# ATOMIC AND MOLECULAR POLARIZABILITIES

Thomas M. Miller

The *polarizability* of an atom or molecule describes the response of the electron cloud to an external field. The atomic or molecular energy shift  $\Delta W$  due to an external electric field  $E$  is proportional to  $E^2$  for external fields that are weak compared to the internal electric fields between the nucleus and electron cloud. The *electric dipole polarizability*  $\alpha$  is the constant of proportionality defined by  $\Delta W = -\alpha E^2/2$ . The induced electric dipole moment is  $\alpha E$ . *Hyperpolarizabilities*, coefficients of higher powers of  $E$ , are less often required. Technically, the polarizability is a tensor quantity but for spherically symmetric charge distributions reduces to a single number. In any case, an *average polarizability* is usually adequate in calculations. Frequency-dependent or *dynamic polarizabilities* are needed for electric fields that vary in time, except for frequencies that are much lower than electron orbital frequencies, where *static polarizabilities* suffice.

Polarizabilities for atoms and molecules in excited states are found to be larger than for ground states and may be positive or negative. Molecular polarizabilities are very slightly temperature dependent since the size of the molecule depends on its rovibrational state. Only in the case of dihydrogen has this effect been studied enough to warrant consideration in Table 3.

Polarizabilities are normally expressed in c.g.s. units of  $\text{cm}^3$ . Ground state polarizabilities are in the range of  $10^{-24} \text{ cm}^3 = 1 \text{ \AA}^3$  and hence are often given in  $\text{\AA}^3$  units. Theorists tend to use atomic units of  $a_0^3$  where  $a_0$  is the Bohr radius. The conversion is  $\alpha(\text{cm}^3) = 0.148184 \times 10^{-24} \times \alpha(a_0^3)$ . Polarizabilities are only recently encountered in SI units,  $\text{C m}^2/\text{V} = \text{J}/(\text{V/m})^2$ . The conversion from c.g.s. units to SI units is  $\alpha(\text{C m}^2/\text{V}) = 4\pi\epsilon_0 \times 10^{-6} \alpha(\text{cm}^3)$ , where  $\epsilon_0$  is

the permittivity of free space in SI units and the factor  $10^{-6}$  simply converts  $\text{cm}^3$  into  $\text{m}^3$ . Thus,  $\alpha(\text{C m}^2/\text{V}) = 1.11265 \times 10^{-16} \times \alpha(\text{cm}^3)$ . Persons measuring excited state polarizabilities by optical methods tend to use units of  $\text{MHz}/(\text{V/cm})^2$ , where the energy shift,  $\Delta W$ , is expressed in frequency units with a factor of  $h$  understood. The polarizability is  $-2 \Delta W/E^2$ . The conversion into c.g.s. units is  $\alpha(\text{cm}^3) = 5.95531 \times 10^{-16} \times \alpha[\text{MHz}/(\text{V/cm})^2]$ .

The polarizability appears in many formulas for low-energy processes involving the valence electrons of atoms or molecules. These formulas are given below in c.g.s. units: the polarizability  $\alpha$  is in  $\text{cm}^3$ ; masses  $m$  or  $\mu$  are in grams; energies are in ergs; and electric charges are in esu, where  $e = 4.8032 \times 10^{-10}$  esu. The symbol  $\alpha(\nu)$  denotes a frequency ( $\nu$ ) dependent polarizability, where  $\alpha(\nu)$  reduces to the static polarizability  $\alpha$  for  $\nu = 0$ . For further information, see Bonin, K. D., and Kresin, V. V., *Electric Dipole Polarizabilities of Atoms, Molecules, and Clusters*, World Scientific, Singapore, 1997; Bonin, K. D., and Kadar-Kallen, *Int. J. Mod. Phys. B*, 24, 3313, 1994; and Miller, T. M., and Bederson, B., *Advances in Atomic and Molecular Physics*, 13, 1, 1977, and Gould, H., and Miller, T. M., *Advances in Atomic, Molecular, and Optical Physics*, 51, 243, 2005. Details on polarizability-related interactions, especially in regard to hyperpolarizabilities and nonlinear optical phenomena, are given by Bogaard, M. P., and Orr, B. J., in *Physical Chemistry, Series Two, Vol. 2, Molecular Structure and Properties*, Buckingham, A. D., Ed., Butterworths, London, 1975, pp. 149–194. A tabulation of tensor and hyperpolarizabilities is included. The gas number density,  $n$ , in Table 1 is usually taken to be that of 1 atm at 0 °C in reporting experimental data.

TABLE 1. Formulas Involving Polarizability

Description	Formula	Remarks
Lorentz-Lorenz relation	$\alpha(\nu) = \frac{3}{4\pi n} \left[ \frac{\eta^2(\nu) - 1}{\eta^2(\nu) + 2} \right]$	For a gas of atoms or nonpolar molecules; the index of refraction is $\eta(\nu)$
Refraction by polar molecules	$\alpha(\nu) + \frac{d^2}{3kT} = \frac{3}{4\pi n} \left[ \frac{\eta^2(\nu) - 1}{\eta^2(\nu) + 2} \right]$	The dipole moment is $d$ , in esu cm ( $= 10^{-18}$ D)
Dielectric constant (dimensionless)	$\kappa(\nu) = 1 + 4\pi n \alpha(\nu)$	From the Lorentz-Lorenz relation for the usual case of $\kappa(\nu) \approx 1$
Index of refraction (dimensionless)	$\eta(\nu) = 1 + 2\pi n \alpha(\nu)$	From $\eta^2(\nu) = \kappa(\nu)$
Diamagnetic susceptibility	$\chi_m = e^2 (a_0 N \alpha)^{1/2} / 4m_e c^2$	From the approximation that the static polarizability is given by the variational formula $\alpha = (4/9a_0) \Sigma(N r_i^2)^2$ ; $N$ is the number of electrons, $m_e$ is the electron mass; a crude approximation is $\chi_m = (E_i/4m_e c^2) \alpha$ , where $E_i$ is the ionization energy
Long-range electron- or ion-molecule interaction energy	$V(r) = -e^2 \alpha / 2r^4$	The target molecule polarizability is $\alpha$
Ion mobility in a gas	$\kappa = -13.87 / (\alpha \mu)^{1/2} \text{ cm}^2 / \text{V} \cdot \text{s}$	This one formula is not in c.g.s. units. Enter $\alpha$ in $\text{\AA}^3$ or $10^{-24} \text{ cm}^3$ units and the reduced mass $\mu$ of the ion-molecule pair in amu. Classical limit; pure polarization potential
Langevin capture cross section	$\sigma(v_o) = (2\pi e / v_o) (\alpha / \mu)^{1/2}$	The relative velocity of approach for an ion-molecule pair is $v_o$ ; the target molecular polarizability is $\alpha$ and the reduced mass of the ion-molecule pair is $\mu$
Langevin reaction rate coefficient	$k = 2\pi e (\alpha / \mu)^{1/2}$	Collisional rate coefficient for an ion-molecule reaction
Rate coefficient for polar molecules	$k_d = 2\pi e \left[ (\alpha / \mu)^{1/2} + cd(2 / \mu \pi kT)^{1/2} \right]$	The dipole moment of the neutral is $d$ in esu cm; the number $c$ is a "locking factor" that depends on $\alpha$ and $d$ , and is between 0 and 1

Description	Formula	Remarks
Modified effective range cross section for electron-neutral scattering	$\sigma(k) = 4\pi A^2 + 32\pi^4 \mu e^2 \alpha A k / 3h^2 + \dots$	Here, $k$ is the electron momentum divided by $h/2\pi$ , where $h$ is Planck's constant; $A$ is called the "scattering length"; the reduced mass is $\mu$
van der Waals constant between two systems A, B	$C_6 = \frac{3}{2} \left[ \frac{\alpha^A \alpha^B E^A E^B}{E^A + E^B} \right]$	For the interaction potential term $V_6(r) = -C_6 r^{-6}$ ; $E^{A,B}$ represents average dipole transition energies and $\alpha^{A,B}$ the respective polarizabilities of A, B
Dipole-quadrupole constant between two systems A, B	$C_8 = \frac{15}{4} \left[ \frac{\alpha^A \alpha_q^B E^A E_q^B}{E^A + E_q^B} \right] + \frac{15}{4} \left[ \frac{\alpha_q^A \alpha^B E_q^A E^B}{E_q^A + E^B} \right]$	For the interaction potential term $V_8(r) = -C_8 r^{-8}$ ; $E_q^{A,B}$ represents average quadrupole transition energies and $\alpha_q^{A,B}$ are the respective quadrupole polarizabilities of A, B
van der Waals constant between an atom and a surface	$C_3 = \frac{\alpha g E^A E^S}{8(E^A + E^S)}$	For an interaction potential $V_3(r) = -C_3 r^{-3}$ ; $E^{A,S}$ are characteristic energies of the atom and surface; $g = 1$ for a free-electron metal and $g = (\epsilon_\infty - 1)/(\epsilon_\infty + 1)$ for an ionic crystal
Relationship between $\alpha(\nu)$ and oscillator strengths	$\alpha(\nu) = \frac{e^2 h^2}{4\pi^2 m_e} \sum \frac{f_k}{E_k^2 - (h\nu)^2}$	Here, $f_k$ is the oscillator strength from the ground state to an excited state $k$ , with excitation energy $E_k$ . This formula is often used to estimate static polarizabilities ( $\nu = 0$ )
Dynamic polarizability	$\alpha(\nu) = \frac{\alpha E_r^2}{E_r^2 - (h\nu)^2}$	Approximate variation of the frequency-dependent polarizability $\alpha(\nu)$ from $\nu = 0$ up to the first dipole-allowed electronic transition, of energy $E_r$ ; the static dipole polarizability is $\alpha(0)$ ; infrared contributions ignored
Rayleigh scattering cross section	$\alpha(\nu) = \frac{8\pi}{9c^4} (2\pi\nu)^4 \times [3\alpha^2(\nu) + 2\gamma^2(\nu) / 3]$	The photon frequency is $\nu$ ; the polarizability anisotropy (the difference between polarizabilities parallel and perpendicular to the molecular axis) is $\gamma(\nu)$
Verdet constant	$V(\nu) = \frac{\nu n}{2m_e c^2} \left[ \frac{d\alpha(\nu)}{d\nu} \right]$	Defined from $\theta = V(\nu)B$ , where $\theta$ is the angle of rotation of linearly polarized light through a medium of number density $n$ , per unit length, for a longitudinal magnetic field strength $B$ (Faraday effect)

Note: All polarizabilities in the tables are experimental values except those values marked by an asterisk (\*), which indicates a calculated result. The experimental polarizabilities are mostly determined by measurements of a dielectric constant or refractive index that are quite accurate (0.5% or better). However, one should treat many of the results with several percent of caution because of the age of the data and because some of the results refer to optical frequencies rather than static. Comments given with the references are intended to allow one to judge the degree of caution required. Interested persons should consult these references. In many cases, the reference given is to a theoretical paper in which the experimental results are quoted. These papers, noted in the References, contain valuable information on polarizability calculations and experimental data which often includes the tensor components of the polarizability.

An empirical additive formula for molecular polarizabilities at 589 nm frequency has been given in Bosque, R., and Sales, J., *J. Chem. Inf. Comput. Sci.* 42, 1154, 2002:  $\alpha = 0.32 + 1.51\#C + 0.17\#H + 0.57\#O + 1.05\#N + 2.99\#S + 2.48\#P + 2.16\#Cl + 3.29\#Br + 5.45\#I$ , where "#C" denotes the number of carbon atoms in the molecule, etc.

- McCullough, E. A., Jr., *J. Chem. Phys.*, 63, 5050, 1975. This calculation is for the parallel component, not the average polarizability.
- Maryott, A. A., and Buckley, F., *U. S. National Bureau of Standards Circular No. 537*, 1953. A tabulation of dipole moments, dielectric constants, and molar refractions measured between 1910 and 1952, and used here to determine polarizabilities if no more recent result exists. The polarizability is  $3/(4\pi N_A)$  times the molar polarization or molar refraction, where  $N_A$  is Avogadro's number. The value  $3/(4\pi N_A) = 0.3964308 \times 10^{-24} \text{ cm}^3$  was used for this conversion. A dagger (†) following the reference number in the tables indicates that the polarizability was derived from the molar refraction and hence may not include some low-frequency contributions to the static polarizability; these "static" polarizabilities are therefore low by 1 to 30%.

# IONIZATION ENERGIES OF ATOMS AND ATOMIC IONS

The ionization energies (often called ionization potentials) of neutral and partially ionized atoms are listed in this table. Data were obtained from the compilations cited below, supplemented by results from the recent research literature. Values for the first and second ionization energies come from Reference 6. All values are given in electron volts (eV).

Following the traditional spectroscopic notation, columns are headed I, II, III, etc. up to VIII, where I indicates the neutral atom, II the singly ionized atom, III the doubly ionized atom, etc. The first section of the table includes spectra I to VIII of all the elements through rutherfordium; subsequent sections cover higher spectra (ionization stages) for those elements for which data are available.

# IONIZATION ENERGIES OF GAS-PHASE MOLECULES

Sharon G. Lias

This table presents values for the first ionization energies (IP) of approximately 1000 molecules and atoms. Substances are listed by molecular formula in the modified Hill order (see Preface). Values enclosed in parentheses are considered not to be well established. Data appearing in the 1988 reference were updated in 1996 for inclusion in the database of ionization energies available at the Internet site of the Standard Reference Data program of the National Institute of Standards and Technology (<http://webbook.nist.gov>). The list appearing here includes these updates.

The list also includes values for enthalpies of formation of the ions at 298 K,  $\Delta_f H_{\text{ion}}$ , given according to the ion convention used by

mass spectrometrists; to convert these values to the electron convention used by thermodynamicists, add 6 kJ/mol. Details on the calculation of  $\Delta_f H_{\text{ion}}$ , as well as data for a much larger number of molecules, may be found in the reference and on the Internet site.

## X-RAY ATOMIC ENERGY LEVELS

The energy levels in this tables are the values recommended by Bearden and Burr on the basis of a thorough review of the literature on x-ray wavelengths and related data. All values are in electron volts (eV). Values in parentheses are interpolated, and an asterisk \* indicates a level which is not resolved from the level above it. See Reference 1 for uncertainties in the levels and a complete description of how the recommended values were obtained.

# ELECTRON BINDING ENERGIES OF THE ELEMENTS

Gwyn P. Williams

This table gives the binding energies in electron volts (eV) for selected electronic levels of the elements. For metallic elements the binding energy is referred to the Fermi level; for semiconductors, to the valence band maximum; and for gases and insulators, to the vacuum level. The atomic number is listed after the element name.

# PHOTON ATTENUATION COEFFICIENTS

Martin J. Berger and John H. Hubbell

This table gives mass attenuation coefficients for photons for all elements at energies between 1 keV (soft x-rays) and 1 GeV (hard gamma rays). The mass attenuation coefficient  $\mu$  describes the attenuation of radiation as it passes through matter by the relation

$$I(x)/I_0 = e^{-\mu\rho x}$$

where  $I_0$  is the initial intensity,  $I(x)$  the intensity after path length  $x$ , and  $\rho$  is the mass density of the element in question. To a high approximation the mass attenuation coefficient is additive for the elements present, independent of the way in which they are bound in chemical compounds.

The power of ten is indicated beside each number in the table; i.e., 7.41 + 03 means  $7.41 \times 10^3$ . A vertical line between two columns indicates that an absorption edge lies between those energy values. The various edges are labeled at the bottom of the table.

The attenuation coefficients were calculated with the computer program XCOM (Reference 1), which uses a cross-section database compiled at the Photon and Charged Particle Data Center at the National Institute of Standards and Technology. Their accuracy has been confirmed at all energies by extensive comparisons with experimental attenuation coefficients. Such comparisons for X-ray energies up to 100 keV can be found in Reference 2.

# CLASSIFICATION OF ELECTROMAGNETIC RADIATION

Hans Dolezalek

Basic Conversions:

$$c = \lambda\nu = v/k$$

$$\nu = c/\lambda = ck$$

$$\lambda = c/\nu = 1/k$$

$$k = \nu/c = 1/\lambda$$

$$c = \text{speed of light} = 2.99792458 \times 10^8 \text{ m/s}$$

Frequency ( $\nu$ )	Wavelength ( $\lambda$ )	Wave number ( $k$ )	Names of bands	Approximate photon energies
$3 \times 10^0 - 3 \times 10^1$ Hz 3 – 30 Hz	$10^8 - 10^7$ m 100 – 10 Mm	$10^8 - 10^7$ m <sup>-1</sup> 10 – 100 Gm <sup>-1</sup>	ELF-(ELF 1), ITU band no. 1	
$3 \times 10^1 - 3 \times 10^2$ Hz 30 – 300 Hz	$10^7 - 10^6$ m 10 – 1 Mm	$10^7 - 10^6$ m <sup>-1</sup> 100 Gm <sup>-1</sup> – 1Mm <sup>-1</sup>	SLF-(ELF 2), ITU band no. 2, megameter waves	
$3 \times 10^2 - 3 \times 10^3$ Hz 300 Hz – 3 kHz	$10^6 - 10^5$ m 1 Mm – 100 km	$10^6 - 10^5$ m <sup>-1</sup> 1 – 10 Mm <sup>-1</sup>	ULF-(ELF 3), ITU band no. 3	
$3 \times 10^3 - 3 \times 10^4$ Hz 3 – 30 kHz	$10^5 - 10^4$ m 100 – 10 km	$10^5 - 10^4$ m <sup>-1</sup> 100 Mm <sup>-1</sup>	VLF, ITU band no. 4, myriameter waves	
$3 \times 10^4 - 3 \times 10^5$ Hz 30 – 300 kHz	$10^4 - 10^3$ m 10 – 1 km	$10^4 - 10^3$ m <sup>-1</sup> 100 Mm <sup>-1</sup> – 1 km <sup>-1</sup>	LF, ITU band no. 5, kilometer waves	
$3 \times 10^5 - 3 \times 10^6$ Hz 300 kHz – 3 MHz	$10^3 - 10^2$ m 1 km – 100 m	$10^3 - 10^2$ m <sup>-1</sup> 1 – 10 km <sup>-1</sup>	MF, ITU band no. 6, hectometer waves	
$3 \times 10^6 - 3 \times 10^7$ Hz 3 – 30 MHz	$10^2 - 10^1$ m 100 – 10 m	$10^2 - 10^1$ m <sup>-1</sup> 10 – 100 km <sup>-1</sup>	HF, ITU band no. 7, decameter waves	
$3 \times 10^7 - 3 \times 10^8$ Hz 30 – 300 MHz	$10^1 - 10^0$ m 10 – 1 m	$10^1 - 10^0$ m <sup>-1</sup> 100 km <sup>-1</sup> – 1 mm <sup>-1</sup>	VHF, ITU band no. 8, meter waves	
$3 \times 10^8 - 3 \times 10^9$ Hz 300 MHz – 3 GHz	$10^0 - 10^{-1}$ m 1 m – 100 mm	$10^0 - 10^1$ m <sup>-1</sup> 1 – 10 m <sup>-1</sup>	UHF, ITU band no. 9, decimeter waves <sup>a</sup>	
$3 \times 10^9 - 3 \times 10^{10}$ Hz 3 – 30 GHz	$10^{-1} - 10^{-2}$ m 100 – 10 mm	$10^1 - 10^2$ m <sup>-1</sup> 10 – 100 m <sup>-1</sup>	SHF, ITU band no. 10, centimeter waves <sup>a</sup>	
$3 \times 10^{10} - 3 \times 10^{11}$ Hz 30 – 300 GHz	$10^{-2} - 10^{-3}$ m 10 – 1 mm	$10^2 - 10^3$ m <sup>-1</sup> 100 m <sup>-1</sup> – 1 mm <sup>-1</sup> (1 – 10 cm <sup>-1</sup> )	EHF, ITU band no. 11, millimeter waves	
$3 \times 10^{11} - 3 \times 10^{12}$ Hz 300 GHz – 3 THz	$10^{-3} - 10^{-4}$ m 1 mm – 100 $\mu$ m	$10^3 - 10^4$ m <sup>-1</sup> (1 – 10 mm <sup>-1</sup> ) (10 – 100 cm <sup>-1</sup> )	Part of micrometer waves, includes part of far or thermal infrared; ITU band no. 12	
$3 \times 10^{12} - 3 \times 10^{13}$ Hz 3 – 30 THz	$10^{-4} - 10^{-5}$ m 100 – 10 $\mu$ m	$10^4 - 10^5$ m <sup>-1</sup> 10 – 100 mm <sup>-1</sup> (100 – 1000 cm <sup>-1</sup> )	Part of micrometer waves includes part of far (thermal) infrared	
$3 \times 10^{13} - 3 \times 10^{14}$ Hz 30 – 300 THz	$10^{-5} - 10^{-6}$ m 10 – 1 $\mu$ m (100,000 – 10,000 Å)	$10^5 - 10^6$ m <sup>-1</sup> 100 mm <sup>-1</sup> – 1 $\mu$ m <sup>-1</sup>	Part of $\mu$ m waves, part of infrared	$(1.6 - 16) \times 10^{-20}$ joule {0.1 – 1 eV}
$3 \times 10^{14} - 3 \times 10^{15}$ Hz 300 THz – 3 PHz	$10^{-6} - 10^{-7}$ m 1 $\mu$ m – 100 m (10,000 – 1000 Å)	$10^6 - 10^7$ m <sup>-1</sup> 1 – 10 $\mu$ m <sup>-1</sup>	Near infrared, visible, near ultraviolet	$(1.6 - 16) \times 10^{-19}$ joule {1 – 10 eV}
$3 \times 10^{15} - 3 \times 10^{16}$ Hz 3 – 30 PHz	$10^{-7} - 10^{-8}$ m 100 – 10 nm (1000 – 100 Å)	$10^7 - 10^8$ m <sup>-1</sup> 10 – 100 $\mu$ m <sup>-1</sup>	Part of vacuum ultraviolet	$(1.6 - 16) \times 10^{-18}$ joule {10 – 100 eV}
$3 \times 10^{16} - 3 \times 10^{17}$ Hz 30 – 300 PHz	$10^{-8} - 10^{-9}$ m 10 – 1 nm (100 – 10 Å)	$10^8 - 10^9$ m <sup>-1</sup> 100 $\mu$ m <sup>-1</sup> – 1 nm <sup>-1</sup>	Part of soft X-rays	$(1.6 - 16) \times 10^{-17}$ joule {100 – 1000 eV}
$3 \times 10^{17} - 3 \times 10^{18}$ Hz 300 PHz – 3 EHz	$10^{-9} - 10^{-10}$ m 1 nm – 100 pm (10 – 1 Å)	$10^9 - 10^{10}$ m <sup>-1</sup> 1 – 10 nm <sup>-1</sup>	Part of soft X-rays	$(1.6 - 16) \times 10^{-16}$ joule {1 – 10 keV}

## BLACK BODY RADIATION

The total power radiated from an ideal black body and the wavelength corresponding to maximum power are given here as a function of absolute temperature. Constants used in the calculation are taken from the table "Fundamental Physical Constants" in

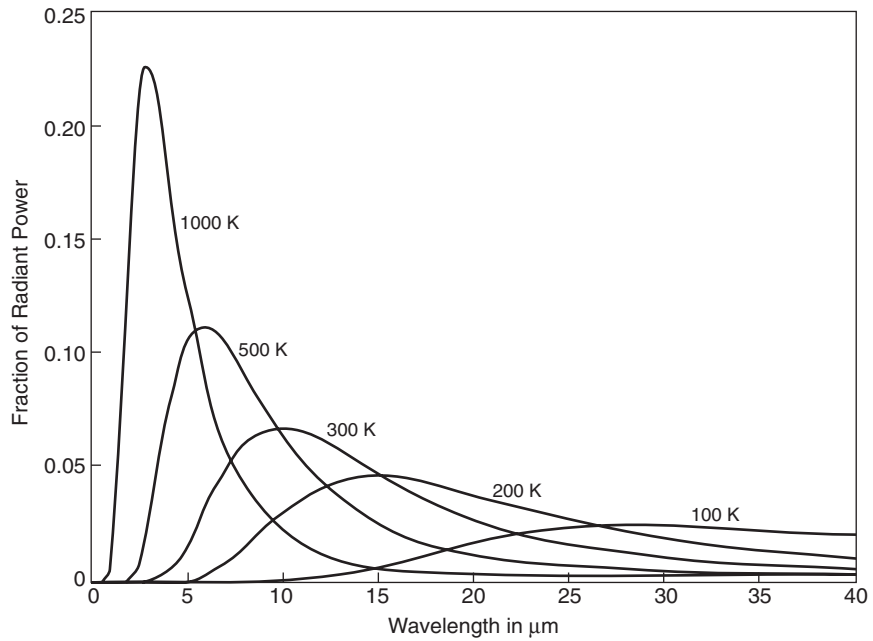

Section 1. The radiated power in a band  $\Delta\lambda$  at  $\lambda_{\max}$  may be calculated from:

$$P_{\max} = 0.657548 (\Delta\lambda/\lambda_{\max}) P_{\text{tot}}$$

$T/K$	$P_{\text{tot}}$	$\lambda_{\max}/\mu\text{m}$	$T/K$	$P_{\text{tot}}$	$\lambda_{\max}/\mu\text{m}$	$T/K$	$P_{\text{tot}}$	$\lambda_{\max}/\mu\text{m}$

The curves below show, for various temperatures, the fraction of radiant power as a function of wavelength. The function plotted is  $P_\lambda/\Delta\lambda P_{tot}$ , where  $P_\lambda$  is the power at wavelength  $\lambda$  in a small interval  $\Delta\lambda$  (in  $\mu\text{m}$ ), and  $P_{tot}$  is the total power.

## CHARACTERISTICS OF INFRARED DETECTORS

This graph summarizes the wavelength response of some semiconductors used as detectors for infrared radiation. The quantity  $D^*(\lambda)$  is the signal to noise ratio for an incident radiant power density of  $1 \text{ W/cm}^2$  and a bandwidth of  $1 \text{ Hz}$  ( $60^\circ$  field of view). The Ge, InAs, and InSb detectors are photovoltaics, while the HgCdTe series are photoconductive devices. The cutoff wavelength of the latter can be varied by adjusting the relative amounts of Hg, Cd,

and Te (three examples are shown at  $77 \text{ K}$ ). The graph also shows the theoretical background limited sensitivity for ideal detectors which introduce no intrinsic noise.

# REFRACTIVE INDEX AND TRANSMITTANCE OF REPRESENTATIVE GLASSES

Typical values of the index of refraction and internal transmittance (fraction of light transmitted through a one centimeter thickness) are tabulated here for selected types of glasses, as well as for synthetic fused (vitreous) silica. Nominal compositions are given in the first part of the table. The second part gives the index of refraction, relative to air, and the internal transmittance for representative samples of each glass at wavelengths in the infrared, visible, and near-ultraviolet regions. It should be emphasized that wide variation of these parameters may be found among subtypes of each glass. More detailed data may be found in Reference 3.

Assuming that the Lambert-Beer Law is followed, the transmittance of a glass plate of thickness  $d$  (in centimeters) can be obtained by raising the transmittance value in the table to the power  $d$ .

## INDEX OF REFRACTION OF WATER

This table gives the index of refraction of liquid water at atmospheric pressure, relative to a vacuum, at several temperatures and wavelengths. It is generated from the formulation in Reference 1, which covers a wide range of temperature, pressure, and wavelength. The wavelengths listed here correspond to prominent lines of cadmium (226.50 and 361.05 nm), potassium (404.41 nm), sodium (589.00 nm), Ne (632.80 nm, from a helium - neon laser), and mercury (1.01398  $\mu\text{m}$ ).

# INDEX OF REFRACTION OF LIQUIDS FOR CALIBRATION PURPOSES

This table gives the index of refraction of six liquids which are available in highly pure form and whose index of refraction has been accurately measured as a function of wavelength and temperature. They are therefore useful for calibration of refractometers. The estimated uncertainty in the values is:

2,2,4-Trimethylpentane	±0.00003
Hexadecane	±0.00008
<i>trans</i> -Bicyclo[4.0.0]decane	±0.00008
1-Methylnaphthalene	±0.00008
Toluene	±0.00003
Methylcyclohexane	±0.00003

Full details are given in the references. This table is reprinted from Reference 1 by permission of the International Union of Pure and Applied Chemistry.

## INDEX OF REFRACTION OF AIR

This is a table of the index of refraction  $n$  of dry air at 15°C and a pressure of 101.325 kPa and containing 0.045% by volume of carbon dioxide (“standard air”). The index of refraction is defined by  $n = \lambda_{\text{vac}} / \lambda_{\text{air}}$  where  $\lambda$  is the wavelength of the radiation. The index is calculated from the expression

$$(n-1) \times 10^8 = 8342.54 + 2406147(130 - \sigma^2)^{-1} + 15998(38.9 - \sigma^2)^{-1}$$

where  $\sigma = 1/\lambda_{\text{vac}}$  and  $\lambda_{\text{vac}}$  has units of  $\mu\text{m}$ . The equation is valid for  $\lambda_{\text{vac}}$  from 200 nm to 2  $\mu\text{m}$ . The table also gives the correction  $(n-1)\lambda_{\text{air}}$  which must be added to the wavelength in air to obtain  $\lambda_{\text{vac}}$ .

If the air is at a temperature  $t$  in °C (ITS-90) and a pressure  $p$  in pascals, a value of  $(n - 1)$  from this table should be multiplied by

$$p[1 + p(60.1 - 0.972t) \times 10^{-10}]/96095.43(1 + 0.003661t)$$

# CHARACTERISTICS OF LASER SOURCES

William F. Krupke

Light amplification by stimulated emission of radiation was first demonstrated by Maiman in 1960, the result of a population inversion produced between energy levels of chromium ions in a ruby crystal when irradiated with a xenon flashlamp. Since then population inversions and coherent emission have been generated in literally thousands of substances (neutral and ionized gases, liquids, and solids) using a variety of incoherent excitation techniques (optical pumping, electrical discharges, gas-dynamic flow, electron-beams, chemical reactions, nuclear decay).

The extrema of laser output parameters that have been demonstrated to date and the laser media used are summarized in Table 1. Note that the extreme power and energy parameters listed in this table were attained with laser systems rather than with simple laser oscillators.

Laser sources are commonly classified in terms of the state-of-matter of the active medium: gas, liquid, and solid. Each of these classes is further subdivided into one or more types as shown in Table 2. A well-known representative example of each type of laser is also given in Table 2 together with its nominal operation wavelength and the methods by which it is pumped.

The various lasers together cover a wide spectral range from the far ultraviolet to the far infrared. The particular wavelength of emission (usually a narrow line) is presented for some six dozen lasers in Figures 1A and 1B.

By suitably designing the excitation source and/or by controlling the laser resonator structure, laser systems can provide continuous or pulsed radiation as shown in Table 3.

Besides the method of excitation and the temporal behavior of a laser, there are many other parameters that characterize its operation and efficiency, as shown in Tables 4 and 5.

Although many lasers only emit in one or more narrow spectral "lines," an increasing number of lasers can be tuned by changing the composition or the pressure of the medium, or by varying the wavelength of the pump bands. The spectral regions in which these tunable lasers operate are presented in Figure 2.

<sup>a</sup> Pressure dependent.

<sup>b</sup> Intrinsic efficiency ≡ energy output/energy deposited in gas.

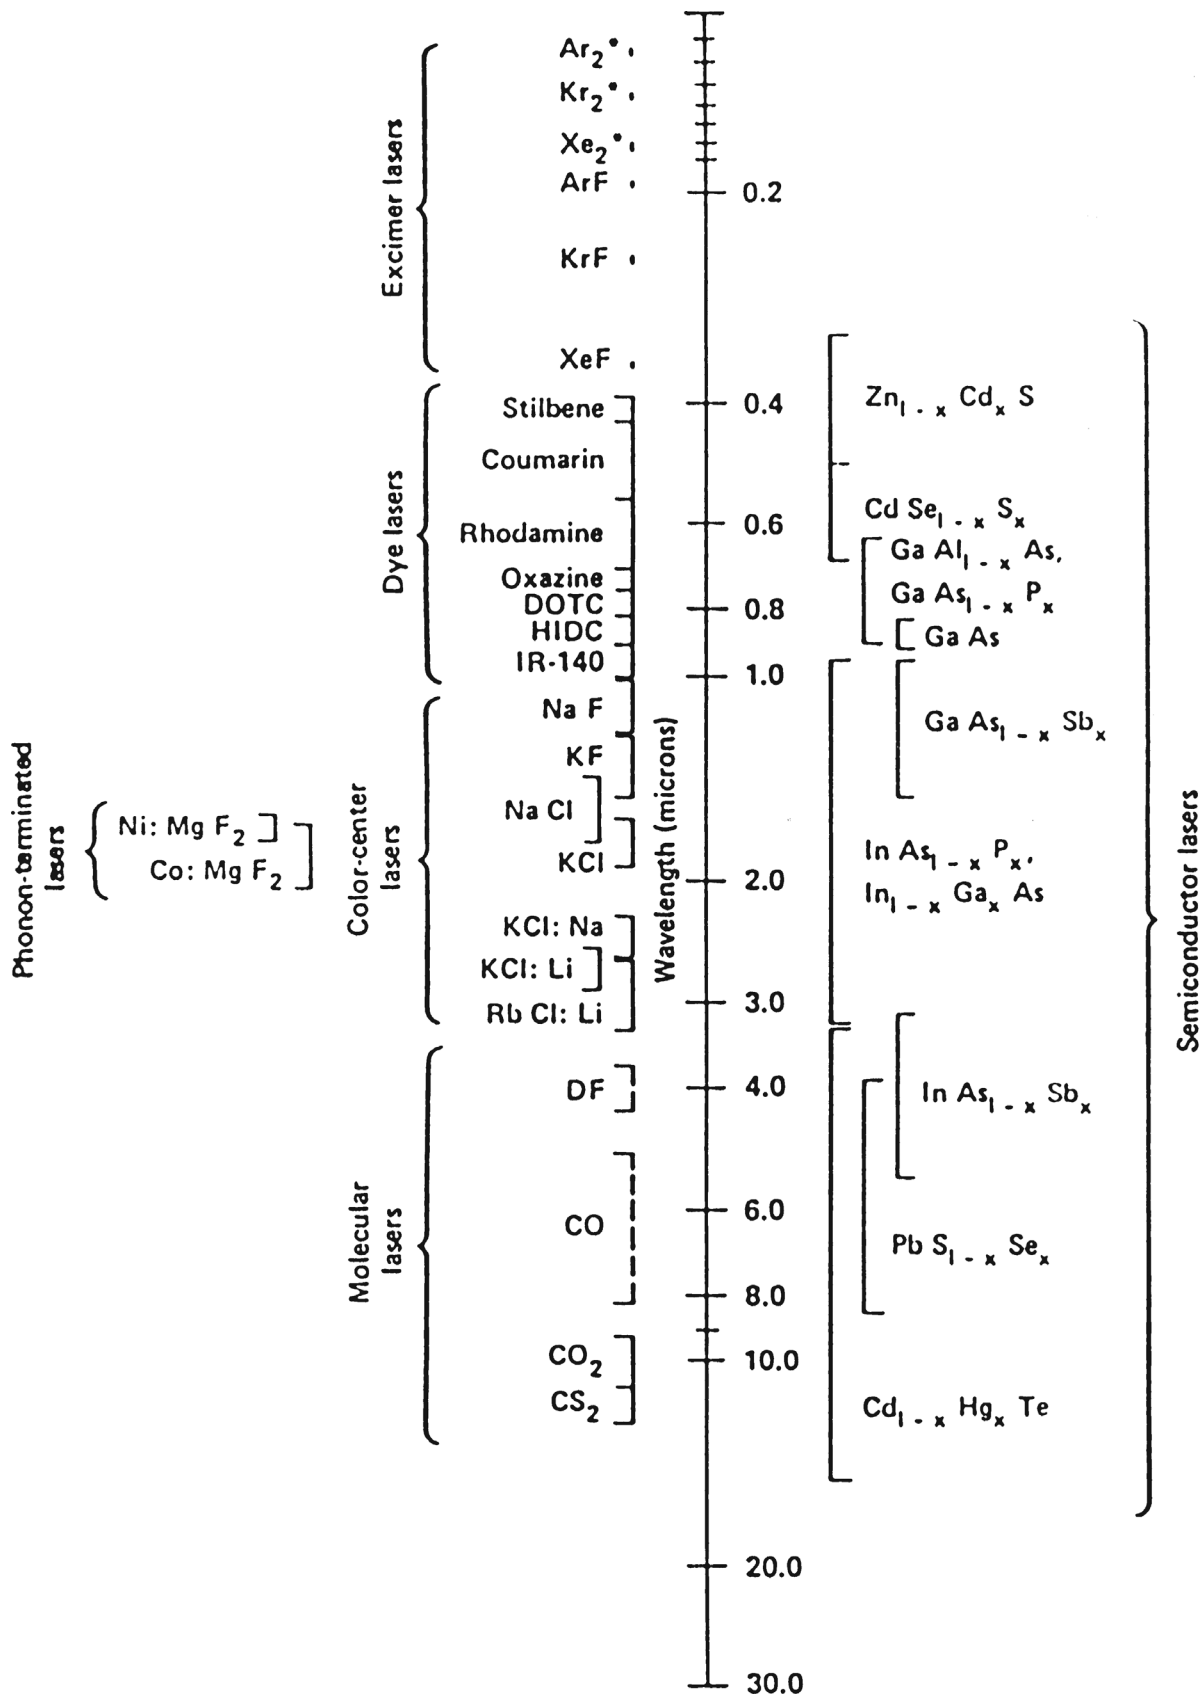

FIGURE 2. Spectral tuning ranges of various types of tunable lasers.

# INFRARED LASER FREQUENCIES

Arthur Maki

The CO<sub>2</sub> laser has been the subject of a number of very accurate frequency measurements. Most of the earlier measurements are given by Bradley et al.<sup>1</sup> That analysis was based on a single absolute frequency measurement and many laser frequency differences. New measurements of the methane frequency<sup>2-4</sup> have made it necessary to slightly revise that single absolute frequency measurement. In addition, there have been several other absolute frequency measurements<sup>5-7</sup> that have been used here to improve the accuracy of the present tables. New frequency difference measurements have also been added to the database used for the present tables.<sup>8</sup>

# INFRARED AND FAR-INFRARED ABSORPTION FREQUENCY STANDARDS

Arthur Maki

Aside from the CO<sub>2</sub> laser transitions, the absorption spectrum of CO has been more accurately and thoroughly measured than any other spectrum. A bibliography of earlier measurements on CO is given by Maki and Wells,<sup>1</sup> and the present tables were calculated from the measurements referred to in that work. In addition, some new and very accurate frequency measurements<sup>2,3</sup> have been made and were incorporated in the present tables. The frequencies of the rotational transitions of HF and HCl were calculated from constants obtained from fitting the measurements of Evenson et al.<sup>4,5</sup> and Jennings and Wells.<sup>6</sup>

A new report on infrared wavenumber standards from the International Union of Pure and Applied Chemistry, Commission on Molecular Structure and Spectroscopy, may be found in Reference 7.

## SENSITIVITY OF THE HUMAN EYE TO LIGHT OF DIFFERENT WAVELENGTHS

The human eye responds to electromagnetic radiation in the wavelength range from about 360 nm (violet) to 820 nm (red), with a peak sensitivity near 555 nm (green). While the detailed shape of this response curve depends on the individual person, studies on representative samples of human subjects have led to adoption of a standard function relating the perceived brightness (luminous flux) to the actual power of the spectral radiation. This function is referred to as  $V(\lambda)$ , the photopic spectral luminous efficiency function, and it plays an important role in photometry.

The function  $V(\lambda)$ , as adopted by the International Commission on Illumination (CIE), is tabulated and plotted below.

# INDEX OF REFRACTION OF INORGANIC CRYSTALS

This table lists the index of refraction of selected crystalline inorganic compounds. When, available, values are given as a function of wavelength in the range from the ultraviolet to the far infrared region. For each compound a value at 589 nm, the wavelength of the principal sodium line, is given. The data have been taken from the references indicated; in many cases, data from a reference have been refitted to generate the index of refraction at the wavelengths used in this table. All values refer to ambient temperature. Entries marked by \* are based on extrapolation beyond the range of available experimental data.

Compounds belonging to the cubic crystal system have only a single refractive index value, but other systems are anisotropic, so that the crystal is characterized by two or three unique indexes. Hexagonal, rhombohedral, and tetragonal crystals have two unique indexes which are traditionally labeled  $n_o$  and  $n_e$  for "ordinary ray" and "extraordinary ray". Orthorhombic, monoclinic, and triclinic crystals are characterized by three indexes which are here called  $n_x$ ,  $n_y$ , and  $n_z$ . The table indicates the crystal system for each entry in order to identify the material uniquely.

The refractive index and other optical properties for metals, semiconductors, and certain other compounds can be found in the tables "Optical Properties of Selected Elements" and "Optical Properties of Selected Inorganic and Organic Solids" in Section 12 of this *Handbook*.

## PROTON AFFINITIES

Proton affinity is a useful parameter for describing gas phase ion-molecule reactions in fields such as atmospheric chemistry, plasma chemistry, mass spectrometry, and astrophysics. The proton affinity  $E_{\text{pa}}$  (often designated in the literature as PA) of a molecular species M is defined as the negative of the enthalpy change for the gas phase reaction

A closely related quantity is the gas phase basicity  $\Delta_{\text{base}} G^\circ$  (often designated as GB), which is the negative of the Gibbs energy change for the same reaction. Thus the two are related by

$$\Delta_{\text{base}} G^\circ = E_{\text{pa}} + T\Delta S,$$

where  $T$  is the temperature and  $\Delta S$  is the entropy change in the reaction (which can be calculated if the molecular structure of M and  $\text{M}^+$  is known).

Direct measurement of the proton affinity is possible for only a few molecules, mainly olefins and carbonyl compounds. However, these measurements have been used to establish a scale of  $E_{\text{pa}}$  values that permits proton affinities to be determined for many other molecules, including unstable species and reaction intermediates. The basis for this scale is described by Hunter and Lias in Reference 1.

The  $E_{\text{pa}}$  and  $\Delta_{\text{base}} G^\circ$  values at a temperature of 298 K are tabulated below for selected molecules. Many values are given to one decimal place, but the majority are not accurate to better than one or two kilojoules per mole. The methods of measurement are de-

scribed in Reference 1, which contains a much more extensive and detailed tabulation.

Compounds are listed by molecular formula in the Hill order, but with all compounds that do not contain carbon appearing before those that do contain carbon.

## INDEX OF REFRACTION OF GASES

This table gives the index of refraction of several gases at selected wavelengths ranging from the blue to the red region of the spectrum. The entries at 0.5893  $\mu\text{m}$  correspond to the prominent sodium D line in the yellow region. All values refer to gas at a pressure of one atmosphere (101.325 kPa) and at a temperature of 0°C.

## GAUGE AND HIGGS BOSONS

$\gamma$   $I(J^{PC}) = 0, 1(1^{--})$

Mass  $m < 6 \times 10^{-17}$  eV  
Charge  $q < 5 \times 10^{-30}$  e  
Mean life  $\tau =$  Stable

$g$   
or gluon  $I(J^P) = 0(1^-)$

Mass  $m = 0^{[a]}$   
SU(3) color octet

$W$   $J = 1$

Charge =  $\pm 1e$   
Mass  $m = 80.403 \pm 0.029$  GeV  
 $m_Z - m_W = 10.785 \pm 0.029$  GeV  
 $m_{W^+} - m_{W^-} = -0.2 \pm 0.6$  GeV  
Full width  $\Gamma = 2.141 \pm 0.041$  GeV  
 $\langle N_{\pi^\pm} \rangle = 15.70 \pm 0.35$   
 $\langle N_{K^\pm} \rangle = 2.20 \pm 0.19$   
 $\langle N_p \rangle = 0.92 \pm 0.14$   
 $\langle N_{\text{charged}} \rangle = 19.41 \pm 0.15$   
 $W^-$  modes are charge conjugates of the modes below.

$W^+$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)
$\ell^+ \nu$	[b] (10.80 $\pm$ 0.09) %		–
$e^+ \nu$	(10.75 $\pm$ 0.13) %		40201
$\mu^+ \nu$	(10.57 $\pm$ 0.15) %		40201
$\tau^+ \nu$	(11.25 $\pm$ 0.20) %		40182
hadrons	(67.60 $\pm$ 0.27) %		–
$\pi^+ \gamma$	$< 8 \times 10^{-5}$	95%	40201
$D_s^+ \gamma$	$< 1.3 \times 10^{-3}$	95%	40177
$c\bar{X}$	(33.4 $\pm$ 2.6) %		–
$c\bar{s}$	(31 $^\pm$ ) %		–
invisible	[c] (1.4 $\pm$ 2.8) %		–

$Z$   $J = 1$

Charge = 0  
Mass  $m = 91.1876 \pm 0.0021$  GeV<sup>[d]</sup>  
Full width  $\Gamma = 2.4952 \pm 0.0023$  GeV  
 $\Gamma(\ell^+ \ell^-) = 83.984 \pm 0.086$  MeV<sup>[b]</sup>  
 $\Gamma(\text{invisible}) = 499.0 \pm 1.5$  MeV<sup>[e]</sup>  
 $\Gamma(\text{hadrons}) = 1744.4 \pm 2.0$  MeV  
 $\Gamma(\mu^+ \mu^-)/\Gamma(e^+ e^-) = 1.0009 \pm 0.0028$   
 $\Gamma(\tau^+ \tau^-)/\Gamma(e^+ e^-) = 1.0019 \pm 0.0032$ <sup>[f]</sup>

#### Average charged multiplicity

$\langle N_{\text{charged}} \rangle = 20.76 \pm 0.16$  ( $S = 2.1$ )

#### Couplings to leptons

$g_V^\ell = -0.03783 \pm 0.00041$   
 $g_A^\ell = -0.50123 \pm 0.00026$   
 $g^{V_e} = 0.53 \pm 0.09$   
 $g^{V_\mu} = 0.502 \pm 0.017$

#### Asymmetry parameters<sup>[g]</sup>

$A_e = 0.1515 \pm 0.0019$   
 $A_\mu = 0.142 \pm 0.015$   
 $A_\tau = 0.143 \pm 0.004$   
 $A_s = 0.90 \pm 0.09$   
 $A_c = 0.670 \pm 0.027$   
 $A_b = 0.923 \pm 0.020$

#### Charge asymmetry (%) at Z pole

$A_{FB}^{(0\ell)} = 1.71 \pm 0.10$   
 $A_{FB}^{(0u)} = 4 \pm 7$   
 $A_{FB}^{(0s)} = 9.8 \pm 1.1$   
 $A_{FB}^{(0c)} = 7.07 \pm 0.35$   
 $A_{FB}^{(0b)} = 9.92 \pm 0.16$

Mass  $m > 90.4$  GeV, CL = 95%  $\tan\beta > 0.4$

$H^\pm$  Mass  $m > 79.3$  GeV, CL = 95%

(See the Particle Listings for a Note giving details of Higgs Bosons.)

### Heavy Bosons Other than Higgs Bosons, Searches for

#### Additional W Bosons

$W'$  with standard couplings decaying to  $e\nu, \mu\nu$

Mass  $m > 800$  GeV, CL = 95%

$W_R$  — right-handed W

Mass  $m > 715$  GeV, CL = 90% (electroweak fit)

#### Additional Z Bosons

$Z_{SM}$  with standard couplings

Mass  $m > 825$  GeV, CL = 95% ( $p\bar{p}$  direct search)

Mass  $m > 1500$  GeV, CL = 95% (electroweak fit)

$Z_{LR}$  of  $SU(2)_L \times SU(2)_R \times U(1)$

(with  $g_L = g_R$ )

Mass  $m > 630$  GeV, CL = 95% ( $p\bar{p}$  direct search)

Mass  $m > 860$  GeV, CL = 95% (electroweak fit)

$Z_X$  of  $SO(10) \times SU(5) \times U(1)_X$  (with  $g_X = e \cos\theta_W$ )

Mass  $m > 690$  GeV, CL = 95% ( $p\bar{p}$  direct search)

Mass  $m > 781$  GeV, CL = 95% (electroweak fit)

$Z_\psi$  of  $E_6 \rightarrow SO(10) \times U(1)_\psi$  (with  $g_\psi = e \cos\theta_W$ )

Mass  $m > 675$  GeV, CL = 95% ( $p\bar{p}$  direct search)

Mass  $m > 366$  GeV, CL = 95% (electroweak fit)

$Z_\eta$  of  $E_6 \rightarrow SU(3) \times SU(2) \times U(1) \times U(1)_\eta$  (with  $g_\eta = e \cos\theta_W$ )

Mass  $m > 720$  GeV, CL = 95% ( $p\bar{p}$  direct search)

Mass  $m > 619$  GeV, CL = 95% (electroweak fit)

### Scalar Leptoquarks

Mass  $m > 256$  GeV, CL = 95% (1st generation, pair prod.)

Mass  $m > 298$  GeV, CL = 95% (1st gener., single prod.)

Mass  $m > 202$  GeV, CL = 95% (2nd gener., pair prod.)

Mass  $m > 73$  GeV, CL = 95% (2nd gener., single prod.)

Mass  $m > 148$  GeV, CL = 95% (3rd gener., pair prod.)

(See the Particle Listings for assumptions on leptoquark quantum numbers and branching fractions.)

### Axions ( $A^0$ ) and Other Very Light Bosons, Searches for

The standard Peccei–Quinn axion is ruled out. Variants with reduced couplings or much smaller masses are constrained by various data. The Particle Listings in the full *Review* contain a Note discussing axion searches.

The best limit for the half-life of neutrinoless double beta decay with Majoron emission is  $> 7.2 \times 10^{24}$  years (CL = 90%).

### NOTES

In this Summary Table:

When a quantity has “(S = . . .)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as  $S = \sqrt{\chi^2/(N-1)}$ , where  $N$  is the number of measurements used in calculating the quantity. We do this when  $S > 1$ , which often indicates that the measurements are inconsistent. When  $S > 1.25$ , we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame.

- [a] Theoretical value. A mass as large as a few MeV may not be precluded.
- [b]  $\ell$  indicates each type of lepton ( $e, \mu$ , and  $\tau$ ), not sum over them.
- [c] This represents the width for the decay of the W boson into a charged particle with momentum below detectability,  $p < 200$  MeV.
- [d] The Z-boson mass listed here corresponds to a Breit–Wigner resonance parameter. It lies approximately 34 MeV above the real part of the position of the pole (in the energy-squared plane) in the Z-boson propagator.
- [e] This partial width takes into account Z decays into  $\nu\bar{\nu}$  and any other possible undetected modes.
- [f] This ratio has not been corrected for the  $\tau$  mass.
- [g] Here  $A \equiv 2g_V g_A / (g_V^2 + g_A^2)$ .
- [h] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [i] See the Z Particle Listings for the  $\gamma$  energy range used in this measurement.
- [j] For  $m_{\gamma\gamma} = (60 \pm 5)$  GeV.
- [k] The limits assume no invisible decays.

# LEPTON SUMMARY TABLE

## LEPTONS

**e**

$$J = \frac{1}{2}$$

Mass  $m = (548.57990945 \pm 0.00000024) \times 10^{-6}$  u

 $\beta'/A = (1 \pm 5) \times 10^{-3}$   
 $\bar{\eta} = 0.02 \pm 0.08$

$\mu^+$  modes are charge conjugates of the modes below.

$\mu^-$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)
$e^- \bar{\nu}_e \nu_{\mu}$	$\approx 100\%$		53
$e^- \bar{\nu}_e \nu_{\mu} \gamma$	[d] (1.4 $\pm$ 0.4) %		53
$e^- \bar{\nu}_e \nu_{\mu} e^+ e^-$	[e] (3.4 $\pm$ 0.4) $\times 10^{-5}$		53
<b>Lepton Family number (LF) violating modes</b>			
$e^- \nu_e \bar{\nu}_{\mu}$	LF [f] < 1.2 %	90%	53
$e^- \gamma$	LF < 1.2 $\times 10^{-11}$	90%	53
$e^- e^+ e^-$	LF < 1.0 $\times 10^{-12}$	90%	53
$e^- 2\gamma$	LF < 7.2 $\times 10^{-11}$	90%	53

**$\tau$**

$$J = \frac{1}{2}$$

Mass  $m = 1776.99^{+0.29}_{-0.26}$  MeV  
 $(m_{\tau^+} - m_{\tau^-})/m_{\text{average}} < 3.0 \times 10^{-3}$ , CL = 90%  
 Mean life  $\tau = (290.6 \pm 1.0) \times 10^{-15}$  s  
 $c\tau = 87.11 \mu\text{m}$   
 Magnetic moment anomaly  $> -0.052$  and  $< 0.013$ , CL = 95%  
 $\text{Re}(d_{\tau}) = -0.22$  to  $0.45 \times 10^{-16}$  e cm, CL = 95%  
 $\text{Im}(d_{\tau}) = -0.25$  to  $0.008 \times 10^{-16}$  e cm, CL = 95%

### Weak dipole moment

$\text{Re}(d_{\tau}^W) < 0.50 \times 10^{-17}$  e cm, CL = 95%  
 $\text{Im}(d_{\tau}^W) < 1.1 \times 10^{-17}$  e cm, CL = 95%

### Weak anomalous magnetic dipole moment

$\text{Re}(\alpha_{\tau}^W) < 1.1 \times 10^{-3}$ , CL = 95%  
 $\text{Im}(\alpha_{\tau}^W) < 2.7 \times 10^{-3}$ , CL = 95%

### Decay parameters

See the  $\tau$  Particle Listings for a note concerning  $\tau$ -decay parameters.

$\rho^{\tau}(e \text{ or } \mu) = 0.745 \pm 0.008$   
 $\rho^{\tau}(e) = 0.747 \pm 0.010$   
 $\rho^{\tau}(\mu) = 0.763 \pm 0.020$   
 $\xi^{\tau}(e \text{ or } \mu) = 0.985 \pm 0.030$   
 $\xi^{\tau}(e) = 0.994 \pm 0.040$   
 $\xi^{\tau}(\mu) = 1.030 \pm 0.059$   
 $\eta^{\tau}(e \text{ or } \mu) = 0.013 \pm 0.020$   
 $\eta^{\tau}(\mu) = 0.094 \pm 0.073$   
 $(\delta\xi)^{\tau}(e \text{ or } \mu) = 0.746 \pm 0.021$   
 $(\delta\xi)^{\tau}(e) = 0.734 \pm 0.028$   
 $(\delta\xi)^{\tau}(\mu) = 0.778 \pm 0.037$   
 $\xi^{\tau}(\pi) = 0.993 \pm 0.022$   
 $\xi^{\tau}(\rho) = 0.994 \pm 0.008$   
 $\xi^{\tau}(a_1) = 1.001 \pm 0.027$   
 $\xi^{\tau}(\text{all hadronic modes}) = 0.995 \pm 0.007$

$\tau^+$  modes are charge conjugates of the modes below. “ $h^{\pm}$ ” stands for  $\pi^{\pm}$  or  $K^{\pm}$ . “ $l$ ” stands for  $e$  or  $\mu$ . “Neutrals” stands for  $\gamma$ 's and/or  $\pi^0$ 's.

Lepton Family number (LF), Lepton number (L),  
or Baryon number (B) violating modes

L means lepton number violation (e.g.  $\tau^- \rightarrow e^+ \pi^- \pi^-$ ). Following common usage, LF means lepton family violation and not lepton number violation (e.g.,  $\tau^- \rightarrow e^- \pi^+ \pi^-$ ). B means baryon number violation.

$e^- \gamma$	LF	$< 1.1 \times 10^{-7}$	CL = 90%	888
$\mu^- \gamma$	LF	$< 6.8 \times 10^{-8}$	CL = 90%	885

### Heavy Charged Lepton Searches

#### $L^\pm$ – charged lepton

Mass  $m > 100.8$  GeV, CL = 95% <sup>[h]</sup> Decay to  $\nu W$ .

#### $L^\pm$ – stable charged heavy lepton

Mass  $m > 102.6$  GeV, CL = 95%

### Neutrino Properties

See the note on “Neutrino properties listings” in the Particle Listings.

Mass  $m < 2$  eV (tritium decay)

Mean life/mass,  $\tau/m > 300$  s/eV, CL = 90% (reactor)

Mean life/mass,  $\tau/m > 7 \times 10^9$  s/eV (solar)

Mean life/mass,  $\tau/m > 15.4$  s/eV, CL = 90% (accelerator)

Magnetic moment  $\mu < 0.9 \times 10^{-10} \mu_B$ , CL = 90% (reactor)

### Number of Neutrino Types

Number  $N = 2.994 \pm 0.012$  (Standard Model fits to LEP data)

Number  $N = 2.92 \pm 0.06$  (Direct measurement of invisible  $Z$  width)

### Neutrino Mixing

The following values are obtained through data analyses based on the 3-neutrino mixing scheme described in the review “Neutrino mass, mixing, and flavor change” by B. Kayser in this *Review*.

$$\sin^2(2\theta_{12}) = 0.86_{-0.04}^{+0.03}$$

$$\Delta m_{21}^2 = (8.0_{-0.3}^{+0.4}) \times 10^{-5} \text{eV}^2$$

The ranges below for  $\sin^2(2\theta_{23})$  and  $\Delta m_{32}^2$  correspond to the projections onto the appropriate axes of the 90% CL contours

in the  $\sin^2(2\theta_{23})$ - $\Delta m_{32}^2$  plane.

$$\begin{aligned} \sin^2(2\theta_{23}) &> 0.92 \\ \Delta m_{32}^2 &= 1.9 \text{ to } 3.0 \times 10^{-3} \text{eV}^{2[i]} \\ \sin^2(2\theta_{13}) &< 0.19, \text{ CL} = 90\% \end{aligned}$$

### Heavy Neutral Leptons, Searches for

For excited leptons, see Compositeness Limits below (see page A-54).

#### Stable Neutral Heavy Lepton Mass Limits

Mass  $m > 45.0$  GeV, CL = 95% (Dirac)

Mass  $m > 39.5$  GeV, CL = 95% (Majorana)

#### Neutral Heavy Lepton Mass Limits

Mass  $m > 90.3$  GeV, CL = 95%

(Dirac  $\nu_L$  coupling to  $e, \mu, \tau$ ; conservative case( $\tau$ ))

Mass  $m > 80.5$  GeV, CL = 95%

(Majorana  $\nu_L$  coupling to  $e, \mu, \tau$ ; conservative case( $\tau$ ))

### NOTES

In this Summary Table:

When a quantity has “(S = ...)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as  $S = \sqrt{\chi^2/(N-1)}$ , where  $N$  is the number of measurements used in calculating the quantity. We do this when  $S > 1$ , which often indicates that the measurements are inconsistent. When  $S > 1.25$ , we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame.

- [a] This is the best limit for the mode  $e^- \rightarrow \nu \gamma$ . The best limit for “electron disappearance” is  $6.4 \times 10^{24}$  yr.
- [b] See the “Note on Muon Decay Parameters” in the  $\mu$  Particle Listings for definitions and details.
- [c]  $P_\mu$  is the longitudinal polarization of the muon from pion decay. In standard  $V-A$  theory,  $P_\mu = 1$  and  $\rho = \delta = 3/4$ .
- [d] This only includes events with the  $\gamma$  energy  $> 10$  MeV. Since the  $e^- \bar{\nu}_e \nu_\mu$  and  $e^- \bar{\nu}_e \nu_\mu \gamma$  modes cannot be clearly separated, we regard the latter mode as a subset of the former.
- [e] See the relevant Particle Listings for the energy limits used in this measurement.
- [f] A test of additive vs. multiplicative lepton family number conservation.
- [g] Basis mode for the  $\tau$ .
- [h]  $L^\pm$  mass limit depends on decay assumptions; see the Full Listings.
- [i] The sign of  $\Delta m_{32}^2$  is not known at this time. The range quoted is for the absolute value.

## QUARK SUMMARY TABLE

### QUARKS

The  $u$ -,  $d$ -, and  $s$ -quark masses are estimates of so-called “current-quark masses,” in a mass-independent subtraction scheme such as  $\overline{\text{MS}}$  at a scale  $\mu \approx 2$  GeV. The  $c$ - and  $b$ -quark masses are the “running” masses in the  $\overline{\text{MS}}$  scheme. For the  $b$ -quark we also quote the 1S mass. These can be different from the heavy quark masses obtained in potential models.

<b>u</b>	$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$	Mass $m = 1.5$ to $3.0$ MeV <sup>[a]</sup> Charge = $\frac{2}{3}e$ $I_z = +\frac{1}{2}$ $m_u/m_d = 0.3$ to $0.6$
<b>d</b>	$I(J^P) = \frac{1}{2}(\frac{1}{2}^+)$	Mass $m = 3$ to $7$ MeV <sup>[a]</sup> Charge = $-\frac{1}{3}e$ $I_z = -\frac{1}{2}$ $m_s/m_d = 17$ to $22$ $\bar{m} = (m_u + m_d)/2 = 2.5$ to $5.5$ MeV
<b>s</b>	$I(J^P) = 0(\frac{1}{2}^+)$	Mass $m = 95 \pm 25$ MeV <sup>[a]</sup> Charge = $-\frac{1}{3}e$ Strangeness = $-1$ $(m_s(m_u + m_d)/2)/(m_d - m_u) = 30$ to $50$
<b>c</b>	$I(J^P) = 0(\frac{1}{2}^+)$	Mass $m = 1.25 \pm 0.09$ GeV    Charge = $\frac{2}{3}e$ Charm = $+1$
<b>b</b>	$I(J^P) = 0(\frac{1}{2}^+)$	Charge = $\frac{1}{3}e$ Bottom = $-1$  Mass $m = 4.20 \pm 0.07$ GeV    ( $\overline{\text{MS}}$ mass) Mass $m = 4.70 \pm 0.07$ GeV    (1S mass)
<b>t</b>	$I(J^P) = 0(\frac{1}{2}^+)$	Charge = $\frac{2}{3}e$ Top = $+1$  Mass $m = 174.2 \pm 3.3$ GeV <sup>[b]</sup> (direct observation of top events) Mass $m = 172.3_{-7.6}^{+10.2}$ GeV (Standard Model electroweak fit)

t DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)
$Wq(q = b, s, d)$			-

### b'(4<sup>th</sup> Generation) Quark, Searches for

Mass  $m > 190$  GeV, CL = 95%    ( $p\bar{p}$ , quasi-stable  $b'$ )  
 Mass  $m > 199$  GeV, CL = 95%    ( $p\bar{p}$ , neutral-current decays)  
 Mass  $m > 128$  GeV, CL = 95%    ( $p\bar{p}$ , charged-current decays)  
 Mass  $m > 46.0$  GeV, CL = 95%    ( $e^+e^-$ , all decays)

### Free Quark Searches

All searches since 1977 have had negative results.

### NOTES

- [a] The ratios  $m_u/m_d$  and  $m_s/m_d$  are extracted from pion and kaon masses using chiral symmetry. The estimates of  $u$  and  $d$  masses are not without controversy and remain under active investigation. Within the literature there are even suggestions that the  $u$  quark could be essentially massless. The  $s$ -quark mass is estimated from SU(3) splittings in hadron masses.
- [b] Based on published top mass measurements using data from Tevatron Run-I and Run-II. Including also the most recent unpublished results from Run-II, the Tevatron Electroweak Working Group reports a top mass of  $172.5 \pm 1.3 \pm 1.9$  GeV. See the note “The Top Quark” in the Quark Particle Listings of this Review.
- [c]  $\ell$  means  $e$  or  $\mu$  decay mode, not the sum over them.
- [d] Assumes lepton universality and  $W$ -decay acceptance.
- [e] This limit is for  $\Gamma(t \rightarrow \gamma q)/\Gamma(t \rightarrow Wb)$ .
- [f] This limit is for  $\Gamma(t \rightarrow Zq)/\Gamma(t \rightarrow Wb)$ .

## MESON SUMMARY TABLE

### LIGHT UNFLAVORED MESONS

$$(S = C = B = 0)$$

$$\Gamma_+/ \Gamma_- = 0.22 \pm 0.06 \quad (S = 1.6)$$

Most decay modes (other than the semileptonic modes) that involve a neutral K meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

#### CPT-violation decay-rate asymmetry

$$A_{CPT}(K^{\mp}\pi^{\pm}) = 0.008 \pm 0.008$$

Most decay modes (other than the semileptonic modes) that involve a neutral  $K$  meson are now given as  $K_S^0$  modes, not as  $\bar{K}^0$  modes. Nearly always it is a  $K_S^0$  that is measured, and interference between Cabibbo-allowed and doubly Cabibbo-suppressed modes can invalidate the assumption that  $2\Gamma(K_S^0) = \Gamma(\bar{K}^0)$ .

**BOTTOM MESONS**

$$(B = \pm 1)$$

$$B^+ = u\bar{b}, B^0 = d\bar{b}, \bar{B}^0 = \bar{d}b, B^- = \bar{u}b, \quad \text{similarly for } B^{*s}$$

**B-particle organization**

Many measurements of  $B$  decays involve admixtures of  $B$  hadrons. Previously we arbitrarily included such admixtures in the  $B^\pm$  section, but because of their importance we have created two new sections: “ $B^\pm/B^0$  Admixture” for  $\Upsilon(4S)$  results and “ $B^\pm/B^0/B_s^0/b$ -baryon Admixture” for results at higher energies. Most inclusive decay branching fractions and  $\chi_b$  at high energy are found in the Admixture sections.  $B^0\text{-}\bar{B}^0$  mixing data are found in the  $B^0$  section, while  $B_s^0\text{-}\bar{B}_s^0$  mixing data and  $B\text{-}\bar{B}$  mixing data for a  $B^0/B_s^0$  admixture are found in the  $B_s^0$  section.  $CP$ -violation data are found in the  $B^\pm, B^0,$  and  $B^\pm B^0$  Admixture sections.  $b$ -baryons are found near the end of the Baryon section.

The organization of the  $B$  sections is now as follows, where bullets indicate particle sections and brackets indicate reviews.

- $B^\pm$   
mass, mean life, branching fractions  $CP$  violation
- $B^0$   
mass, mean life, branching fractions  
polarization in  $B^0$  decay,  $B^0\text{-}\bar{B}^0$  mixing,  $CP$  violation
- $B^\pm B^0$  Admixtures  
branching fractions,  $CP$  violation
- $B^\pm/B^0/B_s^0/b$ -baryon Admixtures  
mean life, production fractions, branching fractions  
 $\chi_b$  at high energy,  $V_{cb}$  measurements
- $B^*$   
mass
- $B_s^0$   
mass, mean life, branching fractions  
polarization in  $B_s^0$  decay,  $B_s^0\text{-}\bar{B}_s^0$  mixing
- $B_c^\pm$   
mass, mean life, branching fractions

At end of Baryon Listings:

- $\Lambda_b$   
mass, mean life, branching fractions
- $b$ -baryon Admixture  
mean life, branching fractions

**$B^\pm$**

$$I(J^P) = \frac{1}{2}(0^-)$$

$I, J, P$  need confirmation. Quantum numbers shown are quark-model predictions.

$$\text{Mass } m_{B^\pm} = 5279.0 \pm 0.5 \text{ MeV}$$

$$\text{Mean life } \tau_{B^\pm} = (1.638 \pm 0.011) \times 10^{-12} \text{ s}$$

$B^-$  modes are charge conjugates of the modes below. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0\bar{B}^0$  and 50%  $B^+B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D, D_s, D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

$\bar{B}^0$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing. Modes which do not identify the charge state of the  $B$  are listed in the  $B^\pm/B^0$  ADMIXTURE section.

The branching fractions listed below assume 50%  $B^0\bar{B}^0$  and 50%  $B^+B^-$  production at the  $\Upsilon(4S)$ . We have attempted to bring older measurements up to date by rescaling their assumed  $\Upsilon(4S)$  production ratio to 50:50 and their assumed  $D, D_s, D^*$ , and  $\psi$  branching ratios to current values whenever this would affect our averages and best limits significantly.

Indentation is used to indicate a subchannel of a previous reaction. All resonant subchannels have been corrected for resonance branching fractions to the final state so the sum of the subchannel branching fractions can exceed that of the final state.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

**$B^\pm/B^0$  ADMIXTURE****CP violation**

$$A_{CP}(B \rightarrow K^*(892)\gamma) = -0.010 \pm 0.028$$

$$A_{CP}(B \rightarrow s\gamma) = 0.00 \pm 0.04$$

$$A_{CP}(b \rightarrow X_s \ell^+ \ell^-) = -0.22 \pm 0.26$$

The branching fraction measurements are for an admixture of  $B$  mesons at the  $\Upsilon(4S)$ . The values quoted assume that  $B(\Upsilon(4S) \rightarrow B\bar{B}) = 100\%$ .

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

$\bar{B}$  modes are charge conjugates of the modes below. Reactions indicate the weak decay vertex and do not include mixing.

<b>B DECAY MODES</b>	Fraction ( $\Gamma_i/\Gamma$ )	Scale factor/ Confidence level	$p$ (MeV/c)				
<b>Semileptonic and leptonic modes</b>							
$B \rightarrow e^+ \nu_e$ anything	[ <i>ooo</i> ] (10.78 ± 0.18) %		–				
$B \rightarrow \bar{\nu}_e e^+$ anything	< 5.9 × 10 <sup>-4</sup>	CL = 90%	–

### $B^\pm/B^0/B_s^0/b$ -baryon ADMIXTURE

These measurements are for an admixture of bottom particles at high energy (LEP, Tevatron,  $Spp\bar{S}$ ).

$$\text{Mean life } \tau = (1.568 \pm 0.009) \times 10^{-12} \text{ s}$$

$$\text{Mean life } \tau = (1.72 \pm 0.10) \times 10^{-12} \text{ s} \quad \text{Charged } b\text{-hadron admixture}$$

$$\text{Mean life } \tau = (1.58 \pm 0.14) \times 10^{-12} \text{ s} \quad \text{Neutral } b\text{-hadron admixture}$$

$$\tau_{\text{charged } b\text{-hadron}}/\tau_{\text{neutral } b\text{-hadron}} = 1.09 \pm 0.13$$

$$|\Delta\tau_b|/\tau_{b,\bar{b}} = -0.001 \pm 0.014$$

The branching fraction measurements are for an admixture of  $B$  mesons and baryons at energies above the  $\Upsilon(4S)$ . Only the highest energy results (LEP, Tevatron,  $Spp\bar{S}$ ) are used in the branching fraction averages. In the following, we assume that the production fractions are the same at the LEP and at the Tevatron.

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm$  anything, the values usually are multiplicities, not branching fractions. They can be greater than one.

The modes below are listed for a  $\bar{b}$  initial state.  $b$  modes are their charge conjugates. Reactions indicate the weak decay vertex and do not include mixing.

$\bar{b}$ DECAY MODES	Scale factor/ Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)
-----------------------	---	------------------	----------------

### PRODUCTION FRACTIONS

The production fractions for weakly decaying  $b$ -hadrons at high energy have been calculated from the best values of mean lives, mixing parameters, and branching fractions in this edition by the Heavy Flavor Averaging Group (HFAG) as described in the note “ $B^0$ - $\bar{B}^0$  Mixing” in the  $B^0$  Particle Listings. Values assume

$$B(\bar{b} \rightarrow B^+) = B(\bar{b} \rightarrow B^0)$$

$$B(\bar{b} \rightarrow B^+) + B(\bar{b} \rightarrow B^0) + B(\bar{b} \rightarrow B_s^0) + B(b \rightarrow b\text{-baryon}) = 100\%.$$

The notation for production fractions varies in the literature ( $f_d, d_{B^0}, f(b \rightarrow \bar{B}^0)$ ,  $Br(b \rightarrow \bar{B}^0)$ ). We use our own branching fraction notation here,  $B(\bar{b} \rightarrow B^0)$ .

#### $B_s^0 \bar{B}_s^0$ mixing parameters

$$\Delta m_{B_s^0} = m_{B_s^0 H} - m_{B_s^0 L} > 14.4 \times 10^{12} \hbar \text{ s}^{-1}, \text{ CL} = 95\%$$

$$> 94.8 \times 10^{-10} \text{ MeV}, \text{ CL} = 95\%$$

$$x_s = \Delta m_{B_s^0} / \Gamma_{B_s^0} > 19.9, \text{ CL} = 95\%$$

$$\chi_s > 0.49878, \text{ CL} = 95\%$$

These branching fractions all scale with  $B(\bar{b} \rightarrow B_s^0)$ , the LEP  $B_s^0$  production fraction. The first four were evaluated using  $B(\bar{b} \rightarrow B_s^0) = (10.7 \pm 1.4)\%$  and the rest assume  $B(\bar{b} \rightarrow B_s^0) = 12\%$ .

The branching fraction  $B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$  is not a pure measurement since the measured product branching fraction  $B(\bar{b} \rightarrow B_s^0) \times B(B_s^0 \rightarrow D_s^- \ell^+ \nu_\ell \text{ anything})$  was used to determine  $B(\bar{b} \rightarrow B_s^0)$ , as described in the note on " $B^0 - \bar{B}^0$  Mixing"

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{ anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

$B_s^0$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)
$D_s^- \text{ anything}$	(94 ± 30) %		-

### BOTTOM, CHARMED MESONS

$$(B = C = \pm 1)$$

$$B_c^+ = c\bar{b}, B_c^- = \bar{c}b, \text{ similarly for } B_c^{*\pm}$$

$$B_c^\pm \quad I(J^P) = 0(0^-)$$

$I, J, P$  need confirmation.

Quantum numbers shown are quark model predictions.

$$\text{Mass } m = 6.286 \pm 0.005 \text{ GeV}$$

$$\text{Mean life } \tau = (0.46_{-0.16}^{+0.18}) \times 10^{-12} \text{ s}$$

$B_c^-$  modes are charge conjugates of the modes below.

$B_c^\pm$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)
The following quantities are not pure branching ratios; rather the fraction $\Gamma_i/\Gamma \times B(\bar{b} \rightarrow B_c)$ .			
$J/\psi(1S)\ell^+ \nu_\ell \text{ anything}$	(5.2 <sup>+2.4</sup> <sub>-2.1</sub> ) × 10 <sup>-5</sup>		-

 $\psi(3770)$ 

$$I^G(J^{PC}) = 0^-(1^{--})$$

Mass  $m = 3771.1 \pm 2.4$  MeV  
 Full width  $\Gamma = 23.0 \pm 2.7$  MeV ( $S = 1.1$ )  
 $\Gamma_{ee} = 0.242_{-0.024}^{+0.027}$  keV ( $S = 1.1$ )

In addition to the dominant decay mode to  $D\bar{D}$ ,  $\psi(3770)$  was found to decay into the final states containing the  $J/\psi$  (BAI 05, ADAM 06). ADAMS 06 and HUANG 06A searched for various decay modes with light hadrons and found a statistically significant signal for the decay to  $\phi\eta$  only (ADAMS 06).

## NOTES

In this Summary Table:

When a quantity has “( $S = \dots$ )” to its right, the error on the quantity has been enlarged by the “scale factor”  $S$ , defined as  $S = \sqrt{\chi^2/(N-1)}$ , where  $N$  is the number of measurements used in calculating the quantity. We do this when  $S > 1$ , which often indicates that the measurements are inconsistent. When  $S > 1.25$ , we also show in the Particle Listings an ideogram of the measurements. For more about  $S$ , see the Introduction.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame.

- [a] See the “Note on  $\pi^\pm \rightarrow \ell^\pm \nu \gamma$  and  $K^\pm \rightarrow \ell^\pm \nu \gamma$  Form Factors” in the  $\pi^\pm$  Particle Listings for definitions and details.
- [b] Measurements of  $\Gamma(e^+ \nu_e)/\Gamma(\mu^+ \nu_\mu)$  always include decays with  $\gamma$ 's, and measurements of  $\Gamma(e^+ \nu_e \gamma)$  and  $\Gamma(\mu^+ \nu_\mu \gamma)$  never include low-energy  $\gamma$ 's. Therefore, since no clean separation is possible, we consider the modes with  $\gamma$ 's to be subreactions of the modes without them, and let  $[\Gamma(e^+ \nu_e) + \Gamma(\mu^+ \nu_\mu)]/\Gamma_{\text{total}} = 100\%$ .
- [c] See the  $\pi^\pm$  Particle Listings for the energy limits used in this measurement; low-energy  $\gamma$ 's are not included.
- [d] Derived from an analysis of neutrino-oscillation experiments.
- [e] Astrophysical and cosmological arguments give limits of order  $10^{-13}$ ; see the  $\pi^0$  Particle Listings.
- [f] Due to a new measurement in the average, this is 0.45 MeV larger than the mass we gave in our 2002 edition,  $547.30 \pm 0.12$  MeV.
- [g] Due to removing an old measurement from the average, this is 0.11 keV larger than the width we gave in our 2002 edition,  $1.18 \pm 0.11$  keV. See the  $\Gamma(2\gamma)$  data block in the Data Listings.
- [h] C parity forbids this to occur as a single-photon process.
- [i] See the “Note on scalar mesons” in the  $f_0(1370)$  Particle Listings. The interpretation of this entry as a particle is controversial.
- [j] See the “Note on  $\rho(770)$ ” in the  $\rho(770)$  Particle Listings.
- [k] The  $\omega\rho$  interference is then due to  $\omega\rho$  mixing only, and is expected to be small. If  $e\mu$  universality holds,  $\Gamma(\rho^0 \rightarrow \mu^+ \mu^-) = \Gamma(\rho^0 \rightarrow e^+ e^-) \times 0.99785$ .
- [l] See the “Note on scalar mesons” in the  $f_0(1370)$  Particle Listings.
- [m] See the “Note on  $a_1(1260)$ ” in the  $a_1(1260)$  Particle Listings.
- [n] This is only an educated guess; the error given is larger than the error on the average of the published values. See the Particle Listings for details.
- [o] See the “Note on non- $q\bar{q}$  mesons” in the Particle Listings (see the index for the page number).
- [p] See the “Note on the  $\eta(1405)$ ” in the  $\eta(1405)$  Particle Listings.
- [q] See the “Note on the  $f_1(1420)$ ” in the  $\eta(1405)$  Particle Listings.
- [r] See also the  $\omega(1650)$  Particle Listings.
- [s] See the “Note on the  $\rho(1450)$  and the  $\rho(1700)$ ” in the  $\rho(1700)$  Particle Listings.
- [t] See also the  $\omega(1420)$  Particle Listings.
- [u] See the “Note on  $f_0(1710)$ ” in the  $f_0(1710)$  Particle Listings.
- [v] See the note in the  $K^\pm$  Particle Listings.
- [w] The definition of the slope parameter  $g$  of the  $K \rightarrow 3\pi$  Dalitz plot is as follows (see also “Note on Dalitz Plot Parameters for  $K \rightarrow 3\pi$  Decays” in the  $K^\pm$  Particle Listings):

$$|M|^2 = 1 + g(s_3 - s_0)/m_{\pi^+}^2 + \dots$$

- [x] For more details and definitions of parameters see the Particle Listings.
- [y] Most of this radiative mode, the low-momentum  $\gamma$  part, is also included in the parent mode listed without  $\gamma$ 's.
- [z] See the  $K^\pm$  Particle Listings for the energy limits used in this measurement.
- [aa] Structure-dependent part.
- [bb] Direct-emission branching fraction.
- [cc] Violates angular-momentum conservation.
- [dd] Derived from measured values of  $\phi_{+-}$ ,  $\phi_{00}$ ,  $|\eta|$ ,  $|m_{K_L^0} - m_{K_S^0}|$ , and  $\tau_{K_S^0}$ , as described in the introduction to “Tests of Conservation Laws.”

[ee] The  $CP$ -violation parameters are defined as follows (see also “Note on  $CP$  Violation in  $K_S \rightarrow 3\pi$ ” and “Note on  $CP$  Violation in  $K_L^0$  Decay” in the Particle Listings):

$$\begin{aligned}\eta_{+-} &= |\eta_{+-}|e^{i\phi_{+-}} = \frac{A(K_L^0 \rightarrow \pi^+\pi^-)}{A(K_S^0 \rightarrow \pi^+\pi^-)} = \epsilon + \epsilon' \\ \eta_{00} &= |\eta_{00}|e^{i\phi_{00}} = \frac{A(K_L^0 \rightarrow \pi^0\pi^0)}{A(K_S^0 \rightarrow \pi^0\pi^0)} = \epsilon - 2\epsilon' \\ \delta &= \frac{\Gamma(K_L^0 \rightarrow \pi^-\ell^+\nu) - \Gamma(K_L^0 \rightarrow \pi^+\ell^-\nu)}{\Gamma(K_L^0 \rightarrow \pi^-\ell^+\nu) + \Gamma(K_L^0 \rightarrow \pi^+\ell^-\nu)}, \\ \text{Im}(\eta_{+-0})^2 &= \frac{\Gamma(K_S^0 \rightarrow \pi^+\pi^-\pi^0)^{CP \text{ viol.}}}{\Gamma(K_L^0 \rightarrow \pi^+\pi^-\pi^0)}, \\ \text{Im}(\eta_{000})^2 &= \frac{\Gamma(K_S^0 \rightarrow \pi^0\pi^0\pi^0)}{\Gamma(K_L^0 \rightarrow \pi^0\pi^0\pi^0)}\end{aligned}$$

where for the last two relations  $CPT$  is assumed valid, i.e.,  $\text{Re}(\eta_{+-0}) \simeq 0$  and  $\text{Re}(\eta_{000}) \simeq 0$ .

- [ff] See the  $K_S^0$  Particle Listings for the energy limits used in this measurement.
- [gg] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [hh]  $\text{Re}(\epsilon'/\epsilon) = \epsilon'/\epsilon$  to a very good approximation provided the phases satisfy  $CPT$  invariance.
- [ii] See the  $K_L^0$  Particle Listings for the energy limits used in this measurement.
- [jj] Allowed by higher-order electroweak interactions.
- [kk] Violates  $CP$  in leading order. Test of direct  $CP$  violation since the indirect  $CP$ -violating and  $CP$ -conserving contributions are expected to be suppressed.
- [ll] See the “Note on  $f_0(1370)$ ” in the  $f_0(1370)$  Particle Listings and in the 1994 edition.
- [mm] See the note in the  $L(1770)$  Particle Listings in Reviews of Modern Physics 56 No. 2 Pt. II (1984), p. S200. See also the “Note on  $K_2(1770)$  and the  $K_2(1820)$ ” in the  $K_2(1770)$  Particle Listings.
- [nn] See the “Note on  $K_2(1770)$  and the  $K_2(1820)$ ” in the  $K_2(1770)$  Particle Listings.
- [oo] This result applies to  $Z^0 \rightarrow c\bar{c}$  decays only. Here  $\ell^+$  is an average (not a sum) of  $e^+$  and  $\mu^+$  decays.
- [pp] This is a weighted average of  $D^\pm$  (44%) and  $D^0$  (56%) branching fractions. See “ $D^+$  and  $D^0 \rightarrow (\eta \text{ anything})/(\text{total } D^+ \text{ and } D^0)$ ” under “ $D^+$  Branching Ratios” in the Particle Listings.
- [qq] The branching fraction for this mode may differ from the sum of the submodes that contribute to it, due to interference effects. See the relevant papers in the Particle Listings.
- [rr] These subfractions of the  $K^-\pi^+\pi^+$  mode are uncertain: see the Particle Listings.
- [ss] The two experiments measuring this fraction are in serious disagreement. See the Particle Listings.
- [tt] This is *not* a test for the  $\Delta C = 1$  weak neutral current, but leads to the  $\pi^+e^+e^-$  final state.
- [uu] This mode is not a useful test for a  $\Delta C = 1$  weak neutral current because both quarks must change flavor in this decay.
- [vv] This  $D_1^0 - D_2^0$  limit is inferred from the  $D^0 - \bar{D}^0$  mixing ratio  $\Gamma(K^+\pi^- \text{ (via } \bar{D}^0)) / \Gamma(K^-\pi^+ \text{ (via } D^0))$  near the end of the  $D^0$  Listings.
- [www] This value is obtained by subtracting the branching fractions for 2-, 4- and 6-prongs from unity.
- [xx] This is the sum of our  $K^-\pi^+\pi^+\pi^-$ ,  $K^-\pi^+\pi^+\pi^-\pi^0$ ,  $\bar{K}^0 2\pi^+2\pi^-$ ,  $2\pi^+2\pi^-$ ,  $2\pi^+2\pi^-\pi^0$ ,  $K^+K^-\pi^+\pi^-$ , and  $K^+K^-\pi^+\pi^-\pi^0$ , branching fractions.
- [yy] The branching fractions for the  $K^-e^+\nu_e$ ,  $K^*(892)^-e^+\nu_e$ ,  $\pi^-e^+\nu_e$ , and  $\rho^-e^+\nu_e$  modes add up to  $6.14 \pm 0.20\%$ .
- [zz] This is a doubly Cabibbo-suppressed mode.
- [aaa] This branching fraction includes all the decay modes of the resonance in the final state.
- [bbb] The experiments on the division of this charge mode among its submodes disagree, and the submode branching fractions here add up to considerably more than the charged-mode fraction.
- [ccc] However, these upper limits are in serious disagreement with values obtained in another experiment.
- [ddd] For now, we average together measurements of the  $Xe^+\nu_e$  and  $X\mu^+\nu_\mu$  branching fractions. This is the *average*, not the *sum*.
- [eee] This branching fraction includes all the decay modes of the final-state resonance.
- [fff] This comes from a  $K$ -matrix parametrization of the  $\pi^+\pi^- S$ -wave and is a sum over the  $f_0(980)$ ,  $f_0(1300)$ ,  $f_0(1200-1600)$ ,  $f_0(1500)$ , and  $f_0(1750)$ . Not all of these correspond to particles in our Tables.
- [ggg] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.
- [hhh] An  $CP(\pm 1)$  indicates the  $CP = +1$  and  $CP = -1$  eigenstates of the  $D^0 - \bar{D}^0$  system.
- [iii]  $D$  denotes  $D^0$  or  $\bar{D}^0$ .
- [jjj]  $X(3872)^+$  is a hypothetical charged partner of the  $X(3872)$ .
- [kkk]  $\Theta(1710)^{++}$  is a possible narrow pentaquark state and  $G(2220)$  is a possible glueball resonance.
- [lll] Stands for the possible candidates of  $K^*(1410)$ ,  $K_0^*(1430)$  and  $K_2^*(1430)$ .
- [mmm]  $B^0$  and  $B_s^0$  contributions not separated. Limit is on weighted average of the two decay rates.
- [nmm]  $\Theta(1540)^+$  denotes a possible narrow pentaquark state.
- [ooo] These values are model dependent.
- [ppp] Here “anything” means at least one particle observed.
- [qqq]  $D^{**}$  stands for the sum of the  $D(1^1P_1)$ ,  $D(1^3P_0)$ ,  $D(1^3P_1)$ ,  $D(1^3P_2)$ ,  $D(2^1S_0)$ , and  $D(2^1S_1)$  resonances.
- [rrr]  $D^{(*)}\bar{D}^{(*)}$  stands for the sum of  $D^*\bar{D}^*$ ,  $D^*\bar{D}$ ,  $D\bar{D}^*$ , and  $D\bar{D}$ .
- [sss]  $Y(3940)$  denotes a near-threshold enhancement in the  $\omega J/\psi$  mass spectrum.
- [ttt] Inclusive branching fractions have a multiplicity definition and can be greater than 100%.
- [uuu]  $D_j$  represents an unresolved mixture of pseudoscalar and tensor  $D^{**}$  ( $P$ -wave) states.
- [vvv] Not a pure measurement. See note at head of  $B_s^0$  Decay Modes.
- [www] Includes  $p\bar{p}\pi^+\pi^-\gamma$  and excludes  $p\bar{p}\eta$ ,  $p\bar{p}\omega$ ,  $p\bar{p}\eta'$ .
- [xxx]  $J^{PC}$  known by production in  $e^+e^-$  via single photon annihilation.  $I^G$  is not known; interpretation of this state as a single resonance is unclear because of the expectation of substantial threshold effects in this energy region.
- [yyy] Spectroscopic labeling for these states is theoretical, pending experimental information.

See also the table of suggested  $q\bar{q}$  quark-model assignments in the Quark Model section.

• Indicates particles that appear in the preceding Meson Summary Table. We do not regard the other entries as being established.

† Indicates that the value of  $J$  given is preferred, but needs confirmation.

## BARYON SUMMARY TABLE

This short table gives the name, the quantum numbers (where known), and the status of baryons in the *Review*. Only the baryons with 3- or 4-star status are included in the main Baryon Summary Table. Due to insufficient data or uncertain interpretation, the other entries in the short table are not established as baryons. The names with masses are of baryons that decay strongly. For  $N$ ,  $\Delta$ , and  $\Xi$  resonances, the partial wave is indicated by the symbol  $L_{2i,2j}$ , where  $L$  is the orbital angular momentum ( $S, P, D, \dots$ ),  $I$  is the isospin, and  $J$  is the total angular momentum. For  $\Lambda$  and  $\Sigma$  resonances, the symbol is  $L_{i,2j}$ .

\*\*\*\* Existence is certain, and properties are at least fairly well explored.

\*\*\* Existence ranges from very likely to certain, but further confirmation is desirable and/or quantum numbers, branching fractions, etc. are not well determined.

\*\* Evidence of existence is only fair.

\* Evidence of existence is poor.

$[\alpha(\Lambda_c^+) + \alpha(\bar{\Lambda}_c^-)]/[\alpha(\Lambda_c^+) - \alpha(\bar{\Lambda}_c^-)]$ in $\Lambda_c^+ \rightarrow \Lambda e^+ \nu_e, \bar{\Lambda}_c^- \rightarrow \bar{\Lambda} e^- \bar{\nu}_e = 0.00 \pm 0.04$	

Nearly all branching fractions of the  $\Lambda_c^+$  are measured relative to the  $pK^- \pi^+$  mode, but there are no model-independent measurements of this branching fraction. We explain how we arrive at our value of  $B(\Lambda_c^+ \rightarrow pK^- \pi^+)$  in a Note at the beginning of the branching-ratio measurements in the Listings. When this branching fraction is eventually well determined, all the other branching fractions will slide up or down proportionally as the true value differs from the value we use here.

$$\Lambda_c(2593)^+ \quad I(J^P) = 0(\frac{1}{2}^-)$$

The spin-parity follows from the fact that  $\Sigma_c(2455)\pi$  decays, with little available phase space, are dominant. This assumes that  $J^P = 1/2^+$  for the  $\Sigma_c(2455)$ .

$$\text{Mass } m = 2595.4 \pm 0.6 \text{ MeV } (S = 1.1)$$

$$m - m_{\Lambda_c^+} = 308.9 \pm 0.6 \text{ MeV } (S = 1.1)$$

$$\text{Full width } \Gamma = 3.6_{-1.3}^{+2.0} \text{ MeV}$$

$\Lambda_c^+\pi\pi$  and its submode  $\Sigma_c(2455)\pi$  — the latter just barely — are the only strong decays allowed to an excited  $\Lambda_c^+$  having this mass; and the submode seems to dominate.

$\Lambda_c(2593)^+$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	$p$ (MeV/c)
$\Lambda_c^+\pi^+\pi^-$	$[q] \approx 67\%$	124
$\Sigma_c(2455)^{++}\pi^-$	$24 \pm 7\%$	28
$\Sigma_c(2455)^0\pi^+$	$24 \pm 7\%$	28
$\Lambda_c^+\pi^+\pi^-$ 3-body	$18 \pm 10\%$	124
$\Lambda_c^+\pi^0$	$[r]$ not seen	261
$\Lambda_c^+\gamma$	not seen	291

$$\Lambda_c(2625)^+ \quad I(J^P) = 0(\frac{3}{2}^-)$$

$J^P$  has not been measured;  $\frac{3}{2}^-$  is the quark-model prediction.

$$\text{Mass } m = 2628.1 \pm 0.6 \text{ MeV } (S = 1.5)$$

$$m - m_{\Lambda_c^+} = 341.7 \pm 0.6 \text{ MeV } (S = 1.6)$$

$$\text{Full width } \Gamma < 1.9 \text{ MeV, CL} = 90\%$$

$\Lambda_c^+\pi\pi$  and its submode  $\Sigma(2455)\pi$  are the only strong decays allowed to an excited  $\Lambda_c^+$  having this mass.

$\Lambda_c(2625)^+$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)

 $\Xi_c(2815)^+$  mass  $m = 2816.5 \pm 1.2$  MeV  
 $\Xi_c(2815)^0$  mass  $m = 2818.2 \pm 2.1$  MeV  
 $m_{\Xi_c(2815)^+} - m_{\Xi_c^+} = 348.6 \pm 1.2$  MeV  
 $m_{\Xi_c(2815)^0} - m_{\Xi_c^0} = 347.2 \pm 2.1$  MeV  
 $\Xi_c(2815)^+$  full width  $\Gamma < 3.5$  MeV, CL = 90%  
 $\Xi_c(2815)^0$  full width  $\Gamma < 6.5$  MeV, CL = 90%  
The  $\Xi_c\pi\pi$  modes are consistent with being entirely via  $\Xi_c(2645)\pi$ .

$\Xi_c(2815)$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	$p$ (MeV/c)
$\Xi_c^+\pi^+\pi^-$	seen	196
$\Xi_c^0\pi^+\pi^-$	seen	191

 **$\Omega_c^0$** 

$$I(J^P) = 0(\frac{1}{2}^+)$$

$J^P$  has not been measured;  $\frac{1}{2}^+$  is the quark-model prediction.  
Mass  $m = 2697.5 \pm 2.6$  MeV (S = 1.2)  
Mean life  $\tau = (69 \pm 12) \times 10^{-15}$  s  
 $c\tau = 21\mu\text{m}$   
No absolute branching fractions have been measured.

$\Omega_c^0$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	$p$ (MeV/c)
$\Sigma^+K^-K^-\pi^+$	seen	691
$\Xi^0K^-\pi^+$	seen	903
$\Xi^-K^-\pi^+\pi^+$	seen	832
$\Omega^-e^+v_e$	seen	830
$\Omega^-\pi^+$	seen	822
$\Omega^-\pi^+\pi^0$	seen	798
$\Omega^-\pi^-\pi^+\pi^+$	seen	754

**BOTTOM BARYONS**

$$(B = -1)$$

$$\Lambda_b^0 = udb, \Xi_b^0 = usb, \Xi_b^- = dsb$$

 **$\Lambda_b^0$** 

$$I(J^P) = 0(\frac{1}{2}^+)$$

$I(J^P)$  not yet measured;  $0(\frac{1}{2}^+)$  is the quark model prediction.  
Mass  $m = 5624 \pm 9$  MeV (S = 1.8)  
Mean life  $\tau = (1.230 \pm 0.074) \times 10^{-12}$  s  
 $c\tau = 369\mu\text{m}$

These branching fractions are actually an average over weakly decaying  $b$ -baryons weighted by their production rates in  $Z$  decay (or high-energy  $p\bar{p}$ ), branching ratios, and detection efficiencies. They scale with the LEP  $b$ -baryon production fraction  $B(b \rightarrow b\text{-baryon})$  and are evaluated for our value  $B(b \rightarrow b\text{-baryon}) = (10.0 \pm 2.0)\%$ .

The branching fractions  $B(b\text{-baryon} \rightarrow \Lambda\ell^-\bar{\nu}_\ell \text{ anything})$  and  $B(\Lambda_b^0 \rightarrow \Lambda_c^+\ell^-\bar{\nu}_\ell \text{ anything})$  are not pure measurements because the underlying measured products of these with  $B(b \rightarrow b\text{-baryon})$  were used to determine  $B(b \rightarrow b\text{-baryon})$ , as described in the note "Production and Decay of  $b$ -Flavored Hadrons."

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{ anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

$\Lambda_b^0$ DECAY MODES	Fraction ( $\Gamma_i/\Gamma$ )	Confidence level	$p$ (MeV/c)
$J/\psi(1S)\Lambda$	$(4.7 \pm 2.8) \times 10^{-4}$		1744
$\Lambda_c^+\pi^-$	seen		2345
$\Lambda_c^+a_1(1260)^-$	seen		2155
$\Lambda_c^+\ell^-\bar{\nu}_\ell \text{ anything}$	[t] $(9.1 \pm 2.3) \%$		-
$\Lambda_c^+\ell^-\bar{\nu}_\ell$	$(5.0^{+1.9}_{-1.4}) \%$		2347
$\Lambda_c^+\pi^+\pi^-\ell^-\bar{\nu}_\ell$	$(5.6 \pm 3.1) \%$		2337
$p\bar{b}^-$	[u] $< 2.3 \times 10^{-5}$	90%	2732
$p\pi^-$	$< 5.0 \times 10^{-5}$	90%	2732
$pK^-$	$< 5.0 \times 10^{-5}$	90%	2711
$\Lambda\gamma$	$< 1.3 \times 10^{-3}$	90%	2701

 **$b$ -baryon ADMIXTURE ( $\Lambda_b^c, \Xi_b^c, \Sigma_b^c, \Omega_b^c$ )**

$$\text{Mean life } \tau = (1.209 \pm 0.049) \times 10^{-12} \text{ s}$$

These branching fractions are actually an average over weakly decaying  $b$ -baryons weighted by their production rates in  $Z$  decay (or high-energy  $p\bar{p}$ ), branching ratios, and detection efficiencies. They scale with the LEP  $b$ -baryon production fraction  $B(b \rightarrow b\text{-baryon})$  and are evaluated for our value  $B(b \rightarrow b\text{-baryon}) = (10.0 \pm 2.0)\%$ .

The branching fractions  $B(b\text{-baryon} \rightarrow \Lambda\ell^-\bar{\nu}_\ell \text{ anything})$  and  $B(\Lambda_b^0 \rightarrow \Lambda_c^+\ell^-\bar{\nu}_\ell \text{ anything})$  are not pure measurements because the underlying measured products of these with  $B(b \rightarrow b\text{-baryon})$  were used to determine  $B(b \rightarrow b\text{-baryon})$ , as described in the note "Production and Decay of  $b$ -Flavored Hadrons."

For inclusive branching fractions, e.g.,  $B \rightarrow D^\pm \text{ anything}$ , the values usually are multiplicities, not branching fractions. They can be greater than one.

$b$ -baryon ADMIXTURE DECAY MODES ( $\Lambda_b^c, \Xi_b^c, \Sigma_b^c, \Omega_b^c$ )	Fraction ( $\Gamma_i/\Gamma$ )	$p$ (MeV/c)
$p\mu^-\bar{\nu}$ anything	$(4.9^{+2.1}_{-1.3})\%$	-

$p$ anything	$(59 \pm 21)\%$	-
$\Lambda\ell^-\bar{\nu}_\ell$ anything	$(3.2 \pm 0.7)\%$	-
$\Lambda/\bar{\Lambda}$ anything	$(33 \pm 8)\%$	-
$\Xi^-\ell^-\bar{\nu}_\ell$ anything	$(5.5 \pm 1.6) \times 10^{-3}$	-

## NOTES

This Summary Table only includes established baryons. The Particle Listings include evidence for other baryons. The masses, widths, and branching fractions for the resonances in this Table are Breit–Wigner parameters, but pole positions are also given for most of the  $N$  and  $\Delta$  resonances.

For most of the resonances, the parameters come from various partial-wave analyses of more or less the same sets of data, and it is not appropriate to treat the results of the analyses as independent or to average them together. Furthermore, the systematic errors on the results are not well understood. Thus, we usually only give ranges for the parameters. We then also give a best guess for the mass (as part of the name of the resonance) and for the width. The *Note on  $N$  and  $\Delta$  Resonances* and the *Note on  $\Lambda$  and  $\Sigma$  Resonances* in the Particle Listings review the partial-wave analyses.

When a quantity has “(S = . . .)” to its right, the error on the quantity has been enlarged by the “scale factor” S, defined as  $S = \sqrt{\chi^2/(N-1)}$ , where  $N$  is the number of measurements used in calculating the quantity. We do this when  $S > 1$ , which often indicates that the measurements are inconsistent. When  $S > 1.25$ , we also show in the Particle Listings an ideogram of the measurements. For more about S, see the Introduction.

A decay momentum  $p$  is given for each decay mode. For a 2-body decay,  $p$  is the momentum of each decay product in the rest frame of the decaying particle. For a 3-or-more-body decay,  $p$  is the largest momentum any of the products can have in this frame. For any resonance, the *nominal* mass is used in calculating  $p$ . A dagger (“†”) in this column indicates that the mode is forbidden when the nominal masses of resonances are used, but is in fact allowed due to the nonzero widths of the resonances.

- [a] The masses of the  $p$  and  $n$  are most precisely known in u (unified atomic mass units). The conversion factor to MeV,  $1 \text{ u} = 931.494043 \pm 0.000080 \text{ MeV}$ , is less well known than are the masses in u.
- [b] These two results are not independent, and both use the more precise measurement of  $|q_p/m_p|/(q_p/m_p)$ .
- [c] The limit is from neutrality-of-matter experiments; it assumes  $q_n = q_p + q_e$ . See also the charge of the neutron.
- [d] The first limit is for  $p \rightarrow$  anything or “disappearance” modes of a bound proton. The second entry, a rough range of limits, assumes the dominant decay modes are among those investigated. For antiprotons the best limit, inferred from the observation of cosmic ray  $\bar{p}$ 's is  $\tau_{\bar{p}} > 10^7 \text{ yr}$ , the cosmic-ray storage time, but this limit depends on a number of assumptions. The best direct observation of stored antiprotons gives  $\tau_{\bar{p}}/B(\bar{p} \rightarrow e^- \gamma) > 7 \times 10^5 \text{ yr}$ .

- [e] There is some controversy about whether nuclear physics and model dependence complicate the analysis for bound neutrons (from which the best limit comes). The first limit here is from reactor experiments with free neutrons.
- [f] The parameters  $g_A, g_V,$  and  $g_{WM}$  for semileptonic modes are defined by  $\bar{B}_f[\gamma_\lambda(g_V + g_A \gamma_5) + i(g_{WM}/m_{B_f}) \sigma_{\lambda\nu} q^\nu] B_i$ , and  $\phi_{AV}$  is defined by  $g_A/g_V = |g_A/g_V| e^{i\phi_{AV}}$ . See the “Note on Baryon Decay Parameters” in the neutron Particle Listings.
- [g] Time-reversal invariance requires this to be  $0^\circ$  or  $180^\circ$ .
- [h] This limit is for  $\gamma$  energies between 35 and 100 keV.
- [i] The decay parameters  $\gamma$  and  $\Delta$  are calculated from  $\alpha$  and  $\phi$  using

$$\gamma = \sqrt{1-\alpha^2} \cos \phi, \quad \tan \Delta = -\frac{1}{\alpha} \sqrt{1-\alpha^2} \sin \phi.$$

See the “Note on Baryon Decay Parameters” in the neutron Particle Listings.

- [j] See the Listings for the pion momentum range used in this measurement.
- [k] The error given here is only an educated guess. It is larger than the error on the weighted average of the published values.
- [l] A theoretical value using QED.
- [m] See the note on “ $\Lambda_c^+$  Branching Fractions” in the  $\Lambda_c^+$  Particle Listings.
- [n] This branching fraction includes all the decay modes of the final-state resonance.
- [o] An  $\ell$  indicates an  $e$  or a  $\mu$  mode, not a sum over these modes.
- [p] The value is for the sum of the charge states or particle/antiparticle states indicated.
- [q] Assuming isospin conservation, so that the other third is  $\Lambda_c^+ \pi^0 \pi^0$ .
- [r] A test that the isospin is indeed 0, so that the particle is indeed a  $\Lambda_c^+$ .
- [s] No absolute branching fractions have been measured. The value here is the branching *ratio* relative to  $\Xi^- \pi^+ \pi^+$ .
- [t] Not a pure measurement. See note at head of  $\Lambda_b^0$  Decay Modes.
- [u] Here  $h^-$  means  $\pi^-$  or  $K^-$ .

## SEARCHES SUMMARY TABLE

**SEARCHES FOR  
MONOPOLES,  
SUPERSYMMETRY,  
TECHNICOLOR,  
COMPOSITENESS,  
EXTRA DIMENSIONS, etc.**

**Magnetic Monopole Searches**

Isolated supermassive monopole candidate events have not been confirmed. The most sensitive experiments obtain negative results.

Best cosmic-ray supermassive monopole flux limit:  
 $< 1.0 \times 10^{-15} \text{ cm}^{-2} \text{sr}^{-1} \text{s}^{-1}$  for  $1.1 \times 10^{-4} < \beta < 0.1$

**Supersymmetric Particle Searches**

Limits are based on the Minimal Supersymmetric Standard Model. Assumptions include: 1)  $\tilde{\chi}_1^0$  (or  $\tilde{\gamma}$ ) is lightest supersymmetric particle; 2) R-parity is conserved; 3) with the exception of  $\tilde{t}$  and  $\tilde{b}$ , all scalar quarks are assumed to be degenerate in mass and  $m_{\tilde{q}_R} = m_{\tilde{q}_L}$ . 4) Limits for sleptons refer to the  $\tilde{\ell}_R$  states.

See the Particle Listings for a Note giving details of supersymmetry.

$\tilde{\chi}_i^0$  — neutralinos (mixtures of  $\tilde{\gamma}$ ,  $\tilde{Z}^0$ , and  $\tilde{H}^0$ )  
 Mass  $m_{\tilde{\chi}_1^0} > 46 \text{ GeV}$ , CL = 95% [all  $\tan\beta$ , all  $\Delta m_0$ , all  $m_0$ ]

Mass  $m_{\tilde{\chi}_2^0} > 62.4 \text{ GeV}$ , CL = 95%  
 [ $1 < \tan\beta < 40$ , all  $m_0$ , all  $m_{\tilde{\chi}_2^0} - m_{\tilde{\chi}_1^0}$ ]

Mass  $m_{\tilde{\chi}_3^0} > 99.9 \text{ GeV}$ , CL = 95%  
 [ $1 < \tan\beta < 40$ , all  $m_0$ , all  $m_{\tilde{\chi}_3^0} - m_{\tilde{\chi}_1^0}$ ]

$\tilde{\chi}_i^\pm$  — charginos (mixtures of  $\tilde{W}^\pm$  and  $\tilde{H}_i^\pm$ )

Mass  $m_{\tilde{\chi}_1^\pm} > 94 \text{ GeV}$ , CL = 95%  
 [ $\tan\beta < 40$ ,  $m_{\tilde{\chi}_1^\pm} - m_{\tilde{\chi}_1^0} > 3 \text{ GeV}$ , all  $m_0$ ]

$\tilde{e}$  — scalar electron (selectron)

Mass  $m > 73 \text{ GeV}$ , CL = 95% [all  $m_{\tilde{e}_R} - m_{\tilde{\chi}_1^0}$ ]

$\tilde{\mu}$  — scalar muon (smuon)

Mass  $m > 94 \text{ GeV}$ , CL = 95%  
 [ $1 \leq \tan\beta \leq 40$ ,  $m_{\tilde{\mu}_R} - m_{\tilde{\chi}_1^0} > 10 \text{ GeV}$ ]

$\tilde{\tau}$  — scalar tau (stau)

Mass  $m > 81.9 \text{ GeV}$ , CL = 95%

[ $m_{\tilde{\tau}_R} - m_{\tilde{\chi}_1^0} > 15 \text{ GeV}$ , all  $\theta_\tau$ ]

$\tilde{q}$  — scalar quark (squark)

These limits include the effects of cascade decays, evaluated assuming a fixed value of the parameters  $\mu$  and  $\tan\beta$ . The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling.

Mass  $m > 250 \text{ GeV}$ , CL = 95% [ $\tan\beta = 2$ ,  $\mu < 0$ ,  $A = 0$ ]

$\tilde{b}$  — scalar bottom (sbottom)

Mass  $m > 89 \text{ GeV}$ , CL = 95% [ $m_{\tilde{b}_1} - m_{\tilde{\chi}_1^0} > 8 \text{ GeV}$ , all  $\theta_b$ ]

$\tilde{t}$  — scalar top (stop)

Mass  $m > 95.7 \text{ GeV}$ , CL = 95%

[ $\tilde{t} \rightarrow c\tilde{\chi}_1^0$ , all  $\theta_t$ ,  $m_{\tilde{t}} - m_{\tilde{\chi}_1^0} > 10 \text{ GeV}$ ]

$\tilde{g}$  — gluino

The limits summarized here refer to the high-mass region ( $m_{\tilde{g}} \sim 5 \text{ GeV}$ ), and include the effects of cascade decays, evaluated assuming a fixed value of the parameters  $\mu$  and  $\tan\beta$ . The limits are weakly sensitive to these parameters over much of parameter space. Limits assume GUT relations between gaugino masses and the gauge coupling,

Mass  $m > 195 \text{ GeV}$ , CL = 95% [any  $m_{\tilde{q}}$ ]

Mass  $m > 300 \text{ GeV}$ , CL = 95% [ $m_{\tilde{q}} = m_{\tilde{g}}$ ]

**Technicolor**

Searches for a color-octet techni- $\rho$  constrain its mass to be greater than 260 to 480 GeV, depending on allowed decay channels. Similar bounds exist on the color-octet techni- $\omega$ .

**Quark and Lepton Compositeness, Searches for**

**Scale Limits  $\Lambda$  for Contact Interactions**  
 (the lowest dimensional interactions with four fermions)  
 If the Lagrangian has the form

$$\pm \frac{g^2}{2\Lambda^2} \bar{\psi}_L \gamma_\mu \psi_L \bar{\psi}_L \gamma^\mu \psi_L$$

(with  $g^2/4\pi$  set equal to 1), then we define  $\Lambda \equiv \Lambda_{LL}^\pm$ . For the full definitions and for other forms, see the Note in the Listings on Searches for Quark and Lepton Compositeness in the full *Review* and the original literature.

$\Lambda_{LL}^+(eeee)$	$>$	8.3 TeV, CL = 95%
$\Lambda_{LL}^-(eeee)$	$>$	10.3 TeV, CL = 95%
$\Lambda_{LL}^+(ee\mu\mu)$	$>$	8.5 TeV, CL = 95%
$\Lambda_{LL}^-(ee\mu\mu)$	$>$	6.3 TeV, CL = 95%
$\Lambda_{LL}^+(ee\tau\tau)$	$>$	5.4 TeV, CL = 95%
$\Lambda_{LL}^-(ee\tau\tau)$	$>$	6.5 TeV, CL = 95%
$\Lambda_{LL}^+(llll)$	$>$	9.0 TeV, CL = 95%
$\Lambda_{LL}^-(llll)$	$>$	7.8 TeV, CL = 95%
$\Lambda_{LL}^+(eeuu)$	$>$	23.3 TeV, CL = 95%
$\Lambda_{LL}^-(eeuu)$	$>$	12.5 TeV, CL = 95%
$\Lambda_{LL}^+(eedd)$	$>$	11.1 TeV, CL = 95%
$\Lambda_{LL}^-(eedd)$	$>$	26.4 TeV, CL = 95%
$\Lambda_{LL}^+(eccc)$	$>$	1.0 TeV, CL = 95%
$\Lambda_{LL}^-(eccc)$	$>$	2.1 TeV, CL = 95%
$\Lambda_{LL}^+(eebb)$	$>$	5.6 TeV, CL = 95%
$\Lambda_{LL}^-(eebb)$	$>$	4.9 TeV, CL = 95%
$\Lambda_{LL}^+(\mu\mu qq)$	$>$	2.9 TeV, CL = 95%
$\Lambda_{LL}^-(\mu\mu qq)$	$>$	4.2 TeV, CL = 95%
$\Lambda(\ell\nu\ell\nu)$	$>$	3.10 TeV, CL = 90%
$\Lambda(e\nu qq)$	$>$	2.81 TeV, CL = 95%
$\Lambda_{LL}^+(qqqq)$	$>$	2.7 TeV, CL = 95%
$\Lambda_{LL}^-(qqqq)$	$>$	2.4 TeV, CL = 95%
$\Lambda_{LL}^+(\nu\nu qq)$	$>$	5.0 TeV, CL = 95%
$\Lambda_{LL}^-(\nu\nu qq)$	$>$	5.4 TeV, CL = 95%

**Excited Leptons**

The limits from  $\ell^* \ell^{*-}$  do not depend on  $\lambda$  (where  $\lambda$  is the  $\ell \ell^*$  transition coupling). The  $\lambda$ -dependent limits assume chiral coupling.

$e^{*\pm}$  — excited electron

Mass  $m > 103.2$  GeV, CL = 95% (from  $e^* e^*$ )

Mass  $m > 255$  GeV, CL = 95% (from  $e e^*$ )

Mass  $m > 310$  GeV, CL = 95% (if  $\lambda_\gamma = 1$ )

$\mu^{*\pm}$  — excited muon

Mass  $m > 103.2$  GeV, CL = 95% (from  $\mu^* \mu^*$ )

Mass  $m > 190$  GeV, CL = 95% (from  $\mu \mu^*$ )

$\tau^{*\pm}$  — excited tau

Mass  $m > 103.2$  GeV, CL = 95% (from  $\tau^* \tau^*$ )

Mass  $m > 185$  GeV, CL = 95% (from  $\tau \tau^*$ )

$\nu^*$  — excited neutrino

Mass  $m > 102.6$  GeV, CL = 95% (from  $\nu^* \nu^*$ )

Mass  $m > 190$  GeV, CL = 95% (from  $\nu \nu^*$ )

$q^*$  — excited quark

Mass  $m > 45.6$  GeV, CL = 95% (from  $q^* q^*$ )

Mass  $m$  (from  $q^* X$ )

**Color Sextet and Octet Particles**

Color Sextet Quarks ( $q_6$ )

Mass  $m > 84$  GeV, CL = 95% (Stable  $q_6$ )

Color Octet Charged Leptons ( $\ell_8$ )

Mass  $m > 86$  GeV, CL = 95% (Stable  $\ell_8$ )

Color Octet Neutrinos ( $\nu_8$ )

Mass  $m > 110$  GeV, CL = 90% ( $\nu_8 \rightarrow \nu g$ )

**Extra Dimensions**

Please refer to the Extra Dimensions section of the full *Review* for a discussion of the model-dependence of these bounds, and further constraints.

**Constraints on the fundamental gravity scale**

$M_H > 1.1$  TeV, CL = 95% (dim-8 operators;  $p \bar{p} \rightarrow e^+ e^-, \gamma \gamma$ )

$M_D > 1.1$  TeV, CL = 95% ( $e^+ e^- \rightarrow G \gamma$ ; 2-flat dimensions)

$M_D > 3\text{--}1000$  TeV (astrophys. and cosmology; 2-flat dimensions; limits depend on technique and assumptions)

**Constraints on the radius of the extra dimensions, for the case of two-flat dimensions of equal radii**

$r < 90\text{--}660$  nm (astrophysics; limits depend on technique and assumptions)

$r < 0.22$  mm, CL = 95% (direct tests of Newton's law; cited in Extra Dimensions review)

# TABLE OF THE ISOTOPES

Norman E. Holden

This table presents an evaluated set of values for the experimental quantities that characterize the decay of radioactive nuclides. A list of the major references used in this evaluation is given below. When uncertainties are not listed, they are assumed to be five or less in the last digit quoted. If they exceed five in the last digit, the value is prefaced by an approximate sign. For quasi-stable nu-

clides, the measured width,  $\Gamma$ , of the resonance is given. To estimate the approximate half-life, the Heisenberg relationship may be used, the half-life =  $4.56 \times 10^{22}$  seconds /  $\Gamma(\text{MeV})$ . The effective literature cutoff date for data in this edition of the Table is December, 2005.

## Table Layout

Column No.	Column title	Description
1	Isotope or Element	For elements, the atomic number and chemical symbol are listed. For nuclides, the mass number and chemical symbol are listed. Isomers are indicated by the addition of m, m1, or m2.
2	Isotopic Abundance	In atom percent.
3	Atomic Mass or Atomic Weight	Atomic mass relative to $^{12}\text{C} = 12$ . Atomic weight of elements is given on the same scale.
4	Half-life/Resonance Width	Half-life in decimal notation. $\mu\text{s}$ = microseconds; ms = milliseconds; s = seconds; m = minutes; h = hours; d = days; and y = years. For quasi-stable nuclides, the measured width at half maximum of the energy resonance is given
5	Decay Mode/Energy	Decay modes are $\alpha$ = alpha particle emission; $\beta^-$ = negative beta emission; $\beta^+$ = positron emission; EC = orbital electron capture; IT = isomeric transition from upper to lower isomeric state; n = neutron emission; sf = spontaneous fission; $\beta\beta$ = double beta decay. Total disintegration energy in MeV units.
6	Particle Energy/Intensity	End point energies of beta transitions and discrete energies of alpha particles in MeV and their intensities in percent.
7	Spin and Parity	Nuclear spin or angular momentum of the nuclides in units of $h/2\pi$ ; parity is positive or negative.
8	Magnetic Dipole Moment	Magnetic dipole moments in nuclear magneton units.
9	Electric Quadrupole Moment	Electric quadrupole moments in barn units ( $10^{-24} \text{ cm}^2$ ).
10	Gamma Ray Energy/Intensity	Gamma ray energies in MeV and intensities in percent. Ann. rad. refers to the 511.006 keV photons emitted in the annihilation of positrons in matter.

# NEUTRON SCATTERING AND ABSORPTION PROPERTIES

Norman E. Holden

This table presents an evaluated set of values for experimental quantities that characterize the properties for scattering and absorption of neutrons. The neutron cross section is given for room temperature neutrons, 20.43°C, corresponding to a thermal neutron energy of 0.0253 electron volts (eV) or a neutron velocity of 2200 meters/second. The neutron resonance integral is defined over the energy range from 0.5 eV to  $0.1 \times 10^6$  eV, or 0.1 MeV.

Bound neutron scattering lengths and neutron cross sections averaged over a Maxwellian spectrum at 30 keV for astrophysical applications are also presented. A list of the major references used is given below. The literature cutoff date is January 2003. Uncertainties are given in parentheses. Parentheses with two or more numbers indicate values to the excited state(s) and to the ground state of the product nucleus.

## Table Layout

Column Number	Column Title	Description
1	Isotope/Element	For elements, atomic number and chemical symbol are listed. For nuclides, mass number and chemical symbol are listed. Isomers are indicated by the addition of m, m1, or m2.
2	Isotopic Abundance	in atom percent
3	Half-life	Half-life in decimal notation. $\mu$ s = microsecond; ms = millisecond; s = second; m = minute; h = hour; d = day; y = year.
4	Thermal Neutron Cross Sections	Cross sections for neutron capture reactions in units of barns ( $10^{-24}$ cm <sup>2</sup> ) or millibarns (mb). Proton, alpha production and fission reactions are designated by $\sigma_p$ , $\sigma_\alpha$ , $\sigma_f$ , respectively. Separate values are listed for isomeric production.
5	Neutron Resonance Integrals	Resonance integrals for neutron capture reactions in barns ( $10^{-24}$ cm <sup>2</sup> ) or millibarns (mb). Proton, alpha production and fission reactions are designated by R.I. <sub>p</sub> , R.I. <sub>α</sub> , R.I. <sub>f</sub> , respectively. Separate values are listed for isomeric production.
6	Neutron Scattering Lengths	Bound coherent scattering lengths for neutron scattering reactions in units of femtometers (fm), which is equal to fermis ( $10^{-13}$ cm).
7	Maxwellian Averaged Cross Section	Astrophysical Cross Sections, averaged over a stellar neutron maxwellian spectrum characterized by a thermal energy of 30 keV, expressed in barns ( $10^{-24}$ cm <sup>2</sup> ), millibarns (mb) or microbarns ( $\mu$ b).

# COSMIC RADIATION

A.G. Gregory and R.W. Clay

## The Nature of Cosmic Rays

Primary cosmic radiation, in the form of high energy nuclear particles, electrons and photons from outside the solar system and from the Sun, continually bombards our atmosphere. Secondary radiation, resulting from the interaction of the primary cosmic rays with atmospheric gas, is present at sea-level and throughout the atmosphere.

The secondary radiation is collimated by absorption and scattering in the atmosphere and consists of a number of components associated with different particle species. High energy primary particles can produce large numbers of secondary particles forming an extensive air shower. Thus, a number of particles may then be detected simultaneously at sea-level.

Primary particle energies accessible in the vicinity of the earth range from  $\sim 10^8$  eV to  $\sim 10^{20}$  eV. At the lower energies, the limit is determined by the inability of charged particles to traverse the heliosphere to us through the outward-moving solar wind. The upper energy limit is set by the practicality of building detectors to record particles with the extremely low fluxes found at those energies (J.G. Wilson, 1976; O.C. Allkofer, 1975a).

## Primary Cosmic Rays

### Primary Particle Energy Spectrum

Figure 1 shows the spectrum of primary particle energies. This includes all particle species. In differential form it is roughly a power law of intensity versus energy with an index of  $\sim -3$ . There appears to be a knee (a steepening) at a little above  $10^{15}$  eV and an ankle (a flattening) above  $\sim 10^{18}$  eV. Figure 2 emphasizes the features in the spectrum at the highest energies through multiplying the flux with a strongly rising power law of energy. This figure should be used with caution as errors for the two axes are not now independent.

Data on the high energy cosmic ray spectrum are uncertain largely because of limited event statistics due to the very low flux which might best be measured in particles per square kilometer per century. The highest energy event recorded to 1995 had an energy of  $3 \times 10^{20}$  eV (D.J. Bird et al., 1993).

It is expected that the highest energy cosmic rays will interact with the 2.7 K cosmic microwave background through photoproduction or photodisintegration. These interactions will appreciably reduce the observed flux of cosmic rays with energies above  $5 \times 10^{19}$  eV if they travel further than  $\sim 150$  million light years. This process is known as the Greisen-Zatsepin-Kuz'min (GZK) cut off (P. Sokolsky, 1989).

At energies below  $\sim 10^{13}$  eV, solar system magnetic fields and plasma can modulate the primary component and Figure 3 shows the extent of this modulation between solar maximum and minimum (E. Juliusson, 1975; J. Linsley, 1981).

### Primary Particle Energy Density

If the above spectrum is corrected for solar effects, the energy density above a particle energy of  $10^9$  eV outside the solar system is found to be  $\sim 5 \times 10^5$  eV  $m^{-3}$ . As the threshold energy is increased, the energy density decreases rapidly, being  $2 \times 10^4$  eV  $m^{-3}$  above  $10^{12}$  eV and  $10^2$  eV  $m^{-3}$  above  $10^{15}$  eV. The energy density at lower energies outside the heliosphere is unknown but may be substan-

tially greater if the particle rest mass energy is included together with the kinetic energy (A. W. Wolfendale, 1979).

### Primary Particle Isotropy

This is measured as an anisotropy  $(I_{\max} - I_{\min})/(I_{\max} + I_{\min}) \times 100\%$ , where  $I$ , the intensity ( $m^{-2}s^{-1}sr^{-1}$ ), is usually measured with an angular resolution of a few degrees.

The measured anisotropy is small and energy dependent. It is roughly constant in amplitude at between 0.05 and 0.1% (with a phase of 0 to 6 hours in right ascension) for energies between  $10^{11}$  eV and  $10^{14}$  eV and appears to increase at higher energies roughly as  $0.4 \times (\text{Energy(eV)}/10^{16})^{0.5}$  up to  $\sim 10^{18}$  eV. The latter rise may well be an artifact of the progressively more limited statistics as the flux drops rapidly with energy. It appears possible that a real anisotropy has been observed at the highest energies (above a few times  $10^{19}$  eV) with a directional preference for the supergalactic plane (this plane reflects the directions of galaxies within about 100 million light years) (A.W. Wolfendale, 1979; R.W. Clay, 1987; T. Stanev et al., 1995).

### Primary Particle Composition

The composition of low energy cosmic rays is close to universal nuclear abundances except where propagation effects are present. For example, Li, Be, and B which are spallation products, are over-abundant by about six orders of magnitude.

Composition at  $10^{11}$  eV per nucleus

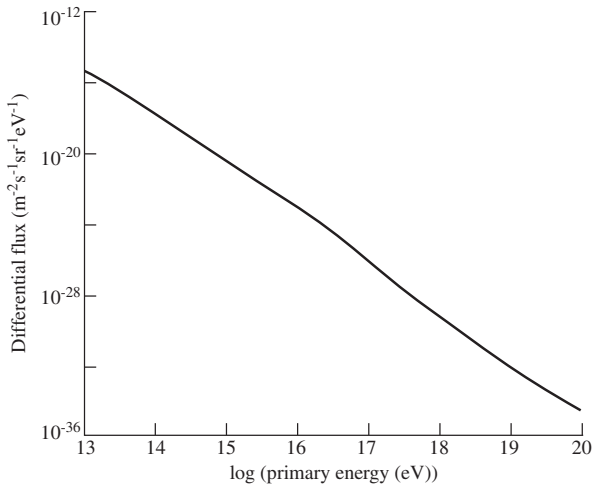

Charge	1	2	(3-5)	(6-8)	(10-14)	(16-24)	(26-28)	$\geq 30$
% Composition	50	25	1	12	7	4	4	0.1
(10% uncertainty)								

Measurements at higher energies indicate that there is an increase in the relative abundances of nuclei with charge greater than 6 at energies above 50 TeV/nucleus (K. Asakimori et al., 1993) ( $1 \text{ TeV} = 10^{12}$  eV).

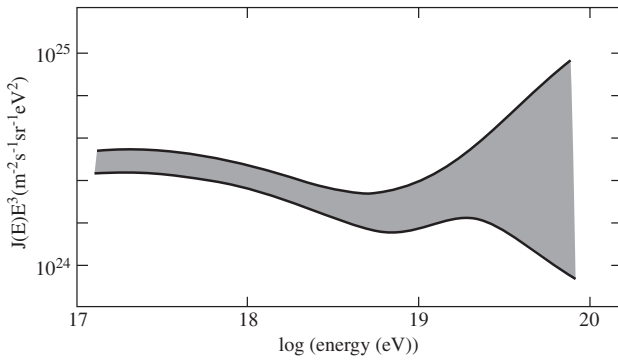

Cosmic ray composition at low energies is often quoted at a fixed energy per nucleon. When presented in this way, protons constitute roughly 90% of the flux, helium nuclei about 10% and the remainder sum to a total of about 1%.

Certain radioactive isotopic ratios show lifetime effects. The ratio of  $Be^{10}/B^9$  abundances is used to measure an "age" of cosmic rays since  $Be^{10}$  is unstable with a half life of about  $1.6 \times 10^6$  years. A ratio of 0.6 is expected in the absence of  $Be^{10}$  decay and a ratio of about 0.2 is found experimentally (E. Juliusson, 1975; P. Meyer, 1981).

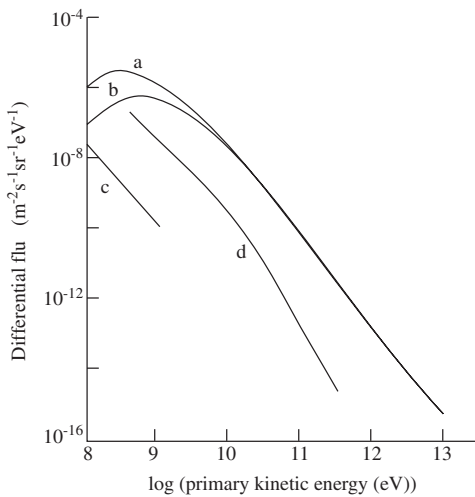

At higher energies, composition determinations are indirect and are rather contradictory and controversial. Experiments aim to differentiate between broad composition models. The measurement technique is based on studies of cosmic ray shower development. A rather direct technique for such studies is to use fluorescence observations of the shower development to determine the atmospheric depth of maximum development of the shower. Such observations suggest a heavy composition (large atomic number) at energies  $\sim 10^{17}$  eV which changes with increasing energy to a light composition (perhaps protonic) above  $\sim 10^{19}$  eV (T. K. Gaisser et al., 1993).

**FIGURE 1.** The energy spectrum of cosmic ray particles. This spectrum is of a differential form and can be converted to an integral spectrum by integration over all energies above a required threshold ( $E$ ). Insofar as the spectrum approximates a power law of index  $-3$ , a simple conversion to the integral at an energy  $E/1.8$  is obtained by multiplying the differential flux by the energy and dividing by  $0.62$ .

**FIGURE 2.** Energy spectrum at the highest energies. This spectrum (after Yoshida et al., 1995) has the differential spectrum multiplied by energy cubed. It is from a compilation of a number of measurements and indicates the good general agreement at the lower energies and a spread due to inadequate statistics at the highest energies.

**FIGURE 3.** Energy spectrum of particles at lower energies. (a) Solar minimum proton energy spectrum. (b) Solar maximum proton energy spectrum. (c) Gamma-ray energy spectrum. (d) Local interstellar electron spectrum.

### Primary Electrons

Primary electrons constitute about 1% of the cosmic ray beam. The positron to negative electron ratio is about 10% (J. M. Clem et al., 1995).

### Antimatter in the Primary Beam

The ratio of antiprotons to protons in the primary cosmic ray beam (at about 400 MeV) is about  $10^{-5}$ . At about 10 GeV the ratio is about  $10^{-3}$ . At the highest measured energies (10 TeV), the upper limit to the ratio is about 20% (S. Orito et al., 1995; M. Amenomori et al., 1995).

### Primary Gamma-Rays

The flux of primary gamma-rays is low at high energies. At 1 GeV the ratio of gamma-rays to protons is about  $10^{-6}$ . The arrival directions of these gamma-rays are strongly concentrated in the plane of the Milky Way although there is a diffuse, near isotropic background flux and some point sources have been detected.

Since the absorption cross section for gamma-rays above 100 MeV is approximately 20 mbarn/electron, less than 10% of gamma-rays reach mountain altitudes (A. W. Wolfendale, 1979; P. F. Michelson, 1994).

### Sea Level Cosmic Radiation

The sea level cosmic ray dose is 300 millirad-yr<sup>-1</sup> and the sea level ionization is  $2.2 \times 10^6$  ion pairs m<sup>-3</sup>s<sup>-1</sup>. The sea level flux has a soft component, which can be absorbed in about 100 mm of lead (about 100 g·cm<sup>-2</sup> of absorber) and a more penetrating (largely muon) hard component. The sea level radiation is largely produced in the atmosphere and is a secondary component from interactions of the primary particles. The steep primary energy spectrum means that most secondaries at sea level are from rather low energy primaries. Thus the secondary flux is dependent on the solar cycle and the geomagnetic latitude of the observer.

### Absolute Flux of the Hard Component

Vertical Integral Intensity  $I(0) \sim 100 \text{ m}^{-2}\text{s}^{-1}\text{sr}^{-1}$   
 Angular dependence  $I(\theta) \sim I(0) \cos^2(\theta)$   
 Integrated Intensity  $\sim 200 \text{ m}^{-2}\text{s}^{-1}$   
 (O.C. Allkofer, 1975b).

### Flux of the Soft Component

In free air, the soft component comprises about one third of the total cosmic ray flux.

### Latitude Effect

The geomagnetic field influences the trajectories of lower energy cosmic rays approaching the Earth. As a result, the background flux is reduced by about 7% at the geomagnetic equator. The effect decreases towards the poles and is negligible at latitudes above about 40°.

### Flux of Protons

The proton component is strongly attenuated by the atmosphere with an attenuation length (reduction by a factor of e) of about 120 g·cm<sup>-2</sup>. It constitutes about 1% of the total vertical sea level flux.

### Absorption

The soft component is absorbed in about 100 g·cm<sup>-2</sup> of matter. The hard component is absorbed much more slowly:

Absorption in lead, 6% per 100 g·cm<sup>-2</sup>  
 Absorption in rock, 8.5% per 100 g·cm<sup>-2</sup>

Absorption in water, 10% per 100 g·cm<sup>-2</sup>  
 (Absorption for depths less than 100 g·pd cm<sup>-2</sup> is given by K. Greisen, 1943.)

### Altitude Dependence

The cosmic ray background in the atmosphere has a maximum intensity of about 15 times that at sea level at a depth of about 150 g·cm<sup>-2</sup> (15 km altitude). At maximum intensity, the soft and hard components contribute roughly equally but the hard component is then attenuated more slowly (S. Hayakawa, 1969).

### Cosmic Ray Showers

High energy cosmic rays produce particle cascades in the atmosphere which can be detected at sea level provided that their energy exceeds about 100 GeV (such low energy cascades may be detected by using the most sensitive atmospheric Cerenkov detectors). The primary particle progressively loses energy which is transferred through the production of successive generations of secondary particles to a cascade of hadrons, an electromagnetic shower component (both positively and negatively charged electrons and gamma-rays) and muons. The secondary particles are relativistic and all travel effectively at the speed of light. As a result, they reach sea level at approximately the same time but, due to Coulomb scattering (for the electrons) and production angles (for the pions producing the muons), are spread laterally into a disk-like shower front with a characteristic lateral width of several tens of meters and thickness (near the central shower core) of 2 to 3 m. The number of particles at sea level is roughly proportional to the primary particle energy:

Number of particles at sea level  $\sim 10^{-10} \times \text{energy (eV)}$ .

At altitudes below a few kilometers, the number of particles in a shower attenuates with an *attenuation length* of about 200 g·cm<sup>-2</sup>.

i.e., particle number = original number  $\times \exp(-(\text{depth increase})/200)$

The above applies to an individual shower. The rate of observation of showers of a given size (particle number at the detector) at different depths of absorber attenuates with an *absorption length* of about 100 g·cm<sup>-2</sup> (J.G. Wilson, 1976).

### Atmospheric Background Light from Cosmic Rays

Cosmic ray particles produce Cerenkov light in the atmosphere and produce fluorescent light through the excitation of atmospheric molecules.

### Cerenkov Light

High energy charged particles will cause the emission of Cerenkov light in air if their energies are above about 30 MeV (electrons). This threshold is pressure (and hence altitude) dependent. A typical Cerenkov light pulse (at sea level, 100 m from the central shower core) has a time spread of a few nanoseconds. Over this time, the photon flux between 430 and 530 nm would be  $\sim 10^{14} \text{ m}^{-2}\text{s}^{-1}$  for a primary particle energy of  $10^{16} \text{ eV}$ . For comparison, the night sky background flux is  $\sim 6 \times 10^{11} \text{ photons m}^{-2}\text{s}^{-1}\text{sr}^{-1}$  in the same wavelength band (J.V. Jelley, 1967).

### Fluorescence Light

Cosmic ray particles in the atmosphere excite atmospheric molecules which then emit fluorescence light. This is weak compared to the highly collimated Cerenkov component when viewed in the direction of the incident cosmic ray particle but is emitted

isotropically. Typical pulse widths are longer than 50 ns and may be up to several microseconds for the total pulse from distant large showers (R.M. Baltrusaitis et al., 1985).

## Effects of Cosmic Rays

### Cerenkov Effects in Transparent Media

Background cosmic ray particles will produce Cerenkov light in transparent material with a photon yield between wavelengths  $\lambda_1$  and  $\lambda_2$

$$\sim (2\pi/137)\sin^2(\theta_c) \int_{\lambda_1}^{\lambda_2} d\lambda / \lambda^2 \text{ photons}(\text{unit length})^{-1}$$

where  $\theta_c$  (the Cerenkov angle) =  $\cos^{-1}(1/\text{refractive index})$ .

This background light is known to affect light detectors, e.g., photomultipliers, and can be a major source of background noise (R.W. Clay and A.G. Gregory, 1977).

### Effects on Electronic Components

If background cosmic ray particles pass through electronic components, they may deposit sufficient energy to affect the state of, e.g., a transistor flip-flop. This effect may be significant where reliability is of great importance or the background flux is high. For instance, it has been estimated that, in communication satellite operation, an error rate of about  $2 \times 10^{-3}$  per transistor per year may be found. Permanent damage may also result. A significant error rate may be found even at sea level in large electronic memories. This error rate is dependent on the sensitivity of the component devices to the deposition of electrons in their sensitive volumes (J.F. Ziegler, 1981).

### Biophysical Significance

When cosmic rays interact with living tissue, they produce radiation damage. The amount of the damage depends on the total dose of radiation. At sea level, this dose is small compared with doses from other sources but both the quantity and quality of the radiation change rapidly with altitude. Approximate dose rates under various conditions are:

- Dose rates (mrem·yr<sup>-1</sup>)
- Sea level cosmic rays, 30
- Cosmic rays at 10 km (subsonic jets), 2000
- Cosmic rays at 18 km (supersonic transports), 10,000
- (c.f., mean total sea level dose, 300)

Astronauts would be subject to radiation from galactic (0.05 rads per day) and solar (a few hundred rads per solar flare) cosmic rays as well as large fluxes of low energy radiation when passing through the Van Allen belts (about 0.3 rads per traverse).

Both astronauts and SST travellers would be subject to a small flux of low energy heavy nuclei stopping in the body. Such particles are capable of destroying cell nuclei and could be particularly harmful in the early stages of the development of an embryo. The rates of heavy nuclei stopping in tissue in supersonic transports and spacecraft are approximately as follows:

- Stopping nuclei ((cm<sup>3</sup> tissue)<sup>-1</sup> hr<sup>-1</sup>)
- Supersonic transport (16 km), 0.0005
- Supersonic transport (20 km), 0.005
- Spacecraft, 0.15
- (O. C. Allkofer, 1975a; O. C. Allkofer et al., 1974).

### Carbon Dating

Radiocarbon is produced in the atmosphere due to the action of cosmic ray slow neutrons. Solar cycle modulation of the very low energy cosmic rays causes an anticorrelation of the atmospheric <sup>14</sup>C activity with sunspot number with a mean amplitude of about 0.5%. In the long term, modulation of cosmic rays by a varying magnetic field may be important (A.A. Burchuladze et al., 1979).

### Practical Uses of Cosmic Rays

There are few direct practical uses of cosmic rays. Their attenuation in water and snow have, however, enabled automatic monitors of water and snow depth to be constructed. A search for hidden cavities in pyramids has been carried out using a muon "telescope".

### Other Effects

Stellar X-rays have been observed to affect the transmission times of radio signals between distant stations by altering the depth of the ionospheric reflecting layer. It has also been suggested that variations in ionization of the atmosphere due to solar modulation may have observable effects on climatic conditions.

# TECHNIQUES FOR MATERIALS CHARACTERIZATION

## Experimental Techniques Used to Determine the Composition, Structure, and Energy States of Solids and Liquids

H.P.R. Frederikse

The many experimental methods, originally designed to study the chemical and physical behavior of solids and liquids, have grown into a new field known as Materials Characterization (or Materials Analysis). During the past 30 years a host of techniques aimed at the study of surfaces and thin films has been added to the many tools for the analysis of bulk samples. The field has benefited particularly from the development of computers and micro-processors, which have vastly increased the speed and accuracy of the measuring devices and the recording of their output. Materials characterization was and is a very important tool in the search for new physical and chemical phenomena. It plays an essential role in new applications of solids and liquids in industry, communications, and medicine. Many of its techniques are used in quality control, in safety regulations, and in the fight against pollution.

In most Materials Characterization experiments the sample is subjected to some kind of radiation: electromagnetic, acoustic, thermal, or particles (electrons, ions, neutrons, etc.). The surface

analysis techniques usually require a high vacuum. As a result of interactions between the solid (or liquid) and the incoming radiation a beam of a similar (or a different) nature will emerge from the sample. Measurement of the physical and/or chemical attributes of this emerging radiation will yield qualitative, and often quantitative, information about the composition and the properties of the material being probed.

The modern tendency of describing practically everything in this world by a combination of a few letters (acronyms) has also penetrated the field of Materials Characterization. The table below gives the meaning of the acronym for every technique listed, the form and size of the required sample (bulk, surface, film, liquid, powder, etc.), the nature of the incoming and of the emerging radiation, the depth and the lateral spatial resolution that can be probed, and the information obtained from the experiment. The last column lists one or two major references to the technique described.

<b>Ions and Neutrons</b>								
39.	ISS (or LEIS) Ion Scattering Spectroscopy (Low Energy Ion Scattering)	Surface	Ion beam He <sup>+</sup> or Ne <sup>+</sup> <3 keV	Sputtered ions (energy analysis)	0.1–0.5 nm	1–100 μm	Elemental analysis (better for low Z) detection limits: 0.01–1%	41
40.	FIM Field Ion Microscopy	Surface: metals, alloys; very sharp tip	(He gas above sample)	He ions + high electric field produce image	≈0.1 nm	0.1–2 nm	Atomic structure of surface	34,42
41.	RBS Rutherford Back Scattering	Solids, thin films	Mono-energetic ions (H <sup>+</sup> or He <sup>+</sup> ) 0.5–3 MeV	Backscattered ions	10 nm–1 μm	1 mm	Element identification (Li to U) detection limit: 0.01–1%	46
42.	NRA Nuclear Reaction Analysis	Solids, thin films	Mono-energetic ions (Li, Be, B, etc.) 200 keV–6 MeV	Protons, deuterons <sup>3</sup> He, α-particles, γ-rays	0.1–5 μm	10 μm–10 mm	Element identification (all) detection limit: 10 <sup>-12</sup> –10 <sup>-2</sup>	47
43.	PIXE Particle Induced X-ray Emission	Thin films, surface layers	High energy ions (H <sup>+</sup> or He <sup>+</sup> )	Characteristic X-rays	<10 μm	1 μm–2 mm	Trace impurities: Z>3 detection limit: 0.1–100 ppm (depending on sample thickness)	48
44.	INS Ion Neutralization Spectroscopy	Surface	He-ions (≈5 eV)	Electrons	–	–	Energies of valence electrons	49
45.	NAA Neutron Activation Analysis	Bulk, >0.5 g	Thermal neutrons	Characteristic γ-rays, (≈1 MeV)	Bulk	–	Trace concentrations (of isotopes) of elements: trans. metals, Pt-group; detection limit: 10 <sup>9</sup> –10 <sup>14</sup> atoms/cm <sup>3</sup>	43
46.	N(P)D Neutron (Powder) Diffraction	Crystalline solids	Thermal neutrons E ≈0.0025 eV	Diffacted neutrons	Bulk	–	Crystallographic structure; porosity, particle size	44
47.	SANS Small Angle Neutron Scattering	Inhomogeneous solids; powders; porous samples	Thermal neutrons 2 θ = 10 <sup>-2</sup> –10 <sup>-4</sup>	Scattered neutrons	1–25 mm	–	Average size of inhomogeneities; range: 1 nm–1 mm	45
<b>Acoustic</b>								
48.	SLAM Scanning Laser Acoustic Microscopy	Bulk, film	Acoustic wave produced by laser 1 MHz–1 GHz	Reflected acoustic wave	μm–cm	0.1–20 mm	Defect structure; thickness measurement	50
<b>Thermal</b>								
49.	DTA Differential Thermal Analysis	Specimen and reference sample	Uniform heating	Temperature difference	Bulk	–	Phase transitions, crystallization	51
50.	DSC Differential Scanning Calorimetry	Specimen and ref. sample	Controlled heating	Measure heat required for equal temperature	Bulk	–	Phase transitions, crystallization; activation energies	51
51.	TGA Thermo Gravimetric Analysis	Bulk, 1–100 g	Controlled heating	Weight as function of temperature (and time)	Bulk	–	Decomposition, non-stoichiometry, kinetics of reaction	52
<b>Resonance</b>								
52.	EPR (ESR) Electron Paramagnetic (Spin) Resonance	Paramagnetic solids or liquids	Microwave radiation in magnetic field 3–300 GHz; 1–100 kG	Microwave absorption (at resonance)	Bulk	–	Local environment of paramagnetic ion; concentration of paramagnetic, species; detection limit: 10 <sup>11</sup> spins/cm <sup>3</sup>	53,54
53.	ECR Electron Cyclotron Resonance	Semiconductors, metals; free electrons (low temperature)	Microwave radiation in magnetic field 10–30 GHz; 5–10 kG	Microwave absorption (at resonance)	Bulk	–	Electronic energy bands, effective masses	55
54.	Mössbauer Effect	Source and absorber	Mono-energetic γ-rays: 5–100 keV	Mössbauer spectrum (Doppler shifted (lines))	50 m	1 cm	Interaction between nucleus and its environment (local electric, magnetic fields; bonds; valency; diffusion, etc.)	56
55.	NMR (MRI) Nuclear Magnetic Resonance (Magnetic Resonance Imaging)	Solids, liquids	R.F. radiation + magnetic field; e.g. for protons: 60 MHz, 14 kG	R.F. absorption	<1 cm	1 cm	Quant. analysis; local magnetic environment; diffusion; imaging	58
56.	ENDOR Electron Nuclear Double Resonance	Solids, liquids	R.F. + microwave radiation in magn. field.	Microwave absorption	–	–	Hyperfine interaction → local atomic structure	54
57.	NQR Nuclear Quadrupole Resonance	Solids	R.F. radiation 0.5–1000 MHz	R.F. absorption	–	–	Asymmetry of the charge distribution at the nucleus	55,59
<b>Other</b>								
58.	BET Brunauer-Emmett-Teller	(Large) surface area 1–20 m <sup>2</sup> /g	Adsorbed gas (e.g., N <sub>2</sub> at low temp.) as function of pressure (monolayer coverage)	–	–	–	Surface area measurement	60

# SYMMETRY OF CRYSTALS

L. I. Berger

The ability of a body to coincide with itself in its different positions regarding a coordinate system is called its symmetry. This property reveals itself in iteration of the parts of the body in space. The iteration may be done by reflection in mirror planes, rotation about certain axes, inversions and translations. These actions are called the symmetry operations. The planes, axes, points, etc., are known as symmetry elements. Essentially, mirror reflection is the only truly primitive symmetry operation. All other operations may be done by a sequence of reflections in certain mirror planes. Hence, the mirror plane is the only true basic symmetry element. But for clarity, it is convenient to use the other symmetry operations, and accordingly, the other aforementioned symmetry elements. The symmetry elements and operations are presented in Table 1.

The entire set of symmetry elements of a body is called its symmetry class. There are thirty-two symmetry classes that describe all crystals that have ever been noted in mineralogy or been synthesized (more than 150,000). The denominations and symbols of the symmetry classes are presented in Table 2.

There are several known approaches to classification of individual crystals in accordance with their symmetry and crystallochemistry. The particles that form a crystal are distributed in certain points in space. These points are separated by certain distances (translations) equal to each other in any chosen direction in the crystal. Crystal lattice is a diagram that describes the location of particles (individual or groups) in a crystal. The lattice parameters

are three non-coplanar translations that form the crystal lattice. Three basic translations form the unit cell of a crystal. August Bravais (1848) has shown that all possible crystal lattice structures belong to one or another of fourteen lattice types (Bravais lattices). The Bravais lattices, both primitive and non-primitive, are the contents of Table 3.

Among the three-dimensional figures, there is a group of polyhedrons that are called regular, which have all faces of the same shape and all edges of the same size (regular polygons). It has been shown that there are only five regular polyhedrons. Because of their importance in crystallography and solid state physics, a brief description of these polyhedrons is included in Table 4.

The systematic description of crystal structures is presented primarily in the well-known *Strukturbericht*. The classification of crystals by the *Strukturbericht* does not reflect their crystal class, the Bravais lattice, but is based on the crystallochemical type. This makes it inconvenient to use the *Strukturbericht* categories for comparison of some individual crystals. Thus, there have been several attempts to provide a more convenient classification of crystals. Table 5 presents a compilation of different classifications which allows the reader to correlate the *Strukturbericht* type with the international and Schoenflies point and space groups and with Pearson's symbols, based on the Bravais lattice and chemical composition of the class prototype. The information included in Table 5 has been chosen as an introduction to a more detailed crystallophysical and crystallochemical description of solids.

TABLE 1. Symmetry Operations and Elements  
Symmetry element

Symmetry operation	Name	Symbol		Presentation on the stereographic projection	
		International (Hermann-Mauguin)	Schoenflies	Parallel	Perpendicular
Reflection in a plane	Plane	m	$C_s$		
Rotation by angle $\alpha = 360^\circ/n$ about an axis	Axis	n = 1, 2, 3, 4 or 6	$C_n$		
		n = 2	$C_2$		
		n = 3	$C_3$		
		n = 4	$C_4$		
		n = 6	$C_6$		
Rotation about an axis and inversion in a symmetry center lying on the axis	Inversion (improper) axis	$\bar{n} = \bar{3}, \bar{4}, \bar{6}$	$C_{ni}$		
		$\bar{n} = \bar{3}$	$C_{3i}$		
		$\bar{n} = \bar{4}$	$C_{4i}$		

**TABLE 1. Symmetry Operations and Elements**  
Symmetry element

Symmetry operation	Name	Symbol		Presentation on the stereographic projection	
		International (Hermann-Mauguin)	Schoenflies	Parallel	Perpendicular
		$\bar{n} = \bar{6}$	$C_{6i}$		
Inversion in a point	Center	$\bar{1}$	$C_i$		
Parallel translation	Translation vector $\vec{a}$ , $\vec{b}$ , $\vec{c}$				
Reflection in a plane and translation parallel to the plane	Glide-plane	a, b, c, n, d			
Rotation about an axis and translation parallel to the axis	Screw axis	$n_m$ ( $m = 1, 2, \dots, n - 1$ )			
Rotation about an axis and reflection in a plane perpendicular to the axis	Rotatory-reflection axis	$\bar{n}$ $\bar{n} = \bar{1}, \bar{2}, \bar{3}, \bar{4}, \bar{6}$	$S_n$		

**TABLE 2. The Thirty-Two Symmetry Classes**

Class name<sup>a</sup> and its symbol – International (Int) and Schoenflies (Sch)

Crystal symbol	Primitive		Central		Planal		Axial		Plane-axial		Inversion primitive		Inversion-planal	
	Int	Sch	Int	Sch	Int	Sch	Int	Sch	Int	Sch	Int	Sch	Int	Sch
Triclinic	1	$C_1$	1	$C_1$										
Monoclinic			—		m	$C_s$	2	$C_2$	2/m	$C_{2h}$				
Orthorhombic					mm2	$C_{2v}$	222	$D_2$	mmm	$D_{2h}$				
Trigonal	3	$C_3$	3	$C_{3i}$	3m	$C_{3v}$	32	$D_3$	$\bar{3}m$	$C_{3d}$				
Tetragonal	4	$C_4$	4/m	$C_{4h}$	4mm	$C_{4v}$	422	$D_4$	4/mmm	$D_{4h}$	$\bar{4}$	$S_4$	$\bar{4}2m$	$D_{2d}$
Hexagonal	6	$C_6$	6/m	$C_{6h}$	6mm	$C_{6v}$	622	$D_6$	6/mmm	$D_{6h}$	$\bar{6}$	$C_{3h}$	$\bar{6}m2$	$D_{3h}$
Cubic	23	T	m3	$T_h$	$\bar{4}3m$	$T_d$	432	O	m3m	$O_h$				

<sup>a</sup> Per Fedorov Institute of Crystallography, Russian Academy of Sciences, nomenclature.

**TABLE 3. The Fourteen Possible Space Lattices (Bravais Lattices)**

Crystal system	Metric category of the system	No. of different lattices in the system	Lattice type <sup>a</sup> (marked by +)					No. of identipoints per unit cell	Characteristic parameters (marked by +)						Description of characteristic parameters $a < X, b < Y, c < Z$		Symmetry of the lattice	
			P	C	I	F	R		a	b	c	$\alpha$	$\beta$	$\gamma$	$\alpha = (b, c), \beta = (a, c), \gamma = (a, b)$	Int	Sch	
Triclinic	Trimetric	1	+					1	+	+	+	+	+	+	$a \neq b \neq c, \alpha \neq \beta \neq \gamma$	1	C	
Monoclinic	Trimetric	2	+	+				1 or 2	+	+	+	+			$a \neq b \neq c, \alpha = \gamma = 90^\circ \neq \beta$	2/m	$C_{2h}$	
Orthorhombic	Trimetric	4	+	+	+	+		1, 2 or 4	+	+	+			$a \neq b \neq c, \alpha = \beta = \gamma = 90^\circ$	mmm	$D_{2h}$		
Trigonal (rhombohedral)	Dimetric	1					+	1	+		+			$a = b = c, 120^\circ > \alpha = \beta = \gamma \neq 90^\circ$	3m	$D_{3d}$		
Tetragonal	Dimetric	2	+	+				1 or 2	+	+				$a = b \neq c, \alpha = \beta = \gamma = 90^\circ$	4/mmm	$D_{4h}$		
Hexagonal	Dimetric	1	+					1	+	+				$a = b \neq c, \alpha = \beta = 90^\circ, \gamma = 120^\circ$	6/mmm	$D_{6h}$		
Isometric (cubic)	Monometric	3	+	+	+			1, 2 or 4	+					$a = b = c, \alpha = \beta = \gamma = 90^\circ$	m3m	$O_h$		

<sup>a</sup> Designations of the space-lattice types: P – primitive, C – side-centered (base-centered), I – body-centered, F – face-centered, R – rhombohedral.

**TABLE 4. The Five Possible Regular Polyhedrons**

Polyhedron	Symmetry (Schoenflies)			Number of <sup>b</sup>		
	Class	Elements	Form of faces	Faces (F)	Edges (E)	Vertices (V)
Tetrahedron	T	$4C_3, 3C_2$	Equilateral triangle	4	6	4

Cube (hexahedron)	O	$3C_4 4C_3 6C_2$	Square	6	12	8
Octahedron	O	$3C_4 4C_3 6C_2$	Equilateral triangle	8	12	6
Pentagonal dodecahedron	J	$6C_5 10C_3 15C_2$	Regular pentagon	12	30	20
Icosahedron	J	$6C_5 10C_3 15C_2$	Equilateral triangle	20	30	12

<sup>a</sup> Per formula by Leonhard Euler:  $F + V - E = 2$

TABLE 5. Classification of Crystals

<sup>a</sup> The first letter denotes the crystal system: triclinic (a), monoclinic (m), orthorhombic (o), tetragonal (t), hexagonal (h) and cubic (c). Trigonal (rhombohedral) system is denoted by combination hR. The second letter of Pearson's symbol denotes lattice type: primitive (P), edge-(base-) centered (C), body-centered (I) or face-centered (F). The following number denotes number of atoms in the crystal unit cell.

<sup>b</sup> Standard ASTM E157-82a has the Bravais lattices designations as following: C – primitive cubic; B – body-centered cubic; F – face-centered cubic; T – primitive tetragonal; U – body-centered tetragonal; R – rhombohedral; H – hexagonal; O – primitive orthorhombic; P – body-centered orthorhombic; Q – base-centered orthorhombic; S – face-centered orthorhombic; M – primitive monoclinic; N – centered monoclinic; A – triclinic.

## IONIC RADII IN CRYSTALS

Ionic radii are a useful tool for predicting and visualizing crystal structures. This table lists a set of ionic radii  $R_i$  in Å units for the most common coordination numbers  $CN$  of positive and negative ions. The values are based on experimental crystal structure determinations, supplemented by empirical relationships, and theoretical calculations. The notation sq after the coordination number indicates a square configuration, while py indicates pyramidal.

The advice of Howard T. Evans and Marvin J. Weber in preparing this table is appreciated.

# POLARIZABILITIES OF ATOMS AND IONS IN SOLIDS

H. P. R. Frederikse

The polarization of a solid dielectric medium,  $\mathbf{P}$ , is defined as the dipole moment per unit volume averaged over the volume of a crystal cell. A component of  $\mathbf{P}$  can be expanded as a function of the electric field  $\mathbf{E}$ :

$$P_i = \sum_j a_j E_j + \sum_{jk} b_{jk} E_j E_k$$

For relatively small electric fields in isotropic substances  $\mathbf{P} = \chi_e \mathbf{E}$ , where  $\chi_e$  is the electric susceptibility. If the medium is made up of  $N$  atoms (or ions) per unit volume, the polarization is  $\mathbf{P} = N \mathbf{p}_m$  where  $\mathbf{p}_m$  is the average dipole moment per atom. The polarizability  $\alpha$  can be defined as  $\mathbf{p}_m = \alpha \mathbf{E}_0$ , where  $\mathbf{E}_0$  is the local field at the position of the atom. Using the Lorentz method to calculate the local field one finds:

$$\mathbf{P} = N\alpha(\mathbf{E} + 4\pi\mathbf{P}) = \chi_e \mathbf{E}$$

Together with the definition of the dielectric constant (relative permittivity),  $\epsilon = 1 + 4\pi\chi_e$ , this leads to:

$$\alpha = \frac{3}{4\pi N} \left( \frac{\epsilon - 1}{\epsilon + 2} \right)$$

This expression is known as the Clausius-Mossotti equation.

The total polarization associated with atoms, ions, or molecules is due to three different sources:

1. Electronic polarization arises because the center of the local electronic charge cloud around the nucleus is displaced under the action of the field:  $\mathbf{P}_e = N\alpha_e \mathbf{E}_0$  where  $\alpha_e$  is the *electronic polarizability*.

2. Ionic polarization occurs in ionic materials because the electric field displaces cations and anions in opposite directions:  $\mathbf{P}_i = N\alpha_i \mathbf{E}_0$ , where  $\alpha_i$  is the *ionic polarizability*.
3. Orientational polarization can occur in substances composed of molecules that have permanent electric dipoles. The alignment of these dipoles depends on temperature and leads to an *orientational polarizability* per molecule:  $\alpha_{or} = p^2/3kT$ , where  $p$  is the permanent dipole moment per molecule,  $k$  is the Boltzmann constant, and  $T$  is the temperature.

Because of the different nature of these three polarization processes the response of a dielectric solid to an applied electric field will strongly depend on the frequency of the field. The resonance of the electronic excitation in insulators (dielectrics) takes place in the ultraviolet part of the spectrum; the characteristic frequency of the lattice vibrations is located in the infrared, while the orientation of dipoles requires fields of much lower frequencies (below  $10^{10}$  Hz). This response to electric fields of different frequencies is shown in Figure 1. Values of the electronic polarizabilities for selected atoms and ions are given in Table 1.

To convert to SI, use the relation  $\alpha(\text{SI})/\text{C m}^2\text{V}^{-1} = 1.11265 \cdot 10^{-16} \alpha(\text{cgs})/\text{cm}^3$

# CRYSTAL STRUCTURES AND LATTICE PARAMETERS OF ALLOTROPES OF THE ELEMENTS

H. W. King

The crystal structures of the allotropic forms of the elements are presented in terms of the Pearson symbol, the Strukturbericht designation, and the prototype of the structure. The temperatures of the phase transformations are listed in degrees Celsius and the pressures are in GPa. A consistent nomenclature is used, whereby all allotropes are labeled by Greek letters. The lattice parameters of the units cells are given in nanometers (nm) and are considered to be accurate to  $\pm 2$  in the last reported digit.

This compilation is restricted to changes in crystal structures that occur as a result of a change in temperature or pressure. Low-

temperature structures are included for the diatomic and rare gases, which show many similarities with respect to the metallic elements. The elements identified with an asterisk (\*) have polymorphic structures based on different molecular configurations. The crystal data given for these elements refer to the most stable structure at room temperature.

Reprinted with the permission of ASM International from T.B. Massalski, Ed., *Binary Alloy Phase Diagrams*, ASM International, Metals Park, Ohio, 1986; certain data on rare earth elements were provided by K.A. Gschneidner.

# LATTICE ENERGIES

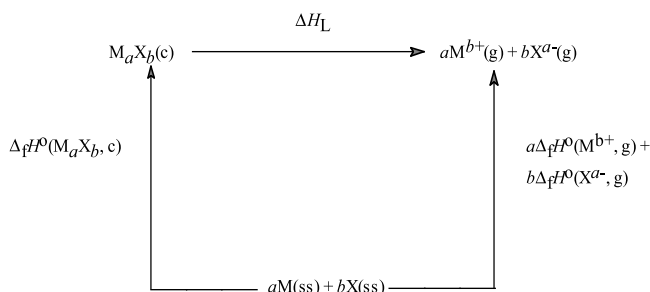

H. D. B. Jenkins and H. K. Roobottom

## THERMOCHEMICAL CYCLE AND CALCULATED VALUES

Table 1 contains calculated values of the lattice energies (total lattice potential energies),  $U_{\text{POT}}$ , of crystalline salts,  $M_aX_b$ .  $U_{\text{POT}}$  is expressed in units of kilojoules per mole,  $\text{kJ mol}^{-1}$ . M and X can be either simple or complex ions. Substances are arranged by chemical class.

Also listed in the table is the lattice energy,  $U_{\text{POT}}^{\text{BFHC}}$ , obtained from the application of the Born - Fajans - Haber cycle (BFHC) described below, using the "Standard Thermochemical Properties of Chemical Substances" table in Section 5 of this *Handbook*, References 1 through 4, and certain other data which are given in Table 3 below.

The lattice enthalpy,  $\Delta H_L$ , is given by the cycle:

where (ss) is the standard state of the element concerned.

The lattice enthalpy,  $\Delta H_L$ , is obtained using the equation:

$$\Delta H_L = a\Delta_f H^\circ(M^{b+}, g) + b\Delta_f H^\circ(X^{a-}, g) - \Delta_f H^\circ(M_aX_b, c)$$

and is further related to the total lattice potential energy,  $U_{\text{POT}}$ , by the relationship:

$$\Delta H_L = U_{\text{POT}} + \left[ a \left( \frac{n_M}{2} - 2 \right) + b \left( \frac{n_X}{2} - 2 \right) \right] RT$$

where  $n_M$  and  $n_X$  equal 3 for monatomic ions, 5 for linear polyatomic ions and 6 for polyatomic non-linear ions.

## METHOD OF ESTIMATION OF VALUES NOT TABULATED

In cases where the lattice energy is not tabulated and we want to furnish an estimate, then the Kapustinskii equation<sup>5</sup> can be used to obtain a value (in  $\text{kJ mol}^{-1}$ ):

$$U_{\text{POT}} = \frac{121.4z_a z_b v}{(r_a + r_b)} \left( 1 - \frac{0.0345}{(r_a + r_b)} \right)$$

where  $z_a$  and  $z_b$  are the moduli of the charges on the  $v$  ions in the lattice and  $r_a$  and  $r_b$  (in nm) are the thermochemical radii given in Table 2. The  $r_a$  for metal ions is taken to be the Goldschmidt<sup>6</sup> radius.

To cite an example, if we wish to estimate the lattice energy of the salt  $[\text{NH}_4^+][\text{HF}_2^-]$  using the above procedure, we see that Table 2 gives the thermochemical radius ( $r_a$ ) for  $\text{NH}_4^+$  to be 0.136 nm and that for  $\text{HF}_2^-$  ( $r_b$ ) to be 0.172 nm. The lattice potential energy is then estimated to be  $700 \text{ kJ mol}^{-1}$  compared with the calculated value of  $705 \text{ kJ mol}^{-1}$  and the Born - Fajans - Haber cycle value of  $658 \text{ kJ mol}^{-1}$ .

## THE MADELUNG CONSTANT AND CRYSTAL LATTICE ENERGY

If  $U$  is the crystal lattice energy and  $M$  is the Madelung constant, then<sup>a</sup>

$$U = \frac{NMz_1z_2e^2}{r}(1 - 1/n)$$

Substance	Ion type	Crystal form <sup>b</sup>	$M$
Sodium chloride, NaCl	M <sup>+</sup> , X <sup>-</sup>	FCC	1.74756
Cesium chloride, CsCl	M <sup>+</sup> , X <sup>-</sup>	BCC	1.76267
Calcium chloride, CaCl <sub>2</sub>	M <sup>++</sup> , 2X <sup>-</sup>	Cubic	2.365
Calcium fluoride (fluorite), CaF <sub>2</sub>	M <sup>++</sup> , 2X <sup>-</sup>	Cubic	2.51939
Cadmium chloride, CdCl <sub>2</sub>	M <sup>++</sup> , 2X <sup>-</sup>	Hexagonal	2.244 <sup>c</sup>
Cadmium iodide (α), CdI <sub>2</sub>	M <sup>++</sup> , 2X <sup>-</sup>	Hexagonal	2.355 <sup>c</sup>
Magnesium fluoride, MgF <sub>2</sub>	M <sup>++</sup> , 2X <sup>-</sup>	Tetragonal	2.381 <sup>c</sup>
Cuprous oxide (cuprite), Cu <sub>2</sub> O	2M <sup>+</sup> , X <sup>--</sup>	Cubic	2.22124
Zinc oxide, ZnO	M <sup>++</sup> , X <sup>--</sup>	Hexagonal	1.4985 <sup>c</sup>
Sphalerite (zinc blende), ZnS	M <sup>++</sup> , X <sup>--</sup>	FCC	1.63806
Wurtzite, ZnS	M <sup>++</sup> , X <sup>--</sup>	Hexagonal	1.64132 <sup>c</sup>
Titanium dioxide (anatase), TiO <sub>2</sub>	M <sup>4+</sup> , 2X <sup>--</sup>	Tetragonal	2.400 <sup>c</sup>
Titanium dioxide (rutile), TiO <sub>2</sub>	M <sup>4+</sup> , 2X <sup>--</sup>	Tetragonal	2.408 <sup>c</sup>
β-Quartz, SiO <sub>2</sub>	M <sup>4+</sup> , 2X <sup>--</sup>	Hexagonal	2.2197 <sup>c</sup>
Corundum, Al <sub>2</sub> O <sub>3</sub>	2M <sup>3+</sup> , 3X <sup>--</sup>	Rhombohedral	4.1719

<sup>a</sup>  $N$  is Avogadro's number,  $z_1$  and  $z_2$  are the integral charges on the ions (in units of  $e$ ), and  $e$  is the charge on the electron in electrostatic units ( $e = 4.803 \times 10^{-10}$  esu).  $r$  is the shortest distance between cation-anion pairs in centimeters. Then  $U$  is in ergs ( $1 \text{ erg} = 10^{-7} \text{ J}$ ).

<sup>b</sup> FCC = face centered cubic; BCC = body centered cubic.

<sup>c</sup> For tetragonal and hexagonal crystals the value of  $M$  depends on the details of the lattice parameters.

The Born Exponent,  $n$  is:

Ion type	$n$
He, Li <sup>+</sup>	5
Ne, Na <sup>+</sup> , F <sup>-</sup>	7
Ar, K <sup>+</sup> , Cu <sup>+</sup> , Cl <sup>-</sup>	9
Kr, Rb <sup>+</sup> , Ag <sup>+</sup> , Br <sup>-</sup>	10
Xe, Cs <sup>+</sup> , Au <sup>+</sup> , I <sup>-</sup>	12

For a crystal with a mixed-ion type, an average of the values of  $n$  in this table is to be used (6 for LiF, for example).

# ELASTIC CONSTANTS OF SINGLE CRYSTALS

H. P. R. Frederikse

This table gives selected values of elastic constants for single crystals. The values believed most reliable were selected from the original literature. The substances are arranged by crystal system and, within each system, alphabetically by name. A reference to the original literature is given for each value; a useful compilation of published values from many sources may be found in Reference 1 below.

Data are given for the single-crystal density and for the elastic constants  $c_{ij}$ , in units of  $10^{11}$  N/m<sup>2</sup>, which is equivalent to  $10^{12}$  dyn/cm<sup>2</sup>.

## ELECTRICAL RESISTIVITY OF PURE METALS

The first part of this table gives the electrical resistivity, in units of  $10^{-8} \Omega \text{ m}$ , for 28 common metallic elements as a function of temperature. The data refer to polycrystalline samples. The number of significant figures indicates the accuracy of the values. However, at low temperatures (especially below 50 K) the electrical resistivity is extremely sensitive to sample purity. Thus the low-temperature values refer to samples of specified purity and treatment. The references should be consulted for further information on this point, as well as for values at additional temperatures.

The second part of the table gives resistivity values in the neighborhood of room temperature for other metallic elements that have not been studied over an extended temperature range.

## ELECTRICAL RESISTIVITY OF SELECTED ALLOYS

These values were obtained by fitting all available measurements to a theoretical formulation describing the temperature and composition dependence of the electrical resistivity of metals. Some of the values listed here fall in regions of temperature and composition where no actual measurements exist. Details of the procedure may be found in the reference.

Values of the resistivity are given in units of  $10^{-8} \Omega \text{ m}$ . General comments in the preceding table for pure metals also apply here

# PERMITTIVITY (DIELECTRIC CONSTANT) OF INORGANIC SOLIDS

H. P. R. Frederikse

This table lists the permittivity  $\epsilon$ , frequently called the dielectric constant, of a number of inorganic solids. When the material is not isotropic, the individual components of the permittivity are given. A superscript S indicates a measurement made under constant strain ("clamped" dielectric constant). If the constraint is removed, the measurement yields  $\epsilon^T$ , the "unclamped" or free dielectric constant.

The temperature of the measurement is given when available; the symbol r.t. indicates a value at nominal room temperature. The

frequency of the measurement is given in the last column (i.r. indicates a measurement in the infrared).

Substances are listed in alphabetical order by chemical formula.

## PROPERTIES OF ANTIFERROELECTRIC CRYSTALS

H. P. R. Frederikse

Some important antiferroelectric crystals are listed here with their Curie Temperatures  $T_c$ . The last column gives the constant  $T_0$  which appears in the Curie-Weiss law describing the dielectric constant of these materials above the Curie Temperature:

$$\epsilon = \text{const.}/(T - T_0)$$

Name or acronym	Formula	$T_c$ /K	$T_0$ /K
ADP	$\text{NH}_4\text{H}_2\text{PO}_4$	148	
ADA	$\text{NH}_4\text{H}_2\text{AsO}_4$	216	
ADDP	$\text{NH}_4\text{D}_2\text{PO}_4$	242, 245

<sup>a</sup> Power factor × dielectric constant equals loss factor.

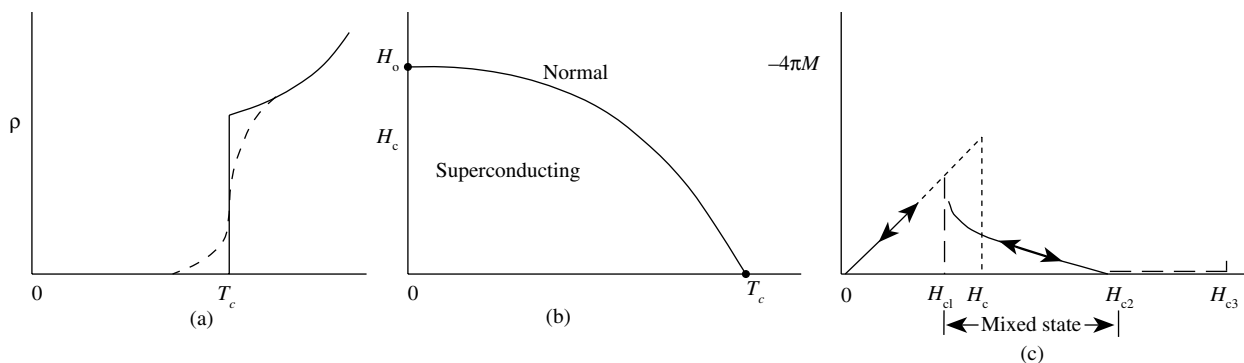

# PROPERTIES OF SUPERCONDUCTORS

L. I. Berger and B. W. Roberts

The following tables include superconductive properties of selected elements, compounds, and alloys. Individual tables are given for thin films, elements at high pressures, superconductors with high critical magnetic fields, and high critical temperature superconductors.

The historically first observed and most distinctive property of a superconductive body is the near total loss of resistance at a critical temperature ( $T_c$ ) that is characteristic of each material. Figure 1(a) below illustrates schematically two types of possible transitions. The sharp vertical discontinuity in resistance is indicated

of that found for a single crystal of a very pure element or one of a few well annealed alloy compositions. The broad transition, illustrated by broken lines, suggests the transition shape seen for materials that are not homogeneous and contain unusual strain distributions. Careful testing of the resistivity limit for superconductors shows that it is less than  $4 \times 10^{-23}$  ohm cm, while the lowest resistivity observed in metals is of the order of  $10^{-13}$  ohm cm. If one compares the resistivity of a superconductive body to that of copper at room temperature, the superconductive body is at least  $10^{17}$  times less resistive.

**FIGURE 1.** Physical properties of superconductors. (a) Resistivity vs. temperature for a pure and perfect lattice (solid line); impure and/or imperfect lattice (broken line). (b) Magnetic-field temperature dependence for Type-I or "soft" superconductors. (c) Schematic magnetization curve for "hard" or Type-II superconductors.

The temperature interval  $\Delta T_c$ , over which the transition between the normal and superconductive states takes place, may be of the order of as little as  $2 \times 10^{-5}$  K or several K in width, depending on the material state. The narrow transition width was attained in 99.9999% pure gallium single crystals.

A Type-I superconductor below  $T_c$ , as exemplified by a pure metal, exhibits perfect diamagnetism and excludes a magnetic field up to some critical field  $H_c$ , whereupon it reverts to the normal state as shown in the  $H$ - $T$  diagram of Figure 1(b).

The magnetization of a typical high-field superconductor is shown in Figure 1(c). The discovery of the large current-carrying capability of  $Nb_3Sn$  and other similar alloys has led to an extensive study of the physical properties of these alloys. In brief, a high-field superconductor, or Type-II superconductor, passes from the perfect diamagnetic state at low magnetic fields to a mixed state and finally to a sheathed state before attaining the normal resistive state of the metal. The magnetic field values separating the four stages are given as  $H_{c1}$ ,  $H_{c2}$ , and  $H_{c3}$ . The superconductive state below  $H_{c1}$  is perfectly diamagnetic, identical to the state of most pure metals of the "soft" or Type-I superconductor. Between  $H_{c1}$  and  $H_{c2}$  a "mixed superconductive state" is found in which fluxons (a minimal unit of magnetic flux) create lines of normal flux in a superconductive matrix. The volume of the normal state is proportional to  $-4\pi M$  in the "mixed state" region. Thus at  $H_{c2}$  the fluxon density has become so great as to drive the interior volume of the superconductive body completely normal. Between  $H_{c2}$  and  $H_{c3}$  the superconductor has a sheath of current-carrying superconductive material at the body surface, and above  $H_{c3}$  the normal state exists. With several types of careful measurement, it is possible to determine  $H_{c1}$ ,  $H_{c2}$ , and  $H_{c3}$ . Table 6 contains some of the available data on high-field superconductive materials.

High-field superconductive phenomena are also related to specimen dimension and configuration. For example, the Type-I superconductor, Hg, has entirely different magnetization behavior in high magnetic fields when contained in the very fine sets of filamentary tunnels found in an unprocessed Vycor glass. The great majority of superconductive materials are Type-II. The elements in very pure form and a very few precisely stoichiometric and well annealed compounds are Type I with the possible exceptions of vanadium and niobium.

**Metallurgical Aspects.** The sensitivity of superconductive properties to the material state is most pronounced and has been used in a reverse sense to study and specify the detailed state of alloys. The mechanical state, the homogeneity, and the presence of impurity atoms and other electron-scattering centers are all capable of controlling the critical temperature and the current-carrying capabilities in high-magnetic fields. Well annealed specimens tend to show sharper transitions than those that are strained or inhomogeneous. This sensitivity to mechanical state underlines a general problem in the tabulation of properties for superconductive materials. The occasional divergent values of the critical temperature and of the critical fields quoted for a Type-II superconductor may lie in the variation in sample preparation. Critical temperatures of materials studied early in the history of superconductivity must be evaluated in light of the probable metallurgical state of the material, as well as the availability of less pure starting elements. It has been noted that recent work has given extended consideration to the metallurgical aspects of sample preparation.

Symbols in tables:  $T_c$ : Critical temperature;  $H_0$ : Critical magnetic field in the  $T = 0$  limit;  $\theta_D$ : Debye temperature; and  $\gamma$ : Electronic specific heat.

TABLE 4. Superconductive Compounds and Alloys

All compositions are denoted on an atomic basis, i.e., AB, AB<sub>2</sub>, or AB<sub>3</sub> for compounds, unless noted. Solid solutions or odd compositions may be denoted as A<sub>x</sub>B<sub>1-z</sub> or A<sub>z</sub>B. A series of three or more alloys is indicated as A<sub>x</sub>B<sub>1-x</sub> or by actual indication of the atomic fraction range, such as A<sub>0-0.6</sub>B<sub>1-0.4</sub>. The critical temperature of such a series of alloys is denoted by a range of values or possibly the maximum value.

The selection of the critical temperature from a transition in the effective permeability, or the change in resistance, or possibly the incremental changes in frequency observed by certain techniques is not often obvious from the literature. Most authors choose the

mid-point of such curves as the probable critical temperature of the idealized material, while others will choose the highest temperature at which a deviation from the normal state property is observed. In view of the previous discussion concerning the variability of the superconductive properties as a function of purity and other metallurgical aspects, it is recommended that appropriate literature be checked to determine the most probable critical temperature or critical field of a given alloy.

A very limited amount of data on critical fields,  $H_c$ , is available for these compounds and alloys; these values are given at the end of the table.

# HIGH TEMPERATURE SUPERCONDUCTORS

C. N. R. Rao and A. K. Raychaudhuri

The following tables give properties of a number of high temperature superconductors. Table 1 lists the crystal structure (space group and lattice constants) and the critical transition temperature  $T_c$  for the more important high temperature superconductors so far studied. Table 2 gives energy gap, critical current density, and penetration depth in the superconducting state. Table 3 gives electrical and thermal properties of some of these materials in the normal state. The tables were prepared in November 1992 and updated in November 1994.

# ORGANIC SUPERCONDUCTORS

H.P.R. Frederikse

Although the vast majority of organic compounds are insulators, a small number of organic solids show considerable electrical conductivity. Some of these materials appear to be superconductors. The superconducting organics fall primarily into two groups: those containing fulvalenes (pentagonal rings containing sulfur or selenium) and those based on fullerenes, involving the nearly spherical cluster  $C_{60}$ .

The transition temperatures  $T_c$  of the fulvalene derivatives are shown in Table 1. The abbreviations of the various molecular groups are listed in Table 2 and their chemical structures are depicted in Figure 1. Most of the  $T_c$ 's are between 1 and 12 K. Several of the compounds only show superconductivity under pressure.

The fullerenes are  $A_3C_{60}$  compounds, where A represents a single or a combination of alkali atoms. The  $C_{60}$  cluster is shown in

Figure 2a, while Figure 2b illustrates how the alkali atoms fit into the  $A_3C_{60}$  molecule to form the A15 crystallographic structure. Their superconducting transition temperatures range from 8 to 31.3 K (see Table 3).

# PROPERTIES OF SEMICONDUCTORS

L. I. Berger

The term *semiconductor* is applied to a material in which electric current is carried by electrons or holes and whose electrical conductivity, when extremely pure, rises exponentially with temperature and may be increased from its low "intrinsic" value by many orders of magnitude by "doping" with electrically active impurities.

Semiconductors are characterized by an energy gap in the allowed energies of electrons in the material that separates the normally filled energy levels of the *valence band* (where "missing" electrons behave like positively charged current carriers "holes") and the *conduction band* (where electrons behave rather like a gas of free negatively charged carriers with an effective mass dependent on the material and the direction of the electrons' motion). This energy gap depends on the nature of the material and varies with direction in anisotropic crystals. It is slightly dependent on

temperature and pressure, and this dependence is usually almost linear at normal temperatures and pressures.

Data are presented in five tables. Table 1 lists the main crystallographic and semiconducting properties of a large number of semiconducting materials in three main categories: "Tetrahedral Semiconductors" in which every atom is tetrahedrally coordinated to four nearest neighbor atoms (or atomic sites) as for example in the diamond structure; "Octahedral Semiconductors" in which every atom is octahedrally coordinated to six nearest neighbor atoms—as for example the halite structure; and "Other Semiconductors."

Table 2 gives electrical, magnetic, and optical properties, while Tables 3 and 4 give more details on the semiconducting properties and band structures of the most common semiconductors. Table 5 lists semiconducting minerals with typical resistivity ranges.

# DIFFUSION DATA FOR SEMICONDUCTORS

B. L. Sharma

The diffusion coefficient  $D$  in many semiconductors may be expressed by an Arrhenius-type relation

$$D = D_0 \exp(-Q/kT)$$

where  $D_0$  is a frequency factor,  $Q$  is the activation energy for diffusion,  $k$  is the Boltzmann constant, and  $T$  is the absolute temperature. This table lists  $D_0$  and  $Q$  for various diffusants in common semiconductors.

Abbreviations used in the table are

- AES – Auger Electron Spectroscopy
- DLTS – Deep Level Transient Spectroscopy
- SEM – Scanning Electron Microscopy
- SIMS – Secondary Ion Mass Spectrometry
- $D(c)$  – Concentration Dependent Diffusion Coefficient
- $D_{\max}$  – Maximum Diffusion Coefficient
- (f) – Fast Diffusion Component
- (i) – Interstitial Diffusion Component
- (s) – Slow Diffusion Component
- (||) – Parallel to  $c$  Direction
- ( $\perp$ ) – Perpendicular to  $c$  Direction

Semiconductor	Diffusant	Frequency factor, $D_0$ (cm <sup>2</sup> /s)	Activation energy, $Q$ (eV)	Temperature range (°C)	Method of measurement	Ref.
Si	H	$6 \times 10^{-1}$	1.03	120–1207	Electrical and SIMS	1
	Li	$2.5 \times 10^{-3}$	0.65	25–1350	Electrical	2
	Na	$1.65 \times 10^{-3}$	0.72	530–800	Electrical and flame photometry	3
	K	$1.1 \times 10^{-3}$	0.76	740–800	Electrical and flame photometry	3
Cu		$4 \times 10^{-2}$	1.0	800–1100	Radioactive	4
		$4.7 \times 10^{-3}$	0.43 (i)	300–700	Radioactive	5
Ag		$2 \times 10^{-3}$	1.6	1100–1350	Radioactive	6
Au		$2.4 \times 10^{-4}$	0.39 (i)	700–1300	Radioactive	7
		$2.75 \times 10^{-3}$	2.05 (s)

# PROPERTIES OF MAGNETIC MATERIALS

H. P. R. Frederikse

## Glossary of Symbols

Quantity	Symbol	Units	
		SI	emu
Magnetic field	$H$	A m <sup>-1</sup>	Oe (oersted)
Magnetic induction	$B$	T (tesla)	G (gauss)
Magnetization	$M$	A m <sup>-1</sup>	emu cm <sup>-3</sup>
Spontaneous magnetization	$M_s$	A m <sup>-1</sup>	emu cm <sup>-3</sup>
Saturation magnetization	$M_0$	A m <sup>-1</sup>	emu cm <sup>-3</sup>
Magnetic flux	$\Phi$	Wb (weber)	maxwell
Magnetic moment	$m, \mu$	A m <sup>2</sup>	erg/G
Coercive field	$H_c$	A m <sup>-1</sup>	Oe
Remanence	$B_r$	T	G
Saturation magnetic polarization	$J_s$	T	G
Magnetic susceptibility	$\chi$		
Magnetic permeability	$\mu$	H m <sup>-1</sup> (henry/meter)	
Magnetic permeability of free space	$\mu_0$	H m <sup>-1</sup>	
Saturation magnetostriction	$\lambda (\Delta l/l)$		
Curie temperature	$T_C$	K	K
Néel temperature	$T_N$	K	K

Magnetic moment  $\mu = \gamma \hbar J = g \mu_B J$

where

$\gamma$  = gyromagnetic ratio;  $J$  = angular momentum;  $g$  = spectroscopic splitting factor ( $\sim 2$ )

$\mu_B$  = bohr magneton =  $9.2741 \cdot 10^{-24}$  J/T =  $9.2741 \cdot 10^{-21}$  erg/G

Earth's magnetic field  $H = 56 \text{ A m}^{-1} = 0.7 \text{ Oe}$

For iron:  $M_0 = 1.7 \cdot 10^6 \text{ A m}^{-1}$ ;  $B_r = 0.8 \cdot 10^6 \text{ A m}^{-1}$

1 Oe =  $(1000/4\pi) \text{ A m}^{-1}$ ; 1 G =  $10^{-4} \text{ T}$ ; 1 emu cm<sup>-3</sup> =  $10^3 \text{ A m}^{-1}$

1 maxwell =  $10^{-8} \text{ Wb}$

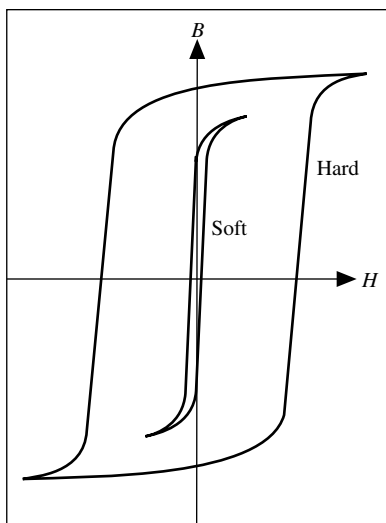

$\mu_0 = 4\pi \cdot 10^{-7} \text{ H m}^{-1}$

### Relation Between Magnetic Induction and Magnetic Field

**FIGURE 1.** Typical curve representing the dependence of magnetic induction  $B$  on magnetic field  $H$  for a ferromagnetic material. When  $H$  is first applied,  $B$  follows curve **a** as the favorably oriented magnetic domains grow. This curve flattens as saturation is approached. When  $H$  is then reduced,  $B$  follows curve **b**, but retains a finite value (the remanence  $B_r$ ) at  $H = 0$ . In order to demagnetize the material, a negative field  $-H_c$  (where  $H_c$  is called the coercive field or coercivity) must be applied. As  $H$  is further decreased and then increased to complete the cycle (curve **c**), a hysteresis loop is obtained. The area within this loop is a measure of the energy loss per cycle for a unit volume of the material.

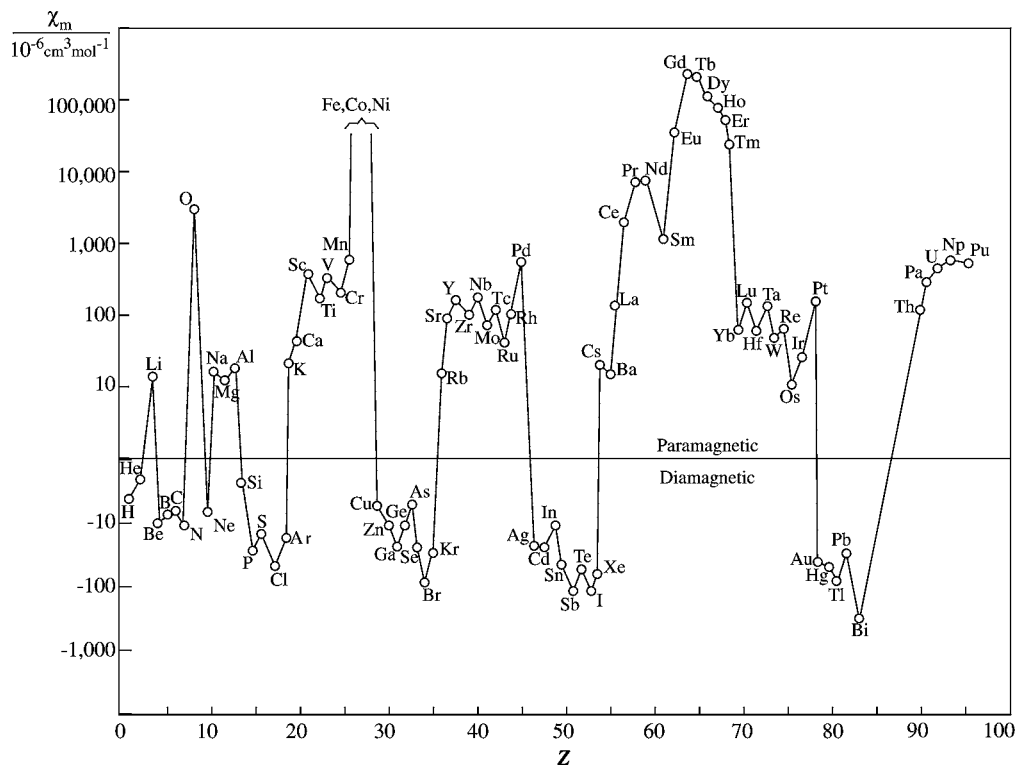

**FIGURE 2.** Schematic curve illustrating the  $B$  vs.  $H$  dependence for hard and soft magnetic materials. Hard materials have a larger remanence and coercive field, and a correspondingly large hysteresis loss.

### Applications of High-Permeability Materials

#### Applications

#### Requirements

#### Power applications

Distribution and power transformers

Low core losses, high permeability, high saturation magnetic polarization

High-quality motors and generators, stators and armatures, switched-mode power supplies

#### Instrument transformers

Audiofrequency transformers

Low core losses, high permeability, high magnetic polarization

Pulse transformers

High permeability

#### Cores for inductor coils

Audiofrequency

Low hysteresis, high permeability

Carrier frequency

Very low hysteresis and eddy current loss

Radiofrequency

High permeability at low fields

#### Miscellaneous

Relays, switches  
 Earth leakage circuit }

High permeability, low remanence, low coercivity

Magnetic shielding

Low core loss for AC applications

**Applications of High-Permeability Materials**

Applications	Requirements
Magnetic recording heads	High initial permeability, low or zero remanence
Magnetic amplifiers } Saturable reactors } Saturable transformers } Transformer cores }	Rectangular hysteresis loops, low hysteresis loss
Magnetic shunts for temperature compensation in magnetic circuits	Low Curie temperature, appropriate decrease in permeability with increase in temperature
Electromagnets in indicating instruments, fire detection, quartz watches, electromechanical devices	High permeability, high saturation magnetic polarization
Magnetic yokes in permanent magnet devices, such as lifting and holding magnets, loudspeakers	High permeability, high saturation magnetic polarization

## ELECTRON WORK FUNCTION OF THE ELEMENTS

The electron work function  $\Phi$  is a measure of the minimum energy required to extract an electron from the surface of a solid. It is defined more precisely as the energy difference between the state in which an electron has been removed to a distance from the surface of a single crystal face that is large enough that the image force is negligible but small compared to the distance to any other face (typically about  $10^{-4}$  cm) and the state in which the electron is in the bulk solid. In general,  $\Phi$  differs for each face of a monocrystalline sample.

Since  $\Phi$  is dependent on the cleanliness of the surface, measurements reported in the literature often cover a considerable range. This table contains selected values for the electron work function of the elements which may be regarded as typical values for a reasonably clean surface. The method of measurement is indicated for each value. The following abbreviations appear:

TE – Thermionic emission  
 PE – Photoelectric effect  
 FE – Field emission  
 CPD – Contact potential difference  
 polycr – Polycrystalline sample  
 amorp – Amorphous sample

Values in parentheses are only approximate.

## SECONDARY ELECTRON EMISSION

The secondary emission yield, or secondary emission ratio,  $\delta$ , is the average number of secondary electrons emitted from a bombarded material for every incident primary electron. It is a function of the primary electron energy  $E_p$ . The maximum yield  $\delta_{\text{max}}$  corresponds to a primary electron energy  $E_{\text{pmax}}$  (see figure). The two primary electron energies corresponding to a yield of unity are denoted the first and second crossovers ( $E_I$  and  $E_{II}$ ). An insulat-

ing target, or a conducting target that is electrically floating, will charge positively or negatively depending on the primary electron energy. For  $E_I < E_p < E_{II}$ ,  $\delta > 1$  and the surface charges positively provided there is a collector present that is positive with respect to the target. For  $E_p < E_I$  or  $E_p > E_{II}$ ,  $\delta < 1$ , and the surface charges negatively with respect to the potential of the source of primary electrons.

# OPTICAL PROPERTIES OF SELECTED ELEMENTS

J. H. Weaver and H. P. R. Frederikse

These tables list the index of refraction  $n$ , the extinction coefficient  $k$ , and the normal incidence reflection  $R(\phi = 0)$  as a function of photon energy  $E$ , which is expressed in electron volts (eV). To convert the energy in eV to the wavelength in  $\mu\text{m}$ , use  $\lambda = 1.2398/E$ . To compute the dielectric function  $\tilde{\epsilon} = \epsilon_1 + i\epsilon_2$  from the complex index of refraction  $\tilde{N} = n + ik$ , use  $\epsilon_1 = n^2 - k^2$  and  $\epsilon_2 = 2nk$ .

The optical constants in these tables are abridged from three more extensive tabulations:

- *Optical Properties of Metals* (OPM), Volumes I and II, *Physics Data*, Nr. 18-1 and 18-2, J. H. Weaver, C. Krafft, D. W. Lynch, and E. E. Koch, Fachinformationzentrum, Karlsruhe, Germany.
- *Handbook of Optical Constants* (HOC), Vol. I, 1985, and Vol. II, 1991. E. D. Palik, Ed., Academic Press, Inc., London.
- *American Institute of Physics Handbook* (AIPH), 3rd Edition, D. E. Gray, Ed., McGraw-Hill, New York, 1972.

The first two of these major sources provide detailed comparisons of all optical data available in the literature at the time of the compilation. For critical applications the reader should refer to the original work. References for individual metals and semiconduc-

tors are listed at the end of the tables. Generally, tabulated values for the optical properties are accurate to better than 10%. Data in parentheses are extrapolated or interpolated values. For most elements the spectral range covered is from the far infrared (0.010 or 0.10 eV) to the far ultraviolet (10, 30 or 300 eV). The intervals between successive energies in the tables are chosen in such a way that the major spectral features are preserved.

Very small values of  $k$  are expressed in exponential notation, e.g., 1.23E-5 means  $1.23 \times 10^{-5}$ .

The following table is convenient for associating the energy entries in these tables with the corresponding wavelengths:

$\lambda$	E/eV	$\lambda$	E/eV
1 mm	0.00124	6000 Å	2.066
500 $\mu\text{m}$	0.00248	5000 Å	2.480
100 $\mu\text{m}$	0.01240	4000 Å	3.100
50 $\mu\text{m}$	0.02480	3000 Å	4.133
10 $\mu\text{m}$	0.12398	2000 Å	6.199
5 $\mu\text{m}$	0.24797	1000 Å	12.398
1 $\mu\text{m}$	1.240	400 Å	30.996

## ELASTO-OPTIC, ELECTRO-OPTIC, AND MAGNETO-OPTIC CONSTANTS

When a crystal is subjected to a stress field, an electric field, or a magnetic field, the resulting optical effects are in general dependent on the orientation of these fields with respect to the crystal axes. It is useful, therefore, to express the optical properties in terms of the refractive index ellipsoid (or indicatrix):

$$\frac{x^2}{n_x^2} + \frac{y^2}{n_y^2} + \frac{z^2}{n_z^2} = 1$$

or

$$\sum_{ij} B_{ij} x_i x_j = 1 (i, j = 1, 2, 3)$$

where

$$B_{ij} = \left[ \frac{1}{\epsilon} \right]_{ij} = \left[ \frac{1}{n^2} \right]_{ij}$$

$\epsilon$  is the dielectric constant or permeability; the quantity  $B_{ij}$  is called impermeability.

A crystal exposed to a *stress*  $\mathbf{S}$  will show a change of its impermeability. The photo-elastic (or elasto-optic) constants,  $P_{ijkl}$ , are defined by

$$\Delta \left[ \frac{1}{\epsilon} \right]_{ij} = \Delta \left[ \frac{1}{n^2} \right]_{ij} = \sum_{kl} P_{ijkl} S_{kl}$$

where  $n$  is the refractive index and  $S_{kl}$  are the strain tensor elements; the  $P_{ijkl}$  are the elements of a 4th rank tensor.

When a crystal is subjected to an *electric field*  $\mathbf{E}$ , two possible changes of the refractive index may occur depending on the symmetry of the crystal.

1. All materials, including isotropic solids and polar liquids, show an electro-optic birefringence (Kerr effect) which is proportional to the square of the electric field,  $\mathbf{E}$ :

$$\Delta \left[ \frac{1}{n^2} \right]_{ij} = \sum_k K_{ijk} E_k E_l = \sum_{k,l=1,2,3} g_{ijkl} P_k P_l$$

where  $E_k$  and  $E_l$  are the components of the electric field and  $P_k$  and  $P_l$  the electric polarizations. The coefficients,  $K_{ijk}$ , are the quadratic electro-optic coefficients, while the constants  $g_{ijkl}$  are known as the Kerr constants.

2. The other electro-optic effect only occurs in the 20 piezoelectric crystal classes (no center of symmetry). This effect is known as the Pockels effect. The optical impermeability changes linearly with the static field

$$\Delta \left[ \frac{1}{n^2} \right]_{ij} = \sum_k r_{ij,k} E_k$$

The coefficients  $r_{ij,k}$  have the name (linear) electro-optic coefficients.

The values of the electro-optic coefficients depend on the boundary conditions. If the superscripts T and S denote, respectively, the conditions of zero stress (free) and zero strain (clamped) one finds:

$$r_{ij}^T = r_{ij}^S + q_{ik}^E e_{jk} = r_{ij}^S + P_{ik}^E d_{jk}$$

where  $e_{jk} = (\partial T_k / \partial E_j)_S$  and  $d_{jk} = (\partial S_k / \partial E_j)_T$  are the appropriate piezoelectric coefficients.

The interaction between a *magnetic field* and a light wave propagating in a solid or in a liquid gives rise to a rotation of the plane of polarization. This effect is known as *Faraday rotation*. It results from a difference in propagation velocity for left and right circular polarized light.

The Faraday rotation,  $\theta_F$ , is linearly proportional to the magnetic field  $H$ :

$$\theta_F = V l H$$

where  $l$  is the light path length and  $V$  is the *Verdet* constant (minutes/oersted-cm).

For ferromagnetic, ferrimagnetic, and antiferromagnetic materials the magnetic field in the above expression is replaced by the magnetization  $M$  and the magneto-optic coefficient in this case is known as the Kund constant  $K$ :

$$\text{Specific Faraday rotation } F = KM$$

In the tables below the *Faraday rotation* is listed at the saturation magnetization per unit length, together with the absorption coefficient  $\alpha$ , the temperature  $T$ , the critical temperature  $T_c$  (or  $T_N$ ), and the wavelength of the measurement.

In the tables that follow, the properties are presented in groups:

- Elasto-optic coefficients (photoelastic constants)
- Linear electro-optic coefficients (Pockels constants)
- Quadratic electro-optic coefficients (Kerr constants)
- Magneto-optic coefficients:
  - Verdet constants
  - Faraday rotation parameters

Within each group, materials are classified by crystal system or physical state. References are given at the end of each group of tables.

## LINEAR ELECTRO-OPTIC COEFFICIENTS

Name					
Cubic ( $\bar{4}3m$ )		Formula	$\lambda/\mu\text{m}$	$r_{41}$	
				pm/V	
	Cuprous bromide	CuBr	0.525	0.85	
	Cuprous chloride	CuCl	0.633	3.6	
	Cuprous iodide	CuI	0.55	-5.0	
	Eulytite (BSO)	$\text{Bi}_4\text{Si}_3\text{O}_{12}$	0.63	0.54	
	Germanium eulytite (BGO)	$\text{Bi}_4\text{Ge}_3\text{O}_{12}$	0.63	1.0	
	Gallium arsenide	GaAs	10.6	1.6	
	Gallium phosphide	GaP	0.56	-1.07	
	Hexamethylenetetramine	$\text{C}_6\text{H}_{12}\text{N}_4$	0.633	0.78	
	Sphalerite	ZnS	0.65	2.1	
	Zinc selenide	ZnSe	0.546	2.0	
	Zinc telluride	ZnTe	3.41	4.2	
	Cadmium telluride	CdTe	3.39	6.8	

Cubic (23)		Formula	$\lambda/\mu\text{m}$	$r_{41}$	
				pm/V	
	Ammonium chloride (77 K)	$\text{NH}_4\text{Cl}$	-	1.5	
	Ammonium cadmium langbeinite	$(\text{NH}_4)_2\text{Cd}_2(\text{SO}_4)_3$	0.546	0.70	
	Ammonium manganese langbeinite	$(\text{NH}_4)_2\text{Mn}_2(\text{SO}_4)_3$	0.546	0.53	
	Thallium cadmium langbeinite	$\text{Tl}_2\text{Cd}_2(\text{SO}_4)_3$	0.546	0.37	
	Potassium magnesium langbeinite	$\text{K}_2\text{Mg}_2(\text{SO}_4)_3$	0.546	0.40	
	Bismuth monogermanate	$\text{Bi}_{12}\text{GeO}_{20}$	-	3.3	
	Bismuth monosilicate	$\text{Bi}_{12}\text{SiO}_{20}$	-	3.3	
	Sodium chlorate	$\text{NaClO}_3$	0.589	0.4	
	Sodium uranyl acetate	$\text{NaUO}_2(\text{CH}_3\text{COO})_3$	0.546	0.87	
	Trenhydrobromide	$\text{N}(\text{CH}_2\text{CH}_2\text{NH}_2)_3 \cdot 3\text{HBr}$	-	1.5	
	Trenhydrochloride	$\text{N}(\text{CH}_2\text{CH}_2\text{NH}_2)_3 \cdot 3\text{HCl}$	-	1.7	

Tetragonal ( $\bar{4}2m$ )		Formula	$T_{\text{tran}}$	$r_{41}$	$r_{63}$
			K	pm/V	pm/V
	Ammonium dihydrogen phosphate (ADP)	$\text{NH}_4\text{H}_2\text{PO}_4$	148	24.5	-8.5
	Ammonium dideuterium phosphate (AD*P)	$\text{NH}_4\text{D}_2\text{PO}_4$	242	-	11.9
	Ammonium dihydrogen arsenate (ADA)	$\text{NH}_4\text{H}_2\text{AsO}_4$	-	-	9.2
	Cesium dihydrogen arsenate (CsDA)	$\text{CsH}_2\text{AsO}_4$	143	-	18.6
	Cesium dideuterium arsenate (CsD*A)	$\text{CsD}_2\text{AsO}_4$	212	-	36.6
	Potassium dihydrogen phosphate (KDP)	$\text{KH}_2\text{PO}_4$	123	8.6	-10.5
	Potassium dideuterium phosphate (KD*P)	$\text{KD}_2\text{PO}_4$	222	8.8	23.8
	Potassium dihydrogen arsenate (KDA)	$\text{KH}_2\text{AsO}_4$	97	12.5	10.9
	Potassium dideuterium arsenate (KD*A)	$\text{KD}_2\text{AsO}_4$	162	-	18.2
	Rubidium dihydrogen phosphate (RDP)	$\text{RbH}_2\text{PO}_4$	147	-	15.5
	Rubidium dihydrogen arsenate (RDA)	$\text{RbH}_2\text{AsO}_4$	110	-	13.0
	Rubidium dideuterium arsenate (RD*A)	$\text{RbD}_2\text{AsO}_4$	178	-	21.4

Tetragonal (4mm)		Formula	$T_{\text{tran}}$	$r_{13}$	$r_{33}$	$r_{51}$
			K	pm/V	pm/V	pm/V
	Barium titanate	$\text{BaTiO}_3$	406	8	28	-
	Potassium lithium niobate	$\text{K}_3\text{Li}_2\text{Nb}_5\text{O}_{15}$	693	8.9	5.9	-
	Lead titanate	$\text{PbTiO}_3$	765	13.8	5.9	-
	Strontium barium niobate (SBN75)	$\text{Sr}_{0.75}\text{Ba}_{0.25}\text{Nb}_2\text{O}_6$	330	6.7	1340	42
	Strontium barium niobate (SBN46)	$\text{Sr}_{0.46}\text{Ba}_{0.54}\text{Nb}_2\text{O}_6$	602	~180	35	-

Hexagonal (6mm)		Formula	$r_{13}$ pm/V	$r_{33}$ pm/V	$r_{42}$ pm/V	$r_{51}$ pm/V
Greenockite	CdS		3.1	2.9	2.0	3.7
Greenockite (const. strain)	CdS		1.1	2.4	–	–
Wurzite	ZnS		0.9	1.8	–	–
Zincite	ZnO		-1.4	+2.6	–	–

Hexagonal (6)		Formula	$r_{13}$ pm/V	$r_{33}$ pm/V	$r_{42}$ pm/V	$r_{51}$ pm/V
Lithium iodate	LiIO <sub>3</sub>		4.1	6.4	1.4	3.3
Lithium potassium sulfate	LiKSO <sub>4</sub>		$r_{13}-r_{33} = 1.6$	–	–	–

Trigonal (3m)		Formula	$T_{\text{tran}}$ K	$r_{13}$ pm/V	$r_{22}$ pm/V	$r_{33}$ pm/V	$r_{42}$ pm/V
Cesium nitrate	CsNO <sub>3</sub>		425	–	0.43	–	–
Lithium niobate	LiNbO <sub>3</sub>		1483	8.6	7.0	30.8	28
Lithium tantalate	LiTaO <sub>3</sub>		890	8.4	–	30.5	–
Lithium sodium sulfate	LiNaSO <sub>4</sub>		–	–	<0.02	–	–
Tourmaline	–		–	–	0.3	–	–

Trigonal (32)		Formula	$T_{\text{tran}}$ K	$r_{11}$ pm/V	$r_{41}$ pm/V
Cesium tartrate	Cs <sub>2</sub> C <sub>4</sub> H <sub>4</sub> O <sub>6</sub>		–	1.0	–
Cinnabar	HgS		659	3.1	1.5
Potassium dithionate	K <sub>2</sub> S <sub>2</sub> O <sub>6</sub>		–	0.26	–
Strontium dithionate	SrS <sub>2</sub> O <sub>6</sub> ·4H <sub>2</sub> O		–	0.1	–
Quartz	SiO <sub>2</sub>		1140	-0.47	0.2
Selenium	Se		398	2.5	–

Orthorhombic (222)		Formula	$T_{\text{tran}}$ K	$r_{41}$ pm/V	$r_{52}$ pm/V	$r_{63}$ pm/V
Ammonium oxalate	(NH <sub>4</sub> ) <sub>2</sub> C <sub>2</sub> O <sub>4</sub> ·4H <sub>2</sub> O		–	230	330	250
Rochelle salt	KNaC <sub>4</sub> H <sub>4</sub> O <sub>6</sub> ·4H <sub>2</sub> O		$T_u = 297$ $T_l = 255$	-2.0	-1.7	+0.32

Orthorhombic (mm2)		Formula	$T_{\text{trans}}$ K	$r_{13}$ pm/V	$r_{23}$ pm/V	$r_{33}$ pm/V	$r_{42}$ pm/V	$r_{51}$ pm/V
Barium sodium niobate (BSN)	Ba <sub>2</sub> NaNbO <sub>15</sub>		833	15	13	48	92	90
Potassium niobate	KNbO <sub>3</sub>		476	28	1.3	64	380	105

Monoclinic (2)		Formula	$T_{\text{trans}}$ K	$r_{22}$ pm/V	$r_{32}$ pm/V
Calcium pyroniobate	Ca <sub>2</sub> Nb <sub>2</sub> O <sub>7</sub>		–	0.33	13.7
Triglycine sulfate (TGS)	(NH <sub>2</sub> CH <sub>2</sub> COOH) <sub>3</sub> ·H <sub>2</sub> SO <sub>4</sub>		322	7.2	13.6

## MAGNETO-OPTIC CONSTANTS

Verdet Constants of Non-Magnetic Crystals<sup>1</sup>

$V$  is the Verdet constant;  $n$  is the refractive index; and  $\lambda$  is the wavelength. "min" is minutes of angle.

Material	$T$ K	$\lambda$ nm	$n$	$V$ min/Oe cm

# NONLINEAR OPTICAL CONSTANTS

H. P. R. Frederikse

The relation between the polarization density  $P$  of a dielectric medium and the electric field  $E$  is linear when  $E$  is small, but becomes nonlinear as  $E$  acquires values comparable with interatomic electric fields ( $10^5$  to  $10^8$  V/cm). Under these conditions the relation between  $P$  and  $E$  can be expanded in a Taylor's series

$$P = \epsilon_0 \chi^{(1)} E + 2\chi^{(2)} E^2 + 4\chi^{(3)} E^3 + \dots \quad (1)$$

where  $\epsilon_0$  is the permittivity of free space, while  $\chi^{(1)}$  is the linear and  $\chi^{(2)}$ ,  $\chi^{(3)}$  etc. the nonlinear optical susceptibilities.

If we consider two optical fields, the first  $E_j^{\omega_1}$  (along the  $j$ -direction at frequency  $\omega_1$ ) and the second  $E_k^{\omega_2}$  (along the  $k$ -direction at frequency  $\omega_2$ ) one can write the second term of the Taylor's series as follows

$$P_i(\omega_1, \omega_2) = 2\chi_{ijk}^{\omega_3=\omega_1 \pm \omega_2} E_j^{\omega_1} E_k^{\omega_2}$$

When  $\omega_1 \neq \omega_2$  the (parametric) mixing of the two fields gives rise to two new polarizations at the frequencies  $\omega_3 = \omega_1 + \omega_2$  and  $\omega_3' = \omega_1 - \omega_2$ . When the two frequencies are equal,  $\omega_1 = \omega_2 = \omega$ , the result is Second Harmonic Generation (SHG):  $\chi_{ijk}(2\omega, \omega, \omega)$ , while equal and opposite frequencies,  $\omega_1 = \omega$  and  $\omega_2 = -\omega$  leads to Optical Rectification (OR):  $\chi_{ijk}(0, \omega, -\omega)$ . In the SHG case the following convention is adopted: the second order nonlinear coefficient  $d$  is equal to one half of the second order nonlinear susceptibility

$$d_{ijk} = 1/2\chi^{(2)}$$

Because of the symmetry of the indices  $j$  and  $k$  one can replace these two by a single index (subscript)  $m$ . Consequently the notation for the SHG nonlinear coefficient in reduced form is  $d_{im}$  where  $m$  takes the values 1 to 6. Only noncentrosymmetric crystals can possess a nonvanishing  $d_{ijk}$  tensor (third rank). The unit of the SHG coefficients is m/V (in the MKSQ/SI system).

In centrosymmetric media the dominant nonlinearity is of the third order. This effect is represented by the third term in the Taylor's series (Equation 1); it is the result of the interaction of a number of optical fields (one to three) producing a new frequency  $\omega_4 = \omega_1 + \omega_2 + \omega_3$ . The third order polarization is given by

$$P_j(\omega_1, \omega_2, \omega_3) = g_4 \chi_{jklm} E_k^{\omega_1} E_l^{\omega_2} E_m^{\omega_3}$$

Third Harmonic Generation (THG) is achieved when  $\omega_1 = \omega_2 = \omega_3 = \omega$ . In this case the constant  $g_4 = 1/4$ . The third order nonlinear coefficient  $C$  is related to the third order susceptibility as follows:

$$C_{jklm} = 1/4\chi_{jklm}$$

This coefficient is a fourth rank tensor. In the THG case the matrices must be invariant under permutation of the indices  $k, l$ , and  $m$ ; as a result the notation for the third order nonlinear coefficient can be simplified to  $C_{jm}$ . The unit of  $C_{jm}$  is  $m^2 \cdot V^{-2}$  (in the MKSQ/SI system).

Applications of second order nonlinear optical materials include the generation of higher (up to sixth) optical harmonics, the mixing of monochromatic waves to generate sum or difference frequencies (frequency conversion), the use of two monochromatic waves to amplify a third wave (parametric amplification) and the addition of feedback to such an amplifier to create an oscillation (parametric oscillation).

Third order nonlinear optical materials are used for THG, self-focusing, four wave mixing, optical amplification, and optical conjugation. Many of these effects – as well as the variation and modulation of optical propagation caused by mechanical, electric, and magnetic fields (see the preceding table on "Elasto-Optic, Electro-Optic, and Magneto-Optic Constants") are used in the areas of optical communication, optical computing, and optical imaging.

# PHASE DIAGRAMS

H. P. R. Frederikse

A phase is a structurally homogeneous portion of matter. Regardless of the number of chemical constituents of a gas, there is only one vapor phase. This is true also for the liquid form of a pure substance, although a mixture of several liquid substances may exist as one or several phases, depending on the interactions among the substances. On the other hand a pure solid may exist in several phases at different temperatures and pressures because of differences in crystal structure (Reference 1). At the phase transition temperature,  $T_{tr}$ , the chemical composition of the solid remains the same, but a change in the physical properties often will take place. Such changes are found in ferroelectric crystals (example  $BaTiO_3$ ) which develop a spontaneous polarization below  $T_{tr}$ , in superconductors (example Pb) which lose all electrical resistance below the transition point, and in many other classes of solids.

In quite a few cases it is difficult to bring about the phase transition, and the high- (or low-) temperature phase persists in its metastable form. Many liquids remain in the liquid state for shorter or longer periods of time when cooled below the melting point (supercooling). However, often the slightest disturbance will cause solidification. Persistence of the high temperature phase in solid-solid transitions is usually of much longer duration. An example of this behavior is found in white tin; although gray tin is the thermodynamically stable form below  $T_{tr}$  (286.4 K), the metal remains in its undercooled, white tin state all the way to  $T = 0$  K, and crystals of gray tin are very difficult to produce.

A *phase diagram* is a map that indicates the areas of stability of the various phases as a function of external conditions (temperature and pressure). Pure materials, such as mercury, helium, water, and methyl alcohol are considered one-component systems and they have *unary* phase diagrams. The equilibrium phases in two-component systems are presented in *binary* phase diagrams. Because many important materials consist of three, four, and more components, many attempts have been made to deduce their multicomponent phase diagrams. However, the vast majority of systems with three or more components are very complex, and no overall maps of the phase relationships have been worked out.

It has been shown during the last 20 to 25 years that very useful partial phase diagrams of complex systems can be obtained by means of thermodynamic modeling (References 2, 3). Especially for complicated, multicomponent alloy systems the CALPHAD method has proved to be a successful approach for producing valuable portions of very intricate phase diagrams (Reference 4). With this method thermodynamic descriptions of the free energy functions of various phases are obtained that are consistent with existing (binary) phase diagram information and other thermodynamic data. Extrapolation methods are then used to extend the thermodynamic functions into a ternary system. Comparison of the results of this procedure with available experimental data is then used to fine-tune the phase diagram and add ternary interaction functions if necessary. In principle this approximation strategy can be extended to four, five, and more component systems.

The nearly two dozen phase diagrams shown below present the reader with examples of some important types of single and multicomponent systems, especially for ceramics and metal alloys. This makes it possible to draw attention to certain features like the kinetic aspects of phase transitions (see Figure 22, which presents a time-temperature-transformation, or TTT, diagram for the precipitation of  $\alpha$ -phase particles from the  $\beta$ -phase in a Ti-Mo alloy; Reference 1, pp. 358–360). The general references listed below and the references to individual figures contain phase diagrams for many additional systems.

ω	(a)	<i>hP3</i>	<i>P6/mmm</i>

(a) Metastable.

Experimental time–temperature–transformation (TTT) diagram for Ti-Mo. The start and finish times of the isothermal precipitation reaction vary with temperature as a result of the temperature dependence of the nucleation and growth processes. Precipitation is complete, at any temperature, when the equilibrium fraction of  $\alpha$  is established in accordance with the lever rule. The solid horizontal line represents the athermal (or nonthermally activated) martensitic transformation that occurs when the  $\beta$  phase is quenched.

**FIGURE 23.** The isothermal section at 900°C (1652°F) of the iron-chromium-nickel ternary phase diagram, showing the nominal composition of 18-8 stainless steel.

## HEAT CAPACITY OF SELECTED SOLIDS

This table gives the molar heat capacity at constant pressure of representative metals, semiconductors, and other crystalline solids as a function of temperature in the range 200 to 600 K.

# THERMAL AND PHYSICAL PROPERTIES OF PURE METALS

This table gives the following properties for the metallic elements:

- $t_m$ : Melting point in °C  
 $t_b$ : Normal boiling point in °C, at a pressure of 101.325 kPa (760 Torr)  
 $\Delta_{\text{fus}}H$ : Enthalpy of fusion at the melting point in J/g  
 $\rho_{25}$ : Density at 25 °C in g/cm<sup>3</sup>  
 $\alpha$ : Coefficient of linear expansion at 25 °C in K<sup>-1</sup> (the quantity listed is 10<sup>6</sup> ×  $\alpha$ )  
 $c_p$ : Specific heat capacity at constant pressure at 25 °C in J/g K  
 $\lambda$ : Thermal conductivity at 27 °C in W/cm K

# THERMAL CONDUCTIVITY OF METALS AND SEMICONDUCTORS AS A FUNCTION OF TEMPERATURE

This table gives the temperature dependence of the thermal conductivity of several metals and of carbon, germanium, and silicon. For graphite, separate entries are given for the thermal conductivity parallel ( $\parallel$ ) and perpendicular ( $\perp$ ) to the layer planes. The thermal conductivity of all these materials is very sensitive to impurities at low temperatures, especially below 100 K. Therefore, the values given here should be regarded as typical values for a highly purified specimen; the thermal conductivity of different specimens can vary by more than an order of magnitude in the low-temperature range. See Reference 2 for details.

# THERMAL CONDUCTIVITY OF ALLOYS AS A FUNCTION OF TEMPERATURE

This table lists the thermal conductivity of selected alloys at various temperatures. The indicated compositions refer to weight percent. Since the thermal conductivity is sensitive to exact composition and processing history, especially at low temperatures, these values should be considered approximate.

# THERMAL CONDUCTIVITY OF CERAMICS AND OTHER INSULATING MATERIALS

Thermal conductivity values for ceramics, refractory oxides, and miscellaneous insulating materials are given here. The thermal conductivity refers to samples with density indicated in the second column. Since most of these materials are highly variable, the values should only be considered as a rough guide.

Material	Dens. g/cm <sup>3</sup>	t °C	Ther. cond. W/m K

## PROPERTIES OF COMMERCIAL METALS AND ALLOYS

This table gives typical values of mechanical, thermal, and electrical properties of several common commercial metals and alloys. Values refer to ambient temperature (0 to 25 °C). All values should be regarded as typical, since these properties are dependent on the particular type of alloy, heat treatment, and other factors. Values for individual specimens can vary widely.

## HARDNESS OF MINERALS AND CERAMICS

There are several hardness scales for describing the resistance of a material to indentation or scratching. This table lists a number of common materials in order of increasing hardness. Values are given, when available, on three different hardness scales: the original Mohs Scale (range 1 to 10); the modified Mohs Scale (range 1

to 15), and the Knoop Hardness Scale. In the last case, a load of 100 g is assumed.

# ORGANIC MAGNETS

J.S. Miller

Magnetic ordering, e.g., ferromagnetism, like superconductivity, is a property of a solid, not of an individual molecule or ion, and very rarely occurs for organic compounds. In contrast to superconductivity, where all electron spins pair to form a perfect diamagnetic material, magnetic ordering requires unpaired electron spins; hence, superconductivity and ferromagnetism are mutually exclusive.

The vast majority of organic compounds are diamagnetic (i.e., all electron spins are paired), and a relative few possess unpaired electrons (designated by an arrow,  $\uparrow$ ) and are paramagnetic (PM), i.e., they are oriented in random directions. A few organic solids, however, exhibit strong magnetic behavior and magnetically order as ferromagnets (FO) with all spins aligned in the same direc-

tion. In some cases the spins align in the opposite direction and compensate to form an antiferromagnet (AF). In some cases these spins are not opposed to each other and do not compensate and lead to a canted antiferromagnet or weak ferromagnet (WF). If the number of spins that align in the opposite direction differs from the number of spins that align in the opposite direction, the spins cannot compensate and a ferrimagnet (FI) results. Metamagnets (MM) are antiferromagnets in which all the spins become aligned like a ferromagnet in an applied magnetic field. Above the ordering or critical temperature,  $T_c$ , all magnets are paramagnets (PM). Organic magnets all possess electron spins in  $p$ -orbitals, but these may be in conjunction with metal ion-based spins.

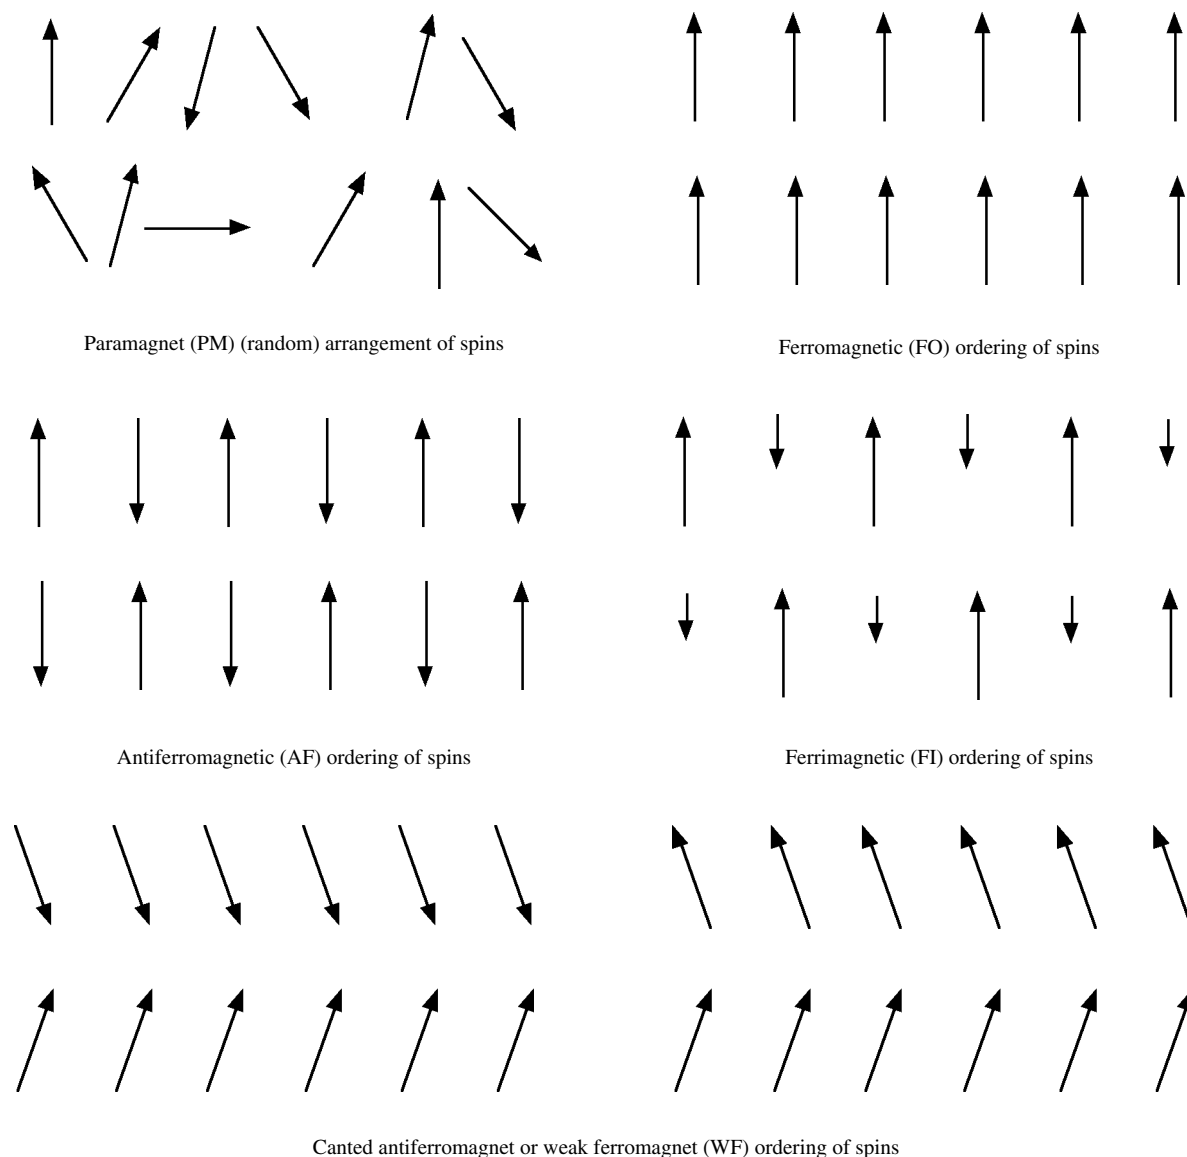

FIGURE 1. Schematic illustration of the different types of magnetic behavior.

# OPTICAL PROPERTIES OF SELECTED INORGANIC AND ORGANIC SOLIDS

L. I. Berger

Optical properties of materials are closely related to their dielectric properties. The complex dielectric function (relative permittivity) of a material is equal to

$$\varepsilon(\omega) = \varepsilon'(\omega) - j\varepsilon''(\omega),$$

where  $\varepsilon'(\omega)$  and  $\varepsilon''(\omega)$  are its real and imaginary parts, respectively, and  $\omega$  is the angular frequency of the applied electric field. For a non-absorbing medium, the index of refraction is  $n = (\varepsilon\mu)^{1/2}$ , where  $\mu$  is the relative magnetic permeability of the medium (material); in the majority of dielectrics,  $\mu \cong 1$ .

For many applications, the most important optical properties of materials are the index of refraction, the extinction coefficient,  $k$ , and the reflectivity,  $R$ . The common index of refraction of a material is equal to the ratio of the phase velocity of propagation of an electromagnetic wave of a given frequency in vacuum to that in the material. Hence,  $n \cong 1$ . The optical properties of highly conductive materials like metals and semiconductors (at photon energy range above the energy gap) differ from those of optically transparent media. Free electrons absorb the incident electromagnetic wave in a thin surface layer (a few hundred nanometers thick) and then release the absorbed energy in the form of secondary waves reflected from the surface. Thus, the light reflection becomes very strong; for example, highly conductive sodium reflects 99.8% of the incident wave (at 589 nm). Introduction of the effective index of refraction,  $n_{\text{eff}} = (\varepsilon')^{1/2} = n - jk$ , where  $\varepsilon' = \varepsilon - j\delta/\omega \varepsilon_0$ ,  $\delta$  is the electrical conductivity of the material in S/m, and  $\varepsilon_0 = 8.8542 \cdot 10^{-12}$  F/m is the permittivity of vacuum, allows one to apply the expressions of the optics of transparent media to the conductive materials. It is clear that the effective index of refraction may be smaller than 1. For example,  $n = 0.05$  for pure sodium and  $n = 0.18$  for pure silver (at 589.3 nm). At very high photon energies, the quantum effects, such as the internal photoeffect, start playing a greater role, and the optical properties of these materials become similar to those of insulators (low reflectance, existence of Brewster's angle, etc.).

The extinction coefficient characterizes absorption of the electromagnetic wave energy in the process of propagation of a wave through a material. The wave intensity,  $I$ , after it passes a distance  $x$  in an isotropic medium is equal to

$$I = I_0 \exp(-\alpha x),$$

where  $I_0$  is the intensity at  $x = 0$  and  $\alpha$  is called the absorption coefficient. For many applications, the extinction coefficient,  $k$ , which is equal to

$$k = \alpha \frac{\lambda}{4\pi},$$

where  $\lambda$  is the wavelength of the wave in the medium, is more commonly used for characterization of the electromagnetic losses in materials.

Reflection of an electromagnetic wave from the interface between two media depends on the media indices of refraction and on the angle of incidence. It is characterized by the reflectivity, which is equal to the ratio of the intensity of the wave reflected back into the first medium to the intensity of the wave approaching the interface. For polarized light and two non-absorbing media,

$$R = \frac{(N_1 - N_2)^2}{(N_1 + N_2)^2},$$

where  $N_1 = n_1/\cos\theta_1$  and  $N_2 = n_2/\cos\theta_2$  for the wave polarized in the plane of incidence, and  $N_1 = n_1\cos\theta_1$  and  $N_2 = n_2\cos\theta_2$  for the wave polarized normal to the plane of incidence;  $\theta_1$  and  $\theta_2$  are the angles between the normal to the interface in the point of incidence and the directions of the beams in the first and second medium, respectively. The reflectivity at normal incidence in this case is

$$R = [(n_1 - n_2)/(n_1 + n_2)]^2$$

For any two opaque (absorbing) media, the normal incidence reflectivity is

$$R = \frac{(n_1 - n_2)^2 + k_2^2}{(n_1 + n_2)^2 + k_2^2}.$$

In the majority of experiments, the first medium is air ( $n \approx 1$ ), and hence,

$$R = \frac{(1 - n)^2 + k^2}{(1 + n)^2 + k^2}.$$

The data on  $n$  and  $k$  in the following table are abridged from the sources listed in the references. The reflectivity at normal incidence,  $R$ , has been calculated from the last equation. For convenience, the energy  $E$ , wavenumber  $\bar{\nu}$ , and wavelength  $\lambda$  are given for the incidence radiation.

$E/eV$	$\bar{\nu}/\text{cm}^{-1}$	$\lambda/\mu\text{m}$	$n$	$n_a$	$n_c$	$k$	$k_a$	$k_c$	$R$	$R_a$	$R_c$

# FERMI ENERGY AND RELATED PROPERTIES OF METALS

## Lev. I. Berger

In the classical Drude theory of metals, the Maxwell-Boltzmann velocity distribution of electrons is used. It states that the number of electrons per unit volume with velocities in the range of  $d\vec{v}$  about any magnitude  $\vec{v}$  at temperature  $T$  is

$$f_B(\vec{v})d\vec{v} = n \left( \frac{m}{2\pi k_B T} \right)^3 \exp\left( -\frac{mv^2}{2k_B T} \right) d\vec{v}$$

where  $n$  is the total number of conduction electrons in a unit volume of a metal,  $m$  is the free electron mass, and  $k_B$  is the Boltzmann constant. In an attempt to explain a substantial discrepancy between the experimental data on the specific heat of metals and the values calculated on the basis of the Drude model, Sommerfeld suggested a model of the metal in which the Pauli exclusion principle is applied to free electrons. In this case, the Maxwell-Boltzmann distribution is replaced by the Fermi-Dirac distribution:

$$f(\vec{v})d\vec{v} = 2 \left( \frac{m}{h} \right)^3 d\vec{v} \left\{ \exp\left[ \left( \frac{mv^2}{2} - k_B T_0 \right) / k_B T \right] + 1 \right\}^{-1}$$

Here  $h$  is the Planck constant and  $T_0$  is a characteristic temperature which is determined by the normalization condition

$$n = \int d\vec{v} \cdot f(\vec{v})$$

The magnitude of  $T_0$  is quite high; usually,  $T_0 > 10^4$  K. So, at common temperatures ( $T < 10^3$  K), the free electron density of a metal is much smaller than in the case of the Maxwell-Boltzmann distribution. This allows us to explain why the experimental data on specific heat for metals are close to those for insulators.

The maximum kinetic energy the electrons of a metal may possess at  $T = 0$  K is called the Fermi energy, e.g.,

$$E_F = \frac{\hbar^2 k_F^2}{2m} = \left( \frac{e^2}{2k_B} \right) (k_F r_B)^2$$

where  $k_F$  is the Fermi momentum or the Fermi wave vector

$$k_F = (3\pi^2 n)^{1/3}$$

$e$  is the electron charge, and  $r_B$  is the Bohr radius

$$r_B = \hbar^2 / m e^2 = 0.529 \cdot 10^{-10} \text{ m}$$

Another, more common expression for the Fermi energy is

$$E_F = \frac{1}{2} m v_F^2$$

where  $v_F = \hbar k_F / m$  is the Fermi velocity which can be expressed using the concept of the electron radius,  $r_s$ . It is equal to radius of a sphere occupied by one free electron. If the total volume of a metal sample is  $V$  and the number of conduction electrons in this volume is  $N$ , then the volume per electron is equal to

$$\frac{V}{N} = \frac{1}{n} = \frac{4}{3} \pi r_s^3$$

and

$$r_s = \left( \frac{3}{4\pi n} \right)^{1/3}$$

The following table contains information pertinent to the Sommerfeld model for some metals. The magnitudes of  $T_0$  are calculated using the expression

$$T_0 = \frac{E_F}{k_B} = \frac{58.2 \cdot 10^4}{(r_s / r_B)^2} \text{ K}$$

# ELECTRON INELASTIC MEAN FREE PATHS

Cedric J. Powell

The inelastic mean free path (IMFP) of electrons is defined as the average of distances, measured along the trajectories, that electrons with a given energy travel between inelastic collisions in the substance. It is an important parameter in analyzing results from surface-characterization techniques such as Auger electron spectroscopy, x-ray photoelectron spectroscopy, low-energy electron diffraction, and others. IMFPs can be measured by the elastic-peak electron spectroscopy technique and other methods, and they can be calculated from optical data. A detailed analysis of the experimental and theoretical considerations in obtaining reliable IMFP values can be found in reference 4.

The table below gives recommended IMFP values for several elements, simple inorganic compounds, and organic materials. Values are given in Ångström units ( $1 \text{ \AA} = 10^{-10} \text{ m}$ ) for a range of

electron energies. Substances are given in alphabetical order by name, with elements and inorganic compounds listed before the organic materials.

## PHASE TRANSITIONS IN THE SOLID ELEMENTS AT ATMOSPHERIC PRESSURE

This table gives the phase transition temperatures for the elements that can exist in two or more crystalline forms (allotropes). The crystal phases are labeled by Greek letters in the most common conventions, although some variation is found. All data refer to normal atmospheric pressure.

## THERMOPHYSICAL PROPERTIES OF STAINLESS STEEL 310

Stainless steel is used in a wide variety of applications, especially at high temperatures. This table gives properties of a reference standard Stainless Steel 310 certified by the U. K. National Physical Laboratory. The properties are:

- $a$ : thermal diffusivity in  $\text{mm}^2 \text{s}^{-1}$
- $c_p$ : specific heat capacity at constant pressure in  $\text{J g}^{-1} \text{K}^{-1}$
- $\rho$ : density in  $\text{g cm}^{-3}$
- $k$ : thermal conductivity in  $\text{W m}^{-1} \text{K}^{-1}$

With kind permission from Springer Science+Business Media: International Journal of Thermophysics, 28, 674, 2007, Table II.

# THERMOELECTRIC PROPERTIES OF METALS AND SEMICONDUCTORS

L. I. Berger

There are three thermoelectric phenomena that result from correlation between propagation of heat through a conductor and displacement of the current carriers in the conductor. The Seebeck effect (Ref. 1) consists of formation of an electric current in an electrical circuit formed by two dissimilar conductors if the contacts between the conductors are held at different temperatures. A reverse phenomenon, the Peltier effect (Ref. 2), consists of formation of a temperature difference between the contacts in a circuit of this type if an electric current is created in the circuit by an external current source to which the circuit is connected. W. Thomson (Lord Kelvin), who explained both effects (Refs. 3,4), predicted and experimentally confirmed the existence of another thermoelectric phenomenon, named the Thomson effect, which consists of absorption or release of heat in a uniform conductor with a current passing through it when a temperature gradient (positive or negative) is present along the current direction.

The electromotive force,  $\Delta U$ , which creates the Seebeck current in the circuit, is the algebraic sum of the emf's created in each of the conductors, and is proportional to the temperature difference,  $\Delta T$ , between the electrical contact points:  $\Delta U = \Delta U_1 + \Delta U_2 = \alpha_1 \Delta T + \alpha_2 \Delta T$ . The coefficient of proportionality,  $\alpha$ , called the Seebeck coefficient or thermoelectric power or thermal electromotive force (thermal emf), of each of the two materials depends on the electrical properties and temperature of the material. The Peltier effect is measured by the amount of heat,  $\Delta Q$ , released or absorbed in a unit of time (in addition to the Joule heat) at a contact of two dissimilar conductors with electric current  $\Delta I$  passing through the contact:  $\Delta Q = \Pi \Delta I$ . Thomson showed that  $\Pi = \alpha T$ . The Thomson effect's heat,  $dQ$ , released or absorbed in a unit of time along a part of a conductor of length  $dx$  is proportional to the current magnitude  $I$ , the temperature gradient along the conductor  $\partial T/\partial x$ , and the increment  $dx$ :  $dQ = \tau I (\partial T/\partial x) dx$ . Thomson showed that the magnitude of the coefficient of proportionality,  $\tau$ , later named the Thomson coefficient, depends on only the properties of the conductor and the ambient temperature and correlates with the other thermoelectric parameters of a material through the equation  $\tau = T(\partial\alpha/\partial T)$ .

Another thermoelectric phenomenon, called the Bridgman effect or the internal Peltier effect (Ref. 5), occurs when an electric current passes through an anisotropic crystal, resulting in absorption or liberation of heat because of non-uniformity in current distribution.

In view of the correlations between  $\alpha$ ,  $\Pi$ , and  $\tau$ , we need only to present data for one of these parameters, namely, thermal emf  $\alpha$

and its dependence on temperature. These values are presented below, first for metals and then for semiconductors. In accordance with modern theory of solids, thermal emf in semiconductors is up to three or even four orders of magnitude higher than that in metals (Ref. 9).

# NOMENCLATURE FOR ORGANIC POLYMERS

Robert B. Fox and Edward S. Wilks

Organic polymers have traditionally been named on the basis of the monomer used, a hypothetical monomer, or a semi-systematic structure. Alternatively, they may be named in the same way as organic compounds, i.e., on the basis of a structure as drawn. The former method, often called “source-based nomenclature” or “monomer-based nomenclature”, sometimes results in ambiguity and multiple names for a single material. The latter method, termed “structure-based nomenclature”, generates a sometimes cumbersome unique name for a given polymer, independent of its source. Within their limitations, both types of names are acceptable and well-documented.<sup>1</sup> The use of stereochemical descriptors with both types of polymer nomenclature has been published.<sup>2</sup>

## Traditional Polymer Names

### Monomer-Based Names

“Polystyrene” is the name of a homopolymer made from the single monomer styrene. When the name of a monomer comprises two or more words, the name should be enclosed in parentheses, as in “poly(methyl methacrylate)” or “poly(4-bromostyrene)” to identify the monomer more clearly. This method can result in several names for a given polymer: thus, “poly(ethylene glycol)”, “poly(ethylene oxide)”, and “poly(oxirane)” describe the same polymer. Sometimes, the name of a hypothetical monomer is used, as in “poly(vinyl alcohol)”. Even though a name like “polyethylene” covers a multitude of materials, the system does provide understandable names when a single monomer is involved in the synthesis of a single polymer. When one monomer can yield more than one polymer, e.g. 1,3-butadiene or acrolein, some sort of structural notation must be used to identify the product, and one is not far from a formal structure-based name.

*Copolymers, Block Polymers, and Graft Polymers.* When more than one monomer is involved, monomer-based names are more complex. Some common polymers have been given names based on an apparent structure, as with “poly(ethylene terephthalate)”. A better system has been approved by the IUPAC.<sup>1</sup> With this method, the arrangement of the monomeric units is introduced through use of an italicized connective placed between the names of the monomers. For monomer names represented by A, B, and C, the various types of arrangements are shown in Table 1.

Table 2 contains examples of common or semi-systematic names of copolymers. The systematic names of comonomers may also be used; thus, the polyacrylonitrile-*block*-polybutadiene-*block*-polystyrene polymer in Table 2 may also be named poly(prop-2-enenitrile)-*block*-polybuta-1,3-diene-*block*-poly(ethenylbenzene). IUPAC does not require alphabetized names of comonomers within a polymer name; many names are thus possible for some copolymers.

These connectives may be used in combination and with small, non-repeating (i.e. non-polymeric) junction units; see, for example, Table 2, line 8. A long dash may be used in place of the con-

nective *-block-*; thus, in Table 2, the polymers of lines 7 and 8 may also be written as shown on lines 9 and 10.

IUPAC also recommends an alternative scheme for naming copolymers that comprises use of “copoly” as a prefix followed by the names of the comonomers, a solidus (an oblique stroke) to separate comonomer names, and addition before “copoly” of any applicable connectives listed in Table 2 except *-co-*.

Table 3 gives the same examples shown in Table 2 but with the alternative format. Comonomer names need not be parenthesized.

TABLE 1. IUPAC Source-Based Copolymer Classification

No.	Copolymer type	Connective	Example
1	Unspecified or unknown	<i>-co-</i>	poly(A- <i>co</i> -B)
2	Random (obeys Bernoullian distribution)	<i>-ran-</i>	poly(A- <i>ran</i> -B)
3	Statistical (obeys known statistical laws)	<i>-stat-</i>	poly(A- <i>stat</i> -B)
4	Alternating (for two monomeric units)	<i>-alt-</i>	poly(A- <i>alt</i> -B)
5	Periodic (ordered sequence for 2 or more monomeric units)	<i>-per-</i>	poly(A- <i>per</i> -B- <i>per</i> -C)
6	Block (linear block arrangement)	<i>-block-</i>	polyA- <i>block</i> -polyB
7	Graft (side chains connected to main chains)	<i>-graft-</i>	polyA- <i>graft</i> -polyB

TABLE 2. Examples of Source-Based Copolymer Nomenclature

No.	Copolymer name
1	poly(propene- <i>co</i> -methacrylonitrile)
2	poly[(acrylic acid)- <i>ran</i> -(ethyl acrylate)]
3	poly(butene- <i>stat</i> -ethylene- <i>stat</i> -styrene)
4	poly[(sebacic acid)- <i>alt</i> -butanediol]
5	poly[(ethylene oxide)- <i>per</i> -(ethylene oxide)- <i>per</i> -tetrahydrofuran]
6	polyisoprene- <i>graft</i> -poly(methacrylic acid)
7	polyacrylonitrile- <i>block</i> -polybutadiene- <i>block</i> -polystyrene
8	polystyrene- <i>block</i> -dimethylsilylene- <i>block</i> -polybutadiene
9	polyacrylonitrile—polybutadiene—polystyrene
10	polystyrene—dimethylsilylene—polybutadiene

TABLE 3. Examples of Source-Based Copolymer Nomenclature (Alternative Format)

No.	Polymer name
1	copoly(propene/methacrylonitrile)
2	<i>ran</i> -copoly(acrylic acid/ethyl acrylate)
3	<i>stat</i> -copoly(butene/ethylene/styrene)
4	<i>alt</i> -copoly(sebacic acid/butanediol)
5	<i>block</i> -copoly(acrylonitrile/butadiene/styrene)
6	<i>per</i> -copoly(ethylene oxide/ethylene oxide/tetrahydrofuran)
7	<i>graft</i> -copoly(isoprene/methacrylic acid)

Source-based nomenclature for non-linear macromolecules and macromolecular assemblies is covered by a 1997 IUPAC document.<sup>11</sup> The types of polymers in these classes, together with their connectives, are given in Table 4; the terms shown may be used as connectives, prefixes, or both to designate the features present.

**TABLE 4. Connectives for Non-Linear Macromolecules and Macromolecular Assemblies**

No.	Type	Connective
1	Branched (type unspecified)	branch
2	Branched with branch point of functionality <i>f</i>	<i>f</i> -branch
3	Comb	comb
4	Cross-link	<i>ι</i> (Greek iota)
5	Cyclic	cyclo
6	Interpenetrating polymer network	ipn
7	Long-chain branched	l-branch
8	Network	net
9	Polymer blend	blend
10	Polymer-polymer complex	compl
11	Semi-interpenetrating polymer network	sipn
12	Short-chain branched	sh-branch
13	Star	star
14	Star with <i>f</i> arms	<i>f</i> -star

Non-linear polymers are named by using the italicized connective as a *prefix* to the source-based name of the polymer component or components to which the prefix applies; some examples are listed in Table 5.

**TABLE 5. Non-Linear Macromolecules**

No.	Polymer name	Polymer structural features
1	poly(methacrylic acid)- <i>comb</i> -polyacrylonitrile	Comb polymer with a poly(methacrylic acid) backbone and polyacrylonitrile side chains
2	<i>comb</i> -poly[ethylene- <i>stat</i> -(vinyl chloride)]	Comb polymer with unspecified backbone composition and statistical ethylene/vinyl chloride copolymer side chains
3	polybutadiene- <i>comb</i> -(polyethylene; polypropene)	Comb polymer with butadiene backbone and side chains of polyethylene and polypropene
4	<i>star</i> -(polyA; polyB; polyC; polyD; polyE)	Star polymer with arms derived from monomers A, B, C, D, and E, respectively
5	<i>star</i> -(polyA- <i>block</i> -polyB- <i>block</i> -polyC)	Star polymer with every arm comprising a tri-block segment derived from comonomers A, B, and C
6	<i>star</i> -poly(propylene oxide)	A star polymer prepared from propylene oxide
7	5- <i>star</i> -poly(propylene oxide)	A 5-arm star polymer prepared from propylene oxide
8	<i>star</i> -(polyacrylonitrile; polypropylene) ( $M_r$ 10000: 25000)	A star polymer containing polyacrylonitrile arms of MW 10000 and polypropylene arms of MW 25000

Macromolecular assemblies held together by forces other than covalent bonds are named by inserting the appropriate italicized connective between names of individual components; Table 6 gives examples.

**TABLE 6. Examples of Polymer Blends and Nets**

No.	Polymer name
1	polyethylene- <i>blend</i> -polypropene
2	poly(methacrylic acid)- <i>blend</i> -poly(ethyl acrylate)
3	<i>net</i> -poly(4-methylstyrene- <i>t</i> -divinylbenzene)
4	<i>net</i> -poly[styrene- <i>alt</i> -(maleic anhydride)]- <i>t</i> -(polyethylene glycol; polypropylene glycol)
5	<i>net</i> -poly(ethyl methacrylate)- <i>sipn</i> -polyethylene
6	[ <i>net</i> -poly(butadiene- <i>stat</i> -styrene)]- <i>ipn</i> -[ <i>net</i> -poly(4-methylstyrene- <i>t</i> -divinylbenzene)]

## Structure-Based Polymer Nomenclature

### Regular Single-Strand Polymers

Structure-based nomenclature has been approved by the IUPAC<sup>4</sup> and is currently being updated; it is used by *Chemical Abstracts*.<sup>5</sup> Monomer names are not used. To the extent that a polymer chain can be described by a repeating unit in the chain, it can be named “poly(repeating unit)”. For regular single-strand polymers, “repeating unit” is a bivalent group; for regular double-strand (ladder and spiro) polymers, “repeating unit” is usually a tetravalent group.<sup>9</sup>

Since there are usually many possible repeating units in a given chain, it is necessary to select one, called the “constitutional repeating unit” (CRU) to provide a unique and unambiguous name, “poly(CRU)”, where “CRU” is a recitation of the names of successive units as one proceeds through the CRU from left to right. For this purpose, a portion of the main chain structure that includes at least two repeating sequences is written out. These sequences will typically be composed of bivalent subunits such as  $-\text{CH}_2-$ ,  $-\text{O}-$ , and groups from ring systems, each of which can be named by the usual nomenclature rules.<sup>6,7</sup>

Where a chain is simply one long sequence comprising repetition of a single subunit, that subunit is itself the CRU, as in “poly(methylene)” or “poly(1,4-phenylene)”. In chains having more than one kind of subunit, a seniority system is used to determine the beginning of the CRU and the direction in which to move along the main chain atoms (following the shortest path in rings) to complete the CRU. Determination of the first, most senior, subunit, is based on a descending order of seniority: (1) heterocyclic rings, (2) hetero atoms, (3) carbocyclic rings, and, lowest, (4) acyclic carbon chains.

Within each of these classes, there is a further order of seniority that follows the usual rules of nomenclature.

**Heterocycles:** A nitrogen-containing ring system is senior to a ring system not containing nitrogen.<sup>4,9</sup> Further descending order of seniority is determined by:

- (i) the highest number of rings in the ring system
- (ii) the largest individual ring in the ring system
- (iii) the largest number of hetero atoms
- (iv) the greatest variety of hetero atoms

**Hetero atoms:** The senior bivalent subunit is the one nearest the top, right-hand corner of the Periodic Table; the order of seniority is: O, S, Se, Te, N, P, As, Sb, Bi, Si, Ge, Sn, Pb, B, Hg.

**Carbocycles:** Seniority<sup>4</sup> is determined by:

- (i) the highest number of rings in the ring system
- (ii) the largest individual ring in the ring system
- (iii) degree of ring saturation; an unsaturated ring is senior to a saturated ring of the same size

**Carbon chains:** Descending order of seniority is determined by:

- (i) chain length (longer is senior to shorter)
- (ii) highest degree of unsaturation
- (iii) number of substituents (higher number is senior to lower number)
- (iv) ascending order of locants
- (v) alphabetical order of names of substituent groups

Among equivalent ring systems, preference is given to the one having lowest locants for the free valences in the subunit, and among otherwise identical ring systems, the one having least hydrogenation is senior. Lowest locants in unsaturated chains are also given preference. Lowest locants for substituents are the final determinant of seniority.

Direction within the repeating unit depends upon the shortest path, which is determined by counting main chain atoms, both cyclic and acyclic, from the most senior subunit to another subunit of the same kind or to a subunit next lower in seniority. When identification and orientation of the CRU have been accomplished, the CRU is named by writing, in sequence, the names of the largest possible subunits within the CRU from left to right. For example, the main chain of the polymer traditionally named “poly(ethylene terephthalate)” has the structure shown in Figure 1.

**Figure 1.** Structure-based name: poly(oxyethyleneoxyterephthaloyl); traditional name: poly(ethylene terephthalate).

The CRU in Figure 1 is enclosed in brackets and read from left to right. It is selected because (1) either backbone oxygen atom qualifies as the “most senior subunit”, (2) the shortest path length from either -O- to the other -O- is via the ethylene subunit. Orientation of the CRU is thus defined by (1) beginning at the -O- marked with an asterisk, and (2) reading in the direction of the arrow. The structure-based name of this polymer is therefore “poly(oxyethyleneoxyterephthaloyl)”, not much longer than the traditional name and much more adaptable to the complexities of substitution. As organic nomenclature evolves, more systematic names may be used for subunits, e.g. “ethane-1,2-diyl” instead of “ethylene”. IUPAC still prefers “ethylene” for the -CH<sub>2</sub>-CH<sub>2</sub>- unit, however, but also accepts “ethane-1,2-diyl”.

Structure-based nomenclature can also be used when the CRU backbone has no carbon atoms. An example is the polymer traditionally named “poly(dimethylsiloxane)”, which on the basis of structure would be named “poly(oxydimethylsilylene)” or “poly(oxydimethylsilanediy)”. This nomenclature method has also been applied to inorganic and coordination polymers<sup>8</sup> and to double-strand (ladder and spiro) organic polymers.<sup>9</sup>

### Irregular Single-Strand Polymers

Polymers that cannot be described by the repetition of a single CRU or comprise units not all connected identically in a directional sense can also be named on a structure basis.<sup>10</sup> These include copolymers, block and graft polymers, and star polymers. They are given names of the type “poly(A/B/C...)”, where A, B, C, etc. are the names of the component constitutional units, the

number of which are minimized. The constitutional units may include regular or irregular blocks as well as atoms or atomic groupings, and each is named by the method described above or by the rules of organic nomenclature.

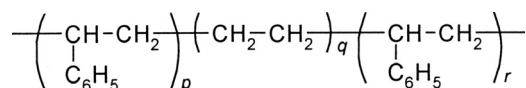

The solidus denotes an unspecified arrangement of the units within the main chain.<sup>10</sup> For example, a statistical copolymer derived from styrene and vinyl chloride with the monomeric units joined head-to-tail is named “poly(1-chloroethylene/1-phenylethylene)”. A polymer obtained by 1,4-polymerization and both head-to-head and head-to-tail 1,2-polymerization of 1,3-butadiene would be named “poly(but-1-ene-1,4-diyl/1-vinylethylene/2-vinylethylene)”.<sup>12</sup> In graphic representations of these polymers, shown in Figure 2, the hyphens or dashes at each end of each CRU depiction are shown *completely within* the enclosing parentheses; this indicates that they are not necessarily the terminal bonds of the macromolecule.

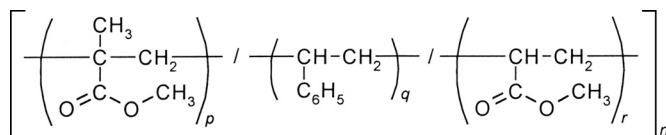

**Figure 2.** Graphic representations of copolymers.

A long hyphen is used to separate components in names of block polymers, as in “poly(A)—poly(B)—poly(C)”, or “poly(A)—X—poly(B)” in which X is a non-polymeric junction unit, e.g. dimethylsilylene.

In graphic representations of these polymers, the blocks are shown connected when the bonding is known (Figure 3, for example); when the bonding between the blocks is unknown, the blocks are separated by solidi and are shown *completely within* the outer set of enclosing parentheses (Figure 4, for example).<sup>10,13</sup>

**Figure 3.** polystyrene—polyethylene—polystyrene.

**Figure 4.** poly[poly(methyl methacrylate)—polystyrene—poly(methyl acrylate)].

Graft polymers are named in the same way as a substituted polymer but without the ending “yl” for the grafted chain; the name of a regular polymer, comprising Z units in which some have grafts of “poly(A)”, is “poly[Z/poly(A)Z]”. Star polymers are treated as a central unit with substituent blocks, as in “tet-rakis(polymethylene)silane”.<sup>10,13</sup>

### Other Nomenclature Articles and Publications

In addition to the *Chemical Abstracts* and IUPAC documents cited above and listed below, other articles on polymer nomenclature are available. A 1999 article lists significant documents on polymer nomenclature published during the last 50 years in books, encyclopedias, and journals by *Chemical Abstracts*,

IUPAC, and individual authors.<sup>14</sup> A comprehensive review of source-based and structure-based nomenclature for all of the major classes of polymers,<sup>15</sup> and a short tutorial on the correct identification, orientation, and naming of most commonly encountered constitutional repeating units were both published in 2000.<sup>16</sup>

12. Poly(1,3-butadiene) obtained by polymerization of 1,3-butadiene in the so-called 1,4- mode is frequently drawn incorrectly in publications as  $-(\text{CH}_2-\text{CH}=\text{CH}-\text{CH}_2)_n-$ ; the double bond should be assigned the lowest locant possible, i.e. the structure should be drawn as  $-(\text{CH}=\text{CH}-\text{CH}_2-\text{CH}_2)_n-$ .

## SOLVENTS FOR COMMON POLYMERS

Abbreviations:

HC: hydrocarbons  
MEK: methyl ethyl ketone

THF: tetrahydrofuran  
DMF: dimethylformamide  
DMSO: dimethylsulfoxide

Polyethylene (HDPE)	HC and halogenated HC
Polypropylene (atactic)	HC and halogenated HC
Polybutadiene	HC, THF, ketones
Polystyrene	ethylbenzene, CHCl <sub>3</sub> , CCl <sub>4</sub> , THF, MEK
Polyacrylates	aromatic HC, chlorinated HC, THF, esters, ketones
Polymethacrylates	aromatic HC, chlorinated HC, THF, esters, MEK
Polyacrylamide	water
Poly(vinyl ethers)	halogenated HC, MEK, butanol
Poly(vinyl alcohol)	glycols (hot), DMF
Poly(vinyl acetate)	aromatic HC, chlorinated HC, THF, esters, DMF
Poly(vinyl chloride)	THF, DME, DMSO
Poly(vinylidene chloride)	THF (hot), dioxane, DMF
Poly(vinyl fluoride)	DME, DMSO (hot)
Polyacrylonitrile	DME, DMSO
Poly(oxyethylene)	aromatic HC, CHCl <sub>3</sub> , alcohols, esters, DMF
Poly(2,6-dimethylphenylene oxide)	aromatic HC, halogenated HC
Poly(ethylene terephthalate)	phenol, DMSO (hot)
Polyurethanes (linear)	aromatic HC, THF, DMF
Polyureas	phenol, formic acid
Polysiloxanes	HC, THF, DMF
Poly[bis(2,2,2-trifluoroethoxy)-phosphazene]	THF, ketones, ethyl acetate

# GLASS TRANSITION TEMPERATURE FOR SELECTED POLYMERS

Robert B. Fox

Polymer names are based on the IUPAC structure-based nomenclature system described in the table "Naming Organic Polymers". Within each category, names are listed in alphabetical order. Source-based and trivial names are also given (in italics) for the most common polymers. The table does not include polymers for which  $T_g$  is not clearly defined because of variability of structure or because of reactions taking place near the glass transition.

All values of  $T_g$  cited in this table have been determined by differential scanning calorimetry (DSC) except those values indicated by:

(D) dynamic method  
(Dil) dilatometry  
(M) mechanical method

Polymer name	Glass transition temperature ( $T_g$ /K)
<b>ACYCLIC CARBON CHAINS</b>

## DIELECTRIC CONSTANT OF SELECTED POLYMERS

This table lists typical values of the dielectric constant (more properly called relative permittivity) of some important polymers. Values are given for frequencies of 1 kHz, 1 MHz, and 1 GHz; in most cases the dielectric constant at frequencies below 1 kHz does not differ significantly from the value at 1 kHz. Since the dielectric constant of a polymeric material can vary with density, degree of crystallinity, and other details of a particular sample, the values given here should be regarded as only typical or average values.

# PRESSURE-VOLUME-TEMPERATURE RELATIONSHIP FOR POLYMER MELTS

Christian Wohlfarth

Numerous theoretical equations of state for polymer liquids have been developed. These, at the minimum, have to provide accurate fitting functions to experimental data. However, for the purpose of this table, the empirical Tait equation along with a polynomial expression for the zero pressure isobar is used. This equation is able to represent the experimental data for the melt state within the limits of experimental errors, i.e., the maximum deviations between measured and calculated specific volumes are about 0.001-0.002 cm<sup>3</sup>/g.

The general form of the Tait equation is:

$$V(P,T) = V(0,T)\{1 - C \ln[1 + P/B(T)]\} \quad (1)$$

where the coefficient  $C$  is usually taken to be a universal constant equal to 0.0894.  $T$  is the absolute temperature in K and  $P$  the pressure in MPa. The volume  $V$  is the specific volume in cm<sup>3</sup>/g. The Tait parameter  $B(T)$  has the very simple meaning that it is inversely proportional to the compressibility  $\kappa$  at constant temperature and zero pressure:

$$\kappa(0,T) = -[1/V(0,T)](dV/dP) = C/B(T) \quad (2)$$

The  $B(T)$  function is usually given by:

$$B(T) = B_0 \exp[-B_1(T-273.15)] \quad (3)$$

but, sometimes a polynomial expression is used:

$$B(T) = b_0 + b_1(T-273.15) + b_2(T-273.15)^2 \quad (4)$$

The zero-pressure isobar  $V(0,T)$  is usually given by:

$$V(0,T) = A_0 + A_1(T-273.15) + A_2(T-273.15)^2 \quad (5)$$

where  $A_0, A_1, A_2$  are specific constants for a given polymer (the expression  $T-273.15$  is used because fitting to the zero-pressure isobar is usually done in terms of Celsius temperature). Other forms for  $V(0,T)$  are also found in the literature, such as

$$V(0,T) = A_3 \exp[A_4(T-273.15)] \quad (6)$$

or

$$V(0,T) = A_5 \exp(A_6 T^{1.5}) \quad (7)$$

where  $A_3$  and  $A_4$  or  $A_5$  and  $A_6$  are again specific constants for a given polymer.

The Tait equation is particularly useful to calculate derivative quantities, such as the isothermal compressibility and the thermal expansivity coefficients. The isothermal compressibility  $\kappa(P,T)$  is derived from equation (1) as:

$$\kappa(P,T) = -(1/V)(dV/dP) = 1/\{[P + B(T)][1/C - \ln(1 + P/B(T))]\} \quad (8)$$

and the thermal expansivity  $\alpha(P,T)$  as:

$$\alpha(P,T) = (1/V)(dV/dT) = \alpha(0,T) - PB_1\kappa(P,T) \quad (9)$$

where  $\alpha(0,T)$  represents the thermal expansivity at zero (atmospheric) pressure and is calculated from any suitable fit for the zero-pressure volume, such as equations (5) through (7) above.

Because polymer melt PVT-behavior depends only slightly on polymer molar mass above the oligomeric region, usually no information is given in the original literature for the average molar mass of the polymers.

Table 1 summarizes the polymers or copolymers considered here and the experimental ranges of pressure and temperature over which data are available. In Table 2 the Tait-equation functions, with parameters obtained from the fit, are given for 90 polymer or copolymer melts.

# UPPER CRITICAL (UCST) AND LOWER CRITICAL (LCST) SOLUTION TEMPERATURES OF BINARY POLYMER SOLUTIONS

Christian Wohlfarth

Liquid-liquid demixing in solutions of polymers in low molar mass solvents is not a rare phenomenon. Demixing depends on concentration, temperature, pressure, molar mass and molar mass distribution function of the polymer, chain branching and end groups of the polymer, the chemical nature of the solvent, isotope substitution in solvents or polymers, chemical composition of copolymers and its distributions, and other variables. Phase diagrams of polymer solutions can therefore show a quite complicated behavior when they have to be considered in detail (see Ref. 1a).

Polymer solutions can undergo demixing when cooling a homogeneous solution as well as when heating such a solution. The corresponding cloud-point curves show a maximum (UCST behavior) or a minimum (LCST behavior). For common polymer solutions, the LCST region is at higher temperatures (in many cases near the critical temperature of the solvent) than the UCST region. The temperature range between both extrema provides the essential information where the one-phase region of a polymer solution can be found. In the case of monodisperse polymers the extrema are equal to the critical points. However, in the case of polydisperse polymers with distribution functions, these extrema are threshold temperatures whereas the critical point shifts to higher concentrations on the shoulder of the cloud-point curve. Usually, the critical concentration is much more strongly influenced than the critical temperature. Thus, the table below does not distinguish between threshold and critical temperatures.

UCST and LCST values depend somewhat on pressure. LCST values in the table are usually given at the vapor pressure of the solvent at this temperature. UCST values are measured in most cases at normal pressure; data at higher pressures are neglected here. The interested reader can find such information, for example, in Refs. 76, 84, 104, 157, 165, 177, 185-187, or 192.

However, UCST and LCST values of a given polymer/solvent pair depend strongly on the molar mass of the polymer. In the case of monodisperse polymers, this dependency can be described in good approximation by the so-called Shultz-Flory plot (see Refs. 6 and 8):

$$\frac{1}{T_{\text{crit}}} = \frac{1}{\theta} \left[ 1 + \text{const.} \left( \frac{1}{\sqrt{r}} - \frac{1}{2r} \right) \right] \quad (1)$$

where  $r$  denotes the number of segments of a polymer (being proportional to the degree of polymerization or to the molar mass or molar volume of the polymer). Extrapolation to  $r \rightarrow \infty$ , i.e., to infinite molar mass, leads to the value of the  $\theta$ -temperature. This  $\theta$ -temperature is the highest temperature for UCST behavior or the lowest temperature for LCST behavior and a given polymer/solvent pair. In the case of polydisperse polymers, the segment number in equation (1) is to be replaced by its weight average,  $r_w$  (related to  $M_w$ ). The constant in equation (1) reflects further thermodynamic properties of the given polymer/solvent pair, but should not depend on molar mass. A detailed discussion can be found in Ref. 1b.

The printed table in the *Handbook* provides only one data line for a given polymer/solvent pair and does not show the molar mass dependence of UCST or LCST data. The entire table with all data at different molar masses for many of the systems is given in the electronic version, however. Nevertheless, the necessary molar mass information for a system is always provided in the table by the corresponding number average,  $M_n$ , mass average,  $M_w$ , or viscosity average,  $M_\eta$ , values of the polymer as given in the original sources.

Polymer	$M_n/\text{g mol}^{-1}$	$M_w/\text{g mol}^{-1}$	$M_\eta/\text{g mol}^{-1}$	Solvent	UCST/K	LCST/K	Ref
Acrylonitrile/butadiene copolymer							
(18% Acrylonitrile)			840000	Ethyl acetate		427	220
(26% Acrylonitrile)			1000000	Ethyl acetate		412	220
Butadiene/ $\alpha$ -methylstyrene copolymer							
(10% $\alpha$ -Methylstyrene)			100000	Ethyl acetate	387	393	220
Carbon monoxide/ethylene copolymer							
(1:1, alternating)		1000000		1,1,1,3,3,3-Hexafluoro-2-propanol		453	159
Cellulose diacetate			120000	Benzyl alcohol	372		86
	59900	75500		2-Butanone	279.7	471.5	111
	59300			2-Propanone	216.2	438.2	42
Cellulose diacetate/styrene graft copolymer							
(77.4 wt% grafted polystyrene)		750000		<i>N,N</i> -Dimethylformamide	262	399	106
		750000		Tetrahydrofuran		363	106
Cellulose nitrate (13.3 wt% N)							
	unknown			2-Propanone	328	182	148

Polymer	$M_n/g\ mol^{-1}$	$M_w/g\ mol^{-1}$	$M_\eta/g\ mol^{-1}$	Solvent	UCST/K	LCST/K	Ref
Cellulose triacetate			20000	Benzyl alcohol	322		86

# VAPOR PRESSURES (SOLVENT ACTIVITIES) FOR BINARY POLYMER SOLUTIONS

Christian Wohlfarth

The vapor pressure of a binary polymer solution is given by the activity of the solvent A,  $a_A$ . Solvent activities in polymer solutions are measured either by the isopiestic method applying a reference system whose solvent activity is precisely known or by determining the solvent partial pressure,  $P_A$ , and calculating the activity of the solvent by equation (1):

$$a_A = (P_A/P_A^s) \exp \left[ \frac{(B_{AA} - V_A^L)(P - P_A^s)}{RT} \right] \quad (1)$$

where  $B_{AA}$  is the second virial coefficient,  $P_A^s$  is the saturation vapor pressure, and  $V_A^L$  is the molar volume of the pure solvent A at the measuring temperature  $T$ . The exponential term is neglected in quite a lot of original papers, however, and only the reduced vapor pressures are given (such data are indicated by an asterisk in the table below). Vapor pressures of polymer solutions have been measured since the 1940s, but the amount of experimental data for polymer solutions is still relatively small in comparison to low-molecular mixtures and solutions. The data scatter with respect to temperature, concentration, molar mass, and other polymer characterization variables. Furthermore, the concentration range for measuring vapor pressures in good thermodynamic quality is often limited to the polymer mass fraction range between 0.4 and 0.85. A recent review on methods for the measurement of vapor pressures/solvent activities of polymer solutions and on related problems is given in Ref. [1]. Experimental data have been collected in several books [2-6].

The table in this *Handbook* provides data for a number of polymer solutions as smoothed values over the complete range of solvent activities between 0 (polymer mass fraction = 1) and 1 (polymer mass fraction = 0). For this purpose, the data were selected from data books [4-6] as well as from a number of original sources [7-22] which are not included in these books. The appropriate data were smoothed. The final table provides then the polymer mass fractions at given fixed solvent activities between 0.1 and 0.9. Of course, the user must keep in mind that the activity vs. concentration range of the experimental data is sometimes smaller than the below given complete range, thus the smoothed data should be used with sufficient care.

Generally, vapor pressures or solvent activities of binary polymer solutions depend on molar mass. However, for high molecular weight polymers (well above the oligomer region), this molar-mass dependence can be neglected in many cases. Therefore, the table below presents only data for polymer solutions where the number average molar mass,  $M_n$ , is in the order of  $10^5$  g/mol or even higher, therefore, the molar mass is not specified. The temperature is

stated, even though the temperature dependence of  $a_A$  is relatively small for the temperature ranges where most of the experimental data exist.

# SPECIFIC ENTHALPIES OF SOLUTION OF POLYMERS AND COPOLYMERS

Christian Wohlfarth

Enthalpies of solution or mixing, expressed as the enthalpy change per unit mass of polymer, are given in the table at infinite dilution, i.e., a very small amount of polymer and a large excess of solvent were mixed isothermally to form a homogeneous solution. By thermodynamics,  $\Delta_{\text{sol}}H_{\text{B}}^{\infty}$  or  $\Delta_{\text{M}}H_{\text{B}}^{\infty}$  are obtained from the following derivatives:

$$\Delta_{\text{sol}}H_{\text{B}}^{\infty} = \lim_{m_{\text{B}} \rightarrow 0} (\partial \Delta_{\text{sol}}h / \partial m_{\text{B}})_{P,T,m_{j \neq \text{B}}} \quad (1)$$

$$\Delta_{\text{M}}H_{\text{B}}^{\infty} = \lim_{m_{\text{B}} \rightarrow 0} (\partial \Delta_{\text{M}}h / \partial m_{\text{B}})_{P,T,m_{j \neq \text{B}}} \quad (2)$$

with a unit of J/g. Thus, they are the partial specific enthalpies of solution or mixing of the polymer B at infinite dilution where  $\Delta_{\text{sol}}h$  or  $\Delta_{\text{M}}h$  is the extensive enthalpy of the solution or mixing process.

The state of the polymer before dissolution can significantly affect the enthalpy of solution. The dissolving of a semicrystalline polymer requires an additional amount of heat associated with the disordering of crystalline regions. Consequently, its enthalpy of

solution is usually positive and depends on the degree of crystallinity of the given polymer sample. An amorphous polymer below its glass transition temperature,  $T_{\text{g}}$  (see the  $T_{\text{g}}$ -table of this Section), often dissolves with the release of heat. The enthalpy of solution of a glassy polymer is additionally dependent to some extent on the thermal history of the glass-forming process. An amorphous polymer above  $T_{\text{g}}$  can show endothermic or exothermic dissolution behavior depending on the nature of the solvent and the interaction energies involved as is the case for any enthalpy of mixing. This enthalpy of mixing is then independent of any crystalline or glassy aspects of the polymer. It can be obtained without difficulties for liquid/molten polymers mixed with a solvent. Therefore, the enthalpies given in the table are either enthalpies of solution or enthalpies of mixing, depending on the state of the polymer.

The enthalpies depend on temperature and molar mass. The necessary molar mass information for a system is provided in the table (if available) by the corresponding number average,  $M_{\text{n}}$ , mass average,  $M_{\text{w}}$ , or viscosity average,  $M_{\text{\eta}}$ , values of the polymer as given in the original sources. Outside the oligomer range, specific enthalpies of solution or mixing do not remarkably depend on molar mass, however. More enthalpy data of polymer-solvent systems can be found in Ref. 106.

# SOLUBILITY PARAMETERS OF SELECTED POLYMERS

Christian Wohlfarth

The concept of cohesive energy density and solubility parameter was introduced by Hildebrand:

$$\delta^2 = \frac{\Delta U_m^{LV}}{V_m} = \frac{\Delta H_m^{LV} - RT}{V_m} \quad (1)$$

$V_m$  is the molar volume,  $\Delta U_m^{LV}$  is the molar energy of vaporization, and  $\Delta H_m^{LV}$  is the molar enthalpy of vaporization. Units for the solubility parameter are  $(\text{MPa})^{1/2} = (\text{J}/\text{cm}^3)^{1/2} = 0.4887(\text{cal}/\text{cm}^3)^{1/2}$ . The energy of vaporization is not accessible for polymers, but cohesive energy density of polymers can be determined from *PVT*-data. However, common ways for determining polymer solubility parameters use thermodynamic properties of polymer solutions and their relations to excess enthalpy or excess Gibbs energy per unit volume. These excess quantities are related to the (square) difference between the solubility parameters of solvents and polymers, i.e.  $(\delta_1 - \delta_2)^2$ .

$$\frac{H^E}{V} \sim (\delta_1 - \delta_2)^2 \quad \text{or} \quad \frac{G^E}{V} \sim (\delta_1 - \delta_2)^2 \quad (2)$$

Often, the Flory-Huggins solvent-polymer interaction parameter is applied instead of  $H^E$  or  $G^E$ . There are some books (Refs. 1–3) giving details for such procedures as well as extensive tables of polymer solubility parameters from which the table below is extracted. Methods for calculating solubility parameters can be found in Refs. 4–7.

# ASTRONOMICAL CONSTANTS

Victor Abalakin

The constants in this table are based originally on the set of constants adopted by the International Astronomical Union (IAU) in 1976. Updates have been made when new data were available. All values are given in SI Units; thus masses are expressed in kilograms and distances in meters.

The astronomical unit of time is a time interval of one day (1 d) equal to 86400 s. An interval of 36525 d is one Julian century (1 cy).

### Defining constants

Gaussian gravitational constant

$$k = 0.01720209895 \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$$

Speed of light

$$c = 299792458 \text{ m s}^{-1}$$

### Primary constants

Light-time for unit distance (1 ua)

$$\tau_A = 499.004786 \text{ s}$$

Equatorial radius of Earth

$$a_e = 6378140 \text{ m}$$

Equatorial radius of Earth (IUGG value)

$$a_e = 6378136 \text{ m}$$

Dynamical form-factor for Earth

$$J_2 = 0.001082636$$

Geocentric gravitational constant

$$GE = 3.986004 \times 10^{14} \text{ m}^3 \text{ s}^{-2}$$

Constant of gravitation

$$G = 6.67428 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$$

Ratio of mass of moon to that of Earth

$$\mu = 0.01230002$$

$$1/\mu = 81.300587$$

General precession in longitude, per Julian century, at standard epoch J2000

$$\rho = 5028''.796$$

Obliquity of the ecliptic at standard epoch J2000

$$\varepsilon = 23^\circ 26' 21''.448$$

### Derived constants

Constant of nutation at standard epoch J2000

$$N = 9''.2025$$

Unit distance ( $ua = c\tau_A$ )

$$ua = 1.49597871464 \times 10^{11} \text{ m}$$

Solar parallax ( $\pi_0 = \arcsin(a_e/ua)$ )

$$\pi_0 = 8''.794143$$

Constant of aberration for standard epoch J2000

$$\kappa = 20''.49552$$

Flattening factor for the Earth

$$f = 1/298.256 = 0.00335282$$

Heliocentric gravitational constant ( $GS = A^3 k^2 / D^2$ )

$$GS = 1.32712438 \times 10^{20} \text{ m}^3 \text{ s}^{-2}$$

Ratio of mass of sun to that of the Earth ( $S/E = (GS)/(GE)$ )

$$S/E = 332946.0$$

Ratio of mass of sun to that of Earth + moon

$$(S/E)/(1 + \mu) = 328900.56$$

Mass of the sun ( $S = (GS)/G$ )

$$S = 1.98844 \times 10^{30} \text{ kg}$$

### Ratios of mass of sun to masses of the planets

Mercury

$$6023600$$

Venus

$$408523.7$$

Earth + moon

$$328900.56$$

Mars

$$3098708$$

Jupiter

$$1047.349$$

Saturn

$$3497.898$$

Uranus

$$22902.98$$

Neptune

$$19412.24$$

## PROPERTIES OF THE SOLAR SYSTEM

The following tables give various properties of the planets and characteristics of their orbits in the solar system. Certain properties of the sun and of the earth's moon are also included.

Explanations of the column headings:

- *Mass*: mass of the planet in units of  $10^{24}$  kg
- *Radius*: radius at the equator in km
- *Density*: mean density in  $\text{g/cm}^3$
- *Flattening*: degree of oblateness, defined as  $(r_e - r_p) / r_e$ , where  $r_e$  and  $r_p$  are the equatorial and polar radii, respectively
- *Potential coefficients*: coefficients in the spherical harmonic representation of the gravitational potential  $U$  by the equation

$$U(r, \phi) = (GM/r) [1 - \sum_n (a/r)^n P_n(\sin \phi)],$$

where  $G$  is the gravitational constant,  $r$  the distance from the center of the planet,  $a$  the radius of the planet,  $M$  the mass,  $\phi$  the latitude, and  $P_n$  the Legendre polynomial of degree  $n$ .

- *Gravity*: acceleration due to gravity at the surface
- *Escape vel.*: velocity needed at the surface of the planet to escape the gravitational pull
- *Dist. to sun*: semi-major axis of the elliptical orbit in astronomical units (1 ua  $\approx$   $1.496 \cdot 10^8$  km)
- $\epsilon$ : eccentricity of the orbit
- *Ecliptic angle*: angle between the planetary orbit and the plane of the earth's orbit around the sun
- *Inclin.*: angle between the equatorial plane of the planet and the plane of the planetary orbit
- *Orbit period*: period of revolution around the sun measured in years
- *Rotation period*: period of rotation of the planet measured in hours. A negative value indicates retrograde rotation.
- *Albedo*: ratio of the light reflected from the planet to the light incident on it
- *No. of satellites*: Number of confirmed satellites; this includes satellites that have not been named.
- $T_{\text{sur}}$ : mean temperature at the surface
- $P_{\text{sur}}$ : pressure of the atmosphere at the surface

The last four entries in the table are *dwarf planets* as defined by the International Astronomical Union. These are bodies in orbit around the sun that are massive enough to adopt a near-spherical shape as a result of their self-gravity, but are appreciably smaller than the major planets. *Plutoids* form a subset of the dwarf plan-

ets; their orbits are larger than that of Neptune (see Ref. 9). As of 2008, the IAU has recognized the names for three plutoids: Pluto, Eris, and Makemake.

The following general information on the solar system is of interest:

- Mass of the earth =  $M_e = 5.9736 \cdot 10^{24}$  kg
- Total mass of planetary system =  $2.669 \cdot 10^{27}$  kg =  $447 M_e$
- Total angular momentum of planetary system =  $3.148 \cdot 10^{43}$   $\text{kg m}^2 \text{s}^{-1}$
- Total kinetic energy of the planets =  $1.99 \cdot 10^{35}$  J
- Total rotational energy of planets =  $0.7 \cdot 10^{35}$  J

Properties of the sun:

- Mass =  $1.9884 \cdot 10^{30}$  kg =  $332943 M_e$
- Radius =  $6.9551 \cdot 10^8$  m
- Surface area =  $6.079 \cdot 10^{18}$   $\text{m}^2$
- Volume =  $1.409 \cdot 10^{27}$   $\text{m}^3$
- Mean density =  $1.411$   $\text{g/cm}^3$
- Gravity at surface =  $27398$   $\text{cm/s}^2$
- Escape velocity at surface =  $6.177 \cdot 10^5$  m/s
- Effective temperature =  $5780$  K
- Total radiant power emitted (luminosity) =  $3.8427 \cdot 10^{26}$  W
- Surface flux of radiant energy =  $6.322 \cdot 10^7$   $\text{W/m}^2$
- Flux of radiant energy at the earth (Solar Constant) =  $1366.4$   $\text{W/m}^2$  (Ref. 8)

## SATELLITES OF THE PLANETS

This table gives characteristics of the known satellites of the planets. The parameters covered are:

- Orbital period in units of earth days. An R following the value indicates a retrograde motion.
- Distance from the planet, as measured by the semi-major axis of the orbit
- Eccentricity of the orbit
- Inclination of the satellite orbit with respect to the equator of the planet
- Mass of the satellite in kilograms
- Radius of the satellite in kilometers
- Geometric albedo, which is a measure of the fraction of incident sunlight reflected by the satellite.

Since this is a very active field of research, the Internet sites listed below should be consulted for the most recent data.

\* In June 2008 the International Astronomical Union decided on the name *plutoid* for the category of transneptunian dwarf planets. Plutoids are celestial bodies in orbit around the sun at a semimajor axis greater than that of Neptune and sufficiently massive to adopt a near-spherical shape. See <[www.iau.org/public\\_press/news/release/iau0804/](http://www.iau.org/public_press/news/release/iau0804/)>.

# MASS, DIMENSIONS, AND OTHER PARAMETERS OF THE EARTH

This table is a collection of data on various properties of the Earth. Most of the values are given in SI units. Note that 1 ua (astronomical unit) = 149,597,870 km.

Quantity	Symbol	Value	Unit
Mass	$M$	$5.9723 \cdot 10^{27}$	g
Major orbital semi-axis	$a_{orb}$	1.000000	ua
		$1.4959787 \cdot 10^8$	km
Distance from sun at perihelion	$r_{\pi}$	0.9833	ua
Distance from sun at aphelion	$r_{\alpha}$	1.0167	ua
Moment of perihelion passage	$T_{\pi}$	Jan. 2, 4 h 52 min	
Moment of aphelion passage	$T_{\alpha}$	July 4, 5 h 05 min	
Siderial rotation period around sun	$P_{orb}$	$31.5581 \cdot 10^6$	s
		365.25636	d
Mean rotational velocity	$U_{orb}$	29.78	km/s
Mean equatorial radius	$\bar{a}$	6378.140	km
Mean polar compression (flattening factor)	$\alpha$	$1/298.257$	
Difference in equatorial and polar semi-axes	$a - c$	21.385	km
Compression of meridian of major equatorial axis	$\alpha_a$	$1/295.2$	
Compression of meridian of minor equatorial axis	$\alpha_b$	$1/298.0$	
Equatorial compression	$\epsilon$	$1/30\,000$	
Difference in equatorial semi-axes	$a - b$	213	m
Difference in polar semi-axes	$c_N - c_S$	$\sim 70$	m
Polar asymmetry	$\eta$	$\sim 1 \cdot 10^{-5}$	
Mean acceleration of gravity at equator	$g_e$	9.78036	m/s <sup>2</sup>
Mean acceleration of gravity at poles	$g_p$	9.83208	m/s <sup>2</sup>
Difference in acceleration of gravity at pole and at equator	$g_p - g_e$	5.172	cm/s <sup>2</sup>
Mean acceleration of gravity for entire surface of terrestrial ellipsoid	$g$	9.7978	m/s <sup>2</sup>
Mean radius	$R$	6371.0	km
Area of surface	$S$	$5.10 \cdot 10^8$	km <sup>2</sup>
Volume	$V$	$1.0832 \cdot 10^{12}$	km <sup>3</sup>
Mean density	$\rho$	5.515	g/cm <sup>3</sup>
Siderial rotational period	$P$	86,164.09	s
Rotational angular velocity	$\omega$	$7.292116 \cdot 10^{-5}$	rad/s
Mean equatorial rotational velocity	$v$	0.46512	km/s
Rotational angular momentum	$L$	$5.861 \cdot 10^{33}$	J s
Rotational energy	$E$	$2.137 \cdot 10^{29}$	J
Ratio of centrifugal force to force of gravity at equator	$q_c$	$0.0034677 = 1/288$	
Moment of inertia	$I$	$8.070 \cdot 10^{37}$	kg m <sup>2</sup>
Relative braking of earth's rotation due to tidal friction	$\Delta\omega_e/\omega$	$-4.2 \cdot 10^{-8}$	century <sup>-1</sup>
Relative secular acceleration of earth's rotation	$\Delta\omega_l/\omega$	$+1.4 \cdot 10^{-8}$	century <sup>-1</sup>
Not secular braking of earth's rotation	$\Delta\omega/\omega$	$-2.8 \cdot 10^{-8}$	century <sup>-1</sup>
Probable value of total energy of tectonic deformation of earth	$E_t$	$\sim 1 \cdot 10^{23}$	J/century
Secular loss of heat of earth through radiation into space	$\Delta E_k$	$1 \cdot 10^{23}$	J/century
Portion of earth's kinetic energy transformed into heat as a result of lunar and solar tides in the hydrosphere	$\Delta''E_k$	$1.3 \cdot 10^{23}$	J/century
Differences in duration of days in March and August	$\Delta P$	0.0025 (March-August)	s
Corresponding relative annual variation in earth's rotational velocity	$\Delta^*\omega/\omega$	$2.9 \cdot 10^{-8}$ (Aug.-March)	
Presumed variation in earth's radius between August and March	$\Delta^*R$	-9.2 (Aug.-March)	cm
Annual variation in level of world ocean	$\Delta h_o$	$\sim 10$ (Sept.-March)	cm
Area of continents	$S_c$	$1.49 \cdot 10^8$	km <sup>2</sup>
		29.2	% of surface

Quantity	Symbol	Value	Unit
Area of world ocean	$S_o$	$3.61 \cdot 10^8$	km <sup>2</sup>
Mean height of continents above sea level	$h_c$	70.8	% of surface
Mean depth of world ocean	$h_o$	3794	m
Mean thickness of lithosphere within the limits of the continents	$h_{c.l.}$	35	km
Mean thickness of lithosphere within the limits of the ocean	$h_{o.l.}$	4.7	km
Mean rate of thickening of continental lithosphere	$\Delta h / \Delta t$	10 – 40	m/10 <sup>6</sup> y
Mean rate of horizontal extension of continental lithosphere	$\Delta l / \Delta t$	0.75 – 20	km/10 <sup>6</sup> y
Mass of crust	$m_1$	$2.36 \cdot 10^{22}$	kg
Mass of mantle		$4.05 \cdot 10^{24}$	kg
Amount of water released from the mantle and core in the course of geological time		$3.40 \cdot 10^{21}$	kg
Total reserve of water in the mantle		$2 \cdot 10^{23}$	kg
Present content of free and bound water in the earth's lithosphere		$2.4 \cdot 10^{21}$	kg
Mass of hydrosphere	$m_h$	$1.664 \cdot 10^{21}$	kg
Amount of oxygen bound in the earth's crust		$1.300 \cdot 10^{21}$	kg
Amount of free oxygen		$1.5 \cdot 10^{18}$	kg
Mass of atmosphere	$m_a$	$5.136 \cdot 10^{18}$	kg
Mass of biosphere	$m_b$	$1.148 \cdot 10^{16}$	kg
Mass of living matter in the biosphere		$3.6 \cdot 10^{14}$	kg
Density of living matter on dry land		0.1	g/cm <sup>2</sup>
Density of living matter in ocean		$15 \cdot 10^{-8}$	g/cm <sup>3</sup>
Age of the earth		$4.55 \cdot 10^9$	y
Age of oldest rocks		$4.0 \cdot 10^9$	y
Age of most ancient fossils		$3.4 \cdot 10^9$	y

## GEOLOGICAL TIME SCALE

Period or epoch	Beginning and end, in 10 <sup>6</sup> years	Key events
<i>Cenozoic era</i>		
Quaternian		
Contemporary	0–10,000 y ± 2,000 y	
Pleistocene	10,000–1,000,000 y ± 50,000 y	Homo Erectus breakout
Tertiary		
Pliocene	1.8–5.3	Ape man fossils
Miocene	5–25	Origin of grass
Oligocene	25–37	Rise of cats, dogs, pigs
Eocene	37–55	Debut of hoofed mammals
Paleocene	55–67	Earliest primates
<i>Mesozoic era</i>		
Cretaceous	67–138	Demise of dinosaurs
Jurassic	138–208	First birds
Triassic	208–245	Appearance of dinosaurs
<i>Paleozoic era</i>		
Permian	245–290	Flowers, insect pollination
Carboniferous	290–360	First conifers
Devonian	360–410	First vertebrates ashore
Silurian	410–435	Spore-bearing plants
Ordovician	435–520	First animals ashore
Cambrian	520–570	Vertebrates appear
<i>Pre-Cambrian</i>		
Pre-Cambrian III (Proterozoic)	570–2500	First plants, jellyfish
Pre-Cambrian II (Archean)	2500–3800	Photosynthetic bacteria
Pre-Cambrian I (Hadean)	3800–4450	Earth formed 4600 million years ago

## ACCELERATION DUE TO GRAVITY

The acceleration due to gravity is tabulated here as a function of latitude and height above the earth's surface. Values were calculated from the expression

$$g/(\text{m/s}^2) = 9.780356 (1 + 0.0052885 \sin^2 \phi - 0.0000059 \sin^2 2 \phi) - 0.003086 H$$

where  $\phi$  is the latitude and  $H$  is the height in kilometers.

# DENSITY, PRESSURE, AND GRAVITY AS A FUNCTION OF DEPTH WITHIN THE EARTH

This table gives the density  $\rho$ , pressure  $p$ , and acceleration due to gravity  $g$  as a function of depth below the earth's surface, as calculated from the model of the structure of the earth in Reference 1. The model assumes a radius of 6371 km for the earth. The boundary between the crust and mantle (the Mohorovicic discontinuity) is taken as 21 km, while in reality it varies considerable with location.

## OCEAN PRESSURE AS A FUNCTION OF DEPTH AND LATITUDE

The following table is based upon an ocean model which takes into account the equation of state of standard seawater and the dependence on latitude of the acceleration of gravity. The tabulated pressure value is the excess pressure over the ambient atmospheric pressure at the surface.

## PROPERTIES OF SEAWATER

In addition to the dependence on temperature and pressure, the physical properties of seawater vary with the concentration of the dissolved constituents. A convenient parameter for describing the composition is the salinity,  $S$ , which is defined in terms of the electrical conductivity of the seawater sample. The defining equation for the practical salinity is:

$$S = a_0 + a_1 K^{1/2} + a_2 K + a_3 K^{3/2} + a_4 K^2 + a_5 K^{5/2},$$

where  $K$  is the ratio of the conductivity of the seawater sample at 15°C and atmospheric pressure to the conductivity of a potassium chloride solution in which the mass fraction of KCl is 0.0324356, at the same temperature and pressure. The values of the coefficients are:

$$\begin{aligned} a_0 &= 0.0080 & a_3 &= 14.0941 \\ a_1 &= -0.1692 & a_4 &= -7.0261 \\ a_2 &= 25.3851 & a_5 &= 2.7081 \\ \Sigma a_i &= 35.0000 \end{aligned}$$

Thus when  $K = 1$ ,  $S = 35$  exactly ( $S$  is normally quoted in units of ‰, i.e., parts per thousand). The value of  $S$  can be roughly equated with the mass of dissolved material in grams per kilogram of seawater. Salinity values in the open oceans at mid latitudes typically fall between 34 and 36.

It is customary in oceanography to define the pressure at a given point as the pressure due to the column of water between that point and the surface. Thus by convention  $P = 0$  at the sea surface. To a good approximation the pressure in decibars (dbar) can be equated to the depth in meters. Thus at 45° latitude the pressure is 5000 dbar at 4902 m, 10000 dbar at 9700 m.

The first table below gives several properties of seawater as a function of temperature for a salinity of 35. The second and third give density and electrical conductivity as a function of salinity at several temperatures, and the fourth lists typical concentrations of the main constituents of seawater as a function of salinity. The final table gives the freezing point as a function of salinity and pressure.
