] According to the Centers for Disease Control and Prevention 1996 document titled "*Guidelines for School Health Programs to Promote Lifelong Healthy Eating*,"[198] students need exposure to healthful foods as well as the support of people around them, and teachers need to be discouraged from using food for disciplining or rewarding students.

In 2004, the American Academy of Pediatrics Committee on Nutrition issued a policy statement about nutrition concerns regarding soft drink consumption in schools.[234] Potential health problems associated with high intake of soft drinks include overweight or obesity because of the additional calories, displacement of milk consumption which results in calcium deficiency with an increased risk of osteoporosis and fractures, and dental caries and enamel erosion.[234]

CHILD AND ADOLESCENT TRIAL FOR CARDIOVASCULAR HEALTH (CATCH)

CATCH was a four-center, randomized field trial that evaluated the effectiveness of a school-based cardiovascular health promotion program.[235] A total of 5106 ethnically diverse students (who were third graders at baseline in the fall of 1991 and fifth graders at the end of the intervention in the spring of 1994) participated in 56 intervention and 40 control public schools in California, Louisiana, Minnesota, and Texas. Of the 56 intervention schools, 28 schools participated in a third-through-fifth-grade intervention, which included school food service modifications, enhanced physical education, and classroom health curricula; the other 28 schools received these components plus family education. Results at the end of the 3-year intervention indicated that the percentage of energy from fat in intervention school lunches fell significantly more (from 39 to 32%) than in control school lunches (from 39 to 36%) ($p < .001$). The intensity of physical activity in physical education classes increased significantly in intervention schools compared with control schools ($p < .02$). The percentage of energy from fat from 24-h recalls among intervention school students was significantly reduced (from 33 to 30%) compared with that among control school students (from 33% to 32%) ($p < .001$). Intervention students reported significantly more daily vigorous activity than controls (59 min vs. 47 min, $p < .003$). However, no significant differences were detected in blood pressure, body size, and cholesterol measures for students at the intervention schools compared to those at the control schools.[160]

A 3-year follow-up was conducted with 3714 students (73%) of the initial CATCH cohort of 5106 students.[236] End-point comparisons were made between students from intervention and control schools to determine whether changes at the end of intervention in grade five were maintained through grade eight. Results for eighth graders indicated that self-reported daily energy intake from fat remained lower for intervention than control students (31 vs. 32%, $p = .01$). Intervention students maintained significantly higher daily vigorous physical activity than controls ($p = .001$), although differences narrowed over time. Significant differences in favor of intervention students persisted at grade eight for dietary knowledge and dietary intentions, but not for social support for physical activity. No significant differences were noted for BMI, blood pressure, or serum lipid and cholesterol levels. In summary, follow-up of the CATCH cohort suggests that behavior changes from the intervention were sufficient to produce effects detectable 3 years later. However, differences between the intervention and control groups were narrowing in magnitude over time. Additional research is needed to determine how best to maintain the intervention effects long-term.[236]

A previous section titled "Trends in Consumption among Children and Adolescents" in this chapter provided results from longitudinal data on selected nutrient intake for a cohort of third, fifth, and eighth graders in CATCH.[51] Those results suggest that the diets of youth change over time, with negative trends more common in girls and in African American students.[51]

The CATCH Institutionalization Study provided insight into maintenance of CATCH school-level goals regarding the amount of total and saturated fat in school lunches 5 years post-intervention in former intervention schools ($n = 56$) and comparison schools ($n = 20$); 12 new schools with no exposure to CATCH during the previous 5 years served as controls.[237] Assessment of 5 consecutive days of school lunch menus from Spring 1999 indicated that the guideline for total fat ($\leq 30\%$ of energy) was met by 50% of former intervention schools compared to 10% of former comparison schools and 17% of unexposed control schools ($p < .005$). However, there were no significant differences in the percentage of schools meeting the guideline for saturated fat ($\leq 10\%$ of energy) with 45% of former intervention schools compared to 30% of former comparison schools and 17% of unexposed control schools ($p = 0.11$), and none of the schools met the guideline for sodium (≤ 1000 mg). The authors commented that the maintenance effect for total fat was probably due in part to policy changes from the SMI (discussed previously in this chapter) that occurred at the end of CATCH. Participation in the full CATCH program appeared to ensure that schools had trained food service staff who were better prepared to comply with federal standards for school meals.[237]

HEALTH PROMOTION AND DISEASE PREVENTION

Healthy People 2010 Nutrition Objectives for Children and Adolescents

Table 16.25 includes Healthy People 2010[238] nutrition objectives, as well as dental objectives related to nutrition, for children and adolescents, along with progress reviews[239] available for these objectives. The nutrition objectives address reducing weight, reducing growth retardation, improving eating behavior (e.g., increasing consumption of fruit, vegetables, grain products, and calcium products; decreasing consumption of fat, saturated fat, and sodium), reducing iron deficiency, and improving meals

TABLE 16.25
Healthy People 2010 Nutrition Objectives for Children and Adolescents with Progress Review

		Baseline 1988 to 1994	Progress Review 1999 to 2000	Target 2010
19-3	Reduce the proportion of children and adolescents who are overweight or obese.			
	Reduction in overweight or obese children and adolescents[a]			
	Children and adolescents age			
19-3a	6 to 11 years	11%	15%	5%
19-3b	12 to 19 years	11%	16%	5%
19-3c	6 to 19 years	11%	15%	5%
19-4	Reduce growth retardation (defined as height-for age below the 5th percentile in the age–sex appropriate population) among low-income children under age 5 years.[b]			
		6% (in 1997)	6% (in 2002)	5%
19-5	Increase the proportion of persons aged 2 years and older who consume at least two daily servings of fruit. [c]			
		28% (in 1994 to 1996)	—	75%
19-5(1)[c]	Fruit intake — average number of daily servings (age adjusted, ages 2 years and older).			
		1.6 (in 1994 to 1996)	1.5	NA
19-6	Increase the proportion of persons aged 2 years and older who consume at least three daily servings of vegetables, with at least 1/3 being dark green or orange vegetables.[d]			
		3 (in 1994 to 1996)	—	50
19-6(1a)[c]	Vegetable intake — proportion who consume ≥ 3 daily servings (age adjusted, ages 2 year and over)			
		49 (in 1994 to 1996)	—	—
19-6(1b)[c]	Vegetable intake — proportion who consume 1/3 or more servings from dark green or orange vegetables (age adjusted, ages 2 year and over)			
		8 (in 1994 to 1996)	—	—
19-6(2a)[c]	Vegetable intake — average number of daily servings (age adjusted, ages 2 years and over).			
		3.4 (in 1994 to 1996)	3.3	—
19-6(2b)[c]	Vegetable intake — average number of daily servings that are dark green or orange vegetables.			
		0.3 (in 1994 to 1996)	0.3	—
19-7	Increase the proportion of persons aged 2 years and older who consume at least six daily servings of grain products, with at least being whole grains.[d]			
		7% (in 1994 to 1996)	—	50%
19-7(1a)[c]	Grain intake — proportion who consume ≥ 6 daily servings (age adjusted, ages 2 years and over)			
		51% (in 1994 to 1996)	—	—
19-7(1b)[c]	Grain intake — proportion who consume ≥ 3 daily whole grain servings (age adjusted, ages 2 years and over)			
		7% (in 1994 to 1996)	—	—
19-7(2a)[c]	Grain intake — average number of daily servings (age adjusted, ages 2 years and over).			
		6.8 (in 1994 to 1996)	6.8	—
19-7(2b)[c]	Grain intake — average number of daily whole grain servings (age adjusted, ages 2 years and over).			
		1.0 (in 1994 to 1996)	0.9	—
19-8	Increase the proportion of persons aged 2 year and older who consume < 10% of calories from saturated fat.[d]			
		36% (in 1994 to 1996)	—	75%
19-8(1)[c]	Saturated fat intake — average percent of calories from saturated fat.			
		11% (in 1994 to 1996)	11%	—
19-9	Increase the proportion of persons aged 2 year and older who consume ≤30% of calories from total fat.[d]			
		33% (in 1994 to 1996)	—	75%
19-9(1)[a]	Total fat intake — average percent of calories from total fat.			
		33% (in 1994 to 1996)	33%	—

Continued

TABLE 16.25
(Continued)

	Baseline 1988 to 1994	Progress Review 1999 to 2000	Target 2010
19-10 Increase the proportion of persons aged 2 years and older who consume ≤2,400 mg of sodium daily.[d]			
	21%	—	65%
19-10(1)[c] Total sodium intake — average daily intake, mg (age adjusted, ages 2 years and over).			
	—	3,574 (in 2000)	—
19-11 Increase the proportion of persons aged 2 years and older who meet dietary recommendation for calcium. [d,e]			
	45%	—	75%
19-12 Reduce iron deficiency among young children and females of childbearing age.			
Reduction in iron deficiency[f]			
19-12a Children aged 1 to 2 years	9%	7%	5%
19-12b Children aged 3 to 4 years	4%	DSU	1%
19-12c Nonpregnant females aged 12 to 49 years	11%	12%	7%
19-15 (Developmental) Increase the proportion of children and adolescents aged 6 to 19 years whose intake of meals and snacks at school contributes proportionally to good overall dietary quality.			
21-1 Reduce the proportion of children and adolescents who have dental caries experience in their primary or permanent teeth.			
Dental Carries Experience			
21-1a Young children (aged 2 to 4 years), primary teeth	18%	23%	11%
21-1b Children (age 6 to 8 years), primary and permanent teeth	52%	50%	42%
21-1c Adolescent (age 15 years), permanent teeth	61%	59%	51%
21-2 Reduce the proportion of children and adolescents with untreated dental decay.			
Untreated Dental Decay			
21-2a Young children (ages 2 to 4 years), primary teeth	16%	20%	9%
21-2b Children (ages 6 to 8 years), primary and permanent teeth[g]	28%	26%	21%
21-2c Adolescent (ages 15 years), permanent teeth	20%	16%	15%
21-13 (Developmental) Increase the proportion of school-based health centers with an oral health component.			

Notes:

— means data are not available for progress review.

DSU means data do not meet the criteria for statistical reliability, data quality, or confidentiality.

[a] Defined as at or above the sex- and age-specific 95th percentile of BMI based on the revised CDC Growth Charts for the United States.

[b] Baseline has been revised according to the 2000 CDC Growth Chart.

[c] Objective measures with numbers in parentheses show supplemental data that were either included in the reporting of the baseline estimates or were recommended by an interagency group.

[d] The reporting of update estimates for Healthy People 2010 objectives 19-5 through 19-11 is pending the availability of additional days of dietary data from NHANES. However, mean intake estimates are shown as supplemental data for these objectives using 1-day diet recall data.

[e] Baseline has been revised according to a new algorithm on the contribution of antacids to total calcium intake.

[f] Defined as having abnormal results for two or more of the following tests: serum ferritin concentration, erythrocyte protoporphyrin, or transferrin saturation.

[g] Baseline has been revised.

and snacks at school. The dental objectives that are related to nutrition address dental caries, untreated dental decay, and school-based health centers with an oral health component. The progress reviews provide a venue for Federal agencies to report progress towards achieving the Healthy People 2010 goals and objectives for each of the 28 focus areas; two rounds of reviews are planned for the decade for each of the focus areas, with the first one held in June, 2002 and others following, usually in alphabetical order.[239] The first progress review for nutrition and overweight (focus area 19) was held in January 2004.[240] The first progress

review for oral health (focus area 21) was held in March 2004.[241] As indicated in Table 16.25, the progress reviews for nutrition and overweight, as well as for oral health, indicate that considerable work will be needed to achieve the Healthy People 2010 objectives.

5-A DAY FOR BETTER HEALTH PROGRAM

The *5-A Day for Better Health* program was instituted in 1991 to encourage Americans to eat five or more servings of fruits and vegetables every day. It originated as a public-private partnership between the National Cancer Institute (NCI) and the Produce for Better Health Foundation (which is a nonprofit foundation representing the fruit and vegetable industry), and included retail, media, community, and research components.[242] At the beginning of the program in 1991, a baseline survey with adults indicated that only 23% reported consuming five or more daily servings of fruits and vegetables.[243] The NCI funded nine studies in the spring of 1993 to develop, implement, and evaluate interventions in specific community channels to increase the consumption of fruits and vegetables in specific target populations; four of the nine projects used school-based programs to target children or adolescents.[244] Of these four projects, one targeted fourth graders and their parents,[221] two targeted fourth and fifth graders,[216,220] and one targeted high-school students.[219] Although all four interventions increased daily consumption of fruits and vegetables, the increases were small for three interventions and ranged from 0.2 servings for "*Gimme 5 Fruit, Juice, and Vegetables for Fun and Health*" in Georgia,[216] 0.4 servings for "*Gimme 5: A Fresh Nutrition Concept for Students*" in New Orleans,[219] and 0.6 servings for "5 A Day Power Plus" in Minnesota.[220] Increases were larger at 1.4 servings for "High Five" in Alabama, possibly because classroom lessons were delivered by trained curriculum coordinators instead of classroom teachers.[221]

In 2000, the *5 A Day for Better Health* program went under review by the NCI.[245] In response to recommendations in the Evaluation Report that resulted from this review, the National 5 A Day Partnership was established in 2001 to guide the 5 A Day program into the future with an expanded base of health-oriented government agencies, businesses, and nonprofits willing to commit significant resources to the 5 A Day effort. The *5 A Day for Better Health* program is the nation's largest public–private nutrition education initiative with 5 A Day coordinators in each state, territory, and the military. The goal of the partnership is to increase fruit and vegetable consumption to five servings a day for 75% of Americans by 2010. The partnership's steering committee is chaired by the president of the Produce for Better Health Foundation and includes representatives from the NCI, USDA, Centers for Disease Control and Prevention, American Cancer Society, Produce Marketing Association, United Fresh Fruit and Vegetable Association, National Alliance for Nutrition and Activity, Directors of Health Promotion and Education, American Heart Association, and Council of 5 A Day Coordinators.[245] More information is available at www.5aday.org.

3-A-DAY OF DAIRY

The *3-A-Day of Dairy* campaign was launched in January 2003 to help make people aware of the health benefits of including three servings of dairy in their daily diet.[246] The nutrition-based marketing and consumer education campaign is managed by the American Dairy Association/National Dairy Council, with monetary support from the dairy industry and professional support from the American Academy of Family Physicians, American Academy of Pediatrics, American Dietetic Association, and the National Medical Association.[247] The 3-A-Day logo may be found on packages of milk, cheese, and yogurt to indicate they are excellent sources of calcium.[246] More information is available at www.3aday.org.

FOOD SAFETY

The *2005 Dietary Guidelines for Americans* include a focus area regarding food safety, because it is estimated that about 76 million people in the United States each year become ill from pathogens in food.[14] Furthermore, a key recommendation in the food safety focus area is that young children (as well as infants, pregnant women, older adults, and people who are immunocompromised) avoid eating or drinking raw or partially cooked eggs or foods containing raw eggs; raw (unpasteurized) milk or any products made from unpasteurized milk; unpasteurized juices; raw or undercooked meat, poultry, fish, or shellfish; and raw sprouts.[14] Food safety messages are woven into appropriate sections of the consumer materials developed for *MyPyramid*.[170]

Fight Bac!® is a food safety education campaign of the Partnership for Food Safety Education that combines resources of the federal government, industry, and consumer organizations to conduct broad-based food safety education.[248] The multi-faceted Fight Bac!® campaign has materials for educators, the media, and consumers. The goal of Fight Bac!® is to educate consumers about four simple steps (clean, separate, cook, and chill) to take to fight foodborne bacteria and reduce the risk of foodborne illnesses.[248] Table 16.26 provides details regarding these four steps.

Children, adolescents, and adults of all ages need to understand the important role they play in decreasing the incidence of foodborne illnesses through proper hand-washing as well as safe food preparation and storage. According to the Hospitality Institute of Technology and Management,[249,250] hands should be washed with soap, a fingernail brush with soft bristles, and a large volume of flowing water to ensure adequate removal of pathogenic microorganisms (e.g., those from fecal sources) from fingertips and under fingernails. Fingernails should be neatly trimmed to less than 1/16 in. to make them easier to clean.

TABLE 16.26

Details Regarding the Four Steps of the Fight Bac!® Campaign

Clean: Wash hands and surfaces often

- Wash hands with hot soapy water before preparing food
- Wash hands with hot soapy water after using the bathroom, changing diapers, and touching animals
- For best results, use warm water to moisten hands and then apply soap; rub hands together for 20 s before rinsing thoroughly
- Wash dishes, utensils, cutting boards, and countertops in hot soapy water after preparing each food item and before preparing the next food item
- Use plastic or other nonporous cutting boards. Always wash cutting boards in the dishwasher or with hot soapy water after use
- Use paper towels to dry hands and clean kitchen surfaces. If cloth towels are used, wash them often in the hot cycle of the washing machine

Separate: Do not cross-contaminate

- Keep raw meat, poultry, and seafood separate from other foods in grocery carts when shopping, and grocery bags when bringing food home
- In the refrigerator, store raw meat, poultry, and seafood in sealed containers or plastic bags to prevent juices from dripping onto other foods
- Use one cutting board for raw meats and another cutting board for salads and other foods ready to be eaten
- Wash hands, cutting boards, dishes, and utensils with hot soapy water after they come in contact with raw meat, poultry, or seafood
- Do not place cooked food on a plate or serving dish that previously held raw meat, poultry, or seafood
- Sauce used to marinate raw meat, poultry, or seafood should not be used on cooked foods unless it is boiled before applying

Cook: Cook to proper temperatures

- Use a meat thermometer to measure the internal temperature of cooked meat and poultry to make sure the meat is cooked all the way through
- Cook roasts and steaks to at least 145° F (62.7°C); cook whole poultry to 180° F (82.2°C)
- Cook ground meat to at least 160° F (71.1°C). Do not eat ground beef that is still pink inside
- Cook eggs until the white and yolk are firm, not runny
- Do not use recipes or eat foods in which eggs remain raw or only partially cooked
- Cook fish until it is opaque and flakes easily with a fork
- When microwaving foods, make sure there are no cold spots by stirring and rotating food for even heating
- Reheat sauce, soup, and gravy to a boil. Heat other leftovers thoroughly to at least 165° F (73.8°C)

Chill: Refrigerate properly and promptly

- Use a refrigerator thermometer to be sure the temperature is consistently 40° F (4.4°C) or below
- Refrigerate or freeze prepared foods, perishables, and leftovers within 2 h or sooner of purchase or use
- Defrost food in the refrigerator, in an airtight package in cold water, or in the microwave, but never at room temperature
- Marinate foods in the refrigerator
- Divide large amounts of leftovers into small, shallow containers for quick cooling in the refrigerator
- Avoid packing the refrigerator because cold air must circulate to keep food safe

Source: Adapted from *Fight Bac!®* Partnership for Food Safety Education, www.fightbac.org (accessed on March 5, 2006).

When working with food, hand washing without the fingernail brush is sufficient, because the pathogen count is much lower. Table 16.27 describes the double and single methods of hand washing. Although young children may be encouraged to wash their hands long enough for them to sing their "A, B, Cs" slowly, the amount of lathering and the volume of water used to wash off the lathering appear to be more important than the length of time spent washing or the temperature of the water.[249,250]

DENTAL HEALTH

Nutrition is an integral component of oral health.[251] Nutrition and diet may affect the development and progression of diseases of the oral cavity. Likewise, oral infectious diseases, and acute, chronic, and terminal systemic diseases with oral manifestations, affect ability to eat and diet and nutritional status. When determining the cariogenic, cariostatic, and anticariogenic properties of the diet, the primary factors to be considered include the form of the food (liquid, solid or sticky, long-lasting), frequency of consumption of sugar and other fermentable carbohydrates, potential to stimulate saliva, nutrient composition, sequence of food intake, and combinations of foods.[251] One of the key recommendations regarding the focus area for carbohydrates in the *2005 Dietary Guidelines for Americans* is to "*reduce the incidence of dental caries by practicing good oral hygiene and consuming sugar- and starch-containing foods and beverages less frequently.*"[14] In 2005, the American Dietetic Association reaffirmed that "*fluoride is an important element for all mineralized tissues in the body. Appropriate fluoride exposure and usage is beneficial to bone and tooth integrity and, as such, has an important, positive impact on health throughout life.*"[252]

Because children of all ages eat frequently, snacks should emphasize foods that are low in sucrose, are not sticky, and that stimulate saliva flow, which helps limit acid production in the mouth.[253] Protein foods such as nuts and cheese may provide nutritional and dental benefits, because some protein foods are thought to have a protective effect against caries. When desserts are consumed, it is best if they are eaten with meals. Fruits, juices, and most bread/cereal products contain fermentable carbohydrate, so try to limit these foods to one serving in a snack, and other servings eaten with meals. Chewing sugarless gum after snacks containing

TABLE 16.27
Two Methods of Hand Washing

Double Wash Procedure (to be used to remove fecal pathogens and other pathogenic microorganisms from skin surfaces when entering the kitchen, after using the toilet, after cleaning up vomitus or fecal material, or after touching sores or bandages):

First wash using the fingernail brush:

● Turn on water so it flows rapidly at 2 gallons/min. (Flowing water, not the temperature of the water, removes the pathogens.) Place hands, lower arms, and fingernail brush under flowing water and thoroughly wet them

● Apply half to one teaspoon of hand soap or detergent (enough to produce a good lather) to fingernail brush

● Brush and lather hand surfaces gently with tips of bristles on fingernail brush under flowing water, especially fingertips and around and under fingernails. (Gently brush means without bending the bristles.) Build a good lather

● Continue to use fingernail brush under water until there is no more soapy lather on hands, lower arms, or nail brush. This takes about 10 s. Hazardous microorganisms in the lather are only removed to a safe level when all the soap is rinsed off the hands, arms, and fingertips with flowing water

● Place nailbrush on holder with bristles up so bristles can dry

Second wash without the nailbrush (~10 s required to complete):

● Apply half to one teaspoon of hand soap or detergent (enough to produce a good lather) to hands

● Under flowing water, massage the hands, fingertips, between the fingers, and lower arms to produce a good lather

● After lathering, rinse all of lather from hands, fingertips, hands, and lower arms in flowing water. This takes about 10 s. The volume of water used for rinsing hands, not the time of the wash or temperature of the water, is the critical factor

● Thoroughly dry hands and arms using disposable paper towels. Discard paper towels in waste container without touching container

Single Wash Procedure (to be used to remove normal low levels of pathogens before and after eating and drinking; after handling garbage; after handling dirty dishes or utensils; between handling raw and cooked foods; after blowing or wiping nose; after touching skin, hair, or soiled clothes; and as often as necessary to keep hands clean after they become soiled):

● Turn on water so it flows rapidly at 2 gallons/min. Place hands and lower arms under flowing water and thoroughly wet them

● Follow directions above for "Second wash without the nailbrush"

---

fermentable carbohydrate may benefit school-age children and adolescents. The efforts of dietary control are complemented by good oral hygiene. A fluoride supplement is recommended into the teen years if the water supply is not fluoridated.[253]

Early childhood caries (ECC), previously referred to as baby bottle tooth decay or maxillary anterior caries, is the major nutrition-related dental disease found in young children; ECC is defined as rampant dental caries in infants and toddlers.[251] The risk of ECC is increased by a combination of infant/child feeding practices and repeated sequential consumption of fermentable carbohydrates.[251] The primary cause of ECC is prolonged exposure of the teeth to a sweetened liquid such as milk, formula, juice, soft drinks, or other sweetened drinks.[253] This often occurs when a child is routinely given a bottle at bedtime or naptime; the liquid pools around the teeth during sleep, saliva flow decreases, and the child may continue to suck liquid over an extended period of time. Toddlers are also at high risk if they hold their own bottles or sippy cups and have access to them throughout the day. The primary strategy to prevent ECC is education. Parents and childcare providers should be encouraged to avoid putting infants or young children to sleep with bottles, and to use regular cups to offer juices and liquids other than breastmilk or formula.[253] Chapter 59 provides additional information regarding the prevention of dental caries in children and adolescents.

17 Health-Promoting Diet for Adults

Marsha Read

CONTENTS

INTRODUCTION

The normal diet for adults is based on the need to provide sufficient nutrients to sustain life and an appropriate balance of nutrient intake to support optimal health. The first *Surgeon General's Report on Nutrition and Health* in 1988[1] brought together a substantial body of research that documented that diet, aside from providing the essential nutrients for daily functioning, was a key factor with respect to chronic diseases such as coronary heart disease, cancer, diabetes, and obesity. The underlying premise of the various dietary guidelines/recommendations that have been developed has been to provide adequate nutrient intake while avoiding dietary patterns that might place an individual at greater risk for chronic disease. The following subsections describe the most commonly used dietary guidelines/recommendations, guidelines for counseling healthy adults, information on current food and nutrient consumption patterns of adults, and current research with respect to health implications of inappropriate macronutrient intake.

DIETARY RECOMMENDATIONS AND GUIDELINES

DIETARY GUIDELINES

Dietary guidelines have undergone several revisions from the late 1970s to the recently released Dietary Guidelines for Americans 2005.[2] The 1970s Dietary Goals provided recommendations with respect to energy intake, carbohydrate, fat, and sodium intakes.

Specific percentage of calories from carbohydrate and fat were put forth, 48% and 30% respectively. Cholesterol intake was recommended at 300 mg/day and sodium intake was recommended not to exceed 5 g/day.[3] The first set of the U.S. Dietary Guidelines was published in 1980[4]. The most recent version is the 2005 Dietary Guidelines for Americans. (See chapter 21 for details on these guidelines)

From the first edition of the guidelines to the current, the focus has been on a variety of foods to supply adequate nutrient intake, increase complex carbohydrate consumption, moderate fat intake, and moderate alcohol consumption if one drinks. The 2005 guidelines add emphasis on "Weight Management," as well as a section on "Food Groups to Encourage." Another new feature to the 2005 guidelines, in contrast to earlier versions, are recommendations for specific population groups under each major guideline and a glossary of terms and appendices and tables for more detailed information. As with previous versions, the guidelines continue to be based on current research.[5] A review of all iterations, including the 2005 Dietary Guidelines, is provided at: www.health.gov/dietaryguidelines/

THE FOOD GUIDE PYRAMID

The 1992 Food Guide Pyramid set forth recommendations for a pattern of daily food choices based on servings from five major food groups — bread, cereal, rice, and pasta; fruit; vegetable; milk, yogurt, and cheese; and meat, poultry, fish, dry beans, eggs, and nuts. The visual presentation as a pyramid was meant to convey that, from the five food groups, emphasis should be placed on those shown in the lower three levels/sections of the pyramid. The Food Guide Pyramid was also meant to be used in concert with the dietary guidelines, that is, to eat a variety of foods and balance the foods eaten with physical activity and either maintain or improve weight. Each food group suggests a range of servings. Selecting the lower number of recommended servings is estimated to provide approximately 1600 kcal, with the midrange providing approximately 2200 kcal, and 2800 kcal at the upper range.[6]

Cited advantages and disadvantages of the 1992 Food Guide Pyramid according to Kant et al.[7] include:

Advantages:
- The Pyramid depicted foods, rather than nutrients and numbers such as Recommended Dietary Intakes (RDAs) or Daily Reference Intakes (DRIs), which made it easier for consumers to relate to.
- The Pyramid was relatively simple, easy to read, and remember.
- The Pyramid food groups and recommended servings from each food group were likely to represent a variety of foods that can provide adequate nutrient intake.
- The Pyramid food groups allowed for personal choice within a food group and thus allowed for individual food choices.

Disadvantages:
- Applicability of the food groups within the Pyramid to alternate dietary patterns such as vegetarianism and ethnic food patterns was unclear.
- The Food Guide Pyramid did not address the dietary guideline regarding alcohol intake.
- The Pyramid did not address the consumption of combination foods such as pizza or stew. Lastly, dietary adequacy might not be obtained if individuals made poor choices within the Pyramid food groups.

The most recent version is titled "My Pyramid" (http://www.mypyramid.gov/tips_resources/menus.html). It is designed to reflect the diversity of nutrient needs and food patterns and to address the disadvantages noted for the 1992 edition. The latest version is intended to allow individuals to formulate a dietary pattern that is consistent with their age, gender, activity levels, etc. The pyramid shows six-color-coded grids that correspond to the food groups of grains, vegetables, fruit, milk, meat, beans, and oils. A chart is provided to give guidance as to amounts (by gender and age) recommended daily. In addition, a serving size is defined; lists of the variety of foods within each category are provided. The importance of physical activity to overall energy intake and healthy weight is depicted by the figure climbing the side of the pyramid. The food Pyramid Web site provides sample menus and provides for the inclusion of mixed dishes as part of the Pyramid serving recommendations. There is also information about vegetarian diets.

RECOMMENDED DIETARY ALLOWANCES, ESTIMATED SAFE AND ADEQUATE DAILY DIETARY INTAKES, DAILY REFERENCE INTAKE, AND DAILY VALUES

The most common reference standard for nutrient intake has been the RDA. This standard was first established by the Food and Nutrition Board in 1941, with the most recent edition in 1989.[8] The original intent was to review and revise the RDAs every four to five years, taking into account current research. The constructs used in formulating a specific RDA were: (1) an estimation of how much of each essential nutrient the average healthy person requires to maintain health, and how those requirements vary among people; (2) an increase in the average requirement to cover the needs of almost all members of the population, based on a bell curve distribution; (3) an increase in the RDA again to cover cooking losses and inefficient body utilization, as well as

provide for cases of greater nutrient need such as in pregnancy and infancy; and (4) use of scientific judgment in establishing the RDA. The following three central premises underlie the RDAs:

- The RDA is an amount intended to be consumed as part of a normal diet.
- The RDA is neither a minimal requirement nor an optimal level of intake, but instead it represents a safe and adequate level of intake based on current scientific knowledge.
- The RDA is most appropriately used as a nutrient intake guide applied to subgroups of the population, but can be used to estimate the probable risk of nutrient deficiency for an individual.

For nutrients that have scientific evidence providing support for their essentiality, but are insufficient to establish an RDA, there are Estimated Safe and Adequate Daily Dietary Intakes (ESADDIs). Most ESADDIs are shown as a range of intake values that represent the upper and lower limits of safe intake. ESADDIs are established for biotin, copper, manganese, and molybdenum.[8]

The current iteration of recommended intakes includes the DRI, which, in essence, replaces the RDA. DRI encompasses four types of nutrient recommendations for healthy individuals: Adequate Intake (AI), Estimated Average Intake (EAR), RDA, and tolerable Upper Intake Levels (UL).[9,10] AI is a nutrient recommendation based on observed or experimentally determined approximation of nutrient intake by a group (or groups) of healthy people when sufficient scientific evidence is not available to calculate an RDA or an EAR. The EAR is the average requirement of a nutrient for healthy individuals in which a functional or clinical assessment has been conducted and measures of adequacy have been made at a specified level of dietary intake. The EAR is an amount of intake of a nutrient at which approximately 50% of subjects would have their needs met and 50% would not. The EAR is intended to be used for assessing nutrient adequacy of populations and not individuals. The new RDA is the amount of a nutrient needed to meet the requirements of nearly all (97% to 98%) of the healthy population of individuals for whom it was developed.

An RDA for a nutrient should serve as an intake goal for individuals and not as a standard of adequacy for diets of populations. This is different than the previous or old RDA. UL values are established in cases where there is adequate scientific evidence to suggest an upper level of intake that is consistent with adverse or toxic reactions. The UL represents the maximum level of intake for a nutrient that will not cause adverse effects in most of the population ingesting that amount. The DRI can be found at: http://www.nal.usda.gov/fnic/etext/000105.html.

One other indication of dietary quality is the Health Eating Index (HEI). The HEI is intended to take into consideration compliance with the Dietary Guidelines for Americans as well as intake data to create a "score" that reflects how well American dietary patterns conform to the recommendations. The HEI score of American diets was 63.8, and can be interpreted as "needing improvement." [11]

WORLD HEALTH ORGANIZATION RECOMMENDATIONS

The World Health Organization (WHO) has also published diet recommendations with the goal of reducing risk for chronic disease.[12] WHO recommendations are expressed as a range of average daily intakes from lower to upper limits (Table 17.1).

Food Labels

Food labeling became mandatory in 1993 with the enactment of the Nutrition Labeling and Education Act (NLEA).[13] The legislation required food labeling on most foods with the exceptions of low-nutrient-dense foods such as coffee, spices, and

---

TABLE 17.1
WHO Dietary Recommendations

Total Energy: sufficient to support normal growth, physical activity, and
  body weight (body mass index = 20–22)
Total Fat: 15%–30% of total energy
Saturated fatty acids: 0%–10% total energy
Polyunsaturated fatty acids: 3%–7% total energy
Dietary cholesterol: 0–300 mg/day
Total carbohydrate: 55%–75% total energy
Complex carbohydrates: 50%–75% total energy
Dietary fiber: 27–40 g/day
Refined sugars: 0%–10% total energy
Protein: 10%–15% total energy
Salt: upper limit of 6 g/day (no lower limit set)

TABLE 17.2
Nutrition Facts Panel Information

Serving size (based on amounts commonly used)

Number of servings per container

Kilocalories per serving

Kilocalories from fat

Percentage Daily Value of total fat, saturated fat, cholesterol, sodium, total
 carbohydrate, dietary fiber, sugars, protein, vitamin A, vitamin C, calcium, and iron

Reference values for total fat, saturated fat, cholesterol, sodium, total carbohydrate,
 and fiber

Kilocaloric conversion guide for protein, fat, and carbohydrates

A more complete description of food labels can be accessed at:
http://www.fda.gov/opacom/backgrounders/foodlabel/newlabel.html

---

ready-to-eat foods prepared on site. Nutrition information remains voluntary on many raw foods. The nutrition facts panel on food labels provides information to help the consumer make more informed choices, including information on calories per serving, calories from fat, saturated fat and cholesterol, and protein among other nutrients (Table 17.2).

Daily Values (DVs) are used as standards in food labeling. DVs provide reference intake standards for nutrients that have an RDA, in which case they are referred to as reference daily intakes (RDIs), and for nutrients for which no RDA exists, in this case referred to as daily reference values (DRVs). DRVs are established for fat, saturated fat, cholesterol, carbohydrate, dietary fiber, sodium, and potassium. As a rule, the RDIs are greater than the RDA for specific nutrients and provide a large margin of safety. The term RDI replaces the term U.S. Recommended Daily Allowances (USRDAs), used earlier on food labels.[13]

AMERICAN CANCER SOCIETY AND NATIONAL CANCER INSTITUTE GUIDELINES

In the 1980s the American Cancer Society issued the following dietary guidelines aimed at reducing cancer risk within the populace[14] (http://www.cancer.org/docroot/PED/content/PED_3_2X_Diet_and_Activity_Factors_That_Affect_Risks.asp?sitearea=PED):

- Choose most of the foods you eat from plant sources.
- Eat five or more servings of fruits and vegetables every day (http://5aday.gov/).
- Eat foods from plant sources, such as breads, cereals, grain products, rice, pasta, or beans several times each day.
- Limit your intake of high-fat foods, particularly from animal sources.
- Choose foods low in fat.
- Limit consumption of meats, especially high-fat meats.
- Be physically active: achieve and maintain a healthy weight.
- Be at least moderately active for 30 min or more on most days of the week.
- Stay within your healthy weight range.
- Limit consumption of alcoholic beverages, if you drink at all.

The National Cancer Institute endorses the following guidelines, which reflect in large part the recommendations of the American Cancer Society:[15]

- Avoid obesity.
- Reduce fat intake to 30% of total energy intake as a start.
- Then consider a reduction closer to 20% of total energy intake if at high risk, such as a family history of cancer.
- Eat more higher-fiber foods, such as fruits, vegetables, and whole-grain cereals.
- Include foods rich in vitamins A, E, and C, as well as carotenoids, in the daily diet.
- If alcohol is consumed, do not drink excessively.
- Use moderation when consuming salt-cured, smoked, and nitrite-cured foods.

There are also guidelines set forth by the National Cholesterol Education Program and the American Heart Association (refer to the section on cardiovascular disease).

NUTRITION COUNSELING FOR ADULTS

DETERMINING ENERGY REQUIREMENTS

To plan a diet consistent with dietary guidelines, the nutrition professional should first determine the caloric requirements of a client. The total energy requirements will be the sum of the resting energy requirement, energy needs for physical activity, and the energy needed for the thermic effect of foods. To determine the total energy requirement:

Step 1: Estimating Appropriate Body Weight. The Hamwi method is a common tool to estimate appropriate body weight. For females, the estimation is 100 lb for the first 5 ft of height and 5 lb/in. over 5 ft; for example, a 5′6″ woman would be calculated as: (100 lb for the first 5 ft) + (5 lb/in. over 5 ft = 5 × 6 = 30) = 130 lb. For men the estimation is 106 lb for the first 5 ft of height and 6 lbs/in. over 5 ft; for example, a 6′0″ man's desirable weight would be calculated as: (106 lb for the first 5 ft) + (6 lb/in. over 5 ft = 6 × 12 = 72) = 178 lb.

Adjustments are made for a large frame (+10%) or a small frame (−10%).

Step 2: Estimating Energy Needs Based on Body Weight. To estimate energy needs, the first step is to determine resting energy requirements (REE). Although several methods exist to calculate energy requirements based on weight, the abbreviated or quick method is probably useful for normal adults. The abbreviated method is as follows:

For adults:

$$\text{Women} \quad \text{weight in kg} \times 23$$
$$\text{Men} \quad \text{weight in kg} \times 24$$

Step 3: Estimating Energy Required for Physical Activity.

- Once the REEs is determined, an estimate of the energy needs for physical activity must be made. Again, there are several alternatives to use to estimate caloric needs for physical activity. The Physical Activity Levels (PALs)[16] method is shown in the following text:
  - Seated work with no option of moving around and little or no strenuous leisure activity (PAL factor = 1.4 to 1.5 × REE)
  - Seated work with ability or requirement to move around but little or no strenuous leisure activity (PAL factor = 1.6 to 1.7 × REE)
  - Standing work (housework, shop clerks) (PAL factor = 1.8 to 1.9 × REE)
  - Significant amounts of sport or strenuous leisure activity (30–60 min 4–5/week) (PAL factor + 0.3 increment over 1.8 to 1.9 × REE)
  - Strenuous work or highly active leisure (PAL factor = 2.0 to 2.4)

Step 4: Add REE (Step 2) and Physical Activity (Step 3).

Step 5: Calculate Thermic Effect of Food.

- To estimate the thermic effect of food, multiply the sum of the REE and physical activity by 10% and add that amount to the total.
- Determining protein, fat, and carbohydrate requirements.
- After the total energy requirements are determined, the contributions from protein, fat, and carbohydrate need to be determined.
  - Protein: by converting grams of protein into its caloric equivalent, the percentage of protein from total calories can be derived.
  - Fat: the recommendation for fat is 30% or less of the total energy requirements.
  - Carbohydrate: the percentage of calories that will come from carbohydrate will be the difference between total energy requirements and the percentage of kilocalories from protein and fat.
- Estimates of Actual Intakes of Adults for Macronutrients

Nutrition monitoring has been going on since the early 1900s in the United States, when the USDA's Food Supply Series was initiated.[17] Currently, the National Nutrition Monitoring and Related Research Program (NNMRRP) is the umbrella for activities that provide regular information about the contribution that diet and nutritional status make to health.[18]

ENERGY INTAKE

With respect to total energy intake, caloric consumption of adult men consistently exceeds that of adult women by approximately 400 kcal. With one age group exception (ages >70 years), men consumed in excess of 2000 kcal on average, whereas women consistently averaged less than 2000 kcal/day. Fat was contributing slightly above the recommended 30% of kcal for

TABLE 17.3

Total Energy Intake and Sources of Energy for Adult Men and Women

			Sources of Energy Intake (Percentage of Total Kilocalories)

TABLE 17.4

Contribution (Percentage of Kilocalories) of Breakfast, Snacks, and Foods Consumed Away from Home to Total Energy Intake (1 Day) 1994–1996[a]

	Breakfast		Snacks		Foods Away from Home	
Age (Years)	M	F	M	F	M	F
20–29	14.2	16.0	18.2	17.0	40.0	34.3
30–39	15.5	16.9	15.5	16.9	31.4	26.6
40–49	16.3	16.9	15.5	17.1	29.4	25.4
50–59	18.2	19.1	15.4	15.2	26.7	23.0
60–69	20.9	19.9	15.0	15.1	20.0	17.6
70 >	23.8	23.0	12.2	12.3	14.2	12.5
20 <	17.1	18.2	15.7	15.9	29.4	24.5

M = males; F = females

[a] http://www.ars.usda.gov/SP2UserFiles/Place/12355000/pdf/Tbs1995.PDF

both men and women. Adult men derive somewhat more kilocalories from alcohol compared with women, but women are considerably higher in their carbohydrate intake than men. Men consumed not quite a third of their total energy intake from foods consumed away from home. The contribution of energy from foods eaten away from home is one-fourth of the total energy intake of women.

Men were more likely than women to consume a diet that met 100% of the RDA. Table 17.3 provides energy intake data on age cohorts for adult men and women based on the 1994 to 1996 Continuing Survey of Food Intake for Individuals (CSFII). Foods eaten away from home are contributing approximately 30% to 40% of total kilocalories consumed by young adults. The percentage of kilocalories derived from foods eaten away from home decreases with age (Table 17.4).

TOTAL PROTEIN, CARBOHYDRATE, AND FAT INTAKES

Protein intake is higher for adult men compared with adult women, yet the mean protein intake for both men and women exceeds the 1989 RDA (Table 17.5). With their higher mean protein intake, more men (80.2%) than women (69.2%) met 100% of the 1989 RDA for protein. As with total energy intake, foods consumed away from home contribute at least 25% of the overall protein intake. For men, 29% of the total protein intake was derived from foods eaten away from home. For women, this was 24.6%.

Total carbohydrate intake is higher for men than women, consistent with their higher total energy intake. The mean intake of carbohydrate for adult men was roughly 50 to 60 g/day higher than the adult female intake (Table 17.5).

The mean fiber intake per day for both men and women is below even the lower level of the recommended 24 to 70 g/day (Table 17.6).

TABLE 17.5
Percentage of Individuals Meeting 100% of the 1989 RDA for Energy (Two-Day Average)

Age (Years)	Males	Females
20–29	35.4	20.5

Fat intake for adult men and women, as with protein and carbohydrate intakes, reflects the gender differences in total energy intake pattern, that is, men consume more than women. The majority of adult men and women exceed the recommended 30% of energy from fat. Only 29.4% of adult men and 36.8% of adult women maintained a diet within the 30% recommendation. Foods eaten away from home contributed 30.9% of the total fat intake for men and 26.2% for women (Table 17.7). Cholesterol intake is considerably lesser in women than men. Women of all age groups consumed under 300 mg/day, whereas adult men generally consumed slightly more than 300 mg/day on average (Table 17.8 and Table 17.9). More adults consumed a diet consistent with the recommended cholesterol intake (55.1% of men; 79.4% of women) than that for total fat, where only 29.4% of adult men and 36.8% of adult women maintained a diet within 30% of the total energy intake. The intake of the types of fat — saturated, polyunsaturated, monounsaturated, and cholesterol — is presented in Table 17.8.

ENERGY AND OBESITY ISSUES

Overweight is associated with several chronic diseases — coronary heart disease, hypertension, non-insulin-dependent diabetes mellitus, and some forms of cancer.[19,20] WHO declared overweight as one of the current top ten health risks.[21] An estimated 300,000 Americans die every year from obesity-related conditions.[20] Obesity is also an associated risk factor for joint disease, gallstones, and obstructive sleep apnea.[22] In 1995, the economic cost associated with obesity was estimated at $62.3 billion.[23] The seriousness of obesity was further emphasized by the *Surgeon General*'s "Call to Action."[24]

From 1976–1980 and 1988–1994, the Centers for Disease Control and Prevention (CDC) reported an increase of 10% in the incidence of overweight in the American population.[25] Data from the CSFII, 1994 (http://www.ars.usda.gov/SP2UserFiles/

Place/12355000/pdf/Tbs1995.PDF), indicate that among adults, both men and women, the incidence of overweight is approximately 30% (Table 17.10). If the incidence of obesity continues to rise at current rates, it is predicted that, by 2230, every adult in the United States will be overweight.[26] Recent Behavioral Risk Factor Surveillance System (BRFSS) data indicate an increase in overweight in all demographic and geographic segments of the U.S. population.[27]

The prevalence of overweight/obesity among Americans is at odds with the perceptions of the importance of maintaining an appropriate body weight. When Americans were surveyed as part of the 1994 to 1996 USDA Diet and Health Knowledge survey, 68.1% of adult males over 20 years of age reported that "maintaining a healthy weight" was very important. For that same survey, 77% of the adult women over 20 years of age reported maintenance of a healthy body weight as very important. Given the importance Americans place on maintaining healthy body weight and given the high incidence of overweight/obesity, it is little wonder that Americans are forecast to spend some $54 billion on weight-loss products in 2009.[28] In addition, there are the myriad of weight-loss diets that appear on the market every year. In 1992, 33% to 40% of American women and 20% to 24% of American men reported being on a diet.[29]

FAD DIETS USED FOR WEIGHT-LOSS PROMOTION

While numerous fad diets come and go, several categories tend to remain fairly common. These include high-protein/low-carbohydrate diet regimens, low-fat diets, and very-low-calorie diets.

HIGH-PROTEIN/LOW-CARBOHYDRATE DIETS

These diets generally restrict the carbohydrate intake to 100 g/day or less. Restriction of carbohydrate leads to an initial mobilization of glycogen and then to gluconeogenesis and ketosis, all of which promote water loss and some lean tissue loss, which constitute a significant portion of the weight loss. Some of the low-carbohydrate diets promote high protein and consequently a higher animal fat intake, which is inconsistent with the dietary guidelines for fat intake.[30] Examples of high-protein/low-carbohydrate diets are Atkins' Diet Revolution, Calories Don't Count, and The Doctor's Quick Weight Loss Diet (Stillman's).

LOW-FAT DIETS

Generally these diets restrict fat intake to 20% or less of the total energy intake. Examples of these types of diets include the T-factor Diet, the Pasta Diet, the Pritikin Diet, and Fit or Fat. The average weight loss on these types of diets is 0.1 to 0.2 kg/week. With the limited fat intake, one drawback is the low-satiety factor, which may prompt noncompliant diet behavior.[31]

VERY-LOW-CALORIE DIETS

These diets arose during the 1970s and were known as protein-sparing modified fasts or liquid protein diets. These diet plans generally rely on liquid supplements to substitute for food intake and restrict the overall caloric level to less than 800 kcal/day. These diets may be indicated for moderately to highly obese patients (body mass index >30). The severe caloric restriction does lead to weight loss, but generally this level of caloric intake cannot be sustained, and weight regain is a potential problem. These diets may also lead to weight loss from lean tissue mass.[26,32]

THE ZONE DIET

The Zone Diet is a modified approach to the low-carbohydrate/high-protein type of diet. The diet promotes a macronutrient intake of 30% protein, 30% fat, and 40% carbohydrate. At this ratio of protein, fat, and carbohydrate, the author contends that insulin levels will remain stable, and this, in turn, dampens insulin's potential to promote the conversion of carbohydrates into fat and thereby to promote weight gain. The Zone Diet claims go beyond the promise of weight loss via insulin regulation into

the realms of disease prevention. The Zone Diet author argues that a high-carbohydrate/low-fat diet promotes an imbalance in "bad" eicosanoid production, which can lead to the development of such diseases as arthritis and coronary heart disease. However, there is no significant body of evidence to support the author's claims.[33,34]

Putting fad diets aside, an approach to weight management that recognizes overweight or obesity as a chronic condition and incorporates the elements of a healthy diet, exercise, and behavior modification is more likely to be successful over time, particularly in the maintenance of weight loss.[35]

The Weight Control Information Network (WIN) provides research-based educational resources to Americans on weight-loss strategies, etc. [36]

PROTEIN INTAKE — HEALTH ISSUES

The average American diet is very liberal with respect to protein intake. The RDA for protein for women aged 19 to 24 years is 46 g, and for men of the same age the RDA is 58 g.[7] In contrast, the average protein intake in grams for adults over 20 years in the United States is 63.8 g for women and 94.9 g for men. Some concern has been expressed over the long-term health consequences of excessive protein intake. There is some evidence in humans that a lifetime on a high-animal-protein diet (typical American diet pattern) can aggravate existing renal problems,[37] may increase the risk for cancer of the kidney,[38] and can accelerate adult bone loss.[39, 40] Lastly, higher animal protein intake is associated with higher-than-desirable levels of total fat and saturated fat intake.

A primary, although not exclusive, source of protein in the American diet is meat. The U.S. Food Guide Pyramid recommends between 5 and 7 oz of cooked lean meat or equivalent in meat alternatives per day. To be consistent with the Dietary Guidelines to reduce total fat and saturated fat in the diet, it would be helpful to consume lower-fat types of meat and perhaps a greater amount of some forms of meat alternatives such as soybean products. However, Americans derive the majority of their protein from meat. The 1994 to 1996 CSFII indicated that, for adult males over 20 years of age, the average daily intake of meat and meat alternatives was 6.4 oz, and for women the total was 3.9 oz. With respect to total intake, men were consuming sufficient amounts of meat and meat alternatives when compared with the recommended 5 to 7 oz. Women, on the other hand, fell below the minimum 5 oz recommended in the U.S. Food Guide Pyramid. With that in mind, data from the CSFII indicate that, regardless of meat servings, protein intake is meeting RDA requirements. Consequently, the source of protein may be an important consideration. The ratio of meat to meat alternatives is skewed heavily in favor of meat (beef, pork, lamb, and veal). In men, of the average 6.4 oz of lean meat and meat alternatives consumed daily, 2.7 oz are derived from lean meat and another 1.0 oz from the higher fat-sources of frankfurter and lunch meat. Consequently, 3.7 of the 6.4 oz, or 58%, were from meat. Only 1.5 and 0.5 oz, respectively, were contributed by poultry and fish. Among women, 1.4 oz of meat and 0.5 oz of frankfurter and lunch meat were consumed on a daily average. This accounts for 49% of the total meat or meat-alternative consumption. In women, poultry contributed 1.1 oz and fish 0.4 oz toward the total meat and meat-alternative intake. Some data suggest that an increase in fish and consequently in omega-3 fatty acid intake may be warranted from a cancer prevention perspective.[41]

PROTEIN SUPPLEMENTS

Protein supplements are quite common among athletes and physically active adults as part of their strength training regimens.[42] Bucci[42] argues that, although there is very little research that documents the benefits of protein supplementation, high-protein diets are safe. However, the amount recommended for endurance athletes is 70 g/day, and for strength athletes 112 to 178 g. The lower range of these recommendations is clearly within the normal intake of American men. This argues against the need for further protein supplementation.

AMINO ACID SUPPLEMENTS

Individual amino acid supplements have periodically been promoted on the market periodically. Again, a target audience has often been the athlete or physically active adult, with promises of enhanced performance. There is a dearth of research that can support such claims.[42] In addition, in 1992 a scientific panel convened to address the safety of amino acid supplements concluded that there is little research on which to support making amino acid supplement recommendations, and some amino acid supplementation (serine and proline) can have adverse health effects. Consequently, the panel concluded that no level of amino acid supplementation may be considered safe at this time.[43]

FAT INTAKE ISSUES — AMOUNT AND TYPE OF FAT

The fat intake in the adult American diet is slightly over the recommended 30% of the total energy. Data from the 1994 to 1996 CSFII reveals that approximately 25% of the total energy intake is contributed by discretionary fats such as cream, butter, margarine, cream

cheese, oil, lard, meat drippings, cocoa, and chocolate. Based on the average energy intake of adult males, discretionary fat contributes 614 kcal/day and, in females, 412 kcal/day. By cutting back on discretionary fat intake, American adults could conceivably lose 0.8 to 1.0 lb/week. This would be helpful in dealing with the adult obesity rates in the United States. Simple changes in discretionary fat intake could be helpful. For example, substituting mustard for mayonnaise on sandwiches gives 5 g (45 kcal) fat savings; ordering a hamburger instead of a cheeseburger gives 9 g(81 kcal) fat savings; using salt and pepper instead of sour cream on a baked potato gives 3 g (27 kcals) fat savings. Americans consume more saturated fat than is generally considered desirable. In addition, approximately 5% of the total fat intake in the American diet is contributed from *trans*-fatty acids.[44]

Biochemically, *trans*-fatty acids act similarly to saturated fatty acids, raising low-density lipoprotein (LDL) levels and decreasing high-density lipoprotein (HDL) levels.[45] Although their effect is not as great as saturated fat, they may contribute to a lipid intake pattern that raises the risk for coronary heart disease.[46] *trans*-Fatty acids are formed as a result of the hydrogenation process and are found in such food items as margarine, shortening, commercial frying fats, and many high-fat baked and snack foods. *trans*-Fatty acids also occur naturally in milk and butter because of the fatty acids synthesized by rumen flora in the rumen. Concern over *trans*-fatty acid intake has led some consumers to question whether they should forgo margarine and return to butter. Research suggests that saturated fat, as in butter, still exerts a greater negative effect on a person's lipid profile than do *trans*-fatty acids. However, use of less-hydrogenated forms such as tub rather than stick margarine may be beneficial.

However, some controversy has recently arisen with respect to the efficacy of low-fat diets with respect to breast cancer, colorectal cancer, and cardiovascular disease. Data from the Women's Health Initiative randomized, controlled dietary modification trial failed to demonstrate that low-fat diets could significantly reduce the risk for these conditions.[47–49]

CARBOHYDRATE INTAKE ISSUES

Two issues arise with respect to the carbohydrate intake of American adults — low-fiber intake and high-sugar intake. Low-fiber intake is associated with a higher incidence of such chronic diseases as heart disease,[50] cancer,[51] and diabetes.[52] At least partial explanation for the low-fiber intake is related to the low fruit and vegetable intake associated with the typical American diet. Data from the 1994 to 1996 CSFII indicated that for adult males the average total servings (based on the Food Guide Pyramid serving recommendations) of vegetables per day was four. For females, the average was three servings. For both men and women, one-third of the vegetable servings were accounted for by white potatoes. Average serving of fruit per day for both men and women was 1.5. This is just under the minimum Food Guide Pyramid recommendation for two servings per day. Another contributing factor to the low-fiber intake is the lack of whole-grain foods in the diet. Adult men consumed on average 8 servings of grain products per day, which is approximately midrange of the 6 to 11 servings of grain products recommended by the Food Guide Pyramid. Women averaged 6 servings from grain products. However, for both men and women, only one of these servings was from whole-grain products. The health benefits of a higher-fiber diet are addressed in other relevant sections of this handbook.

The other carbohydrate intake issue is the consumption of refined sugar, which contributes calories but little other nutritive value to the diet. The 1994 to 1996 CSFII data revealed that approximately 14% of the average energy intake for adult males was from added sugars. For women, the caloric contribution from added sugars was slightly higher at approximately 15%. Foods such as breads, cakes, soft drinks, jam, and ice cream were contributing to the discretionary sugar intake. In 1994 to 1996, soft drink consumption outpaced milk and coffee, and approximately 75% of the soft drink consumption is of the sugar-sweetened variety.[53]

During the last decade, consumption of snack foods such as cakes, cookies, pastries, and pies has increased 15%, likely contributing to the high intake of discretionary sugar.[52] These data are in contrast to the importance consumer's report they place on a diet moderate in sugar intake. A majority (slightly over 50%) of adults surveyed in the 1994 to 1996 CSFII indicated that it was very important to consume a diet moderate in sugar.

SUMMARY

Counseling the normal healthy American adult should focus on dietary intake patterns that promote health and reduce risk for chronic disease, that is, diet recommendations should follow the U.S. Dietary Guidelines. Therefore, consistent with the 2005 version of the U.S. Dietary Guidelines, the focus on nutrition counseling should be:

Adequate nutrients within calorie needs:
- Consume a nutrient-dense diet and adopt a healthy eating pattern as recommended in the USDA Food Guide or the DASH eating pattern.

Weight management:
- Calculate the appropriate weight for the individual.
- Consider the fat distribution pattern and take a more aggressive posture with individuals whose body fat distribution is more "apple" than "pear" shaped as that places them at higher health risk.

For individuals whose body weight is inappropriate, initiate counseling to assist in weight reduction. This may include calculation of appropriate caloric intake, recommendations of sources of caloric intake from the macronutrients of protein, fat, and carbohydrate, appropriate portion sizes to control caloric intake, and increases in physical activity.

Be physically active each day (see following guideline):

- *Physical Activity*: To reduce risk of chronic disease in adulthood, engage in 30 min of moderate intensity activity most days of the week. To manage body weight and prevent gradual weight loss, engage in 60 min of moderate intensity activity most days of the week. To sustain weight loss, participate in 60 to 90 min of moderate intensity activity daily.
- *Fats*: Keep total fat to 20% to 35% of total calories with less than 10% from saturated fats and a minimum of *trans*-fatty acids, as well as 300 mg of cholesterol or less per day.
- *Carbohydrates*: Choose fiber-rich sources of carbohydrates, and select and/or prepare foods with little added sugar or caloric sweeteners.
- *Sodium and Potassium*: Consume less than 2300 mg of sodium per day (<1 teaspoon of salt). Choose and prepare foods with low sodium content/added sodium/salt. Consume more potassium-rich foods such as fruits and vegetables.
- *Alcoholic Beverages*: For those who drink, do so in moderation (defined as one drink per day for women and two drinks per day for men). Alcohol should not be consumed by those at risk for addiction to alcohol, pregnant or lactating women, children and adolescents, and those whose medication contraindicates alcohol consumption.
- *Food Safety*: Practice safe food preparation methods — washing of hands, clean contact surfaces in the preparation of foods, cooking to the appropriate temperature, refrigeration/freezing of food for proper storage, and the avoidance of raw eggs, poultry, sprouts, unpasteurized milk, and juices.

CONTENTS

INTRODUCTION

Older adults are a diverse and growing population. They range in age from 65 to more than 100 years and include the very fit and the very frail. Older adults vary in ethnicity and culture, income, mobility, knowledge of nutrition and health, health behaviors, and health status. The main nutritional problems are poor food patterns and nutrient intake, as well as an increasing prevalence of overweight and obesity. The requirements for most essential vitamins and minerals do not change with advanced age, with only a few exceptions. Requirements for calcium and vitamin D are increased, and the recommended chemical form of vitamin B_{12} changes to crystalline. Decreased lean body mass and low physical activities are the main determinants of the low energy requirements of older people. Paradoxically, older adults are at increased risk for both overnutrition (overweight and obesity) and undernutrition, with the accompanying problems of nutritional deficiencies and weight loss. This chapter will review the primary nutritional problems associated with aging and recommend ways to improve the nutritional status of older people.

DEMOGRAPHICS OF AGING

The growth rate of elderly population (over 65 years) has rapidly increased during the last few decades and will continue to increase for the next 50 years in the United States.[1] The number of people over 65 was 36 million in 2003 and is expected to increase to nearly 55 million in 2020 and to 87 million in 2050.[1,2] About 88% of older adults were aged 65 to 84, and 12% were aged 85 and older in 2000 (Figure 18.1).[1] The majority of people aged 65 and more are white, followed by black and Hispanic (Figure 18.2).[2] Over 96% of older adults live in the community rather than in long-term care facilities.[2] Human life expectancy has increased dramatically during the last decades. Those who are 65 years old today can expect to live more than 18 additional years, and 85 year olds can expect more than 6 additional years.[2]

Aging is an inevitable process. The efficiencies of cell function and homeostatic mechanisms decrease with advanced age. In some organs, new cells replace old cells.[3] However, during each replication; the telomeres are shortened in chromosomes.

359
FIGURE 18.1   Projected population over 65 years of age in the United States: 2000 to 2050. (From U.S. Census Bureau, U.S. Interim projection by age, sex, race, and Hispanic origin, 2004.)
FIGURE 18.2   Projected population aged 65 and older in the United States by race: 2003 and 2050. (From Federal Interagency Forum on Aging and Related Statistics, Older Americans 2004: Key Indicators of well being, 2004.)

This incomplete replication is a part of the aging process and results in diminished cell functions.[4] Cells in some organs (e.g., reproductive organs) are not replaced by new cells. The numbers of cells are decreased as part of the natural aging process. However, aging itself may not cause visible diminished cell function. For example, physically and emotionally active older adults have better body function than less-active older adults.[3]

Most older adults have one or more age-related diseases. Common diseases are memory loss, cognitive impairment, depression, chronic disability, hearing impairment, visual impairment, osteopenia, Parkinson's disease, dental and oral health problems, gastrointestinal disorders, neoplasms, kidney disease, and paralysis (Table 18.1). Nutrition is a component in the prevention or management of most of this health conditions.[5] With increased human longevity, healthy aging, and well-being are important issues. Although certain age-related diseases are common in older adults, healthy diet, and lifestyle may delay the onset of diseases and diminish the severity of symptoms.[4,6]

NUTRITION ASSESSMENT

As will be discussed throughout this chapter, overnutrition and undernutrition are serious and prevalent problems in older people. Undernutrition and overnutrition can impair many aspects of the quality of life.[7] However, nutrition assessment is not routinely considered in geriatric assessments.[6] Nutrition assessment helps to prevent or improve health risks caused by malnutrition.[8] Most tools are questionnaires that collect information about food intake, ingestion and digestion, alcohol intake, mobility, age, presence of diseases, medical history, mental condition, family history, anthropometric measures, biochemical measures, and functional impairment.[9] Some tools are developed for hospital patients or for fragile older adults[9] and may not provide useful information for healthy, community-dwelling older adults who may have different nutrition problems and goals than frail individuals.[10] Nutritional assessment tools that meet criteria for reliability, validity, sensitivity, and specificity are recommended and are described elsewhere.[9]

DIET, LIFESTYLE, MORBIDITY, AND MORTALITY

Similar to other age groups, the older adult population does not consume the recommended amounts of key nutrients and food groups such as fruits, vegetables, whole grains, and milk products (Table 18.2). Healthy diets and body weight, along with other healthy lifestyle practices, delay disability, improve quality of life, and compress morbidity — that is, shorten the period of poor health and disability prior to death.[22–25] Abundant intakes of fruits, vegetables, and whole grains with adequate protein and essential fats are associated with the lowest risk of chronic diseases.[19,25–28] In midlife, for example, controlling body weight and cardiovascular disease risk factors, both of which are profoundly affected by food patterns and portion sizes, leads to better quality of life in the domains of physical and mental limitations, bodily pain, energy and fatigue, social functioning, and mental health later in life.[22,23] The combination of a healthy lifestyle and a "Mediterranean diet" reduced mortality from cardiovascular diseases, coronary heart disease, and cancer[25] and lowered blood pressure.[29] Men in the Baltimore Longitudinal Study of Aging who consumed ≥ 5 servings and fruits and vegetables daily and $\leq 12\%$ of energy from saturated fat were 76% less likely to die of cardiovascular disease and 31% less likely to die of any cause.[30]

Increasing health care costs and the personal burdens of chronic diseases caused by the global obesity epidemic are prompting serious evaluation of the roles of nutrition and other lifestyle factors in preventing and managing chronic diseases.[31] The Institute of Medicine (IOM) evaluated the role of nutrition in maintaining health for the Medicare population.[32] They emphasized that poor nutrition, inadequate nutrient intakes, and obesity are major problems, and the vast majority (86%) of older Americans have chronic conditions in which nutrition interventions have been shown to improve both health and quality of life. As part of a comprehensive management and treatment approach, nutrition therapy was recommended for dyslipidemia (high blood cholesterol and triglycerides), hypertension, heart failure, diabetes, and kidney failure. The IOM recognized the Registered Dietitian (RD) as the most qualified health professional to provide medical nutrition therapy, which includes individualized nutrition services and procedures to treat an illness, injury, or condition.

RISK FACTORS FOR POOR NUTRITIONAL STATUS

Many social, mental, physical, economical, and individual choice factors contribute to poor nutritional status (Table 18.3).[10,33] Hearing and visual impairments may cause social segregation due to difficulty in communicating with others. Physical disability may decrease mobility and limit daily activities, such as shopping for groceries and cooking meals.[6,34] Low income,[35,36] taking several medications,[37] eating alone, loneliness, bereavement, depression, and cognitive impairment,[38,39] cause poor nutritional status in the elderly. Oral health disorders may limit food intakes and choices because of chewing and swallowing difficulties. Therefore, diminished quantity and quality of food are concerns.[40–43] In addition to being homebound, residing in a nursing home or being hospitalized may also impair nutrition status.[33] Although older adults are less likely to be in poverty than children, poverty rates are high among older adults (10 vs. 17% in 2002).[2] Poverty increases the risk of having inadequate income for food, housing, health care, and other needs. Some older adults may have difficulty with transportation,[44] which could impair access to food.

HUNGER AND FOOD SECURITY

Incomes below poverty line increase the risk of food insufficiency, food insecurity, hunger, low intakes of calories, vitamins, and minerals, and low body weight.[35,36,45,46] For example, compared to older adults with sufficient food, those experiencing

food insufficiency were four times more likely to have a low body weight, consumed nearly 300 fewer calories each day, and consumed less protein, meat, and vegetables.[36] Older adults have low participation rates in food stamp programs and other federal, state, and local assistance programs.[35] Reasons include a lack of awareness of the programs, perception that the benefits are too low to be worth the effort of applying, reluctance to accept food assistance because of stigma associated with receiving public assistance, and a lack of transportation or physical mobility to reach the site of the program.[35] Residence in rural and urban areas can present problems related to food access. Older adults may not have transportation to the grocery store or may have physical impairments in their ability to shop, cook, or eat. Elder abuse or neglect also can interfere with the ability to obtain adequate food.

TABLE 18.3

Lifestyle and Socioeconomic Changes Affecting the Nutritional Status of the Elderly

Changes with aging include:
- Reduced income with retirement
- Insufficient funds for purchase of food
- Skipping meals
- Illness and increased medical expenses
- Loss of mobility
- Diminished acuity in sensory perceptions (hearing, vision, and taste)
- Inability to drive to doctor's appointments or to the grocery store
- Inability to prepare or store food
- Loss of balance
- Diminished self-esteem
- Social isolation

Diseases that are common in the elderly and impact on their nutritional status include:
- Senile dementia of Alzheimer's type, with cognitive impairment and memory
- Arthritis, with fractures and deformities
- Parkinson's disease, with rigidity and tremor
- Dental and oral health problems — problems with chewing
- Gastrointestinal disorders — swallowing difficulties
- Neoplasms, with hypercatabolism, anorexia, and cachexia
- Diabetes mellitus, with restrictive diets and medication interactions
- Renal insufficiency, with restrictive diets and dialysis treatment
- Paralysis, limiting mobility
- Depression, leading to anorexia

There are several ways to address the problem of food security.[45] Screening for food insecurity with tools that assess all the dimensions of food insecurity in older adults will improve identification of those in need. Screening and information about local food resources and food budgeting can be provided in many settings such as senior centers, public health programs, faith-based organizations, physician's offices, and hospitals.

UNDERNUTRITION, POOR APPETITE, AND WEIGHT LOSS

A physiological decrease in food intake called "anorexia of aging" occurs even in healthy older adults.[39,42] Weight loss is common and is associated with frailty, functional impairment, immune disorders, pressure ulcers, hip fractures, cognitive impairment, low quality of life, and increased mortality. Weight loss results in loss of muscle mass, which decreases energy needs. Physical activity helps maintain muscle mass, so physically active older people experience fewer declines in muscle mass. The digestion process in the stomach diminishes with advanced age, which leads to faster feelings of satiety and lower food intake. Also, changes in some hormones that sense satiety and changes in energy expenditure contribute to decreased food intake. The ability to adjust subsequent food intake after under- or overeating is impaired with advanced age. Sensing and responding to thirst is impaired, increasing the risk of dehydration.

Some chronic diseases are associated with negative energy balance (e.g., more energy is expended than is taken in) and weight loss.[42] Weight loss associated with low food intake is common in Alzheimer's disease. Energy needs are increased with congestive heart failure, chronic obstructive pulmonary disease, Parkinson's disease, and infections. Infectious diseases can increase energy needs and at the same time interfere with appetite. Low income,[35,36] taking several medications,[37] poor oral health and dysphagia (swallowing difficulties),[6,41,42] alcoholism,[39,47] eating alone, loneliness, social isolation, bereavement, depression, and cognitive impairment[38,39] are also risk factors for poor appetite, low food intake, malnutrition, and weight loss. Changes in taste and smell associated with aging, chronic health problems, and medications can interfere with appetite and the ability to enjoy food.[42]

Treatment for poor appetite, weight loss, and undernutrition is guided by a medical evaluation and recommendations and should involve the older adult, as well as their family members and caregivers.[38,39,48,49] Poor appetite and eating habits are not a normal part of aging. The goal is to improve oral intake, which can be facilitated by honoring food preferences at meals and

snacks, using stronger flavorings and seasonings, or substituting higher-calorie versions of familiar foods. Taste tests by the older individual can help identify nutritional supplements, such as liquids and bars that are most palatable and best tolerated in addressing poor appetite, weight loss, and undernutrition.

Families, caregivers, and the health care team needs to find a balance between the benefits and risks of therapeutic diets for older people experiencing poor appetite and weight loss. When medically appropriate, therapeutic diets should be liberalized for the undernourished older adult. Overly restrictive diets, such as those low in cholesterol, fat, salt, and sugar, may take much of the enjoyment out of eating. Therefore, these restrictions should be used with caution in those with poor appetite and unintentional weight loss. To maintain muscle mass and energy levels, it is vitally important that those with poor appetite and weight loss ingest adequate proteins, vitamins, and minerals from a variety of foods insofar as possible. Failure to consume protein will result in further deterioration of muscle mass, loss of strength, and poor recovery from illness.

BODY COMPOSITION, OBESITY, OVERWEIGHT AND CHRONIC DISEASE

Older adults are affected by the obesity epidemic.[48,50–55] The prevalence of overweight (BMI ≥ 25 to < 30 kg/m^2) and obesity (BMI ≥ 30 kg/m^2) among those aged ≥ 60 is 73.9% in men and 68.4% in women (National Health and Nutrition Examination Survey, NHANES, 1999–2000).[51] The prevalence of obesity among those aged ≥ 60 in men is 30.5% and in women is 34.7%.

In addition to weight gain, aging is associated with marked increases in total body fat and visceral fat increases and decreases in skeletal muscle.[55,56] This loss of skeletal muscle is called sarcopenia, and may be caused by low physical activity, changes in hormone function, resistance to insulin, and perhaps increased dietary protein needs.[56] The process of sarcopenia is accelerated by low physical activity, weight loss, and low protein intake. "Sarcopenic obesity" is a condition in which low muscle mass and high-fat mass coexist.[57] High-fat mass promotes a biochemical imbalance that promotes insulin resistance and further muscle loss, eventually leading to disability and obesity-related disorders (Figure 18.3).[57]

Overweight and obesity are associated with increased health care costs and numerous chronic disorders in older adults including hypertension, diabetes mellitus, metabolic syndrome, dyslipidemia, coronary artery disease, respiratory disease, and some types of cancers.[48,50,55,59,60] Depressive symptoms may accompany obesity. Of particular significance are the physical
FIGURE 18.3 (a) Changes in percentage of body fat by age and gender. (b) Changes in fat-free mass (kg) by age and gender. (From Schutz, Y. et al., *Int. J. Obes.*, 26: 953; 2002.)[58]

disabilities associated with overweight and obesity, such as impaired walking, traveling, shopping, and preparing food. Obesity may cause premature aging. For example, the prevalence of severe disability (having three or more impairments in activities of daily living) was 6% in those aged 51 to 60, which was similar to nonobese people aged 70 and older (7%).[50]

Although genetic predisposition is related to obesity, there are several modifiable risk factors for obesity such as environment, lifestyle, and behavioral issues. During middle age, many people experience weight gain that is associated, at least in part, with a sedentary lifestyle. Weight gain and a sedentary lifestyle might be accepted as a normal part of the aging process, which might cause older adults to make few efforts toward prevention.[48]

In the older adult, obesity appears to be associated with poor food choices, high intakes of fat and saturated fat, low intakes of fiber and micronutrients, and low blood levels of micronutrients.[61,62] Obesity also has been associated with poor vitamin D status, perhaps because of low vitamin D intakes or redistribution of vitamin D into the fat mass.[63] Thus, obese older adults are at risk for nutrient excesses (energy, fat, and carbohydrate) as well as nutrient deficiencies (protein, vitamins, and minerals).[61–63]

The American Society for Nutrition (ASN) and NAASO, The Obesity Society provided a technical review and position statement regarding obesity in older adults.[55] They noted that appropriate treatment for obesity in older adults is controversial, but current research shows that weight-loss therapy in obese older people improves physical function, quality of life, and the medical complications associated with obesity. Of the three treatment options, lifestyle intervention is the primary approach, while pharmacotherapy and surgery appear to have less support and higher complication rates. It is widely agreed that overweight or obese older adults should not gain additional weight, but weight loss cannot be broadly recommended or attempted without medical evaluation and supervision.[48,53,54,64] Thus, ASN and NAASO emphasize the importance of a thorough medical history, physical examination, medication review, and assessment of readiness to lose weight before initiating weight loss therapy.[55]

The value of medically supervised lifestyle intervention has been demonstrated.[55,64] For example, a medically supervised 3-month weight loss program was conducted in obese older women ($N = 18$, 16 non-Hispanic white, 2 African Americans, 60 to 75 years).[64] At baseline, there was an average of 3.2 comorbidities per participant, 72% had a history of hypertension, 39% had a history of dyslipidemia, 6% had a history of diabetes, 11% had elevated glucose, and 39% presented with a history of the metabolic syndrome. Participants took an average of more than seven medications. Women met with a bariatric physician at the beginning and end of the intervention and had eight 30-min counseling sessions with a dietitian. This intervention emphasized prudent diet, behavior modification, and physical activity (primarily walking). Participants were advised to take multivitamins, as well as calcium and vitamin D supplements to help prevent the bone loss that may accompany weight loss. After the intervention, these women had decreased body weight (4.3 kg), BMI, fat-free mass (muscle), fat mass, diastolic blood pressure, total cholesterol, triglycerides, improved physical performance and vitality, and increased step counts.[64] Given the overall disease history of these obese women, it is clear that medical supervision is required. In agreement with others,[53–55] Jensen et al.[64] emphasized that management of weight loss in older adults should be guided by an evaluation of the potential risks and benefits for each individual. It was also emphasized that the preservation of strength and flexibility, rather than weight loss, might be a better goal than weight reduction in the obese and frail older adult.

NUTRIENT REQUIREMENTS AND INTAKES

The authoritative sources of nutrient recommendations for older adults are the Dietary Reference Intakes[65] and the Dietary Guidelines for Americans.[19] Recommended intakes vary with age and gender (Table 18.2 and Table 18.4). The low intake of several key nutrients and food groups shows a great need for nutrition education and health promotion targeted to older adults (Table 18.2). Compared to younger people, nutrient requirements are not uniformly increased or decreased. Aging decreases energy needs because of the loss of muscle mass and low physical activity. Iron needs are decreased in women because of the cessation of menstruation. The increased need for calcium is related to decreased absorption efficiency, and the increased recommendation for vitamin D is related to decreased sun exposure and skin synthesis.

DIETARY SUPPLEMENTS

Dietary supplements include vitamins, minerals, herbs and other botanicals, amino acids, and other substances. Dietary supplement use is high among older adults — about 40% in women and 52% in older men.[66] Non-Hispanic black and Mexican Americans are less likely to use dietary supplements than non-Hispanic whites.[66]

Some nutrient-containing dietary supplements are recommended for older adults by the Dietary Guidelines and other reliable sources.[67] Recommended supplements include vitamin B_{12}[19] and vitamin D[19,67] from fortified foods or supplements, and calcium supplements for those not consuming adequate calcium from dietary sources.[67] While typical foods can be consumed to meet the dietary requirements for vitamin B_{12} and calcium, it is unlikely that those foods will be fortified to the high levels needed to meet the recommendation of 1000 IU of vitamin D daily. It has been recognized for several years that older adults are particularly vulnerable to deficiencies of vitamin B_{12}, vitamin D, and calcium,[68] so these three nutrients will be discussed in the next sections.

TABLE 18.4
Vitamin and Mineral Recommendations for the Elderly (Recommended Dietary Allowances, Adequate Intakes or Dietary Guidelines for Americans)

	Males (Age in Years)		Females (Age in Years)	
	51 to 70	> 70	51 to 70	> 70

Vitamin B_{12}

Vitamin B_{12} is essential for cognition, the nervous system, vascular health, and red blood cell synthesis.[69] Poor vitamin B_{12} status has been linked to depression in some studies.[70] Poor vitamin B_{12} status is prevalent among older adults (5% to 20%)[69] and is particularly high among recipients of home delivered or congregate meals.[71] Vitamin B_{12} deficiency among these vulnerable elders was associated with poor cognition.[71,72] The prevalence of vitamin B_{12} deficiency increases with age, mainly because of decreased ability to digest the natural chemical form of vitamin B_{12} found in meat, poultry, fish, and dairy foods.[69] About 10 to 30% of older adults have atrophic gastritis, which is caused by infection of the stomach with *Helicobacter pylori* and subsequent atrophy of the cells in the stomach that secrete acid and digestive enzymes needed for the digestion and absorption of vitamin B_{12}.[69] Protein-bound vitamin B_{12} from animal foods requires these digestive enzymes, while the crystalline form does not. Crystalline vitamin B_{12} from fortified foods and dietary supplements is believed to be normally absorbed in those with atrophic gastritis. About 1 to 2% of older adults have pernicious anemia, which is a loss of the intrinsic factor needed for intestinal absorption of vitamin B_{12}. Under medical supervision, vitamin B_{12} status in these individuals is maintained by monthly injections of vitamin B_{12} or daily oral doses of 500 to 2000 μg.[73]

Similar to the Dietary Reference Intakes, the Dietary Guidelines recommends that the RDA for vitamin B_{12} (2.4 μg/day) be met from crystalline sources such as a vitamin B_{12}-containing fortified foods or supplements. Crystalline vitamin B_{12} is in many, but not all, fortified breakfast cereals and multivitamin supplements. The Daily Value for vitamin B_{12} is 6 μg;[74] therefore, a single serving of a vitamin B_{12}-containing food and supplement with at least 40% of the Daily Value would meet the RDA for vitamin B_{12}. Several studies show that older adults consuming between 9 and 50 μg of vitamin B_{12} daily, often found in

multivitamins marketed to older adults, have improved vitamin B_{12} status.[46] There is no Upper Level for vitamin B_{12}, and it is generally considered nontoxic.

Vitamin D

The 2005 Dietary Guidelines for Americans recommends that older adults consume 1000 IU (25 μg) daily of vitamin D, which is a substantial increase above the Adequate Intake (50 to 70 years: 400 IU; >70 years: 600 IU).[11] There is considerable interest in vitamin D, which was the subject of two recent symposia.[75,76] Adequate vitamin D status is needed for optimal calcium absorption,[19] and poor vitamin D status has been linked to numerous health conditions.[75,76] There is evidence from randomized control trials that vitamin D or calcium supplements decrease the risk of falls and bone fractures.[77–82]

Vitamin D comes from diet, supplements, and skin synthesis. Older adults, as well as people with dark pigmented skin or people who use sunscreen properly, have low synthesis of vitamin D precursors in the skin, even in sunny areas of the United States such as southern Florida.[83,84] People living at higher altitudes in the northern United States are particularly at risk for vitamin D deficiency. In addition to low skin synthesis, darker skinned ethnic/racial groups may be at increased risk of poor vitamin D status because of lower intakes of dairy foods and vitamin D containing supplements, as well as from obesity which may lead to less time spent in the sun or sequestration of vitamin D in the fat mass.[84]

The best marker of vitamin D status from oral intake and skin synthesis is serum 25-hydroxyvitamin D. Optimal serum 25-hydroxyvitamin D may be as high as 80 nmol/L based on randomized control trials of vitamin D supplementation and bone fractures and minimization of parathyroid hormone.[85] Mean concentrations of serum 25-hydroxyvitamin D are well below 80 nmol/L, particularly in darker-skinned older individuals.[86] In NHANES III, concentrations among older non-Hispanic whites, Hispanics, and non-Hispanic blacks in men were 76, 66, and 53 nmol/L, respectively, and in women were 64, 59, and 47.[86]

It is very difficult to meet vitamin D recommendations from food alone, so supplements are needed. The amount of supplement needed depends on the dietary intake of vitamin D. Salmon has about 324 to 624 IU vitamin D per 100 g, and canned tuna has 236 IU vitamin D per 100 g, and the average among the 26 fish products was about 300 IU per 100 g.[87] Milk has 100 IU per cup. Most other vitamin-D-fortified foods have less than 40 IU of vitamin D per serving. The Upper Level of vitamin D is 2000 IU daily, so older adults should carefully read the labels on supplements to ensure staying below the Upper Level. This will be particularly important if the supplement industry markets higher potency vitamin D supplements than those currently available.

Calcium

Calcium is most well-known for its role in bone health and is required for many other essential functions.[11,19] Diet provides only 55 to 66% of the recommended amounts of calcium (Table 18.2). The Dietary Guidelines recommend food sources of calcium, but does not mention calcium supplements. The Surgeon General's report on bone health and osteoporosis provides an algorithm to calculate calcium intake from the diet,[67] which can then be used to determine the amount of calcium, if any, needed from supplements. For older adults, they suggest starting with a baseline amount of calcium of 290 mg, which is the average of amount of calcium from non-calcium-rich foods, then adding 300 mg for each 8-ounce serving of milk or equivalent serving of other calcium-rich foods (e.g., yogurt, cheese, calcium-fortified juice). The shortfall can be obtained from supplements. Careful labeling reading should ensure that the Upper Level for calcium 2500 mg daily is not exceeded.

Antioxidant Supplements

The United States Preventive Services Task Force (USPSTF)[88] concluded that there is insufficient evidence to recommend for or against the use of vitamin A, C, or E supplements, multivitamins with folic acid, or antioxidant combinations for prevention of cancer or cardiovascular disease. The USPSTF did recommend against using supplements of β-carotene for prevention of cancer or cardiovascular disease because of adverse outcomes in some people such as heavy smokers.

Nonnutrient Supplements

The top ten nonnutrient supplements in order of use are Echinacea, ginseng, ginkgo biloba, garlic supplements, glucosamine, St. John's wort, peppermint, fish oils/omega-3 fatty acids, ginger supplements and soy supplements.[89] Very few of these supplements have been systematically reviewed for safety and efficacy, such as by the Agency for Healthcare Research and Quality or the Cochrane Review system. Such reviews have shown that glucosamine is both effective and safe for relieving some symptoms of osteoarthritis.[90] St. John's wort may be effective for short-term treatment of mild to moderately severe depressive disorders.[91] Some studies show that ginkgo biloba modestly improves cognition and function in those with cognitive impairment or dementia.[92] Garlic modestly improves blood lipid profiles, but has little effect on other indices of cardiovascular health or cancer.[93] Fish or fish oils containing omega-3 fatty acids reduce all cause mortality and some cardiovascular disease outcomes.[94]

CAUTIONS ABOUT DIETARY SUPPLEMENTS

Older adults must use dietary supplements carefully (see Chapters 70 – 75), treat them like any other medication, and inform their physicians about the products they are using.[95] Most supplements contain active ingredients that may interfere with several medications, making them stronger or weaker. For example, garlic, ginkgo, Echinacea, ginseng, St. John's wort, and kava are all suspected of interacting with medications, especially anticancer drugs and blood thinners.[96–98] Some supplements promote bleeding or interfere with other aspects of surgery and recovery.

Food Safety

Although the most important food safety problem is microbial foodborne illness from bacteria and viruses, there are also food safety risks from parasites, toxins, and chemical and physical contaminants in foods. The food safety recommendations in the 2005 Dietary Guidelines are based on the FightBAC principles of safe food handling practices (clean, separate, cook, and chill). Two specific recommendations for older people are to (1) avoid raw animal products, raw sprouts, and unpasteurized juices[19] and (2) reheat certain deli meats and frankfurters to steaming hot. Other reliable sources of information on food safety and foodborne illness are the FightBAC Partnership for Food Safety Education (www.fightbac.org), the American Dietetic Association,[99,100] and the medical profession.[101] Risk of foodborne illness may be decreased by education targeted to older adults, caregivers, and foodservice staff in nursing homes, cafeterias, restaurants, assisted living facilities, congregate meal sites, and home-delivered meals programs.[100–102]

Foodborne illness can cause mild to fatal reactions involving diarrhea, vomiting, and other symptoms. The Centers for Disease Control and Prevention reported that, compared to younger people, older adults have safer food handling and food consumption behaviors and lower rates of infection from several foodborne illnesses.[102] However, along with children and immune-compromised people, older adults are at high risk for severe complications from foodborne illness, such as death from gastroenteritis. These high complication rates may result from poor nutritional status, age-related decreases in stomach acid which allow more microorganisms to survive in the gastrointestinal tract, dehydration related to impaired sense of thirst, increased intestinal transit time, age-related impairments in immunity, and surgery or other illnesses that may also impair immunity.

People in nursing homes are particularly vulnerable to foodborne illness, with fatality rates 10 to 100 times higher than the general population.[102] Risk factors include illness, impaired immunity, and close confinement with others. Proactive steps that nursing homes take in preventing foodborne illness include cooking eggs and meat thoroughly, and using pasteurized eggs and irradiated meats with decreased bacterial loads. Older adults living in assisted living facilities, receiving home-delivered meals, or receiving meals at congregate meal sites may also be at higher risk for foodborne illness than other older adults because of their advanced age and higher prevalence of frailty.

PHYSICAL ACTIVITY

Along with a healthy diet, physical activity can extend years of active life, help maintain a healthy body weight, decrease risk of cardiovascular disease and other chronic diseases, reduce disability, relieve symptoms of depression, help maintain independent living, and enhance the overall quality of life.[19,52,103] An alarming 75% of older Americans do not engage in at least 30 min of daily physical activity.[104] The Best Practices Statement from the American College of Sports Medicine recommends a well-rounded physical activity program encompassing strength, endurance, balance and flexibility for overall health, fitness, and well being.[103] Strength training can reverse and slow the progression of sarcopenia. However, only 12% of older people reported engaging in strengthening exercises in 2001 to 2002.[105] Flexibility training increases the range of motion around the joint. Endurance training may provide the greatest protection against the deleterious effects of chronic diseases associated with aging. Balance exercises improve the body's base of support to decrease the risk of falling. Balance training, static or dynamic, improves the ability to maintain standing balance and balance while moving. Physical activity programs targeted at older adults are available in hospitals, senior centers, and other community-based organizations.

CONCLUSION

A growing body of evidence shows that nutrition promotes health and quality of life as people age. To reap the full benefits, nutrition needs to be integrated into all aspects of health promotion, disease prevention, and disease management. This can be accomplished in a variety of ways, including nutrition screening, assessment and referral to registered dietitians and other appropriate health professionals in routine physician visits, as well as community-based nutrition education programs that target older adults, families, caregivers, and health professionals. Key recommendations from the 2005 White House Conference on Aging that are relevant to nutrition include reauthorizing the Older Americans Act; supporting geriatric education and training for all healthcare professionals, paraprofessionals, health profession students, and direct care workers; attaining adequate

numbers of health care personnel in all professions who are skilled, culturally competent, and specialized in geriatrics; and improving state- and local-based integrated delivery systems to meet 21st century needs of seniors.[106] Such strategies will improve the quality and availability of nutrition services for older people.

19 Exercise and Nutrient Need

Emma M. Laing

CONTENTS

INTRODUCTION

Nutrition is fundamental to exercise performance, whether the goal is to attain health and fitness or a desired peak competition level. Achieving the appropriate combination of energy, macronutrient, micronutrient, and hydration needs will support the regulation of metabolism, maintenance of normal endocrine function, and the provision of adequate fuel during exercise participation. Together, these factors impact body weight and composition, level of fatigue, recovery from exercise, and overall health.

According to the most recent (2000) Nutrition and Athletic Performance Position Statement[1] issued by the American Dietetic Association, Dietitians of Canada, and the American College of Sports Medicine, the individual seeking to optimize exercise performance should "follow good nutrition and hydration practices, use supplements and ergogenic aids carefully, minimize severe weight-loss practices, and eat a variety of foods in adequate amounts." This chapter highlights the basic principles outlined in the Nutrition and Athletic Performance Position Statement[1] while integrating national recommendations for healthy adults such as those from the Institute of Medicine's Dietary Reference Intakes (DRIs)[2–7] and the 2005 Dietary Guidelines for Americans.[8] "Nutrient/Exercise Considerations" are presented for each nutrient (in Table 19.2 and Table 19.3) to provide additional recommendations based on the most contemporary information supporting the role of nutrition in exercise performance (e.g., nutrient functions in the metabolic processes of exercise, nutrient recommendations for physically active individuals, groups at risk for nutrient deficiency, and possible effects of dietary/supplemental interventions on exercise performance). At present, available data are not sufficient to develop specific nutrient reference values for recreational, modestly competitive, and elite athlete categories. Therefore, national recommendations should be considered appropriate for all athletic individuals, unless otherwise stated. Whereas exercising vs. inactive persons generally require higher caloric and fluid intakes, the needs of most nutrients to support exercise participation can be met by consuming an adequate, well-balanced diet, while considering the timing and frequency of food intake to optimize nutrient metabolism and availability.

This chapter begins by summarizing energy intake requirements for Americans, categorized by physical activity level (PAL; shown in Table 19.1). Table 19.2 and Table 19.3 outline the recommendations for macronutrients and micronutrients, respectively. Table 19.4 lists the number of daily servings within each food group according to varying levels of caloric need. Table 19.5 highlights recommendations for the timing of foods and fluids, including water and electrolytes, for optimal exercise performance. Finally, Table 19.6 lists some of the more popular nutritional supplements touted to enhance physical performance. The recommendations presented here should be specially modified by nutritional professionals to target variations in age, sex, fitness level, mode of activity, intensity and duration of training, time between exercise sessions, as well as body weight and composition goals. The content of this chapter reflects data collected from adults, rather than children, and does not center on any particular type of athlete or sporting event. Nutrition guidelines tailored to specific sports, as well as to child and adolescent athletes, are summarized elsewhere.[9–11] For individualized nutrient assessment, MyPyramid, recently developed by the U.S. Department of Agriculture, provides useful dietary and physical activity assessment tools, which are available online at http://www.mypyramid.gov/. Importantly, this program provides higher "discretionary calories" to meet the energy needs of physically active individuals.

ENERGY INTAKE

Meeting energy intake requirements is essential for achieving optimal physical performance. Energy balance (energy intake = energy expenditure) in most healthy adults occurs at an energy availability of 45 kcal/kg fat-free mass.[12] The types of physical activities performed can have an impact on energy intake regulation.[13] For example, participation in strenuous endurance activities (that use predominantly oxidative phosphorylation as the main energy source) produces an increase in overall energy turnover and leads to either a loss of body weight or to a compensatory increase in food intake. In order to achieve the health benefits of an active lifestyle, 30 to 60 min/day of moderately intense activity is currently recommended by national authorities.[7,8,14–16] According to the 2005 *Dietary Guidelines for Americans*,[8] 60 min of moderately intense physical activity is required

TABLE 19.1
Energy Intake Recommendations Based on the Position on Nutrition and Athletic Performance, the Dietary Reference Intakes, and the Dietary Guidelines for Americans

Position on Nutrition and Athletic Performance[1]	Dietary Reference Intakes[7] Estimated Energy Requirement (EER)[a–c]			Dietary Guidelines for Americans[8] Estimated Kilocalorie Requirements[d]		
	Height (m)/ Activity Level	**EER Males BMI 18.5–24.99**	**EER Females BMI 18.5–24.99**	**Age (Years)/ Activity Level**	**Males Average BMI 21.5**	**Females Average BMI 22.5**
2200 kcal/day for females and	1.50			19–30		
2900 kcal/day for males 19 to	Sedentary	1848–2080	1625–1762	Sedentary	2400	2000
50 years of	Low Active	2009–2267	1803–1956	Moderate	2600–2800	2000–2200
age who are slightly to	Active	2215–2506	2025–2198	Active	3000	2400
moderately active	Very Active	2554–2898	2291–2489			
1.5 to 1.7 times resting energy	1.65			31–50		
expenditure or at a rate of 37 to	Sedentary	2068–2349	1816–1982	Sedentary	2200	1800
41 kcal/kg body weight/day	Low Active	2254–2566	2016–2202	Moderate	2400–2600	2000
	Active	2490–2842	2267–2477	Active	2800–3000	2200
44 to 50 kcal/kg body weight/day	Very Active	2880–3296	2567–2807			
for strength athletes	1.80			51+		
	Sedentary	2301–2635	2015–2211	Sedentary	2000	1600
>50 kcal/kg body weight/day for	Low Active	2513–2884	2239–2459	Moderate	2200–2400	1800
those in more serious training	Active	2782–3200	2519–2769	Active	2400–2800	2000–2200
	Very Active	3225–3720	2855–3141			

[a] *Dietary Reference Intake* values represent requirements for males and females 30 years of age; for each year below/above 30, add/subtract 7 kcal/day for females and add/subtract 10 kcal/day for males, respectively.

[b] EER= the average energy intake that is predicted to maintain energy balance in healthy, normal weight individuals of a defined age, sex, weight, height, and level of physical activity consistent with good health (based on body mass index [BMI; kg/m^2] values of 18.5 and 24.99).

[c] Regression equations based on doubly labeled water data:
- Female EER= $354 - 6.91 \times$ age (years) + PA $\times$ [$9.36 \times$ weight (kg) + $726 \times$ height (m)]
- Male EER= $662 - 9.53 \times$ age (years) + PA $\times$ [$15.91 \times$ weight (kg) + $539.6 \times$ height (m)]

PA represents physical activity, which differs depending on PAL (physical activity level; the ratio of total energy expenditure/basal energy expenditure):
- PA= 1.0 for both males and females if PAL 1.0–1.39; *Sedentary* (Typical daily living activities)
- PA= 1.11 (males) 1.12 (females) if PAL 1.4–1.59; *Low Active* (Typical daily living activities + 30 to 60 min of daily moderate activity)
- PA= 1.25 (males) 1.27 (females) if PAL 1.6–1.89; *Active* (Typical daily living activities + at least 60 min of daily moderate activity)
- PA= 1.48 (males) 1.45 (females) if PAL 1.9–2.5; *Very Active* (Typical daily living activities + at least 60 min of daily moderate activity + 60 min of vigorous activity; or 120 min of moderate activity)

[d] Values are based on EER and the reference size of median height and weight for that height to give a BMI of 21.5 for adult females and 22.5 for adult males:
- *Sedentary* = a lifestyle that includes only the light physical activity associated with typical day-to-day life
- *Moderate* = a lifestyle that includes physical activity equivalent to walking ~1.5 to 3 mi/day at 3 to 4 miles/h, in addition to the light physical activity associated with typical day-to-day life
- *Active* = a lifestyle that includes physical activity equivalent to walking more than 3 mi/day at 3 to 4 mi/h, in addition to the light physical activity associated with typical day-to-day life
- The kilocalorie ranges shown are to accommodate the needs of different ages within the group; fewer calories are needed at older ages

to maintain a healthy weight, by increasing energy expenditure to approximately 150 to 200 kcal/day. Various levels of physical activities and their associated energy requirements are described in Table 19.1.

Consistent overconsumption of calories can hinder athletic performance because of increases in body weight or changes in body composition. By contrast, low-energy intakes (<1800 to 2000 kcal/day) can lead to such declines in exercise performance as muscle and bone mass losses and increased risk of fatigue, injury, and illness.[1,17,18] The overt practice of energy restriction is common among both men and women who are driven to achieve a body weight/composition goal believed to be desirable for peak exercise performance; however, disordered eating among women has escalated considerably in recent years (reported to occur in up to 78% of female athletes).[19,20] Likewise, menstrual dysfunction is quite common in female athletes (up to 79%),[21] resulting mostly from an energy deficit vs. a low proportion of body fat or excessive exercise.[17,22] When energy availability is below 30 kcal/kg fat-free mass/day, leuteinizing hormone pulsatility, glucoregulatory hormones, and bone formation are disrupted. In most amenorrheic females, normal menstrual function can return after additional energy is supplied in the diet. However, in prolonged cases of menstrual disturbances where bone resorption exceeds that of bone formation, the rate of bone mass accretion can be slowed (in adolescents) or bone loss can occur (in adults).[19,23] In 1997, the syndrome describing the phenomenon of disordered eating, coupled with amenorrhea and osteoporosis, was termed the "female athlete triad."[23] As stated in the International Olympic Committee Medical Commission Position Statement,[24] "[a]lthough any one of these [triad] problems can occur in isolation, inadequate nutrition for a woman's level of physical activity often begins a cycle in which all three occur in sequence." The most recent evidence to date on this topic estimates that up to 27% of elite athletes and up to 15% of nonelite recreational athletes have at least two components of this triad syndrome.[25,26] As further evidence of the importance of meeting energy needs with exercise, a negative energy balance has also been shown to result in poor macro- and micronutrient intakes, loss of strength and endurance (due to the use of lean tissue by the body for fuel), as well as early fatigue, frequent injuries, irritability, an increased susceptibility to infection, and overall poor athletic performance.[27,28]

Table 19.1 summarizes energy intake recommendations based on the Position on Nutrition and Athletic Performance.[1] These recommendations (as well as those provided in Table 19.2 and Table 19.3) are presented alongside those contained in the DRI reports, to allow for comparison with target intakes for the general population. Table 19.1 also includes recommendations from the recently published Dietary Guidelines for Americans,[8] although energy intake values in this publication are derived from the DRIs.[7] The DRI recommendations for energy (i.e., the Estimated Energy Requirement [EER]) should meet the needs of most active individuals; however, data from competitive elite athletes who participate in high-intensity training for several hours per day (e.g., PAL values >2.5) were not included in establishing the predictive equations for energy need.[7,29] Therefore, the EER should be modified according to macronutrient recommendations (i.e., the Acceptable Macronutrient Distribution Range [AMDR]) addressed later to meet the energy needs of highly trained elite athletes.[29]

MACRONUTRIENTS

Macronutrients supply the energy required by the body, as well as important dietary constituents for varying physiological functions. The macronutrient needs of individuals who exercise regularly are influenced by total caloric intake; the ratio, timing and quality of macronutrients in the diet; intensity, duration and type of activity; as well as training history, sex, and age.[30] Table 19.2 summarizes the carbohydrate, protein, and fat intake recommendations based on the Position on Nutrition and Athletic Performance[1] and the current DRI.[7] New to this DRI report[7] is the AMDR, which represents a range of intakes (as percentage of energy) associated with reduced risk of chronic disease, within the context of suggested intakes for each macronutrient. The macronutrient needs for physically active individuals should fit within these ranges; however, specific nutrient guidelines presented as Recommended Dietary Allowance (RDA) and/or Adequate Intake (AI) reference standards should also be adhered to.[29]

Carbohydrate is the primary energy source used by the body during endurance-type activities. When suboptimal levels of endogenous sources (i.e., muscle and liver glycogen) occur, usually after 60 to 90 min of exercise, there may be deleterious effects on physical performance. Carbohydrate loading to elevate glycogen stores prior to exercise does not appear to delay fatigue in activities that are <90 min in duration.[31] Numerous studies, however, support the efficacy of consuming carbohydrates during endurance-type exercise for the purpose of delaying fatigue, improving feelings of perceived exertion, and enhancing overall physiologic performance.[32,33] Carbohydrate supplementation has also demonstrated glycogen-sparing effects during shorter bouts of intermittent, high-intensity exercise (e.g., in sports such as tennis and soccer),[34] and has been shown to suppress the release of cortisol and promote muscle glycogen resynthesis following resistance training exercise.[35,36]

Proteins serve to repair exercise-induced microdamage to muscle fibers and improve energy utilization during endurance activities. With an increase in exercise duration, maintenance of blood glucose may occur through gluconeogenesis in the liver.[30,37,38] In general, proteins should not be consumed in excess of the DRI[7] to enhance exercise performance. However, some physically active individuals may need slightly more protein than the current DRI recommendations, depending on the type, frequency, and duration of the exercise (Table 19.2). Although it has often been suggested that supplementation with macronutrient molecules (e.g., fatty acids and amino acids) is not necessary for improved athletic performance unless intakes of energy or particular food groups are restricted,[29,30,38] recent evidence in the area of amino acid supplementation in both highly trained

TABLE 19.2

Macronutrient Recommendations Based on the Dietary Reference Intakes and the Position on Nutrition and Athletic Performance

Macronutrient/Function	Dietary Reference Intakes[7] Recommendations	Position on Nutrition and Athletic Performance[1] Recommendations and other Nutrient/Exercise Considerations
Carbohydrate: Important for maintaining normal levels of glucose in the brain and in circulation; compler carbohydrates are needed to supply fiber, a key nutrient to reducing blood cholesterol and maintaining blood glucose levels; excess amounts can result in low intakes of essential fatty acids and indispensable amino acids, and could lead to surplus body fat storage, body weight gain, and associated chronic diseases	*AMDR[a] (% of Energy)* Adults aged 19 to >70 years: 45–65 *Carbohydrate RDA[b] (g/day)* Males aged 19 to >70 years: 130 Females aged 19 to >70 years: 130 *Total Fiber AI[c,d] (g/day)* Males aged 19 to 50 years: 38 Females aged 19 to 50 years: 25 Males aged 51 to >70 years: 30 Females aged 51 to >70 years: 21 *Added Sugars[e]* Limit to no more than 25% of energy	*Position Stand Recommendation:* • Range for exercising adults: 6–10 g/kg body weight/day *Nutrient/Exercise Considerations:* • Carbohydrates serve as the most efficient fuel for exercise (producing more adenosine triphosphate per unit of oxygen) compared with other macronutrients; they are essential for maintaining blood glucose levels and muscle glycogen stores; their availability for muscle contraction during exercise is inversely related to the rate of protein catabolism[30,43] • As intensity and length of exercise increases, the source of carbohydrate shifts from muscle glycogen to circulating blood glucose; an ingestion rate of 1g carbohydrate/min (0.04 oz/min in beverage form) maintains optimal carbohydrate metabolism during endurance exercise[44,45] • Glycemic index and glycemic load were not considered in current carbohydrate recommendations for exercise;[1,7] however, recent data suggest that consumption of low-glycemic-index foods may be beneficial in increasing fat oxidation[46,47]
Protein: Needed to maintain body nitrogen and supply indispensable amino acids for the synthesis of protein (during growth, repair of damaged tissues, muscle hypertrophy, and enzyme synthesis); provides indispensable amino acids, which are found in high-quality-protein foods in the diet; excess protein can interfere with maintaining sufficient dietary carbohydrates to replenish muscle glycogen as well as maintaining proper hydration; excess protein ingestion could lead to the progression of renal function impairments, surplus body fat storage, and associated chronic diseases	*AMDR (% of Energy)* Adults aged 19 to >70 years: 10–35 *Protein RDA[f] (g/day)* Males aged 19 to >70 years: 56 Females aged 19 to >70 years: 46 *Indispensable Amino Acids RDA (mg/kg/day)* Adult Males and Females: Histidine: 14 Isoleucine: 19 Leucine: 42 Lysine: 38 Methionine + cysteine: 19 Phenylalanine + tyrosine: 33 Threonine: 20 Tryptophan: 5 Valine: 24	*Position Stand Recommendations:* • Range for endurance exercisers: 1.2–1.4 g/kg body weight/day • Range for strength-trained exercisers: 1.6–1.7 g/kg body weight/day • Range for vegetarian exercisers: 1.3–1.8 g/kg body weight/day • The use of branched-chain amino acid supplements cannot be advocated *Nutrient/Exercise Considerations:* • Skeletal muscle oxidizes up to 6% of total energy from amino acids during endurance exercise[48] • Protein needs are increased depending on exercise level, in order to maintain a greater protein synthetic rate to accommodate augmented lean tissue mass (strength training) or enzyme (endurance training) levels[30,49] • Increasing dietary protein beyond the recommended levels is unlikely to result in endurance benefits or additional increases in lean mass because there is a limit to the rate at which protein tissue can be accrued[37,49,50] • Prolonged intakes of excess protein are associated with increased urea production and excretion,[51] blood urea nitrogen and urine-specific gravity,[52] and may affect the hydration status of exercising individuals • Branched-chain amino acids (isoleucine, leucine and valine) are preferentially oxidized during exercise compared to other amino acids[48,53] • The effects of amino acid supplementation with exercise, particularly in conjunction with carbohydrates, may be useful for improving short-term training efficiency and recovery; however, confirming research is needed[39–42]

Fat: Provides energy, essential fatty acids, and fat-soluble vitamins; assists in the absorption of these vitamins; serves as a structural component for the development of tissues and as a precursor to numerous compounds; excess dietary fat could lead to alterations in carbohydrate and protein intakes and ultimately body weight gain; linoleic acid is an essential component of structural membrane lipids; α-linolenic acid is involved in neurological development and growth; both fatty acids are precursors of eicosanoids

AMDR (% of Energy) for Fat[g]
  Adults aged 19 to >70 years: 20–35
AMDR (% of Energy) for n-6 Polyunsaturated Fatty Acids[h]
  Adults aged 19 to >70 years: 5–10
AMDR (% of Energy) for n-3 Polyunsaturated Fatty Acids[i]
  Adults aged 19 to >70 years: 0.6–1.2
Linoleic Acid AI (g/day)
  Males aged 19 to 50 years: 17
  Females aged 19 to 50 years: 12
  Males aged 51 to >70 years: 14
  Females aged 51 to >70 years: 11
α-Linolenic Acid AI (g/day)
  Males aged 19 to >70 years: 1.6
  Females aged 19 to >70 years: 1.1

Position Stand Recommendations:
- Total fat intake should be >15% and <25% of total energy intake
- Fat composition should be 10% saturated, 10% polyunsaturated and 10% monounsaturated

Nutrient/Exercise Considerations:
- Lipids are transported to the site of oxidation in the exercising muscle where they are used in the oxidative process to supply energy and spare carbohydrate stores[7]
- There is no physical performance benefit in consuming a fat-restricted diet (less than 15% of energy from fat) vs. a diet containing 20%–25% energy from fat[1]
- The practice of "fat loading" (i.e., consumption of a high-fat diet (65%–70% of total energy) to increase fat oxidation and spare the use of muscle glycogen during exercise has been shown to either have no effect or impair high-intensity training efficiency[54,55]
- Supplementation with essential fatty acids in well-trained athletes has no beneficial effect on body composition, muscle strength, exercise fatigue, immune function, or exercise-induced elevation of pro- or anti-inflammatory cytokines[56–58]

[a] AMDR = Acceptable Macronutrient Distribution Range; a range of intakes associated with reduced risk of chronic diseases while providing adequate intakes of essential nutrients; values are expressed as percentages of total energy intake.

[b] RDA = Recommended Dietary Allowances; values are set to meet the needs of almost all (97% to 98%) individuals in a group.

[c] AI = Adequate Intake; values are set to cover the needs of all individuals in a group, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered by this intake.

[d] AI for fiber is based on 14 g total fiber/1000 kcal.

[e] Added sugars are defined as sugars and syrups that are added to food during processing and preparation.

[f] RDA for protein is based on 0.8 g protein/kg body weight/day.

[g] No RDA or AI was set due to insufficient data linking a defined level of dietary fat to prevention of chronic disease; however, the recommendation states that intakes of dietary cholesterol, *trans*-fatty acids and saturated fatty acids should be "as low as possible while consuming a nutritionally adequate diet."

[h] Linoleic acid.

[i] α-Linolenic acid, eicosapentaenoic acid, and docosahexaenoic acid.

and untrained individuals shows promise for improving training effectiveness and recovery from exercise.[39–42] But, advocating amino acid supplementation for improved performance in physically active individuals is rather premature since the long-term effectiveness of such practices, given varying training conditions and combinations with other nutrients, have not yet been elucidated.

Dietary fat provides the free fatty acids needed to supply energy for mild to moderate intensity endurance exercise. Physically active individuals should consume dietary fat in amounts similar to what is recommended in the DRI report[7] (Table 19.2). Supplementation with free fatty acids is generally not recommended to improve exercise performance. Consultation with a registered dietitian, particularly in the case of elite athletes who have increased energy requirements, should be encouraged to ensure a balanced macronutrient intake and to assess the need for supplementation on an individual basis.

MICRONUTRIENTS

Vitamins and minerals facilitate the use of macronutrients for all physiologic processes, including exercise-related energy metabolism, immune response, growth and maintenance of bone mineral, as well as the protection of body tissues from oxidative stress. Table 19.3 outlines the micronutrient intake recommendations, categorized as B-complex vitamins, antioxidants, and other vitamins and minerals, based on the Position on Nutrition and Athletic Performance[1] and the current DRI report.[7] Physical activity was examined as a key factor in approximately one-third of the micronutrients considered for the RDA and AI guidelines (i.e., vitamins B_6, C, E, choline, and thiamin, as well as calcium, iron, magnesium, and sodium); however, no specific recommendations within the DRI reports were made with regard to micronutrient needs during exercise.[59] The recommendations issued by the DRI panel for micronutrients should be appropriate for most physically active individuals unless otherwise indicated.

During prolonged, high-intensity exercise, micronutrient requirements are expected to increase relative to inactive individuals.[59] Since caloric requirements also increase with exercise intensity and duration, micronutrient needs should easily be met with appropriate energy consumption, and supplementation above what is achieved through a well-balanced diet may not be necessary. As stated in the Position on Nutrition and Athletic Performance,[1] "[s]upplementation with single micronutrients is discouraged unless clear medical, nutritional, or public health reasons are present." In cases where energy intake is restricted or food groups omitted, there is a greater probability for poor micronutrient status in exercising individuals.[1,27] In these cases, consumption of a multivitamin/mineral supplement may be warranted.

Because of their increased energy needs, it may be challenging for more highly active individuals (particularly elite athletes) to balance the recommended intakes of vitamins and minerals. That is, there may be a risk for overconsumption of micronutrients, either with food intake alone or with supplement use. The risk may be further exacerbated if one erroneously perceives that consuming "more" of a nutrient marketed to improve exercise performance is actually "better." Most micronutrients in the DRI reports have an assigned Tolerable Upper Intake Level (UL), defined as the maximum level of daily nutrient intake that is likely to pose no risk of adverse effects. The UL represents total intake from food, water, and supplements.[109] It would be prudent for exercising individuals to consider the ULs before making decisions about altering their intake of micronutrients. Further discussions concerning UL recommendations are available in detail elsewhere.[109-112]

Table 19.4 provides an example from The Dietary Guidelines for Americans report[8] indicating how the macronutrient- and micronutrient-focused recommendations summarized in the preceding text can be expressed in terms of whole food serving sizes. This example outlines the number of daily servings within each food group to meet recommended nutrient intakes presented across a range of calorie levels. The exact numbers of servings in this eating plan are not intended to be consumed every day, but on average, over time. Table 19.1 should serve as a tool to help identify an individual's caloric requirement based on sex, age, and PAL, which can then be applied to the recommendations presented in Table 19.4.

TIMING OF FOODS AND FLUIDS

The nutrition status of an individual prior to exercise training or event competition can have a considerable impact on athletic performance. Dietary recommendations should focus primarily on adequate hydration and maximizing liver and muscle glycogen stores with sufficient carbohydrates. The timing of meals and snacks depends on the intensity of the exercise and an individual's gastrointestinal ability to tolerate varying amounts of foods and fluids. Therefore, strategies typically include consuming meals that are composed of familiar foods, moderate in protein, and low in fat and fiber to facilitate gastric emptying and to minimize gastrointestinal distress. Table 19.5 summarizes the recommendations for the timing of meals and fluids to promote optimal exercise performance.

Maintaining proper hydration status is critical both to overall health and physiological performance with exercise. Optimal exercise performance can occur if the rates of fluid ingestion/absorption are equal to the rate of fluid loss through sweat and/or urination.[1] Dehydration and associated health risks result from a fluid imbalance, in which fluid losses exceed fluid intakes and exercise performance becomes impaired.[112] Dehydration can be further exacerbated in temperature/humidity extremes, where hot/humid conditions produce increased fluid losses through evaporation, and cold environments result in reduced rates of

TABLE 19.3

Micronutrient Recommendations Based on the Dietary Reference Intakes and the Position on Nutrition and Athletic Performance

B-Complex Vitamins

Overall Function

The B-complex vitamins are involved in energy production during exercise and are required for the production of red blood cells, protein synthesis, as well as for tissue repair and maintenance.

Position on Nutrition and Athletic Performance[1] Recommendation

Exercise may increase the need for the B-complex vitamins, perhaps up to twice the current recommended amounts. These increased needs can generally be met via the higher energy intakes required by exercising individuals to maintain body weight.

Micronutrient Function	Dietary Reference Intakes[3] Recommendations	Nutrient/Exercise Considerations
Thiamin: plays a role in carbohydrate and amino acid metabolism; acts as a coenzyme in the conversion of pyruvate to acetyl CoA and α-ketoglutarate to succinyl CoA; participates in the decarboxylation of branched-chain amino acids	RDA[a] *(mg/day)* Males age 19 to >70 years: 1.2 Females age 19 to >70 years: 1.1	• Individuals who consume low-energy diets or low-nutrient-dense foods may be at risk for inadequate thiamin status[59] • 0.5 mg thiamin/1000 kcal has been recommended for physically active individuals who have increased energy needs[3,59] • Short-term variations in dietary thiamin do not appear to have direct effects on strength or performance indices; however, a temporary thiamin insufficiency can lead to pyruvate accumulation and an increase in circulating lactate during exercise, which may result in muscle fatigue[60] • Thiamin supplementation has been shown to improve perceived recovery from exercise fatigue but has not been shown to alter metabolic or other physical performance indices[61,62]
Riboflavin: required for oxidative energy production; functions specifically in the mitochondrial electron transport system as the coenzymes flavin mononucleotide and flavin adenine dinucleotide	RDA *(mg/day)* Males age 19 to >70 years: 1.3 Females age 19 to >70 years: 1.1	• Riboflavin needs increase during the initiation of strenuous physical activities; however, performance is generally not affected with variations in dietary intake[63] • 0.6 mg riboflavin/1000 kcal has been recommended for physically active individuals who have increased energy needs[3] • For exercising women who may be restricting energy intake or choosing to omit certain food groups, 1.4 to 1.6 mg riboflavin/day has been suggested for those engaging in moderate exercise and 2 to 3 mg riboflavin/day for those participating in high-intensity competitive activities[27,59,64] • For older competitive adults (aged 50+ years), increases to 1.7 mg riboflavin/day for males and 1.3 mg riboflavin/day for females have been suggested[65,66] • Marginal riboflavin deficiency, in combination with other B-complex vitamin deficiencies, has been shown to negatively impact measures of exercise performance[67]
Niacin: an electron carrier in many oxidative reactions; a precursor of electron (nicotinamide adenine nucleotide) and proton (nicotin-amide adenine dinucleotide) acceptors	RDA *(as NE;[b] mg/day)* Males age 19 to >70 years: 16 Females age 19 to >70 years: 14	• Individuals who consume low-energy, low-nutrient-dense, or strict vegetarian diets may be at risk for inadequate niacin status[59,64] • While niacin supplementation has been shown to decrease circulating free fatty acid concentrations and reduce excess postexercise oxygen consumption, supplementation does not appear to improve overall performance outcomes during exercise[68–70]
Vitamin B₆: a cofactor for transfer-ases, transaminases, decarboxyl-ases, and cleavage enzymes used in transformations of amino acids; needed for gluconeogenesis and glyconeogenesis processes	RDA *(mg/day)* Males age 19 to 50 years: 1.3 Females age 19 to 50 years: 1.3 Males age 51 to >70 years: 1.7 Females age 51 to >70 years: 1.5	• Individuals who consume low-energy/low-protein diets or low-nutrient dense foods may be at risk for inadequate vitamin B₆ status[71,72] • Because vitamin B₆ is involved in the process of muscle glycogen breakdown, exercise may increase the turnover and urinary losses of vitamin B₆[71,73,74] • Physically active females may need up to 2–3 mg vitamin B₆/day, in proportion to increased energy needs[27] • 2.0 mg vitamin B₆/day has been recommended for older (aged 50+ years), competitive males and females[75]

Continued

**TABLE 19.3
(Continued)**

B-Complex Vitamins (*Continued*)

Micronutrient/Function	RDA	Position
Vitamin B₁₂: a coenzyme for the reaction that converts homocysteine to methionine; required for normal erythrocyte production and neurologic function	*RDA (μg/day)*[c] Males aged 19 to >70 years: 2.4 Females aged 19 to >70 years: 2.4	• Individuals consuming low-energy or strict vegetarian diets may be at risk for vitamin B₁₂ deficiency[59,64,76] • 2.8 μg vitamin B₁₂/day has been recommended for older male and female competitive athletes, aged 50+ years[75] • Vitamin B₁₂ supplementation has not been shown to demonstrate positive effects on physical performance[77,78]
Choline: a constituent of lecithin; essential in the metabolism of fat; a precursor of the neurotransmitter, acetylcholine	*AI*[d] *(mg/day)* Males aged 19 to >70 years: 550 Females aged 19 to >70 years: 425	• Strenuous physical activity has been shown to reduce plasma choline concentrations[3] • Choline supplementation appears to lower lipid peroxidation following mild exercise[79] • No effect of choline supplementation during prolonged exercise has been demonstrated on physical performance measures or in delaying fatigue[80–82]

Antioxidants

Overall Function		Vitamins A, C, E, and selenium may protect cell membranes from oxidative damage. Because exercise can increase oxygen consumption 10- to 15-fold, chronic exercise produces a constant "oxidative stress" on the muscles and other cells. Muscle tissue damage caused by intense exercise can lead to lipid peroxidation of membranes. Increased exercise duration and intensity appear to elevate levels of lipid peroxide by-products,[83,84] and may necessitate increases in dietary antioxidants; however, the evidence to date on this topic is conflicting[85,86] and remains uncertain
Position on Nutrition and Athletic Performance[1] **Recommendation**		There is no clear consensus on whether supplementation of antioxidant nutrients is necessary. Habitual exercise has been shown to result in an augmented antioxidant system and a reduction of lipid peroxidation. Thus, a well-trained athlete may have a more developed endogenous antioxidant system than a sedentary person. Active individuals at greatest risk for poor antioxidant intakes are those who follow a low-energy, low-fat diet, or those with limited dietary intakes of fruits and vegetables
Micronutrient/Function	Dietary Reference Intakes[4,5]	Recommendations Nutrient Exercise Considerations
Vitamin A: a fat-soluble antioxidant; essential for vision, gene expression, immune function, and growth; β-carotene, a precursor of vitamin A, also has antioxidant properties	*RDA (as RAE;*[e] *μg/day)* Males aged 19 to >70 years: 900 Females aged 19 to >70 years: 700	• The risk for vitamin A insufficiency is increased if total energy and/or fruit and vegetable intakes are restricted[59] • Evidence is lacking to suggest that exercise increases vitamin A needs, since competitive athletes have improved β-carotene status compared to non-athletes[87] • Supplementation with vitamin A, in combination with vitamins C and E has been shown to prevent exercise-induced oxidative stress[88]
Vitamin C: a water-soluble antioxidant; participates in bone formation and scar tissue repair; needed for synthesis of carnitine for fatty acid transport; serves to regenerate vitamin E from its oxidized by-product	*RDA (mg/day)* Males aged 19 to >70 years: 90 Females aged 19 to >70 years: 75	• The requirement for vitamin C may be increased during physical activity due to its roles in immune and antioxidant function and in collagen repair[59] • Vitamin C supplementation, in combination with vitamin E, has been shown to prevent endurance exercise-induced lipid peroxidation[89] • Vitamin C supplementation alone, or in combination with vitamin E or carbohydrate, does not appear to have a beneficial effect on exercise-induced increases in muscle damage or recovery, on the hormonal, or immune response after prolonged exercise[90,91]
Vitamin E: a fat-soluble antioxidant; acts on polyunsaturated fatty acids in cell membranes; essential for maintaining erythrocyte and neurological function	*RDA (mg/day)*[f] Males aged 19 to >70 years: 15 Females aged 19 to >70 years: 15	• Vitamin E deficiency results in oxidative stress and muscle degeneration[59] • Older, competitive athletes (aged 50+ years) may require supplementation of vitamin E (100–200 mg/day)[75] • Vitamin E supplementation in younger adults has little beneficial effect on performance related parameters, other than reducing lipid membrane peroxidation[90,92] • Those who are unaccustomed to exercise training are likely to gain more benefit from supplementation vs. trained exercisers[93] • Large doses of α-tocopherol supplementation may actually exhibit prooxidant effects during high-intensity exercise[94]

Micronutrient/Function	Dietary Reference Intakes[2,5] Recommendations	Position on Nutrition and Athletic Performance[1] Recommendations and other Nutrient/Exercise Considerations
Selenium: an essential element in the glutathione peroxidase enzyme system; involved in DNA repair, enzyme activation, and immune system function	*RDA (μg/day)* Males aged 19 to >70 years: 55 Females aged 19 to >70 years: 55	• The risk for selenium insufficiency is increased if total energy and/or fruit and vegetable intakes are restricted • Selenium supplementation, in combination with several other antioxidants, has not been shown to protect against DNA damage or plasma cytokine concentrations following aerobic exercise[95,96] • Selenium supplementation for exercise performance is generally not recommended due to potential toxic effects of overconsumption **Other Micronutrients**
Micronutrient/Function	**Dietary Reference Intakes[2,5] Recommendations**	**Position on Nutrition and Athletic Performance[1] Recommendations and other Nutrient/Exercise Considerations**
Calcium: needed for growth and repair of bone tissue and the maintenance of blood calcium levels; required for blood clotting, muscle contraction, nerve transmission and overall bone health	*AI (mg/day)* Males age 19–50 years: 1000 Females age 19–50 years: 1000 Males age 51 to >70 years: 1200 Females age 51 to >70 years: 1200	**Position Stand Recommendations:** • Exercising individuals should strive to meet the recommended intakes for calcium because inadequate dietary calcium increases the risk of osteopenia and stress fractures.[27] Females are at greatest risk for low bone mineral density if energy intakes are low, dairy products are eliminated or restricted in the diet and menstrual dysfunction is present Nutrient/Exercise Considerations: • The amount of calcium in the diet has been shown to modify the musculoskeletal response to exercise; where the combination of dietary calcium and moderate physical activity produces a dose-response effect on bone mineral density in both older and younger females[97,98]
Vitamin D: promotes growth and mineralization of bone by maintaining calcium and phosphorus homeostasis; enhances absorption of calcium; has a role in the modulation of immune cells	*AI (μg/day)*[g,h] Males age 19 to 50 years: 5 Females age 19 to 50 years: 5 Males age 51 to 70 years: 10 Females age 51 to 70 years: 10 Males age >70 years: 15 Females age >70 years: 15	Position Stand Recommendations: • Exercising individuals living at northern latitudes or who train primarily indoors throughout the year (e.g., gymnasts and figure skaters) may be at risk for poor vitamin D status, especially if foods fortified with vitamin D are not consumed. These individuals would benefit from vitamin D supplementation at the level of the DRI[2,8] Nutrient/Exercise Considerations: • Among both active and inactive elderly persons (aged 60+ years), higher circulating 25(OH)D concentrations (due to diet and/or sunlight exposure) have been associated with improved musculoskeletal function and strength[99,100]
Magnesium: involved in numerous enzymatic reactions such as glycolysis, fat and protein metabolism, adenosine triphosphate hydrolysis, and the second messenger system; regulates neuromuscular, cardiovascular, immune and hormonal functions	*RDA (mg/day)* Males age 19 to 30 years: 400 Females age 19 to 30 years: 310 Males age 31 to >70 years: 420 Females age 31 to >70 years: 320	Position Stand Recommendations: N/A Nutrient/Exercise Considerations: • The risk for magnesium insufficiency is increased if energy intakes are restricted[27] • Magnesium depletion has been directly related to impairments in exercise performance[59] • Supplementation with magnesium in physically active, magnesium-replete individuals has not consistently shown to aid in the recovery of muscle function or improve immune cell function[101–103]
Iron: required for the formation of hemoglobin, myoglobin, cytochromes, and for enzymes involved in energy production	*RDA (mg/day)* Males age 19 to 50 years: 8 Females age 19 to 50 years: 18 Females age 19 to 50 years who use oral contraceptives:[i] 11 Males age 51 to >70 years: 8 Females age 51 to >70 years: 8	Position Stand Recommendations: • As iron depletion is one of the most prevalent nutrient deficiencies observed in athletic females (up to 36%), there is an increased risk for impaired physical performance associated with symptoms of iron deficiency.[104–106] • Assessment of iron status in physically active females should be done routinely, especially in amenorrheic cases; these individuals may benefit from iron supplementation.[27] Nutrient/Exercise Considerations: • For those who perform regular endurance or intense exercises, the iron requirement is higher (30 to 70%) than what is recommended for inactive individuals.[5] • Other considerations for iron and athletic performance include blood donation, which adds 0.65 to basal losses, and practicing vegetarianism, which reduces iron absorption from 18% to 10%.[5] • Older female endurance exercisers (particularly those who are vegetarian), aged 50+ years, and training in extreme temperatures, may need up to 15 mg iron/day.[75]

TABLE 19.3
(Continued)

Zinc: important for growth and repair   *RDA (mg/day)*
of muscle and skeletal tissues,   Males aged 19 to >70 years: 11
maturation and reproduction,   Females aged 19 to >70 years: 8
wound healing and energy
production; functions in a number
of metallic enzymes including
carbonic anhydrase, alkaline
phosphatases and RNA polymer-
ases; required to maintain the
structure of nucleic acid protein

Antioxidants

Position Stand Recommendations:

● Exercising individuals should strive to meet the recommended intakes for zinc, because athletic females,
   particularly those who are vegetarian, have been shown to have diets low in zinc

Nutrient/Exercise Considerations:

● The training ability of athletic females who avoid animal products and limit intakes of whole or fortified cereals
   and grains may be enhanced with zinc supplementation[27]
● Supplementation with zinc has been shown to improve measures of muscle strength and endurance in healthy
   women[107]
● Zinc supplementation, in combination with several antioxidants, has not been shown to protect against oxidative
   stress following aerobic exercise[108]

---

[a] RDA= Recommended Dietary Allowances; values are set to meet the needs of almost all (97–98%) individuals in a group.

[b] NE= niacin equivalents; 1 mg niacin = 60 mg tryptophan.

[c] People over age 50 years are advised to consume vitamin B_{12} in its crystalline form from fortified foods and/or supplements[8].

[d] AI= Adequate Intake; values are set to cover the needs of all individuals in a group, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered
by this intake.

[e] RAE= Retinol Activity Equivalents; 1 RAE = 1 μg retinol, 12 μg β-carotene, 24 μg α-carotene, or 24 μg β-cryptoxanthin.

[f] As α-tocopherol.

[g] As cholecalciferol; 1 μg cholecalciferol = 40 IU vitamin D; values are in the absence of adequate exposure to sunlight.

[h] For older adults, people with dark skin, and people exposed to insufficient ultraviolet band radiation (i.e., from sunlight), the recommendation is to consume 25 μg or 1000 IU vitamin D/day via vitamin-D-fortified
foods and/or supplements[8].

[i] The RDA for iron is reduced for women who use oral contraceptives, because of their lower menstrual iron losses.

TABLE 19.4
The Number of Daily Servings in a Food Group Based on Caloric Need

Food Group	1600 Calories	2000 Calories	2600 Calories	3100 Calories
Grains[a]	6	7–8	10–11	12–13
Vegetables[b]	3–4	4–5	5–6	6
Fruits[c]	4	4–5	5–6	6
Low-fat or fat-free dairy foods[d]	2–3	2–3	3	3–4
Meat, poultry, fish[e]	1–2	2 or less	2	2–3
Nuts, seeds, legumes[f]	3–4/week	4–5/week	1	1
Fats and oils[g]	2	2–3	3	4
Sweets[h]	0	5/week	2	2

Source: Adapted from the 2005 Dietary Guidelines for Americans[8] and the U.S. Department of Agriculture
MyPyramid Food Intake Patterns: http://www.mypyramid.gov/
Values are number of servings.
Serving sizes:
[a] 1 slice bread; 1 oz dry cereal; ½ cup cooked rice, pasta or cooked cereal.
[b] 1 cup raw leafy vegetable; ½ cup cooked vegetable; 6 oz vegetable juice.
[c] 6 oz fruit juice; 1 medium fruit; ¼ cup dried fruit; ½ cup fresh, frozen or canned fruit.
[d] 8 oz milk; 1 cup yogurt; 1 ½ oz cheese.
[e] 3 oz cooked meats, poultry or fish.
[f] ⅓ cup or 1 ½ oz nuts; 2 tablespoons or ½ oz seeds; ½ cup cooked dry beans or peas.
[g] 1 teaspoon soft margarine; 1 tablespoon low-fat mayonnaise; 2 tablespoons light salad dressing; 1 teaspoon
vegetable oil.
[h] 1 tablespoon sugar, 1 tablespoon jelly or jam; ½ oz jelly beans; 8 oz lemonade.

fluid ingestion.[113] In higher altitudes (higher than 2500 m), diuresis and respiratory fluid losses increase the recommendation for fluid intake up to 3 to 4 l/day to sustain optimal kidney function.[1] According to the DRI report concerning hydration,[6] the AI recommendation for total water (including drinking water, water in beverages, and water that is part of food) is 2.7 and 3.7 l/day for adult females and males, respectively. Both reports from the DRI and Dietary Guidelines for Americans recommend that drinking according to thirst and consuming beverages with meals are adequate to achieve these recommendations and maintain the hydration status of most Americans.[6,8] Furthermore, the AI guidelines for water consumption were established for individuals participating in light/moderate activities in relatively mild temperatures (~20°C). For more physically active individuals who may exercise in warmer climates, these recommendations would need to be adjusted accordingly.[59,113,115]

Elite athletes or individuals who engage in higher-intensity, endurance-type exercises may be at risk of developing hyponatremia.[116,117] Exercise-associated hyponatremia (EAH) is defined as "the occurrence of hyponatremia in individuals engaged in prolonged physical activity (>4 h) defined by a serum or plasma sodium concentration below the normal reference range (usually 135 mmol/l)."[117] According to the (2005) EAH Position Statement,[117] women, novice athletes, slow-paced runners, and athletes with relatively low body weight, exercising in extreme hot/cold environments or have excessive drinking behaviors (either water or sports drinks), are at risk for hyponatremia. Therefore, it is the recommendation of the EAH Position Statement panel[117] that any individual participating in endurance exercise should avoid overconsumption of fluids, by either drinking according to thirst or to their estimated hourly sweat rate. The panel[117] recommended using a method such as the U.S. Track and Field Self-Testing Program for Optimal Hydration formula (summarized as follows)[118] for estimating fluid needs according to hourly sweat rate:

Fluid needs per h of exercise (oz) = [(preexercise body weight; lb) – (postexercise body weight following 1 h of typical intensity exercise; lb)] × [15.3 (conversion factor for body weight to fluid ounces)] + [(fluid intake; oz) – (urine volume; ml)]

To eliminate urine volume from the preceding equation, the individual should be weighed before and after a typical 1 h exercise bout and should not be permitted to urinate during this session. The following indices of hydration status, based on percent body weight change,[45] could also help guide individuals in maintaining proper hydration and avoiding serious dehydration during exercise: well hydrated (+1% to –1%); minimal dehydration (–1% to –3%); significant dehydration (–3% to –5%); and (>5%) serious dehydration.

NUTRITIONAL NEEDS FOR THE AGING ATHLETE

Among U.S. adults over the age of 55 years, 29.9% of men and 26.5% of women routinely participate in regular leisure time or competitive physical activities.[119] Dietary recommendations within the Position on Nutrition and Athletic Performance[1]

TABLE 19.5
Timing of Foods and Fluids for Optimal Exercise Performance

Timing and Recommendations

Preexercise

- Sufficient fluid in the 24 h before an exercise session
- 400–600 ml of fluid 2–3 h before exercise
- 200–300 ml of fluid 10–20 min before exercise
- 200–300 g carbohydrate in food or fluid consumed 3–4 h before exercise
- Moderate amounts of low-glycemic-index carbohydrates (may promote the availability of the sustained carbohydrate)
- Limited or no caffeine, alcohol (both increase urine output) or carbonated beverages (may promote stomach fullness)

During Exercise

Goal: consume sufficient fluids to maintain fluid balance and carbohydrates (fluid, solid or gel) to maintain blood glucose levels and muscle glycogen stores that are easily tolerated and are sufficient in calories to prevent hunger during the exercise session. The nutrition plan should include:

- 150–350 ml of fluid at 15–20 min intervals during exercise
- Plain water or fluids/foods containing carbohydrate in concentrations of 4%–8% for activities lasting <1 h
- Fluids containing carbohydrate in concentrations of 4%–8% for activities lasting >1 h; or 0.7 g carbohydrate/kg/h (~ 30–60 g/h) for activities >1 h
- Carbohydrates that yield primarily glucose and no more than 2%–3% (2–3 g/100 ml) fructose; or fructose in amounts that do not cause gastrointestinal discomfort/diarrhea
- 0.5–0.7 g sodium/l for exercise lasting >1 h (to increase the drive to drink fluids)[a]
- Adjusting fluid intake not to exceed sweat rate (to decrease risk of hyponatremia)
- Limited or no caffeine or alcohol

Postexercise

Goal: if completed exercise session was long enough in duration to deplete glycogen stores (usually >90 min), consume sufficient fluids/foods to replenish these stores before next exercise session. The nutrition plan should include:

- Consuming fluids up to 150% of the weight lost during an exercise session
- A meal containing carbohydrates alone (yielding primarily glucose or sucrose) or carbohydrates + protein and fat, in close proximity to the end of exercise
- 1.5 g carbohydrate/kg at 2 h intervals following intense training sessions (only applies if exercise sessions are <1–2 days apart)
- Moderate amounts of high glycemic index carbohydrates (may promote greater insulin and glucose responses)
- Modest amounts of sodium may be consumed in fluids and/or meals following high-intensity/duration exercise[a]
- Limited or no caffeine or alcohol

[a] Sodium intake recommendations from the Dietary Guidelines for Americans report:[8]
- Consume less than 2300 mg (~1 tsp of salt) sodium/day
- Individuals with hypertension, people with dark skin, and middle-aged and older adults should aim to consume no more than 500 mg sodium/day and meet the potassium recommendation (4700 mg/day) with food

Note: Recommendations are targeted toward individuals who perform exercise at a moderate- to high-intensity, and are based on the Position on Nutrition and Athletic Performance,[1] the ACSM Position Stand on Exercise and Fluid Replacement,[113] and the National Athletic Trainers' Association Position Statement: Fluid Replacement for Athletes.[45]

---

do not distinguish between the nutrient needs of younger vs. older physically active persons. The following section highlights nutritional areas of concern for the older athlete, which are addressed in more detail in the papers by Campbell and Geik[120] and Larkin[121]:

1. *Energy*: Identifying nutrient needs for peak performance in the aging athlete can be complicated by weight gain, decreases in the level of physical activity, changes in hormonal status, and losses in muscle mass; older athletes have a lower energy requirement compared with younger athletes, but higher than what is recommended for aged-matched sedentary controls;[122] the goal should be to balance energy intake with expenditure and maintain desired body weight and composition.
2. *Macronutrients*: Older athletes should aim for meeting goals set within the nutrient-specific DRIs, appropriate for their age group, and the Position on Nutrition and Athletic Performance[1] recommended ranges for macronutrients; a diet low in energy intake (<2000 kcal/day) may pose a risk for insufficient macronutrient intakes.
3. *Micronutrients*: Older athletes who have a reduced energy requirement and are unable to at least meet the recommended DRIs may require supplementation with select micronutrients.
4. *Fluids*: Older competitors may have an increased risk for dehydration due to a blunting of the thirst mechanism and changes in kidney function and sweat responses that occur with increased age.[123–126]

ERGOGENIC AIDS

Supplementation with ergogenic aids (products claiming to enhance exercise performance) is a widespread practice among exercising individuals and deserves consideration when evaluating one's dietary and supplemental habits.[127] Regulation of these substances is not performed by the Food and Drug Administration; rather, the Dietary Supplement Health and Education Act (1994) has permitted supplement manufacturers to make claims of improved exercise performance, as long as there are no claims on the packaging to "diagnose, mitigate, treat, cure, or prevent" disease. The Position on Nutrition and Athletic Performance[1] reports the following criteria for assessing the validity of such claims:

- Evaluate the scientific validity of an ergogenic claim
- Evaluate the quality of the supportive evidence for using the ergogenic aid
- Evaluate the safety and legality of the ergogenic aid

Discretion is advised when using any nutritional supplement in an attempt to enhance physical performance. The consumption of improper amounts of certain ergogenic aids may cause a wide range of health problems, from diarrhea to more serious illnesses and fatalities. The recommendation by the Position on Nutrition and Athletic Performance[1] states that ergogenic products should be "used with caution and only after careful examination of the product [by a nutritional professional] for safety,

---

TABLE 19.6
Popular Nutritional Ergogenic Supplements Categorized by Performance-Enhancing Claim

Performance-Enhancing Claim

Increase energy supply/delay fatigue
Alkaline salts (e.g., sodium bicarbonate)[a]
Bee Pollen[b]
Caffeine[a,c,d]
Carnitine[b]
Coenzyme Q10 (ubiquinone)[b]
Creatine (methylguanidine-acetic acid)[a]
Dihydroxyacetone pyruvate[b]
Ephedrine (ephedra, ma huang)[b,c]
Ginseng[b]
Glycerol[b]
Phosphates[b]
Ribose[b]

Promote immune system function
Bee Pollen[b]
Coenzyme Q10 (ubiquinone)[b]
Echinacea[a]
Ginseng[b]

Achieve neuromuscular relaxation;
  decrease anxiety
Alcohol[b,c]

Maintain joint/cartilage health
Boron[b]
Glucosamine[a]
Chondroitin[a]
Collagen[b]

Enhance muscle anabolism and strength; reduce muscle catabolism
Androstenediol[b,c]
Androstenedione[b,c]
Bee Pollen[b]
Boron[b]
Chromium[b]
Chrysin[b]
Colostrum[b]
Creatine (methylguanidine-acetic acid)[a]
Dehydroepiandrosterone (DHEA)[b,c]
Dihydroxyacetone pyruvate[b]
Ginseng[b]
β-hydroxy-β-methylbutyrate (HMB)[a]
Mummio[b]
Norandrostenedione[b,c]
Ornithine alphaketoglutarate (OKG)[b]
Saw palmetto[b]
Smilax[b]
Tribulus terrestris[b]
Vanadium[b]
Yohimbine[b]

Increase fatty acid oxidation; promote weight loss
Caffeine[a,c,d]
Carnitine[b]
Collagen[b]
Ephedrine (ephedra, ma huang)[b,c]

Strength of Evidence (refers to individual supplements taken alone):

[a] Available studies generally support effectiveness for some individuals in some circumstances; confirming research is needed.

[b] Modest, inconclusive, or no positive data available to support effectiveness.

[c] Refers to substances that are currently banned by the Federal Drug Administration, International Olympic Committee, National Collegiate Athletic Association, National Football League, National Basketball Association, and/or Major League Baseball.

[d] Substance is prohibited in competition by most sports-governing organizations if urine concentrations >12 to 15 μg/ml.

Note: Information in this table was obtained from the National Center for Drug Free Sport, Inc.: http://www.drugfreesport.com/, the National Institutes of Health Office of Dietary Supplements: http://dietary-supplements.info.nih.gov/, and the President's Council on Physical Fitness and Sports Research Digest: Nutritional Ergogenics & Sports Performance: http://www.fitness.gov/

efficacy, potency, and legality." A detailed review of available ergogenic aids is beyond the focus of this chapter; however, some of the more popular nutritional supplements touted to improve physical performance not featured in earlier sections are listed in Table 19.6. Organizations such as the International Olympic Committee, the National Collegiate Athletic Association, and several sport-specific authorities (e.g., the National Football League, the National Basketball Association, and Major League Baseball) maintain updated lists of available performance-enhancing products and strive to enforce the prohibition of unsafe substances for use in competitive sport. Comprehensive examinations of the basic science, side effects, and efficacy of presently existing ergogenic supplements are published elsewhere.[127,128]

SUMMARY AND PRACTICAL APPLICATIONS

Appropriate intakes of energy, macronutrients, micronutrients, and water are necessary to ensure optimal performance with exercise. If any nutrient associated with the production of energy is limited in the diet, physical functioning during exercise could also be limited. A key strategy to meeting nutrient needs of almost all exercising individuals is to maintain variety in the diet; that is, consume the appropriate number of servings for a given caloric requirement, such as those reported in the 2005 Dietary Guidelines for Americans. If energy intakes are appropriate for energy expenditure, the specific nutrient needs for the exercising individual should not differ considerably from the foremost recommendations targeted at the general population (e.g., as outlined in the DRI reports). Activities of moderate to vigorous intensity typically require additional energy, primarily in the form of carbohydrates, and fluids in order to maintain glycogen stores and optimize physical performance. Special considerations related to vigorous activity place several nutrient recommendations for elite and/or endurance athletes above the DRI guidelines, which are most often required in proportion to individual caloric needs.

There is insufficient scientific evidence to recommend supplementing with individual micronutrients, unless intakes from major food groups, such as fruits and vegetables, are inadequate. For individuals on energy-restricted diets, vitamin/mineral supplements may be necessary to improve exercise performance (and at the very least, help achieve the AI/RDA recommendations), whereas such supplements may not be as effective in well-nourished individuals. Similarly, the level of training proficiency can impact the metabolic response to nutrients with exercise, where the presence of nutrients (or supplements) in the diet may elicit more pronounced effects on physiological responses in the inexperienced vs. the experienced exerciser.

As supplementation with certain nutrients above the DRI may actually have a negative impact on exercise performance and overall health, consumption of megadoses of vitamins and minerals is not advised. Furthermore, supplementation with any ergogenic aid is discouraged unless the product has been evaluated for safety, efficacy, potency, and legality. Physically active individuals should be encouraged to seek advice from a registered dietitian to provide advice with regard to food, fluid, and supplement intakes based on personalized nutrient needs.

20 Vegetarian Diets in Health Promotion and Disease Prevention

Claudia S. Plaisted Fernandez and Kelly M. Adams

CONTENTS

OVERVIEW/INTRODUCTION

Vegetarianism is rapidly growing in popularity. Technically defined, vegetarians are individuals who do not eat any meat, poultry, or seafood.[1,2] Estimates on the number of vegetarians in the United States vary greatly according to the definition of vegetarianism provided in the survey. True vegetarians make up about 2.8% of the population representing approximately 5.7 million adults according to a 2003 poll.[3] A higher percentage of teenagers than adults follow a vegetarian diet. [3]

Vegetarian dietary patterns can represent an exceptionally healthy way of eating. They are typically rich in vitamins, minerals, phytochemicals, and fiber while often also low in fat, saturated fat, and cholesterol.[1,4] However, each individual diet will need to be assessed for its nutritional adequacy. This chapter provides some guidance in characterizing vegetarian dietary patterns, health benefits, and concerns as well as in identifying sources of various nutrients that may be marginal in many vegetarian diets.

CHARACTERISTICS OF VEGETARIAN EATING STYLES

When working with someone who follows a vegetarian diet, it is important to ask them a variety of questions about their usual dietary patterns. Many people consider themselves to be vegetarian when they eat nonflesh foods several days a week. Others will claim to be vegetarians when they consume fish or poultry. Table 20.1 lists the types of vegetarian diets and describes what foods fall into or out of those categories.

In popular culture, there are many diets that incorporate principles of vegetarianism and may represent more restrictive ways of eating as described in Table 20.2. For the purposes of this chapter, "vegetarian" will refer to an individual following a lacto and/or ovo pattern or a vegan dietary pattern.

A more restrictive diet makes the individual following it more susceptible to dietary deficiencies and imbalances.[1,2] Table 20.3 describes the nutrients that may be of concern in many vegetarian diets.

HEALTH BENEFITS AND RISKS OF VEGETARIANISM

Most health risks associated with a vegetarian diet are found with strict vegetarianism (veganism) only, not with the more liberal forms of intake found in lacto-vegetarians, ovo-vegetarians, or lacto-ovo vegetarians.[1,10,11] Table 20.4 lists the health risks of vegetarianism, most of which are related to the potential for nutrient deficiencies found with this type of diet. These health risks are not unique to vegetarians, however, as they can be quite common in people following an imbalanced omnivorous diet.

TABLE 20.1

Types of Vegetarian Diets

Vegan	Consumes nuts, fruits, grains, legumes, and vegetables. Does not consume animal-based food products, including eggs, dairy products, red meats, poultry, or seafood. Some vegetarians may avoid foods with animal processing (honey, sugar, vinegar, wine, beer, etc.)
Lacto-vegetarian	Consumes milk and other dairy products, nuts, fruits, grains, legumes, and vegetables. Does not consume eggs, red meats, poultry, or seafood
Ovo-vegetarian	Consumes eggs, nuts, fruits, grains, legumes, and vegetables. Does not consume milk or dairy, red meats, poultry, or seafood
Lacto-ovo vegetarian	Consumes milk and other dairy products, eggs, nuts, fruits, grains, legumes, and vegetables. Does not consume red meats, poultry, or seafood
Pollo-vegetarian[a]	Not technically considered a vegetarian type of diet, although often referred to as "vegetarian" in popular culture. Consumes milk and other dairy products, eggs, nuts, fruits, grains, legumes, vegetables, and poultry
Peche-vegetarian, also called pesco- and pecto-vegetarian[a]	Not technically considered a vegetarian type of diet, although often referred to as "vegetarian" in popular culture. Consumes milk and other dairy products, eggs, nuts, fruits, grains, legumes, vegetables, and seafood
Omnivore	Consumes from a wide variety of foods, including meats, grains, fruits, vegetables, legumes, and dairy products. Individuals who consume red meats (beef, pork, lamb, etc), poultry, seafood, or any still or once living nonplant based matter are not vegetarians

[a] This is not technically a vegetarian diet, although it is often referred to as such.

TABLE 20.2

Types of Popular Diets[a] Incorporating Various Principles of Vegetarianism

Fad diets	Popular weight loss diets often incorporate various principles of vegetarianism, although not generally in nutritious, balanced ways. The cabbage soup diet is an example, which is based on consuming only a vegetable soup based on cabbage as a weight-loss technique
Fruitarian	Consumes botanical fruits (including nuts and seeds), avoids meats, poultry, seafood, dairy, eggs, and vegetables. May avoid legumes
Macrobiotic	Largely based on grains and in-season foods, including vegetables (except those of the nightshade family), sea vegetables, soups, and beans. Nuts and seeds are not consumed on a daily basis, along with fruits, which are included with the exception of tropical ones. Seafood is sometimes included as well. Asian foods contribute significantly to food choices
	This is an example of a diet following a food-combining philosophy
Natural hygiene or raw foods diet	Generally raw vegetables, fruits, whole grains or sprouted grains (in some cases may be cooked), sprouted or nonsprouted legumes, nuts, and seeds. Some consumers may consume raw dairy products. There is great variation in this diet plan: many followers do consume cooked foods and some consume meat as well
	This is an example of a diet following a food-combining philosophy, but has many variations among followers

[a] Many variations exist on each of these types of diets. This is not intended as a comprehensive listing.

Many vegetarians follow a dietary pattern that reduces their risks for common chronic diseases as noted in Table 20.5 and Table 20.6.[4] New vegetarians, in particular, however, may rely heavily on high fat dairy products, which may actually increase risk for cardiovascular disease. Other practical concerns for new vegetarians are found in Table 20.7.

Table 20.8 compares the typical dietary intake of vegans and lacto-ovo vegetarians with omnivores while the health risks/outcomes associated with specific kinds of vegetarian diets are mentioned in Table 20.9. The nutrients of special concern will vary depending on the type of vegetarian diet followed. As discussed in Table 20.10, some nutrients are more critical during specific developmental phases; deficiency of that particular nutrient at that stage of the lifecycle can have dramatic consequences.[10,12,29,30]

ENERGY AND MACRONUTRIENTS IN THE VEGETARIAN DIET

A common misconception about a vegetarian diet concerns protein. Many new vegetarians are frequently confronted with the question: "So how do you get your protein?" Individuals following a lacto-ovo vegetarian diet rarely have to worry about protein. Even vegans eating a reasonably balanced diet with adequate calories can easily meet their protein needs.[1,4] In reality, it is much more likely that the individual is suffering from a dietary deficiency of a micronutrient, such as calcium or zinc, than a protein deficiency. Energy and protein can be of concern in some adult vegetarian diets, particularly if the individual follows severe dietary restrictions, and in children.[29]

TABLE 20.3

Nutrients Potentially at Risk in Vegetarian Diets, Dietary Reference Intakes (DRIs), Functions, and Sources [2,5–7]

Vitamin/Mineral	RDA (Unless otherwise Noted): Adult Value 31–50 Year Old, Nonpregnant, per Day	Function	Good Sources in Vegetarian Diet
Vitamins			
Vitamin B$_{12}$	M: 2.4 mcg F: 2.4 mcg	Works with folic acid to make red blood cells; important in maintaining healthy nerve fibers; helps the body use fat and protein	Dairy products, eggs, fortified cereals, fortified soy products/meat substitutes, and fortified nutritional yeast
Vitamin D	Adequate Intake (AI): M: 5 mcg F: 5 mcg	Promotes absorption of calcium and phosphorus and helps deposit them in bones and teeth	Fortified milk; made in body when skin is exposed to sunlight
Riboflavin (B$_2$)	M: 1.3 mg F: 1.1 mg	Helps the body release energy from protein, fat, and carbohydrates	Fortified dairy products, fortified breads and cereals, tomatoes, lima beans, raisins, avocado, beans, and legumes
Minerals			
Calcium	AI: M: 1000 mg F: 1000 mg	Used to build bones and teeth and keep them strong; important in muscle contraction and blood clotting	Dairy products, broccoli, mustard, and turnip greens
Iron[a]	M: 8 mg F: 18 mg	Carries oxygen in the body, both as a part of hemoglobin (in the blood), and myoglobin (in the muscles)	Whole-grain and enriched cereals, some dried fruits, and soybeans
Zinc	M: 11 mg F: 8 mg	Assists in wound healing, blood formation, and general growth and maintenance of all tissues; component of many enzymes	Plant and animal proteins
Manganese[b]	AI: M: 2.3 mg F: 1.8 mg	Found in most of body's organs and tissues, particularly in bones, liver, and kidneys. Serves as a cofactor in many metabolic processes. Deficiency not seen in human populations	Whole grains, cereal products, tea, some fruits, and vegetables
Iodine	150 mcg	Constituent of thyroid hormones (regulation of metabolic rate, body temperature, growth, reproduction, making body cells, muscle function, and nerve growth).	Fortified in salt, found widely in processed foods and grains where soil concentration is adequate.
Copper[c]	AI: M: 900 mcg F: 900 mcg	Necessary for the formation of hemoglobin; keeps bones, blood vessels, and nerves healthy	Nuts, legumes, and whole grains
Selenium	Males: 55 mcg Females: 55 mcg	Antioxidant functions, role in eicosanoid metabolism, regulation of arachadonic acid and lipid peroxidation, and some hormone conversions	Eggs, whole grains, legumes, and brazil nuts
Macronutrients and other dietary components			
Protein	Male: 56 g or .8g/kg Female: 46 g or .8 gm/kg	Building of nearly all body tissues, particularly muscle tissue, energy	Dairy products, legumes, meat analog products often made from soy; whole grains and vegetables are poorer sources
Omega-3 fatty acids	AI: M: 1.6 g F: 1.1 g	Energy source, cell wall structure, may play a role in disease prevention. Fats also play a role in the absorption and transport of fat-soluble vitamins. Linolenic acid cannot be made by the body, omega-3 series fatty acids can be found in grains, seeds, nuts, and soybeans and the body can manufacture eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) from these precursors, but conversion is inefficient	Fats and oils (bean, nut, and grain oils), nuts, and seeds (butternuts, walnuts, and soybean kernels), soybeans, flax seeds, and flax seed oil

[a] There is some evidence that vegetarian diets tend to be quite high in iron and that iron deficiency anemia is no more common among vegetarians than in meat eaters.[1]

[b] Manganese is not necessarily at risk for deficiency in vegetarians. Some research has indicated that vegetarians have a higher intake of this nutrient; however, bioavailability may be a concern.[8,9]

[c] Copper is not necessarily at risk for deficiency in vegetarians. Some research has indicated that vegetarians have a higher intake of this nutrient; however, bioavailability may be a concern. [8,9]

TABLE 20.4
Health Risks of Vegetarianism[1,10,12–20]

Dietary Factor	Risk
Calcium	Low calcium intake in vegan or macrobiotic diet can lead to low bone mineral density.
Iodine	A strict vegan consuming no iodized salt or processed food products can develop goiter.
Vitamin B_{12}	In strict vegans or in the offspring of vegan mothers only, deficiency can lead to anemia or in far more severe cases, neuropathy.
Energy	Impaired growth can result in infants and children with inadequate energy intake or those weaned to "homemade" formulas.
Docosahexaenoic acid (DHA)	Greatest concern for fetus and young infants. DHA is needed for neural and retinal development.
Dairy products	Iron deficiency with excessive consumption of dairy products in young children. Limited evidence exists linking high consumption of dairy products to diabetes (type 1).

TABLE 20.5
Health Benefits of Vegetarianism[1,2,4,13,21–26]

Lower risk of:
   Cancer (particularly colon and lung)
   Obesity
   Heart disease
   Type 2 Diabetes
   Hypertension
   Constipation and Hemorrhoids
   Kidney stones
   Gallstones
Potential lower risk for (limited evidence suggesting):
   Arthritis
   Gout
   Dementia
   Tooth decay
   Duodenal ulcers

TABLE 20.6
Protective Factors in the Typical
Lacto-Ovo Vegetarian Diet[1,4,21,27,28]

Higher fiber
Lower fat, saturated fat, and cholesterol
Higher folate intake
Higher intake of antioxidants
Higher intake of phytochemicals
Lower intake of total and animal protein

TABLE 20.7
Practical Concerns about Vegetarianism

New vegetarians or those who are vegetarian for philosophical (as opposed to health) reasons may rely heavily on the use of dairy products and eggs.
Whole-milk cheeses, 2% and higher-fat-content milk, eggs, and whole-milk yogurts are rich in fat, saturated fat and, in some cases, cholesterol as well. These can contribute to higher risks for cardiovascular disease in particular and should be evaluated.
Some adolescents with eating disorders may use vegetarianism as a rationalization for avoiding foods or entire food groups.

TABLE 20.8

Nutrient Differences between Omnivore, Lacto-Ovo, and Vegan Dietary Patterns[1,2]

Dietary Component	Vegan	Lacto-Ovo	Omnivore
Total fat (% of total energy)	25–30	28–34	34
Saturated Fat	Generally low saturated fat intake	Generally moderate saturated fat intake	Generally higher saturated fat intake
P/S ratio	High P/S	Mod P/S	Poor P/S
Fiber (g/d range)	25–50	20–35	15–20
Carbohydrate (% total calories)	50–65	50–55	<50
Protein (% of total calories)	10–12 (none from animal sources)	12–14 (~1/2 from animal sources)	14–18 (~2/3 from animal sources)
Folate (mcg/d ranges)	170–385	214–455	252–471
Cholesterol (mg dietary intake)	0	150–300	300
Cholesterol serum levels (mmol/L)	4.29	4.88	5.31
Blood pressure (mm HG systolic/diastolic)	112.5/65.3	111.8/68.8	120.8/76.4

TABLE 20.9

Health Risks of Individuals Following Various Types of Vegetarian Diets[1,2]

Type of Vegetarian Diet	Health Risk Profile	Nutrients at Greatest Risk
Vegan	Low risk of obesity, heart disease, cancer, hypertension, and diabetes. Vegans may have a lower health risk than lacto-ovo vegetarians due to the typical lower fat and higher fiber content than either lacto-ovo or nonvegetarians	Vitamin B_{12} Vitamin D Calcium Zinc Energy Potentially Iron
Lacto-vegetarian	Generally low risk of obesity, heart disease, cancer, hypertension, and diabetes. Unskilled or new vegetarian may rely heavily on whole-milk-based products, thus consuming high fat, saturated fat and cholesterol intakes, which could increase the risk of cardiovascular-related diseases	Zinc Potentially Iron
Ovo-vegetarian	Generally low risk of obesity, heart disease, cancer, hypertension, and diabetes. Unskilled or new vegetarian may rely heavily on eggs and egg-based products, thus consuming high fat, saturated fat, and cholesterol intakes, which could increase the risk of cardiovascular-related diseases	Zinc Potentially Iron
Lacto-ovo Vegetarian	Generally low risk of obesity, heart disease, cancer, hypertension, and diabetes. Unskilled or new vegetarian may rely heavily on whole-milk- or egg-based products, thus consuming high fat, saturated fat and cholesterol intakes, which could increase the risk of cardiovascular-related diseases	Zinc Potentially Iron

Table 20.11 through Table 20.13 provides information about essential and nonessential amino acids and protein complementation. In the 1970s, carefully complementing proteins at each meal was thought to be the only way that vegetarians could avoid protein deficiency. We now know that it is not necessary to combine proteins at each meal,[1,4] yet it is important to understand the terminology related to the body's protein needs and the principles of complementation.

Table 20.14 compares average protein intakes in the United States, while Table 20.15 and Table 20.16 provide information about protein and nutrient dense/energy dense food sources. As an arbitrary guideline, foods with 2 g or less of protein were not included. The information about nutrient- and energy-dense foods can be useful for young children who may fill up quickly on a bulky vegetarian diet without meeting their calorie and nutrient needs.[30]

TABLE 20.10
Critical Periods of Importance for Selected Nutrients[2,5,17]

Nutrient	Critical Periods During Lifecycle
Vitamin B_{12}	Throughout, particularly critical during pregnancy, infancy, and childhood
Riboflavin (B_2)	Pregnancy, periods of growth
Vitamin D	Childhood and prepuberty, pregnancy, and elderly
Calcium	Childhood and prepuberty, elderly
Iron	Infancy, childhood, adolescence, pregnancy, and adulthood (women particularly)
Zinc	Puberty, pregnancy, and elderly
Iodine	Adolescence, pregnancy, and lactation
Protein	Infancy, childhood, adolescence, and pregnancy
Omega-3 fatty acids (especially DHA)	Pregnancy and infancy
Energy	Periods of growth, especially toddlers/preschoolers, due to small stomach capacity

TABLE 20.11
Definitions Related to Protein Complementation[2]

Complete protein	Contains all essential amino acids in ample amounts; amino acid pattern is very similar to humans
Incomplete protein	May be low in one or more amino acids; amino acid pattern is very different from humans
Limiting amino acid	The essential amino acid(s) that are in the smallest supply in the food
Essential amino acid	Cannot be synthesized by the human body. Include: Arginine, Histidine, Isoleucine, Leucine, Lysine, Methionine, Phenylalanine, Threonine, Tryptophan, and Valine

TABLE 20.12
Limiting Essential Amino Acids and Vegan Sources[1,2]

Food	Limiting Amino Acids	Vegan Sources of the Limiting Amino Acids
Legumes	Methionine, cysteine	Grains, nuts, seeds, and soybeans
Cereals/grains	Lysine and threonine	Legumes
Nuts and seeds	Lysine	Legumes
Peanuts	Methionine, lysine, and threonine	Legumes, grains, nuts, seeds, and soybeans
Vegetables	Methionine	Grains, nuts, and seeds, and soybeans
Corn	Tryptophan, lysine, and threonine	Legumes, sesame and sunflower seeds, and soybeans

TABLE 20.13
Guidelines for Protein Complementation[1,2]

Type of Vegetarian Diet	Guidelines for Complementation[a]
Lacto-ovo	Dairy products and eggs provide complete protein, as do other animal products
Vegan	A vegan diet that contains a variety of grains, legumes, vegetables, seeds, and nuts over the course of a day in amounts to meet a person's calorie needs will provide adequate amino acids in appropriate amounts. Soybeans match human needs for essential amino acids as precisely as animal foods and are, thus, a complete protein.
Any	It is not necessary to combine proteins in each meal. Young children, however, may need to have the complementary proteins consumed within a few hours of each other.

[a] All proteins except gelatin provide all of the amino acids. Some protein sources have relatively low levels of some amino acids, so large amount of that food would need to be consumed if it were the only source of those "limiting" amino acids.[1]

TABLE 20.14
Protein Intakes in United States[1]

Type of Diet	Percentage of Calories from Protein	Sufficient to Meet RDA?
Typical U.S. diet	14–18	Yes
Lacto-ovo vegetarians	12–14	Yes, provided adequate calories are consumed
Vegans	10–12	Yes, provided adequate calories are consumed

TABLE 20.15
Protein: Vegetarian Sources and Amounts[5,31,32]

Food	Portion Size	Protein (g)	Kcal
Cereals/Grains			
Quinoa	0.5 cup	11.1	318
Millet, cooked	1 cup	8.4	286
Wheat germ, toasted	0.25 cup	8.4	111
Bagel, plain	1 bagel	7.5	195
Couscous, cooked	1 cup	6.8	200
Macaroni, enriched, cooked	1 cup	6.7	197
Pita, whole wheat	1 pita	6.3	170
Grape-Nuts, Post	0.5 cup	6.0	200
Oatmeal Crisp, almond, and General Mills	1 cup	6.0	220
Oatmeal, old fashioned, and Quaker	0.5 cup dry	5.5	148
Oat bran, raw	0.33 cup	5.4	76
Brown rice, medium grain, cooked	1 cup	4.5	218
English muffin, plain	1 muffin	4.4	134
Barley, pearled, cooked	1 cup	3.5	193
Whole wheat bread	1 slice	2.7	69
Corn grits, instant, white, enriched	1 oz. packet dry	2.4	96
Vegetables			
Peas, green, canned	0.5 cup	3.8	59
Corn, yellow, boiled	0.5 cup	2.7	89
Broccoli, boiled	0.5 cup	2.3	22
Fruits			
Prunes, dried	10 prunes	2.2	201
Dairy/Soymilk			
Cottage cheese, 1% fat	1 cup	28.0	164
Yogurt, low fat (1.5% milk fat), plain, Breyers	1 cup	11.0	130
Simple Pleasures, chocolate	0.5 cup	8.9	134
Gruyere cheese	1 oz.	8.5	117
Milk, low fat (1%)	1 cup	8.0	102
Cheddar cheese	1 oz.	7.1	114
Soymilk	1 cup	6.6	79
American processed cheese	1 oz.	6.3	106
Pudding, all flavors, from instant mix Jell-O Brand	0.5 cup	4.0	155
Frozen yogurt, soft serve	0.5 cup	2.9	115
Ice cream, vanilla, regular (10% fat)	0.5 cup	2.3	133
Beans/Legumes			
Soybean nuts, roasted	0.5 cup	30.3	405
Lentils, boiled	1 cup	17.9	230
Lima beans, boiled	1 cup	14.7	216
Kidney beans, canned	1 cup	13.3	207
Garbanzo beans, canned	1 cup	11.9	286

Continued

**TABLE 20.15
(Continued)**

Food	Portion Size	Protein (g)	Kcal
Soy Products/Meat Substitutes			
Tofu, raw, firm	0.5 cup	19.9	183
Tempeh	0.5 cup	15.7	165
Pepperoni from meat substitute	16 slices	14	70
Better 'n Burger, Morningstar Farms	1 patty	11.3	75
Soybeans, green, boiled	0.5 cup	11.1	127
Ground Meatless, frozen, Morningstar Farms	0.5 cup	10.3	60
Meatless deli turkey	3 slices	9	40
Nuts/Seeds			
Peanut butter, chunk style/crunchy	2 T	7.7	188
Sunflower seeds, dried	1 oz.	6.2	160
Almonds, blanched	1 oz.	6.0	174
Sesame butter (tahini)	2 T	5.0	174
Cashews, dry roasted	1 oz.	4.3	163
Eggs			
Egg substitute, frozen	0.25 cup	6.8	96
Egg, chicken, whole, fresh/frozen	1 large	6.2	75
Egg, chicken, yolk fresh	1 large	2.8	61
Mixed Foods			
Frozen french bread pizza, vegetarian	6 oz. pizza	17.0	270
Shells and cheese, from mix	1 cup	16.0	360
Burritos with beans	2 burritos	14.1	447
Biscuit with egg	1 item	11.1	316
Potato, baked, with sour cream and chives	1 potato	6.7	393

Adult RDA: Males 56 g/day Females 46 g/day; taking into account the lower digestibility and amino acid profile, a reasonable RDA for vegans is approximately 10% more protein than omnivores.

**TABLE 20.16
Vegetarian Sources of Energy-Dense, Nutrient-Dense Foods[31,32]**

Food	Portion Size	Kcal
Cereals/Grains		
Granola, low-fat	1 cup	422
Quinoa	0.5 cup	318
Millet, cooked	1 cup	286
Pancakes, Bisquick, and blueberry	3 each	220
Oatmeal Crisp	1 cup	210
Grape-Nuts, Post	0.5 cup	200
Macaroni, enriched, cooked	1 cup	197
Bagel, plain	1 bagel	195
Raisin bran, dry	1 cup	175
Corn muffin (2.5 × 2.25 in.)	1 muffin	174
Pita, whole wheat	1 pita (6.5 in diameter)	170
Banana nut muffin, from mix	1 muffin	160
Oat bran muffin	1 muffin	154
Vegetables		
Tater Tots, frozen, heated	4 oz.	204
Potatoes, mashed from granules	1 cup	166

TABLE 20.16
(Continued)

Food	Portion Size	Kcal
Fruits		
Avocado, California, raw	0.5 medium	153
Raisins, golden, seedless	0.66 cup	302
Mixed fruit, dried, diced, Delmonte	0.66 cup	220
Dairy/Soymilk		
Milkshake, thick vanilla	1 cup	256
Yogurt, flavored, low-fat, 1% milk-fat, Breyers	1 cup	251
Ricotta cheese, part-skim	0.5 cup	171
Cottage cheese (1% fat)	1 cup	164
Pudding, all flavors, from instant mix Jell-O)	0.5 cup	155
Milk, whole	1 cup	150
Yogurt, low-fat (1.5 % milk fat), plain, Breyers	1 cup	130
Cheddar cheese	1 oz.	114
Milk, low fat (1%)	1 cup	102
Soymilk	1 cup	79
Beans/Legumes		
Soybean, dried, boiled, mature	1 cup	298
Garbanzo beans, canned	1 cup	286
Lentils, boiled	1 cup	230
Soy Products/Meat Substitutes		
Soybean nuts (roasted)	0.5 cup	405
Tempeh	1 cup	330
Soyburger with cheese	1 each	316
Chicken nuggets, meatless	5 pieces	245
Frankfurter, meatless	1 each	102
Nuts/Seeds		
Peanut butter, chunky style	2 T	188
Almonds, blanched	1 oz.	174
Sesame butter (tahini)	2 T	174
Sunflower seeds, dried	1 oz.	160
Mixed Foods		
Egg salad	1 cup	586
Burritos, with beans	2 burritos	447
Potato, baked, with sour cream and chives	1 potato	393
Shells and cheese, from mix	1 cup	360
Peanut butter and jam sandwich on wheat	1 each	344
Cheese enchilada	1 item	320
Biscuit with egg	1 item	316
Lasagna, no meat, recipe	1 piece	298
Chili, meatless, canned	0.66 cup	190
Trail mix, regular	0.25 cup	150
Vegetable soup	1 cup	145
Pizza, cheese	1/8 of 12-in.	140
Pasta with marinara sauce	1 cup	180–450

MICRONUTRIENTS IN THE VEGETARIAN DIET

Although vegetarian dietary patterns can be extremely healthful,[1,13,21–23] certain micronutrients can be challenging to obtain in sufficient quantities depending on the specific dietary restrictions the individual follows. Table 20.17 through Table 20.28 provide information about sources of micronutrients that can be of concern for some vegetarian individuals.[1,4,8–13,22,37,38] As a guideline, foods with less than 5 to 10% of the recommended amount of that particular nutrient per serving were not included in the table.

Bioavailability of minerals can influence the amount available for absorption. Table 20.24 and Table 20.28 list factors that may enhance or inhibit the absorption of iron and zinc.

TABLE 20.17
Riboflavin[a]: Vegetarian Sources and Amounts[5,6,31,32]

Food	Portion Size	Riboflavin (mg)	Kcal
Cereals[b,c]/Grains			
Raisin bran	1 cup (2.1 oz.)	0.678	175
Bran flakes	0.66 cup (1 oz.)	0.43	91.5
Corn flakes, Kellogg's	1 cup (1 oz.)	0.375	90
Bagel, plain	1 bagel (3.5 in.)	0.22	195
Sesame breadsticks	2 sticks	0.22	120
Pita, white	1 pita (6.5 in. diameter)	0.20	165
Lasagna noodles	2 oz. dry	0.20	210
Cornbread, homemade from low-fat milk	1 slice	0.19	173
Corn muffin (2.5 × 2.25 in.)	1 muffin	0.19	174
English muffin, wheat	1 muffin	0.17	127
English muffin, plain	1 muffin	0.16	134
Muffin, blueberry, homemade (2.75 × 2 in.)	1 muffin	0.16	163.5
Macaroni, enriched and cooked	1 cup	0.14	197
Wild rice, cooked	1 cup	0.14	166
Rye bread	1 slice	0.11	83
Vegetables			
Mushrooms, boiled	0.5 cup	0.23	21
Tomato puree, canned	1 cup	0.14	100
Sweet potatoes, baked, with skin	1 medium	0.14	117
Tomato, red, sun-dried	0.5 cup	0.13	69.5
Garden cress, boiled	0.5 cup	0.11	16
Fruits			
Raisins, golden seedless	0.66 cup	0.19	302
Banana	1 medium	0.11	105
Raspberries, raw	1 cup	0.11	60
Avocado, Calif. raw	0.5 medium	0.105	153
Dairy/Soymilk			
Yogurt, plain, low fat	1 cup	0.493	209
Milk, whole	1 cup	0.395	150
Cottage cheese, 1% fat	1 cup	0.37	164
Milk, nonfat	1 cup	0.34	86
Feta cheese	1 oz.	0.24	75
Ricotta cheese, part-skim	0.5 cup	0.23	171
Soymilk	1 cup	0.17	79
Cheddar cheese, reduced fat	1 oz.	0.14	80
Cheddar cheese	1 oz.	0.11	114
Goat cheese, soft	1 oz.	0.11	76
Beans/Legumes			
Soybeans, boiled	1 cup	0.49	298
Kidney beans, canned	1 cup	0.18	207
Great northern beans, canned	1 cup	0.16	299
Pinto beans, boiled	1 cup	0.16	234
Lentils, boiled	1 cup	0.14	230
Soy Products/Meat Substitutes			
Chicken nuggets, meatless	5 pieces	0.30	245
Vegetarian burger, grilled, Morningstar Farms	1 patty	0.24	140
Breakfast links, Morningstar Farms	2 links	0.22	63
Tofu, raw, firm	0.5 cup	0.13	183
Nuts/Seeds			
Almonds, dry roasted	1 oz.	0.17	166
Eggs			
Egg, chicken, boiled	1 large	0.298	89.9
Egg substitute, frozen	0.25 cup	0.188	52.8

TABLE 20.17
(Continued)

Food	Portion Size	Riboflavin (mg)	Kcal
Mixed Foods			
Bean burrito	2 each	0.61	447
Cheese enchilada	1 each	0.42	319
Egg omelet with onion, pepper, tomato, and mushroom	1 each	0.344	125
Vegetarian chili, fat-free with black beans, Health Valley	5 oz.	0.255	70
Beverages			
Coffee substitute with milk	0.75 cup	0.298	120
Miscellaneous			
Brewers yeast	1 T	0.342	22.6

Adult RDA: Males 1.3 mg/day; females 1.1 mg/day.

[a] Also called vitamin B_2.
[b] Most fortified breakfast cereals contain 0.43–0.51 mg per serving.
[c] Many "100% Natural" breakfast cereals are not enriched and contain 0.03–0.12 mg per serving.

TABLE 20.18
Vitamin B_{12}: Vegetarian Sources and Amounts[5,6,31,32]

Food	Portion Size	Vitamin B_{12} (mcg)	Kcal
Cereals[a]/Grains			
Total, wheat	1 cup	7.00	116
Waffle, whole grain	2 each	3.11	154
Bran flakes	1 cup	2.49	152
Granola, low-fat	0.33 cup	1.50	120
Kix	1.5 cup	1.50	110
Corn flakes, dry	1 cup	1.27	92.9
Waffle, frozen, toasted	1 each	0.882	92.4
Dairy/Soy milk[b]			
Soymilk, Edensoy Extra	1 cup	3.0	130
Cottage cheese, 1% fat	1 cup	1.43	164
Milk, skim	1 cup	0.93	86
Yogurt, flavored, low-fat 1% milk-fat, Breyers	1 cup	0.90	251
Milk, whole	1 cup	0.87	150
Yogurt, whole, plain	1 cup	0.84	139
Yogurt, nonfat, flavored with aspartame, Light 'n Lively Free 70 Cal	1 cup	0.60	70
Buttermilk, cultured	1 cup	0.54	99
Feta cheese	1 oz.	0.479	74.8
Swiss cheese	1 oz.	0.476	107
Ricotta cheese, part-skim	0.5 cup	0.36	171
Havarti cheese	1 oz.	0.357	105
American processed cheese food	1 oz.	0.235	68.9
Cheddar cheese	1 oz.	0.23	114
Soy Products/Meat Substitutes[c]			
Breakfast links	2 each	3.41	63
Soyburger with cheese	1 each	1.72	316
Soyburger	1 each	1.70	142
Tempeh	1 cup	1.66	330
Breakfast patties	1 each	1.49	68
Chicken, meatless, breaded, fried patty	1 piece	0.95	177

Continued

TABLE 20.18
(Continued)

Food	Portion Size	Vitamin B$_{12}$ (mcg)	Kcal
Eggs			
Egg, chicken, boiled	1 large	0.56	78
Mixed Foods			
Spinach soufflé	1 cup	1.37	219
Cheese pizza	1 piece (1/8 of a 15-in. pie)	0.53	223
Miscellaneous			
Fortified nutritional yeast (Red Star T6635)	1 T	4.0	40

Adult RDA: 2.4 mcg/day.

[a] Some commercial cereals are not fortified with vitamin B$_{12}$, check labels carefully.
[b] Subject to fortification; unfortified soymilk contains no vitamin B$_{12}$.
[c] Subject of fortification; check labels of individual product carefully.

TABLE 20.19
Vitamin D: vegetarian sources and amounts[5,6,31–33]

Food	Portion Size	Vitamin D (IU)[a]	Kcal
Cereals/Grains			
Raisin bran	1 cup (2.1 oz.)	56	175
Corn Pops	1 cup	50	110
Lucky Charms	1 cup	44.8	125
Corn flakes	1 cup (1 oz.)	44	90
Granola, low-fat	0.33 cup	39.9	120
Wheat bran muffin from recipe with 2% milk	1 muffin (57 g)	25.1	161
Waffles, plain, recipe	1 each (75 g)	23.5	218
Vegetables			
Mushrooms, boiled	0.5 cup	59.3	21.1
Dairy/Soymilk			
Soymilk, Soy Moo, fat free, Health Valley	1 cup	100	110
Milk, nonfat	1 cup	98	85.5
Milk, whole	1 cup	97.6	150
Pudding, vanilla, instant, with whole milk	0.5 cup	49.0	162
Eggs			
Egg, chicken, boiled	1 large	26	78
Egg yolk, cooked	1 each	24.6	59.2
Mixed Foods			
Soup, tomato bisque, with milk	1 cup	49.2	198
Egg salad	0.5 cup	38.5	293
Egg omelet with mushroom	1 each (69 g)	36.4	91.2
Fats/Oils/Dressings			
Margarine, hard, hydrogenated soybean[b]	1 tsp.	19.9	29.8
Desserts			
Egg custard pie, frozen, baked	1 piece (105 g)	40.1	221
Chocolate-filled crepe	1 each (78 g)	28.1	119
Coffee cake, from mix	1 piece (72 g)	22.2	229

Adult Adequate Intake: 5 mg cholecalciferol (200 IU/day).

[a] 1 IU vitamin D = 0.025 μg cholecalciferol.
[b] Subject to fortification; check labels.

TABLE 20.20
Calcium: Vegetarian Sources and Amounts[5,6,19,31,32]

Food	Portion Size	Calcium (mg)	Kcal
Cereals/Grains			
Calcium fortified cereal bars	1 bar (37 g)	200	140
Vegetables			
Collards, frozen, boiled	0.5 cup	179	31
Kale, frozen, boiled	1 cup	179	39
Turnip greens, canned	0.5 cup	138	16
Squash, acorn, baked	1 cup	90.2	115
Okra, boiled	0.5 cup	88	34
Squash, butternut, baked	1 cup	84	82
Broccoli, cooked	1 cup	72	44
Peas, green, cooked, from frozen	0.5 cup	19.2	62.4
Fruits			
Calcium-fortified orange juice	8 oz	300	120
Dairy/Soymilk			
Soy milk, fortified	8 oz (1 cup)	400	110
Malted milk, chocolate (Ovaltine)	8 oz	384	225
Evaporated milk, skim	4 oz	372	100
Evaporated milk, whole	4 oz	329	169
Goat's milk	8 oz (1 cup)	327	168
Yogurt, tofu yogurt, frozen	8 oz	309	254
Cow's Milk, skim	8 oz (1 cup)	302	86
Cow's Milk, 1/2%	8 oz (1 cup)	300	90
Cow's Milk, 1%	8 oz (1 cup)	300	102
Yogurt, fat-free	8 oz	300	100
Yogurt, low-fat	8 oz	300	200
Yogurt, regular	8 oz	300	250
Cow's Milk, 2%	8 oz (1 cup)	297	121
Cow's Milk, whole		290	150
Swiss cheese	1 oz	272	107
Cheddar cheese	1 oz	204	114
American cheese	1 oz	174	106
Mozzarella cheese, part skim	1 oz	183	72
Feta cheese	1 oz	140	75
Soy milk, nonfortified	8 oz (1 cup)	79.3	150
Cottage cheese, 1% fat	0.5 cup	69	82
Beans/Legumes			
Great Northern Beans	0.5 cup	60	105
Soy Products/Meat Substitutes			
Tofu, raw, firm	0.5 cup	258	183
Tempeh	1 cup	154	330
Nuts/Seeds			
Almonds, dried	1 oz (about 24 nuts)	75	167
Desserts			
Custard, 2% milk	1 cup	394	298
Sherbet, orange	1 cup	264	104
Soft serve ice cream, French vanilla	1 cup	226	370
Frozen yogurt, soft serve	1 cup	212	230
Ice cream, vanilla, regular, 10% fat	1 cup	168	226
Miscellaneous			
Blackstrap Molasses	1 tbsp	172	47

Adult AI: Males 1000 mg/day; females: 1000 mg/day.

TABLE 20.21
Copper[a]: Vegetarian Sources[b] and Amounts [5,31,32]

Food	Portion Size	Copper (mg)	Kcal
Cereals/Grains			
100% Bran	1 c	1.04	178
Granola, low-fat, Kellogg's	0.5 c	0.655	211
Vegetables			
Potatoes, baked, stuffed with cheese	1 ea (254 g)	0.671	373
Vegetable juice cocktail, V-8	1 c	0.484	46.0
Potatoes, baked, with skin	1 ea (122 g)	0.372	133
Fruits			
Avocado, California	1 ea	0.460	306

Coconut milk, canned	.25 cup	1.9	—	111
Almonds, dried, whole	.25 cup	1.3	—	209
Mixed nuts, dry roasted with peanuts	.25 cup	1.27	—	204
Miscellaneous				
Molasses, blackstrap	1 Tbsp	3.5	—	47

Adult RDA: Male 8 mg/day; female: 18 mg/day.

NONNUTRITIVE AND OTHER IMPORTANT FACTORS IN THE VEGETARIAN DIET

Typical vegetarian diets are rich in many beneficial nonnutritive factors such as dietary fiber and phytochemicals.[24,27,28] Table 20.29 and Table 20.30 provide information about sources of these beneficial but nonnutritive factors.

Omega-3 fatty acids are a type of polyunsaturated fatty acid that are thought to reduce the risk of cardiovascular disease through their effects on triglyceride levels and platelet aggregation.[2,39] One type of omega-3 fatty acid, alpha-linolenic acid, is an essential fatty acid and must be consumed in the diet to prevent deficiency. Two other types of omega-3 fatty acids are eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Omega-3 fatty acids may be of concern to vegetarians, because although alpha-linolenic acid is found in many plant foods, EPA and DHA are not.[1] For healthy adults, this is not usually a concern, because the body has the ability to manufacture EPA and DHA from alpha-linolenic acid although vegetarians still have lower levels of blood DHA.[1,14] The fetus and young infant have a dramatically reduced ability to perform this conversion.[15] Because DHA is needed for brain and retinal development, some pregnant or breastfeeding vegetarian women may need to reduce their intake of linoleic acid (an omega-6 fatty acid) relative to their intake of alpha-linolenic acid to increase DHA levels, or they may choose to try DHA-enriched eggs or DHA supplements derived from microalgae although the safety of this has not

TABLE 20.24
Iron: Absorption Enhancers and Inhibitors[1,2,34]

Class of Inhibitors	Examples	Found in	Effect on Iron Absorption
Polyphenols	Tannic acid, gallic acid and catechin	Coffee, tea, red wines, certain spices, fruits and vegetables	Coffee: 35–40% Tea: 60% Red wine: 50%
Phytates	Substances that form insoluble complexes with nonheme iron	Whole grains, bran, soy products	
EDTA (ethylenediamine-tetraacetic acid)	Food additive used as sodium EDTA, calcium EDTA (prevents color changes and oxidation in foods)	Used broadly	Possibly up to 50% in some cases
Calcium	Calcium chloride (naturally occurring sources of calcium in self selected diets did not show an inhibitory effect, however there is a potential effect of other forms of calcium)	Additive to bread products, potential effect of other forms of calcium	Possibly up to 30–50% in some cases found with calcium chloride fortification
Fiber	Insoluble fibers, Phytate content may be responsible	Whole grains	Possibly 30–50%

Class of enhancers	Examples	Found in	Effect on Iron Absorption
Organic acids[a]	Malic, ascorbic, citric, and bile acids	Found widely in foods	Enhances absorption
Amino acids	Some amino acids such as cysteine	Protein foods, also found widely in vegetables and grains	Enhances absorption
Vitamin A and β-carotene	Retinol, retinaldehyde, retinoic acid, β-carotene	Spinach, carrots, squash, sweet potatoes, greens, cantaloupe, and mango	Enhances absorption, possibly by forming a complex with iron

[a] The presence of these acids with a meal will significantly improve iron absorption and in some cases potentially overcome the inhibitory effects of other components in foods.

TABLE 20.25
Manganese: Vegetarian Sources and Amounts[5,31,32]

Food	Portion Size	Manganese (mg)	Kcal
Cereals/Grains			
100% Bran	1 c	5.96	178
Most Cereal	1 c	3.63	175
Grape Nuts	1 c	2.65	389
Bran Chex	1 c	2.53	156
All Bran	0.33 c	2.39	70.7
Raisin Bran	1 c	2.16	175
Noodles, cooked, Spinach	1 c	2.1	182
Noodles, cooked, Macaroni, whole wheat	1 c	1.93	174
Rice flour, brown	0.25 c	1.59	144
Noodles, cooked, Lasagna, whole wheat	2 ea	1.52	136
Wheat Chex	1 c	1.34	169
Vegetables			
Lima bean, boiled	0.5 c	1.07	105
Fruits			
Pineapple, chunks	1 c	2.56	76.0
Blackberries	1 c	1.86	74.9
Soy products/meat substitutes			
Tofu, raw, firm, with Nigari	0.5 c	1.49	181
Tempeh	0.5 c	1.19	165

AI: Males: 2.3 mg/day; female: 1.8 mg/day.

Manganese is not necessarily at risk for deficiency in vegetarians. Some research has indicated that vegetarians have higher intake of this nutrient, however, bioavailability may be a concern. [8,9]

TABLE 20.26
Selenium[a]: Vegetarian Sources and Amounts[5,31,32,35]

Food	Portion Size	Selenium (mcg)	kcal
Cereals/Grains			
Special K, Kellogg's	1 cup	54.9	100
Bagel, plain, toasted	1 each	22.7	195
Granola, low-fat	1 cup	22.5	422
Pita pocket, 100% whole wheat, toasted	1 each	20.2	120
Barley, whole, cooked	0.5 cup	18.2	135
Pita pocket, white	1 each	18	165
Egg noodles, cooked	0.5 cup	17.4	107
Spaghetti/macaroni, enriched, cooked	0.5 cup	14.9	98.5
Puffed wheat	1 cup	14.8	44.4
Whole wheat bread	1 slice	12.8	86.1
Oatmeal, instant, prepared	0.5 cup	12.68	159
Buns, hamburger-style	1 each	12.5	129
English muffin, plain	1 each	11.5	134
Cheerios	1.25 cup	10.6	111
Matzo, whole wheat	1 each	9.89	99.5
Brown rice, long grain	0.5 cup	9.6	108.5
Vegetables			
Brussels sprouts, boiled	1 cup	21.1	60.8
Cucumbers, slices with peel	0.5 cup	6.19	6.76
Mushrooms, raw	5 pieces	14.3	32.4
Fruits			
Grapes, Thompson seedless	0.5 cup	7.7	57
Applesauce, canned	0.5 cup	6.5	52.5
Dairy/Soymilk			
Cottage cheese, 1%	1 cup	13.6	164
Yogurt, fruit, low-fat (12 g protein/8 oz.)	1 cup	8.09	155
Milk, nonfat	1 cup	5.15	85.5
Frozen yogurt, chocolate, nonfat	1 cup	5.02	208
Beans/Legumes			
Black beans, dry, boiled	1 cup	13.7	227
Lima Beans, cooked	1 cup	8.19	229
Great northern beans, cooked	1 cup	7.26	209
Chickpeas, boiled	1 cup	6.10	269
Soy Products/Meat Substitutes			
Tofu	0.5	1.79	94.2
Nuts/Seeds			
Brazil nuts, dried	0.25 cup	1036	230
Sunflower seeds, kernels, dry	0.25 cup	21.4	205
Cashew, dry roasted, unsalted	0.25 cup	8	197
Eggs			
Egg, hard cooked	1 each	10.7	77.5
Egg yolk, cooked	1 each	7.50	59.2
Egg white, cooked	1 each	5.88	16.6
Mixed Foods			
Lasagna, no meat, recipe	1 piece (218 g)	29.9	298
Avocado and cheese sandwich on wheat bread	1 each	25.2	456
Peanut butter and jam sandwich on wheat	1 each	24.3	344
Pizza, cheese	1/8 of 15-in. (120 g)	20.0	268
Bean burrito	1 each	14.1	223.5
Cucumber and vinegar salad	1 cup	11.1	47.8
Desserts			
Coffee cake, from mix	1 piece (72 g)	11.0	229
Carrot, with cream cheese icing, recipe	1 piece (112 g)	9.91	488

Adult RDA: Males 55 mcg/day; females 55 mcg/day.

[a] Selenium content of food can vary widely, according to the selenium content of the soil.[35]

TABLE 20.27
Zinc: Vegetarian Sources and Amounts[5,31,32,36]

Food	Portion Size	Zinc (mg)[a,b]	Kcal
Cereals/Grains			
Just Right	1 cup	22.8	152
Product 19, Kellogg's	1 cup	15	100
Complete bran	1 cup	8.07	195
100% Bran	1 cup	5.74	178
Raisin bran, dry	1 cup	5.71	175
Bran flakes	1 cup	5.15	127
Cap'n Crunch	1 cup	4.00	156
Granola, low-fat	0.33 cup	3.74	120
Quinoa	1 cup	3.4	576
Muffin, wheat bran, from recipe with 2% milk	1 each (57 g)	1.57	161
Noodle, spaghetti, spinach, cooked	1 cup	1.53	182
Bagel, oat bran	1 each	1.42	173
Pancakes, Aunt Jemima, blueberry	3 each (106 g)	1	246
Vegetables			
Palm hearts, cooked	1 cup	5.45	150
Dairy/soymilk			
Soymilk	1 cup	2.90	150
Frozen, nonfat, chocolate yogurt	1 cup	2.18	208
Ricotta cheese, part-skim	0.5 cup	1.66	170
Edam/ball cheese	1 oz.	1.07	101
Buttermilk, cultured	1 cup	1.03	99
Beans/legumes			
Adzuki, cooked	1 cup	4.07	294
Lentils, cooked	1 cup	2.52	230
Blackeye peas, boiled from dry	1 cup	2.22	198
Soybean, dried, boiled	1 cup	2.0	298
Kidney beans, red, cooked	1 cup	1.89	225
Chickpeas, canned	0.5 cup	1.28	143
Soy products/meat substitutes			
Natto	1 cup	5.32	371
Miso	0.5 cup	4.60	284
Tempeh	1 cup	3.02	330
Tofu, raw, firm	0.5 cup	1.98	183
Chili with meat substitute	0.66 cup	1.67	186
Meatless scallops, breaded, fried	0.5 cup	1.24	257
Luncheon slice, meatless	1 piece	1.07	188
Nuts/Seeds			
Pumpkin seeds, kernel, dry roasted	0.25 cup	2.58	187
Cashew, dry roasted,	0.25 cup	1.9	197
Almonds, dry roasted	0.25 cup	1.7	203
Sunflower seeds, kernels, dry roasted	0.25 cup	1.7	186
Sesame butter/tahini from nonroasted kernels	1 T	1.58	91.1
Peanuts, dry roasted	0.25 cup	1.2	214
Peanut butter, natural	2 T	1.06	187
Eggs			
Egg substitute	0.5 cup	1.6	74
Mixed Foods			
Cheese enchilada	1 each	2.51	319
Avocado and cheese sandwich on wheat bread	1 each	1.83	456
Pizza, cheese	1/8 of 15-in.	1.56	268

TABLE 20.27
Zinc: Vegetarian Sources and Amounts[5,31,32,36]

Food	Portion Size	Zinc (mg)[a,b]	Kcal
Desserts			
Nutrigrain bar, fruit filled	1 each	1.5	150
Pecan pie, 1/8 of a 9" pie	1 piece (122 g)	1.26	503
Trail mix, regular	0.25 cup	1.21	173
Doughnut, egg-less, carob-coated, raised	1 piece (78 g)	1.14	285

Adult RDA: Males 11 mg; females 8 mg.

[a] Zinc content of food is influenced by genetic breeding and fertilizer and soil conditions.
[b] Bioavailability is greater from animal than plant sources.

TABLE 20.28
Zinc: Absorption Enhancers and Inhibitors[1,2,36]

Possible Absorption Enhancers[a]	Sources	Possible Absorption Inhibitors[b]	Sources
Yeast (acts by reducing phytates)	Fermented bread dough	Phytates	Whole grains (rye, barley, oatmeal, and wheat), soy products
Animal proteins	Animal products	Oxalate	Spinach, Swiss chard, leek, kale, collard greens, okra, rhubarb, raspberries, coffee, chocolate, tea, peanuts, and pecans
Histidine	Amino acid widely distributed in foods containing protein	Fiber	Whole grains, fruits, vegetables, and legumes
Albumin	Widely distributed in foods containing protein, egg white	Nonheme iron	Legumes, fortified cereals, and leafy greens
Organic acids	Found widely in foods	Copper	Legumes, whole grains, nuts, seeds, and vegetables
		Calcium supplements	Over-the-counter supplements, multivitamins, some antacids
		Iron supplements	
		Casein	Milk

[a] Yeast and animal proteins are the only noncontroversial zinc absorption enhancers.
[b] Phytates is the only noncontroversial zinc absorption inhibitors.

TABLE 20.29
Fiber: Types, Functions and Sources[1,2,5,32]

Type of Fiber	Fiber Type	Food Sources	Function
Cellulose	Incompletely fermented	Whole wheat flour, bran, cabbage, peas, green beans, broccoli, cucumbers, peppers, apples, and carrots	Increases stool bulk and water absorption, decreases transit time through the GI system
Hemicellulose	Incompletely fermented	Bran cereals, whole grains, brussels sprouts, greens, and beet root	,,
Lignin	Incompletely fermented	Breakfast cereals, bran, older vegetables, strawberries, eggplant, pears, green beans, and radishes	,,
Gums	Viscous	Oatmeal, oat products, dried beans, oat bran, and barley	Binds to bile acids and certain lipids to help lower blood cholesterol
Pectin	Viscous	Squash, apples, citrus fruits, cauliflower, cabbage, dried peas and beans, carrots, and strawberries	levels, metabolized to short-chain fatty acids in the gut, which may play a role in signaling hepatic slowed cholesterol production

AI: Male: 38 g/day; female: 25 g/day.

been established.[14–18] Due to the increased interest in the health benefits of DHA, food companies are exploring incorporating it into products such as cereals. DHA has been developed from *Crypthecodinium cohnii* and *schizochytrium* microalgae strains. Martek Biosciences Corporation markets this vegetarian DHA source, and products containing it must display the MARTEK DHA[TM] logo.[40] Vegetarians can also include two daily servings of foods such as flaxseed (or flaxseed oil), canola or soybean oil, walnuts, or hempseed products (such as a veggie burger), to promote healthy intakes of alpha linolemic acid, but the longer chanin omega 3 fatty acids, DHA and EPA are absent from a vegetarian diet without supplementation. Table 20.31 lists vegetarian dietary sources of the omega-3 fatty acid alpha-linolenic acid.

TABLE 20.30
Common Phytochemicals[a] in Foods[27]

Chemical Names	Sources	Proposed Mechanism of Action
Sulforaphane	Isothiocyanates found in broccoli, cauliflower, cress, cabbages, and radishes	Activates phase II enzymes in liver (removes carcinogens from cells)
Flavonoids	Citrus fruits and berries	Blocks the cancer-promotion process
Monoterpenes (polyphenols)	Perillyl alcohol in cherries	May inhibit the growth of early cancers
	Limonene in citrus	
	Ellagic acid in strawberries and blueberries	
Genistein	Soybeans, tofu	Prevents the formation of capillaries required to nourish tumors
Indoles	Cruciferous vegetables (broccoli, cauliflower, cress, cabbages, and radishes)	Increase immunity, facilitate excretion of toxins
Saponins	Kidney beans, chickpeas, soybeans, and lentils	May prevent cancer cells from multiplying.
Lycopene	Tomatoes	May fight lung and prostate cancer

[a] More than 10,000 phytochemicals are thought to exist. This table represents only a partial listing.

TABLE 20.31
Omega-3 Fatty Acids: Vegetarian Sources and Amounts[2,5,7,41]

Food	Portion Size	Alpha-Linolenic Acid (18:3) (mg)	Kcal
Cereals/Grains			
Oats, germ	0.25 cup	0.4	119
Wheat germ	0.25 cup	0.2	104
Barley, bran	0.25 cup	0.1	115
Vegetables			
Soybeans, green, raw	0.5 cup	4.1	188
Kale, raw, chopped	1 cup	0.13	21
Broccoli, raw, chopped	1 cup	0.1	24
Cauliflower, raw	1 cup	0.1	26
Fruits			
Avocados, California, raw	1 medium	0.173	306
Dairy/Soymilk			
Cheese, Roquefort	1 oz.	0.2	105
Beans/Legumes			
Soybeans, dry	0.5 cup	1.5	387
Beans, pinto, boiled	1 cup	0.2	234
Nuts/Seeds			
Butternuts (dried)	1 oz.	2.4	174
Walnuts, dried, English/Persian	1 oz.	1.9	182
Fats/Oils/Dressings			
Linseed oil	1 T	7.5	124
Flax seed	1 T	2.2	124
Canola oil (rapeseed oil)	1 T	1.6	124
Walnut oil	1 T	1.5	124
Salad dressing, comm., mayonnaise, soybean	2 T	1.38	116
Soybean oil	1 T	1.0	124
Wheat germ oil	1 T	1.0	124
Salad dressing, comm., Italian, regular	2 T	1.0	140

AI: Males: 1.6 g/day; females: 1.1 g/day.

THE EFFECTS OF COOKING, STORAGE, AND PROCESSING ON THE CRITICAL NUTRIENTS

Cooking, storage, and processing methods can influence the amount of a nutrient present in a food. Table 20.32 presents the effects of cooking, storage, and processing on the nutrients that may be of concern in a vegetarian diet.

GENERAL VITAMIN AND MINERAL DEFICIENCY AND TOXICITY SYMPTOMS

It is important for practitioners to be aware of the symptoms of nutrient deficiencies in any patient. As a group, vegetarians tend to be more health-conscious and knowledgeable about nutrition than the general public.[1] Some vegetarians choose megadoses of vitamins or minerals to combat real or perceived threats to their health. Therefore, toxicity may be more of a risk than a nutrient deficiency. Table 20.33 presents deficiency and toxicity symptoms of the nutrients potentially at risk in a vegetarian diet.

SAMPLE MEAL PLANS

Table 20.34 through Table 20.37 present sample meal plans for adults and children following a lacto-ovo or vegan diet. These menus provide the Recommended Dietary Allowances (RDA) for energy and protein while presenting an appropriate macro-nutrient breakdown.

TABLE 20.32
Effects of Cooking, Storage, and Processing on the Critical Nutrients[2]

Nutrient	Cooking	Storage	Processing
Riboflavin	Stable to heat	Destroyed by light and irradiation	—
Vitamin B$_{12}$	Some losses (30%)	Stable	Small losses (10%)
Copper	Increased content using water from copper pipes	Canning with copper adds content to the food	—
Iron	Cooking in iron vessels increases iron content of foods	—	—
Omega-3 fatty acids (a polyunsaturated fatty acid)	Stable in baking; unstable if smoking point is reached	May go rancid with prolonged storage	—

TABLE 20.33
General Vitamin and Mineral Deficiency and Toxicity Symptoms[2,5,8,33]

Vitamin/Mineral[a]	Deficiency Symptoms[b]	Toxicity Symptoms[c]
Vitamins		
Vitamin D	Children — rickets	Excessive bone and soft tissue calcification (lung, kidney, kidney stones, and tympanic membrane)
	Adults — osteomalacia	Hypercalcemia with symptoms of headache, weakness, nausea and vomiting, constipation, polyuria, and polydipsia
		In infants: retarded growth, gastrointestinal upsets, and mental retardation
Vitamin B$_{12}$	Pernicious (megaloblastic) anemia	Physiological stores substantial (~2000 mcg). Stores and enterohepatic recycling may prevent deficiency symptoms for several years (~5) in the absence of intake
	Smooth red tongue	
	Fatigue	
	Skin hypersensitivity (numbness, tingling and burning of the feet, and stiffness and generalized weakness of the legs)	None known up to 100 mcg/d. No known benefit to high doses
	Degeneration of peripheral nerves progressing to paralysis	
	Other (glossitis and hypospermia)	
Riboflavin (vitamin B$_2$)	Anemia (normocytic and normochromic)	None known
	Neuropathy	
	Purple/magenta tongue	
	General B-vitamin deficiency symptoms (soreness and burning of lips, mouth, and tongue)	
	Cheilosis, glossitis, angular stomatitis, seborrheic dermatitis of nasolabial fold, vestibule of the nose, and sometimes the ears and eyelids, scrotum and vulva	

TABLE 20.33
Continued

Vitamin/Mineral[a]	Deficiency Symptoms[b]	Toxicity Symptoms[c]
Minerals		
Calcium	Bone deformities including osteoporosis, tetany, and hypertension	Hypercalcemia of soft tissues and bone (children and adults)
		Poor iron and zinc absorption (of particular concern during pregnancy)
Iron	Hypochromic, microcytic anemia	Seen at >45 mg intake
	Seen across populations, particularly in women, children, and those from low socioeconomic status	Constipation
		Liver toxicity
	Fatigue	Infections
	Spoon-shaped nails	Hemochromatosis
		Potential increased risk for heart disease and myocardial infarction
Zinc	Growth retardation resulting in short stature, mild anemia, low plasma zinc levels, and delayed sexual maturation.	Toxicity is rare (300 mg/d)
		Tolerable Upper Intake Level is 40 mg/day
	Possible in diets very rich in fiber and phytate, which chelates the zinc in the intestine, thus preventing absorption	Continuous supplementation with high dose zinc can interfere with copper absorption
	Poor taste acuity, poor wound healing, night blindness, baldness and skin lesions have also been reported	Excessive supplementation may decrease HDL and can result in nausea, vomiting, diarrhea, and dizziness
		Iron and copper losses in urine with doses as low as 25 mg/day and if large doses (10–15 × the RDA) are taken for even short periods of time
Copper	Severe copper deficiency: rare in humans	Gastrointestinal distress, liver damage
	Adults: neutropenia and microcytic anemia	Seen in genetic diseases such as Wilson's disease (genetic deficiency in liver synthesis of ceruloplasmin)
	Children: neutropenia and leukopenia	
	Decrease in serum copper and ceruloplasmin levels followed by failure of iron absorption leading to microcytic, hemochromic anemia	
	Neutropenia, leukopenia and bone demineralization are later symptoms	
	Deficiencies have not been reported in otherwise healthy humans consuming a varied diet	

[a] Absorption of some nutrients is affected by concentration of others; intestinal absorption of some nutrients is competitive.

[b] Deficiency can result from inadequate provision in the diet or via inadequate absorption.

[c] Toxicity is typically from overuse of nutritional supplements, although in some cases can be the cause of improper food fortification procedures (such as milk vitamin D fortification problems that arose in 1992).

TABLE 20.34
Sample Meal Plan for Lacto-Ovo Vegetarian Adult[31,32]

Breakfast	Lunch	Dinner
Raisin bran (1 cup, 2.15 oz)	Whole wheat bread, 2 slices	Bean Burrito
Milk, 1% fat, 0.75 cup (for cereal)	Griller veg. Burger patty, 1 each	Black beans, 1 cup
Milk, 1% fat, 1 cup (beverage)	Mustard	Corn tortilla, 2 each, 6"
Orange juice, 1 cup	Tomato, sliced, 1/2 tomato	Rice, brown, 1 cup
Banana, 1 med	Jack cheese, 1 oz	Salsa, 2 tbsp
	Apple, 1 med	Sour Cream, 1 tbsp
		Cheddar cheese, 1 oz
		Green salad, 2 cups
		Vinegar and oil dressing (1 tsp olive oil)
		Broccoli, 1 cup
		Milk, 1% fat, 1 cup

Snack
Cereal bar, raspberry
Dried apricots, 10 halves

Kcals: 2218; Carbohydrate: 374 g (67.35%); Protein: 100 g (18.%); Fat: 55 g (22.29%).

TABLE 20.35
Sample Meal Plan for Vegan Adult[31,32]

Breakfast	**Lunch**	**Dinner**
Raisin bran (1 cup, 2.15 oz)	Whole wheat bread, 2 slices	Bean Burrito
Soy milk, 1% fat, 1 cup (for cereal)	Griller veg. Burger patty (Morningstar	Black beans, e cup
Soy milk, 1% fat, 1 cup (beverage)	Farms), 1 each, cooked	Corn tortilla, 2 each, 6"
Orange juice, 1 cup, Ca fortified	Mustard	Rice, brown, 1 cup
Banana, 1 med	Tomato, sliced, 1/2 tomato	Salsa, 2 Tbsp
	Almonds, slivered, blanched, 1 oz	Walnuts, ground, .5 oz
	Apple, 1 med	Green salad, 2 cups
		Vinegar and Oil dressing
		(1 tsp olive oil)
		Broccoli, 1 cup
		Soy milk, 1 cup

Snack
Cereal bar, raspberry
Dried apricots, 10 halves

Kcals: 2217; Carbohydrate: 350g (63%); Protein: 90g (16%); Fat: 62g (25%).

TABLE 20.36
Sample Meal Plan for Vegan Child Age 4 to 6[31,32]

Breakfast	**Lunch**	**Dinner**
1 packet instant oatmeal	0.5 cup hummus spread made from	Veggie hot dog on bun
8 oz soymilk fortified with calcium	chickpeas and sesame butter	0.5 cup mashed potatoes
and vitamin B_{12}	2 slices whole wheat bread	0.5 cup cooked "creamed" spinach
1 banana	6 oz. 100% orange pineapple banana	0.5 cup applesauce
	juice	8 oz soymilk
	Carrot sticks	
	2 molasses cookies	

Snack	**Snack**
4 oz fortified soymilk	1.5 oz (~0.25 cup) trail mix
4 graham crackers	4 oz fortified soy milk

Kcals: 1864; Carbohydrate: 283 g (60.8%); Protein: 68 g (14.5%); Fat: 62 g (30%).

TABLE 20.37
Sample Meal Plan for Lacto-Ovo Vegetarian Child Age 4 to 6[31,32]

Breakfast	**Lunch**	**Dinner**
1 cup Honey Nut Cheerios with 4 oz	0.5 cup homemade macaroni and cheese	Burrito with salsa and sour cream,
milk on cereal	celery sticks and 2 Tbsp peanut butter	made with vegetarian chili
4 oz 1% milk to drink	2 fruit cookies	0.5 cup rice
Orange slices		4 oz 1% milk
		0.5 cup green salad with broccoli
		0.5 cup applesauce

Snack	**Snack**
1.5 oz cheese	Fruit smoothie made with juice,
5 Ritz crackers	frozen yogurt, and fruit
4 oz 1% milk	

Kcal: 1794; Carbohydrate: 255 g (57%); protein: 63 g (14%); fat: 63 g (31.5%).

SUMMARY

In summary, the term "vegetarianism" may mean different things to different people. Before making or accepting generalizations about vegetarianism, it is important to define the term. A person following a vegetarian lifestyle can have significantly lower risks of many chronic diseases, such as heart disease or cancer, than an omnivore does. However, some nutrients are more difficult to easily obtain from a vegetarian diet and may be a concern for deficiency, especially in children or during other critical lifecycle periods.

Part IV

Nutrition Assessment

21 Dietary Guidelines, Food Guidance, and Dietary Quality

Eileen Kennedy and Jeanne Goldberg

CONTENTS

DIETARY GUIDELINES

The Dietary Guidelines for Americans have served as the cornerstone of federal nutrition policy in the United States since the first edition was released in 1980. While many factors may have contributed to the development of that document, two earlier efforts were of particular importance. One was the 1969 White House Conference on Food, Nutrition, and Health,[1] which recommended that the government examine the links between diet and chronic disease. The second was the U.S. Senate Dietary Goals, released in 1977[2]; that document, the product of several years of hearings before the Senate Select Committee on Nutrition and Human Needs, for the first time, summarized specific recommendations for diet-related goals for the American public.

The Dietary Guidelines that came 3 years later have served as the basis of nutrition standards for all government food programs. Programs such as Food Stamps, School Lunch/School Breakfast, and Women, Infants, and Children (WIC) use them to develop program services; nutrition education programs at the federal level must have messages consistent with the Dietary Guidelines. An estimated one out of every five Americans participates in at least one federal nutrition program. As a result, the impact of the Dietary Guidelines is broad.

HISTORY OF THE DIETARY GUIDELINES FOR AMERICANS

The Dietary Guidelines attempt to answer the question, "What should Americans eat to stay healthy?" Specifically, the Guidelines provide advice for healthy Americans aged 2 years and over about food choices that promote health and reduce the risk of disease.

Since the first edition was released in 1980[3] they have been updated every 5 years in 1985, 1990, 1995, 2000, and most recently in 2005.[4–8] It was not until the passage of the National Nutrition Monitoring and Related Research Act of 1990,[9] however, that the Secretary of Agriculture and the Secretary of Health and Human Services were required by law to jointly publish a report

every 5 years entitled "The Dietary Guidelines for Americans." The 1995 edition was the first to be statutorily mandated by the U.S. Congress. The report must (1) contain nutrition and dietary information and guidelines for the general public, (2) be based on the preponderance of scientific and medical knowledge current at the time of publication, and (3) be promoted by each federal agency in carrying out federal food, nutrition, or health programs.

Since 1985, the United States Department of Agriculture (USDA) and the Department of Health and Human Services (HHS) have used essentially the same process to prepare the Dietary Guidelines. An external Dietary Guidelines Advisory Committee (DGAC) that includes widely recognized nutrition and medical experts is appointed by the secretaries of the two agencies to review and revise the Guidelines where indicated by newer evidence. The Committee holds a series of open public meetings to review and discuss the guidelines and then prepares a technical report, which they transmit to the two secretaries for review within the two departments. In addition, in 1995, 2000, and 2005 consumer research was conducted[10–11] to test reactions to specific design and content elements of the technical report. The consumer research is also used as one element in promoting the Guidelines.

DIETARY GUIDELINES FOR AMERICANS

The 1995 Dietary Guidelines

For the first three editions, the Dietary Guidelines were relatively stable (Table 21.1), maintaining seven guidelines. However, the 1995 guidelines reflected some exciting and important changes. More than ever before, the emphasis was on total diet. The wording moved away from individual foods in the direction of a total diet based on variety, moderation, and proportionality. The concept of total diet is reflected symbolically through the graphic of the 1995 Dietary Guidelines bulletin that links all seven guidelines together, anchored around "Eat a Variety of Food."

Each edition has been accompanied by a bulletin for consumers that describe the Guidelines in some detail. In the 1995 guideline on variety, the bulletin[6] stresses a total diet rather than an individual foods approach to healthy eating. The recommendation is to choose foods from each of the five major food groups in the Food Guide Pyramid. Also, there is an emphasis on foods from the base of the pyramid (grains) to form the center of the plate, accompanied by food from other food groups.

For the first time, the 1995 document recognized that, with careful planning, a vegetarian diet can be consistent with the both the Dietary Guidelines and the Recommended Dietary Allowances (RDAs).[11] The guidelines also present a clear message that food sources of nutrients are preferred to supplements. This "food first" strategy is reinforced by a discussion of other healthful substances present in food but not in dietary supplements. However, the 1995 guidelines do provide specific examples of situations in which dietary supplements may be needed.

The 1995 guidelines provided a more direct discussion of the link between diet and health. Weight gain with age was discouraged for adults. Weight maintenance is encouraged as a first step to achieving a healthy weight. The benefits of physical activity are emphasized, and for the first time, the Guidelines included a statement on the benefits of moderate alcohol consumption in reducing the risk of heart disease. On this point, both HHS and USDA were clear that the alcohol guideline was not intended to recommend that people start drinking.

The 1995 Guidelines included a direct reference to nutrition education tools that could be used to promote them. They explain how consumers can use the "three crown jewels" of consumer nutrition education to build a healthy diet — the Dietary Guidelines, the Food Guide Pyramid,[12] and the Nutrition Facts Label.

TABLE 21.1
Dietary Guidelines for Americans, 1980–1995

1980	1985	1990	1995
Eat a variety of foods	Eat a variety of foods	Eat a variety of foods	Eat a variety of foods
Maintain ideal weight	Maintain desirable weight	Maintain healthy weight	Balance the food you eat with physical activity — maintain or improve your weight
Avoid too much fat, saturated fat, and cholesterol	Avoid too much fat, saturated fat, and cholesterol	Choose a diet low in fat, saturated fat, and cholesterol	Choose a diet low in fat, saturated fat, and cholesterol
Eat foods with adequate starch and fiber	Eat foods with adequate starch and fiber	Choose a diet with plenty of grain products, vegetables, and fruits	Choose a diet with plenty of grain products, vegetables, and fruits
Avoid too much sugar	Avoid too much sugar	Use sugars only in moderation	Choose a diet moderate in sugars
Avoid too much sodium	Avoid too much sodium	Use salt and sodium only in moderation	Choose a diet moderate in salt and sodium
If you drink alcohol, do so in moderation	If you drink alcoholic beverages, do so in moderation	If you drink alcoholic beverages, do so in moderation	If you drink alcoholic beverages, do so in moderation

---

TABLE 21.2
Dietary Guidelines for Americans, 2000

Let the Pyramid guide your food choices
Aim for a healthy weight
Be physically active each day
Choose a diet that is low in saturated fat and cholesterol, and
   moderate in total fat
Choose a variety of grains daily, especially whole grains
Choose a variety of fruits and vegetables daily
Choose beverages and foods to moderate your intake of sugars
Choose and prepare foods with less salt
If you drink alcoholic beverages, do so in moderation
Keep food safe to eat

The 2000 Dietary Guidelines

The Dietary Guidelines 2000, released by President Clinton in May 2000,[7] broke the tradition of seven guidelines and included ten guidelines. Not only did the Guidelines continue to emphasize a total diet approach, they also emphasized a healthy lifestyle. This is reflected clearly in three concepts that are used as organizing principals for the 2000 Guidelines: aim for fitness, build a healthy base, and choose sensibly. Three new guidelines were added in the 2000 edition (Table 21.2). For the first time, Dietary Guidelines 2000 included a guideline on physical activity: "Be physically active every day." In addition to help in maintaining a healthy weight, this guideline discusses other health benefits of physical activity. Specific quantitative recommendations are given for amount of physical activity for adults (30 min or more) and children (60 min or more) per day. In addition, for the first time, there is a guideline on food safety. Again, this reinforces components of a healthy diet and healthy lifestyle. Finally, there is a separate guideline for fruits and vegetables.

Consumer research conducted as part of the Dietary Guidelines 2000 process[11] influenced the development of the guidelines. One clear message from that research was that consumers preferred simple, action-oriented guidelines. Thus, the 2000 guidelines are much more direct and action oriented as evidenced by "aim for a healthy weight" and "keep foods safe to eat." The 2000 guidelines are also more consumer friendly, and emphasize practical ways for consumers to put the concepts into practice. To that end, a section entitled "Advice for Today" at the end of each guideline includes suggestions on key ways to operationalize it. Consumer research on the 2000 Dietary Guidelines indicated that consumers particularly appreciated sections such as "Advice for Today."

Dietary Guidelines 2005

The Dietary Guidelines 2005 are even more of a departure from earlier editions. Since the first edition, it has been clear that the guidelines needed to be based on the preponderance of scientific evidence. For the 2005 edition, it was clearly specified that conclusions from the Dietary Guidelines Advisory Committee must rest on an evidence-based rating system in order to minimize the potential for individual bias to influence decisions. It was further specified that the task of the advisory committee would be limited to the preparation of a set of evidence-based recommendations. The Committee was not to concern itself with how these recommendations would be communicated to the public.[13] An internal group from USDA/DHHS would assume the task of translating the guidelines into a set of recommendations for policymakers, nutrition educators, nutritionists, and health care providers. These guidelines would then serve as the basis for the development of communications to the public. The brochure, "Finding Your Way to a Healthier You," released on the same day as the guidelines, was a first attempt at this approach to consumer communications.[14]

What emerged from the 2005 Dietary Guidelines Advisory Committee was a set of nine key messages (Table 21.3). Notably, the wording for just three of them — physical activity, food safety, and alcohol is exactly the same as that in the 2000 guidelines. The internal USDA/DHHS committee translated the messages into a total of 41 key recommendations, including 23 for the general public and 18 for specific population groups (Table 21.4). These recommendations are designed to take into account nutrients that are in short supply in the diets of significant numbers of individuals in the population. They include Vitamin E, calcium, magnesium, potassium, as well as fiber in children and adults, and Vitamins A and C in adults.

In sum, modification of the approach to developing the 2005 Dietary Guidelines for Americans finally appears to address one of the frustrations of earlier committees. It divides the process into two distinct components, one focusing solely on the science that drives the recommendations and the other on the translation of those recommendations.

TABLE 21.3
Nine Key Messages, Dietary Guidelines for Americans, 2005

Consume a variety of foods within and among the basic food groups while staying within energy needs

Control calorie intake to manage body weight

Be physically active every day

Increase daily intake of fruits and vegetables, whole grains, and nonfat or low-fat milk and milk products

Choose fats wisely for good health

Choose carbohydrates wisely for good health

Choose and prepare foods with little salt

If you drink alcoholic beverages, do so in moderation

Keep food safe to eat

TABLE 21.4
Key Recommendations, Dietary Guidelines for Americans, 2005

Adequate Nutrients within Calorie Needs

- Consume a variety of nutrient-dense foods and beverages within and among the basic food groups while choosing foods that limit the intake of saturated and *trans*-fats, cholesterol, added sugars, salt, and alcohol
- Meet recommended intakes within energy needs by adopting a balanced eating pattern, such as the U.S. Department of Agriculture (USDA) Food Guide or the Dietary Approaches to Stop Hypertension (DASH) Eating Plan

Weight Management

- To maintain body weight in a healthy range, balance calories from foods and beverages with calories expended
- To prevent gradual weight gain over time, make small decreases in food and beverage calories and increase physical activity

Physical Activity

- Engage in regular physical activity and reduce sedentary activities to promote health, psychological well-being, and a healthy body weight
- To reduce the risk of chronic disease in adulthood: Engage in at least 30 min of moderate-intensity physical activity, above usual activity, at work or home on most days of the week
- For most people, greater health benefits can be obtained by engaging in physical activity of more vigorous intensity or longer duration
- To help manage body weight and prevent gradual, unhealthy body weight gain in adulthood: Engage in approximately 60 min of moderate- to vigorous-intensity activity on most days of the week while not exceeding caloric intake requirements
- To sustain weight loss in adulthood: Participate in at least 60 to 90 min of daily moderate-intensity physical activity while not exceeding caloric intake requirements. Some people may need to consult with a health care provider before participating in this level of activity
- Achieve physical fitness by including cardiovascular conditioning, stretching exercises for flexibility, and resistance exercises or calisthenics for muscle strength and endurance

Food Groups to Encourage

- Consume a sufficient amount of fruits and vegetables while staying within energy needs. Two cups of fruit and two-and-half cups of vegetables per day are recommended for a reference 2000 cal intake, with higher or lower amounts depending on the calorie level
- Choose a variety of fruits and vegetables each day. In particular, select from all five vegetable subgroups (dark green, orange, legumes, starchy vegetables, and other vegetables) several times a week
- Consume three or more ounce-equivalents of whole-grain products per day, with the rest of the recommended grains coming from enriched or whole-grain products. In general, at least half the grains should come from whole grains
- Consume three cups per day of fat-free or low-fat milk or equivalent milk products

Fats

- Consume less than 10% of calories from saturated fatty acids and less than 300 mg/day of cholesterol, and keep *trans*-fatty acid consumption as low as possible
- Keep total fat intake between 20% to 35% of calories, with most fats coming from sources of polyunsaturated and monounsaturated fatty acids, such as fish, nuts, and vegetable oils
- When selecting and preparing meat, poultry, dry beans, and milk or milk products, make choices that are lean, low-fat, or fat-free
- Limit intake of fats and oils high in saturated or *trans*-fatty acids, and choose products low in such fats and oils

TABLE 21.4
(Continued)

Carbohydrates
- Choose fiber-rich fruits, vegetables, and whole grains often
- Choose and prepare foods and beverages with little added sugars or caloric sweeteners, such as amounts suggested by the USDA Food Guide and the DASH Eating Plan
- Reduce the incidence of dental caries by practicing good oral hygiene and consuming sugar- and starch-containing foods and beverages less frequently

Sodium and Potassium
- Consume less than 2300 mg (approximately 1 teaspoon of salt) of sodium per day
- Choose and prepare foods with little salt. At the same time, consume potassium-rich foods, such as fruits and vegetables

Alcoholic Beverages
- Those who choose to drink alcoholic beverages should do so sensibly and in moderation — defined as the consumption of up to one drink per day for women and up to two drinks per day for men
- Alcoholic beverages should not be consumed by some individuals, including those who cannot restrict their alcohol intake, women of childbearing age who may become pregnant, pregnant and lactating women, children and adolescents, individuals taking medications that can interact with alcohol, and those with specific medical conditions
- Alcoholic beverages should be avoided by individuals engaging in activities that require attention, skill, or coordination, such as driving or operating machinery

Food Safety
- To avoid microbial food-borne illness:
  - Clean hands, food contact surfaces, and fruits and vegetables. Meat and poultry should not be washed or rinsed
  - Separate raw, cooked, and ready-to-eat foods while shopping, preparing, or storing foods
  - Cook foods to a safe temperature to kill microorganisms
  - Chill (refrigerate) perishable food promptly and defrost foods properly
  - Avoid raw (unpasteurized) milk or any products made from unpasteurized milk, raw or partially cooked eggs or foods containing raw eggs, raw or undercooked meat and poultry, unpasteurized juices, and raw sprouts

TABLE 21.5
U.S. Dietary Guidelines 2000 and Countries Having Similar Guidelines

U.S. Dietary Guidelines 2000[7]	Countries Having Similar Guidelines[1]
Aim for a healthy weight	Australia, Canada, China, Japan, Korea, Malaysia, The Netherlands, New Zealand, Philippines, Singapore, Thailand, United Kingdom
Let the Pyramid guide your food choices	Variety: Australia, Canada, China, France, Germany, Hungary, Indonesia, Korea, Malaysia, New Zealand, Philippines, Singapore, South Africa, Sri Lanka, Thailand, United Kingdom, Japan Five Steps to Healthy Eating: India
Eat a variety of grains daily, especially whole grains	Australia, Canada, Denmark, Germany, Hungary (choose potatoes over rice), India, Malaysia, Norway, Singapore, South Africa (starchy foods), Thailand
Choose a diet that is low in saturated fat, and cholesterol, and moderate in total fat	Australia (but low fat diets not suitable for children), Canada, Japan, The Netherlands, New Zealand, Singapore, South Africa
Choose and prepare foods with less salt	Australia, Canada, China, Denmark, Germany, Hungary, India, Japan, Korea, Malaysia, The Netherlands, Singapore, South Africa, Thailand
If you drink alcoholic beverages, do so in moderation	Canada, China, France, Germany, Indonesia (avoid), Hungary (forbidden for pregnant women and children), Korea, The Netherlands, New Zealand, Singapore, South Africa, United Kingdom

COMPARISON OF DIETARY GUIDELINES FOR AMERICANS WITH OTHER DIETARY GUIDELINES

Many countries — both industrialized and developing — have authoritative sets of dietary guidelines.[15] Despite vastly different geographical and sociocultural contexts, there are six fairly consistent elements (Table 21.5).

A guideline on variety is common; it is often the core element of the different sets of dietary guidelines, and is used to reflect the concepts of dietary diversity. The variety guidelines range from general statements such as, "Eat a variety of foods" to very specific quantifications, such as that as found in the Japanese guideline: "Obtain well-balanced nutrition with a variety of foods; eat 30 foodstuffs a day."

Many of the country-specific dietary guidelines emphasize limiting or moderating total fat and saturated fat intake. Where an amount is quantified, this is most commonly specified as a diet containing no more than 30% of total energy from fat and less than 10% of energy from saturated fat.

Countries typically also include weight guidelines, clearly emphasizing maintaining or achieving a healthy weight; in the French guideline this is more specific, indicating that individuals should weigh themselves monthly.[15] Most of the dietary guidelines worldwide promote a plant-based diet as the building block of healthful eating. To that end, many countries emphasize grains as the basis of a good diet. Reduction of salt or sodium is emphasized in a number of the sets of dietary guidelines.

Finally, the issue of alcohol consumption is addressed in many sets of dietary guidelines. There is always a level of caution related to the role of alcohol as part of a healthy diet. The most recent 2005 Dietary Guidelines for Americans, for example, indicates that there are many strategies, other than alcohol, to reduce the risk of heart disease: maintaining a healthy weight, cessation of smoking, increasing physical activity, and reducing the level of fat and saturated fat in the diet. The report specifies further that it is not recommended that anyone begin drinking or drink more frequently on the basis of health considerations. Indeed, countries such as Venezuela go so far as to specify that "alcoholic beverages are not part of a healthy diet."[16]

FUTURE DIRECTIONS

Many countries have been successful in developing and promoting food-based Dietary Guidelines. Typically they apply to individuals aged two and older. That has been the case in the United States since the first Dietary Guidelines were released in 1980. There is a clear gap in addressing the needs of younger children.

A limited number of countries do address that group in their food-based guidelines. In most cases the advice relates to a discussion of breast-feeding. Australia, for example, has a guideline that states: "encourage and support breast-feeding." Similar wording is found in guidelines from the Philippines and Singapore.

Most industrialized countries rely on national pediatric associations to guide the broad policy recommendations for infant feeding and/or feeding practices for the first 2 years of life. In almost all cases, advice from pediatric associations stresses that human milk is the preferred form of infant feeding.[17]

If food-based dietary guidelines for children under two were to be developed, it would be necessary to segment by age groups based upon the relevant dietary issues of three groups: birth to 6 months, 6–12 months, and 13–24 months.

OTHER DIETARY GUIDANCE

The previous section traced the development of the U.S. Dietary Guidelines. USDA has a long, rich history of providing science-based nutrition information and education for the general public. The Organic Act of 1862 not only created USDA but also mandated that the Department "acquire and diffuse among people useful information on subjects connected to agriculture." This led to some of the pioneering work of W.O. Atwater, who in the 1890s began "identifying the links between food composition, dietary intake, and health." This seminal science led to the development of the USDA food guides. Dissemination of the food guides was facilitated by the 1914 Smith-Lever Act, which created the Cooperative Extension Service and specified that the Extension Service provide people with, "useful and practical information on subjects relating to agriculture and home economics."

THRIFTY FOOD PLAN

In the 1930s the USDA began developing family food plans at four separate cost levels. These food plans have been used ever since.

The best known of these, the Thrifty Food Plan, served as the nutritional basis that were used to establish the benefits package of the Food Stamp Program. Even among upper-income people there was a lack of understanding of the elements of good nutrition. Former Secretary of Agriculture Henry Wallace once commented, "The lack of commonsense knowledge of nutrition even among the many well-to-do people in the U.S. is appalling."

In 1941 the first set of RDAs was released at the National Nutrition Conference for Defense; at this conference USDA scientists noted that consumers spent enough money on food but did not obtain an adequate diet. As a result, the USDA was urged to develop nutrition education and media-type materials to promote good nutrition for the American public. This emphasis on nutrition education continued in the 1950s and 1960s, culminating with the 1969 White House Conference on Food, Nutrition, and Health.[18–19] The 1969 conference reinforced the need for aggressive nutrition promotion activities for all Americans, with a special emphasis on reaching low-income populations.

Throughout the 1970s, federal agencies increased funding for nutrition programs and nutrition education activities. New programs were created, including the Special Supplemental Food Program for Women, Infants, and Children (WIC), School Breakfast; other programs such as Food Stamps and School Lunch were expanded nationwide.

The 1977 Food and Agriculture Act named USDA as the lead agency for nutrition research, extension, and teaching. Throughout the 1980s and into the 1990s USDA placed a renewed emphasis on developing comprehensive, coordinated efforts to promote nutrition for all Americans.

USDA Food Guide Pyramid

The release of the 1980 Dietary Guidelines for Americans provided the impetus for the development of a new food guide that would allow consumers to put the dietary guidelines into action. Work throughout the 1980s and into the early 1990s culminated in the now well-known 1992 USDA Food Guide Pyramid.[12] The Pyramid has been a popular success, recognized by the majority of Americans. It reflects the extensive experience with food guidance systems within USDA. The three essential concepts underlying the Food Guide Pyramid are variety, balance, and moderation. Different visuals were tested with consumers to assess which graphic portrayal most effectively communicated the underlying concepts of balance, variety, and moderation. The graphics were tested first with adults with at least a high school education; consumer testing was expanded later to include children and low-literacy and low-income adults. The Pyramid shape emerged as the most effective graphic, communicating the concepts of variety, balance, and moderation (Figure 21.1).

1992 Food Guide Pyramid

The USDA 1992 Pyramid communicated a wealth of information with little accompanying text. A more detailed publication explains the complex information provided in the visual. This publication discusses the differing energy needs of individuals illustrated at 1600, 2200, and 2800 kcal. The Food Guide Pyramid Bulletin[12] includes an in-depth discussion of "How to Make the Pyramid Work for You." Topics such as what constitutes serving, different types of fats, and how to use the Pyramid to make low-fat selections are also included.

The Pyramid graphic shown in Figure 21.1 communicates not only balance, variety, and moderation but also provides the basis of a healthful diet. The number and amounts of foods recommended in the Pyramid are based on three factors:

- RDAs for age and gender groups
- Dietary Guidelines for Americans
- Typical consumption patterns of Americans

The advice provided in the Food Guide Pyramid was designed to provide dietary guidance that ensures nutritional adequacy — defined as the RDAs and Dietary Guidelines — within the framework of typical consumption patterns. Thus, while ostensibly an infinite number of food combinations could be used to ensure nutritional adequacy, the five major food groups emphasized in the USDA Pyramid anchor the food selections to current consumption patterns.

A proliferation of pyramids has emerged since the USDA version was published in 1992. However, all of them, whether Asian, Mediterranean, or vegetarian, are based on the same building blocks — grains, vegetables, and fruits. The similarities in the various pyramids are more dominant than the differences.
FIGURE 21.1 1992 Food Guide Pyramid.

In addition, in 1999, USDA released a children's version of the Food Guide Pyramid targeted at children aged 2 to 6 years. Here again, the concepts of balance, variety, and moderation underpin the graphic (Figure 21.2). The specific icons used in the food groups are based on foods typically consumed by children. Worth noting are the age-specific recommendations for serving sizes at the bottom of the graphic as well as the deliberate inclusion of exercise icons.

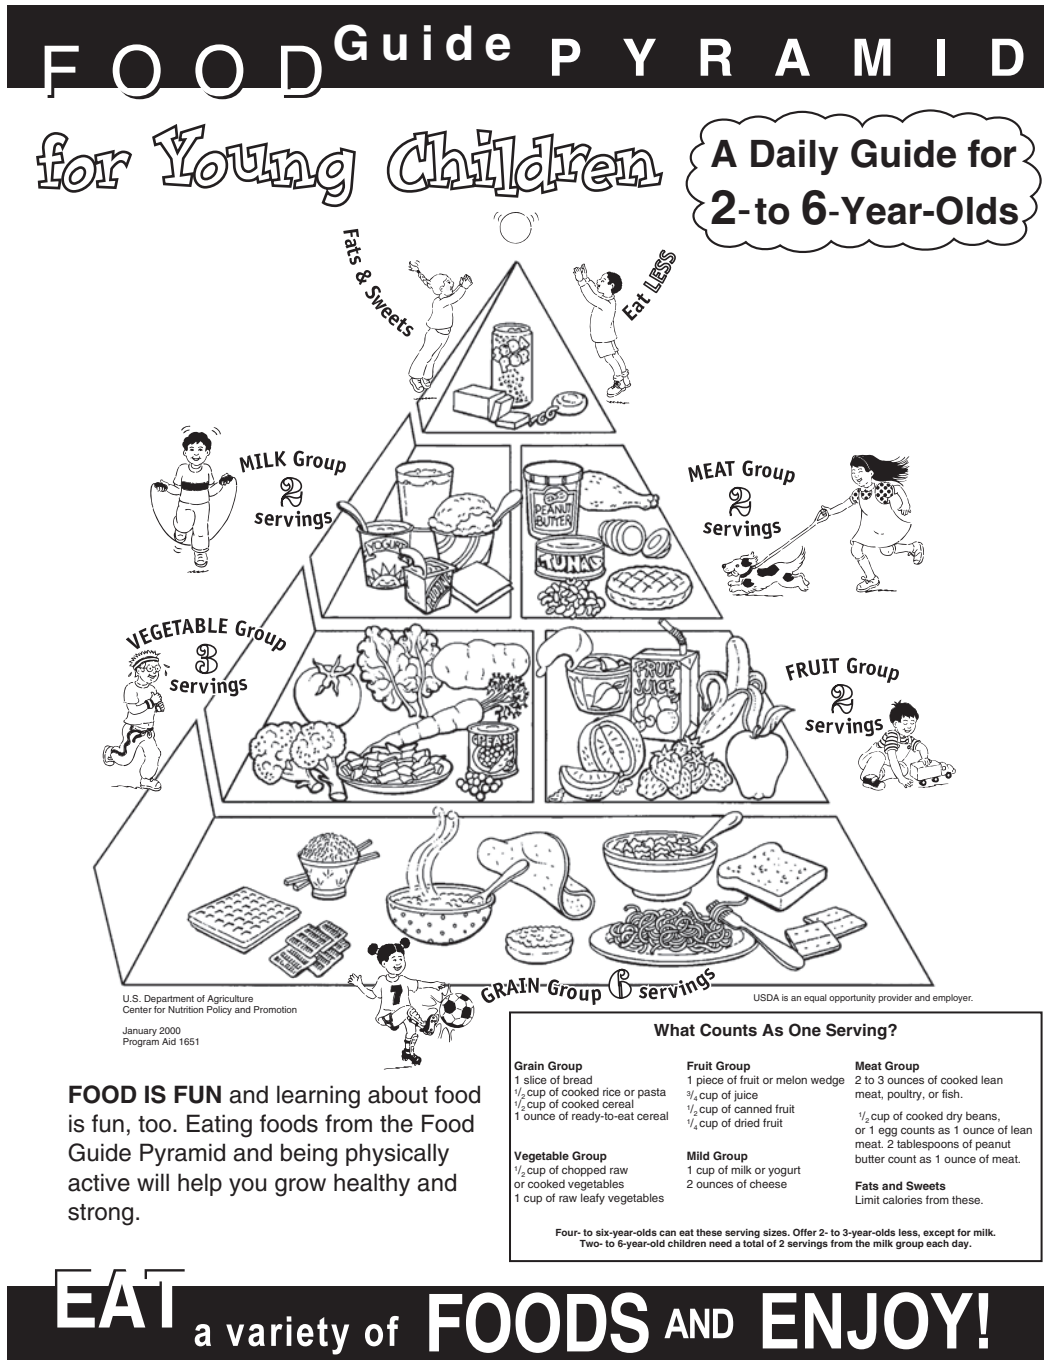
The 2000 Dietary Guidelines for Americans[7] for the first time included the Food Guide Pyramid as part of a specific guideline; "Let the Pyramid Guide Your Food Choices." Including it as a direct part of the Dietary Guidelines reflects the wide-ranging familiarity of consumers with the Pyramid and the messages embedded within. The USDA Food Guide Pyramid (and more recently, MyPyramid) and the Children's Food Guide Pyramid will continue to be essential parts of the nutrition education and nutrition promotion efforts within the USDA.


FIGURE 21.2   1999 Children's Food Guide Pyramid.

USDA's MyPyramid, 2005

MyPyramid, the first revision to the Food Guide Pyramid, was released on April 19, 2005, almost 13 years to the day after the original graphic made its appearance and just 4 months after the release of the 2005 Dietary Guidelines for Americans (Figure 21.3). According to the USDA/DHHS the rationale for the revision was "to motivate consumers to make healthier choices and to ensure that USDA's food guidance system reflects the latest nutrition science." Extensive qualitative research was conducted by USDA to provide information about the development of the new graphic. This included a series of focus groups in 2002 to assess the understanding and clarity of messages embedded in the graphic. Consumers recognized the pyramid but had difficulty understanding the specific messages.

A second series of eight focus groups was designed to identify alternative ways to describe the food recommendations so that consumers would understand them. These focus groups also explored consumers' ability to understand nutrition language and messaging about grains, vegetables, types of fats, sugars and added sugars, and physical activity levels. This research documented the fact that consumers did not understand the intended meaning of servings and serving sizes and, more broadly, that their understanding of nutrition terms was limited.

In July 2004, USDA's Center on Nutrition Policy and Promotion (CNPP) solicited public comments on the proposed Food Guidance System and it graphic representation and educational materials through a notice in the Federal Register. Over 1200 comments were received. CNPP also requested a synthesis of previous research that could inform further revisions to the Food Guidance System. In October 2004, ten 2 h focus groups explored participants' awareness of healthy-eating messages and the information conveyed in those messages. This was the first series that explored different concepts for the new graphic. Two months later 200 adults participated in a Web–TV survey to provide feedback to further refine the elements of the graphic. This phase also included testing of actionable messages.

Publicity on the day that MyPyramid was released was extensive and obtained as many as 15 million hits to the Web site within the first 6 h. As reported in the media, many members of the academic community reacted negatively, pointing out that the new materials do not provide messages about which specific foods to eat more of and which to eat in lesser quantities. Some complained more specifically that the new materials cater to the food industry.

DIET QUALITY MEASURES

Since the early 1900s, the major areas of concern in public health nutrition have shifted from problems of nutritional deficiency to problems of excesses and imbalances. Problems of relative overconsumption are, on average, more prevalent today than problems of underconsumption. The successive sets of U.S. Dietary Guidelines that have emerged since 1980 have emphasized the links between diet and a range of chronic diseases. An extensive body of scientific literature documents the association between diets high in total and saturated fat and low in fiber and complex carbohydrate with coronary heart disease, stroke, diabetes, and certain forms of cancer.

While extensive research links the typical American diet to a range of chronic diseases, there has been considerably less progress in improving approaches and techniques that measure diet quality. Until recently, most diet quality measures focused on individual nutrients; most often these measures were based on standards such as mean percentage of the RDAs.[20] Despite the U.S. Dietary Guidelines' emphasis on total diet, indices based on the dietary guidelines have tended to be selective in the components included.[21–22] Few indices have been developed to assess overall diet quality. In an effort to measure how well American diets conform to recommended healthy eating patterns, USDA developed the Healthy Eating Index (HEI) in 1995.

HEI STRUCTURE

HEI was designed to measure various aspects of a healthful diet.[23] As shown in Table 21.6; the HEI is a ten-component index; components 1 through 5 measure the degree to which a person's diet conforms to the Food Guide Pyramid's serving recommendations for the five major food groups of grains, vegetables, fruits, milk, and meat. The number of recommended servings for each food group varies with the individual's age, gender, physiological status, and energy requirements. The use of food groups rather than nutrients was meant to provide consumers with an easier standard against which to judge their dietary patterns. In addition, there may be as-yet-unknown components in foods that would not be picked up by measuring only the nutrients in foods.

Components 6 to 9 measure various aspects of the Dietary Guidelines, including total fat, saturated fat, cholesterol, and sodium, respectively. Component 10 provides a measure of dietary variety. Despite general agreement that dietary variety is important, it is surprising how few studies have attempted to quantify the concept of variety.[24] The HEI counted the total number of different foods that contribute substantially to meeting one or more of the five food group requirements. Foods were counted only if they were eaten in amounts sufficient to contribute at least a half serving in any of the food groups. Identical foods eaten on separate occasions were aggregated before imposing the one-half serving cutoff point. Foods that were similar, such as different forms of potatoes or two different forms of white bread, were counted only once in the variety category.

TABLE 21.6
Components of the Healthy Eating Index

Component	Range of Score	Criteria for Perfect Score of 10	Criteria for Minimum Score of Zero
Food Group			
1. Grains	0–10	6–11 servings	0 servings
2. Vegetables	0–10	3–5 servings	0 servings
3. Fruits	0–10	2–4 servings	0 servings
4. Milk	0–10	2–3 servings	0 servings
5. Meat	0–10	2–3 servings	0 servings
Dietary Guidelines			
6. Total Fat	0–10	30% or less energy from fat	45% or greater energy from fat
7. Saturated fat	0–10	Less than 10% energy from saturated fat	15% or greater energy from saturated fat
8. Cholesterol	0–10	Less than 300 mg	Greater than or equal to 450 mg
9. Sodium	0–10	Less than 2400 mg	Greater than or equal to 4800 mg
10. Variety	0–10	16 different kinds of food over a 3-day period	6 or fewer food items over a 3-day period

Each of the ten components has a score ranging from 0 to 10; cutoffs for scoring the minimum and maximum scores are shown in Table 21.6. Thus, the HEI can vary from 1 to 100.

HEI APPLIED: WHAT ARE AMERICANS EATING?

The HEI was applied to nationally representative data derived from the Continuing Survey of Food Intake by Individuals (CSFII) for two time periods, 1989 to 1990 and 1994 to 1996. The combined score for 1989 to 1990 was 63.9,which contrasted with 63.6, 63.5, and 63.8 for 1994, 1995, and 1996, respectively.[25] Clearly there were not wide variations in the average HEI across this 7-year period.

In addition, the distribution of the average HEI scores did not vary dramatically over the period of 1989 to 1996. Throughout this time period, the majority of individual scores fell in the 51% to 80% range, a category defined as "needs improvement." No more than 12% of individuals fell in the "good diet" category at any point in time; conversely, approximately 18% of individuals were classified in the "poor diet" category. Scores for the individual HEI components varied with the average score. The fruit category was consistently the lowest, and the cholesterol score was the best.

The HEI score varied with some economic and demographic factors.[25] Females had slightly higher scores than males, and persons in the younger and older groups scored higher than adults in the 19 to 50 age category. Children aged 2 to 3 years had the highest HEI score. Children in this age category scored particularly high on the fruit and dairy component of the HEI when compared with older children, suggesting changes in dietary habits as children age.

Throughout the 7-year period there is a pattern of increasing HEI with increased income. The effect of increased education on HEI is even more dramatic, however. One interpretation is that higher education may enable individuals to translate dietary guidance into improved food patterns.

The scientific rigor of the HEI depends on its ability to accurately measure diet quality. Research has documented that the average HEI in 1989 and 1990 correlated with a range of nutrients and energy intake. For most nutrients, the likelihood of falling below 75% of the RDA for a selected nutrient decreased as the HEI score increased. For example, only 47% of persons with an HEI of 50 or less had vitamin C intake greater than 75% of the RDA, compared with approximately 91% of people scoring 80 or more on the HEI. The data would suggest that as the HEI increases, levels of nutrient intake also increase. Interestingly, the correlation of the HEI with overall energy intake was modest, suggesting that simply consuming larger quantities of food will not by itself result in a better diet.

Finally, the HEI was compared with individuals' self-rating of their diets. Persons who rated their diets as excellent or good had a significantly higher probability of having an HEI classified as a "good diet." Conversely, individuals who self-rated their diet as fair or poor had an HEI more likely to be classified as "needs improvement."

The most recent data from the National Health and Nutrition Examination Survey from 1999 to 2000 show similar trends.[26] The average HEI score during 1999 to 2000 was 63.8, indicating again that the typical American diet "needs improvement."[27]

POLICY IMPLICATIONS

The Food Guide Pyramid/MyPyramid and the Dietary Guidelines for Americans provide a standard against which to evaluate the total diet. However, neither the Pyramid nor the Dietary Guidelines provide a method for easily assessing total diet. The development of the USDA HEI provided an easy to use, single summary measure of diet quality. The HEI also provides a method for monitoring diet quality over time using national survey data. In addition, it has the potential to serve as a tool for individuals to self-evaluate diet quality.

The data from both 1989 to 1990 and 1994 to 1996 and most recently in 1999 to 2000 indicate that the dietary patterns of most Americans need improvement. The data obtained from applying the HEI to nationally representative surveys can continue to be one tool to help focus our national nutrition promotion interventions.

SUMMARY

Major improvements worldwide in public health will be accomplished by improvement in dietary patterns. Food-based dietary guidelines have been developed in a broad range of countries. A move toward consensus on food-based dietary guidelines is a practical way to develop core elements of global dietary guidelines that can be effectively promoted by individual countries as well as international health organizations.

22 Dietary Guidelines around the World: An Update

Odilia I. Bermudez, Johanna T. Dwyer, Winifred Yu, and Linda G. Tolstoi

CONTENTS

INTRODUCTION AND OVERVIEW

Dietary guidelines are "recommendations for achieving appropriate diets, and healthy lifestyles."[1] In this chapter, we examine the similarities and differences as well as strengths and weaknesses of examples of dietary guidelines in five regions of the world. Dietary guidelines from many other countries are also available at the Food and Agricultural Organization's website http://www.fao.org/ag/agn/nutrition/education_guidelines_country_en.stm

The chapter concludes with some recommendations for crafting dietary guidelines in the future.

Effective dietary guidelines have several elements in common. They are designed to address and mitigate the major diet-related nutrition problems of the population to which they are addressed. Health problems change over time and, therefore, the recommendations cannot be static but must also shift when the problems demand, as guidelines in the United States of America have done.[1,2] Effective guidelines are evidence-based, and the strength of supportive evidence underlying them is strong. Eating habits, cultural beliefs, and available food supplies are considered. The dietary guideline messages conveyed are tested prior to their finalization to ensure that the guidelines can be communicated effectively. Successful guidelines are also integrated with other nutritional guidance of a public health nature. Effective guidelines are also recognized as only one of a group of essential components of effective food and nutrition policies. Other factors include access to a variety of safe and affordable foods from available resources and sustainability. Ideally, successful guidelines are promulgated simultaneously with ways to evaluate their effectiveness.

In this chapter we draw examples of guidelines from regions representing different health realities, culinary approaches, dietary practices, food ways, and economies. The European, American, Canadian, Japanese, Taiwanese, and Australian/ New Zealand guidelines are directed to highly industrialized, affluent populations. The Indian, Latin American, and African guidelines are tailored to populations that are often in the nutrition transition, with both highly affluent and very poor populations differing in degree of urbanization and standards of living all within the same country.

In English-speaking North America and Oceania, diseases of affluence (i.e., obesity, heart disease, and certain cancers) are common, and these issues are therefore given attention. All of these affluent countries share similar dietary patterns and nutrition-related problems, including a diet excessive in calories, fat, salt, sugars, and alcohol, and diets too low in fruits, vegetables, and whole grains. Their guidelines have addressed excessive as well as inadequate food consumption, weight, and physical activity since they were first formulated in the late 1970s and early 1980s.

Each of these countries has an ethnically diverse population. In the United States, according to 2000 census data, 12% of the population was African American and 9% was of Hispanic origin.[3] The Aboriginal and Torres Strait Islander people comprise only about 2% of the Australian population, but they often live under impoverished, overcrowded conditions that put them at nutritional risk,[4] and have a high prevalence of android pattern obesity, which is associated with many health problems.[5] In New Zealand, 13% of the population belongs to the rapidly growing Maori minority, and another 5% of the population is Pacific Islanders.[6] Some of these minority groups have increased risks of chronic degenerative diseases as they move away from traditional customs to modern diets and lifestyles. The information accompanying the Australian and New Zealand dietary guidelines refers to these special problems of minority populations, although the dietary guidelines are targeted to the general population.

NORTH AMERICA AND OCEANIA

FORMULATION

Table 22.1 shows the approaches used in the development of the dietary guidelines in these countries and their key characteristics. In guideline development, all of these countries used nutrition experts and scientists, and all of the guidelines were endorsed by a relevant government agency. In the United States, the National Nutrition Monitoring and Related Research Act of 1990 required that the Dietary Guidelines for Americans be updated every 5 years and reviewed by the Departments of Health and Human Services and Agriculture. The latest Dietary Guidelines for Americans were issued in 2005, and are summarized in Table 22.2.

TABLE 22.1
Development of Dietary Guidelines in the United States, Canada, Australia, and New Zealand

Country	United States	Canada	Australia	New Zealand
Title of Guidelines	Dietary Guidelines for Americans	Canada's Guidelines for Healthy Eating	Dietary Guidelines for All Australians	Food and Nutrition Guidelines
Year	2000, 2005	2002	2003	1991
Endorsing Unit	U.S. Department of Agriculture and U.S. Department of Health and Human Services	Department of National Health and Welfare	National Health and Medical Research Council	Nutrition Task Force at the Ministry of Health
Approaches[a]	1–5, 7	1–5, 7	1–5	1–5
Number of Guidelines	27	5	13	6
Target audiences[b]	G, H, P, N	G, H, P, N	G, H, P	G, H, P
Major Nutrition Problems Addressed in Guidelines[c]	C, E, I, O	C, E, I, O	C, E, I, O	C, E, I, O

Other Dietary Guidelines	National Cancer Institute, American Institute of Cancer Research and American Heart Association		National Physical Activity Guidelines	Dietary Guidelines for: • Healthy Children • Healthy Adolescents • Healthy Breast-feeding women • Healthy Pregnant women • Older People

[a] 1 = Nutrition experts, nutrition scientists views; 2 = Review of former guidelines; 3 = From food groups; 4 = From consumption/nutrition survey; 5 = Definition of nutritional objectives; 6 = Economic data; 7 = Consumer focus groups.

[b] G = general population; H = health professionals; P = policy makers; N= nutrition education of school children.

[c] C = diet-related chronic degenerative diseases; I = dietary inadequacy; E = dietary excess (other nutrients); O = overnutrition (energy); PEM = protein-energy malnutrition.

TABLE 22.2
2005 Dietary Guidelines for Americans: Main Areas and Key Recommendations

Adequate Nutrients within Calorie Needs

Key Recommendations

Consume a variety of nutrient-dense foods and beverages within and among the basic food groups while choosing foods that limit the intake of saturated and
  trans fats, cholesterol, added sugars, salt, and alcohol

Meet recommended intakes within energy needs by adopting a balanced eating pattern, such as the USDA Food Guide or the DASH Eating Plan

Key Recommendations for Specific Population Groups

People above age 50: Consume vitamin B_{12} in its crystalline form (i.e., fortified foods or supplements)

Women of childbearing age who may become pregnant: Eat foods high in heme-iron or consume iron-rich plant foods or iron-fortified foods with an enhancer
  of iron absorption, such as vitamin C-rich foods

Women of childbearing age who may become pregnant and those in the first trimester of pregnancy: Consume adequate synthetic folic acid daily
  (from fortified foods or supplements) in addition to food forms of folate from a varied diet

Older adults, people with dark skin, and people exposed to insufficient ultraviolet band radiation (i.e., sunlight): Consume extra vitamin D from vitamin D-
  fortified foods or supplements

Weight Management

Key Recommendations

To maintain body weight in a healthy range, balance calories from foods and beverages with calories expended

To prevent gradual weight gain over time, make small decreases in food and beverage calories and increase physical activity

Key Recommendations for Specific Population Groups

Those who need to lose weight: Aim for a slow, steady weight loss by decreasing caloric intake while maintaining an adequate nutrient intake and increasing
  physical activity

Overweight children: Reduce the rate of body weight gain while allowing growth and development. Consult a healthcare provider before placing a child on a
  weight-reduction diet

Pregnant women: Ensure appropriate weight gain as specified by a healthcare provider

Breast-feeding women: Moderate weight reduction is safe and does not compromise weight gain of the nursing infant

Overweight adults and overweight children with chronic diseases or on medication: Consult a healthcare provider about weight loss strategies prior to
  starting a weight-reduction program to ensure appropriate management of other health conditions

Physical Activity

Key Recommendations

Engage in regular physical activity and reduce sedentary activities to promote health, psychological well-being, and a healthy body weight

To reduce the risk of chronic disease in adulthood: Engage in at least 30 min of moderate-intensity physical activity, above usual activity, at work or home on
  most days of the week

For most people, greater health benefits can be obtained by engaging in physical activity of more vigorous intensity or longer duration

To help manage body weight and prevent gradual, unhealthy body weight gain in adulthood: Engage in approximately 60 min of moderate- to
  vigorous-intensity activity on most days of the week while not exceeding caloric intake requirements

To sustain weight loss in adulthood: Participate in at least 60 to 90 min of daily moderate-intensity physical activity while not exceeding caloric intake
  requirements. Some people may need to consult with a healthcare provider before participating in this level of activity

Achieve physical fitness by including cardiovascular conditioning, stretching exercises for flexibility, and resistance exercises or calisthenics for muscle
  strength and endurance

Key Recommendations for Specific Population Groups

Children and adolescents: Engage in at least 60 min of physical activity on most, preferably all, days of the week

Pregnant women: In the absence of medical or obstetric complications, incorporate 30 min or more of moderate-intensity physical activity on most, if not all,
  days of the week: Avoid activities with a high risk of falling or abdominal trauma

Breast-feeding women: Be aware that neither acute nor regular exercise adversely affects the mother's ability to successfully breast-feed

Older adults: Participate in regular physical activity to reduce functional declines associated with aging and to achieve the other benefits of physical activity
  identified for all adults

Food Groups to Encourage

Key Recommendations

Consume a sufficient amount of fruits and vegetables while staying within energy needs. Two cups of fruit and 2½ cups of vegetables per day are recom-
  mended for a reference 2000-calorie intake, with higher or lower amounts depending on the calorie level

Choose a variety of fruits and vegetables each day. In particular, select from all five vegetable subgroups (dark green, orange, legumes, starchy vegetables,
  and other vegetables) several times a week

Consume 3 or more ounce-equivalents of whole-grain products per day, with the rest of the recommended grains coming from enriched or whole-grain
  products. In general, at least half the grains should come from whole grains

Consume 3 cups per day of fat-free or low-fat milk or equivalent milk products

Continued

TABLE 22.2
Continued

Food Groups to Encourage (*Continued*)

Key Recommendations for Specific Population Groups

Children and adolescents. Consume whole-grain products often; at least half the grains should be whole grains. Children 2 to 8 years should consume 2 cups per day of fat-free or low-fat milk or equivalent milk products. Children 9 years of age and older should consume 3 cups per day of fat-free or low-fat milk or equivalent milk products

Fats

Key Recommendations

Consume less than 10% of calories from saturated fatty acids and less than 300 mg/day of cholesterol, and keep *trans* fatty acid consumption as low as possible

Keep total fat intake between 20 to 35% of calories, with most fats coming from sources of polyunsaturated and monounsaturated fatty acids, such as fish, nuts, and vegetable oils

When selecting and preparing meat, poultry, dry beans, and milk or milk products, make choices that are lean, low-fat, or fat-free

Limit intake of fats and oils high in saturated or *trans* fatty acids, and choose products low in such fats and oils

Key Recommendations for Specific Population Groups

Children and adolescents. Keep total fat intake between 30 to 35% of calories for children 2 to 3 years of age and between 25 to 35% of calories for children and adolescents 4 to 18 years of age, with most fats coming from sources of polyunsaturated and monounsaturated fatty acids, such as fish, nuts, and vegetable oils

Carbohydrates

Key Recommendations

Choose fiber-rich fruits, vegetables, and whole grains often

Choose and prepare foods and beverages with little added sugars or caloric sweeteners, such as amounts suggested by the USDA Food Guide and the DASH Eating Plan

Reduce the incidence of dental caries by practicing good oral hygiene and consuming sugar- and starch-containing foods and beverages less frequently

Sodium and Potassium

Key Recommendations

Consume less than 2300 mg (approximately 1 tsp of salt) of sodium per day

Choose and prepare foods with little salt. At the same time, consume potassium-rich foods, such as fruits and vegetables

Key Recommendations for Specific Population Groups

Individuals with hypertension, blacks, and middle-aged and older adults: Aim to consume no more than 1500 mg of sodium per day, and meet the potassium recommendation (4700 mg/day) with food

Alcoholic Beverages

Key Recommendations

Those who choose to drink alcoholic beverages should do so sensibly and in moderation—defined as the consumption of up to one drink per day for women and up to two drinks per day for men

Alcoholic beverages should not be consumed by some individuals, including those who cannot restrict their alcohol intake, women of childbearing age who may become pregnant, pregnant and lactating women, children and adolescents, individuals taking medications that can interact with alcohol, and those with specific medical conditions

Alcoholic beverages should be avoided by individuals engaging in activities that require attention, skill, or coordination, such as driving or operating machinery

Food Safety

Key Recommendations

To avoid microbial foodborne illness:

  Clean hands, food contact surfaces, and fruits and vegetables. Meat and poultry should not be washed or rinsed

  Separate raw, cooked, and ready-to-eat foods while shopping, preparing, or storing foods

  Cook foods to a safe temperature to kill microorganisms

  Chill (refrigerate) perishable food promptly and defrost foods properly

  Avoid raw (unpasteurized) milk or any products made from unpasteurized milk, raw or partially cooked eggs or foods containing raw eggs, raw or undercooked meat and poultry, unpasteurized juices, and raw sprouts

Key Recommendations for Specific Population Groups

Infants and young children, pregnant women, older adults, and those who are immunocompromised. Do not eat or drink raw (unpasteurized) milk or any products made from unpasteurized milk, raw or partially cooked eggs or foods containing raw eggs, raw or undercooked meat and poultry, raw or undercooked fish or shellfish, unpasteurized juices, and raw sprouts

Pregnant women, older adults, and those who are immunocompromised: Only eat certain deli meats and frankfurters that have been reheated to steaming hot

TABLE 22.3
Dietary Guidelines of Canada, Australia, and New Zealand

Canada	Australia	New Zealand
1. Enjoy a variety of foods	1. Prevent excess weight gain	1. Eat a variety of foods from each of the four major food groups each day
2. Emphasize cereals, breads, other grain products, vegetables, and fruits	2. Enjoy a wide variety of nutritious foods	2. Prepare meals with minimal added fat (especially saturated fat), salt, and sugar
3. Choose lower-fat dairy products, leaner meats, and foods prepared with little or no fat	3. Eat plenty of vegetables, legumes, and fruits	3. Choose prepared foods, drinks and snacks that are low in fat (especially saturated fat), salt, and sugar
4. Achieve and maintain a healthy body weight by enjoying regular physical activity and healthy eating	4. Eat plenty of cereals, preferably wholegrain	4. Maintain a healthy body weight by regular physical activity and by healthy eating
5. Limit salt, alcohol, and caffeine	5. Include lean meats, fish, poultry or alternatives	5. Drink plenty of liquids each day
	6. Include milk, yoghurt, cheese or alternatives	6. If drinking alcohol, do each day so in moderation
	7. Drink plenty of water	
	8. Limit saturated fats and moderate total fat intake	
	9. Choose foods low in salt	
	10. Limit your alcohol intake if you choose to drink	
	11. Consume only moderate amounts of sugars and foods containing added sugars	
	12. Care for your food; prepare and store it safely	
	13. Encourage and support breast-feeding	

Other U.S. federal food guidance for the general public is now being modified to be consistent with these guidelines.[1,2] In the United States, several professional associations have also promulgated guidelines for those at risk or already suffering from chronic degenerative diseases such as cancer or heart disease.[1,2]

All four countries address their guidelines to either the general population and health professionals or other policy makers. New guidelines usually follow the precedents established in earlier versions. Some changes simply involve a change in wording. For example, the American guideline regarding sugar is evolved from "Avoid too much sugar" in 1980[7] to "Use sugars only in moderation" in 1990[8] and "Choose a diet moderate in sugars" in 1995[9] to the 2000 "Choose beverages and foods that limit your intake of sugars"[10] and the current one "Choose and prepare foods and beverages with little added sugars or caloric sweeteners"[11]. Other changes are more innovative. The United States added new guidelines on food safety in 2000 and expanded them in 2005. It also included recommendations for specific population groups at high nutritional risk with the guidelines.

Table 22.3 shows that in 2003 Australia continued to have a hybrid of food-based and nutrient-based recommendations. Australia and New Zealand both have specific guidelines for infants, toddlers, school-age children, adolescents, and the elderly that also address other health recommendations related to nutrition, such as breast-feeding of infants and physical activity for everyone. New Zealand also has dietary guidelines for pregnant and breast-feeding women.

As described in Table 22.1, the United States, Canada, and Australia all have pictorial representations or graphics for their dietary recommendations. The United States updated its food pyramid with a set of personalized interactive pyramids entitled MyPyramid (www.Mypyramid.gov).[12] Canada uses a rainbow graphic to depict the components of a healthy diet. Australia has two graphics; a pyramid and also used a circular plate in the past.

SIMILARITIES AND DIFFERENCES

All these countries have recommendations for certain nutrients and also for groups of foods, such as fruits/vegetables, grains, dairy, and meats. Food-based guidelines are easier for consumers to implement than nutrient-based guidelines since human beings eat foods, and not specific nutrients. In all of these countries, heart disease, hypertension, diabetes with its complications, and cancer are the leading causes of death.[5,11,13–15] Obesity is prevalent and increases the severity and adverse outcomes from many of these diseases.[15,16]

Although the core messages in all of these dietary guidelines are similar — eat a variety of foods and include physical activity to achieve/maintain a healthy weight (Table 22.3) — the American dietary guidelines (Table 22.2) have adopted a particularly strong emphasis on weight control through diet and physical activity. They note that major causes of illness and death are related to poor diet and a sedentary lifestyle, both associated with the epidemic of obesity in that country, and this is the reason for the stress on weight control.

The report of the 2005 Dietary Guidelines for Americans committee[11] is now oriented toward policy makers and health professionals, rather than to the general public, since its intent is to summarize current knowledge regarding individual nutrients and food components into recommendations for a pattern of eating that can be adopted by the public. A simplified booklet for consumers has also been prepared by communications experts.[17]

All these countries have recommendations on limiting fat, salt, and alcohol, and increasing fruits, vegetables, and whole grains. The United States, Canada, and New Zealand, all suggest limiting alcoholic beverages to less than 2 drinks per day for men and one for women. Australia has a higher limit; less than four drinks for men and two for women per day.

The background and supporting information accompanying the Dietary Guidelines provides the rationale for quantitative suggestions for intakes of specific nutrients.[5,11,18,19] All these countries suggest that 50 to 55% of total calories should come from carbohydrates. The United States, Canada, and Australia recommend less than 10% from saturated fat but vary in the amount of total fat from 30 to 35% of calories. New Zealand is more liberal, suggesting no more than 12% from saturated fat.

There are some differences in the guidelines of these highly industrialized countries. In the 2000 edition of the U.S. guidelines, food safety was addressed and it continues to be included in 2005. Australia includes a guideline specifically to encourage and support breast-feeding.[18] Most of the guidelines for the United States and Canada are for all healthy individuals over age 2 years. However, the fat guideline in Canada is not applicable until a child reaches age 5 years.

Other health recommendations that are included in New Zealand's guidelines are nonsmoking, especially for adolescents, pregnant, and breast-feeding women. The elderly, who may suffer from isolation and therefore poor nutrition, are encouraged to "make mealtime a social time." Australia encourages its elderly to eat at least three meals per day. Elderly people and pregnant women are especially vulnerable to risks associated with food-borne illnesses. Australia's food safety guidelines specifically address food safety in the elderly (care for your food: prepare and store it correctly) and the New Zealand guidelines discuss *Listeria* in the information specifically directed to pregnant women.

CONCLUSIONS

The guidelines for these English-speaking countries in different parts of the world are very similar, reflecting the affluent lifestyles and common food ways that they share.

LATIN AMERICA

Dietary guidelines were first formulated in Latin America in the late 1980s.[20] Guidelines from Chile, Guatemala, Mexico, Panama, and Venezuela are provided as examples of dietary guidelines in the region.

Latin America is a region with great inequalities in the distribution of welfare and also large variations in the nutritional health of its population groups. There has been a shift from dietary deficiency disease to problems of dietary excess in many countries of the region over the past two decades. In Chile, the prevalence of protein–calorie malnutrition in children is declining rapidly. However, the prevalence of chronic degenerative diseases associated with imbalances in food intake and sedentary lifestyles is rising.[21] In contrast, in Guatemala, Mexico, and Panama, poverty-related undernutrition and dietary deficiency diseases are still prevalent, especially among children and women of reproductive age in rural areas. At the same time, the prevalence of diet-related chronic diseases is rising. Venezuela is an oil-exporting country, but still has large economic inequalities and grapples with poverty-related malnutrition as well as dietary excess.

In most Latin American countries, food consumption patterns are influenced by those of the United States. Changing cultural and economic influences, rural–urban migration, greater availability of processed foods, and advertising are also affecting food consumption,[22] resulting in both over- and undernutrition.[23] The development of poor ghettos in metropolitan areas, short lactation periods, low wages, and low maternal educational levels is associated with undernutrition in young children. The interactions of urbanization, sedentary lifestyles, lack of nutrition education, and excessive consumption of cheap foods low in nutritional value lead to diseases of overconsumption, such as obesity, diabetes, and cardiovascular disease.[23] Other countries in Latin America, including Argentina, Brazil, Cuba, Peru, Colombia, Costa Rica, Honduras, and El Salvador are either formulating or have completed country-specific dietary guidelines.

FORMULATION

Most of the Latin American countries are in the implementation stage in formulating dietary guidelines.[24] The dietary guidelines for the Mexican population were issued by the Mexican Institute of Nutrition.[25] Venezuela issued dietary guidelines in the late 1980s that were later revised and updated.[26] The dietary guidelines have been implemented in many ways. For example, they have been incorporated into Venezuelan kindergarten, elementary, and secondary school curricula.[26–28]

Table 22.4 contains details about the dietary guidelines development process in selected Latin American countries: Chile, Guatemala, Mexico, Panama, and Venezuela.[21,26,29–31] All have dietary guidelines for the general population. Some also have guidelines for specific population groups (Chile, Panama, and Venezuela) or target certain groups on specific concerns (Guatemala for food safety among the poor). Governmental or quasi-governmental organizations develop and promulgate the guidelines based on the views and opinions of experts and scientists. Some also use background data on food consumption surveys (Chile, Mexico, and Panama) and economic data (Venezuela and Mexico). Most of the countries also refer to food groups in their dietary guidelines.[21,26,32]

[b] G = general population; H = health professionals; P = policy makers; N= nutrition education of school children.

Four of the countries also use graphic representations of food groups and supporting messages (see Table 22.4). Chile and Panama adapted the food guide pyramid used in the United States. Mexico now uses a plate rather than the pyramid it formerly employed. Guatemala summarized its food groups and dietary guidelines in a family pot or "crock pot" graphic. Venezuela has no graphic, but the government has produced an extensive set of educational materials directed to different target groups.[27,28]

SIMILARITIES AND DIFFERENCES

Table 22.5 summarizes the dietary guidelines for certain Latin American countries. The number of guidelines range from five in Panama to ten in Mexico; Venezuela has issued nine guidelines and also 40 educational messages to facilitate the implementation of the guidelines. Mexico has 10 dietary guidelines, but each guideline contains several additional messages.

In general, the guidelines are focused on foods and provide general guidance. Variety is mentioned in all guidelines. Guatemala, Mexico, and Venezuela discuss economic disparities in supporting documents. For example, Guatemala recommends to those with limited resources to eat meats, eggs, and dairy products at least once or twice a week, while Venezuela urges prudence in the management of financial resources (see Table 22.5).

Some countries incorporate specific concerns about food consumption (Table 22.5). Guatemala emphasizes the importance of washing hands, and keeping food and water well covered in its graphic. Venezuela has a guideline emphasizing good hygiene in handling food.

Guidelines directed to overconsumption are included by all the countries. These include specific recommendations to increase physical activity (Mexico), maintain a healthy weight (Mexico and Panama) or to moderate or reduce the use of fats and sugars (Chile, Mexico, Panama, and Venezuela). Chronic disease risks are also addressed. These include recommendations to moderate use of salt (Chile and Venezuela) or sodium (Panama), limiting consumption of fats and sugars (Chile, Mexico, Panama, and Venezuela), saturated fats (Mexico and Panama), cholesterol (Mexico and Panama). Other guidelines are directed to limiting specific foods or nutrients, or to increase other more nutrient-rich foods (fruits, vegetables, and whole grains) (see Table 22.5).

The Latin American guidelines focus mostly on foods, not specific nutrients (Table 22.5). However, Panama recommends moderation in the use of sodium and salt. Guatemala, a country with low literacy rates, also emphasizes nutrients but in simple, short messages; it singles out energy, protein (both animal and vegetable), vitamins A and C, calcium, iron, and zinc, as well as fiber. This emphasis reflects Guatemala's goals of preventing both dietary deficiencies and excesses. Venezuela's guidelines have little emphasis on specific foods and focus on salt, alcohol, and sugar, and also stress economical choices of foods (Table 22.5). Mexico and Venezuela share an emphasis on nutrition-related healthy behaviors such as physical activity and breast-feeding.

All of the Latin American countries include advice on consuming fruits, vegetables, and grains daily. Guatemala specifically mentions beans and tortillas. Other countries (Chile, Mexico, and Venezuela) mention the need for limiting fat. Salt restriction is mentioned in Mexico, Venezuela, and Panama. Both Mexico and Venezuela have a guideline limiting alcohol. Chile and Guatemala include a guideline on use of dairy products; Chile focuses on low-fat milk products; Guatemala urges at least 1 to 2 servings of whole-fat milk products, since many members of the population are poor and do not consume milk. Mexico and

TABLE 22.5
Dietary Guidelines of Selected Latin American Countries

Chile	Guatemala	Mexico	Panama	Venezuela
1. Eat different types of foods throughout the day.	1. Include, at each meal, grains, cereals, or potatoes, because they are nutritious, tasty, and have low cost	1. Avoid monotony by consuming a wide variety of foods	1. Eat a variety of foods	1. Eat food from all food groups
2. Increase your consumption of fruits, vegetables, and green vegetables	2. Eat every day vegetables and greens to benefit your body	2. Include, at every meal, at least two servings of fruits and vegetables	2. Eat sufficient grains, roots, vegetables, and fruits	2. Daily, do 30 minutes of physical activity
3. Prefer vegetable oil and limit animal fats	3. Every day, eat some type of fruit, because they are healthy, easy to digest, and nutritious	3. Eat, at every meal, a variety of grains and grain products, preferably whole grains, mixing cereals and legumes	3. Select a diet low in saturated fat, cholesterol, and oil	3. Practice hygienic habits in your food preparation
4. For meat, prefer fish and poultry	4. If you eat tortilla and beans every day, eat one spoonful of beans with each tortilla to make it more nutritious	4. Include, at every meal, a moderate serving of animal products, choosing those with the least fat	4. Eat sugar and sweets in moderation	4. Use your money wisely in your food selection and expenditures
5. Increase your consumption of low-fat milk	5. At least twice a week, eat one egg, or one piece of cheese, or drink one glass of milk, to complement your diet	5. Limit your consumption of fats, including cooking oils and fatty foods (to less than 30% of daily energy intake). Also, limit saturated fats, of animal origin (to lees than 10% of total energy). And, reduce cholesterol intake to less than 300 mg per day	5. Eat salt and sodium in moderation	5. Breast milk is the only food without substitute for infants below 6 months of age
6. Reduce salt intake	6. At least once per week, eat a serving of liver (beef) or meat to strengthen your body	6. Reduce the consumption of salt and sugar, starting by not using salt at the table and reducing sugars in your liquids (coffee, tea, drinks, or juices)	6. Maintain a healthy weight	6. Increase your consumption of fruit, vegetables, legumes and cereals
7. Moderate the consumption of sugar	7. To stay healthy, eat a variety of foods as indicate in the household pot	7. Restrict the consumption of products with excess of additives (colorants, flavorings, etc. Avoid alcohol and do not smoke		7. Use moderation in the consumption of sugar, salt, and alcoholic beverages
		8. Breast-feed children from birth and start comple mentary food at the fourth month of age		8. Consume animal products in moderate amounts
		9. Avoid obesity by monitoring your weight according to the suggested weight for your stature		9. Water is indispensable for life and its consumption helps to maintain your help
		10. Increase your physical activity, walk briskly or practice any other type of aerobic exercise for about 20 to 30 minutes 4 or 5 times a week		

Venezuela have specific guidelines stressing the importance of breast-feeding. Panama has special dietary guidelines for infants that recommend exclusive breast-feeding during the first 6 months of life and for complementary feeding thereafter.

CONCLUSIONS

Dietary guidelines for Latin American countries reflect the diversity in socioeconomic situations and nutritional problems in the region and each country's unique perspectives. They offer the general public, service providers, and policy maker's actionable recommendations for improving nutrition and health status. Some of these countries have already identified barriers that limit the use of the dietary guidelines (Chile, Venezuela). Others, such as Mexico, still need to evaluate the applicability of their guidelines to the eating practices of the diverse Mexican population. Dietary guidelines in Guatemala were directed to the poor; problems associated with overconsumption of foods and sedentary lifestyles still need to be addressed.

ASIAN COUNTRIES

Asia's diversity is reflected in the many nutritional problems that were evident in the ten countries we reviewed: China, India, Indonesia, Japan, Korea, Malaysia, Philippines, Singapore, Taiwan, and Thailand.[33–43,44] Until the mid-1950s, poverty-related malnutrition was the major problem. The primary concern was to ensure adequate energy intakes and prevention or control of dietary deficiency diseases.[32,45] Today, nutrition problems in Asia cover the entire spectrum from deficiency disease to excess. Some countries are experiencing new affluence, and increasingly issues of chronic degenerative disease also have to be addressed.

Asian dietary guidelines focus on reducing or preventing both chronic deficiency and chronic degenerative diseases since both problems are often prevalent.[46–48] Presently, India still has high rates of protein-energy malnutrition among some groups as well as very affluent population groups with chronic disease problems. The national guidelines address both groups. In countries such as Korea, Japan, Taiwan, and Singapore, deficiency diseases have declined dramatically in the past three decades.[45,48,49] Countries such as Thailand and China have low rates of protein-energy malnutrition, but micronutrient deficiencies (iron, iodine, vitamin A, and riboflavin) are still common.[33,37,43,50] Indonesia and the Philippines face both persistent problems of undernutrition and deficiency disease among the poor, coupled with emerging problems of overnutrition and increased chronic degenerative disease rates, particularly among the affluent.[32,35,37] Filipino guidelines for more affluent populations focus on chronic degenerative diseases and avoiding excess,[51] whereas Filipino guidelines for less affluent population groups emphasize achieving sufficiency of nutrient intakes.[35]

FORMULATION

Table 22.6 shows the various approaches used in developing dietary guidelines in Asia. The guidelines are all intended to provide nutrition education and dietary guidance to the general public in terms that are understandable to most consumers. They are also often used to help officials in the health, agricultural, and education sectors in program planning. All of the countries surveyed rely on government agencies or professional societies to develop and endorse their official guidelines.[35] Some countries (Philippines, Korea, and Japan) formulate guidelines based on findings from national nutrition or food consumption surveys. Others develop their dietary guidelines based on what experts deem to be appropriate.

Graphics have been adopted by many Asian countries to help the public visualize these dietary guidelines and food guides. These include pyramids (Malaysia and Singapore), stairs (India), pagodas (Korea and China), a flag (Thailand), a plum flower (Taiwan), the "big 6" for the six food groups (Japan), and a six-sided star (Philippines). A pyramid is also available for more affluent Filipinos.[51]

SIMILARITIES AND DIFFERENCES

Table 22.7 presents information on representative dietary guidelines from the Asian region. Most of the guidelines are general, and are food rather than nutrient-based. The exception is Singapore, which has guidelines that are quantitative and nutrient-specific.[52] There are common core food-based messages in all the guidelines, these include: choose a diet composed of a wide variety of foods; eat enough food to meet bodily needs and maintain or improve body weight; select foods that are safe to eat; and enjoy your food.

The guidelines also vary with respect to number and in relative emphasis given on balance, adequacy, moderation, and restriction. Although all the Asian dietary guidelines recommend eating a variety of foods, they differ on how they suggest achieving a varied pattern (see Table 22.7). Some include recommendations for frequency of consumption. Eating breakfast daily is recommended in the Indonesian guidelines, and having regular meals is recommended in the Korean guidelines.[37,38] Other guidelines recommend specific amounts of different kinds of foods. For example, to assure a well-balanced diet, the Japanese guidelines

TABLE 22.6

Thailand	The Thai Dietary Guidelines for Better Health	1995	The Division of Nutrition, Department of Health, Ministry of Public Health	1	G	None

[a] 1 = Nutrition experts and nutrition scientists views. 2 = Review of former guidelines. 3 = From food groups. 4 = From consumption/nutrition survey. 5 = Definition of nutritional objectives. 6 = Economic data.

[b] G = General population. H = Health professionals. P = Policy makers. N = Nutrition education of school children.

recommend eating 30 or more different kinds of foods daily.[41] Japanese guidelines also suggest balancing main and side dishes around staple foods. Malaysia recommends choosing foods from each of the food group's daily.[42] The Filipino and Chinese guidelines also focus on achieving dietary adequacy, emphasizing food rather than nutrient-based interventions.

Virtually all examined Asian countries emphasize ensuring adequacy of energy/calorie intake (see Table 22.7). Korea mentions achieving and maintaining energy balance by balancing intakes and expenditure.[37] Most guidelines stress getting enough food with increased intakes of fruits, vegetables, cereal, and dairy food to promote fiber, vitamins, and minerals intakes. Some also indicate the proportion of foods that should be consumed in relation to total energy intake. The national Indian guidelines are very general emphasizing: variety, food safety, moderation with respect to sugar and salt, adequate diets especially by children and adolescents, and a nutrient-rich diet for elders. They represent a change from the older guidelines that focused on specific population groups by economic status.[34]

In countries in which deficiencies of vitamins and minerals have been identified as public health problems, the guidelines reflect this, and emphasize food sources rich in those nutrients (see Table 22.7). For example, calcium is mentioned specifically in some guidelines. A specific calcium-rich food (milk) is mentioned in the Taiwanese, Chinese, Filipino, and Korean guidelines, and fish and seaweed in the Japanese guidelines. In Indonesia, people are advised to "consume iron-rich foods, and to use only iodized salt."[38] The Filipino guidelines recommend "choosing foods fortified with nutrients."[35] The guidelines for poor Indonesians recommend eating enough food.[34,38]

The more affluent countries such as Taiwan, Singapore, Korea, and Japan, (and also the guidelines for the more affluent members of the population in Indonesia) emphasize moderation in fat, saturated fat, or simple sugars. The major difference between the various guidelines in Asia is in the amounts and the relative balance suggested between dietary constituents. The Asian guidelines on moderation in fat and salt intake vary greatly. Some simply say to avoid excess, or to limit/restrict the use of fat (see guidelines for India, Malaysia, Taiwan, China), others specify the type of fat to be consumed. For example, the Japanese guidelines recommend use of vegetable oil instead of animal fat.

China, Taiwan, and Singapore are three countries with similar ethnic origins and dietary patterns that share similar dietary guidelines recommending reducing intake of salt and salt-cured foods. Singapore is the most specific, recommending eating less than 5 g of salt or 2000 mg of sodium per day.[52] General recommendations on limiting salt intake are present in other guidelines throughout the region. The Japanese guidelines recommend eating less than 10 g of salt per day. Neither Malaysia nor the Philippines mentions salt.[52]

TABLE 22.7
Dietary Guidelines of Selected Asian Countries

China

1. Eat a variety of foods
2. Eat appropriate quantity of foods
3. Moderate oil and fat
4. Eat moderately polished cereals
5. Limit salt intake
6. Eat fewer sweets
7. Limit alcohol balance food distribution through three meals

India

1. Nutritionally adequate diet should be consumed through a mix: choice from a variety of foods
2. Additional food and extra care are required during pregnancy and lactation
3. Exclusive breast-feeding should be practiced for 4–6 months. Breast-feeding can be continued up to 2 years
4. Food supplements should be introduced to infants by 4–6 months
5. Adequate and appropriate diet should be taken by children and adolescents, both in health and disease
6. Green leafy vegetables, other vegetables and fruits should be used in plenty
7. Cooking oils and animal foods should be used in moderation, and vanaspati/ghee/butter should be used only sparingly
8. Overeating should be avoided to prevent overweight and obesity Proper physical activity is essential to maintain desirable body weight
9. Salt should be used in moderation
10. Foods consumed should be safe and clean
11. Healthy and positive food concepts and cooking practices should be adopted
12. Water should be taken in adequate amounts and beverages should be consumed in moderation
13. Processed and ready-to-eat foods should be used judiciously. Sugar should be used sparingly
14. The elderly should eat a nutrient-rich diet to keep fit and active

Indonesia

1. Eat a wide variety of foods
2. Consume foods that provide sufficient energy
3. Obtain about half of total energy requirements from complex CHO-rich foods
4. Obtain not more than a quarter of total energy intake from fats or oils
5. Use only iodized salt
6. Consume iron-rich foods
7. Breast-feed your baby exclusively for four months
8. Have breakfast everyday
9. Drink adequate quantities of fluids that are free of contaminants
10. Take adequate exercise
11. Avoid drinking alcoholic drinks
12. Consume foods prepared hygienically
13. Read the labels of packaged foods

Japan

1. Obtain well-balanced nutrition with a variety of foods (30 foods a day); take staple food, main dish, and side dishes together
2. Take energy corresponding to daily activity
3. Consider the amount and the quality of the fats and oils you eat: avoid too much; eat more vegetable oils than animal fat
4. Avoid too much salt, not more than 10 g a day
5. Happy eating makes for happy family life; sit down and eat together and talk; treasure family taste and home cooking

Korea

1. Eat a variety of grains, vegetables and fruits, fish, meat, poultry, and dairy products
2. Choose less salt-preserved foods and prepare foods with less salt
3. Increase physical activity for a healthy weight and balance what you eat with your activity
4. Enjoy every meal, and do not skip breakfast
5. If you drink alcoholic beverages, do so in moderation
6. Prepare foods properly and order sensible amounts
7. Enjoy our rice-based diet

Malaysia

1. Enjoy a variety of foods
2. Maintain healthy body weight by balancing food intake with regular physical activity
3. Eat more rice and other cereal products, legumes, fruit, and vegetables
4. Minimize fat in food preparation and choose foods that are low in fat and cholesterol
5. Use a small amount of salt and choose foods low in salt
6. Drink plenty of water daily
7. Practice and promote breast-feeding

Philippines

1. Eat a variety of foods every day
2. Breast-feed infants exclusively from birth to 6 months, and then, give appropriate foods while continuing breast-feeding
3. Maintain children's normal growth through proper diet and monitor their growth regularly
4. Consume fish, lean meat, poultry, or dried beans
5. Eat more vegetables, fruits, and root crops
6. Eat foods cooked in edible/cooking oil in your daily meals
7. Consume milk, milk products, and other calcium-rich foods
8. Use iodized salt, but avoid excessive intake of salty foods

Singapore

1. Eat a variety of foods
2. Maintain desirable body weight
3. Restrict total fat intake to 20 to 30% of total energy intake
4. Modify composition of fat in the diet to one-third polyunsaturated, one-third monounsaturated, and one-third saturated
5. Reduce cholesterol intake to less than 300 mg/day
6. Maintain intakes of complex carbohydrates at about 50% total energy intake
7. Reduce salt intake to less than 5 g a day (2000 mg Na)
8. Reduce intake of salt-cured, preserved, and smoked foods
9. Reduce intake of refined and processed sugar to less than 10% of energy
10. Increase intake of fruit and vegetables and whole-grain cereal products
11. For those who drink, have not more than two standard drinks (about 30 g alcohol) per day
12. Encourage breast-feeding in infants until at least 6 months of age

Thailand

1. Eat a variety of foods from each of the five food groups and maintain proper weight
2. Eat adequate amount of rice or alternative carbohydrate sources
3. Eat plenty of vegetables and fruits regularly
4. Eat fish, lean meat, eggs, legumes, and pulses regularly
5. Drink milk in appropriate quality and quantity for one's age
6. Eat a diet containing appropriate amounts of fat
7. Avoid sweet and salty foods
8. Eat clean and safe food
9. Avoid or reduce the consumption of alcoholic beverages

The majority of the guidelines stress common nonfood-related healthy behaviors such as not smoking, dental hygiene, stress management, weight control, and physical activity. Asian dietary guidelines also specify the settings (places or environments) or other circumstances surrounding food and eating (Table 22.7). Most countries in this region also acknowledge the impacts of lifestyle changes on health, and emphasize attaining a healthy body weight to prevent diet-related disease. The Indonesian guideline recommends "consuming foods to provide sufficient energy."[38] Some of these differences in emphasis reflect the vastly different levels of affluence, within and between countries in Asia. For many years, India had two sets of guidelines. One was for the poor and emphasized nutrient adequacy and avoidance of dietary deficiency diseases. The other Indian guidelines were for affluent individuals and emphasized energy balance, restricting energy intakes to levels "commensurate with sedentary occupation, so that obesity is avoided," coupled with moderation and restriction of fat, saturated fat, and sugar to reduce chronic degenerative disease.[34] The 2003 Indian guidelines are 14 in number and are national guidelines rather than specific recommendations by economic group.

Asian guidelines also recognize that eating is more than just "refueling" or nourishment from the physiological standpoint. They recognize that food provides pleasure and has strong links to family, tradition, and culture. Therefore, enjoyment of meals is a concern in all countries, but it is especially evident in the Japanese and Korean guidelines. In Japan, dietary guidelines that promote family values are included; citizens are advised to "make all activities pertaining to food pleasurable ones." Another Japanese guideline also advises to "enjoy cooking and use mealtimes as occasions for family communication."[36,53] In Korea, eating is viewed as a way to keep harmony between diet and other aspects of daily life, and this is stated in the guidelines.[37]

CONCLUSIONS

Dietary guidelines for the Asian countries are all directed to the general population. Many countries, including Malaysia, Indonesia, China, and Japan, also have specific guidelines focusing on those of different ages, sexes, and conditions, such as infants, pregnant and lactating women.[33,36,52,53] Specific foods are recommended for these population groups. For example, breast-feeding in early infancy is a common recommendation in the dietary guidelines of many Asian countries. Human breast milk is recognized as the best food for infants. Encouragement of breast-feeding and recognition of breast milk's unique properties are included in the guidelines.[53] The duration of exclusive breast-feeding, ranges from 4 months (Indonesia) to 4–6 months (Philippines), and to 6 months in Singapore. Another difference is age of weaning, introduction of other foods in addition to breast milk. For example, it is at 4 to 6 months in the Philippines, but weaning is recommended at no earlier than 5 to 6 months in the Malaysian guidelines, with breast-feeding continuing for up to 2 years.

Some dietary guidelines are common to all Asian countries. One is to eat clean and safe foods; such recommendations are especially important in areas where the climate is very hot and foods are easily spoiled. The hygienic messages range from "consume food that is hygienically prepared" in Malaysia, to "eat clean and safe food to prevent food-borne disease in the family" in the Philippines. Similar guidelines are provided in both the Taiwan and the People's Republic of China's guidelines. "Drink more boiled water" is mentioned in Taiwan, and the guidelines for Mainland China are "avoiding unsanitary and spoiled foods."[38,54,55]

AFRICA

Africa consists of more than 50 nations, most of which are developing countries. Food insecurity is a prominent phenomenon in the majority of this continent. Protein–energy malnutrition, nutrient deficiencies, infectious diseases such as HIV, tuberculosis, and malaria are prevalent especially in central Africa, while diseases of affluence raise concerns in more wealthy and developed southern African countries. Dietary guidelines for South Africa, Nigeria, and Republic of Namibia are summarized here.[56–58]

FORMULATION

South Africa Guidelines for Healthy Eating were revised by Department of Health of South Africa in 2004. The guidelines aim to improve health as well as to relieve chronic diseases, overweight, nutrient deficiencies, and malnutrition. In the process of dietary guidelines formulation, scientific findings, dietary recommendations from other countries, WHO guidelines, and health status surveys were reviewed. Dietary guidelines for Nigeria, published in four languages spoken in the country, were established collaboratively by several ministries, WHO, and other professional organizations in 2001[56] (see Table 22.8).

The Food and Nutrition Guidelines for Namibia were prepared by the National Food Security and Nutrition Council in 2000 (see Table 22.8). However, there is limited information related to the development process that was involved in the Nigerian and Namibian guidelines. South Africa published brochures with detailed illustration and suggested applications on each guideline. South Africa recommends specific numbers of servings on each food group, but similar feature from Namibia and Nigeria is not found. No graphic representation of dietary guidelines was designed in African countries.

While South African guidelines target all adults and children older than 7 years of age, Nigerian guidelines were presented in ten age categories, and Namibian guidelines were not age-specific.

TABLE 22.9
Dietary Guidelines for South Africa and the Republic of Namibia

South Africa	Republic of Namibia
1. Enjoy a variety of foods	1. Eat a variety of foods
2. Be active	2. Eat vegetables and fruit every day
3. Make starchy foods the basis of most meals	3. Eat more fish
4. Eat dry beans, split peas, lentils, and soy regularly	4. Eat beans or meat regularly
5. Chicken, fish, milk, meat, or eggs can be eaten daily	5. Use whole-grain products
6. Drink lots of clean, safe water	6. Use only iodized salt, but use less salt
7. Eat plenty of vegetables and fruits every day	7. Eat at least three meals a day
8. Eat fats sparingly	8. Avoid drinking alcohol. Consume clean and safe water and food
9. Use salt sparingly	9. Achieve and maintain a healthy body weight
10. Use food and drinks containing sugar sparingly and not between meals	

SIMILARITIES AND DIFFERENCES

Dietary guidelines for South Africa and Namibia are summarized in Table 22.9, and those for Nigeria in Table 22.10. Dietary guidelines from all three African countries are food-based instead of nutrient-based. While South Africa has 11 dietary guidelines and Namibia has 10, Nigeria presents over 40 recommendations in three general sections — Good Nutrition, Physical Activity, and Healthy Lifestyle.

All the African dietary guidelines are similar in several ways (see Table 22.9 and Table 22.10). All three guidelines recommend choosing a variety of foods, and at the same time emphasize vegetables and fruits intake. Similarly, all of African guidelines suggest consuming beans, meat, and fish regularly or daily. Additionally, advice on reducing salt intakes as well as avoiding or limiting alcohol intake is found in all guidelines. Furthermore, South Africa and Nigeria recommend limitation on sugar and fat intake. However, only Namibia advocates consuming whole grain products. Only South Africa alone suggests daily milk intake.

All African guidelines recognize the importance of maintaining a healthy body weight with physical activities. South Africa, but not Nigeria and Namibia, further defines healthy body weight in terms of body mass index and provides specific guidelines on the duration and ways to be physically active (see Table 22.9 and Table 22.10).

TABLE 22.10
Dietary Guidelines for the Nigerian Population

1. Good Nutrition

No single food by itself (except breast milk) provides all the nutrients in the
right amounts that will promote growth and maintain life. To achieve good
nutrition, therefore, it is necessary to consume as wide a variety of foods as
possible from the age of 6 months

1.1. Infants (0–6 months)
- Start exclusive breast-feeding immediately after birth and continue
  for 6 months
- There should be no bottle-feeding

1.2. Infants (7–12 months)
- Continue breast-feeding
- Introduce complementary feeds made from a variety of cereals, tubers,
  legumes, fruits, animal foods and give with cup and spoon

1.3. Toddlers (13–24 months)
- Continue to breast-feed until child is 2 years
- Give enriched pap or mashed foods twice daily
- Give family diet made soft with less pepper and spices
- Give fruits and vegetables in season

1.4. Children (25–60 months)
- Give diet that contains a variety of foods in adequate amounts.
- Add palm oil or vegetable oil to raise the energy level of
  complementary foods
- Gradually increase food intake to 4–5 times daily as baby gets older
- Provide dark green leafy vegetables, yellow/orange colored fruits,
  citrus fruits, cereals, legumes, tubers and foods of animal origin.
  – Limit the consumption of sugary food
- Continue feeding even when child is ill

1.5. School-aged children (6–11 years)
- Give diet that contains a variety of foods in adequate amounts
- Encourage consumption of good quality snacks, but limit the
  consumption of sugary snacks

1.6. Adolescents (12–18 years)
- Consume diet containing a variety of foods
- Most of the energy should be delivered from roots/tubers, legumes,
  cereals, vegetables, and less from animal foods
- An increase in total food intake is very important at this stage, so is
  the need to enjoy family meals
- Snacks especially pastry and carbonate drinks should not replace
  main meals. If you must eat out, make wise food choices
- Liberal consumption of whatever fruits that is in season should be
  encouraged
- Females need to eat more iron-containing foods like meat, fish, poultry,
  legumes, cereals as well as citrus fruits to enhance body's use of iron

1.7. Adults (male and female)

Total food intake should take into consideration the level of physical activity.
Individuals who do manual work need to consume more food
than those who do sedentary work
- Limit the fat intake from animal foods
- Diet should consist of as wide a variety of foods as possible for
  example, cereals, legumes, roots/tubers, fruits, vegetables, fish,
  lean meat, local cheese (wara)
- Limit intake of salt, bullion cubes, and sugar
- Liberal consumption of whatever fruits that is in season is encouraged

1.8. Pregnant women
- Eat diet that contains a variety of foods in adequate amounts
- Consume enough food to ensure adequate weight gain
- Eat more of cereals, legumes, fruits, vegetables, dairy products,
  and animal foods
- Take iron and folic acid supplements as prescribed
- Avoid alcohol, addictive substances, and smoking

1.9. Breast-feeding mothers
- Eat diet that contains a variety of available food items like cereals,
  tubers, legumes, meat, fish, milk, fruits, vegetables, etc.
- Consume more of foods rich in iron such as liver, fish, beef, etc.
- Eat fruits in season at every meal
- Consume fluids as needed to quench thirst
- Avoid alcohol, addictive substances and smoking

1.10. The elderly
- Eat diets that are prepared from a variety of available foods for
  example cereals, tubers, fruits, vegetables, etc.
- Increase consumption of fish and fish-based diets
- Eat more of fruits and vegetables
- Eat more frequently

2. Physical Activity/Exercise

Physical activity both as short periods of intense exercise or prolonged
periods of modest activity on a daily basis generally has beneficial
effects.
- Children and adolescents should engage in leisure time exercise
- Adults should undertake some form of exercise as recommended
  by their doctors

3. Healthy Lifestyle

Some habits and lifestyles for example tobacco use and excessive alcohol
consumption have been found to be bad for health
Prolonged indulgence in these lifestyles predisposes to
noncommunicable diseases like cancer, diabetes, heart problems,
and hypertension

3.1. Alcohol

Too much alcohol consumption can lead to risk of hypertension, liver
damage, malnutrition, and various cancers. There is also the problem of
alcohol abuse
- If you must drink, take alcohol in moderation
- Avoid drinking alcohol when driving a vehicle or operating any
  machinery

3.2. Tobacco

Tobacco use is associated with lung cancers and other chronic disorders.
Smoking during pregnancy can harm the developing baby and can result
in low birth weight babies
- Avoid the use of tobacco in any form

South Africa and Namibia include food safety guidelines by suggesting drinking clean and safe water only. Both South Africa and Nigeria emphasize enjoyment of meals. Nigeria developed different guidelines on food intake along the life cycle, categorizing the lifespan into infants of 0 to 6 months, infants of 7 to 12 months, toddlers, preschool children, school-aged children, adolescents, adults, and elderly. Guidelines for pregnant and lactating women are also available. Breast-feeding is suggested to be the sole nutrition for infants under 6 months of age, and to be continued till 2 years old. Such age-specific division is not observed in South African and Namibian dietary guidelines.

CONCLUSIONS

Dietary guidelines for Africa reflect the large economic differences among African countries. South Africa, being a more wealthy country, emphasizes on promotion of balanced diet and prevention of diseases of affluence. In contrast, others, such as Namibia and Nigeria, aim to advocate food safety and adequacy of nutrition intake. Education and literacy level also affect the content and complexity of dietary guidelines in these countries. Many African countries have yet to develop their own dietary guidelines.

EUROPE

With a rich and varied history, Europe demonstrates a variety of economic, political, and healthcare conditions. European countries have numerous differences in culture and dietary habits. In 2000, the WHO Regional Office for Europe developed a Countrywide Integrated Noncommunicable Disease Intervention (CINDI) effort that included a section on "Twelve Steps to Healthy Eating" (see Table 22.11), which serve as the basis for formulating country-specific dietary guidelines in European countries. Most countries in the Nordic, western, southern, and central eastern regions of Europe have their national dietary guidelines in various stages of development and, as seen in Table 22.11, have incorporated some of the 12 steps to healthy eating in their own national guidelines. The heterogeneous nature within Europe makes the review of these guidelines interesting and complex.

Beginning in the late 1990s, European countries started a regional process of development and implementation of Food-based Dietary Guidelines (FBDG),[59] following the recommendations issued by the World Health Organization in 1996.[60] The evolution of the process is a regional enterprise coordinated by regional groups who work closely with the national sectors involved in the establishment of their FBDG.

12. Exclusive breast-feeding[b]	3	4	2	3	5	5

[a] Include Baltic countries and Commonwealth of Independent States.
[b] Many countries include guidelines on these areas in separate guidelines.

The efforts in developing FBDG are continuing and are changing rapidly, because the European countries are at different stages in guidelines development. The process of developing guidelines in Europe is dynamic, and well integrated into other regional efforts as well nutrient recommendations which are also based on the deliberations of the WHO/FAO joint expert consultation group's report.[61]

FORMULATION

To develop this section, we selected arbitrarily a group of European countries: United Kingdom, Germany, Spain, Greece, Finland, and Portugal with enough literature in English, Spanish, or Portuguese, and analyzed their process for the establishment and implementation of their FBDG (see Table 22.12). All of these dietary guidelines are based on scientific reviews and what was in the former guidelines of the countries. All of the countries chosen as examples use national government bodies for defining and formulating them.

SIMILARITIES AND DIFFERENCES

Tables 22.13 and 22.14 present the dietary guidelines for the selected European countries. WHO advocates the use of food-based dietary guidelines for better comprehension and application by the general public. All of the European dietary guidelines examined present their key recommendations in terms of food. Among the European dietary guidelines reviewed, Finland and Portugal offered the most detailed nutrient-based recommendations that they present in addition to the food-based guidelines. Finnish guidelines include all macro- and micronutrients. Portugal, on the other hand, focuses only on carbohydrates, fiber, fats, saturated fats, cholesterol, and calcium. Portugal has one set of 9 nutrient-based guidelines and a separate set of 11 food-based dietary recommendations that are available for different purposes (planning for nutrients, and communications to the public for the food based guidelines).

The United Kingdom, Germany, and Spain display their guidelines in short, bulleted sentences (with 9, 10, and 10 points, respectively). In contrast, the Greek and Finnish guidelines are presented in narrative form (data not shown). Virtually all of the European guidelines categorize food into different groups, but the classifications of food are slightly different from country to country. For example, most countries consider potatoes in the starch group but Finland and Greece discuss potatoes separately and classify them in neither the vegetable nor the starch groups.

Virtually all of the European countries include a variety guideline, emphasize fruit, vegetables and whole grains, and all have some guideline for the amount of alcohol and fat in the diet. All except Spain have a guideline on salt, and all but Germany have guidelines about sweets. Countries differ to the extent they are nutrient-based and which nutrients they concentrate upon; for example, Finland and Portugal are more quantitative in terms of nutrient recommendations, whereas Spain and Greece are more food-based. For example, Finland recommends 5% or less of food energy from alcohol.

European guidelines are consistent in that variety in food choices is encouraged but the message is conveyed in various ways. Germany promotes the idea that there is no "forbidden food" and that people should pay attention to the quantity of food intake.

TABLE 22.13
Dietary Guidelines for the Populations of Selected European Countries

United Kingdom	Germany	Spain
1. Eat a wide variety of different foods	1. Choose from among many different foods	1. To adjust energy intake to energy output in order to achieve an energy balance conductive to maintain body mass index (BMI) within the desirable range
2. Eat the right amount to be a healthy weight	2. Cereal products several times per day and plenty of potatoes	2. To harmonize the percentage contribution of macronutrients to energy intake
3. Eat plenty of fruit and vegetables	3. Fruit and vegetables - take "5 a day"	3. To achieve a healthier lipid profile in the diet by enhancing a relevant contribution of monounsaturated fatty acids (MUFAs), mostly from olive oil
4. Eat plenty of foods rich in starch and fiber	4. Milk and dairy products daily, fish once a week, meat, sausages, and eggs in moderation	4. To stimulate changes in carbohydrate profile, through a higher proportion of complex carbohydrates
5. Try to limit fat intake	5. Low-fat diet	5. To adjust daily frequency of consumption of sugary foods to less than four occasions per day
6. Choose fruit or bread rather than chocolate or sweets	6. Sugar and salt in moderation	6. A daily consumption of vegetables equal to or greater than 250 g is recommended, including at least one portion as fresh raw vegetables in a salad. A consumption of 400 g or more of fruit per person per day is also recommended
7. Look after the vitamins and minerals in your food	7. Plenty of liquid	7. Moderation in the consumption of alcoholic beverages is advised, within the Mediterranean consumption pattern, i.e., small amounts of wine with meals
8. If you drink, keep within sensible limits	8. Make sure your dishes are prepared gently and taste well	8. Introducing moderate physical exercise for at least 30 minutes within daily practices is highly recommended
9. Taste your food before adding salt	9. Take your time and enjoy eating	9. It would be advisable that public administrations and institutions stimulate, support, and implement programs at developing individual skills contributing to food choices and preparations conductive to a healthy food pattern. Actions targeted to socially deprived environments should be a priority
	10. Watch your weight and stay active	10. The need to draw global strategies to protect and recover traditional cooking styles is also notices (gastronomic heritage) as a source of cultural and health wellness

TABLE 22.14
Dietary Guidelines for the Portuguese Population

Nutrient-Based Guidelines	Food-Based Guidelines
1. Total carbohydrates should contribute a total daily energy value of 50–70%	1. Breast-feeding in the first months of a baby's life, especially during the first 6 months
2. Fiber intake should vary between 27 and 40 g/day	2. Adequate consumption of cereals and cereal products
3. Total lipids consumption ≤ 30% of total daily energy	3. Increase of the consumption of vegetable products and fresh fruit
4. Consumption of saturated fatty acids < 10% of total daily energy	4. Reduction of the consumption of fats, especially solid and overheated fats; preference giving to olive-oil consumption
5. Cholesterol consumption < 300 mg/day	5. Increase of fish consumption
6. Total saccharose < 20–30 g/day	6. Reduction of sugar and sugar-like products consumption
7. Salt < 6 g/day	7. Reduction of salt consumption
8. Reduce alcohol consumption	8. Moderate consumption of alcoholic drinks. Pregnant women, children and those younger than 17 should not drink alcohol
9. Calcium — total daily intake of 800 mg	9. Adequate consumption of milk and dairy products
	10. Weight control kept through a balanced diet and physical activity
	11. A balanced meal first thing in the morning

European guidelines also agree in promoting fruit and vegetable intakes. Although most countries do not specify the appropriate amounts of fruits and vegetables, Spain recommends consumption of at least 250 g of vegetables and 400 g of fruits daily and Germany advocates "5 a day" for five portions of fruits and vegetables on each day. The majority of European countries suggest daily consumption of dairy products and an increase in fish intake, but there is no consensus concerning the optimal amount of intake.

All countries suggest moderation in eggs, meats, and poultry reflecting the fact that these protein-rich foods are abundant in current diets these countries. All European dietary guidelines urge limiting sugar and consumption of sweets, but the recommended numbers of servings from these guidelines vary. Greece suggests half a serving of sweets per day, while Spanish recommends having sweets on no more than "4 occasions" per day. United Kingdom, Finland, and Spain relate sugar intake to dental problems and obesity.

All countries except for Greece recommend limiting fat intake to 30–35% of total food energy. In Mediterranean countries such as Greece, Portugal, and Spain, use of olive oil is encouraged over other types of lipids. Greece, Finland, and Spain also mention the negative effect of trans-fatty acids on health.

All countries but Spain advice reducing salt intake. Greece and Germany suggest using more herbs to substitute salt. Recommended salt intakes range from 3 g in United Kingdom to 6 g in Portugal.

Recommendations on alcohol intake differ among European countries. Portugal, Spain, Greece, and Finland advise moderate consumption of alcohol, while Germany and United Kingdom recommend limiting ethanol intake. Greece proposes 1.5 servings for women and 3 servings for men of wine for more beneficial health effects, whereas Finland suggests that energy from alcohol should not exceed 5% of total energy intake.

Body weight is mentioned in most of the European guidelines. Although some guidelines simply advise for a "healthy" or "desirable" weight, the Portuguese and Spanish guidelines discuss energy balance. Spain and Finland offer specific physical activity guidelines on duration and frequency. Virtually all of the countries with the exception of the United Kingdom have physical activity guidelines, but all countries address weight control.

Interestingly, Finland and Germany encourage the leisurely enjoyment of meals and avoiding stress and haste in eating. Germany mentions that food should be appetizing and processed as little as possible. Germany has an interesting and unique guideline that refers to protecting and recovering traditional cooking styles.

In addition to written documents, graphic presentations of dietary guidelines are available in most European countries. The icons used to represent the guideline are usually a pyramid (Spain and Greece), circle (Finland), a wheel with slices representing the amounts of recommended foods (Portugal) or a food plate (United Kingdom and Germany). Finland also has a pyramid and plate.

Conclusions

In contrast to many parts of the world, most European countries have developed dietary guidelines. Many of these guidelines were developed using the WHO CINDI dietary guidelines as a template. The dietary guidelines from different European countries are quite similar in their main ideas. Key common recommendations are food-based, and they encourage the public to increase fruits and vegetables intake, to decrease fat and sugar usage, to moderate meat, dairy, and egg consumption, and to increase physical activities. Despite the similarity among European dietary guidelines, there are variations between each of the country to cater the unique cultural and health concerns of each country.

Some European countries offer additional guidelines for children and elderly. The Finns prepared nutrient recommendations for ages between 1 month and above 75 years while Portugal encouraged breast-feeding for at least the first 6 months. Other countries like Greece referred to other publications like the "European Union Project on Promotion of Breast-feeding in Europe" for specific breast-feeding guidelines.

SUMMARY AND CONCLUSIONS

Dietary guidelines in the future must continue to take into account local dietary patterns, cultural traditions, and food availability. They are most effective when they indicate what aspects of diet need to be addressed to promote nutritional health in both the poor and rich. In some countries where disparities in incomes are very large, two sets of guidelines may be necessary.

Dietary guidelines should be flexible so that they can be used by people with different lifestyles, as well as by people of different ages, and with different population groups (pregnant, lactating, infant, children, and elderly persons). Different guidelines may be needed for urban and rural populations or for other special groups such as ethnic minorities in some countries.

Messages delivered to the public in dietary guidelines should provide advice on the selection of a nutritionally balanced diet and encourage other suitable lifestyle behaviors to promote health in such target group. It is difficult to include all without making the guidelines so long that their communicability is compromised. Therefore, other ancillary forms of nutrition education are also needed. Graphics allow people to put dietary guidelines and other recommendations about food consumption into action.

Nutrition education using dietary guidelines is only one ingredient for ensuring that knowledge is sufficient to choose a healthful diet. Motivation and opportunities for people to change their nutrition and health behaviors in favorable directions are also necessary. Knowledge, science, technology, culture, and food sources all change with the times, and so do food ways. Therefore, it is necessary to review guidelines periodically and make appropriate modifications (i.e., every 5 or 10 years).

In conclusion, dietary guidelines can and do serve multiple purposes. These include providing useful information to the public policy maker; serving as communication tools to nutrition and health professionals, as guides to the food industry in product formulation and as instructional objectives for those involved in the provision of food, nutrition, and health education. Food is not the only factor that can influence health. Most health problems in modern society are multifactorial in origin. However, people can help themselves by establishing healthy dietary habits and paying attention to other factors (such as physical activity,

not smoking, decreasing stress, and improving their work environments). Such measures increase their chances for a long and active life. It is what individuals and families understand, accept, and do in their living from day-to-day that matters the most in implementing healthy lifestyles. The Dietary Guidelines help them to ensure the nutritional health of the population, and represent a useful advance in the public health.

CONTENTS

INTRODUCTION

Most descriptions of nutrition monitoring use the comprehensive definition developed by Mason et al. in 1984, "an ongoing description of nutrition conditions in the population, with particular attention to subgroups defined in socioeconomic terms, for purposes of planning and analyzing the effects of policies and programs on nutrition problems, and predicting future trends."[1] In the United States, nutrition monitoring refers to the many federal and state surveys and surveillance activities that provide information about food composition, food consumption, nutrition status, or health status. These surveys and activities were first identified as the U.S. National Nutrition Monitoring System in 1978, and were renamed as the National Nutrition Monitoring and Related Research Program (NNMRRP) with the passage of the National Nutrition Monitoring and Related Research Act of 1990.[2] Although the act expired in 2002 and has not been reauthorized, many of the surveys and activities of the NNMRRP are still ongoing, and federal and state agencies continue to work together to produce and disseminate information about food composition and consumption and about nutrition and health status.

The five measurement areas of the NNMRRP were identified as nutrition and related health measurements; food and nutrient consumption; consumer knowledge, attitudes, and behavior assessments; food composition and nutrient databases; and food-supply determinations.[2] Previous reports, publications, and book chapters have covered the topic of nutrition monitoring and described the NNMRRP surveys and activities.[3–9] This chapter provides a brief history of the development of the U.S. nutrition

monitoring program from 1977 to 2005, a summary of ongoing nutrition monitoring surveys and surveillance activities, an overview of the uses of nutrition monitoring data, and a discussion of future challenges.

HISTORY OF NUTRITION MONITORING

BEGINNINGS

A 1977 act of Congress required that the U.S. Department of Agriculture (USDA) and the U.S. Department of Health, Education, and Welfare (now the Department of Health and Human Services [DHHS]) develop plans to coordinate the DHHS National Health and Nutrition Examination Survey (NHANES) and USDA Nationwide Food Consumption Survey (NFCS).[10] This act mandated the development of a reporting system to translate the findings from these two national surveys and other monitoring activities into periodic reports to Congress on the nutritional status of the American population. A proposal for a comprehensive nutrition monitoring system was submitted to Congress in 1978, and the NHANES and NFCS became the cornerstones for the beginning of the National Nutrition Monitoring System.

In 1983, the Joint DHHS/USDA Nutrition Monitoring Evaluation Committee was formed, and in 1986 this Committee provided an overview of the dietary and nutritional status of the population and recommendations for improvements in the *First Progress Report on Nutrition Monitoring in the United States*.[11] Several papers on nutrition monitoring were published in 1984.[12–14] In 1987, the Operational Plan for the National Nutrition Monitoring System was developed, and in 1988, the Interagency Committee on Nutrition Monitoring was established to improve the planning, coordination, and communication of nutrition monitoring activities among agencies.[15] In 1989, An updated *Report on Nutrition Monitoring* (the *Second Progress Report on Nutrition Monitoring in the United States*) was prepared by an expert panel, and the *Directory of Federal Nutrition Monitoring Activities* was published.[16,17]

THE 1990 ACT AND BEYOND

The National Nutrition Monitoring and Related Research Act of 1990 established the National Nutrition Monitoring and Related Research Program (NNMRRP) and helped establish the collaboration and coordination of federal, state, and local government agencies involved in nutrition monitoring.[2] Under this act, the secretaries of DHHS and USDA had joint responsibility for implementing the Program and transmitting the required reports to Congress.

In 1991, the previous Interagency Committee on Nutrition Monitoring became the Interagency Board for Nutrition Monitoring and Related Research (IBNMRR) and included 22 agencies that contributed or used national nutrition monitoring data. The IBNMRR served through 2002 as the central focus for federal nutrition monitoring activities. The Board coordinated the preparation of an annual budget report on nutrition monitoring, biennial reports on progress and policy implications of scientific findings to the President and Congress, and the periodic scientific reports that described the nutritional and related health status of the population to Congress.

The 1990 act also established the National Nutrition Monitoring Advisory Council to provide scientific and technical guidance to the IBNMRR. The council was formed in 1992 and included nine members (five appointed by the president and four by Congress) with expertise in the areas of public health, nutrition, monitoring research, and food production and distribution. Also in 1992, the *Directory of Federal Nutrition Monitoring Activities* was updated and expanded to include state surveillance efforts.[18]

The 1990 act called for the development of a Ten-Year Comprehensive Plan to guide federal actions for nutrition monitoring. The proposed DHHS/USDA Ten-Year Comprehensive Plan was published in 1991 and finalized in 1993.[3,19] The primary goal of this plan was "to establish a comprehensive nutrition monitoring and related research program by collecting quality data that are continuous, coordinated, timely, and reliable; using comparable methods for data collection and reporting of results; conducting relevant research; and efficiently and effectively disseminating and exchanging information with data users."[3]

Three federal working groups were established by the Board to improve communication and coordination among member agencies. The Survey Comparability group was led by DHHS National Center for Health Statistics (NCHS), and USDA's Agriculture Research Service (ARS) assisted the IBNMRR in working toward close communication and coordination on federal surveys and surveillance activities, including continued efforts to address the development of a common automated dietary assessment system. The group also assisted in the determination of resource needs and options for developing the dietary system in a timely manner for the next round of surveys. The Federal-State Relations and Information Dissemination and Exchange Group was led by ARS and the Centers for Disease Control and Prevention (CDC) and assisted the IBNMRR in the identification of measures, methodologies, and interpretive criteria for nutrition indicators that would improve the capacity of states and localities to conduct nutrition monitoring. The Food Composition Group, led by ARS, continued to assess progress in meeting the nutrition monitoring program needs for food composition data and assisted in identification of future needs. After the enactment of the welfare reform law in 1996, the Welfare Reform, Nutrition, and Data Needs Working Group, with both federal and nonfederal members, was established to determine if federal surveys and surveillance activities could capture the effects of welfare reform on nutrition, hunger, and health status and to foster collaborative research on nutrition and welfare reform.

In 1993, the IBNMRR published *Chartbook I: Selected Findings from the National Nutrition Monitoring and Related Research Program*.[20] In 1995, the IBNMRR published *Third Report on Nutrition Monitoring in the United States*, which identified food components (energy, total fat, saturated fatty acids, cholesterol, alcohol, iron, calcium, and sodium) that were of public health concern in the U.S. population.[4] The report also included a range of health issues of concern for low-income, high-risk populations including anemia, low birth weight, overweight, high serum total cholesterol, hypertension, osteoporosis, low intakes of a number of nutrients (including folate, calcium, and iron), and food insufficiency.

The major nutrition monitoring issue during 1997 to 2002 was the integration of NHANES and the Continuing Survey of the Food Intakes of Individuals (CSFII).[21] NCHS (responsible for NHANES) and the ARS (responsible for CSFII) signed a memorandum of understanding in 1998 to integrate these two national food consumption surveys. An Expert Panel on Survey Integration was convened in 1998 to review the scope of the proposed merger and provide recommendations to the two agencies to strengthen the overall integration plan and the dietary research and evaluation component. The survey integration was completed in 2002 when the ARS What We Eat in America survey became the dietary data collection component of the NHANES.[21,22] In 2002, a workshop was held with nutrition monitoring stakeholders to develop recommendations on how best to meet data needs for policy and research with the integrated survey.[23]

CURRENT STATUS

In December 1999, the National Academy of Sciences (NAS) organized a public symposium entitled "Nutrition Monitoring in the US: Preparing for the Next Millennium to draw attention to the federal, research, industry, media, and consumer uses of monitoring data, to discuss future challenges for the NNMRRP, and to encourage reauthorization of the 1990 act. This symposium convened nutrition scientists from industry, academia, government, and the public sector along with policymakers to discuss efforts to streamline and integrate the monitoring program and to identify and highlight future diet, nutrition, and health data needs. The participants discussed ways to optimize the utility and relevance of the nutrition monitoring program for organizations whose activities depend on the availability and reliability of the data obtained from the program.

DHHS and USDA sponsored the National Nutrition Summit during May 30–31 2000, in Washington, D.C., to provide an opportunity to highlight accomplishments in food, nutrition, and health; identify continuing challenges and emerging opportunities; and focus on nutrition and lifestyle issues, especially those related to overweight and obesity.[24] Also in 2000, the *Directory of Federal Nutrition Monitoring Activities* was updated.[25] The American Society for Nutritional Sciences convened a Working Group on Nutrition Monitoring, and a report from this group was published in 2002.[26]

In 2004, an Institute of Medicine (IOM) panel made recommendations to improve the data infrastructure on food consumption to support food and nutrition programs and policies within the USDA.[27,28] In 2005, the IOM published a review of the infrastructure to support food and nutrition programs, research, and decision making and provided recommendations to improve the data for such purposes.[28]

NUTRITION MONITORING SURVEYS AND SURVEILLANCE ACTIVITIES

As noted earlier, the nutrition monitoring legislation was not renewed in 2002. Many of the nutrition monitoring surveys and surveillance activities are continuing, but without the coordinated guidance of an interagency board or legislative mandate. Descriptions of the surveys and surveillance activities within the five measurement components of the NNMRRP have been described elsewhere.[3,4,17–20,25,29] Bialostosky et al.[7] summarized the major activities through 1999, and Briefel[9] provided a similar summary focusing on surveys and activities from the mid-1990s through 2005. Some of the ongoing surveys and surveillance activities are described in the following sections, and Table 23.1 provides a list of those that have Web sites for easy reference.

NUTRITION AND RELATED HEALTH MEASUREMENTS

1. *NHANES.* The NCHS NHANES provides national data on nutrition and related health measurements as well as data on food and nutrient consumption.[30] It also provides national population reference distributions, prevalence rates of disease and risk factors, and trends in nutritional and health status over time. NHANES includes a household interview followed by a physical examination and personal interviews in a mobile examination center. It includes body measurements, blood pressure, dental examinations, and biochemical and hematological tests. NHANES became a yearly survey in 1999 and has a nationally representative sample design of Black, White, and Mexican-American persons for all income and low-income households. There is oversampling of Mexican-Americans, Blacks, older persons, adolescents, pregnant women, and low-income Whites to allow for comparisons of differences in health conditions and prevalence of risk factors for these groups.

2. *NHANES I Epidemiologic Follow-up Study (NHEFS).* The NCHS NHANES I NHEFS allows for epidemiologic investigations of the relationships of nutrition and health to risk of death and disability.[31] The NHEFS is a longitudinal

ARS: Agricultural Research Service, USDA; CB: Census Bureau, DOC; CDC: Centers for Disease Control and Prevention, DHHS; CNPP: Center for Nutrition Policy and Promotion, USDA; DOC: Department of Commerce; FDA: Food and Drug Administration, DHHS; ERS: Economic Research Service, USDA; FNS: Food and Nutrition Service, USDA; FSIS: Food Safety and Inspection Service, USDA; DHHS: Department of Health and Human Services; NCHS: National Center for Health Statistics, CDC, DHHS; NIH: National Institutes of Health, DHHS; NMFS: National Marine Fisheries Service, NOAA, DOC; NOAA: National Oceanic and Atmospheric Administration; ODS: Office of Dietary Supplements, NIH, DHHS; USDA: U.S. Department of Agriculture.

follow-up study, which includes 14,407 participants, 25 to 74 years of age, who completed a medical examination during the NHANES I survey period (1971 to 1975). NCHS conducted a mortality linkage of NHEFS with the NCHS National Death Index to investigate the association of a variety of health factors with mortality. The current version of the NHEFS linked mortality file includes information for all deaths including those previously identified during the NHEFS periods of 1982–1984, 1986, 1987, and 1992.

3. *National Health Interview Survey (NHIS).* The NCHS NHIS provides annual information about self-reported health conditions and periodic information about special nutrition and health topics such as dietary supplement use, youth risk behavior, food program participation, diet and nutrition knowledge, cancer and disability, and food preparation.[32] In 2004, NHIS collected data on self-reported height and weight, diagnosed diabetes, and alcohol consumption. The large sample numbers of NHIS allow the data to be reported by race/ethnicity, age, sex, and income.

4. *State and Local Area Integrated Telephone Survey (SLAITS).* The NCHS SLAITS was developed as a telephone survey to supplement national data on identified topics with state and regional data.[33] Previous topics were a child well-being and welfare survey module and a national study on early childhood health.

5. *Pediatric Nutrition Surveillance System (PedNSS).* The CDC PedNSS has been used since 1973 to monitor indicators of nutritional status among low-income, high-risk infants and children who participate in health, nutrition, and food assistance programs.[34,35] Information on anemia, weight, birth weight, breast-feeding, and television/video watching are collected primarily from children in the Special Supplemental Nutrition Program for Women, Infants, and Children's (WIC). The data can be evaluated at individual, clinic, county, state, and national levels.

6. *Pregnancy Nutrition Surveillance System (PNSS).* Since 1978, the CDC PNSS has monitored nutrition-related problems and behavioral risk factors associated with low birth weight among high-risk prenatal women.[34] The PNSS sample is drawn primarily from the WIC Program. PNSS data are used to identify preventable nutrition-related problems and behavioral risk factors to target interventions.

7. *National Health Care Survey (NHCS).* The NCHS NHCS collects nutrition-related information on physician-reported hypertension and obesity and on counseling services for diet, weight reduction, and cholesterol reduction for hospital outpatient department visits.[36]

8. *National Survey of Family Growth (NSFG).* The NCHS NSFG collects information on maternal and child health such as breast-feeding and prenatal care.[37] The information is obtained with personal in-home interviews with a probability sample of subjects 15 to 44 years of age.

9. *National Vital Statistics System (NVSS).* The NVSS is the mechanism by which NCHS collects and disseminates national vital statistics.[38] The data are provided to NCHS through contracts in jurisdictions responsible for the registration of births, deaths, marriages, divorces, and fetal deaths. In the United States, legal authority for the registration of these events resides within the 50 states, 2 cities (Washington, D.C., and New York City), and 5 territories (Puerto Rico, the Virgin Islands, Guam, American Samoa, and the Commonwealth of the Northern Mariana Islands). These jurisdictions are responsible for maintaining registries of vital events and for issuing copies of birth, marriage, divorce, and death certificates. Standard forms for the collection of the data and model procedures for the uniform registration of the events have been developed for nationwide use.

FOOD AND NUTRIENT CONSUMPTION

1. *NHANES.* The dietary component of NHANES, What We Eat in America, is an automated multiple-pass 24 h dietary recall that was developed by ARS.[22,39–42] The first day's interview is conducted in person and the second day's is conducted by telephone. In 2002, NHANES included a food propensity questionnaire along the 2 days of dietary.[40,41,43] The food propensity questionnaire was developed by the National Cancer Institute to assess infrequently consumed foods and thus augment the two dietary recalls.[41,44] A recent report from the ARS Food Surveys Research Group compares dietary data from 2001 to 2002 with Dietary Reference Intakes.[45]

   Progress continues to be made in research regarding dietary intake assessment. Doubly labeled water studies have been used to validate energy intakes assessed with 24 h recalls and other dietary methods, such as food frequency instruments.[46] The 24 h recall method, which is used in NHANES, has a systematic bias and underestimates total energy intake.[46–48] The doubly labeled water technique provides a noninvasive method of assessing energy expenditures that allows for interpreting energy intakes derived from dietary survey methods.

   The National Cancer Institute's Observing Protein and Energy Nutrition Study (OPEN) assessed measurement error using two self-reported dietary methods — one 24 h recall and a food frequency questionnaire (FFQ) and two unbiased methods (doubly-labeled water and urinary nitrogen) — and found that men and women underreported energy and protein on both instruments.[49] About 9% of men and 7% of women underreported energy intake based on the 24 h recall compared with 35% and 23%, respectively, based on the FFQ. Protein intake was underreported by 11% to 12% by the 24 h recall and 30 to 34% by the FFQ. Underreporting of energy and protein was even higher when compared with total energy expenditure.

   Research and information about techniques for dietary assessment are shared at the International Dietary Assessment Conference (IDAC), which is held every 2 years. The first IDAC was held in 1995 in Boston, Massachusetts; the fifth IDAC was held in Chiang Rai, Thailand, in 2004; and the sixth IDAC was held in Copenhagen, Denmark, in 2006.[50]

2. *Total Diet Study.* The Food and Drug Administration (FDA) Total Diet Study provides annual analytical data on the levels of dietary minerals, folic acid, heavy metals, radionuclides, pesticide residues, industrial chemicals, and other chemical contaminants in the core foods of the U.S. food supply and assesses dietary intakes of these food components for eight age/sex group diets on an annual basis.[51–53] The core foods of the U.S. food supply are identified based on data from NHANES. The foods are purchased from retail markets, prepared for consumption, and analyzed individually for nutrients and other food components at the FDA Total Diet Laboratory in Missouri. Yearly results are available from the Total Diet Study Web site.[53]

3. *Infant Feeding Studies.* The FDA Infant Feeding Study II assessed the diets of pregnant women and new mothers and their infant-feeding practices.[54] FDA plans to conduct a second Infant Feeding Practices Survey to assess the diets of pregnant and new mothers and to track breast-feeding and other infant-feeding practices.[54]

4. *WIC.* The USDA Food and Nutrition Service (FNS) WIC Program provides supplemental foods, information on healthy eating, and referrals to health care to low-income women, infants, and children up to age five who are at nutritional risk. A number of studies have been conducted to evaluate the nutrition and health effects of participation in WIC and to provide current participant and program characteristics of the WIC program.[55–57]

5. *School Nutrition Dietary Assessment Study (SNDAS).* The USDA FNS SNDAS assessed the diets of American school children and the contribution of the National School Lunch Program to overall nutrient intake in 1992.[58] A second study was conducted from 1998 to 1999 to compare changes in the food and nutrient content of USDA school meals and food service operations.[59] The study reported that schools had made substantial improvements in the nutritional quality of the meals they were providing, especially with regard to total fat and saturated fat content, and were meeting one-third of the daily nutrient recommendations. A third study was conducted in 2005 and measured school children's heights and weights, usual nutrient intake and food intake, and collected information on school food service operations, the quality of meals offered, and food and beverages available in vending machines, school stores, and *a la carte* lines.

6. *School Health Policies and Programs Study (SHIPPS).* The CDC SHIPPS is a national survey conducted periodically to assess school health policies and programs at the state, district, school, and classroom levels, including those related to nutrition and physical activity.[60] Fact sheets available from the Web site provide information on foods sold outside the school meal programs, food service, health services, nutrition services, and physical educations and activities.[60]

7. *Current Population Survey (CPS).* CPS is a monthly survey of about 50,000 households conducted by the Bureau of the Census for the Bureau of Labor Statistics.[61] The CPS is the primary source of information on the labor force characteristics of the U.S. population; respondents are interviewed to obtain information about the employment status of each member of the household 15 years of age and older. Estimates obtained from the CPS include employment, unemployment, earnings, hours of work, and other indicators. Supplemental questions on a variety of topics including school enrollment, income, previous work experience, health, employee benefits, and work schedules are also often added to the regular CPS questionnaire. Since 1995, the yearly CPS supplement has been devoted to measuring the extent of food insecurity and hunger among people living in low-income households.[62–64]

8. *Food Security Efforts.* The USDA Economic Research Service (ERS) plays a leading role in federal research on food security and hunger in U.S. households and communities.[65–67] The ERS annual publication, *Household Food Security in the United States*, provides data on food security, the amount U.S. households spend on food, and the extent to which food-insecure households participated in federal and community food assistance programs.[67]

9. *FoodNet.* FoodNet-Foodborne Disease Active Surveillance Network is a cooperative surveillance effort of the CDC Emerging Infections Program, FDA, and the USDA Food Safety and Inspection Service to monitor food-borne illness and to conduct epidemiologic research on illnesses attributable to food-borne pathogens.[68] The core of FoodNet is laboratory-based active surveillance at over 650 clinical laboratories that test stools samples in the ten FoodNet sites. Population surveys are conducted to assess diarrhea disease and exposure to food-borne illness.

Knowledge, Attitudes, and Behavior Assessments

National surveys that measure knowledge, attitudes, and behavior about diet and nutrition and how these relate to health were added to the nutrition monitoring program in 1982. The focus of these surveys is on consumer awareness of relationships between diet and risk for chronic disease and on health-related knowledge and attitudes.

1. *Behavioral Risk Factor Surveillance System (BRFSS).* The CDC BRFSS is a telephone survey of adults that focuses on personal health practices such as food intake, physical activity, weight-control practices, and health-screening practices.[69,70] BRFSS has been used by state health departments to plan, initiate, and guide health promotion and disease prevention programs, and to monitor their progress over time.[69,70] BRFSS collects self-reported height and weight for estimates of overweight and includes modules on dietary habits that states can collect periodically. Topics have included the consumption of fruits and vegetables and high-fat and high-cholesterol foods, binge drinking, physical activity, and the use of supplements, particularly folic acid. Since 2002, BRFSS data have been used for prevalence estimates for metropolitan and smaller statistical areas, allowing CDC to make estimates for counties to assist local public health planners and program evaluators.[71]

2. *Youth Risk Behavior Surveillance System (YRBSS).* The CDC YRBSS includes national school-based surveys of high school students as well as state, territorial, and local school-based surveys conducted by health and education agencies.[72–74] Information is collected on students' health risk behaviors such as smoking, dietary intake, weight-loss practices, and physical activity.[72,73] Every 2 years, CDC conducts a national YRBSS to produce data representative of students in grades 9 to 12 in the 50 states and the District of Columbia. The CDC Youth Risk Behavior Survey identifies the percentage of high school students who are overweight, engage in unhealthy dietary behaviors, or are physically inactive by selected states and cities.[75]

3. *Pregnancy Risk Assessment Monitoring System (PRAMS).* The CDC PRAMS is used by 29 states to monitor selected maternal attitudes, behaviors, and experiences related to adverse maternal and infant outcomes.[76]

4. *FDA Consumer Surveys.* The focus of the FDA Health and Diet Survey is on consumer awareness of relationships between diet and risk for chronic disease and on health-related knowledge and attitudes.[77] The survey has studied consumer use of food labels and weight-loss practices.[78,79] The FDA Food Safety Survey tracks consumers' knowledge, behaviors, and perceptions about food safety and consumption of potentially risky foods.[80] FDA conducted a study to assess consumer food-handling practices and awareness of microbiological hazards and several studies to evaluate the usefulness of shelf-labeling for consumers.[80,81]

5. *Diet and Health Knowledge Survey (DHKS).* The ARS DHKS was initiated in 1989 as a telephone follow-up to the CSFII and focused on the relationship of knowledge and attitudes about dietary guidance, food safety, food choices, and nutrient intakes.[82] The DHKS was last conducted in 1994 to 1996, and there are plans to collect similar information via a future NHANES module.[83]

Food Composition and Nutrient Databases

1. *National Nutrient Database for Standard Reference (NNDSR).* ARS, USDA, maintains the NNDSR, which currently contains up to 140 food components for approximately 7000 foods.[84] Data are obtained from the food industry, USDA-initiated analytical contracts, and the scientific literature. The NNDSR is updated periodically to incorporate data from new analyses (from foods not previously analyzed and from newer analytical methods).[85,86] The NNDSR nutrient data are used as the core of most nutrient databases developed in the Unites States, such as those used in colleges, universities, medical facilities, hospitals, clinics, and commercial dietary analysis programs.[87] ARS also produces special interest databases (e.g., fluoride, choline, oxalic acid, flavonoids, isoflavones, and proanthocyanidins) as requested and supported by other agencies.[84,88] As the information in the special databases increases in quantity and quality, it may be added to the NDDSR in new data fields.

2. *Food and Nutrient Database for Dietary Studies (FNDDS).* ARS also produces the FNDDS, which contains data for energy and 60 food components for foods reported as being consumed in the NHANES dietary component What We Eat in America.[89,90] The FNDDS is periodically updated with current information from the NNDSR. Revised and new food composition data are retroactively applied to earlier versions of the FNDDS to allow for tracking nutrient consumption patterns.[86] ARS uses the Food Databases Management System software to manage the NDDS.[91] This software is used to update the database files with new information, to integrate time-related changes, and to replace older data values in the database (with start and end dates for time-specific changes). An online search tool, "What's In the Foods You Eat," provides access to nutritional information for 13,000 foods in the FNDDS.[92]

3. *Dietary Supplement Databases.* Because of the extensive use of dietary supplements in the United States, it is necessary to have a national dietary supplement database to estimate total nutrient intakes from both foods and supplements and to determine the impact of dietary supplements on nutrition and health.[93–96] NCHS and NIH have developed a database on dietary supplements for use with NHANES.[93,94] The NIH Office of Dietary Supplements (ODS) is planning to undertake the project of developing a Dietary Supplement Database using label data for use in national surveys.[97] ODS has several other initiatives regarding dietary supplements. They maintain the International Bibliographic Information on Dietary Supplements (IBIDS), which provides access to bibliographic citations and abstracts from published, international, and scientific literature on dietary supplements as well as Computer Access to Research on Dietary Supplements (CARDS), a database of federally funded research projects pertaining to dietary supplements.[98–100]

4. *Food Label and Package Survey (FLAPS).* The FDA FLAPS monitors the labeling practices of U.S. food manufacturers.[101–104] The FLAPS database includes the ingredient list, Nutrition Facts Panel information, nutrition and health claims, and food safety and other statements about the product. FLAPS also includes a surveillance program to identify the accuracy of selected nutrient declarations compared with values obtained form nutrient analyses. FDA uses FLAPS data to provide weighted estimates of the percentage of products sold with nutrition labeling, health or nutrient content claims, and food safety statements.

Progress in Food Composition Data and Databases

1. *National Food and Nutrient Analysis Program (NFNAP).* Nutrient data are lacking for some foods and food components in the NNDSR primarily because of the high cost and secondarily because of the lack of reliable analytical methods for certain food components. NFNAP was initiated in 1997 to help ARS produce accurate and current food composition data characterizing the U.S. national food supply.[105] NFNAP provides for stratified random sample collection and analysis of commonly eaten foods. The data obtained through NFNAP are incorporated into the NNDSR. The activities of NFNAP are: evaluation of existing data for scientific quality, identification of key foods and nutrients for sampling and analysis, development and implementation of nationally-based sampling plans for foods selected for analyses, and analyses of sampled foods under USDA-supervised laboratory contracts.[85,86] NFNAP is funded primarily by NIH Institutes and Centers and also by other government agencies.[88,105]

2. *National Nutrient Databank Conference (NNDC).* The NNDC meets yearly as a forum for food composition database developers and users.[106] ARS activities with regard to the NNDSR, Food and Nutrient Database for Dietary Studies (FNDDB), dietary supplement database, special databases, and analytical methods are presented at these meetings, and other researchers share their work on food analysis, database development, and software development. The 27th NNDC was held in Washington, D.C., in conjunction with the 5th International Food Data Conference (IFDC).[107] The focus of the meeting was data quality, and papers from the conference are available.[107] The 28th NNDC focused on the practical application of quality food composition data, and papers from this conference are available.[108] The 30th NNDC will be held as a Workshop to the American Dietetic Association Food and Nutrition Conference and

Exposition in Honolulu, Hawaii, in September 2006.[106] The theme for this meeting was the importance of food composition data for dietitians.

3. *International Food Data Conference (IFDC).* The IFDC was initiated in the International Network of Food Data Systems (INFOODS) in 1995 and are held every 2 years.[109] The 6th IFDC was held in Pretoria, South Africa in September 2005.[110] As noted earlier, papers from the 5th IFDC, which was held in conjunction with the 27th NNDC in 2003, are available.[107]

4. *Journal of Food Composition and Analysis (JFCA). JFCA* is the publication of INFOODS and is cosponsored by The United Nations University and the Food and Agriculture Organization of the United Nations.[111] Papers in the journal focus on the composition of human foods and emphasize new methods of analysis; the production, compilation, and dissemination of food composition data; and data use, including nutritional epidemiology, clinical research, agro-biodiversity, food security, and food trade.

FOOD-SUPPLY DETERMINATIONS

1. *U.S. Food and Nutrient Supply Series.* Since the early 1900s, USDA has provided food-supply estimates for foods and food components available to the population for per capita consumption for about 400 foods.[112–115] These data, which are published annually by USDA as the U.S. Food and Nutrient Supply Series, are used to assess the potential of the U.S. food supply to meet the nutritional needs of the population and to track changes in the food supply over time. They are also used to evaluate the effects of technological and marketing changes of the food supply over time; to study the relationships between food and nutrient availability and nutrient–disease associations; and to facilitate management of federal food assistance, nutrition education, and food fortification policies. Food-supply data indicate trends in food available for consumption rather than actual food consumption estimates. Food-supply data overestimate actual consumption because they include food wastage, food fed to pets, and other nonhuman use of food.

2. *Fisheries of the U.S. Survey.* The Fisheries of the U.S. Survey has been conducted by the National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration, Department of Commerce, since 1909 to provide annual per capita estimates of fish and shellfish availability in the United States.[116]

3. *AC Nielsen SCANTRACK Services.* Since 1985, monthly and annual proprietary sales data have been purchased by USDA ERS and USDA Center for Nutrition Policy and Promotion (CNPP) from AC Nielsen Company to measure grocery store sales of scannable packaged food products.[117] Households participating in the Homescan Consumer Panel transmit data on scanned purchases, including fresh packaged foods, weekly through a telephone line. These supermarket scanner data (SCANTRACK) do not reflect all fruits and vegetables or prepared foods from supermarkets, nor do they include foods obtained from restaurants or other food outlets.

USES OF NUTRITION MONITORING DATA

The NNMRRP surveys and surveillance activities were designed for the primary goals of each initiating agency, and these goals relate specifically to each agency mission. These primary goals were identified earlier for each survey/surveillance activity. In general, they include:

- Assessment of the nutrient intake of population groups compared with reference standards
- Monitoring of the nutrient and contaminant/toxin content of the food supply and identification of at-risk groups
- Assessment of the nutrition and health status of population groups and attempts to relate this to food/nutrient intake
- Tracking trends in food/nutrient intake and in nutrition/health status

In addition to these primary goals, nutrition monitoring data have additional uses when they are evaluated in greater detail and/or when data from several surveys/surveillance activities are combined. Some of these additional data uses include establishing national health objectives, tracking progress to reach national health objectives, development of nutrition education programs, policy decisions (i.e., regulations regarding food labeling, fortification, and safety), development of dietary and physiological reference standards and distributions, and identification of research opportunities. For example, monitoring and surveillance data are used to identify high-risk population groups to plan public health intervention programs and target food assistance awareness efforts and to evaluate progress towards achieving the Healthy People national health objectives[118,119]; establish guidelines for the prevention, detection, and management of nutritional conditions[120–126]; and evaluate the impact of nutrition initiatives for military feeding systems.[127,128] Specific examples of the use of nutrition monitoring data are mentioned in the following text for tracking national progress, nutrition education, food assistance/security, dietary/nutrition standards, regulatory activities, and research opportunities.

TRACKING NATIONAL PROGRESS

1. *Healthy People Year 2010 Health Objectives.* Nutrition monitoring data are essential to track progress in meeting the Healthy People 2010 agenda for the nation.[119] The major research questions currently under consideration include the role of diet and lifestyle with regard to overweight and obesity; diet-related chronic diseases (diabetes, cardiovascular disease); health disparities with regard to gender, race/ethnicity, and income; food insecurity; behavior modification of consumer habits; biomarkers for nutrition/health status; and genetic differences in food component actions/needs.

2. *Overweight/Obesity.* Overweight and obesity are likely the top priority of national and state nutrition monitoring efforts. Data on dietary intake; physical activity patterns; weight-loss efforts; and consumer knowledge, attitudes, and behaviors are important for public health education and research efforts to reduce the prevalence of overweight and obesity in the United States. Trends in energy and food and nutrient intake based on national dietary data have been used to understand the relationship between changes in dietary intake and the population's increase in overweight and health status.[4,119,129,130] For men and women aged 20 to 74 years, the prevalence of overweight (body mass index [BMI] ≥ 25) was 59% and obesity (BMI ≥ 30) was 20% in NHANES III (1988 to 1994), compared with 51% and 12%, respectively, in NHANES II (1976 to 1980).[119,131] This increasing trend has also been observed for adolescents, children, and preschoolers.[132,133] Using the 95th percentile of BMI from NHANES II as the definition of overweight and the 85th to 95th percentile as the definition of risk for overweight, 11% of children and adolescents were overweight and another 14% were at risk for overweight during 1988 to 1994.[132] The prevalence of overweight in children and adolescents increased from about 5% in the 1960s and 1970s.[132]

NHANES III anthropometry data serve as the baseline measure for the Healthy People 2010 weight objectives.[119] Future NHANES data will be used to track progress in reducing the prevalence of overweight and obesity. NIH published *Clinical Guidelines on the Identification, Evaluation and Treatment of Overweight and Obesity in Adults — The Evidence Report* in 1998.[122] NIH continues to fund research related to the etiology and prevention of overweight and obesity and supports public health efforts to educate the public about overweight and obesity.[134–136]

NUTRITION EDUCATION

1. *Nutrition Education Programs.* Nutrition monitoring data are used to develop nutrition education programs such as the NIH 5 A Day for Better Health (now a CDC program),[137,138] the National Cholesterol Education Program,[120] the National High Blood Pressure Education Program,[121] and the Weight-Control Information Network (WIN).[134] The DHHS initiative, HealthierUS focuses on physical fitness, nutrition, prevention (i.e., screenings), and healthy choices (i.e., avoiding risky behaviors), and offers various Web sites relating to these topics as well as sponsoring the National Prevention Summits and Steps to a HealthierUS.[139–141]

2. *Nutrition Education Materials.* Consumers and practitioners are beneficiaries of national nutrition data as the information is translated into nutrition education materials so that consumers and practitioners can learn about diet and health. Monitoring data are used to develop nutrition education materials such as the *Dietary Guidelines for Americans*[142] and the Dietary Guidelines Report upon which they are based.[143] Other government nutrition education materials include the USDA MyPyramid[144] and the FDA nutrition labels.[145,146] Many government agencies provide nutrition education materials for the public. For example, a listing of materials developed by NIH Institutes and Centers is available at the NIH Division of Nutrition Research Coordination (DNRC) Web site.[147]

3. *Review of Nutrition Education Materials.* Title III of the National Nutrition Monitoring and Research Act of 1990 requires joint review by the DHHS and USDA of any dietary guidance materials developed by any federal agency for the general population or identified subpopulation.[2] This joint review process is carried out by the DHHS Nutrition Policy Board Committee on Dietary Guidance and the USDA Dietary Guidance Working Group.[148] The DHHS group is chaired by the ODPHP and consists of members representing DHHS agencies; the USDA group is chaired by CNPP and consists of members from USDA agencies. Each submitted document is reviewed by members of each group, and comments are summarized by the two chairs. The comments are then forwarded to the authors, who revise the document in accordance with the comments. Issues of concern are addressed through conference calls or meetings. This review process has continued despite the lack of reauthorization of the 1990 act.

FOOD ASSISTANCE/SECURITY

1. *Food Assistance Programs.* Evaluations of the USDA nutrition and food assistance programs are routinely conducted.[149,150] Monitoring data are used to develop federally supported food assistance programs[27,28,150] such

as the National School Lunch Program,[151] Food Stamp Program,[152] WIC,[55,153] and the US food Plans,[154] as well as programs to provide foods and meals for older Americans[155] and Native Americans.[156] NHANES III data have also been used to assess the usual nutrient intake of the low-income population, school-age children, older adults, and participants in WIC and the Food Stamp Program for USDA.[30,57]

2. *Food Security.* Food Security refers to assured access to nutritionally adequate and safe foods "without resorting to emergency food supplies, scavenging, stealing, and other coping strategies."[157] National surveys such as NHANES and the USDA food consumption surveys used questions related to food security as early as 1977.[63,158–161] Efforts by the private sector and academia paved the way toward a scientific basis for defining and measuring food insecurity and hunger in the mid-1980s.[162–164]

The Ten-Year comprehensive Plan for the NNMRR Program called for the development of a standard measure of food insecurity.[3] An 18-item food security measure was developed to track the prevalence of hunger and food insecurity in the population and high-risk subgroups and was first included as a supplement to the 1995 CPS.[63] Using the scale, it was estimated that the prevalence of food security in U.S. households was approximately 88%.[64] The 18-item food security scale developed in the 1990s was used in NHANES and several other surveys and is under review by an expert IOM panel.[165] A short form (6 items derived from the 18 items) was developed to meet state and local needs to assess food insecurity.[166] Policy documents such as Healthy People 2010[119] and the U.S. Action Plan on Food Security[167] use the food security measure to assess progress, and the scale can also be used as a yardstick by which to evaluate federal food and nutrition assistance programs with respect to welfare reform. Logan et al.[149] summarized the types of data available from national surveys and surveillance systems that can be used to assess the relationship between food assistance program participation and nutrition and health outcomes.

DIETARY/NUTRITION STANDARDS

1. *U.S. Growth Charts.* Data from NHANES III were used to develop the revised U.S. Growth Charts, which were released in 2000.[168] The revised standards include charts for infants through 19 years of age, as well as a chart for BMI by age.

2. *Dietary Reference Intakes (DRIs).* National data on dietary intakes and serum nutrient levels have been used for the investigation of nutrient requirements for age and sex groups for the development of the DRIs by the NAS.[169,170]

REGULATORY ACTIVITIES

1. *Food Fortification.* Dietary intake and serum data collected in NHANES III were used to assess folate status and the relationships between serum determinations, diet, and other nutrition and health variables prior to, and following, folate food fortification rulemaking by FDA.[171–174]

2. *Contaminants/Toxin Intakes.* NHANES data have been used to assess levels of metals, including lead, cadmium, and mercury.[175] The Environmental Protection Agency (EPA) has used monitoring data to provide dietary exposure estimates for nutrient and nonnutrient food components.[176,177] CSFII 1994 to 1996 and 1998 data were used to assess the exposure of children to pesticides in the diet for EPA,[178] and NHANES III data were used to prepare methyl mercury intake estimates for an EPA report to Congress assessing human exposure to mercury from fish and shellfish intake.[177]

RESEARCH OPPORTUNITIES

Nutrition monitoring data have been used to identify food and nutrition research priorities of significance to public health.[118, 119,125,126,178–180] Much of the data generated by the NNMRRP are available from published government and peer-reviewed reports, CD-ROMs, and/or the Internet, along with documentation on sampling methods, survey design, sample sizes, and survey instruments and questionnaires. The Web sites for the major surveys and surveillance systems are listed in Table 23.1. NHANES data are available on the Internet,[30] and ARS posts food composition data on its Web site.[84] NCHS releases short reports and Health-E Stats,[181] and CDC publishes the *Morbidity and Mortality Weekly Report* online.[182] Thus, government survey and surveillance data are widely available for academics and graduate student to test new hypothesis and discover new diet–health relationships.

Nutrition research that is done with federal funds is tracked through the Human Nutrition Research and Information (HNRIM) System, which is housed at NIH.[183] The HNRIM database provides information for each research project including an abstract, principal investigator and organization, nutrition classification categories, percent nutrition related, and fiscal year and start date.

FUTURE CHALLENGES

Nutrition monitoring, research, and policy are interrelated. Nutrition monitoring provides data needed for public policy decisions and for establishing research priorities. Nutrition research provides data for policymaking and for identifying nutrition monitoring data needs. Continuous collection of diet- and nutrition-related data in cross-sectional and longitudinal surveys and surveillance systems are used to assess the health of the U.S. population and to plan nutrition services and educational programs.

Current U.S. nutrition monitoring surveys and surveillance activities are firmly grounded in NHANES and the other surveys and surveillance activities identified in Table 23.1. The future of nutrition monitoring will be based on the nutrition issues and needs of the population. The focus may shift as past health problems are resolved through nutrition education and public policy changes and as new diet-related health concerns emerge. The surveys and surveillance activities will be adapted to meet changing needs, and new studies will be added as resources permit.

Improvements to the nutrition monitoring surveys and surveillance activities may result from research that develops new methodologies and improves existing ones to assess nutrition and health status. New and improved methods may allow more accurate and efficient assessment of food and nutrient intake, assessment of physiological measures of nutrient status, and techniques to relate food and nutrient intake to health status. Newer data from NHANES and other surveys/activities may shift the focus of the nutrition monitoring. Availability of monitoring data may prompt researchers to do unique analysis, and the development of biomarkers may spur refinements to the surveys. Biochemical measures of long-term nutritional status or exposure are not subject to the same inaccuracies or bias as the reporting of long-term dietary intake, but the sensitivity and specificity of biomarkers need to be evaluated for their role in assessing exposure to foods and nutrients and for identifying high-risk population groups.[184]

Speculation about the future of the nutrition monitoring requires consideration of the factors that may change the health concerns of the population. Some of the factors are changes in the food supply, in the demographics of the U.S. population, and in individual dietary and other lifestyle behaviors.

CHANGES IN THE FOOD SUPPLY

The U.S. food supply is in a constant state of flux with new products and alterations of the food supply. Recent examples include the introduction of sports beverages, traditional foods with nutrients and phytochemicals added, and new formulations to reduce levels of *trans*-fats. The nutrient intake of the population or of specific population groups may change as these altered or new foods are consumed. Changes in the food supply may also result from genetic engineering of plants or animals, changes in agricultural practices, and new manufacturing processes or technologies. Over the past several decades there has been increased consumption of food from fast food chains and other restaurants, increased availability of prepared foods from grocery stores that require only microwave heating prior to consumption, and increased consumption of ethnic dishes. Such changes towards convenience, food diversity, and complexity of the food system are likely to continue.

There is also considerable activity within the United States toward a more sustainable food supply with the introduction of gardens in schools and emphasis on use of local foods to reduce food miles.[185,186] This may also affect food consumption as well as the nutrient content of foods consumed.

DEMOGRAPHICS OF THE UNITED STATES

Alternations in the demographics of the U.S. population may affect the mean food and nutrient intakes from national surveys because the surveys reflect the food preferences, patterns, and practices of the population. The number of Hispanics and Blacks in the U.S. population is increasing at a rate faster than the White, non-Hispanic population. The population is also becoming older as post–World War II "boomers" and their children age. Income disparities among racial/ethnic and age groups will continue to be important in identifying population groups that are more vulnerable to diet- and health-related problems.

DIETARY AND LIFESTYLE BEHAVIORS

Modification in individual dietary and other lifestyle behavior may lead to changes in health. Consumers are encouraged to follow the Dietary Guidelines for Americans[142] with regard to diet and physical activity and the MyPyramid food guide,[144] and to use Nutrition Facts Labels[145,146] for comparison shopping. These nutrition education efforts may help consumers improve their health. Consumers may become increasing knowledgeable of the health effects of overweight and obesity and make attempts to alter their eating patterns and physical activity to lose weight. People are also influenced by the nutrition information they receive from other sources (the Internet, TV, radio, books, magazines, and advertisements). They may begin to take (or alter their intake of) dietary supplements, increase intake of functional foods, or become interested in organic produce, herbal products, or botanicals. Such behavior changes could affect health. Hopefully, consumers will adopt behaviors that will improve their health; however, it is possible that poor dietary advice may have the opposite effects. It is also possible that continued

sedentary lifestyles and wide access to food will maintain the current problems of overweight and obesity in the United States and the health problems related to them.

CONCLUSIONS

Recent progress in nutrition monitoring has included the development of the ARS multiple-pass 24 h dietary intake methodology[22] and integration and merging of NHANES and CSFII into one national dietary data collection effort.[21,22] Recent uses of nutrition monitoring data include development of the DRIs,[169,170] the *2005 Dietary Guidelines Report*,[143] the 2005 edition of the Dietary Guidelines for Americans, [142] the HealthierUS Initiative,[139] and the USDA development and release of the MyPyramid food guide.[144] Communication among federal and state agencies helps improve the quality of these efforts and also helps prevent duplication of effort and efficient use of available resources. Reinstitution of the IBNMRR and reauthorization of the 1990 act would result in a more focused, comprehensive nutrition monitoring program to help improve methodologies for the collection and interpretation of data, timely processing and release of data, adequate coverage of population subgroups, and research that addresses current nutrition and public health issues.

24 Nutrition Monitoring and Research Studies: Observational Studies

Jenifer H. Voeks, Suzanne E. Perumean-Chaney, and Gary Cutter

CONTENTS

INTRODUCTION

The purpose of this chapter is to give an overview and to provide current examples of observational studies. Specifically, cohort observational studies that incorporate nutritional assessment are the primary focus of this chapter. After a brief review of the types and purposes of observational studies, a detailed description of the characteristics, advantages, and disadvantages of a cohort study is provided. Next, several cohort studies, which utilized nutritional assessments, are discussed to demonstrate the use of the cohort design in the area of nutrition. Finally, selected nutrition-related publications from these cohort studies are referenced along with the corresponding measured nutritional variables.

OBSERVATIONAL STUDIES

Epidemiology is classically known as the study of the distribution of disease in human populations; however, the definition expands and often overlaps with other areas of research. Observational studies in epidemiology include natural history studies, case-control studies, prevalence (cross-sectional or population) studies, and cohort (incidence) studies. The research question of interest would generally dictate which type of observational study would be used (see Table 24.1). For example, the diagnosis or frequency of a disease would be facilitated by using the prevalence study design. Cohort studies provide the opportunity to observe populations prospectively, thereby enabling the observation of incidence rates as well as prevalence rates. Risk factors and prognosis of a disease can be identified through several different types of observational studies.

OBSERVATIONAL STUDIES AND CLINICAL TRIALS

In this section we are primarily concerned with observational studies, but will briefly discuss the relationship between observational studies and randomized clinical trials. The primary difference between these two types of research is the randomization of subjects into study groups. Clinical trials allow for the randomization of subjects into various treatment or control groups,

TABLE 24.1
The Question and Appropriate Design

Question	Observational Studies
Diagnosis	Prevalence
Prevalence	Prevalence
Incidence	Cohort
Risk factors	Cohort, case/control, nested case-control, prevalence
Prognosis	Cohort, natural history

whereas observational studies examine the subjects according to their natural selection into groups.[1] In many instances, the results from randomized clinical trials and cohort studies do not always agree. For example, observational studies have consistently found an association between low β-carotene levels and elevated risk of lung cancer in smokers; however, clinical trials have failed to find beneficial effects of supplementary β-carotene, and indeed there is some evidence of harm.[2–4] Similarly, observational studies have shown hormone replacement therapy to have a protective effect on myocardial infarction, but randomized trials have shown a slight increase in risk.[5–8] These two recent examples have raised many questions about when observational studies will be as convincing as randomized trials.

A major reason for the discrepancy in results between randomized trials and cohort studies is related to measurement error of the exposure variable of interest, or, stated another way, selection biases. This measurement error, known as residual confounding, can result from confounding from unmeasured variables and confounding from measurement error in variables. In the smoking and β-carotene studies mentioned above, it has been suggested that residual confounding occurred in the observational studies due to imperfect measurement of smoking status.[9] If smoking exposure is imperfectly measured, and β-carotene is related to true smoking exposure but β-carotene is not related to decreased risk of lung cancer then there will still be an apparent protective effect of β-carotene on lung cancer even after controlling for smoking exposure.

A number of statistical methods exist to address this potential confounding after the fact; however, taking preventive measures to reduce the problem in the design of the cohort study may be a better and ultimately a more convincing strategy. Restricting the research topics, design, and analysis may help observational research to attain some of the desired benefits of randomization.[10] Other suggested approaches are for cohort studies to utilize biomarkers to more accurately measure the exposure of interest.

COHORT STUDIES

As noted in Table 24.1, the purpose of cohort studies is to identify the risk factors associated with a disease of interest, obtain the incidence of disease, or the prognosis of disease.[11] Cohort studies allow the development of a disease to be described and, as such, are often considered to be a preferred type of observational study.[12]

Some of the defining characteristics of a cohort study are given in Table 24.2. The first characteristic is the identification of a study cohort that currently does not have the disease of interest. Any group of individuals who have either been exposed to the same occurrence, live in a defined geographic area or have the same risk factors may be identified as a cohort.[1,12,13] When similar risk factors identify a cohort, a second, similar cohort without the identified risk factors and the disease of interest must also be obtained for comparison purposes[12].

A second characteristic is that the study cohort(s) is followed over time. Because the study cohort(s) is disease free, the cohort(s) is followed over time to see which individuals in the cohort(s) actually develop the disease of interest.[1,12,13] The new cases of the particular disease which developed within a specified time period are then measured to obtain the incidence and absolute risk of the particular disease. Finally, a comparison between the incidence in those individuals who had the risk factors and those who did not have the risk factors produce a relative risk and attributable risk of these factors on the development of the disease of interest.

Some argue that placebo groups from clinical trials offer excellent opportunities for cohort studies. This may or may not be true and depend heavily on the entrance criteria for the trial. For example, a prevention study in the general population may provide useful data as a cohort study, while one that attempts to prevent prostate cancer, for example, would be deficient because of the all male gender and the likelihood of self selection for participation by the "healthy' at risk participants.

ADVANTAGES AND DISADVANTAGES OF COHORT STUDIES

There are several advantages and disadvantages of using cohort studies over other types of observational studies (see Table 24.3). With respect to the advantages, cohort studies make it easier to distinguish cause from simply an association. Because the risk

---

TABLE 24.2
Characteristics of a Cohort or Incidence Study

1. Selection of a study cohort WITHOUT disease.
2. Follow study cohort over time (prospective).
3. Measurement of incidence and/or absolute risk (new cases developed in a time period).
4. Comparison of incidence in those with and without the risk factor (relative risk and attributable risk).

TABLE 24.3
Advantages and Disadvantages of a Cohort Study

Advantages	Disadvantages
1. Easier to distinguish cause from association	1. Results are delayed for low incidence or long incubation
2. Incidence can be obtained	2. Large N may be needed
3. Multiple outcomes can be studied	3. Expensive in resources
4. Standard questions and measurements can be used	4. Losses may bias results
5. May lead to identification of variables that can be experimentally examined.	5. Methods, criteria, and exposure status may change over time

---

TABLE 24.4
Factors Associated with Causality

1. The magnitude of the association's strength
2. The ability to show the association's consistency through replication
3. The association's identification of one risk factor to one outcome
4. The risk factor must precede the outcome
5. The outcome is sensitive to different levels of the risk factor
6. The association's logical adherence to current theory
7. The association's consistency with other information about the outcome
8. The association's correspondence to other causal associations

---

factors are measured prior to the development of the disease of interest, temporal order is established. Temporal order is one of eight factors classically associated with causality (see Table 24.4)[14] and strengthens a causal conclusion instead of simply describing a relationship between risk factors and outcome that is often found in other study designs.[1,11,14] To compare different cohorts based on risk factors assumes that both cohorts are similar except for the suspected risk factor. Because this assumption can rarely be completely supported, causal implications are restricted.[11]

Another important advantage to cohort studies is that the incidence of a disease can be useful to provide estimates of the impact that preventive programs might have, and can be used to identify programmatic needs and support budgetary plans for achievable reductions over specified time periods.[14] Further, multiple outcomes can be studied, and standard questions and measurements can be used to compare results found in this study to previously completed studies. For example, the Framingham study has provided important information on blood pressure, cholesterol, diet, eye disease, and a number of other risk factors and outcome measures.[15–21] Other studies, such as the Coronary Artery Risk Factor Development in Young Adults (CARDIA) study have emulated Framingham. In this study,[22] variables were selected for inclusion in the baseline examination because of their known or suspected relationships to cardiovascular disease and as such can be compared to Framingham results. The availability of multiple and often related endpoints in the same populations further enables one to study the temporal development and to study their inter-relationships. Finally, cohort studies may permit the identification of additional variables related to specific outcome measures, which can then be further examined experimentally.[13]

One of the most obvious disadvantages of the cohort studies is that the study's length has to be adequate enough to allow for the development of the disease or a surrogate of the disease of interest.[11,14] For example, consider blood pressure and cardiovascular disease. Cardiovascular disease is the ultimate outcome of interest, but the surrogate development of blood pressure is sufficiently linked to the outcome to make it a reasonable outcome in its own right. For those diseases or surrogates with low incidence or long incubation periods, the results are delayed. With low disease incidence rates, the sample size for each study cohort may need to be extremely large in order to make the necessary comparisons.[11,14] From a statistical perspective, power is directly related to the number of events and not just the sample size. With both a lengthy process and large sample size being usually necessary, another disadvantage is the expense associated with conducting the study.[4] The length of the study may also influence the ability to recapture all the individuals at the end of the study. This ability to recapture the study participants depends on their geographic mobility, interest in continuing the study, and their mortality rates.[14] The inability to capture all study participants and take account of their experience may bias the results[11,12] by so-called informative censoring and even if the biases are not there, low follow-up rates leave a suspicion of bias that is often difficult to overcome. The length of the study dictates other potential concerns. Methods, criteria, and exposure status may change over time. For example, environmental, cultural, or technological changes may influence the risk factors identified and the measurement of the variables under study, and this is especially true of biological risk factors such as weight.[12,14]

One modification of the basic cohort study design, known as a nested case-control study, inserts a case-control study into a retrospective or prospective cohort study.[1] In a nested case-control design, the baseline risk factor data is collected for the entire cohort, and all participants are followed for development of the disease. Once an adequate number of cases are identified, the risk factor is analyzed for the cases and a comparison group of controls. This type of study design can often be conducted at a fraction of the cost of conducting a cohort study. These studies cannot estimate the relative risk of occurrences, but can, because of the cohort from whom the nested case-control study comes, offer more information than a stand-alone case-control study.

SUMMARY OF OBSERVATIONAL STUDIES

Observational studies are an important part of epidemiological research, in that diseases are studied in their natural environment. Of the various types of observational studies, cohort studies provide the most valuable approach for identifying temporal relationships between risk factors and outcomes. The primary characteristic of cohort studies is that it enables the cohort (or a subgroup of it) to be identified disease-free at the beginning of the study, facilitating the study of the incidence of disease. The development of the disease of interest can then be measured and compared across cohorts. Like all observational studies, cohort studies have both advantages and disadvantages. The primary advantage is the cohort study's ability to distinguish cause from association while the primary disadvantage is the cost in time, money, large sample size, and loss of subjects, which can lead to substantive biases in the inferences.

EXAMPLES OF COHORT STUDIES UTILIZING NUTRITION ASSESSMENT

The remainder of this chapter focuses on eight selected examples of cohort studies that utilized some form of nutritional assessment (see Table 24.5). Although there are many cohort studies available and additional cohort studies that include nutritional assessments, the following examples were selected to provide a wide range of nationally recognized studies, unique uses of the cohort design, and, most importantly, different methods of collecting nutritional data. The selected examples include the following studies:

1. Framingham Study: Heart and Vascular Disease Program
2. The Nurses' Health Study
3. Coronary Artery Risk Development in Young Adults (CARDIA)
4. The RENO (Relationship of Energy and Nutrition to Obesity) Diet-Heart Study
5. The Health Professionals Follow-up Study
6. The Atherosclerosis Risk in Communities (ARIC) study
7. Women's Health Initiative Observational Study
8. Reasons for Geographic and Racial Differences in Stroke (REGARDS) Study.

FRAMINGHAM STUDY: HEART AND VASCULAR DISEASE PROGRAM

The purpose of the Framingham Study was to provide a population-based prospective examination of the development of cardiovascular disease and its risk factors.[23] The sample consisted of 5209 primarily white men and women between the ages of 30 and 62 years who lived in Framingham, Massachusetts.[23,24] Measurements were taken biennially from 1949 through 1989, representing one of the first prospective observational studies of its kind. Measurements included blood labs, medical history,

TABLE 24.5

Examples of Cohort Studies Utilizing Nutrition Assessments

Cohort Study	Years Conducted	Sample Studied	Outcome	Nutrition Intake Measurement
Framingham Study: Heart and Vascular Disease Program	1949–1989	5209 men and women, primarily whites, 30 to 62 years old	Cardiovascular risk factors	Semi-Quantitative Food Frequency Questionnaire (Willet)
The Nurses' Study	1976–1996	121,700 female registered nurses, primarily whites, 30 to 55 years old	Cancer risk factors	Semi-Quantitative Food Frequency Questionnaire (Willet)
Coronary Artery Risk Development in Young Adults (CARDIA)	Baseline: 1985–1986 Year 2: 1987–1988	5116 men and women, blacks and whites, 18 to 30 years old	Coronary heart disease risk factors	Baseline: Diet History Questionnaire (Interview Administered) Year 2: NCI (Block) Food Frequency Questionnaire
The RENO (Relationship of Energy and Nutrition to Obesity) Diet-Heart Study	1985–1993	508 men and women, primarily whites, 20 to 69 years old, normal/ overweight	Cardiovascular risk factors	1. 24-h Dietary Recall 2. 7-Day Food Record 3. NCI (Block) Food Frequency Questionnaire
The Health Professionals Follow-Up Study	1986–1994	51,529 male health professionals, primarily whites, 40 to 75 years old	Heart disease and cancer risk factors	Semi-Quantitative Food Frequency Questionnaire (Willet)
Atherosclerosis Risk in Communities (ARIC)	1987–1998	15,792 men and women	Coronary heart disease risk factors and atherosclerosis and CHD events	Semi-Quantitative Food Frequency Questionnaire (Willet)
Women's Health Initiative Observational Study	1993–1998	93,721 women, primarily whites 50–79 years old	Causes of morbidity and mortality in postmenopausal women	WHI Food Frequency Questionnaire
REGARDS	2003–Ongoing	21,734 (to date) with in-home interview, Equal number of whites and African-Americans, 45 and older	Underlying causes for the geographic and racial differences in stroke mortality	NCI (Block 98) self-administered food frequency questionnaire completed after in-home interview

and a physical examination.[23] Additional assessments of stress, nutrition intake, and physical activity were added to the study at a later time. The latest nutrition intake was assessed through the Willet Semi-Quantitative Food Frequency Questionnaire.[24]

THE NURSES' HEALTH STUDY

Initially, the purpose of the Nurses' Health Study was to examine the relationship between oral contraceptives and breast cancer.[25] The study was then expanded to examine other female-related cancers, lung cancer, and life-style factors such as diet and exercise.[26] The sample consisted of 121,700 registered female nurses who were 30 to 55 years of age. Nurses, selected from 11 states, were chosen because they were expected to be more accurate in the reporting of the incidence of diseases and life-style factors and, in addition, were expected to have higher participation and retention rates.[25,27]

Measurements were requested biennially from 1976 to 1996. Unique to this study, researchers did not have personal contact with the nurse participants; instead, all contact was maintained through the mail. That is, study participants were required to mail in their bodily samples, anthropometric information and the various questionnaires.[25–29] Only when a participant was nonresponsive to mailing in the measurements were telephone interviews conducted. Measurements included basic demographics, medical history including the use of medications, blood and toenail samples, anthropometrics, lifestyle factors such as diet, exercise, and cigarette smoking, quality of life, and social support questionnaires.[25,26] In order to confirm the presence of a specified outcome (e.g., cancer, myocardial infarction, diabetes, or fractures), medical chart reviews were conducted when participants indicated an outcome's existence.[25,27,29] Nutrition intake was measured with Willett's semi-quantitative food frequency questionnaire, which assessed the consumption frequency of specified portions of food within the last year.[25,27–29] In 1980, the food frequency questionnaire identified only 61 common foods,[25] while the 1984, 1986, 1990, and 1994 measures were expanded to include 120 common foods and both vitamin and mineral supplementations.[26]

Coronary Artery Risk Development in Young Adults

The purpose of the CARDIA study was to identify risk factors that either contributed to or protected young adults from coronary heart disease.[22] The sample consisted of 5116 black and white men and women from four cities, who were 18 to 30 years of age.[22,30] Measurements were taken at baseline (1985 through 1986) and at two years (1987 through 1988) and biannually thereafter.[30–32] Baseline measurements included a sociodemographic questionnaire, medical (family history, current medical history, and use of medications), anthropometrics (weight, height, skinfolds, and various circumferences), lab work (lipids, apolipoprotein, insulin, and cotinine), blood pressure, lifestyle (treadmill test, questions on tobacco and marijuana use, and nutrition intake) and psychosocial questionnaires (type A/B personality, life satisfaction, hostility, social support, and job demand or latitude).[22]

Dietary intake was assessed with an interview-administered Diet History Questionnaire at baseline and the NCI (Block) Food Frequency Questionnaire at year two.[30,32] Reliability and validity of the Diet History Questionnaire were assessed in a preliminary study prior to its use in the main study. Reliability was measured through the simple correlation between a one-month test, and retest methods of the Diet History Questionnaire.[31,33] Accuracy was compared to 24-h recalls.

The nutrient intakes and mean caloric intakes of the Diet History Questionnaire were compared to the same variables derived from 24-h recalls,[31,33] NCI (Block) Food Frequency Questionnaire,[32] NHANES II,[31] and RDA's Body Mass Index[31] as an assessment of concurrent validity. For both reliability and validity, the Diet History Questionnaire appears to be more applicable for whites than for blacks. The relationship between diet and disease will await the results for this cohort, now entering their 20th year of observation and disease development.

The Reno (Relationship of Energy and Nutrition to Obesity) Diet-Heart Study

The purpose of the RENO Diet-Heart Study was to examine prospectively over a 5-year period the behavioral patterns with respect to weight between normal-weight and mild-to-severe obese individuals.[34] The sample consisted of 508 healthy primarily white men and women between the ages of 20 and 69. Subjects were stratified by gender, weight (overweight and normal weight), and five age decades. Measurements were taken over an 8-year period (1985 through 1993). Measurements included history questionnaires (weight, activity, health, and demographics), anthropometrics, energy expenditure, laboratory analyses, blood pressure, pulse, weight and dieting measures, activity data (Caltrac Monitors and activity diary), nutrition intake and attitudes, cancer questionnaire, and psychosocial questionnaires (general well-being, depression, cohesion, locus of control, hostility inventory, social support, and perceived stress).[35]

Dietary intake was assessed through several measures. The first nutrition assessment was the 24-h dietary recalls measured at years one and five.[36] The NCI (Block) Food Frequency Questionnaire[37] was used to measure nutrient intake at years two, three, and five. Finally, a 7-day food record that collected information about the day, time, location, and the amount and type of food eaten was measured at years one, three, and five.[38,39]

The Health Professionals Follow-Up Study

The purpose of the Health Professionals Follow-Up Study was to examine the relationship between diet and two types of chronic diseases: heart disease and cancer.[40] The sample consisted of 51,529 primarily white male health professionals who were 40 to 75 years of age.[29,40,41] The health professions included dentists, optometrists, osteopaths, pharmacists, podiatrists, and veterinarians.

Measurements were taken biennially from 1986 through 1994.[29,40,41] Similar to the Nurses' Health Study, the measures were all self-administered, mailed, and the outcome identifications were verified through medical chart reviews.[29,41–43] The measurements included demographics, medical history, anthropometrics (height, weight, and body mass index), chronic disease risk factors (heart disease and cancer in particular), and lifestyle factors such as diet, physical activity, cigarette smoking, and alcohol use.[40–44]

Dietary intake was assessed with Willett's 131-item semi-quantitative food frequency questionnaire used as the expanded version in the Nurse's Health Study.[29,42] As in the Nurse's Health Study, the food frequency questionnaire assessed the consumption frequency of specified portions of food within the last year.[29,42,44] Dietary intake was assessed in 1986 and 1990.[41]

The Atherosclerosis Risk in Communities (Aric) Study

The purpose of ARIC, a complementary study to CARDIA, was to measure associations of established and suspected coronary heart disease risk factors with both atherosclerosis and new coronary heart disease (CHD) events in men and women from four geographically diverse communities.[45] The project had two components: community surveillance of morbidity and mortality and a cohort component with repeated examinations of men and women from the selected communities. The cohorts were comprised of randomly selected samples of 4000 individuals aged 45 to 64 from a defined population in each of the four communities. A total of 15,792 participants received an extensive examination at which time medical, social, and demographic data were collected. All cohort participants were examined four times at 3-year intervals (baseline occurring in 1987–1989, the

second in 1990–1992, the third in 1993–1995, and the final exam in 1996–1998) and then contacted annually to update their medical histories. Atherosclerosis was measured by carotid ultrasonography. Some of the risk factor data collected included: blood lipids and lipoprotein cholesterols, plasma haemostatic factors, blood chemistries and hematology, blood pressures, anthropometry, fasting blood glucose and insulin levels, electrocardiography findings, physical activity levels, dietary aspects, cigarette and alcohol use, and family history.[45] Diet was assessed using a semi-quantitative food frequency questionnaire adapted from the questionnaire developed by Willett.[46–48] The questionnaire was asked at baseline and then at each of 3-year follow-up visits.

WOMEN'S HEALTH INITIATIVE OBSERVATIONAL STUDY

The purpose of the Women's Health Initiative (WHI) Observational Study (OS) was to explore predictors and natural history of causes of morbidity and mortality in postmenopausal women and also to serve as a secular control for the WHI Trial.[49] The sample consisted of 93,676 women aged 50 to 79, enrolled from 40 centers throughout the United States between October 1, 1993, and December 31, 1998. These women met exclusion criteria for the various randomized trial components of the WHI (including not wanting to be randomized), but were willing to be followed. The follow-up interval for the OS was approximately 7 years. All OS women had a physical examination at baseline and 3 years. Additional data (risk exposures, health behaviors, and other less common diseases) were obtained with annual mailed questionnaires. Demographic, family, and medical history data, as well as risk exposure, were collected by self-report through standardized questionnaires. Physical measurements including blood pressure, height and weight, as well as blood samples, were collected at the clinic visits. Nutrition intake was assessed using the WHI Food Frequency Questionnaire,[49] which was derived from survey instruments used in previous studies.[50–53] The WHI food frequency questionnaire was composed of three sections including 19 adjustment questions used to calculate nutrient content of specific food items, 122 foods or food groups with questions on portion size and usual frequency of intake, and several summary questions on usual intake of fruits, vegetables, and fat.[54] The reference time for all questions was "in the past 3 months."

REASONS FOR GEOGRAPHIC AND RACIAL DIFFERENCES IN STROKE (REGARDS) STUDY

The purpose of the REGARDS study is to understand the underlying causes for the geographic and racial differences in stroke mortality.[55] REGARDS is an ongoing population-based longitudinal cohort study. The goal of the study is to recruit 30,000 individuals over the age of 45 with equal representation of men and women and whites and African Americans. Participants are randomly sampled with recruitment by mail, and then by telephone. Data on stroke risk factors, sociodemographic, lifestyle, and psychosocial characteristics are collected at the initial telephone interview. Physical and physiological measures, in addition to fasting samples, are collected during a subsequent in-home visit.[55] The NCI (Block 98) semi-quantitative food frequency questionnaire is used to collect dietary information. Participants are given this questionnaire at their in-home visit and are asked to return it by mail. Patients are then followed via telephone at 6-month intervals for up to 4 years for identification of stroke-like symptoms and events.

   Selected nutrition-related publications from the aforementioned studies and their respective measured nutrient variables are shown in Table 24.6.

SUMMARY

In summary, this chapter briefly describes the benefits of the cohort study and has provided examples of several studies that have used this form of design. There are certainly other forms that can be utilized to assess the impact of diet on disease or health. The value of prospective observational studies relative to cross-sectional studies, the necessary must be weighed against the real difficulty in obtaining, funding for them. Many such studies today are either directly sponsored by the government through direct funding via a contract or as add-ons to multicenter clinical trials. It is difficult to convince funding sources that observational studies, especially in disease areas where a good deal of information already exists, are worth the investment. Thus, adding components to existing studies such as a clinical trial can sometimes be done to gather prospective information. However, in this type of observation add-on, care must be taken to consider generalizability due to the eligibility criteria in the primary study.

25 Nutrition Screening and Monitoring Tools

Ronni Chernoff

CONTENTS

INTRODUCTION

Malnutrition is not a condition that occurs rapidly; it is a chronic condition that develops slowly over time. It is widely accepted that malnutrition from any etiology is not a positive factor in health status, and may have a negative impact on other health conditions. There have been many reports of the health consequences of malnutrition, particularly in hospitalized individuals where poor nutritional status has been associated with increased lengths of hospital stay, poor wound healing, other comorbidities, complications, incomplete rehabilitation, readmissions, and mortality.[1–6] This is particularly important because it has been estimated that 85% of noninstitutionalized older adults have one or more chronic conditions, many of which are related to nutritional status.[7] If it is possible to identify indicators of risk for the development of malnutrition, and these factors are reversible conditions, then interventions that will alleviate risk can be instituted before malnutrition becomes overt and worsens chronic conditions.[8]

SCREENING FOR MALNUTRITION

Nutritional screening is of value if it: (1) reliably identifies the existence of risk factors for malnutrition, (2) recognizes the existence of poor nutritional status, (3) contributes to the avoidance of malnutrition, (4) minimizes suffering, and (5) the condition causing the malnutrition can be reversed.[7,9] Reuben et al.[7] describe criteria necessary to define the potential effectiveness of interventions; these criteria are whether or not identification of malnutrition can be achieved more accurately with screening than without it, and whether or not individuals who have malnutrition detected early have a better outcome than those who have malnutrition detected later in the course of their illness. Rush[10] defines the role of nutrition screening in older adults in different terms. He describes another criteria set for screening including specificity, sensitivity, inexpensive screening devices, and interventions in which health benefit is not sacrificed by not treating those who are at moderate or low risk. He indicates that screening is appropriate where there is a relatively small but important proportion of the population that is affected, where those who are affected can be identified by an easily applied tool, and where there is an effective intervention.

SUBJECTIVE GLOBAL ASSESSMENT (SGA)

One of the first tools developed for screening was the Subjective Global Assessment (SGA). Devised by a group of clinicians in Canada, the SGA uses a brief set of history and physical assessment items to make an evaluation of nutritional status.[11] The SGA includes an analysis of weight changes, dietary change, gastrointestinal symptoms, functional capacity, medical status, and physical assessment (Figure 25.1). This tool relies on a subjective rating by using clinical judgment on weight loss, dietary intake, loss of subcutaneous tissue, functional capacity, fluid retention, and apparent muscle wasting.[8,11] This tool has been successfully adopted and used by physicians and nurses in clinical settings. The SGA has been tested in the clinical setting with different assessors with a high degree of interrater reliability (0.91).[12,13] Most of validity reports of the SGA were conducted on hospitalized subjects with a mean age of 50 years or older, which may contribute to some questions about its general applicability. In a recent report by a group of German investigators, the SGA was able to identify malnutrition-related muscle dysfunction, validated by using a measure of grip strength.[14] However, the addition of laboratory values to the SGA did not improve its validity.[12]

Nursal and colleagues[15,16] explored different approaches to increasing the reliability of the SGA in predicting malnutrition in hospitalized patients. In a series of 2211 patients, they examined two approaches to evaluating malnutrition and found that the issue of unintended weight loss and loss of subcutaneous fat on the SGA predicted malnutrition with 93% accuracy. In a subsequent study,[16] these investigators found that weighting several items on the SGA (MQ-SGA) outperformed the usual SGA in predictive value. The most important factor was loss of subcutaneous fat, whereas the least effective item on the SGA was weight loss during the previous 6 months. The sensitivity and specificity were derived from statistical tests conducted on their data from a sample of 2167 patients and those among them who had a score of 18 on the MQ-SGA, which is highly predictive of malnutrition. The most heavily weighted items were the loss of subcutaneous fat (10 points), sacral edema (6 points), and ascites (3 points).

Although the SGA is a short tool that can be used successfully by health practitioners, there are limitations as to its use as a screening tool. It requires a trained clinician to administer it because there is some clinical judgment involved, which would not be expected in someone who is not a health professional. It requires that the individual being assessed is undressed, which does not lend itself to community-based assessment programs, and able to be turned, which may not be possible for extremely ill patients.

A. History
   1. Weight change
     Overall loss in past 6 months: amount = # _____ kg; % loss = # _____
     Change in past 2 weeks: _____ Increase
                       _____ no change
                       _____ decrease
   2. Dietary intake change (relative to normal
      _____ No change
      _____ Change   Duration = # _____ weeks
                         Type: _____ suboptimal solid diet _____ full liquid diet
                                  _____ htoicakiruc kuqyuds _____anorexia
   3. Gastrointestinal symptoms (that persisted for >2 weeks)
      _____ none _____ nausea_____ vomiting _____ diarrhea _____ anorexia
   4. Functional capacity
      _____ No dysfunction (e.g., full capacity)
      _____ Dysfunction   Duration = # _____ weeks
                         Type: _____ working suboptimally
                              _____ ambulatory
                              _____ bedridden
   5. Disease and its relation to nutritional requirements   _____
     Primary diagnosis (specify(_____
     Metabolic demand (stress):   _____ no stress   _____ low stress
                              _____ moderate stress_____ high stress
B. Physical (for each trait specify: 0 = normal, 1+ = mild, 2+ = moderate, 3+ = severe)
   # _____ loss of subcutaneous fat (triceps, chest)
   # _____ muscle wasting (quadriceps, deltoids)
   # _____ ankle edema
   # _____ sacral edema
   # _____ ascites
C. SGA rating (select one)
      _____ A = Well nourished
      _____ B = Moderately (or suspected of being) malnourished
      _____ C = Severely malnourished
      _____

FIGURE 25.1 Features of the SGA.

THE NUTRITION SCREENING INITIATIVE

Keeping these criteria in mind, and looking for a way to make both professional and volunteer care providers more attentive to the malnutrition risks encountered by older adults, the Nutrition Screening Initiative (NSI) was established as a public awareness initiative with tools that could easily be used by community and health care workers who have regular contact with older adults. The tools included a checklist to identify risk factors — level I and level II nutrition assessment instruments. These tools were developed as a joint venture project, begun in 1990, of The American Dietetic Association, the American Academy of Family Physicians, and the National Council on the Aging. The premise of the NSI is that, if factors associated with malnutrition risk are identified early, interventions can be instituted that may delay or avoid the progression of the risk factors towards overt malnutrition.[17,18]

The NSI was developed as a nested set of tools that serve to identify risk factors for poor nutritional status and then to diagnose malnutrition. The items on the tools were developed by reviewing the literature and consensus among a technical advisory committee of experts. The checklist was tested using a follow-up sample from a previous study of nutritional status in older people.[19]

The Checklist

The checklist was created as a public awareness screening tool for use by health care and social services personnel and other providers who work in community-based programs in which older adults participate. The checklist was conceived and designed to bring awareness to nutritional issues that may impact on the health status of elderly clients. It is widely available for reproduction and information collection.

The checklist was titled "DETERMINE Your Nutritional Health" based on a mnemonic that contains the risk factors for malnutrition listed on the reverse side of the checklist. (Figure 25.2a and 25.2b) The checklist is a one-page questionnaire that can be used in community, long-term care, or acute health settings by volunteers, health aides, or health professionals. The objective of awareness of potential nutritional problems in older people was easily achieved; those who have been critical have built their criticisms on the basis of assumptions that have gone further than the original intent of the tool or the Nutritional Screening Initiative campaign.[20]

The items on the checklist were developed using the reference literature, expert opinion, existing databases, and pilot testing.[17–19] Using biochemical or laboratory parameters to define nutritional status may be misleading because the most commonly used measures, such as serum proteins, are affected by so many different factors that are independent of diet or nutritional status.[21]

Implementation Strategies

Screening can be conducted in many settings and by health professionals as well as health care workers or lay volunteers. Involving interested participants (nurses, aides, admission clerks, etc.) will increase the likelihood that data collection (weights, heights, completion of screening instruments) being more complete.

Modifications that allow the screening tools to be used in different settings and for unique purposes make this approach and instrument user friendly, applicable, and relevant. A tool that is flexible, valid and reliable, and allows different applications in diverse settings is very valuable. The easier and less time consuming it is to collect data that give insights into an individual's nutrition and health status, the more valuable the information. One example is the slight modifications made to the NSI Checklist for use in a dental office (Figure 25.3).[22,23] Dental professionals are in a unique position to monitor their patients' nutritional status as many of the consequences of poor nutrition manifest themselves in the oral cavity (bleeding or swollen gums; pain in mouth, teeth, and gums; angular cheilosis; alterations in the surface of the tongue). Additionally, oral health problems may contribute to the development of inadequate nutritional status because of lesions, loose or missing teeth, poorly fitting dentures, dry mouth, tooth decay or disease, and difficulty in chewing or swallowing.

The checklist can also be modified for use in specialized community or clinical settings. One example is the use of the checklist in a rural community setting as reported by Jensen et al.[24] They found that the checklist items indicating poor appetite, eating problems, low income, eating alone, and depression were associated with functional limitation.

Implementation Partners

The NSI was designed to be a project that included many health professionals working in partnership to identify nutritional problems in older adults. It is important to include any professional who has direct patient contact. Therefore, nurses are essential partners and participants in nutrition screening. They are the best individuals to gather anthropometric data and health history information; they are well-positioned to evaluate individuals' functional status by assessing ability to engage in activities of daily living (ADL) (self-care) and instrumental activities of daily living (IADL) (managing independence). Clinical nurse specialists (CNS) are uniquely positioned to conduct health and nutrition screenings in clinic settings, particularly to identify

nutritional health.**

FIGURE 25.2 DETERMINE Your Nutritional Health.

risk factors that are modifiable before nutritional status begins a slippery slope downward. The advantage of implementing
health promotion programs before or concurrently with the emergence of risk-associated conditions should be apparent.[25]

Other health practitioners (dentists, social workers, physical therapists, speech pathologists, etc.) may also use the screening
tool for clients who may have risk factors for the development of malnutrition. Community workers who run senior centers,
senior meal programs, home health agencies, etc. can also use the checklist to help identify those clients who may require more
attention to their dietary intake, social circumstance, and chronic disease management.

The NSI contributed a unique approach to addressing the issues of malnutrition in older adults. It also opened the creativity
of others to develop and test new tools in nutrition screening and assessment.

(b)

The Nutrition Checklist is based on the Warning Signs described below. Use the word DETERMINE to remind you of the Warning Signs.

DISEASE

Any disease, illness, or chronic condition which causes you to change the way you eat, or makes it hard for you to eat, puts your nutritional health at risk. Four out of five adults have chronic diseases that are affected by diet. Confusion or memory loss that keep getting worse is estimated to affect one out of five or more older adults. This can make it hard to remember what, when, or if you've eaten. Feeling sad or depressed which happens to about one in eight older adults, can cause big changes in appetite, digestion, energy level, weight, and well-being.

EATING POORLY

Eating too little and eating too much both lead to poor health. Eating the same foods day after day or not eating fruit, vegetables, and milk products daily will also cause poor nutritional health. One in five adults skips meals daily. Only 13% of adults eat the minimum amount of fruit and vegetables needed. One in four older adults drinks too much alcohol. Many health problems become worse if you drink more than one or two alcoholic beverages per day.

TOOTH LOSS/MOUTH PAIN

A healthy mouth, teeth, and gums are needed to eat. Missing, loose, or rotten teeth, or dentures which don't fit well or cause mouth sores make it hard to eat.

ECONOMIC HARDSHIP

As many as 40% of older Americans have incomes of less that $6000 per year. Having less - or choosing to spend less - than $25 to 30 per week for food makes it very hard to get the foods you need to stay healthy.

REDUCED SOCIAL CONTACT

One-third of all older people live alone. Being with people daily has a positive effect on morale, well-being, and eating.

MULTIPLE MEDICINES

Many older Americans must take medicines for health problems. Almost half of older Americans take multiple medicines daily. Growing old may change the way we respond to drugs. The more medicines you take, the greater the chance for side effects such as increased or decreased appetite, change in taste, constipation, weakness, drowsiness, diarrhea, nausea, and others. Vitamins or minerals when taken in large doses act like drugs and can cause harm. Alert your doctor to everything you take.

INVOLUNTARY WEIGHT LOSS/GAIN

Losing or gaining a lot of weight when you are not trying to is an important warning sign that must not be ignored. Being overweight or underweight also increases your chance of poor health.

NEEDS ASSISTANCE IN SELF CARE

Although most older people are able to eat, one of every five has trouble with walking, shopping, and buying and cooking food, especially as they get older.

ELDER YEARS ABOVE AGE 80

Most older people lead full and productive lives, but as age increases, risk of frailty and health problems increase. Checking your nutritional health regularly makes good sense.

The Nutrition Screening Initiative, 1010 Wisconsin Avenue, NW, Suite 800, Washington, D.C. 20007
The Nutrition Screening Initiative is funded in part by a grant from Ross Laboratories, a division of Abbott Laboratories.

FIGURE 25.2   (Continued).

MINI-NUTRITIONAL ASSESSMENT

The Mini-Nutritional Assessment (MNA) is a tool that was developed to be used easily to evaluate the nutritional status of frail elderly individuals.[26,27] This instrument was developed to meet a perceived need to go beyond the DETERMINE checklist developed by the NSI, which was designed to raise the awareness of potential malnutrition risks, and the SGA, which was designed for use with hospitalized individuals. The MNA, therefore, was created to complement the screening tools already described.

The objectives for the MNA were to meet the criteria of: (1) a reliable instrument, (2) defined thresholds, (3) ability to be used with minimal training, (4) ability to be free of rater bias, (5) ability to be minimally intrusive to patients, and (6) ability to be inexpensive. The tool was designed to collect 18 items that combine objective and subjective data. These data include simple anthropometric measures (height, weight, arm and calf circumferences, and weight loss), general geriatric assessment items, a brief general dietary assessment, and self-assessment of health and nutrition perception. (Figure 25.4)

This tool has been validated in many clinical studies by comparing the scores with the judgments of trained nutrition clinicians, the NSI instruments, and a comprehensive nutritional assessment that collected in-depth data about the nutritional status

The warning signs of poor nutritional health are often overlooked. A checklist can help determine if someone is a nutritional risk:

Read the statements below. Circle the number in the yes column for those that apply to you. For each yes answer, score the number in the box. Total your nutritional score.

	YES
An illness or condition makes me change the kind and/or amount of food I eat.	2
I avoid eating a food group, i.e., meat, dairy, vegetables, and/or fruit.	2
I have two or more drinks of beer, liquor, or wine almost every day	2
I have tooth pain or mouth sores that make it hard to eat or make me avoid certain foods.	2
I snack or drink sweetened beverages two or more times per day between meals.	2
I had three or more new cavities at a recent dental check-up	2
I don't always have enough money to buy the food I need.	4
I eat alone most of the time.	1
I have a dry mouth, which makes me drink or use gum, hard candy, cough drops, or mints to moisten my mouth two or more times per day.	1
I take three or more different prescription or over-the-counter drugs daily.	1
Without wanting to, I have lost or gained 10 pounds in the last six months.	2
I am not always physically able to shop, cook, and/or feed myself.	2
Total	

Totaly your nutritional score, if it is:

0–2	Good! recheck your nutritional score in 6 months.
3–5	You are at moderate nutritional risk. Try to improve your eating habits and lifestyle.
6 or more	You are at high nutritional risk. take with your doctor, dental hygienist, or dietitian about any problems you may have. Ask for help to improve your nutritional health.

FIGURE 25.3   Nutritional assessement form modified for use in dental office.

of the subjects.[28] The MNA has also been tested in a variety of populations including cognitively impaired elderly[29] linked to other conditions common in older adults such as osteoporosis,[30] long-term care residents, and elderly individuals in different populations throughout the world.[29–38] These studies found that the threshold for the well-nourished on this instrument with a 30-point scale was 22 to 24 points; the threshold for malnutrition was 16 to 18 points on this scale. A short form with only six items[39] has been used with some success as a quick screening tool.[40]

The MNA meets its objectives of being a practical, noninvasive tool that contributes to the rapid evaluation of an elderly subject's nutritional status, contributing early intervention to correct nutritional deficits. This tool is easily used in a variety of settings including hospital, nursing home, home care settings, or physician offices or clinics.

Unique Nutritional Screening Tools

Investigators from around the world have developed tools, using validated nutrition screening instruments such as the MNA as a starting point but modified for their unique populations. One example is the Chinese nutrition screen that uses the MNA as a base and adjusts for Chinese eating patterns, health care system, and culture. Using physicians' physical examinations as a method of validation, this tool had a 60% chance of correctly identifying people at nutrition risk.[41]

Another instrument using the MNA as a base was tested for use with elderly South Africans and validated using measures of ADL and IADL. The investigators[42] reported a sensitivity of 87.5% and a specificity of 95%.

Another group in Iceland, using the MNA as a base along with a screening sheet for malnutrition and a full nutrition assessment as validation, identified four items predictive of malnutrition (body mass index [BMI], unintended weight loss, recent surgery, and loss of appetite). The investigators suggest validation of this screening tool in other populations.[43]

The British Association for Parenteral and Enteral Nutrition (BASPEN) developed a nutrition screening tool based on four parameters (weight, height, recent unintentional weight loss, and appetite).[44] Another screening tool was developed and validated using interrater reliability between dietitians and nurses for the South Manchester University Hospitals Trust; this instrument used BMI, mid-upper-arm circumference, percentage of weight loss, and energy intake using the patients' first full hospital day intake.[45]

MINI NUTRITIONAL ASSESSMENT

ANTHROPOMETRIC ASSESSMENT

1. Body Mass Index (BMI) (weight in kg) / (height in m)^2 **Points**
   a. BMI < 19   = 0 points
   b. BMI 19 to < 21 = 1 points
   c. BMI 21 to < 23 = 2 points
   d. BMI ≥ 23   = 3 points   ☐

2. Mid-arm circumference (MAC) in cm
   a. MAC < 21   = 0.0 points
   b. MAC 21 ≤ 22 = 0.5 points
   c. MAC > 22   = 1.0 points   ☐.☐

3. Calf circumference (CC) in cm
   a. CC < 31 = 0 points   b. CC ≥ 31 = 1 point   ☐

4. Weight loss during last 3 months
   a. weight loss greater than 3kg (6.6 lbs) = 0 points
   b. does not know   = 1 point
   c. weight loss between 1and 3 kg
      (2.2 and 6.6 lbs)   = 2 points
   d. no weight loss   = 3 points   ☐

GENERAL ASSESSMENT

5. Lives independently (not in a nursing home or hospital)
   a. no = 0 points   b. yes = 1 point   ☐

6. Takes more than 3 prescription drugs per day
   a. yes = 0 points   b. no = 1 point   ☐

7. Has suffered psychological stress or acute
   disease in the past 3 months
   a. yes = 0 points   b. no = 2 points   ☐

8. Mobility
   a. bed or chair bound   = 0 points
   b. able to get out of bed/chair but does
      not go out   = 1 point
   c. goes out   = 2 points   ☐

9. Neuropsychological problems
   a. severe dementia or depression = 0 points
   b. mild dementia   = 1 point
   c. no psychological problems   = 2 points   ☐

10. Pressure sores or skin ulcers
    a. yes = 0 points   b. no = 1 point   ☐

DIETARY ASSESSMENT

11. How many full meals does the patient eat daily?
    a. 1 meal   = 0 points
    b. 2 meals = 1 point
    c. 3 meals = 2 points   ☐

12. Selected consumption markers for protein intake   **Points**
    • At least one serving of dairy products (milk,
      cheese, yogurt) per day?   yes ☐   no ☐
    • Two or more servings of legumes or eggs per week?
                                              yes ☐   no ☐
    • Meat, fish, or poultry every day? yes ☐   no ☐
      a. if 0 or 1 yes = 0.0 points
      b. if 2 yes   = 0.5 points
      c. if 3 yes   = 1.0 points   ☐.☐

13. Consumes two or more servings of fruits or
    vegetables per day?
    a. no = 0 points   b. yes = 1 point   ☐

14. Has food intake declined over the past three
    months due to loss of appetite, digestive problems,
    chewing or swallowing difficulties?
    a. severe loss of appetite   = 0 points
    b. moderate loss of appetite = 1 point
    c. no loss of appetite   = 2 points   ☐

15. How much fluid (water, juice, coffee, tea, milk,...)
    is consumed per day? (1 cup = 8 oz.)
    a. less than 3 cups   = 0.0 points
    b. 3 to 5 cups   = 0.5 points
    c. more than 5 cups   = 1.0 points   ☐.☐

16. Mode of feeding
    a. Unable to eat without assistance = 0 points
    b. self-fed with some difficulty   = 1 point
    c. self-fed without any problem   = 2 points   ☐

SELF ASSESSMENT

17. Do they view themselves as having nutritional problems?
    a. major malnutrition   = 0 points
    b. does not know or moderate malnutrition = 1 point
    c. no nutritional problem   = 2 points   ☐

18. In comparison with other people of the same age. how
    do they consider their health status?
    a. not as good   = 0.0 points
    b. does not know   = 0.5 points
    c. as good   = 1.0 points
    d. better   = 2.0 points   ☐.☐

ASSESSMENT TOTAL (max.30 points):   ☐☐.☐

MALNUTRITION INDICATOR SCORE

≥ 24 points   well-nourished   ☐

17 to 23.5 points   at risk of malnutrition ☐

< 17 points   malnourished   ☐

FIGURE 25.4   MNA form.

Investigators in the Netherlands developed and validated a short nutritional assessment questionnaire (SNAQ) for early detection and screening for malnutrition in hospital patients.[46] The questions most predictive of malnutrition focused on unintentional weight loss, a decrease in appetite, and use of supplemental drinks or tube feedings. Another group in the Netherlands focused on community interventions for elderly people in a randomized controlled trial[47] of an EASYcare instrument that includes IADLs, cognition evaluation, mood, and a goal-setting item, which were assessed in follow-up visits at 3 and 6 months after inclusion in this validation study.

It is evident that adjustments and refinements will continue to be made to nutrition screening tools so that the available validated, reliable instruments can meet the needs of unique populations. Although there are screening instruments that are widely used, adapting these tools to make them more useful in different settings with different racial or ethnic groups is important.

NUTRITIONAL ASSESSMENT IN OLDER ADULTS

The descriptions of the screening tools used to define nutritional status among elderly people highlight the fact that one of the more difficult determinations in elderly people is the accurate assessment of their nutritional status. This evaluation is more challenging in older adults because of the physiologic changes that occur with normal aging. Many of the commonly used assessment standards are not reliable in this population for a variety of reasons, one being the lack of validated standards.[48]

ANTHROPOMETRIC MEASURES

Anthropometric measures, including height, weight, and skin-fold measures, are usually important components of a nutritional assessment. These parameters are the ones most affected by the aging process.[49] The most apparent age-related change occurs in height. Height decreases as people get older because of changes in skeletal integrity, most noticeably affecting the spinal column. Loss of height may be due to thinning of the vertebrae, compression of the vertebral discs, development of kyphosis, and the effects of osteomalacia and osteoporosis.[50] Loss of height occurs in both males and females, although it may occur more rapidly in elderly women with osteoporosis. Therefore, stature changes and body appearance may be altered.

Height is difficult to measure in individuals who are unable to stand erect, cannot stand unaided, cannot stand at all owing to neuromuscular disorders, paralysis or loss of lower limbs, or are bed-bound due to other medical problems. One estimate of stature in these individuals is to measure their recumbent height or the bone lengths of extremities.[51] This estimate of stature may not be very reliable but it provides some estimate of height to help determine whether body weight is appropriate for height.

Weight is another important anthropometric measure that is altered with advancing age. Weight changes occur at different rates among elderly people. Use of most standard height and weight tables is not valid in older people as most reference tables do not include elderly people in their subject pool, and most are not age-adjusted.

BMI is a commonly used measure to evaluate relative weight for height using a mathematical ratio of weight (in kilograms) divided by height (meters squared).

$$\text{Wt (kg)/Ht (m}^2)$$

This formula yields a whole number that should be greater than 21 and less than approximately 35.[17] (*Note*: The upper healthy limit in older people is a matter of current dispute, but most experts consider that the limit is somewhat higher than in younger persons.) Nomograms and tables are available that minimize the need for calculation. Use of the BMI depends on accurate height and weight measures. It is used frequently to evaluate weight for height, but standards are not available for an elderly population.[52]

Skin-fold measurements (triceps, biceps, subscapular, suprailiac, and thigh) are often included in a thorough nutritional assessment. However, loss of muscle mass, shifts in body fat compartments, changes in skin compressibility and elasticity, and lack of age-adjusted references serve to decrease the reliability of skin-fold measures in the assessment of nutritional status in elderly people.[53]

BIOCHEMICAL MEASURES

Biochemical assessment parameters are also affected by advancing age.[54] Laboratory measures may reflect an age-related decline in renal function, fluid imbalances or hydration status, or the effects of long-term chronic illnesses. Among the commonly used biochemical markers of nutritional status, serum transferrin is one that is markedly affected by advancing age. As tissue iron stores increase with age, circulating serum transferrin levels are reduced. A lower-than-normal serum transferrin should be evaluated in relation to other biochemical measures and serum iron levels, if obtainable.[55]

The most commonly used predictor of nutritional status in elderly people is serum albumin. Serum albumin below 4.0 g/dl (depending on local laboratory normal ranges) is not usual in an older person unless the subject is overhydrated, has cancer, renal or hepatic disease, or is taking medications that may interfere with hepatic function. Recent evidence suggests that serum albumin is also altered when there is an inflammatory response, common with the presence of chronic disease, infection, or injury.[21] A depressed serum albumin level seems to be a primary prognostic indicator of rehospitalization, extended lengths of stay, and other complications associated with protein energy malnutrition in elderly people.[56,57] However, this malnutrition may be secondary to other causes and not correctable by increasing food intake. Unless there are medical reasons, most biochemical measures should remain within normal limits.

Serum cholesterol has been considered a risk factor for coronary heart disease, but a depressed serum cholesterol level is also associated with poor health status in older people.[57] It may be predictive of impending mortality[58] and should be evaluated carefully within the context of other health measures.

IMMUNOLOGIC ASSESSMENT

Tests for immunocompetence are often included as part of a nutritional assessment because malnutrition results in compromised host-defense mechanisms. However, the incidence of anergy is reported to increase with advanced age and the response to skin test antigens appears to peak after longer intervals in older people.[59] The value of these tests is limited in elderly people.

SOCIOECONOMIC STATUS

Social history, economic status, drug history, oral health condition, family and living situations, and alcohol use should be evaluated along with the physical and physiologic measures usually assessed.[48] It is also useful to assess elderly individuals using instruments that evaluate how well elderly people perform the ADL. Available tools assess the capability of an individual in managing the activities necessary for independence; these tools add another valuable dimension to the assessment of elderly people (Table 25.1 and Table 25.2).[60,61]

SUMMARY

Nutrition monitoring, screening, and assessment in the older adult population pose challenges to health care professionals because of the heterogeneity of this group and the wide range of their health status. The difficulty in using the tools discussed here is that people age at different rates and in different ways related to their health status, their lifestyle, and their genetic inheritance. Particularly in long-term care, the available instruments, particularly the Minimum Data Set (MDS 2.0), are not sensitive or specific for malnutrition risk.[62] Although there are a variety of reasonable approaches to nutrition assessment and

---

TABLE 25.1
Activities of Daily Living

Toileting
Cares for self; no incontinence
Needs to be reminded or needs help with cleanliness; accidents rare
Soiling or wetting at least once a week
No control of bladder or bowels

Feeding
Eats without assistance
Eats with minor assistance or with help with cleanliness
Feeds with assistance or is messy
Requires extensive assistance with feeding
Relies on being fed

Dressing
Independent in dressing and selecting clothing
Dresses and undresses with minor assistance
Requires moderate assistance with dressing and undressing
Needs major assistance with dressing but is helpful
Completely unable to dress and undress oneself

Grooming
Always neatly dressed and well groomed
Grooming adequate; may need minor assistance
Requires assistance in grooming
Needs grooming care but is able to maintain groomed state
Resists grooming

Ambulation
Totally independent
Ambulates in limited geographical area
Ambulates with assistance (cane, wheelchair, walker, railing)
Sits unsupported in chair or wheelchair but needs help with motion
Bedridden

Bathing
Bathes independently
Bathes self with help getting into bath or shower\
Washes hands and face but needs help with bathing
Can be bathed with cooperation
Does not bathe and is combative with those trying to help

26 Dietary Intake Assessment: Methods for Adults

Helen Smiciklas-Wright, Diane C. Mitchell, and Jenny Harris Ledikwe

CONTENTS

INTRODUCTION

> One of the most difficult tasks in nutrition research is documenting the actual or habitual food and nutrient intake of individuals or groups.
>
> National Research Council[1]

There has been long-standing interest in assessing diets of individuals. Early in the twentieth century, nutritionists studied food and nutrient intakes in order to provide guidance in food selection,[2] to interpret clinical and laboratory findings,[3] and to establish dietary requirements.[4] In the latter part of the century, interest in dietary assessment was stimulated with the increasing evidence for the role of diet in promoting health and reducing chronic disease risk.[1,5]

Early investigators were concerned with many of the issues that continue to be important for dietary assessment: (1) selecting appropriate methods for collecting dietary data,[6,7] (2) assessing the day-to-day variability of intakes by individuals,[8–10] (3) establishing procedures for data analysis,[11,12] and (4) estimating food/food group and nutrient intake.[3]

We should not be surprised that assessment of dietary intake is a challenging undertaking. Food intake can be a complex behavior.[13] on any day, an individual may consume many different foods, on different occasions, both at home and away from home. Willingness and ability to report what is consumed can be influenced by social, environmental, and cognitive events.[14–16] Furthermore, food composition databases must continuously be updated to reflect an expanding food market place and an increasing number of dietary components associated with health.[17]

This chapter is organized to review the methods that are most commonly used to assess intakes by individuals. Attention is given to methodological validity as well as to the current emphasis on indexes of dietary quality, dietary supplements, and functional foods.

METHODS OF DIETARY ASSESSMENT

The common methods for assessing intakes by individuals are food records, recalls, and food frequency questionnaires. Several reviews of dietary assessment methods have considered appropriate uses, modes of administration and sources of error.[18–23] These are generally characterized either by the reference period in which respondents are asked to provide information (i.e., retrospective and prospective methods)[23] or by the time frame for which data are collected (i.e., quantitative daily and food frequency methods).[20]

There is no single, optimal dietary assessment method. The objectives of an assessment should be used as a guide in selecting the most appropriate method. Some 30 years ago, Christakis advised that the assessment method selected should be no more detailed, no more cumbersome, and no more expensive than necessary.[24] This advice is still sound. Assessment protocols, regardless of method, may need to provide highly quantitative and detailed data on food consumption. This would be the case for research studies such as clinical trials.[25] More qualitative data is likely to be appropriate when food intake information is used for dietary guidance and counseling.

FOOD RECORDS

Food records, also known as food diaries, provide a prospective account of foods and beverages consumed in a defined period of time. Generally, records are kept for brief time periods (1 to 7 days), but they have been kept for up to a month[26] and even a year.[27] To be representative of usual intake, multiple days of records are needed.[28]

Food records may be used to meet a variety of objectives. Records are useful for detecting imbalances in food intake and making dietary change recommendations.[29] They are used as self-management tools in weight loss interventions and may be valuable in predicting successful weight loss.[30] Food records have been used extensively to calibrate other dietary assessment methods.[31–33] Records are also useful for documenting compliance of an individual's food intake with a feeding protocol in studies where adherence to a specific diet regimen is important.[34] Intervention studies may use food records to document effectiveness.[35]

Food portions may be either weighed or estimated depending on the subjects and the purposes of the assessment.[36] While weighing foods will increase the accuracy of the portion size recorded, it can also increase respondent burden. Sophisticated scales that do not disclose food weights to subjects are available, decreasing respondent recording burden,[37] but increasing cost. A variety of portion size aids, listed in Table 26.1, are available when portion sizes are to be estimated.

While records are usually kept by respondents, they may also be kept by observers. When food intake is recorded by observation, trained personnel visually estimate dietary intake.[43] Observation is particularly useful when circumstances preclude self-reporting of food intake. Thus, observation has been used in assessing intake of nursing home residents. The Omnibus Budget Reconciliation Act[44] requires that all Medicare- and Medicaid-certified nursing facilities implement a standardized comprehensive assessment, including a measure of nutrient intake, for all residents. Observers visually estimate the portion of served items consumed (i.e., from all to none) by a resident.[45]

When using food records, consideration should be given to the record forms to be used as well as instructions and training for subjects, particularly regarding portion size. Instructions should include guidance on completing the record form as well as

TABLE 26.1
Tools for Portion Size Estimation

Type	Examples
Household measures	• Measuring cups and spoons[38]
	• Rulers[38]
Food models	• Food replicas[39]
	• Graduated food models[40]
	• Thickness sticks[38]
Pictures	• 2-Dimensional portion shape drawings[41]
	• Portion photos of popular foods[42]
	• Portion drawings of popular foods[38]
Food labels	• Nutrition facts label
	• Food package weights

TABLE 26.2

Sample Instructions for the Administration of a Food Record

To help us do the best analysis of your food intake, please follow these instructions

1. *Maintain your usual eating pattern*. Try not to modify your food intake, because you are keeping a record
2. *Record everything you eat or drink*. Be sure to include all snacks and drinks. Also include any vitamin or mineral supplements and the dosage for each day
3. *Write foods down as soon as you eat them*. Three daily record pages are provided for each day; however, you may not need to use all three. Try to write clearly

Details are Important!

Completing the food record form

1. *Date*. Please record the date at the top of each form
2. *Name*. Please write your name in the space at the top of the form
3. *Time of Day*. Record the time of the day you ate each meal, including AM or PM
4. *Meal/where prepared*? Record the name of the meal eaten (i.e., breakfast, lunch, dinner, supper, or snack) and where the meal was prepared (i.e., at home or at a restaurant)
5. *Food item*. Write the name of each food item eaten
6. *Description/preparation*. Include information on how each food was prepared
7. *Amount*. Record the amount of each food either by using the poster provided or common household measures

---

directives encouraging subjects to record foods at the time of consumption and not to alter normal eating patterns. Table 26.2 provides sample instructions for the administration of a food record.

After records have been completed, they should be reviewed to ensure completion. If reviewed with the subject, probing questions may be used to clear up ambiguities and ensure the completeness of the record. These are termed interviewer-assisted food records. When data from food records are to be compiled and analyzed, records will need to be coded using a standard method.

As subject burden can be high for food records, participant willingness and abilities are to be considered when using this method. Literacy is required for completion of records; therefore, the method may not be appropriate for all individuals. The act of keeping food records can affect dietary intake,[46] which may be critical for estimates of usual intake. Cost is an additional consideration, as reviewing records for completeness, data entry, and data analysis can be expensive.[23]

RECALLS

Dietary recall provides a retrospective record of intake over a defined time period. While dietary recall may be for any length of time, this method is almost always administered to cover a 24-h time period and is generally termed the 24-h recall. Data can be collected either for the previous day or for the 24-h preceding the interview. To estimate the usual intake of individuals, multiple recalls are needed, preferably on random, nonconsecutive days, including weekends and weekdays.[21,27] Typically, an individual is asked to recall all foods eaten during the reference time period, describe the foods, and estimate the quantities consumed.

The 24-h recall has become a favored way of collecting dietary data[47] as recalls can be administered easily and quickly with low respondent burden. Depending on the objectives of the recall, the amount and depth of information collected will vary. This method is becoming the gold standard; particularly as methodological improvements[48–52] and technological capabilities[53] increase validity. With the emergence of technological aids in dietary assessment, it is becoming more common for interviewers to collect intake data using interactive software, entering intake data directly into a computer as it is collected.

Recalls may be obtained either in-person or by telephone-administered interviews. Because recalls by telephone interview have been shown to be practical, valid, and cost-effective,[53–55] they are becoming an increasingly popular mode of data collection, especially for research and population-monitoring purposes.

Prior to conducting recalls, training of interviewers is important. This is particularly relevant when more quantitative data are required, increasing the need to use multiple pass and probing techniques. Figure 26.1 provides a sample probing sequence to elicit detailed information regarding one specific food (i.e., macaroni and cheese). The complexity of this probing sequence exemplifies the potentially complex nature of probing questions and need for good interviewer training. More qualitative food intake data can be achieved with more limited questions.

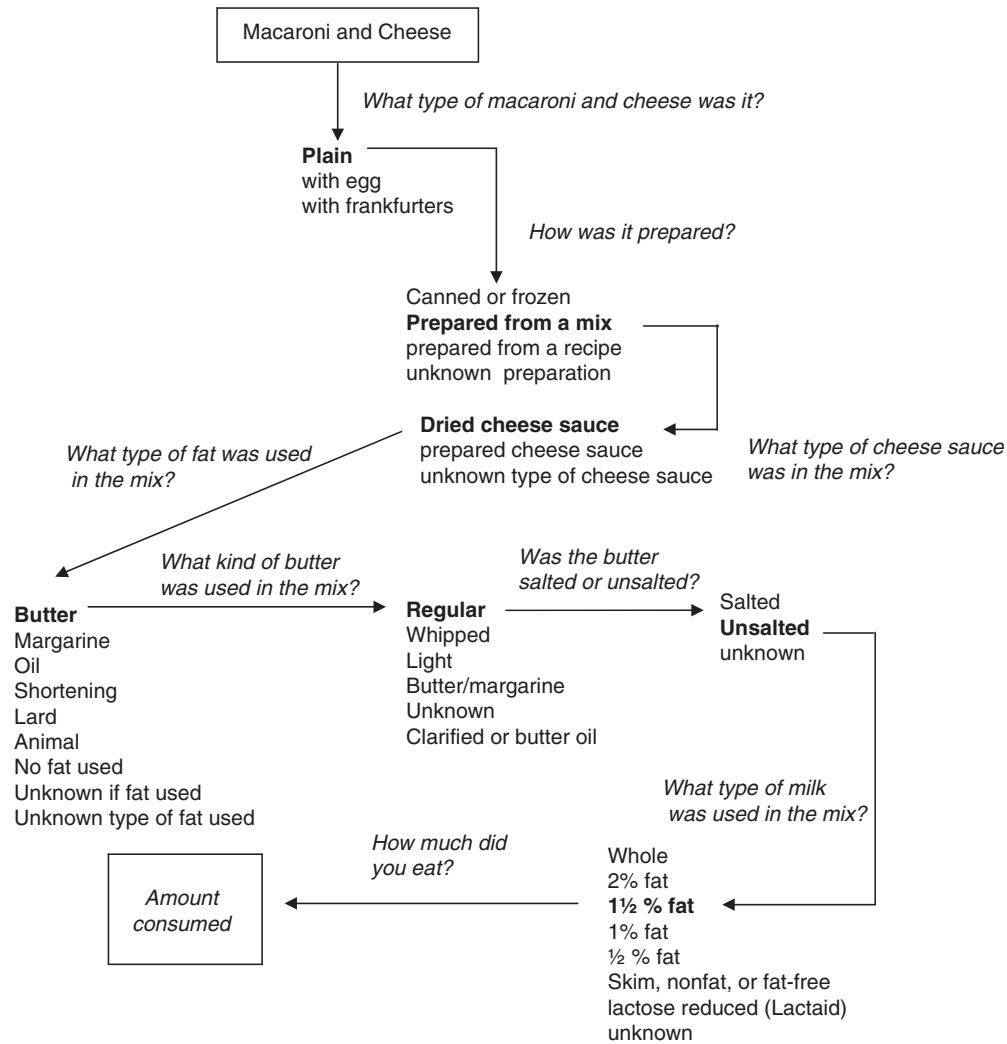
The 24-h recall has been criticized because of accuracy related to portion size estimation and subject memory. Portion size estimation aids are available to facilitate quantity estimation (Table 26.1). While 24-h recalls are not designed to affect the "encoding" of food information, they can incorporate strategies to facilitate memory retrieval. Those strategies include


FIGURE 26.1 A sample probing scheme. This scheme could be used with recalls to elicit more information from a respondent that consumed macaroni and cheese. Bold print indicates respondent's reply. Probing questions, which are specific for each response, are italicized. (Adapted from Nutrition Data System for Research [NDS-R] software, developed by the Nutrition Coordination Center [NCC], University of Minnesota, Minneapolis, MN.)

standardized data collection protocols, structured probes to ensure standardized collection and interactive interview systems.[47] The multiple-pass technique, which will be discussed in "Current Issues in Assessment and Analysis," has also been designed to facilitate memory retrieval.

FOOD FREQUENCY METHODS

Food frequency methods are designed to obtain information about usual long-term food consumption patterns. The methods evolved from the dietary history method originally developed by Burke.[56] The dietary history interview included a 24-h recall, a 3-day food record, and a check-list of foods with questions about likes, dislikes, and consumption over the previous month. It was time consuming to administer and process the dietary information. However, the checklist with its list of foods and consumption options was the basis of food frequency questionnaires (FFQ) widely used in epidemiologic studies. The use of FFQ in large epidemiologic studies assumes the importance of usual dietary exposures to morbidity and mortality.[22] The use in epidemiologic studies also reflects the feasibility of administration.

FFQs consist of a list of foods, frequency-of-use response categories and may also include portion size response categories. Food lists may be extensive in order to provide estimates of total intake. Commonly used FFQs are The Nurses' Health Study Dietary Questionnaire[22] and the NCI FFQ developed by Block et al.[31]

Food frequency questionnaires may be abbreviated when used to screen for nutritional risk or when the focus is on specific foods (e.g., fruits and vegetables[57] and soy foods[58]) or nutrients (e.g., fats[59] and folate[60]). While not necessarily appropriate

for identifying precise nutrient intake, these instruments can provide a rapid, cost-effective way to estimate usual intake. Very abbreviated instruments may not be representative of true intake.[61]

Subar has provided a succinct but thorough summary of considerations in selecting an FFQ.[62] A basic question is whether to select or adapt a commonly used questionnaire, or to develop and validate a new instrument. Willett[22] and others[63,64] have described the very intensive processes involved with the development of new FFQs. An example of the development process and the use of cognitive interviewing are described for the new National Cancer Institute Diet History Questionnaire.[64] Validating a new instrument or administration of a standard instrument on a specific population is also challenging. FFQs are commonly validated by calibrations with other dietary assessment method.[33,65,66] Kipnis and colleagues used biomarkers for energy and protein validation in the Observing Protein and Energy Nutrition (OPEN) study.[67]

FFQs without portion size information generally provide qualitative data. If portion size information is included, nutrient intakes may be estimated to enable relative ranking of intakes. Several investigators have studied the use of standard versus reported portion intakes. Laus and colleagues[68] found little difference in nutrient estimates when a standard (medium-size) portion was substituted for reported sizes. However, others have indicated that the use of standard portion size data may attenuate relationships between diet and disease.[69]

SUMMARY

Several methods have been listed that can be used to assess the dietary intake of adults. Well-designed quality control procedures are particularly important in research studies to ensure consistency of data across time and subjects. Additionally, the advantages and disadvantages of data collection modes (i.e., self- or interviewer-completed) should be considered (see Table 26.3). The success of any assessment method is based on a partnership between the individual respondent and the assessment staff. Care should be taken to ensure the appropriateness of the method and the level of detail collected. Respecting participants' abilities and ensuring their dignity is not compromised is salient in establishing a successful partnership.

ISSUES AFFECTING VALIDITY

In his address at the First International Conference on Dietary Assessment Methods, Beaton stated, "There has been a great deal published about the errors in dietary data … this is understandable, but unfortunate because it can easily leave the impression that dietary data are worthless."[70] He reminded his audience that, while dietary intake data cannot and never will be estimated without error, a serious limitation is not the errors themselves, but failure to understand the nature of the errors and the consequent impact on data analysis and interpretation. Several reviews have delineated potential sources of error for different assessment methods.[21,22,37] Issues for consideration include: (1) accuracy with which individuals can or are willing to report food items eaten as well as portion sizes, (2) representation of usual intake and (3) adequacy of diet calculation systems, both data entry and food composition bases, to reflect composition of foods eaten.[22] Food composition database issues are covered in Chapter 1. In this chapter, we include potential error sources that can affect validity. Consideration of strategies to minimize error is pertinent in yielding accurate intake data, regardless of assessment method (see Table 26.4).

TABLE 26.3
Self-Completed and Interviewer Completed Data Collection

Collection mode	Advantages	Disadvantages
Self	• Interviewer training not needed • Sense of privacy • Data collection time may be reduced	• Response rate may be low • Respondent burden may be high • Tasks may be misinterpreted • Respondent training needed for more complete data • Data preparation and entry time may be high
Interviewer by phone	• Good Response rate • Opportunities for probing • Low Respondent Burden • Relatively quick • Interviewer anonymity	• Contact times may be inconvenient • Hearing problems for some subjects • Availability of portion aids • Data collection may be more expensive for toll calls • Potential for interviewer bias
Interviewer in person	• Good response rate • Opportunities for probing • Low respondent burden • Respondent interviewer rapport	• Contact times may be inconvenient • Potential for interviewer bias

---

TABLE 26.4
Benefits Derived from Minimizing Assessment Error

Clinical setting	Research Setting
• Improve ability to detect inadequate, imbalanced, or excessive dietary intake	• Improve accuracy of nutrient intake estimations
• Provide a better basis for nutrition counseling and interventions	• Decrease attenuation between intake data and biomarkers
• Improve ability to monitor dietary changes	• Provide a better basis for nutrition education program
	• Provide a better basis for elucidation of diet-disease relationships

---

MEMORY

Recalls and FFQs require that respondents remember intakes, albeit for different time frames. Our understanding of memory for diet assessment has been developed from advances in cognitive psychology as described by Dwyer and colleagues.[14] Critical memory processes include: encoding information, transmission to long-term memory, and retrieval.[71–73] Early studies described strategies for encoding information as well as strategies for retrieving memories, such as free recall, recognition, and cued recall.

The memory model of cognitive psychology is applicable to dietary recall.[74] To accurately report intake, people must be able to remember what foods were consumed, how the foods were prepared and the quantities of foods eaten. This requires the acquisition of specific food memories and the ability to retrieve the memories. Individuals that pay little attention to foods consumed as well as people that have difficulty storing information in memory, and those that lack the cognitive ability to retrieve food memories may have difficulty in recalling dietary intake.

Several techniques have been developed to reduce memory-related error in dietary data. For the 24-h recall, techniques such as probing (See Figure 26.1),[75] encoding strategies,[74] memory retrieval cues,[25] and multiple pass[48,51,52,63] have been employed to improve memory. Campbell and Dodd's[75] classic paper showed that probing elicited additional information with significant impact on total caloric intake. Ervin and Smiciklas-Wright found that older adults were able to remember more foods when a deeper processing strategy was used during encoding and a recognition task was used for memory retrieval.[74] Record assisted recalls may be used to help reduce memory-related errors in food records.[76,77]

Recent work suggest that 24-h recalls which incorporate a multiple-pass technique into a standardized interview protocol with structured probes can reduce the commonly observed underestimation of intake for groups of individuals. A multiple-pass technique provides respondents several opportunities (i.e., passes) to recall foods eaten using both free recall and cued (probed recall) strategies.[48,50–52] Historically, the strategy involves three recall passes: an introductory opening sequence in which a respondent is asked to recall all items eaten; an interactive, structural probe sequence to elicit detailed food descriptions and amounts; and a final review of the recall. The multiple-pass technique is theoretically sound and when incorporated into a well-structured interactive interview process may decrease underreporting for groups of individuals.[48,50] More recently, Conway et al. have developed and tested newer multiple pass methodologies that include five passes: (1) a quick list or uninterrupted listing of all foods and beverages; (2) a forgotten foods list or questions about nine food categories that are often forgotten; (3) time of day foods were consumed and the eating occasion; (4) detailed questions about each food including preparation and amounts consumed; (5) a final review and probe of all foods consumed. Research using these newer methods has demonstrated in an experimental setting that individuals are able to accurately report intakes within 10% of actual intake for obese and normal weight men and women.[51,52] While these studies are encouraging for the presentation of group data, there is room for improvement in assessing individuals' intakes.[48] There is little data, however, comparing alternative modes of administering a multiple pass strategy and the "gains" at each pass.

A multiple-pass technique can be facilitated by the use of interactive software.[78] This allows for a greater level of detail and facilitates data collection, but the technology is generally expensive and is not used commonly in clinical settings. However, written tools, such as probing guides, may be used to mimic this process when quantitative analysis is critical.

PORTION SIZES

Many individuals have difficulty estimating amounts of foods and beverages.[79–81] Errors may occur because the visual memory is not retained or knowledge is lacking to estimate amounts.[74] There is a tendency toward overestimation of smaller portion sizes and underestimation of larger portion sizes. Portion size estimation aids (Table 26.1) may reduce portion size estimation error.[82]

Estimation aids vary in sophistication and cost. Choice of tools is dictated partially by feasibility. In a clinical setting, aids such as food replicas, real foods, and food picture books may be appropriate. For interviews conducted by phone, tools that are compact for mailing, such as a chart with two-dimensional portions,[83,84] would be more appropriate. Commonly used food models and portion estimation aids may not adequately depict the increased portion sizes customarily consumed by many persons.[85] Harnack and coworkers[86] reported that typically used models resulted in underreporting of several foods served in a restaurant. With larger-sized modes, reported amounts more closely matched amounts actually consumed. This is consistent with cognitive studies that support respondents' preferences for aids more similar to portions eaten.[87] Cognitive psychologists have recommended aids such as moldable objects or modifiable computer images to assist in portion estimation.[87]

A number of investigators have investigated whether training subjects to "judge" portion sizes improves quantity estimates.[88–90] These studies suggest that training effects may be retained for some days after training and may have significant impact on some, but not all foods. For example, amorphous foods (e.g., salads) are more resistant to training effects. Methods such as digital photography have been shown to reduce reported portion size errors and may be useful in settings allowing for direct observation of food selection.[91]

CONSUMPTION FREQUENCY

Accurate estimation of how often foods are consumed is important for accurate estimations by food frequency methods. The cognitive demands required to estimate consumption frequency contribute to the error involved with these methods. For food frequency questionnaires, frequency of consumption estimates may contribute more error than portion size estimates.[92] Willett[22] considers the challenges to selecting proper response format. Options include multiple-choice versus open-ended responses. It has been suggested that the precision of food frequency questionnaires can be increased by not using predefined consumption frequency categories (i.e., multiple choice), instead allowing participants to simply enter a number to reflect intake (i.e., open-ended).[92] However, multiple-choice categories may lead to fewer errors than open-ended categories. Decisions about number of response options may also affect ease of recall and precision of responses. Not surprisingly, Willett alludes to FFQ formats as appearing simple but providing opportunities for pitfalls.[22]

RESPONSE BIAS

All assessment methods are subject to response bias. Social desirability may lead some individuals to selectively omit foods that may be regarded as unacceptable (e.g., alcohol and high-fat foods),[23] while others may report eating a healthier diet than was actually consumed.[93,94] Self-reported assessment data may also be biased by participation in a dietary intervention.[95]

For both interviewer-assisted and self-completed assessments, questions should be reviewed for face validity to help ensure that the participant's comprehension of the questions is appropriate. When using interviewers to collect data, training to avoid leading questions and verbal and nonverbal cues that may appear to be judgmental can decrease response bias. Quality control procedures can ensure that interviewer questioning is consistent and nonbiasing.[96,97] Conducting interviews by telephone may reduce bias as compared to face-to-face interviews.[48]

In regard to particular assessment methods, food frequency questionnaires may be subject to response bias as current diet may influence recall of dietary intake in the past,[98] especially, for individuals with a diet-related illness.[99] Response bias can also be induced by methods with a high participant burden. For example, the burden of keeping food records may lead subjects to submit incomplete records, introducing a response bias.[100] Techniques that reduce respondent burden, such as interviewer-assisted food records, can reduce this effect and may improve the quality of data collected.

VARIABILITY OF INTAKE

Day-to-day variation of food intake has been well documented in the literature.[27,101,102] Accordingly, assessment of an individual's total dietary intake, particularly by quantitative daily methods, at any one time may not yield an accurate measure of usual intake.[27] Basiotis et al.[103] found that over 100 days of dietary data may be needed to accurately estimate an individual's typical intake for certain nutrients, such as vitamin A. To lessen the effect of day-to-day dietary variation when using 24-h recalls, assessment should be done on multiple, random, nonconsecutive days[27,104] that include both weekend and weekdays. For food records and 24-h recalls, increasing the number of assessment days will decrease error related to variation in food intake; however, this must be balanced with subject tolerability and assessment objectives.

Several statistical approaches have been developed for estimating usual dietary intake distributions at the population level when intake data are collected by 24-h recalls. A method developed at Iowa State University, the ISU method, based its estimates from distributions available for two independent days from a subsample of individuals.[105,106] Freedman and colleagues[107] adjusted 24-h recall energy intake estimates in the OPEN study using doubly labeled water (DLW) as the reference biomarker.

DATA ENTRY

Data entry is the link between the information that is provided by a respondent and the analysis of the data. Data entry often requires decisions by coders to adjust information provided to meet the demands of a specific data analysis program.[108] If the respondent provides incomplete data or the database does not include all diet items, coders must decide on reasonable substitutions for portion size or food items. Thus, the quality of the data provided by respondents, the quality of the database, and the default assumptions by coders can all contribute to variability in the final food and nutrient data descriptions.[108]

Decisions about amounts of foods eaten may be guided by U.S. Department of Agriculture (USDA) publications on portions commonly consumed in the United States. The USDA has published several reports on foods commonly eaten and the quantities consumed at an eating occasion.[109,110] These reports provide data on amounts reported as eaten by participants in nationwide food consumption surveys.

SUMMARY

Dietary assessment is a dynamic field, with novel approaches being developed, such as computer-assisted self-interviews.[111] Various techniques to improve validity have been developed (see Table 26.5); but much work still needs to be done to decrease both systematic and random errors. Refinement of current methods and the development of new, innovative techniques will further confidence in the accuracy of dietary data.

CURRENT ISSUES IN ASSESSMENT AND ANALYSIS

REPORTING ACCURACY

Recent attention to the accuracy of dietary intake data has focused on the underreporting of energy by 10 to almost 40%.[48,64,112–115] These findings are based on an extensive literature comparing intakes to energy needs estimated using doubly labeled water,[63,67,116,117] weight maintenance data,[48] or age- and sex-specific equations to estimate energy requirements.[112,118] Although DLW is considered an unbiased biomarker of energy expenditure, the procedure is costly and not feasible for many studies. Prediction equations are widely used as an alternative to DLW to estimate energy requirements. The prediction equations based on DLW studies consider estimated basal metabolic rate and physical activity level (PAL) in determining the total energy expenditure.[118–120] Cutoff limits are used to establish minimum energy to sustain life. Limits are used to determine both implausibly low and high self-reported intakes. The cutoffs developed by Goldberg[118] have been updated with new assumption about PAL. Recent updates have been based on U.S. population data.[121,122] Correlates between energy intake and weight are much stronger for plausible reporters than all reporters.[123]

TABLE 26.5
Considerations to Reduce Error when Collecting Assessment Data

Potential Error Sources	24-h Recalls	Food Records	Food Frequency Questionnaire
Memory	• Multiple-Pass Technique • Probing Questions • Encoding Strategies	• Interviewer-Assisted Records • Encouraging Adherence to Appropriate Instructions	• Memory Retrieval Techniques
Portion size	• Portion Size Estimation Aids • Subject Training • Interviewer Training	• Portion Size Estimation Aids • Weighing Scale • Subject Training	• Portion Size Estimation Aids • Subject Training
Day-to-day variability	• Multiple Recall Days • Nonconsecutive Days of Data • Include Weekdays and Weekends • Collect Data in Different Seasons	• Multiple Days of Records • Include Weekdays and Weekends • Collect Data in Different Seasons	N/A
Response bias	• Interviewer Training • Clearly Worded, Open-ended Questions • Objective Interviewer Responses • Recalls on Unannounced, Random Days	• Objective Instructions • Reduce Respondent Burden • Limit Days of Data Collection	• Objective Responses for Interviewer Mode
Data Entry	• Documentation of Decisions • Interactive Software with Detailed Probes and Automatic Coding	• Strict Coding and Data Entry Rules • Interviewer Assisted Records • Detailed Probing Guides and Instructions	• Strict Coding and Data Entry Rules • Computer Scannable Forms for Automatic Coding

Underreporting has been found to be more common among women and older persons[124,125] as well as overweight,[126] postobese,[112] and weight-conscious individuals. Low literacy,[127] depression,[128] and diet-related social desirability[129] have been associated with underreporting. Underreporting may be more prevalent in participants assigned to an intervention group in clinical trials.[130,131] Selective underreporting has also been associated for certain food types such as fats and sweets[123,132] and bias toward underreporting of fat and carbohydrate over protein.[63]

While underreporting of energy is common in groups of individuals,[48,98,99,133–135] both underreporting and overreporting can occur.[48,125] Black and Cole reviewed studies with repeated dietary assessment, by more than one method and over time and found evidence for subject-specific bias. Thus, underreporters by one method were likely to be underreporters when tested by other methods and were likely to be so when reporting data over time.[136]

Reporting inaccuracies occur with all methods. In their review of dietary misreporting in the OPEN Study, and using DLW as reference, Subar and colleagues[63] reported more underreporting with a FFQ than 24-h recalls. They also indicated that accuracy declines the more respondents consume, suggesting that more foods and larger portion sizes present a challenge to accurate reporting.

DIET QUALITY

Indexes

Many indexes have been developed to assess diet quality. Kant summarized the three major categories as follows: indexes derived from nutrients only; indexes based on foods/food groups; and indexes based on combinations of nutrients and foods.[137]

Individual nutrient scores have been a method of interpreting nutrient intakes of an individual by comparison with a dietary standard such as the Recommended Dietary Allowances and the Dietary Reference Intakes or relative to energy intake. The nutrient adequacy ratio (NAR), which is the amount of a particular nutrient in the diet divided by the dietary standard, is an example of a single nutrient score.[138] A mean adequacy ratio (MAR) can also be calculated and represents the mean of NARs for several nutrients of interest.[138] Recently Drewnowski[139] reviewed various nutrient density scores and proposed a "naturally nutrient rich" score based on a nutrients-to-calorie ratio.

Food-based assessment indexes of quality vary from estimates of food diversity/variety to intakes of designated food groups. Kant[137] described such indexes as promising, because they "retain the complexity of foods and permit an indirect assessment of nonnutrient constituents" as well as nutrients.

A commonly used food-based approach is to calculate the number of servings from each food group and compare this with food grouping standards such as the USDA Food Guide Pyramid.[140] Another approach is to group intakes (e.g., low, medium, and high) for analysis with health outcomes.[141] However, depending on the food group scheme used, serving sizes and placement of foods into groups may vary considerably. Approaches to food group analyses also differ.[142] For individuals, a behavioral approach, in which food group changes are based on nutrition education strategies, is more appropriate. This approach usually defines specific nutritional education programs for health promotion, such as the National Cancer Institute's 5-a-day program.

Increasingly, diet pattern analyses are applied in studies of diet and health outcomes.[141,143–146] Kant recently provided a comprehensive review of diet patterns and health outcomes.[146] A number of multivariate statistical techniques is used for diet pattern analyses, including factor and cluster analyses. With these methods, a number of foods or nutrients are combined into composite variables or patterns that are reasonably homogenous. Across many studies, diet patterns identified as "prudent," "healthy," or "nutrient dense" are associated with more favorable micronutrient intakes, and reduced morbidity. Fruits, vegetables, fish, and whole grains are characteristics of such patterns.

A few global nutrition indexes (i.e., nutrient and food combination) have been developed. The Healthy Eating Index (HEI) score, created by the USDA,[147] as well as others such as the Diet Quality Index (DQI)[148] represent indexes of overall diet quality. They are based on the premise that diets are not comprised of single nutrients or foods but combinations of nutrients and nonnutrient components. The interactions of all these dietary components make it difficult to determine the effects of single dietary components. Additionally, dietary behaviors are complex, and many different patterns of intake may be occurring simultaneously such as decreasing fat intake while increasing fruits and vegetables.

Energy Density

Energy density is another way dietary quality can be addressed. Energy density refers to the amount of energy in a particular weight of food. It is generally presented as the number of calories in a gram. Foods with a low energy density provide less energy relative to their weight than foods with a high energy density. Energy density values, which are influenced by the moisture content and macronutrient composition of foods, range from 0 to 9 kcal/g. The component of food with the greatest impact on energy density is water.[149] Water has an energy density of 0 kcal/g as it contributes weight but not energy to foods. Foods with high water content, such as fruits and vegetables, have a relatively low energy density. Fiber also has a relatively low energy density, providing 1.5 to 2.5 kcal/g and can lower the energy density of foods. However, the influence of fiber on

energy density is more modest than that of water since only a limited amount can be added to foods. On the opposite end of the energy density spectrum, fat is the most energy-dense component of food. Fat increases the energy content of foods, providing 9 kcal/g, more than twice as many as carbohydrates or protein, which provide 4 kcal/g.

Energy density values reported in the literature have been calculated by a variety of different methods that include only food, as well as food and various combinations of beverages, such as all beverages, all beverages excluding water, energy-containing beverages, milk, juice, and so forth.[150–152] Since energy density values vary widely depending on the beverage inclusion method,[150,153] studies investigating energy density should clearly define the treatment of beverages. Although insufficient data are available to state definitively which beverage calculation method is superior, calculations based on food, excluding all beverages, are becoming increasingly common. This method lacks some of the controversies associated with other methods. For example, values based on food and all beverages (including water) are rarely reported in the literature, as water intake is not commonly collected in research studies. Calculations based on food and all beverages excluding water may not provide meaningful measures of dietary energy density because noncaloric beverages such as diet cola, coffee, and tea, are not excluded. Additionally, values based on food- and energy-containing beverages may lead to increased within-person variance values, which may diminish associations with outcome variables.[153]

While calculating dietary energy density can be challenging due to the data coding and manipulations necessary to appropriately deal with beverages, recent evidence indicating that energy density is associated with weight status[151,154,155] necessitates additional energy density investigations in a variety of populations. Furthermore, given that low-energy-dense diets have been associated with high intakes of fruits and vegetables, high intakes of fiber, high intakes of a variety of vitamins and minerals, and good overall diet quality,[152] dietary energy density values appear to a marker for a healthy diet pattern.

Glycemic Index/Glycemic Load

Because of the considerable attention given to low-carbohydrate-diet approaches and the new Dietary Guidelines emphasis on whole grains, interest in carbohydrate quality as assessed by glycemic index and glycemic load is increasing.[156] International of tables of glycemic index values[157] are quickly becoming integrated into nutrient databases used to enter, collect, and analyze dietary data.

Glycemic index is the scale used to classify the quality of carbohydrates by their potential to increase blood glucose independent of its carbohydrate content, whereas the glycemic load of the diet reflects the total glycemic effect of the diet and is the product of the carbohydrate content that each food and its glycemic index value.[157] Carbohydrate-containing foods vary widely with respect to their glycemic response. Many dietary factors such as grain size and structure, fiber content, cooking methods, amylose content, previous meal, and satiety all play a role in the total glycemic effect of the diet.[158] Glycemic index is measured *in vivo* by comparing the glucose responses of a test food with an amount of carbohydrate equivalent to a reference food (usually 25 or 50 g of glucose or starch). Because of the differences in methodology and the wide variety of factors affecting glycemic response, the glycemic values of foods vary considerably and, for this reason, assessing glycemic is still somewhat controversial. Databases are still somewhat incomplete, and they are subject to errors in measurement and interpolation, not unlike nutrient databases and other food component databases.

Lower dietary glycemic index and glycemic load of the diet has, never-the-less, been shown to have beneficial health effects by altering metabolic endpoints such as improved blood glucose, insulin, and lipid levels, improved glycemic control in diabetes, decreased fat mass, and reduced colon cancer risk.[159–164] Recently, Davis et al.[156] studied the glycemic load of older adults, finding that a healthier dietary pattern was associated with a lower glycemic index and glycemic load.

Any method of assessing an individual's dietary intake is dependent on the methods of interpretation. More comprehensive methods of interpretation may facilitate the identification of more specific patterns of intake and their relationship to disease.

DIETARY SUPPLEMENTS

Increased nutrient intakes from supplements have been related to certain disease risk such as cardiovascular disease (vitamin E), neural tube defects (folate), osteoporosis (calcium), and cancer (antioxidants such as vitamin C and beta carotene). Approximately 40–50% of the general population over the age of 2 years in the United States takes a dietary supplement (see Table 26.6).[165,166] These numbers continue to rise especially for more nontraditional or complementary therapies such as herbal or botanical supplements. Supplement use is higher in non-Hispanic white females and increases with age in some segments of the population.[165,167] The supplement intake of special populations such as those individuals with cancer diagnosis is much high, as high as 80% in some studies.[167,168] Knowledge of dietary supplements as well as an understanding of assessment methods is critical to the overall assessment of nutrient and other dietary components.

Supplement intake data can be assessed in a variety of ways and is usually collected by questionnaire, including food frequency questionnaires, or as part of intake data such as by 24-h dietary recall or by food records. When collected by the latter methods, it is important to recognize that the intake of supplements for the day of data collection may not reflect the pattern of intake over an extended period of time. Detailed questionnaires, which are better for capturing long-term intake and frequency of intake, are used frequently in research studies, clinical practice, and in nutrition monitoring and surveys.[169]

TABLE 26.6
Categories of Supplements

Category	Examples
Vitamins (single or multiple formulations)	Vitamin C, E, D, B-6
Minerals (single or multiple formulations)	Iron, calcium, chromium, and zinc
Vitamins with minerals	Calcium with vitamin D; vitamin E with selenium
Herbs and other botanicals	St. John's Wort, ginkgo biloba, ginseng, saw palmetto
Flavonoids	Quercetin, rutin, hesperidin, diadzin
Carotenoids	Lycopene, zeaxanthin, lutein, dried carrot extract, and other vegetable extracts
Fatty acids/fish oils, other oils	Linoleic acid, omega 3 fatty acids, and DHA EPA
Amino acids/nucleic acids/proteins including coenzymes, enzymes, and hormones	L-glutamine, coenzyme Q-10, bromelain, tryptophan
Microbial preparations/probiotics	*Lactobacillus acidophilus*, *B. bifidus*, *L. bulgaris*
Glandular and other organ preparations	Desiccated glands such thyroid and adrenal
Miscellaneous	Shark cartilage, pycogenol, chrondoitin sulfate

Quantifying supplement intake is a difficult and tedious process. When collecting supplement information, it is important to identify what level of detail is needed to describe or quantify dietary intakes with dietary supplements. Strategies may include having those individuals bring in their supplement labels, or photocopy the labels. Other strategies include having the participants respond to questionnaires that provide lists of single vitamins and minerals as well as common brand names for multiple formulations. For herbal and botanical ingredients and other components not typically found in common formulations, it might be necessary to identify the active components and, above all else, to obtain brand name and label information.

FUNCTIONAL FOODS

A *functional food* has been defined as "any food or food ingredient that may provide a health benefit beyond the traditional nutrients it contains."[170] Functional foods are both natural or formulated (designed) foods with components in addition to nutrients that prevent or treat diseases. Potential mechanisms of action for physiologically active compounds include antioxidants, antimutagens, antiinflammatory agents, neuroregulatory substances, to cite a few.[171] Physiologically active components may occur naturally in foods, may be enhanced with biotechnological techniques, or may be added to fortified foods. Excellent reviews of physiologically active substances' potential mechanisms of action and functional food products have been published in recent years.[171–173]

Since many of the phytochemicals in foods are still under investigation, it is premature to emphasize quantification of single functional food components in dietary assessment. However, improvements in individual assessment methods will make it possible to quantify and link these components in functional foods with their potential health benefits. Examples of where individual assessment plays a significant role in providing this linkage can be found in the literature examining fruit and vegetable intakes. There are now databases that can accurately quantify the carotenoid content of foods.[174] As cooking methods, storage, and exposure to air and water are known to affect the carotenoid content of fruits and vegetables, the development of these databases has been a challenge. In the case of assessing carotenoids, for example, it is important to distinguish between pink and white grapefruit (i.e., pink grapefruit has 3740 mg lycopene, whereas white grapefruit has 0 mg). This one simple observation in assessing an individual's intake can have a significant impact on determining the relationship between dietary carotenoids and blood carotenoids and the potential role they may have in cancer risk in groups of individuals.

In assessing diets for research purposes, it is important to consider the level of detail required for other components in foods as well. The assessment issues outlined in the chapter are the same for assessing functional foods. As more components are identified and quantification is possible, databases need to be developed that make analysis of functional foods and their components possible. The knowledge gained in the study of functional foods will drive the type and level of detail in methodology and database development.

27 Use of Food Frequency Questionnaires in Minority Populations

Rebecca S. Reeves and Patricia W. Pace

CONTENTS

INTRODUCTION

Food frequency questionnaires (FFQ) are selected by investigators to assess the usual food or nutrient intakes of groups or individuals because they are relatively easy to administer, less expensive than other dietary assessment methods, and can be adapted to all racial and ethnic populations in the United States.[1] Investigators can also modify these dietary instruments for telephone interviews or a self-administered mailed survey. FFQs are commonly used in epidemiologic studies on diet and disease, and are also chosen by investigators as the dietary assessment instrument in clinical intervention studies. The use of these questionnaires in minority populations in the United States is increasing for several reasons: the country is becoming more racially and ethnically diverse,[2] government agencies have placed emphasis on including minority population in health-related research,[3] and variations in disease incidence and dietary practices within and across ethnic minorities offer important opportunities for examining the role of diet in relation to risk of chronic disease.[4]

    This chapter reviews 16 published studies evaluating the validity or reliability of FFQs used in measuring dietary intakes in adult minority populations in the United States over the last 25 years. Also included in this chapter are selected samples of FFQs and information on obtaining copies of them. Recommendations on the use of these FFQs are discussed.

VALIDITY AND RELIABILITY OF QUESTIONNAIRES

A search of the National Library of Medicine's (Bethesda, MD) MEDLINE system was conducted using various terms such as validity, reliability, reproducibility, diet, FFQ, minority, Hispanic, black, Asian, pacific-islander, and native American to identify articles published between 1980 and 2005. These searches were supplemented by cross-referencing from author reference lists. Articles were selected that described the evaluation of any FFQ that assessed the usual daily diet and provided data on the validity or reliability of the instrument in a specific U.S. ethnic minority population or a diverse population representing at least 40% minority persons. The degree of reliability or validity of the instrument reported was not considered an inclusion factor. Validity and reliability studies that were reported in the same article were considered separately and are referenced in different tables. The measures of performance that were chosen were reliability, comparison of means (when available), and validity because these are usually reported to describe the results of the evaluation of the FFQ. Correlation coefficients were selected as indicators of reliability and validity because they are commonly used and are more easily summarized. Factors that

can influence correlation coefficients are the number of days between the times the questionnaire is administered (reliability coefficients) and the number of days of food records or 24 h recalls used for the referent period (validity coefficients). Adjusted and unadjusted correlation coefficients are reported in the tables. The methods for adjusting the coefficients are discussed in each article.

Terms used to describe FFQs in the tables are as follows:

Quantitative: Quantity of food consumed was estimated using weights, measures, or food models. Responses were open ended.

Semiquantitative: Quantity of food consumed was estimated using a standard portion size, serving, or a predetermined amount, and the respondent was asked about the number of portions consumed.

Nonquantitative: Quantity of food was not assessed.

Self-administered: An adult completed the dietary assessment without assistance.

Interviewer administered: A trained interviewer collected the dietary information from the adult in a one-on-one setting.

Diverse Studies: Publications that include various combinations of racial or ethnic groups.

Minority Studies: Publications that include only one racial or ethnic group.

The 16 studies reviewed for this chapter were divided into two groups based on ethnic participation. Within the group labeled "Minority" studies, three consisted of only Black subjects,[5–7] one of Asian,[8] and one of Hispanic subjects.[9] In the group labeled "Diverse," five studies included Black and White subjects,[10–14] one study Black and Hispanic,[15] two studies Black, Hispanic, and White subjects,[16,17] one study Hispanic and White,[18] one study Asian and White[19] and one recruited Asian, Black, Hispanic and White subjects.[20]

The review of the validation studies on FFQs was not conclusive. The median correlations (Table 27.1) between questionnaire-based estimates of nutrient intakes and estimates derived from referent methods were not consistent for ethnic groups, but trends were suggested. The median correlations for Black males and females across validations studies were in the range of 0.23 to 0.42; for Hispanic females, 0.32 to 0.49 except for one study conducted in Starr County, Texas, which reported a median correlation of 0.75; for White males and females, 0.53, and Asian males and females, 0.53. If it is considered that a measure of ≥ 0.05 is satisfactory or good, 0.30 to 0.49 is fair, and < 0.30 is poor,[19] then these median correlations suggest that Black and Hispanic groups do not perform well on FFQs.

The validation correlations for total energy, total fat, and vitamin A were inconsistent and in some cases very low across studies. In Table 27.2 the correlation coefficients for total fat ranged from 0.23 to 0.65 with the higher correlations usually found in the Asian or White populations. A similar trend was found for energy among the various groups. The correlation coefficients for Hispanic and Black populations were commonly in the range of 0.24 to 0.43, but in the White and Asian groups the coefficients ranged from 0.41 to 0.61. Values for vitamin A were more inconsistent ranging from 0.15 to 0.67 across all groups. The number of days of food records and recalls that are compared against FFQs can explain some of these low correlations especially for vitamin A. Many days are required to provide a precise estimate of vitamin A intake, and in these studies the greatest number of daily recalls or records collected over 1 year was 28. Even in this study, certain subgroups correlations for vitamin A were still 0.23 and 0.29.

The study[5] that reported serum nutrient concentrations of carotenoids, vitamin E, lycopene and lutein as a referent reported correlations that were much lower for smokers (<0.02) than for nonsmokers (<0.40). The investigators concluded that their FFQ is reasonably valid for use in a southern, urban, low-income Black population except for the analysis of lutein and lycopene. Another study comparing adipose tissue fatty acids and dietary fat intake collected from eight different 24 h recalls and a 200-item FFQ confirmed previous findings that 24 h recalls are valid for assessing dietary intake of different types of fat. The correlation of FFQ values for fat intake and adipose tissue fatty acids resulted in correlations on the order of 0.4 to 0.6.[14]

In most of the studies reviewed, the FFQ overestimated the mean of the referent recall or records and in some cases by nontrivial amounts. One explanation for this difference was again the number of days of recalls or records collected for comparison to the FFQ. Depending on which nutrient is of interest in the study and the time period the participant is asked to recall on the FFQ, more than 4 to 7 days may be required to capture the actual intake of the individual.

The reliability coefficients across all diverse and minority studies were much higher than the validity coefficients (Table 27.3). The median correlations for Black males and females across studies were in the range of 0.51 to 0.88; for Hispanic females, 0.51 to 0.58 except for one study conducted in Starr County, Texas, which reported a median correlation of 0.85; for White males and females, 0.64 to 0.71. These coefficients would suggest that, within minority and diverse populations, the FFQ can usually describe, with some consistently, the food or nutrient intakes of individuals when administered at two points in time.

In most of the studies reviewed, the investigators made suggestions and recommendations for improving the performance of the FFQ in minority populations. It was repeatedly mentioned that a "gold standard" referent method was not available, so collecting valid dietary intake data remains challenging. The need to identify a complete food list on the FFQ that captures all of the foods in the usual diet of the study population was highly recommended. Depending on the study, the food list should

References	Sample	Instrument	Response categories	Validation Standard	Design	Results
Stram et al.[20]	African-American 151 BM, 186 BF Japanese 224 JM, 222 JF Hispanics 136 HM, 123 HF Caucasians 264 WM, 264 WF	Based on Hawaiian Cancer Research Center FFQ; quantitative by placing serving size photos beside the amount category; eight frequency categories for food and nine for beverages	Unknown; highest response for food is >2 times/day; for beverages, 4 times/day	Three random, 24 h recalls conducted by phone	An initial FFQ was mailed to random sample of prospective subjects; 3 – 24 h recalls were collected by phone after the initial contact; a second FFQ was sent 4 to 6 weeks after the recalls were completed; the subjects' responses on the second FFQ were compared against the 24 h recall values	Corrected correlations for the regression of mean 24 h recalls on the second FFQ by ethnic sex/group for following nutrients: *Total kilocalories:* BM 0.16 BF 0.17 JM 0.34 JF 0.19 HM 0.33 HF 0.40 WM 0.48 WF 0.28 *Total Protein:* BM 0.17 BF 0.22 JM 0.31 JF 0.25 HM 0.27 HF 0.35 WM 0.51 WF 0.38 *Total Fat:* BM 0.29 BF 0.24 JM 0.41 JF 0.32 HM 0.33 HF 0.57 WM 0.57 WF 0.39 *Vitamin A:* BM 0.30 BF 0.22 JM 0.45 JF 0.49 HM 0.62 HF 0.52 WM 0.59 WF 0.58
Suitor et al.[17]	Initially who provided three diet recalls: WF: 54 BF: 20 HF: 18 Subjects who provided FFQ2 and FR = 62 but no ethnic breakdown	Willett (Harvard Un.) 111 items, self-administered (edited foods, portion size information deleted; developed as a prenatal FFQ	Unknown (recall of past 2 weeks)	3 – 24 h recalls conducted by phone	Compared female's report of food intake between food recalls and FFQ2 which were mailed.	Pearson correlation (unadjusted, log transformed values) between FFQ2's and recalls: *Energy:* 0.41 *Protein:* 0.33 *Vitamin A:* 0.12 *Calcium:* 0.52
Coates et al.[5]	91 BF	HHHQ: original 98 item FFQ revised to include 19 ethnic/regional foods resulting in 117 item FFQ; past year	4 (times/day, week, month or year)	Serum carotenoids, α-tocopherol, lycopene, crytoxanthin, lutein/xeaxanthin	Compared female's FFQ responses to 15 ml nonfasting venous blood sample	Pearson's correlations (log-transformed, unadjusted) between FFQ and serum for nonsmokers: *α-Tocopherol (food only):* 0.19 *Provitamin A carotenoids:* 0.37 *β-Carotene:* 0.34 *Cryptoxanthin:* 0.37 *Lycopene:* –0.02 *Lutein:* 0.12

Pearson's correlations (log-transformed, unadjusted) for smokers were:
α-Tocopherol: −0.12
Provitamin A carotenoids: 0.07
β-Carotene: 0.11
Cryptoxanthin: 0.18
Lycopene: −0.02
Lutein: 0.11
Results suggest that FFQ was reasonably valid for black females. Analysis of lycopene and lutein may not reflect validity of the assessment of these nutrients.

Forsythe et al.[10]

80 BF ethnic mix of African blacks, Asian Indians, Caribbean whites, Guyanese Amerindians, and Caribbean Chinese

FFQ: 82 items compiled from Caribbean food tables, Willett FFQ, Stower prenatal food guide, and regional recipes

Unknown (weekly intake patterns)

3, 24-h recalls

Compared female's report of intake against 3, 24-h recalls, one recall at prenatal visit and two others by phone during next 7 days. Second FFQ administered 3 weeks later

Paired *t*-tests examined differences between the food recall means and the means of the FFQ at time 1. Most of the 14 nutrients were significantly different using the two instruments, with the exception of saturated fat, vitamin A and caffeine. The percentage of energy from protein, CHO, and fat showed no significant differences on either method of assessment. Mean difference scores were computed between food recalls and time two FFQ responses in the subsample. Significant differences were found for energy, CHO and vitamin C and the percentage of energy from CHO The 24 h recalls did not fully support the responses provided on the FFQ's

Those returning FFQ2 were unrepresentative of the original sample	Pearson's correlation (unadjusted, log-transformed values) between FFQ1 and FFQ2: *Energy:* 0.92 *Protein:* 0.87 *Vitamin A:* 0.89 *Calcium:* 0.80

include foods that will contribute substantially to the nutrients under investigation. This importance of a food list capturing the usual intake of study participants was demonstrated in the study conducted in Starr County, Texas. Because of the limited number of overall foods that the participants consumed, the food list of the FFQ was able to reflect the major sources of food and nutrient intake of these individuals. Because of this unique situation, the nutrient values from the FFQ were more likely to agree with the values from the food records.

Several suggestions were made regarding the administration of the dietary assessment forms in minority populations. It is recommended that any staff person who is responsible for interviewing a subject for any dietary assessment measure should be of the same ethnic background of the subject irrespective of whether the conversation takes place in person or over the phone.

Educational attainment of participants appeared to be a major determinant of the validity of the dietary assessment measures in several studies. Agreement between the food frequency and the criterion measure of 24 h dietary recalls was substantially compromised among individuals with less than a high school education. This was particularly true within a Hispanic group of one study. In another study, it was found that increasing validity with increased education suggested that poor education is a barrier to accurate completion of the FFQ, the food record, or both. In this same study, low educational levels did not affect reliability measures. These findings would suggest that special efforts are needed when using dietary assessment tools with participants of low educational status or culturally diverse dietary habits. Small group instruction and practice in using the dietary tools could improve the dietary information collected. Instructing participants by videotape on completing dietary forms is another method to help improve the accuracy of information.

EXAMPLES OF FFQS

This section includes examples of the FFQs that have been used or adapted for studies of minority populations. This is not intended to be a complete list of all the questionnaires that were used in the 16 studies reviewed, nor is inclusion in this set of examples an implied endorsement of one instrument. The FFQs included are those that are widely available. The FFQs in this set were originally selected by an investigator for modification to his or her population or are the actual instrument used to assess dietary intake. Readers who are interested in using or adapting these dietary assessment tools should contact the resource persons listed with each tool.

In selecting a FFQ, the reader should consider several points:

1. What is the primary purpose of the project or study you are planning to conduct and how does the food intake data relate to the outcome?
2. For what length of time are you interested in assessing food intake? 12 months, 3 months?
3. How current is the food list? Does it reflect the current food supply?
4. Does the food list contain foods that contribute significantly to the nutrients you are interested in assessing?
5. Does the food list reflect the traditional or cultural foods eaten by your population?
6. Is the nutrient software analysis program updated on a regular basis to reflect the changing composition of our food supply?
7. Can you individualize the food list of the FFQ to your specific population? How much latitude do you have to modify the existing questionnaire? Can the existing software be modified to reflect the changes you wish to make?
8. Request a list of the validity and reliability studies that investigators have conducted using the FFQ you are considering. Were these studies conducted with populations similar to the groups of persons you wish to recruit into your study?

Diet History Questionnaire

Investigators at the National Cancer Institute have developed a new self-administered, scannable FFQ, the Diet History Questionnaire (DHQ). This instrument was designed with particular attention to cognitive ease and has been updated with respect to the food list and nutrient database using national dietary data (USDA's 1994–1996 Continuing Survey of Food II). This instrument is available on the Internet and can be downloaded from the site http://appliedresearch.cancer.gov. The data analysis program that accompanies this questionnaire became available for downloading from this site in November, 2005. Validity studies have been completed but not within minority populations.

Harvard University FFQ ("Willett Questionnaire")

Several FFQs are available from the Harvard School of Public Health including this current version designed for use in African-American populations. This is a scannable, self-administered FFQ and is referred to as the "green version." This questionnaire

contains a section on the assessment of vitamin and mineral intake, which is followed by approximately 174 food items. The assessment period of the FFQ is the past 12 months, and respondents are asked to average seasonal use of foods over the entire year. This tool is designed to enhance an individual's ability to respond more appropriately to the food items. For example, the response categories are individualized for each item ranging from "never" to "six or more times/day" and probing questions are asked regarding specific characteristics of foods consumed. Information can be found at https://wchanning.bwh.harvard.edu/KIDS/files.

Fred Hutchinson Cancer Research Center FFQ ("Kristal Questionnaire")

This questionnaire links answers from an extensive list of food questions to specific food frequency items to derive more precise nutrient estimates for those items. The FFQ is machine-readable and is accompanied by a software system to process the questionnaire. The format has nine frequency categories and a small, medium, and large portion size. The food list is composed of 122 foods and is preceded by 19 behavioral questions related to preparation techniques and types of food selected. Answers to these questions are used directly in the program to choose more appropriate nutrient composition values for certain foods in the food list. This questionnaire is available in Spanish.

Cancer Research Center of Hawaii's Dietary Questionnaire (The Hawaii Cancer Research Survey)

The Cancer Research Center of Hawaii, part of the University of Hawaii, has developed a variety of quantitative FFQs for use with the multiethnic population of Hawaii. Recently a questionnaire was developed to assess the diets of the five main ethnic groups in the Hawaii-Los Angeles Multiethnic Cohort Study: Hispanics, African-Americans, Japanese, Hawaiians, and Caucasians. Unlike previous questionnaires, the cohort questionnaire was designed to be self-administered. Three-day measured food records were collected from all ethnic groups in advance and were used to identify food items for inclusion in the questionnaire. To ensure more accurate specifications of amounts usually consumed, photographs showing three portion sizes were printed on the questionnaire. A customized, and in part ethnic-specific, food composition table was developed for the cohort questionnaire. A calibration study, comparing questionnaire responses to three 24 h recalls for the same subjects showed highly satisfactory correlations, particularly after energy adjustment.

New Mexico Women's Health Study, Epidemiology, and Cancer Control Program, University of New Mexico Health Sciences Center

This FFQ was developed for an adjunct trial to the New Mexico Women's Health Study, a population-based case-control study of breast cancer in non-Hispanic and Hispanic women. The 140-item FFQ was a modified version of a questionnaire developed by the Human Nutrition Center, University of Texas School of Public Health, Houston, for a Texas Hispanic population. The FFQ was revised to include important food sources of energy, macronutrients, and vitamins that were identified following an analysis of food intake recalls. Emphasis was placed on specific rather than grouped food items because recall is considered better for specific items. Usual portion size, based on two-dimensional food models, included data on number of servings, the type of food model, and thickness of food. Common serving descriptions were included for each food item and were based either on food models or a defined portion size. This FFQ was translated into Spanish.

Insulin Resistance Atherosclerosis Study Food Frequency Questionnaire, School of Public Health, University of South Carolina

The Insulin Resistance Atherosclerosis Study (IRAS) provided the opportunity to evaluate the comparative validity and reproducibility of a FFQ within and across subgroups of non-Hispanic White, Hispanic, and African-American individuals. The 114-item questionnaire was modified from the National Cancer Institute — Health Habits and History Questionnaire, whichwas originally created by Gladys Block, Ph.D. This interviewer-administered FFQ was modified to include regional and ethnic food choices that were commonly consumed by the participants of the study. The FFQ contains nine categories of possible responses ranging from "never or less than once a month" to "two or more times a day." Portion sizes are determined as "small, medium, or large compared to other men/women about your age." At the end of the FFQ an open-ended question is asked to describe foods that are usually eaten "at least once a week" and were not asked on the FFQ. Also, nine additional questions probe for information regarding common food preparation methods, specific fats used in cooking, and frequency of consumption of fruits and vegetables.

28 Methods and Tools for Dietary Intake Assessment in Individuals vs. Groups

Marian L. Neuhouser and Ruth E. Patterson

CONTENTS

INTRODUCTION

Dietary intake is an important, modifiable determinant of health and longevity. Comprehensive reviews of the literature have consistently concluded that there are clear causal links between food intake and major causes of morbidity and mortality, such as coronary heart disease, cancer, diabetes, and obesity.[1–3] In addition, undernutrition contributes to substantial health problems, particularly in resource-poor countries.[4]

Given the importance of diet in human health, assessment of dietary intake plays a pivotal role in efforts to improve the health of individuals and populations throughout the world. Dietary intake data are used for three major purposes:

1. At the individual level, assessment of dietary intake is necessary for determining a person's dietary adequacy or risk, assessing adherence to recommended dietary patterns, and tailoring education and counseling efforts.
2. Dietary intake assessment is an integral part of research studies investigating how diet determines the health of individuals and populations. Etiologic studies assess dietary intake as an exposure for association with disease outcomes. Behavioral research assesses dietary intake (or change in intake) as an outcome in studies designed to develop and test strategies to encourage adoption of healthful eating patterns.

3. Finally, at the population level, assessment of dietary intake is necessary to identify national health priorities and develop public health dietary recommendations. These data are used to determine the success of public health interventions to improve dietary patterns and for identification of population subgroups at risk or in need of special assistance. Nutrition monitoring also serves as a key role in food assistance programs, fortification initiatives, food safety evaluations, and food labeling programs.

It is clear that dietary assessment is a cornerstone of efforts to improve the health of individuals and groups. However, there are significant concerns about the accuracy and usefulness of self-reported dietary data. The challenges associated with assessing dietary intake are well known and have to do with day-to-day variation in intake, respondent reporting errors and biases, limitations of the assessment instruments, and error in food composition databases.[5] Several different assessment methods and tools have been developed to address these difficulties, and each method has different strengths and weaknesses with regard to the type and quality of data produced. In addition, there are significant differences among these assessment methods in practical matters of respondent burden and cost. Therefore, it is necessary to carefully consider the specific objectives of the dietary assessment as a precursor to choosing the best or most appropriate method. Perhaps the first and most important question is whether the data will be used for assessing intake in individuals or groups.

Here, we describe the three major types of dietary assessment methods: (1) food records and 24-h dietary recalls, (2) food frequency questionnaires (FFQs), and (3) brief assessment instruments. We summarize both the scientific and practical advantages and disadvantages of each of these methods. Then, we consider the use of these three dietary assessment methods for assessing diet in individuals vs. groups. More specifically, we discuss these three assessment methods when used for: (1) determination of an individual's dietary adequacy for purposes of counseling, (2) research studies of dietary intake and disease risk, and (3) nutrition monitoring of populations. Additional information on dietary assessment can be found in the Chapters 26 and 29.

A DESCRIPTION OF THE THREE MAJOR DIETARY ASSESSMENT METHODS

FOOD RECORDS AND DIETARY RECALLS (RECORDS/RECALLS)

For many years, food records were considered the "gold standard" of dietary assessment methods. Briefly, food records or diaries require individuals to record everything consumed over a specified period of time, usually 1 to 7 days. Participants are typically asked to carry the record with them and to record foods as eaten. Some protocols require participants to weigh or measure foods before eating, while less stringent protocols use models and other aids to instruct respondents on estimating serving sizes. While most protocols specify that the food record be reviewed by a dietitian to confirm portion sizes of foods, fats added in cooking and at the table, and other food details, a recent study showed when detailed instructions about completion of the food record are given to participants, the review and documentation by a dietitian may not be necessary.[6] Regardless of the data collection protocol, ultimately the food consumption information from records/diaries is entered into a specialized software program for calculation of nutrient intakes. This data-entry step is a time-consuming task and requires trained data technicians or nutritionists.

Food records are somewhat burdensome for clients or study-participants to complete. In the foreseeable future, the use of personal digital assistants (PDAs), digital cameras, mobile telephones, and other electronic devices both to record and transmit food record data will likely alleviate some of the participant burden.[7,8] In a crossover intervention study, diabetic patients were asked to record their diet and blood glucose values using either traditional methods or a hand-held electronic device that would transmit the data to medical staff. The digital device was much preferred by the patients; the ease of operation reported by 95% of patients is likely to result in better quality food recording than a burdensome paper and pencil record.[9]

A dietary recall is a 20 to 30 min interview in which the respondent is asked to recall all foods and beverages consumed over the previous 24 h. Dietary supplement use may be included in the recall although methods for doing so are still under development (Dr. Lisa Harnack, personal communication, 2005). Dietary recall-interviews can be conducted in person or by telephone. In some settings, this information is captured on paper forms and subsequently entered into a software program for nutrient analysis. However, ideally the interview will be conducted simultaneously with direct data entry into the software program. It is very important that the interviewer be well-trained; tone of voice, body posture (when in-person), and reactions to participant descriptions of foods consumed can influence the quality of the data.

The use of portion size estimate aids increases the reliability of the recall data.[10,11] Recalls conducted in person utilize three-dimensional food models while those conducted over the telephone use two-dimensional booklets. For the latter approach, the portion size aids should be sent to clients or study participants in advance of the recall. Before the recall begins the interviewer should ask the participant to retrieve the portion size aid to use during the course of the interview. In some special population groups, in-person training in the proper use of the portion size estimators may improve the quality of the data.[12] Among older adults with poor memory, additional memory cues such as recall of the previous day's activities may be needed to stimulate recollection of food intake.[13]

One of the most widely used approaches to collect standardized dietary recall data is the USDA Automated Multiple Pass method that is currently in use in the integrated NHANES–CSFII survey, "What We Eat in America." [14–16] This five-step method includes the following sequence of queries:

1. *Quick list*: Trained interviewers first ask participants to list all foods and beverages consumed during the previous 24 h.
2. *Forgotten food list*: Interviewers probe for details about foods or additions to foods that are frequently forgotten. Examples of foods that are often added to this list are milk on cereal, sugar in coffee, and between meal snacks and beverages.
3. *Time and place*: The interviewer asks the participant to recall the time of day and the location (e.g., home, school, restaurant, etc.) of the food consumption. This time and place memory probe frequently helps participants to better recall the foods consumed.
4. *Detail cycle*: The interviewer probes for details about each food named in the quick list and forgotten list, including cooking methods, portion size, brand names, type, and amount of fat added during cooking and at the table. These details include the collection of information on mixed dishes and recipes. The questions in the detail cycle are highly standardized with computerized prompts to ensure uniform data collection.
5. *Final review*: The interviewer does a final review of the foods and beverages consumed and queries participants about any additional items that may have been omitted.

Advantages and Disadvantages of Records/Recalls

Both records and recalls provide the same type of data: detailed information on all foods and beverages consumed on specified days. In theory, a food record provides a "perfect" snapshot of intake. In practice, there are significant limitations associated with this method for assessing food intake. The principal problems are the large respondent burden of recording food intake and the impact on usual food consumption caused by record keeping. Respondents may alter their normal food choices merely to simplify record keeping because they are sensitized to food choices. The latter reason appears more likely among women,[17] restrained eaters,[18] obese respondents,[19] or participants in a dietary intervention.[20–23] Other sources of error by respondents include mistakes or omissions in describing foods and assessing portion sizes.

Unannounced, interviewer administered 24-h dietary recalls are often recommended because respondents cannot change what they ate retrospectively.[24] One major disadvantage of dietary recalls is that they rely on the respondent's memory and ability to estimate portion sizes, although the latter limitation can be alleviated by the use of portion size aids. In addition, it cannot be verified that social desirability does not influence self-report of the previous day's intake.[25] A noteworthy benefit of recalls is that they are appropriate for low literacy populations and children.[26,27]

Both records and recalls are expensive and time-consuming methods of assessing dietary intake. However, the major scientific issue with records/recalls concerns the issue of day-to-day variability in intake, which means that several days of records/recalls are required to characterize usual intake. Using data on variability in intake from food records completed by 194 participants in the Nurses Health Study,[28] the number of days needed to estimate the mean intakes for individuals within 10% of "true" means would be 57 days for fat, 117 days for vitamin C, and 67 days for calcium. For estimating food consumption for individuals, variability can be even greater. For example, the number of days needed to estimate the following foods within 10% of "true" means would be 55 days for white fish and 217 days for carrots. Unfortunately, research has shown that reported energy intake, nutrient intake, and recorded numbers of foods decreases with as few as 4 days of recording dietary intake.[29] These changes may reflect reduced accuracy and completeness of recording intake or actual changes in dietary intake to reduce the burden of recording intake. In either case, there are considerable limitations on the usefulness of this methodology for characterizing usual intake in individuals.

FOOD FREQUENCY QUESTIONNAIRES

FFQs were developed for conducting research on dietary intake and chronic diseases, such as heart disease and cancer. Because these diseases develop over 10 or more years, the biologically relevant exposure is long-term diet consumed many years prior to disease diagnosis. Therefore, instruments that only capture data on short-term or current intake (i.e., food records or recalls) are generally of limited usefulness for chronic disease research.

FFQs are designed to capture standardized, semiquantitative data on current or past, long-term diet. Although these questionnaires vary, they usually include three sections: (1) adjustment questions, (2) the food list, and (3) summary questions. Adjustment questions assess the nutrient content of specific food items. For example, participants are asked what type of milk they usually drink and are given several options (e.g., whole, skim, and soy), which saves space and reduces participant burden compared to asking for the frequency of consumption and usual portion sizes of many different types of milk. Adjustment questions also permit more refined analyses of fat intake by asking about food preparation practices (e.g., removing skin from chicken) and types of added fats (e.g., use of butter vs. margarine on vegetables).

The main section of an FFQ consists of a food or food group list, with questions on usual frequency of intake and portion size. To allow for machine scanning of these forms, frequency responses are typically categorized from "never or less than once per month" to "2+ per day" for foods and "6+ per day" for beverages. Portion sizes are often assessed by asking respondents to mark "small," "medium," or "large" in comparison to a given medium portion size. However, some questionnaires only ask about the frequency of intake of a "usual" portion size (e.g., 3 ounces meat).

The food list in a FFQ is chosen to capture data on: (1) major sources of energy and nutrients in the population of interest, (2) between-person variability in food intake, and (3) specific scientific hypotheses. The choice of a food list is part data-driven and part scientific judgment. One data-based approach uses record/recall data to determine the foods that are the major nutrient sources in the diet (i.e., the contribution of specific foods to the total population intake of nutrients). Information on food sources of nutrients in the American population has been an important part of the NHANES and CSFII surveys and now the integrated "What We Eat in America" survey.[14,15,30] Details about nutrients are limited, though, for foods consumed in specific population groups that may not be included on the food list (e.g., immigrants who retain their food habits) and there are very limited data on bioactive constituents of foods that are not considered nutrients, but nonetheless have biological actions (e.g., isothiocyanates).

However, a food is only informative if intake varies from person to person such that it discriminates between respondents. Therefore, another data-based approach to choosing the food list is to start with an extensive list of foods that is completed by a representative sample of the larger population. Stepwise regression analysis is performed where the dependent variable is the nutrient and the independent variable is frequency of consumption of foods.[28] In this process, the computer algorithm ranks foods by the degree to which they explain the most between-person variance in nutrient intake, which is reflected in change in cumulative R^2. In addition to these two data-driven methods, items are often added to a questionnaire because of specific hypotheses (e.g., does consumption of soy foods reduce breast cancer risk?).

A particularly challenging issue in FFQ food lists has to do with assessing intake of mixed dishes. For example, many FFQs ask about frequency of pizza consumption. However, from a nutrient perspective, there is no accurate way to define "pizza." Depending on whether it is meat or vegetarian, thick or thin crust, tomato or pesto sauce (and so forth), pizza may be either low-fat and high-carbohydrate or extremely high-fat and high-protein. However, it is unreasonable to ask individuals to disaggregate their pizza into servings of: (1) breads, (2) vegetables, (3) meats, (4) cheese, and (5) added fats. Therefore, FFQs typically strike an uneasy compromise between asking about some mixed dishes (e.g., pizza, hamburgers, and tacos) while also asking the respondent to provide information on foods contained in their mixed dishes: "Cheese, including cheese added to foods and in cooking." Unfortunately, asking about both "lasagna" and "Cheese in cooking" presents the peril of double counting. There are little or no data to guide an investigator in making these judgments.

Finally, to save space and reduce respondent burden, similar foods are often grouped into a single line item (e.g., white bread, bagels, and pita bread). When grouping foods, important considerations include whether they are nutritionally similar enough to be grouped and whether the group will make cognitive sense to the respondent. For example, a food group composed of rice, macaroni, and cooked breakfast cereal may be nutritionally sensible. However, this question could be difficult to answer, because it requires summing food consumption events across different meal occasions.

Finally, FFQ summary questions that ask about usual intake of fruits and vegetables are often included in the questionnaire, because the long lists of these foods needed to capture micronutrient intake can lead to over-reporting of intake.[31] Algorithms using the summary question are typically applied to the sum of the line items all fruits and vegetables consumed to give a more conservative estimate of fruit and vegetable consumption.

Assessing the Reliability and Validity of FFQs

Because records and recalls are open-ended, they can (in theory) be applied in a standardized manner across populations with markedly different eating patterns. However, as noted above, FFQs are close-ended forms with limited food lists. Because the food list varies from questionnaire to questionnaire, every FFQ will have different measurement characteristics. In addition, a questionnaire with appropriate foods and portion sizes for one population group (e.g., older non-Hispanic white men) may be wholly inappropriate for another subgroup (e.g., adolescent African American females). Finally, given the changes in the food supply over time, such as the introduction of specially manufactured low-fat or low-carbohydrate foods, questionnaires can become obsolete. Therefore, the measurement characteristics (i.e., reliability and validity) of an FFQ need to be assessed for each new questionnaire and each new population group being assessed.

Reliability generally refers to reproducibility, or whether an instrument will measure an exposure (e.g., nutrient intake) in the same way twice on the same respondents. Validity, which is a higher standard, refers to the accuracy of an instrument. Generally, a validity study compares a practical, epidemiologic instrument (e.g., an FFQ) with a more accurate but more burdensome and expensive method (e.g., dietary recalls).

Reliability and validity of an FFQ are typically investigated using measures of bias and precision. Bias is the degree to which the FFQ accurately assesses mean intakes in a group. Lack of bias is especially important when the goal is to measure absolute intakes for comparison to dietary recommendations or some other objective criteria. For example, when the aim is to estimate

how close Americans are to meeting the dietary recommendation to eat five servings of fruits and vegetables per day, it is critical to know whether the assessment instrument being used under- or overestimates fruit and/or vegetable intake. Precision concerns whether an FFQ accurately ranks individuals from low to high nutrient intakes, which is typically the information needed to assess associations of dietary intake with risk of disease. It is important to remember than an instrument can be reliable without being accurate (valid or precise). That is, it can yield the same nutrient estimates two times and be wrong (e.g., biased upward) both times. Alternatively, an instrument can be reliable and consistently yield an accurate group mean (e.g., unbiased), but have poor precision such that it does not accurately rank individuals in the group from low to high in nutrient intake.

A reliability study compares intake estimates from two administrations of the FFQ in the same group of respondents. If an instrument is reliable, the mean intake estimates should not vary substantially between the two administrations. In addition, correlation-coefficients between nutrient intakes estimated from two administrations of the FFQ in the same group of respondents should be high, and are generally in the range of 0.6 to 0.7. Reliability is easy to measure and gives an upper bound as to the accuracy of an instrument. While a high reliability-coefficient does not imply a high validity coefficient, a low reliability-coefficient clearly means poor validity. That is, if an instrument cannot measure a stable phenomenon (such as usual nutrient intake) the same way twice, it clearly cannot be accurate.

In a validity study, bias is assessed by comparing the mean estimates from an FFQ to those from multiple days of records/recalls in the same respondents. This comparison allows us to determine whether nutrient intake estimates from an FFQ appear to be under- or over-reported in comparison to the criterion measure. Precision is measured as the correlation coefficients between nutrient intake estimates from the FFQ in comparison to a criterion measure, and typically range from 0.4 to 0.6. However, lower correlation coefficients (<0.4) are not unusual for nutrients that are poorly estimated with an FFQ, such as energy.[32] In addition, inclusion of dietary supplement use will often markedly improve correlation-coefficients (>0.8), because supplement use may be more accurately assessed and its doses can be extraordinarily high compared to dietary intake, and thereby markedly increase the variability in intake for a nutrient. Some studies also assess precision by ranking nutrient intake estimates, dividing them into categories (e.g., quartiles) and comparing these to similar categories calculated from another instrument. However, classifying a continuous exposure into a small number of categories does not reduce the effects of measurement error, and, therefore, this analysis does not provide additional information above correlation-coefficients.[33]

The theory behind these (so-called) validity studies is that the major sources of error associated with FFQs are independent of those associated with records and recalls, which avoids spuriously high estimates of validity resulting from correlated errors. The errors associated with FFQs are the limitations imposed by a fixed list of foods and the respondents' ability to report usual frequency of food consumption (and usual portion sizes) over a broad time frame. Since recent studies have documented the increase in typical food and meal portion sizes of American meals over the past 30 years, the fixed portion sizes on FFQs may quickly become obsolete.[34,35] For example, most FFQs list a 12-ounce soft drink as a medium portion, when it is more likely a "small" using today's portion standards. In contrast, diet records are open-ended, do not depend on memory, and permit measurement of portion sizes. Errors in food records result from coding errors and changes in eating habits while keeping the records. Errors in recalls results from estimation of portion sizes, participant memory, and coding errors. All dietary assessment methods are limited by the food composition databases used to derive nutrient estimates.

Nonetheless, it is apparent that there are correlated errors between FFQs and records or recalls.[36,37] Social desirability could influence how participants record or recall food intake across all types of dietary assessment instruments.[17,18,38] Participant errors in estimating portion sizes could bias recall and FFQ estimates of intake in similar ways. There are also correlated errors in nutrient databases. Finally, research using doubly labeled water to estimate total energy expenditure and 24-h urine samples to estimate protein consumption have demonstrated significant underreporting of energy and protein intakes from records, recalls, and FFQs.[36,39] This underreporting may vary by participant characteristics such as age, sex, body mass index, and various psychosocial characteristics.[19,20,38] Taken together, current data suggests that it is important to be aware of the limitations of records and recalls as criterion measures of dietary intake and cautiously interpret results using these assessment tools.

A final note is that an FFQ cannot, in and of itself, be validated. Only individual nutrient intake estimates can be validated by comparison of a nutrient estimate from the FFQ to a more accurate measure.

Advantages and Disadvantages of FFQs

The major advantage of FFQs is that they attempt to assess usual long-term diet, either current or in the past. In addition, they have relatively low respondent burden and are simple and inexpensive to analyze, because they can be self-administered and are machine scannable. A disadvantage of these questionnaires is that respondents must estimate usual frequency of consumption of approximately 100 foods and the associated usual portion sizes. These types of questions (i.e., this cognitive task) can be exceedingly difficult for many respondents, as evidenced by the prevalence of energy estimates from FFQs that are well outside of the realm of plausibility.[28,40] For example, it is not unusual for respondents to report usual energy intakes that are less than 500 kcal/day or greater than 5000 kcal/day. In addition, the format of the questionnaire itself is not user-friendly. Because FFQs are machine-scannable, respondents need to indicate their responses by filling in circles in a food-by-frequency matrix, similar to that used in standardized testing. Some population groups may be unfamiliar or uncomfortable with such

data collection methods. As might be hypothesized, validity studies of FFQs suggest that these forms may be less valid in less educated respondents.[41] Elderly participants with poor eyesight may have difficulty completing the questionnaire.

Another major disadvantage of these questionnaires is related to the close-ended nature of the form. The limited food list and fixed portion size will not be appropriate for all individuals in a population and different forms have different measurement characteristics across various populations. For example, use of an FFQ with a typical American food list is not likely to be useful in some special populations or in places outside the United States. There is recent work, though, to develop culturally appropriate FFQs. For example, one FFQ is available for use in rural populations in the southern United States[42] and another for use in South Africa.[43] Therefore, data from different FFQs are not directly comparable, nor are data from the same FFQ used in different populations, nor are data from the same FFQ used at different points in time (because of changes in the food supply). Finally, dependent upon the food list chosen by an investigator, the validity of nutrient intake estimates will vary from nutrient to nutrient.

Brief Dietary Assessment Instruments

Comprehensive dietary assessments (records/recalls and FFQs) are not always necessary or practical, which has led to the development of a diverse collection of brief assessment instruments. These brief methods include three general types: (1) ecologic-level measures such as food disappearance data or household food inventories, (2) short instruments that target a limited number of foods and nutrients, and (3) questionnaires that assess dietary behaviors.

Ecologic-Level Measures

One well-known ecologic assessment of dietary intake is per capita food consumption estimated using national data on the total food supply. Publications from the FAO provide data on a country's total food supply from which nonconsumption uses (such as exports, livestock feed, and industrial uses) are subtracted, after which the total remaining food available can be divided by the population to obtain the per capita estimate of intake. These population intakes have been correlated with disease incidence across countries in provocative hypothesis generating studies.[44–47] One caution about the use of these data is that it is not always clear how the nonhuman uses are tallied and subtracted due to fluctuating market demand for the agricultural goods. For example, soybean farmers may sell their crop in 1 year to an oil manufacturer for human use, but in the process of oil purification, some of the by-product may be drawn off and sold for industrial use. Thus, the best use of food supply data is to give an overall snapshot of food availability.

Other ecologic measures, such as supermarket sale receipts, have been developed and evaluated.[48,49] Household food inventories are another example of ecological measures of diet. In one study, the presence (in the house) of 15 high-fat foods was found to correlate with household members dietary fat intake at 0.42 ($p < .001$).[50] Individuals with ≤4 high-fat foods in their house had a mean of 32% energy from fat compared to 37% for those with ≥8 high-fat foods. Poor household food availability has also been shown to be significantly associated with greater individual-level measures of food insecurity.[51] Household inventories may be especially good assessment tools to use with new immigrants where language or cultural barriers may preclude use of records, recalls or FFQs.[52,53]

Targeted Instruments

Dietary assessment instruments that measure a limited number of foods or nutrients are most useful when the target food/nutrient is not distributed throughout the food supply. For example, dietary fat is widely distributed in dairy foods, meats, added fats, desserts, prepared foods, etc. Therefore, short instruments that attempt to estimate fat intake tend to be biased and imprecise.[54,55] Alternatively, intake of the isoflavones genestein and daidzain, which are largely limited to soy foods, can be captured with relatively short instrument (15 foods).[56] Similarly, a focused recall that can be completed in 5 to 7 min has been shown to give carotenoid estimates that are comparable to those obtained from a full 30-min, 24-h recall.[57] In many situations, the lower participant or patient burden, cost, and staff time associated with targeted instruments may be strong motivations for their use.

Food Checklists

Food checklists and food preference lists have been developed primarily for use as screening tools. In format they are similar to a short FFQ but include no portion size information and may be limited to a certain class of foods, such as sweets or fruits and vegetables.[58–61] These checklists may be appropriate to use when monitoring adherence to a dietary intervention or to use as a counseling tool.

Behavioral Instruments

The development of diet behavioral instruments was motivated by problems with assessing dietary intervention effectiveness, particularly low-fat interventions. Traditional comprehensive instruments, such as records and FFQs, yield fairly imprecise

estimates of fat intake that may not be sensitive to an intervention focused on changing participants' dietary behavior. One of the best known instruments of this type is the fat-related diet habit questionnaire.[62] This instrument was based on an anthropologic model that described low-fat dietary change as four types: (1) avoiding high-fat foods (exclusion), (2) altering available foods to make them lower in fat (modification), (3) using new, specially formulated or processed, lower-fat foods instead of their higher-fat forms (substitution), and (4) using preparation techniques or food ingredients that replace the common higher-fat alternative (replacement). Although originally developed for intervention assessment, the diet-habits questionnaire has since been used as a short assessment instrument in other research settings.[63,64]

Advantages and Disadvantage of Brief Assessment Instruments

The principal advantage of ecologic measures is that they are simple, inexpensive, nonintrusive, and objective measures of nutritional status. However, these environmental indicators do not provide precise measures of individual intake and it can be difficult to disentangle human consumption from livestock and industrial use.

Targeted questionnaires also tend to yield rather imprecise food or nutrient estimates. For example, short questionnaires for assessing fruit and vegetable intake have been extensively used in surveillance and intervention research. The typical approach uses two summary questions to capture consumption of most fruits and vegetables ("How often did you eat a serving of fruit [not including juices]?" and "How often did you eat a serving of vegetables [not including salad and potatoes]?"), to which are added usual consumption of juice, salad, and potatoes.[65] Comparison of this brief measure with food records, food frequency estimates, and serum carotenoids indicates that this method yields particularly biased (underestimated) and imprecise measures of vegetable intake, likely because vegetables in mixed foods such as casseroles or sandwiches may be forgotten and unreported.[31] However, more detailed, but short, targeted questionnaires are an improvement to the more global questions mentioned above.

The major advantage of the behavioral questionnaires is that they are short and simple (i.e., low respondent burden) and can be easily data-entered and scored. The disadvantage of these tools is that the diet "score" derived from these measures can be difficult to interpret, because it is not comparable to nutrient or food intake measures. In addition, because these questionnaires have typically been "validated" in relation to records or recalls, which have many sources of error and bias, the degree to which these questionnaires accurately reflect dietary intake is unknown.

USE OF DIETARY ASSESSMENT METHODS IN INDIVIDUALS VS. GROUPS

Determination of an Individual's Dietary Adequacy for Purposes of Counseling

Records/Recalls

Records and recalls are used in clinical and counseling settings to assess dietary intake and are often used in a qualitative fashion. That is, respondents are asked to describe a usual day's intake and the nutritionist simply "eyeballs" the eating pattern for estimating dietary adequacy or risk, adherence to a prescribed diet, or areas for improving eating habits. The individualized nature of the interview can allow for probing and personalization of the feedback.

Whether these methods are used in a quantitative or qualitative manner, records and recalls can provide useful and understandable information to a respondent. The respondent can observe that the dietary recommendations are based directly on the food intake information provided and can use the advice to alter future food choices, food preparation techniques, or portion sizes. Therefore, on an individual level, records and recalls can serve an important teaching function. In addition, there is a considerable literature indicating the act of keeping records (i.e., self-monitoring) is a significant predictor of success in achieving weight loss or making other dietary changes.[55]

Food Frequency Questionnaires
